We also represented the results of Spearman correlations between text-based similarity and vector-based simlarity across 9 platforms in Table S2. The Spearman correlations are all higher than 0.2 in every platform, which shows a substantial agreement between text-based similarity and vector-based similarity.

In Table S3, We represented the scores of different widely-used automatic metrics for word level sentence generation evaluation on Vec2Text task, including BLEU-1(Papineni et al., 2002), BLEU-2, ROUGE-1(Lin, 2004), ROUGE-L, METEOR(Lavie and Agarwal, 2007) and NIST(Doddington, 2002). The results indicated consistent improvement of our method over comparison approaches on different automatic metrics.

A Contrastive Framework for Learning Sentence Representations from Pairwise and Triple-wise Perspective in Angular Space

Abstract

Learning high-quality sentence representations is a fundamental problem of natural language processing which could benefit a wide range of downstream tasks. Though the BERT-like pre-trained language models have achieved great success, using their sentence representations directly often results in poor performance on the semantic textual similarity task. Recently, several contrastive learning methods have been proposed for learning sentence representations and have shown promising results. However, most of them focus on the constitution of positive and negative representation pairs and pay little attention to the training objective like NT-Xent, which is not sufficient enough to acquire the discriminating power and is unable to model the partial order of semantics between sentences. So in this paper, we propose a new method ArcCSE, with training objectives designed to enhance the pairwise discriminative power and model the entailment relation of triplet sentences. We conduct extensive experiments which demonstrate that our approach outperforms the previous state-of-the-art on diverse sentence related tasks, including STS and SentEval.

s_c: He was born in Nazareth-Palestine, but immigrated to Lebanon.

(d) Example Sentences

Figure 1: Sentence representations visualization. We generate the representations of three related sentences by passing them to BERT$_{\text{base}}$, SimCSE-BERT$_{\text{base}}$ and ArcCSE-BERT$_{\text{base}}$ multiple times. With different dropout masks, we can generate different representations for each sentence. Then we normalize the embeddings and use t-SNE for dimensionality reduction.

1 Introduction

Learning sentence representations, which encodes sentences into fixed-sized dense vectors such that semantically similar ones stay close, is a fundamental problem of natural language processing. It could benefit a wide range of downstream applications such as information retrieval, semantic similarity comparison, question answering, and so on.

Recently, with the great success of pre-trained Transformer-based language models (Devlin et al., 2019; Liu et al., 2019; Raffel et al., 2020; Brown et al., 2020; Liu et al., 2019) like BERT, they have been widely adopted for generating sentence representations. A straightforward way is by leveraging the [CLS] embedding (Devlin et al., 2019) or applying mean pooling on the last layers of a BERT-like pre-trained language model (Reimers and Gurevych, 2019). However, the sentence embeddings coming from a pre-trained language model without further fine-tuning could not capture the semantic meaning of sentences very well as shown in Figure 1(a), and sometimes even underperform non-contextualized embeddings like GloVe (Pennington et al., 2014).

To make pre-trained language models more suitable for generating sentence embeddings, supervised methods like SBERT (Reimers and Gurevych, 2019) are proposed, which improve the performance by fine-tuning on a labeled dataset. As labeled data is not available or expensive to annotate in many tasks or domains, it is of great value

Volume 1: Long Papers, pages 4892 - 4903
May 22-27, 2022

for developing unsupervised/self-supervised approaches for learning sentence representations. So recent works like BERT-Flow (Li et al., 2020) and BERT-Whitening (Su et al., 2021) propose post-processing methods to improve the BERT-based sentence representation. They address that the non-smooth anisotropic semantic space of BERT is a bottleneck and alleviate the problem through normalizing flows and whitening operation. To further improve the quality of sentence representations, several works (Kim et al., 2021; Yan et al., 2021; Giorgi et al., 2021; Carlsson et al., 2021; Gao et al., 2021) adopt self-supervised contrastive learning approach, which learns sentence representations by minimizing the distance of positive sentence representation pairs and maximizing the distance of negative pairs. In these works, positive pairs are often constituted through data augmentation or encoders with different structure or parameters, while negative pairs are derived from different sentences within the same batch. Then contrastive learning objective like normalized temperature-scaled cross-entropy loss (NT-Xent) (Chen et al., 2020; Gao et al., 2021) is used for optimizing. A typical example unsup-SimCSE (Gao et al., 2021) achieves state-of-the-art performance with a simple and effective idea of using standard dropout for data augmentation.

Though existing contrastive methods for learning sentence representation have shown promising results, most of them focus on the positive and negative pairs constitution, and the optimization objective itself is not fully exploited. The contrastive learning objective NT-Xent loss used in recent works (Yan et al., 2021; Giorgi et al., 2021; Gao et al., 2021) is a variation of cross-entropy loss with softmax function. Recent studies (Wang et al., 2018; Deng et al., 2019) have shown that the traditional softmax-based loss is insufficient to acquire the discriminating power, as shown in Figure 1(b) in which SimCSE-BERT$_{\text{base}}$ adopts the NT-Xent loss and could not separate s_b and s_c completely. In addition, the current optimization objectives only models sentence relations in a pairwise perspective, which tries to pull sentences with similar semantics closer and push dissimilar ones away from each other. However, there are different degrees of semantic similarity among related sentences. For example in Figure 1(d), s_b is more similar to s_a than s_c is. The current optimization objectives lack the ability to model the partial order of semantics between sentences.

To alleviate these problems, in this paper, we propose a new approach ArcCSE for sentence representation learning. For pairwise sentence relation modeling, we propose Additive Angular Margin Contrastive Loss (ArcCon Loss), which enhances the pairwise discriminative power by maximizing the decision margin in the angular space. Besides, in order to model the partial order of semantics between sentences, we propose a new self-supervised task that captures the entailment relation among triplet sentences. The task is implemented through automatically constituted triplet sentences with entailment relation among them. A visualization example of the generated representations through ArcCSE is shown in Figure 1(c). We evaluate our method on standard semantic textual similarity (STS) tasks and SentEval transfer tasks, and it outperforms the previous state-of-the-art approaches.

2 Related Work

2.1 Unsupervised Sentence Representation Learning

Early works usually learn sentence representations by augmenting the idea of word2vec (Mikolov et al., 2013), such as predicting surrounding sentences (Kiros et al., 2015; Hill et al., 2016; Logeswaran and Lee, 2018) or summing up n-gram embeddings (Pagliardini et al., 2018). With the rise of pre-trained language models, many works try to generate sentence representations through BERT-like models. A common way is leveraging the [CLS] embedding or applying mean pooling on the last layers of BERT (Reimers and Gurevych, 2019; Li et al., 2020). Instead of using BERT embeddings directly, BERT-Flow (Li et al., 2020) and BERT-Whitening (Su et al., 2021) further improve sentence representation through post-processing.

Recently, several works adopt the contrastive learning framework for sentence representation learning. They propose different strategies to constitute contrastive pairs, either through different data transforming methods (Zhang et al., 2020; Yan et al., 2021; Giorgi et al., 2021), or through encoders with different structures or parameters (Carlsson et al., 2021; Kim et al., 2021; Gao et al., 2021). A typical example SimCSE (Gao et al., 2021) uses dropout as data augmentation strategy and achieves state-of-the-art performance. However, most existing works pay little attention to the training objective and use the traditional contrastive

Figure 2: The framework of ArcCSE. ArcCSE models pairwise and triple-wise sentence relations simultaneously. For pairwise sentence relation modeling, we pass sentences to a BERT-like encoder with dropout turn on twice. Then we feed the representations into ArcCon loss which is more discriminative than NT-Xent loss. Triplet sentences are constituted through masking. We pass them to the same BERT-like encoder with dropout turn off and use a triplet loss to model their relations.

loss directly, which is insufficient in discrimination and unable to model the partial order of semantics between sentences. So, in our work, we propose a new approach that jointly models the pairwise and triple-wise sentence relations and further improves the sentence representations' quality.

2.2 Deep Metric Learning Objectives

The goal of Deep Metric Learning (DML) is to learn a function that maps objects into an embedded space, in which similar objects stay close and dissimilar ones are far away. In order to achieve this goal, many approaches have been proposed, and designing appropriate loss functions plays a key role in it. Contrastive training objectives like Contrastive Loss (Chopra et al., 2005), N-Pair Loss (Sohn, 2016), Structured Loss (Song et al., 2016) and Triplet Margin Loss (Ma et al., 2021) apply the definition of metric learning directly. These objectives are among the earliest training objectives used for deep metric learning. Later, softmax-based losses which learn a center for each class and penalize the distances between deep features and their corresponding class centers achieve more promising results in supervised metric learning. Typical examples like Center Loss (Wen et al., 2016), SphereFace (Liu et al., 2017), CosFace (Wang et al., 2018) and ArcFace (Deng et al., 2019) are widely adopted in deep learning applications such as face recognition and sentence classification (Coria et al., 2020). However, these losses need class labels and are not suitable for learning sentence representations. So inspired by ArcFace, we propose a new training objective ArcCon that does not need class labels and can model pairwise sentence relations with more discriminative power than traditional contrastive training objectives.

3 Method

In this section, we present ArcCSE, an angular based contrastive sentence representation learning framework, which could generate superior sentence embeddings from unlabeled data. Given a pre-trained language model $\mathcal{M}$ and an unlabeled text dataset $\mathcal{D}$, the task is fine-tuning $\mathcal{M}$ on $\mathcal{D}$ so that the sentence representations generated through $\mathcal{M}$ could be more semantic discriminative.

Our framework consists of two components that model pairwise and triple-wise sentence relations simultaneously, as shown in Figure 2. We start with angular margin based contrastive learning in Section 3.1, which models pairwise relations between sentences by pulling semantic similar ones closer while pushing dissimilar ones away. Then we introduce the method which models the partial order of semantics between automatically constituted triplet sentences in Section 3.2.

3.1 Angular Margin based Contrastive Learning

To model the positive/negative pairwise relations between sentences, we first need to generate sentence representations and group them into positive and negative pairs. Then we feed these pairs to a training objective for optimizing.

Given a collection of sentences $\mathcal{D} = \{s_i\}_{i=1}^{N}$, we generate the sentence representations through a BERT-like pre-trained language model $\mathcal{M}$. Following SimCSE, we use dropout as the data augmentation method. For each sentence s_i, we generate two different representations h_i and h_i^* from s_i by passing s_i to $\mathcal{M}$ twice with independently sampled dropout masks. These two representations with the same semantics constitute a positive pair, while the negative pairs are derived from the representations of different sentences within the same batch.

After getting the positive and negative sentence pairs, we put them into a training objective for model fine-tune. The most widely adopted training objective is NT-Xent loss (Chen et al., 2020; Gao et al., 2021), which has been used in previous sentence and image representation learning methods and can be formulated as follows:

$$\mathcal{L}_{\text{NT-Xent}} = -\log \frac{e^{sim\left(h_i, h_i^*\right)/\tau}}{\sum_{j=1}^{n} e^{sim\left(h_i, h_j\right)/\tau}} \qquad (1)$$

where $sim\left(h_i, h_j\right)$ is the cosine similarity $\frac{h_i^{\top} h_j}{||h_i|| * ||h_j||}$, τ is a temperature hyperparameter and n is the number of sentences within a batch.

Though the training objective tries to pull representations with similar semantics closer and push dissimilar ones away from each other, these representations may still not be sufficiently discriminative and not very robust to noise. Let us denote angular $\theta_{i,j}$ as follows:

$$\theta_{i,j} = \arccos\left(\frac{h_i^{\top} h_j}{||h_i|| * ||h_j||}\right) \qquad (2)$$

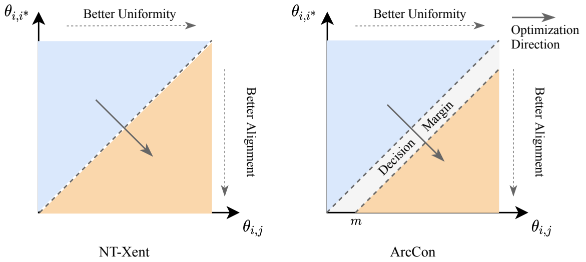

Figure 3: Comparison of NT-Xent loss and ArcCon loss. For sentence representation h_i, we try to make θ_{i,i^*} smaller and $\theta_{i,j}$ larger, so the optimization direction follows the arrow. With an extra margin m, ArcCon is more discriminative and noise-tolerant.

The decision boundary for h_i in NT-Xent is $\theta_{i,i^*} = \theta_{i,j}$, as show in Figure 3. Due to lack of decision margin, a small perturbation around the decision boundary may lead to an incorrect decision.

To overcome the problem, we propose a new training objective for sentence representation learning by adding an additive angular margin m between positive pair h_i and h_i^*. We named it Additive Angular Margin Contrastive Loss (ArcCon Loss), which can be formulated as follows:

$$\mathcal{L}_{\text{arc}} = -\log \frac{e^{\cos\left(\theta_{i,i^*}+m\right)/\tau}}{e^{\cos\left(\theta_{i,i^*}+m\right)/\tau} + \sum_{j \neq i} e^{\cos\left(\theta_{j,i}\right)/\tau}} \qquad (3)$$

In this loss, the decision boundary for h_i is $\theta_{i,i^*} + m = \theta_{i,j}$, as show in Figure 3. Compared with NT-Xent, it further pushed h_i towards to the area where θ_{i,i^*} get smaller and $\theta_{i,j}$ get larger, by increasing the compactness of sentence representations with the same semantics and enlarging the discrepancy of different semantic representations. This help enhance the alignment and uniformity properties (Wang and Isola, 2020), which are two key measures of representation quality related to contrastive learning, indicating how close between positive pair embeddings and how well the embeddings are uniformly distributed. The quantitative analysis is illustrated in Section 4.5. Besides, the decision boundary leaves an extra margin m to boundary $\theta_{i,i^*} = \theta_{i,j}$ which is often used during inference, making it more tolerant to noise and more robust. All these properties make ArcCon loss more discriminative than traditional training objectives like NT-Xent. Compared with Arcface (Deng et al., 2019) which is often used in large-scale fine-grained categorization in computer vision community, ArcCon loss does not need classification labels, and could handle contrastive task properly.

3.2 Modeling Entailment Relation of Triplet Sentences

Previously the training objectives for sentence representation learning like NT-Xent loss only considered pairwise sentence relations, in which sentences are either similar or dissimilar in semantics. But in fact, there are varying degrees of semantic similarity. For example, sentence s_2 could be more similar to sentence s_1 than sentence s_3 to s_1. Existing methods lack the ability to model such partial order of semantics between sentences.

In order to distinguish the slight differences in semantics between different sentences, we propose a new self-supervised task which models the entailment relation of automatically generated triplet sentences. For each sentence s_i in the text dataset $\mathcal{D}$, we first generate an external sentence s_i' by masking contiguous segments of s_i with a masking rate of 20%. Then we enlarge the masking area and get a new sentence s_i'' with a masking rate of 40% to s_i. The masking rates are set up experimentally, and an ablation study about the effect of masking rates is illustrated in Section 4.4. An example of the masking procedure is shown as follows:

s_i Al Jaber's first long distance travel was of 800km which he covered by circling Qatar.

s_i' Al Jaber's first long distance travel was ~~of 800km which~~ he covered by circling Qatar.

s_i'' Al Jaber's first long distance travel was ~~of 800km which he covered by~~ circling Qatar.

We can constitute a triplet (s_i, s_i', s_i'') with entailment relation among them. Though in rare cases, the strategy may generate sentences that do not exhibit the desired relationship and introduce some noise, the entailment relation holds true most of the time. We expect encountering enough data will reinforce the correct ones whereas the impact of incorrect ones will diminish.

Since the s_i, s_i' and s_i'' are similar literally and semantically, generating their representations with dropout noise may obscure their entailment relation and add inaccurate signals to the representation learning process. So we turn off the dropout of the encoder when modeling the triplet relation.

As s_i' is more similar to s_i in semantics than s_i'' is, we could model such relation with a triplet objective:

$$\mathcal{L}_{\text{tri}} = max\left(0, sim(\bar{h}_i, \bar{h}_i'') - sim(\bar{h}_i, \bar{h}_i') + m\right) \tag{4}$$

in which $\bar{h}_i$ is the sentence representation of s_i generated without dropout noise and $sim(i, j)$ is the cosine similarity between i and j. As the semantic difference between s_i' and s_i'' may be subtle depending on the original sentence s_i and the masked words, here we set m to zero.

Combine formula (3) and formula (4), the final form of our training objective is:

$$\mathcal{L} = \mathcal{L}_{\text{arc}} + \lambda \mathcal{L}_{\text{tri}} \tag{5}$$

in which λ is a coefficient.

4 Experiments

4.1 Setups

Evaluation Tasks We evaluate our method on two kinds of sentence related tasks:

- Unsupervised Semantic Textual Similarity (STS): These tasks measure the model's ability to estimate the semantic similarities between sentences.
- SentEval Transfer Tasks: These tasks measure the effectiveness of sentence embeddings used in downstream transfer tasks.

Baselines We compare ArcCSE to several representative methods on STS and SentEval tasks, such as average GloVe embeddings (Pennington et al., 2014), Skip-thought (Kiros et al., 2015), average BERT embeddings from the last layer (Devlin et al., 2019), BERT-Flow (Li et al., 2020), and BERT-Whitening (Su et al., 2021). We also include the recently proposed contrastive learning methods, such as ISBERT (Zhang et al., 2020), CT-BERT (Carlsson et al., 2021), ConSERT (Yan et al., 2021), and the current state-of-the-art method SimCSE (Gao et al., 2021).

Implementation Details We train ArcCSE with the pre-trained checkpoints of $\text{BERT}_{\text{base}}$ and $\text{BERT}_{\text{large}}$ (Devlin et al., 2019). We also employ our method to SBERT (Reimers and Gurevych, 2019), which has been trained on NLI datasets, to verify the generalizability of our method.

Following SimCSE (Gao et al., 2021), we use the output of the MLP layer on top of the [CLS] as

Table 1: Sentence representation performance on the STS tasks. We employ our method to BERT and SBERT in both base and large versions and report Spearman's correlation.

the sentence representation during training, and use the [CLS] output without MLP layer for evaluation. The dropout rate is set to 0.1. For ArcCon loss, we set the angular margin m to 10 degrees and the temperature τ to 0.05. When modeling the entailment relation of triplet sentences, we set the masking ratios as 20% and 40% respectively. Since the semantic difference between triplet sentences is more obvious for long sentences, we filter out sentences with less than 25 words and use the left ones for the triplet loss. The loss coefficient λ is set to 0.1 experimentally.

We use one million random sampled sentences from English Wikipedia for training, which has been used in previous work (Gao et al., 2021) [1]. During training, the sentences are sampled by length. We set different maximum sentence lengths for ArcCon loss and triplet loss to save memory. The length is set to 32 for the ArcCon loss in large models, and to the maximum length within a batch for all other cases. We train our model for one epoch and the learning rate is set to 3e-5 for base models and 1e-5 for large models. We search the batch size within {8, 16, 32} and always update the parameters every 64 steps. The model is optimized by the AdamW with Sharpness-Aware Minimization (Foret et al., 2021) and default configurations.

We evaluate our model every 125 training steps on the development set of STS-B, and the best checkpoint is used for the final evaluation on test sets. Our implementation is based on HuggingFace's Transformers (Wolf et al., 2020).

4.2 Unsupervised STS Tasks

We conduct experiments on 7 semantic textual similarity (STS) tasks, including STS tasks 2012-2016 (Agirre et al., 2012, 2013, 2014, 2015, 2016), STS Benchmark (Cer et al., 2017), and SICK-Relatedness (Marelli et al., 2014). Within these datasets, each sample contains two sentences and a gold score between 0 and 5 which indicates their semantic similarity. We use SentEval toolkit (Conneau and Kiela, 2018) for evaluation and report the Spearman's correlation following previous works (Reimers and Gurevych, 2019; Gao et al., 2021).

The evaluation results are shown in Table 1,

Table 2: Sentence representation performance on SentEval transfer tasks. We report the accuracy results of both BERT$_{\text{base}}$ and BERT$_{\text{large}}$ level models.

from which we can see that ArcCSE outperforms the previous approaches. Compared with the previous state-of-the-art method SimCSE, ArcCSE-BERT$_{\text{base}}$ raises the average Spearman's correlation from 76.25% to 78.11%, and ArcCSE-BERT$_{\text{large}}$ further pushes the results to 79.37%. The performance is even better than strong supervised method SBERT, which has already been trained on NLI datasets. Furthermore, we can also employ our method to SBERT and improve its performance to 79.06% and 80.69% for the base and large models respectively, which is more effective than SimCSE.

We also explore the improvements made by the ArcCon loss and triplet loss independently based on BERT$_{\text{base}}$. From Table 1 we can see that with ArcCon loss alone, the average Spearman's correlation is 77.25%. When combining the traditional NT-Xent loss with our proposed triplet loss, the average Spearman's correlation is 77.02%. Both of them outperform the previous state-of-the-art method SimCSE, whose average Spearman's correlation is 76.25%. This demonstrates the effectiveness of ArcCon and triplet loss we proposed.

4.3 SentEval Tasks

We evaluate our model with SentEval toolkit on several supervised transfer tasks, including: MR (Pang and Lee, 2005), CR (Hu and Liu, 2004), SUBJ (Pang and Lee, 2004), MPQA (Wiebe et al., 2005), SST-2 (Socher et al., 2013), TREC (Voorhees and Tice, 2000) and MRPC (Dolan and Brockett, 2005). For each task, SentEval trains a logistic regression classifier on top of the sentence embeddings and tests the performance on the downstream task. For a fair comparison, we do not include models with auxiliary tasks like masked language modeling.

The results are shown in Table 2. We can see that ArcCSE performs on par or better than baseline methods in both BERT$_{\text{base}}$ and BERT$_{\text{large}}$ level. This demonstrates the effectiveness of our method in learning domain-specific sentence embeddings.

4.4 Ablation Studies

Effect of Angular Margin The angular margin m in ArcCon loss affects the discriminative power directly. To investigate the effect of m, we conduct an experiment by varying m from 0 degrees to 20 degrees, increased by 2 degrees at each step. We tune the hyper-parameter based on Spearman's correlation on the development set of STS-B following previous works (Kim et al., 2021; Gao et al., 2021). The results are shown in Figure 4.

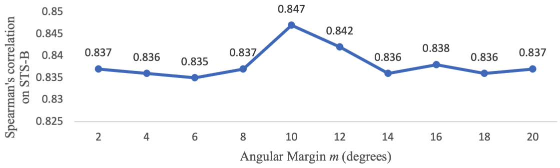

Figure 4: Effect of the angular margin m in ArcCon loss. Results are reported on the development set of STS-B based on the Spearman's correlation.

We can see that the best performance is achieved when $m = 10$, either larger or smaller margin degrade the performance. This matches our intuition since small m may have little effect, and large m may negatively influence the positive pair relation modeling.

Effect of Temperature The temperature τ in ArcCon Loss affects its effectiveness, so we carry out an experiment with τ varying from 0.01 to 0.1, increased by 0.01 at each step. The results are shown in Figure 5. We can see that the model

ArcCSE-BERT$_{\text{base}}$	STS12	STS13	STS14	STS15	STS16	STS-B	SICK-R	Avg.
w/ Dropout$_{\text{on/off}}$	**72.08**	**84.27**	**76.25**	**82.32**	**79.54**	**79.92**	**72.39**	**78.11**
w/ Dropout$_{\text{mix/off}}$	70.51	83.59	75.85	82.30	78.87	78.74	71.58	77.35
w/ Dropout$_{\text{on/on}}$	69.62	83.13	74.42	82.15	78.39	78.39	70.89	76.71

Table 3: Effect of on-off Switching of Dropout. We use different dropout settings to generate sentence embeddings used for ArcCon loss and triplet loss respectively. The "on", "off" and "mix" mean turn dropout on, turn dropout off and use different settings for two passes separately.

performs best when $\tau = 0.05$, so we use this value throughout our experiments.

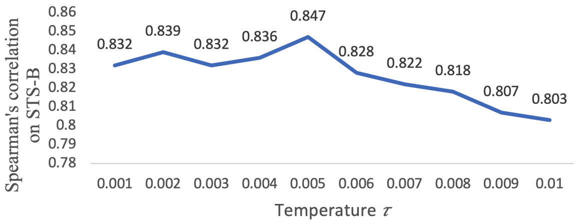

Figure 5: Effect of the temperature τ in ArcCon loss. Results are reported on the development set of STS-B based on the Spearman's correlation.

Effect of Masking Ratios The masking ratios determine the sentences generated for the entailment relation modeling and their differences in semantics, so we conduct an experiment to explore the effect of different masking ratios. The first masking ratio r_1 is varied from 10% to 25%, increased by 5% for each step. The second masking ratio r_2 is derived by adding an extra value r_d to r_1. r_d is varied from 10% to 35%, increased by 5% for each step. The results are shown in Figure 6.

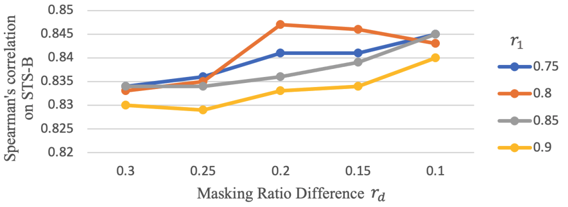

Figure 6: Effect of the masking ratios. Different lines correspond to different values of r_1. The abscissa is r_d, representing the difference between r_1 and r_2. Results are reported on the development set of STS-B based on the Spearman's correlation.

We can see that large differences between the two masking ratios tend to lead lower Spearman's correlation compared to the smaller ones. The reason may be that the larger the semantic difference is, the easier for the model to estimate the entailment relations among the triplet sentences, which makes the triplet loss less helpful. The best performance is achieved when r_1 is 20% and r_2 is 40%, and the corresponding Spearman's correlation is 0.847. We use them as our hyper-parameters.

Effect of on-off Switching of Dropout The on-off switching of dropout in the BERT-like sentence encoder affects the generated sentence representations directly. Since dropout performs a kind of averaging over the ensemble of possible subnetworks, an embedding generated with dropout turned off can be seen as a kind of "averaging" representation, while an embedding generated with dropout turned on can be seen as generated through a subnetwork.

In ArcCSE, we use the embeddings generated with the encoder dropout turned on as input for ArcCon loss, which regularizes the network by making representations generated through different subnetworks similar. When modeling the entailment relation, we generate "averaging" representations with dropout turn-off to avoid inaccurate signals. In order to verify our intuition, we conduct two experiments with different dropout settings. In the first experiment, we feed ArcCon two sentence representations generated with dropout turns on and off respectively. We carry out this experiment with angular margins ranging between 2 degrees to 12 degrees and report the best result. In the second one, we feed the triplet loss representations that are generated with dropout turns on and maintain the other settings. The results are shown in Table 3. We can see that the original settings that turn dropout on for ArcCon and turn dropout off for triplet loss achieve the best performance, which confirms our intuition.

Effect of Coefficient in the Training Objective The coefficient λ in the final optimization objective adjusts the relative weights between ArcCon and the triplet loss, as shown in formula (5). To find the most suitable λ, we conduct an experiment by varying λ from 0 to 1.2 and increased by 0.1 at each step. The results are shown in Figure 7.

We can see that the best performance is achieved

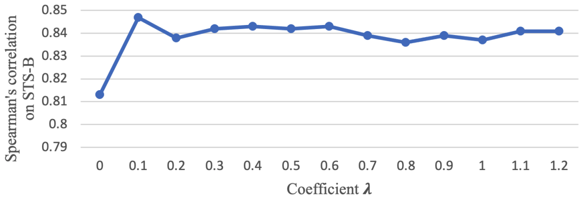

Figure 7: Effect of the coefficient in the training objective. Results are reported on the development set of STS-B based on the Spearman's correlation.

when $\lambda = 0.1$, and the corresponding Spearman's correlation is 0.847. This demonstrates that we can get the best performance by combining ArcCon and the triplet loss with proper λ.

4.5 Alignment and Uniformity Analysis

Alignment and uniformity are two properties closely related to contrastive learning and could be used to measure the quality of representations(Wang and Isola, 2020). Alignment favors encoders that generate similar representations for similar instances. It could be defined with the expected distance between embeddings of the positive paired instances:

$$\ell_{\text{align}} = \underset{(x,x^+)\sim p_{\text{pos}}}{\mathbb{E}} \left\|f(x) - f\left(x^+\right)\right\|^2 \tag{6}$$

where p_{pos} denotes the distribution of positive paired instances. Uniformity prefers uniformly distributed representations, which helps preserve maximal information. It could be defined as:

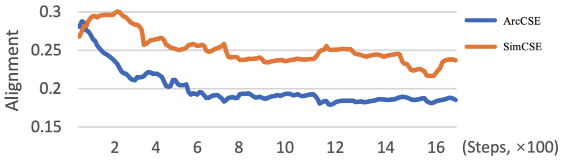
$$\ell_{\text{uniform}} = \log \underset{x,y \overset{i.i.d}{\sim} p_{\text{data}}}{\mathbb{E}} e^{-2\|f(x)-f(y)\|^2} \tag{7}$$

where p_{data} denotes whole data distribution.

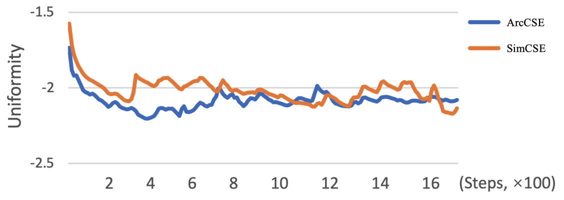
To justify the inner workings of our approach, we calculate the alignment and uniformity metrics every 10 steps during training on the STS-B development set. We compare our approach with SimCSE and visualize the results in Figure 8. We can see that compared to the original BERT checkpoint, both ArcCSE and SimCSE improve the alignment and uniformity measures during training. ArcCSE performs better on the alignment measure and on par with SimCSE on the uniformity measure. This verifies the intuition of our approach and demonstrates that ArcCSE could help improve the quality of sentence representations.

5 Conclusion

In this work, we propose ArcCSE, a self-supervised contrastive learning framework for learning sentence representation. We propose a new optimizing objective ArcCon loss to model pairwise sentence relations with enhanced discriminating power, and a new self-supervised task to model the partial order of semantics between sentences. Experimental results on semantic textual similarity tasks (STS) and SentEval tasks demonstrate that both techniques bring substantial improvements and our method outperforms previous state-of-the-art method for sentence representation learning.



(a) ℓ_{align}



(b) ℓ_{uniform}

Figure 8: ℓ_{align} and ℓ_{uniform} of ArcCSE and SimCSE, visualized by calculating alignment and uniformity every 10 training steps. For both measures, lower numbers are better.

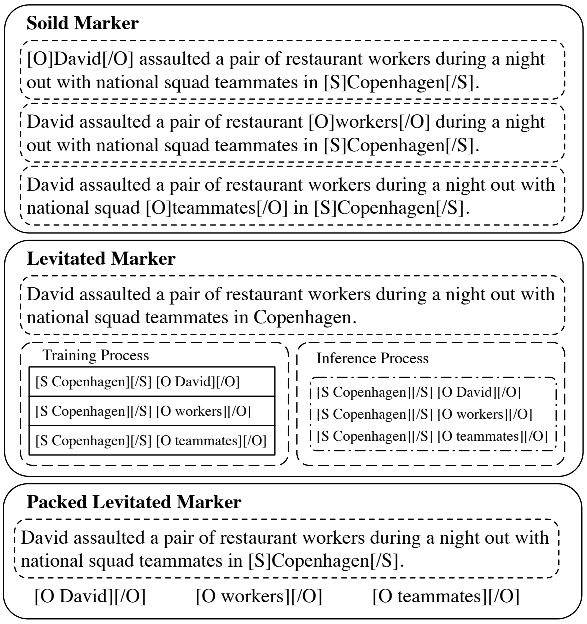
Abstract

Recent entity and relation extraction works focus on investigating how to obtain a better span representation from the pre-trained encoder. However, a major limitation of existing works is that they ignore the interrelation between spans (pairs). In this work, we propose a novel span representation approach, named Packed Levitated Markers (PL-Marker), to consider the interrelation between the spans (pairs) by strategically packing the markers in the encoder. In particular, we propose a neighborhood-oriented packing strategy, which considers the neighbor spans integrally to better model the entity boundary information. Furthermore, for those more complicated span pair classification tasks, we design a subject-oriented packing strategy, which packs each subject and all its objects to model the interrelation between the same-subject span pairs. The experimental results show that, with the enhanced marker feature, our model advances baselines on six NER benchmarks, and obtains a 4.1%-4.3% strict relation F1 improvement with higher speed over previous state-of-the-art models on ACE04 and ACE05. Our code and models are publicly available at `https://github.com/thunlp/PL-Marker`.

1 Introduction

Recently, pre-trained language models (PLMs) (Devlin et al., 2019; Liu et al., 2019) have achieved significant improvements in Named Entity Recognition (NER, Luo et al. (2020); Fu et al. (2021)) and Relation Extraction (RE, Wadden et al. (2019); Zhou and Chen (2021)), two key sub-tasks of information extraction. Recent works (Wang et al., 2021c; Zhong and Chen, 2021) regard these two tasks as span classification or span pair classification, and thus focus on extracting better span representations from the PLMs.



[O]David[/O] assaulted a pair of restaurant workers during a night out with national squad teammates in [S]Copenhagen[/S].

David assaulted a pair of restaurant [O]workers[/O] during a night out with national squad teammates in [S]Copenhagen[/S].

David assaulted a pair of restaurant workers during a night out with national squad teammates in Copenhagen.

David assaulted a pair of restaurant workers during a night out with national squad teammates in [S]Copenhagen[/S].

Figure 1: An example in the RE task. Solid Marker separately processes three pairs of spans with different insertions of markers. Levitated Marker processes the span pairs independently during training and processes them in batches during inference. Our proposed Packed Levitated Marker packs three objects for the same subject into an instance to process.

Three span representation extraction methods are widely used: (1) **T-Concat** (Lee et al., 2017; Jiang et al., 2020) concatenates the representation of the span's boundary (start and end) tokens to obtain the span representation. It collects information at the token level but ignores the connection between boundary tokens of a span when they pass through the network; (2) **Solid Marker** (Soares et al., 2019; Xiao et al., 2020) explicitly insert two solid markers before and after the span to highlight the span in the input text. And it inserts two pair of markers to locate the subject and object of a span pair. However, the method cannot handle multiple span pairs at the same time because of its weakness in specifying the solid markers of a span pair from more than two pairs of markers in the sequence. (3)

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics
Volume 1: Long Papers, pages 4904 - 4917
May 22-27, 2022

Levitated Marker (Zhong and Chen, 2021) first sets a pair of levitated markers to share the same position with the span's boundary tokens and then ties a pair of markers by a directional attention. To be specific, the markers within a pair are set to be visible to each other in the attention mask matrix, but not to the text token and other pairs of markers. Existing work (Zhong and Chen, 2021) simply replaces solid markers with levitated markers for an efficient batch computation, but sacrifices the model performance.

As the RE example shown in Figure 1, to correctly identify that David, workers and teammates are *located_in* Copenhagen, it is important to separate out that David *attacked* the restaurant workers and he had *social* relation with his teammates. However, prior works with markers (Zhong and Chen, 2021) independently processes the span pairs with different insertions of markers in the training phrase, and thus ignore interrelation between spans (pairs) (Sorokin and Gurevych, 2017; Luan et al., 2019; Wadden et al., 2019).

In this work, we introduce Packed Levitated Marker (PL-Marker), to model the interrelation between spans (pairs) by strategically packing levitated markers in the encoding phase. A key challenge of packing levitated markers together for span classification tasks is that the increasing number of inserted levitated markers would exacerbate the complexity of PLMs quadratically (Ye et al., 2021). Thus, we have to divide spans into several groups to control the length of each input sequence for a higher speed and feasibility. In this case, it is necessary to consider the neighbor spans integrally, which could help the model compare neighbor spans, *e.g.* the span with the same start token, to acquire a more precise entity boundary. Hence, we propose a neighborhood-oriented packing strategy, which packs the spans with the same start token into a training instance as much as possible to better distinguish the entity boundary.

For the more complicated span pair classification tasks, an ideal packing scheme is to pack all the span pairs together with multiple pairs of levitated markers, to model all the span pairs integrally. However, since each pair of levitated markers is already tied by directional attention, if we continue to apply directional attention to bind two pairs of markers, the levitated marker will not be able to identify its partner marker of the same span. Hence, we adopt a fusion of solid markers and levitated markers, and use a subject-oriented packing strategy to model the subject with all its related objects integrally. To be specific, we emphasize the subject span with solid markers and pack all its candidate object spans with levitated markers. Moreover, we apply an object-oriented packing strategy for an intact bidirectional modeling (Wu et al., 2020).

We examine the effect of PL-Marker on two typical span (pair) classification tasks, NER and end-to-end RE. The experimental results indicate that PL-Marker with neighborhood-oriented packing scheme performs much better than the model with random packing scheme on NER, which shows the necessity of considering the neighbor spans integrally. And our model also advances the T-Concat model on six NER benchmarks, which demonstrates the effectiveness of the feature obtained by span marker. Moreover, compared with the previous state-of-the-art RE model, our model gains a 4.1%-4.3% strict relation F1 improvement with higher speed on ACE04 and ACE05 and also achieves better performance on SciERC, which shows the importance of considering the interrelation between the subject-oriented span pairs.

2 Related Work

In recent years, span representation has attracted great attention from academia, which facilitates various NLP applications, such as named entity recognition (Ouchi et al., 2020), relation and event extraction (Luan et al., 2019), coreference resolution (Lee et al., 2017), semantic role labeling (He et al., 2018) and question answering (Lee et al., 2016). Existing methods to enhance span representation can be roughly grouped into three categories:

Span Pre-training The span pre-training approaches enhance the span representation for PLMs via span-level pre-training tasks. Sun et al. (2019); Lewis et al. (2020); Raffel et al. (2020) mask and learn to recover random contiguous spans rather than random tokens. Joshi et al. (2020) further learns to store the span information in its boundary tokens for downstream tasks.

Knowledge Infusion This series of methods focuses on infusing external knowledge into their models. Zhang et al. (2019); Peters et al. (2019); Wang et al. (2021a) learn to use the external entity embedding from the knowledge graph or the synonym net to acquire knowledge. Soares et al. (2019); Xiong et al. (2020); Wang et al. (2021b);

Yamada et al. (2020) conduct specific entity-related pre-training to incorporate knowledge into their models with the help of Wikipeidia anchor texts.

Structural Extension The structural extension methods add reasoning modules to the existing models, such as biaffine attention (Wang et al., 2021d), graph propagation (Wadden et al., 2019) and memory flow (Shen et al., 2021). With the support of modern pre-training encoders (*e.g.* BERT), the simple model with solid markers could achieve state-of-art results in RE (Zhou and Chen, 2021; Zhong and Chen, 2021). However, it is hard to specify the solid markers of a span pair from more than two pairs of markers in the sequence. Hence, previous work (Zhong and Chen, 2021) has to process span pairs independently, which is time-consuming and ignores the interrelation between the span pairs. In this work, we introduce the neighborhood-oriented and the subject-oriented packing strategies to take advantage of the levitated markers to provide an integral modeling on spans (pairs).

To our best knowledge, we are the first to apply the levitated markers on the NER. On the RE, the closest work to ours is the PURE (Approx.) (Zhong and Chen, 2021), which independently encodes each span pair with two pairs of levitated markers in the training phase and batches multiple pairs of markers to accelerate the inference process. Compared to their work, our model adopts a fusion subject-oriented packing scheme and thus handle multiple span pairs well in both the training and inference process. We detail the differences between our work and PURE in Section 4.4.2 and explain why our model performs better.

3 Method

In this section, we first introduce the architecture of the levitated marker. Then, we present how we pack the levitated marker to obtain the span representation and span pair representation.

3.1 Background: Levitated Marker

Levitated marker is used as an approximation of solid markers, which allows models to classify multiple pairs of entities simultaneously to accelerate the inference process (Zhong and Chen, 2021). A pair of levitated markers, associated with a span, consists of a start token marker and an end token marker. These two markers share the same position embedding with the start and end tokens of the corresponding span, while keeping the position id of original text tokens unchanged. In order to specify multiple pairs of levitated markers in parallel, a directional attention mask matrix is applied. Specifically, each levitated marker is visible to its partner marker within pair in the attention mask matrix, but not to the text tokens and other levitated markers. In the meantime, the levitated markers are able to attend to the text tokens to aggregate information for their associated spans.

3.2 Neighborhood-oriented Packing for Span

Benefiting from the parallelism of levitated markers, we can flexibly pack a series of related spans into a training instance. In practice, we append multiple associated levitated markers to an input sequence to conduct a comprehensive modeling on each span.

However, even though the entity length is restricted, some of the span classification tasks still contain a large number of candidate spans. Hence, we have to group the markers into several batches to equip the model with higher speed and feasibility in practice. To better model the connection between spans with the same start tokens, we adopt a neighborhood-oriented packing scheme. As shown in Figure 2, we first sort the pairs of levitated markers by taking the position of start marker as the first keyword and the position of end marker as the second keyword. After that, we split them into groups of size up to K and thus gather adjacent spans into the same group. We packs each groups of markers and dispersedly process them in multiple runs.

Formally, given a sequence of N text tokens, $X = \{x_1, \dots, x_N\}$ and a maximum span length L, we define the candidate spans set as $S(X) = \{(1,1), .., (1, L), ..., (N, N-L), .., (N, N))\}$. We first divide $S(X)$ into multiple groups up to the size of K in order. For example, we cluster K spans, $\{(1,1),(1,2), ..., (\lceil \frac{K}{L} \rceil, K - \lfloor \frac{K-1}{L} \rfloor * L)\}$, into a group S_1. We associate a pair of levitated markers to each span in S_1. Then, we provide the combined sequence of the text token and the inserted levitated markers to the PLM (*e.g.* BERT) to obtain the contextualized representations of the start token marker $H^{(s)} = \{h_i^{(s)}\}$ and that of the end token marker $H^{(e)} = \{h_i^{(e)}\}$. Here, $h_a^{(s)}$ and $h_b^{(e)}$ are associated with the span $s_i = (a, b)$, for which we obtain the span representations:

$$\psi(s_i) = [h_a^{(s)}; h_b^{(e)}] \tag{1}$$

where $[A; B]$ denotes the concatenation operation

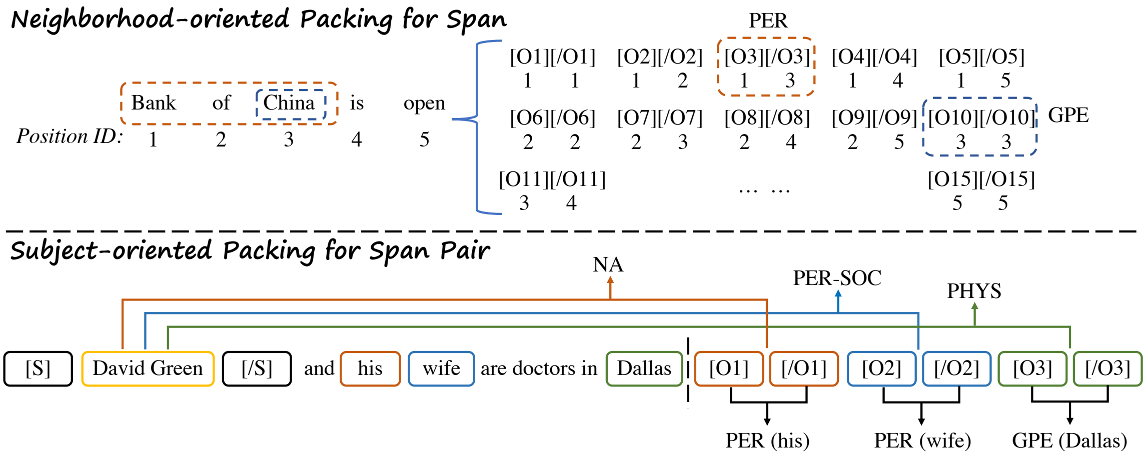

Figure 2: An overview of our neighborhood-oriented packing and subject-oriented packing strategies. [S][/S] are solid markers. [O][/O] are levitated markers. With a maximum group size, the neighborhood-oriented packing strategy clusters the neighbor spans, *e.g.* {(1,1),(1,2),...,(1,5)}, in the same group. The subject-oriented packing strategy encloses the subject span, *David Green*, with solid markers, applies levitated markers on its candidate object spans, *his*, *wife* and *Dallas*, and packs them into an instance.

on the vector A and B.

For instance, we apply the levitated marker to a typical overlapping span classification task, NER, which aims to assign an entity type or a non-entity type to each possible span in a sentence. We obtain the span representation from the PLM via the packed levitated markers and then combine the features of PL-Marker and T-Concat to better predict the entity type of the cadidate span.

3.3 Subject-oriented Packing for Span Pair

To obtain a span pair representation, a feasible method is to adopt levitated markers to emphasize a series of the subject and object spans simultaneously. Commonly, each pair of levitated markers is tied by the directional attention. But if we continue to apply directional attention to bind two pairs of markers, the levitated marker will not be able to identify its partner marker of the same span. Hence, as shown in Figure 2, our span pair model adopts a fusion subject-oriented packing scheme to offer an integral modeling for the same-subject spans.

Formally, given an input sequence X, a subject span, $s_i = (a, b)$ and its candidate object spans $(c_1, d_1), (c_2, d_2), ...(c_m, d_m)$, We insert a pair of solid markers [S] and [/S] before and after the subject span. Then, we apply levitated markers [O] and [/O] to all candidate object spans, and pack them into an instance. Let $\hat{X}$ denotes this modified sequence with inserted markers:

$$\hat{X} = ...[\text{S}], x_a, ..., x_b, [/\text{S}], ..., x_{c_1} \cup [\text{O1}], ..., \\ x_{d_1} \cup [/\text{O1}], ..., x_{c_2} \cup [\text{O2}], ..., x_{d_2} \cup [/\text{O2}]...,$$

where the tokens jointed by the symbol $\cup$ share the same position embedding. We apply a pre-trained encoder on $\hat{X}$ and finally obtain the span pair representation for $s_i = (a, b)$ and $s_j = (c, d)$:

$$\phi(s_i, s_j) = [h_{a-1}; h_{b+1}; h_c^{(s)}; h_d^{(e)}] \qquad (2)$$

where [;] denotes the concatenation operation. h_{a-1} and h_{b+1} denote the contextualized representation of the inserted solid markers for s_i; $h_c^{(s)}$ and $h_d^{(e)}$ are the contextualized representation of the inserted levitated markers for s_j.

Compared to the method that applies two pairs of solid markers on the subject and object respectively (Zhong and Chen, 2021), our fusion marker scheme replaces the solid markers with the levitated markers for the object span, which would impair the emphasis on the object span to some extent. To provide the supplemental information, we introduce an inverse relation from the object to the subject for a bidirectional prediction (Wu et al., 2020).

For instance, we evaluate our model on a typical span pair classification task, end-to-end RE, which concentrates on identifying whether all span pairs are related and their relation types. Following Zhong and Chen (2021), we first use a NER model to filter candidate entity spans, and then acquire the span pair representation of the filtered entity span pairs to predict the relation between them. Moreover, to build the connection between entity type and relation type, we add an auxiliary loss for predicting the type of object entity (Zhou and Chen, 2021; Han et al., 2021).

3.4 Complexity Analysis

Dominated by the large feed-forward network, the computation of PLM rises almost linearly with the increase in small sequence length (Dai et al., 2020; Ye et al., 2021). Gradually, as the sequence length continues to grow, the computation dilates quadratically due to the Self-Attention module (Vaswani et al., 2017). Obviously, the insertion of levitated markers extends the length of input sequence. For the span pair classification tasks, the number of candidate spans is relatively small , thus the increased computation is limited. For the span classification tasks, we group the markers into several batches, which can control the sequence length within the interval in which the complexity increases nearly linearly. For the NER, we enumerate candidate spans in a small-length sentence and then use its context words to expand the sentence to 512 tokens, for which the number of candidate spans in a sentence is usually less than the context length in practice. Hence, with a small number of packing groups, the complexity of PL-Marker is still near-linearly to the complexity of previous models.

Moreover, to further alleviate the inference cost, we adopt PL-Marker as a post-processing module of a two-stage model, in which it is used to identify entities from a small number of candidate entities proposed by a simpler and faster model.

4 Experiment

4.1 Experimental Setup

4.1.1 Dataset

For the NER task, we conduct experiments on both flat and nested benchmarks. Firstly, on the flat NER, we adopt CoNLL03 (Sang and Meulder, 2003), OntoNotes 5.0 (Pradhan et al., 2013) and Few-NERD (Ding et al., 2021). Then, on the nested NER, we use ACE04 (Doddington et al., 2004), ACE05 (Walker et al., 2006) and SciERC (Luan et al., 2018). The three nested NER datasets are also used to evaluate the end-to-end RE. We follow Luan et al. (2019) to split ACE04 into 5 folds and split ACE05 into train, development, and test sets. For other datasets, we adopt the official split. Table 1 shows the statistics of each dataset.

Dataset	#Sents	#Ents (#Types)	#Rels (#Types)
CoNLL03	22.1k	35.1k (4)	-
OntoNotes 5.0	103.8k	161.8k (18)	-
Few-NERD	188.2k	491.7k (66)	-
ACE05	14.5k	38.3k (7)	7.1k (6)
ACE04	8.7k	22.7k (7)	4.1k (6)
SciERC	2.7k	8.1k (6)	4.6k (7)

Table 1: The statistics of the adopted datasets.

4.1.2 Evaluation Metrics

For NER task, we follow a span-level evaluation setting, where the entity boundary and entity type are required to correctly predicted. For the end-to-end RE, we report two evaluation metrics: (1) **Boundaries evaluation** (Rel) requires the model to correctly predict the boundaries of the subject entity and the object entity, and the entity relation; (2) **Strict evaluation** (Rel+) further requires the model to predict the entity types on the basis of the requirement of the boundary prediction. Moreover, following Wang et al. (2021d), we regard each symmetric relational instance as two directed relational instances.

4.1.3 Implementation Details

We adopt *bert-base-uncased* (Devlin et al., 2019) and *albert-xxlarge-v1* (Lan et al., 2020) encoders for ACE04 and ACE05. For SciERC, we use the in-domain *scibert-scivocab-uncased* (Beltagy et al., 2019) encoder. For flat NER, we adopt *roberta-large* encoder. We also leverage the cross-sentence information (Luan et al., 2019; Luoma and Pyysalo, 2020), which extends each sentence by its context and ensures that the original sentence is located in the middle of the expanded sentence as much as possible. As discussed in Section 4.4.1, for the packing scheme on NER, we set the group size to 256 to improve efficiency. We run all experiments with 5 different seeds and report the average score. See the appendix for the standard deviations and the detailed training configuration.

4.2 Named Entity Recognition

4.2.1 Baselines

Our packing scheme allows the model to apply the levitated markers to process massive span pairs and to our best knowledge, we are the first to apply the levitated markers on the NER task. We compare our neighborhood-oriented packing scheme with

Model	CoNLL03	OntoN5	F-NERD
Ma and Hovy (2016)	91.0	86.3	-
Devlin et al. (2019)	92.8	89.2	68.9
Li et al. (2020)	93.0	91.1	-
Yu et al. (2020)	93.5	91.3	-
Yan et al. (2021)	93.2	90.4	-
SeqTagger (Our impl.)	93.6	91.2	69.0
T-Concat (Our impl.)	93.0	91.7	70.6
Random Packing	93.9	91.8	61.5
PL-Marker (Our model)	**94.0**	**91.9**	**70.9**

Table 2: Micro F1 on the test set for the flat NER. OntoN5: OntoNotes 5.0; F-NERD: Few-NERD.

the **Random Packing**, which randomly packs the candidate spans into groups. We adopt two common NER models: (1) **SeqTagger** (Devlin et al., 2019) regards NER as a sequence tagging task and applies a token-level classifier to distinguish the IOB2 tags for each word (Sang and Veenstra, 1999). (2) **T-Concat** (Jiang et al., 2020; Zhong and Chen, 2021) assigns an entity type or a non-entity type to each span based on its T-Concat span representation. Note that solid markers cannot deal with the overlapping spans simultaneously, thus it is too inefficient to apply solid markers independently on the NER task.

4.2.2 Results

We show the flat NER results in the Table 2 and the nested NER results in the Ent column of Table 3, where PURE (Zhong and Chen, 2021) applies the T-Concat feature on its NER module. As follow, some observations are summarized from the experimental results: (1) The model with our neighborhood-oriented packing strategy outperforms the model with random packing strategy on all three flat NER datsets, especially obtaining a 9.4% improvement on Few-NERD. Few-NERD contains longer sentences and thus includes 325 candidate spans on average, while CoNLL03 and OntoNotes 5.0 only contain 90 and 174 respectively. It shows that the neighborhood-oriented packing strategy can well handle the dataset with longer sentences and more groups of markers, to better model the interrelation among neighbor spans. (2) With the same large pre-trained encoder, PL-Marker achieves an absolute F1 improvement of +0.1%-1.1% over T-Concat on all six NER benchmarks, which shows the advantage of levitated markers in aggregating span-wise representation for the entity type prediction; (3) PL-Marker outperforms SeqTagger by an absolute F1 of +0.4%, +0.7%, +1.9% in CoNLL03, OntoNote 5.0 and Few-NERD respectively, where CoNLL03, OntoNote 5.0 and Few-NERD contain 4, 18 and 66 entity types respectively. Such improvements prove the effectiveness of PL-Marker in handling diverse interrelation between entities of diverse types.

4.3 Relation Extraction

4.3.1 Baselines

For the end-to-end RE, we compare our model, PL-Marker, with a series of state-of-the-art models. Here, we introduce two of the most representative works with T-Concat and Solid Markers span representation: (1) **DyGIE++** (Wadden et al., 2019) first acquires the T-Concat span representation, and then iteratively propagates coreference and relation type confidences through a span graph to refine the representation; (2) **PURE** (Zhong and Chen, 2021) adopts independent NER and RE models, where the RE model processes each possible entity pair in one pass. In their work, PURE (Full) adopts two pairs of solid markers to emphasize a span pair and the PURE (Approx) employs two pairs of levitated markers to underline the span pair.

4.3.2 Results

As shown in Table 3, with the same BERT$_{\texttt{BASE}}$ encoder, our approach outperforms previous methods by strict F1 of +1.7% on ACE05 and +2.5% on ACE04. With the SciBERT encoder, our approach also achieves the best performance on SciERC. Using a larger encoder, ALBERT$_{\texttt{XXLARGE}}$, both of our NER and RE models are further improved. Compared to the previous state-of-the-art model, PURE (Full), our model gains a substantially +4.1% and +4.3% strict relation F1 improvement on ACE05 and ACE04 respectively. Such improvements over PURE indicate the effectiveness of modeling the interrelation between the same-subject or the same-object entity pairs in the training process.

4.4 Inference Speed

In this section, we compare the models' inference speed on an A100 GPU with a batch size of 32. We use the `BASE` size encoder for ACE05 and SciERC in the experiments and the `LARGE` size encoder for flat NER models.

4.4.1 Speed of Span Model

We evaluate the inference speed of PL-Marker with different group size K on CoNLL03 and Few-NERD. We also evaluate a cascade **Two-stage**

model, which uses a fast `BASE`-size T-Concat model to filter candidate spans for our model. As shown in Table 4, PL-Marker achieves a 0.4 F1 improvement on CoNLL03 but sacrifices 60% speed compared to the SeqTagger model. And we observe that our proposed Two-stage model achieves similar performance to PL-Marker with 3.1x speedup on Few-NERD, which shows it is more efficient to use PL-Marker as a post-processing module to elaborate the coarse prediction from a simple model. In addition, when the group size grows to 512, PL-Marker slows down due to the increased complexity of the Transformer. Hence, we choose a group size of 256 in practice.

Model	**ACE05**		**SciERC**	
	Rel (F1)	Speed (sent/s)	Rel (F1)	Speed (sent/s)

Table 5: Comparison of our RE model and PURE in relation F1 (boundaries) and speed. We report the result with `BASE` encoders. All models adopt the same entity input from the entity model of PURE.

4.4.2 Speed of Span Pair Model

We apply the subject-oriented and the object-oriented packing strategies on levitated markers for RE. Here, we compare our model with the other two marker-based models. Firstly, **PURE (Full)** (Zhong and Chen, 2021) applies solid markers to process each entity pair independently. Secondly, **PURE (Approx.)** packs the levitated markers of all entity pairs into an instance for batch computation. Since the performance and the running time of the above methods rely on the quality and the number of predicted entities, for a fair comparison, we adopt the same entity input from the entity model of PURE on all the RE models. Table 5 shows the relation F1 scores and the inference speed of the above three methods. On both datasets, our RE model, PL-Marker, achieves the best performance and PURE (Approx.) has highest efficiency

Table 7: The relation F1 (boundaries) on the test set of ACE05 and SciERC with different input features for the ablation study. gold: use the gold entities; e2e: use the entities predicted by our entity model. w/o.: without. w.: with.

in the inference process. Compared to the PURE (Full), our model obtains a 2.2x-2.8x speedup and better performance on ACE05 and SciERC. Compared to PURE (Approx.), our model achieves a 2.8%-4.0% relation F1 (boundaries) improvement on ACE05 and SciERC, which again demonstrates the effectiveness of our fusion markers and packing strategy. Overall, our model, with a novel subject-oriented packing strategy for markers, has been proven effective in practice, with satisfactory accuracy and affordable cost.

4.5 Case Study

We show several cases to compare our span model with T-Concat and to compare our span pair model with PURE (Full). As shown in Table 6, our span model could collect contextual information, such as *Taiwan* and *mainland*, for underlined span, *Cross Strait*, assisting in predicting its type as organization rather than work of art. Our span model learns to integrally consider the interrelation between the same-object relational facts in training phase, so as to successfully obtain the fact that both *Liana* and *her parents* are located in *Manhattan*.

4.6 Ablation Study

In this section, we conduct ablation studies to investigate the contribution of different components to our RE model, where we apply `BASE` size encoder in the experiments.

Two pairs of Levitated Markers We evaluate the *w/o solid marker* baseline, which applies two pairs of levitated markers on the subject and object respectively and packs all the span pairs into an instance. As shown in Table 7, compared to PL-Marker, the model without solid markers drops a huge 2.0%-3.8% F1 on ACE05 and SciERC when the golden entities are given. The result demonstrates that it is sub-optimal to continue to apply directional attention to bind two pairs of levitated markers, since a pair of levitated marker is already tied by the directional attention.

Inverse Relation We establish an inverse relation for each asymmetric relation for a bidirectional prediction. We evaluate the model without inverse relation, which replaces the constructed inverse relation with a non-relation type and adopts a unidirectional prediction. As shown in Table 7, the model without inverse relation drops 0.9%-1.1% F1 on both datasets with the gold entities given, indicating the significance of modeling the information from the object entity to the subject entity in our asymmetric framework.

Entity Type We add an auxiliary entity type loss to RE model to introduce the entity type information. As shown in Table 7, when the gold entities are given, the model without entity type loss drops 0.4%-0.7% F1 on both datasets, which shows the importance of entity type information in RE. Moreover, we try to apply the type markers (Zhong and Chen, 2021), such as *[Subject:PER]* and *[Object:GPE]*, to inject entity type information predicted by the NER model into the RE model. We find the RE model with type marker performs slightly worse than the model with entity type loss in the end-to-end setting. It shows that the entity type prediction error from the NER model may be propagated to the RE model if we adopt the type markers as input features. Finally, we discuss when to use the entity type prediction from the RE model to refine the NER prediction in the Appendix and we finally refine entity type for ACE04 and ACE05 except SciERC according to their dataset statistic.

5 Conclusion

In this work, we present a novel packed levitated markers, with a neighborhood-oriented packing strategy and a subject-oriented packing strategy, to obtain the span (pair) representation. Considering the interrelation between spans and span pairs, our model achieves the state-of-the-art F1 scores and a promising efficiency on both NER and RE tasks across six standard benchmarks. In future, we will further investigate how to generalize the marker-based span representation to more NLP tasks.

Acknowledgement

This work is supported by the National Key R&D Program of China (No. 2020AAA0106502), Institute Guo Qiang at Tsinghua University, and International Innovation Center of Tsinghua University, Shanghai, China. We thank Chaojun Xiao and other members of THUNLP for their helpful discussion and feedback. Deming Ye conducted the experiments. Deming Ye, Yankai Lin, Xiaojun Xie and Peng Li wrote the paper. Maosong Sun provided valuable advices to the research.

A Training Configuration

We train all the models with Adam optimizer (Kingma and Ba, 2015) and 10% warming-up steps. And we adopt a learning rate of 2e-5 for models with `BASE` size and a learning rate of 1e-5 for models with `LARGE` or `XXLARGE` size. We run all experiments with 5 different seeds (42, 43, 44, 45, 46). For the bidirectional prediction on RE, we set the forward and inverse relation of symmetric labels to be consistent. The symmetric labels include the *PER-SOC* in the ACE04/ACE05 and the *Compare* and *Conjunction* in the SciERC.

For NER model, we set the maximum length of expanded sentence C as 512. For RE model, we set C as 256 for ACE05 and SciERC and set C as 384 for ACE04. To enumerate possible spans, we set the maximum span length L as 16 for OntoNote 5.0 and Few-NERD and set 8 for the other datasets. For the NER on CoNLL03 and the RE on ACE05, we search the batch size in [4,8,16,32] and observe the model with a batch size of 8 achieves a sightly better performance. Hence, we choose a batch size of 8 for all the datasets. We search the number of epochs in [3,5,8,10,15,50] for all the datasets and finally choose 8 for CoNLL03, 4 for OntoNote 5.0, 3 for Few-NERD, 10 for ACE05-NER, 15 for ACE04-NER, 50 for SciERC-NER and 10 for all the RE models.

B Prompt Initialization for NER

Inspired by the success of prompt tuning (Brown et al., 2020; Schick and Schütze, 2021), we use the embedding of meaningful words instead of randomness to initialize the embedding of markers for the NER models. To be specific, we initialize a pair of markers for the span with the words `[MASK]` and *entity*. As shown in Table 8, using meaningful words as prompt to initialize the markers can bring a slight improvement to all six NER benchmarks.

C Refine Entity Type

We attempt to apply the entity type prediction from the RE model to refine the entity type prediction from the NER model. As shown in Table 9, using the entity type predicted by the RE model brings +0.5% and -0.9% strict relation F1 on ACE05 and SciERC respectively. We observe that the most frequent entity type pair for each relation occupies 48.5% for ACE05, 52.0% for ACE04 and 19.1% for SciERC, which shows that the relation is more relevant to the entity type in ACE05 than that in SciERC. Hence, we only use the RE model to refine the NER results for ACE04 and ACE05.

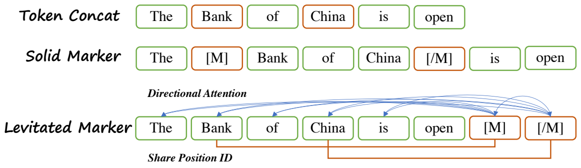

Figure 3: Span representation of T-Concat, Solid Marker and Levitated Marker. We highlight the attention direction for the levitated marker and omit the bidirectional attention line between other token pairs. Token Concat conveys the representation of edged token, [Bank] and [China], through the classifier, while Solid Marker and Levitated Marker employ the features of two markers, [M] and [/M] for classification.

Init Strategy	**CoNLL03**	**OntoNote 5.0**	**Few-NRED**

Chen, 2021) to obtain the PURE w. InvRel. model. As shown in Table 10, except for our asymmetric framework, the bidirectional prediction can also improve the symmetrical baseline PURE by 0.7%-2.4% relation F1 on ACE05 and SciERC.

E Detailed NER Results

We illustrate the span representation adopted by the NER models in Figure 3. And we show the average scores of the baselines and PL-Marker on flat NER with standard deviations in Table 11.

F Detailed RE Results

We show the average scores of PL-Marker on RE with standard deviations in Table 12.

An Interpretable Neuro-Symbolic Reasoning Framework for Task-Oriented Dialogue Generation

Shiquan Yang[1], **Rui Zhang**[2], **Sarah Erfani**[1], **and Jey Han Lau**[1]

Abstract

We study the interpretability issue of task-oriented dialogue systems in this paper. Previously, most neural-based task-oriented dialogue systems employ an *implicit* reasoning strategy that makes the model predictions uninterpretable to humans. To obtain a transparent reasoning process, we introduce neuro-symbolic to perform *explicit* reasoning that justifies model decisions by reasoning chains. Since deriving reasoning chains requires multi-hop reasoning for task-oriented dialogues, existing neuro-symbolic approaches would induce error propagation due to the one-phase design. To overcome this, we propose a two-phase approach that consists of a hypothesis generator and a reasoner. We first obtain multiple hypotheses, i.e., potential operations to perform the desired task, through the hypothesis generator. Each hypothesis is then verified by the reasoner, and the valid one is selected to conduct the final prediction. The whole system is trained by exploiting raw textual dialogues without using any reasoning chain annotations. Experimental studies on two public benchmark datasets demonstrate that the proposed approach not only achieves better results, but also introduces an interpretable decision process. Code and data: `https://github.com/shiquanyang/NS-Dial`.

1 Introduction

Neural task-oriented dialogue systems have enjoyed a rapid progress recently (Peng et al., 2020; Hosseini-Asl et al., 2020; Wu et al., 2020), achieving strong empirical results on various benchmark datasets such as SMD (Eric et al., 2017) and Multi-WOZ (Budzianowski et al., 2018). However, most existing approaches suffer from the lack of explainability due to the black-box nature of neural networks (Doshi-Velez and Kim, 2017; Lipton, 2018; Bommasani et al., 2021), which may hurt the trustworthiness between the users and the system. For instance, in Figure 1, a user is asking for a hotel recommendation at a given location. The system performs reasoning on a knowledge base (KB) and incorporates the correct entity in the response. However, when the system fails to provide the correct entities, it would be difficult for humans to trace back the issues and debug the errors due to its intrinsic *implicit* reasoning nature. As a result, such system cannot be sufficiently trusted to be deployed in real-world products.

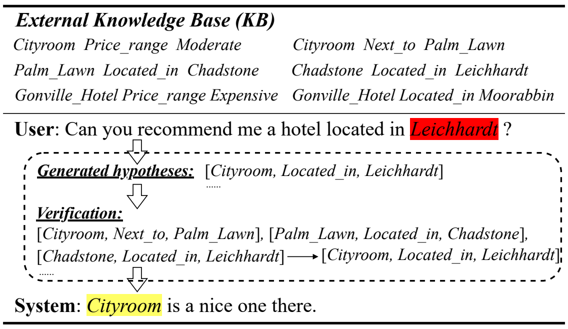

Figure 1: An example dialogue that incorporates external KB. The context entity (i.e., *Leichhardt*) and answer entity (i.e., *Cityroom*) are marked as Red and Yellow, respectively. The triple containing the context entity and answer entity is not directly stored in KB and should be derived by a reasoning chain formed by multiple KB triplets.

To achieve trustworthy dialogue reasoning, we aim to develop an interpretable KB reasoning as it's crucial for not only providing useful information (e.g., locations in Figure 1) to users, but also essential for communicating options and selecting target entities. Without interpretability, it's difficult for users to readily trust the reasoning process and the returned entities.

To tackle this challenge, we present a novel **N**euro-**S**ymbolic **Dial**ogue framework (**NS-Dial**) which combines representation capacities of neural networks and explicit reasoning nature of symbolic approaches (e.g., rule-based expert systems). Existing neuro-symbolic approaches (Vedantam et al.,

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics
Volume 1: Long Papers, pages 4918 - 4935
May 22-27, 2022

2019; Chen et al., 2020) mostly employ a one-phase procedure where a tree-structured program composed of pre-defined human interpretable neural modules (e.g., attention and classification modules in Neural Module Networks (Andreas et al., 2016)) is generated to execute to obtain the final predictions. However, since the KB reasoning task involves a reasoning process spanning over multiple triplets in a diverse and large-scale KB, only generating and following a single program (i.e., a reasoning chain formed by KB triplets) is prone to error propagation where a mistake in one step could lead to a failure of the subsequent reasoning process and may result in sub-optimal performances.

To address this, we propose a two-phase procedure to alleviate the effects of error propagation by first generating and then verifying multiple hypotheses. Here, a hypothesis is in the form of a triplet containing an entity mentioned in dialogue context and an entity within KB, and their corresponding relation. The valid (i.e., correct) hypothesis is the one that contains the entity mentioned in the ground-truth response. Once we obtain multiple hypothesis candidates during the generation phase, we employ a reasoning engine for verifying those hypotheses. For instance in Figure 1, given the user query "*Can you recommend me a hotel located in Leichhardt?*", in order to find the valid hypothesis, the hypothesis generator obtains multiple candidates e.g., *[Cityroom, Located_in, Leichhardt]* and *[Gonville_Hotel, Located_in, Leichhardt]*. The reasoning engine will then construct proof trees to verify them, e.g., for the first hypothesis *[Cityroom, Located_in, Leichhardt]*, it can be verified with the following reasoning chain in the KB: *[Cityroom, Next_to, Palm_Lawn]* → *[Palm_Lawn, Located_in, Chadstone]* → *[Chadstone, Located_in, Leichhardt]*. The whole framework is trained end-to-end using raw dialogues and thus does not require additional intermediate labels for either the hypothesis generation or verification modules.

To summarize, our contributions are as follows:

- We introduce a novel neuro-symbolic framework for interpretable KB reasoning in task-oriented dialogue systems.
- We propose a two-phase "generating-and-verifying" approach which generates multiple hypotheses and verifies them via reasoning chains to mitigate the error-propagation issue.
- We conduct extensive experimental studies on two benchmark datasets to verify the effectiveness of our proposed model. By analyzing the generated hypotheses and the verifications, we demonstrate our model's interpretability.

2 Related Work

Task-Oriented Dialogue Traditionally, task-oriented dialogue systems are built via pipeline-based approaches where task-specific modules are designed separately and connected to generate system responses (Chen et al., 2016; Zhong et al., 2018; Wu et al., 2019a; Chen et al., 2019a; Huang et al., 2020). In another spectrum, many works have started to shift towards end-to-end approaches to reduce human efforts (Bordes et al., 2017; Lei et al., 2018; Madotto et al., 2018; Moon et al., 2019; Jung et al., 2020). Lei et al. (2018) propose a two-stage sequence-to-sequence model to incorporate dialogue state tracking and response generation jointly in a single sequence-to-sequence architecture. Zhang et al. (2020) propose a domain-aware multi-decoder network (DAMD) to combine belief state tracking, action prediction and response generation in a single neural architecture. Most recently, the success of large-scale pre-trained language models (e.g., BERT, GPT-2) (Devlin et al., 2018; Radford et al., 2019) has spurred a lot of recent dialogue studies starting to explore large-scale pre-trained language model for dialogues (Wolf et al., 2019; Zhang et al., 2019). In task-oriented dialogue, Budzianowski and Vulić (2019) use GPT-2 to fine-tune on MultiWOZ dataset for dialogue response generation. Peng et al. (2020) and Hosseini-Asl et al. (2020) employed a single unified GPT-2 model jointly trained for belief state prediction, system action and response generation in a multi-task fashion. However, most existing approaches cannot explain why the model makes a specific decision in a human understandable way. We aim to address this limitation and introduce interpretability for dialogue reasoning in this study.

Neuro-Symbolic Reasoning Neuro-Symbolic reasoning has attracted a lot of research attentions recently due to its advantage of exploiting the representational power of neural networks and the compositionality of symbolic reasoning for more robust and interpretable models (Andreas et al., 2016; Hu et al., 2017; Hudson and Manning, 2018; Vedantam et al., 2019; Chen et al., 2019b; Vedantam et al., 2019; van Krieken et al., 2022). The main difference between neuro-symbolic vs. pure neural networks lies in how the former combines basic rules or modules to model complex functions. Rocktäschel and Riedel (2017) propose a neuro-symbolic model that can jointly learn sub-symbolic representations and interpretable rules from data via standard back-propagation. In visual QA, Andreas et al. (2016) propose neural module networks to compose a chain of differentiable modules wherein each module implements an operator from a latent program. Yi et al. (2018) propose to discover symbolic program trace from the input question and then execute the program on the structured representation of the image for visual question answering. However, these approaches cannot be easily adapted to task-oriented dialogues due to the error propagation issue caused by multi-hop reasoning on large-scale KBs. Thus, we aim to bridge this gap by developing a neuro-symbolic approach for improving task-oriented dialogues.

3 Preliminary

In this work, we focus on the problem of task-oriented dialogue response generation with KBs. Formally, given the dialogue history X and knowledge base B, our goal is to generate the system responses Y word-by-word. The probability of the generated responses can be written as:

$$p(Y|X,B) = \prod_{t=1}^{n} p(y_t|X,B,y_1,y_2,...,y_{t-1}) \tag{1}$$

where y_t is the t-th token in the response Y. The overall architecture is shown in Figure 2. We start by introducing the standard modules in our system and then explain the two novel modules afterward.

3.1 Dialogue Encoding

We employ pre-trained language model BERT (Devlin et al., 2019) as the backbone to obtain the distributed representations for each token in the dialogue history. Specifically, we add a $[CLS]$ token at the start of the dialogue history to represent the overall semantics of the dialogue. The hidden states $H_{enc} = (h_{CLS}, h_1, ..., h_M)$ for all the input tokens $X = ([CLS], x_1, ..., x_M)$ are computed using:

$$H_{enc} = \text{BERT}_{\text{enc}}(\phi^{emb}(X)) \tag{2}$$

where M is the number of tokens in the dialogue history, ϕ^{emb} is the embedding layer of BERT.

3.2 Response Generation

To generate the system response, we first utilize a linear layer to project H_{enc} to $H'_{enc} = (h'_{CLS}, h'_1, ..., h'_M)$ that are in the same space of the decoder. We initialize the decoder with h'_{CLS}. During decoding timestep t, the model utilizes the hidden state $h_{dec,t}$ to attend H'_{enc} to obtain an attentive representation $h'_{dec,t}$ via standard attention mechanism. We then concatenate $h_{dec,t}$ and $h'_{dec,t}$ to form a context vector C and project it into the vocabulary space $\mathcal{V}$:

$$C = [h_{dec,t}, h'_{dec,t}] \tag{3}$$

$$P_{vocab,t} = \text{Softmax}(U_1 C) \tag{4}$$

where U_1 is a learnable linear layer, $P_{vocab,t}$ is the vocabulary distribution for generating the token y_t.

Next, we aim to estimate the KB distribution $P_{kb,t}$, i.e., the probability distribution of entities in the KB, in an interpretable way and fuse $P_{vocab,t}$ and $P_{kb,t}$ for generating the final output tokens. We follow See et al. (2017) and employ a soft-switch mechanism to fuse $P_{vocab,t}$ and $P_{kb,t}$ to generate output token y_t. Specifically, the generation probability $p_{gen} \in$ [0,1] is computed from the attentive representation $h'_{dec,t}$ and the hidden state $h_{dec,t}$:

$$p_{gen} = \sigma(U_2([h'_{dec,t}, h_{dec,t}])) \tag{5}$$

where σ is sigmoid function, U_2 is a linear layer. The output token y_t is generated by greedy sampling from the probability distribution $P(w)$:

$$P(w) = p_{gen} P_{vocab,t} + (1 - p_{gen}) P_{kb,t} \tag{6}$$

We next describe how to obtain the KB distribution $P_{kb,t}$ in details using the two novel modules we proposed, i.e., hypothesis generator and hierarchical reasoning engine.

4 Neuro-Symbolic Reasoning For Task-Oriented Dialogue

To compute the KB distribution $P_{kb,t}$, we present two novel modules: hypothesis generator (HG) and hierarchical reasoning engine (HRE). We take the context vector C (Equation 3) as the input of HG module and generate K hypotheses $\mathbb{H}$, each of which are then fed into the HRE module to generate the logical reasoning chains and their belief scores. The estimated belief scores are then served as $P_{kb,t}$, giving us a distribution over the entities in the KB. Next, we describe how each component works in detail and explain how they interact with each other for generating $P_{kb,t}$.

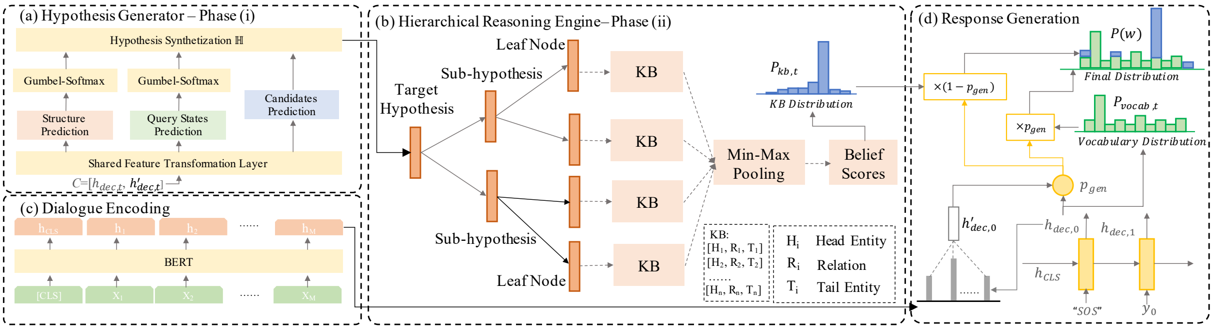

Figure 2: Illustration of the overall architecture: (a) hypothesis generator generating a set of synthesized hypotheses; (b) reasoning engine used to verify the generated hypotheses; (c) dialogue encoding; (d) response generation.

4.1 Hypothesis Generator

Let a hypothesis be a 3-tuple of the form "$[H, R, T]$", where H and T are the head and tail entities, and R is the relation between entities. In this paper, we are interested in three types of hypotheses including the H-Hypothesis, T-Hypothesis, and R-Hypothesis. The H-Hypothesis is the structure where the tail entity T and relation R are inferred from the context and the head entity H is unknown (which needs to be answered using the KB), and it takes the form "$[\triangleright, R, T]$". In a similar vein, the T-Hypothesis and R-Hypothesis have unknown tail entity T and relation R, respectively. The goal of the Hypothesis Generator module is to generate hypotheses in this triple format which will later be verified by the Hierarchical Reasoning Engine.

Intuitively, a hypothesis can be determined by its content and structure. The structure indicates the template form of the hypothesis while the content fills up the template. For instance, the H-Hypothesis has its template form of "$[\triangleright, R, T]$" and the content that needs to be realised includes candidate entities (i.e., "$\triangleright$"), and query states (i.e., the tail "T" and relation entities "R"). To this end, we employ a divide-and-conquer strategy to jointly learn three sub-components: structure prediction, query states prediction, and candidates prediction. Next, we describe each sub-component in details.

Structure Prediction (SP) The goal of the structure prediction module is to determine the structure of the hypothesis (i.e., H/T/R-Hypothesis) based on the context. For example in Figure 1, one might expect an H-Hypothesis at timestep 0. Specifically, SP uses a shared-private architecture to predict the hypothesis type. It first takes the context vector C (Equation 3) as input and utilizes a shared transformation layer between all the three sub-components to learn task-agnostic feature h_{share}:

$$h_{share} = W_2(\text{LeakyReLU}(W_1 C)) \tag{7}$$

where W_1 and W_2 are learnable parameters (shared by the structure prediction, query states prediction and candidate prediction components) and LeakyReLU is the activation function.

The shared layer can be parameterised with complicated neural architectures. However, to keep our model simple, we use linear layers which we found to perform well in our experiments. SP next uses a private layer on top of the shared layer to learn task-specific features for structure prediction:

$$h^{sp}_{private} = W_4(\text{LeakyReLU}(W_3 h_{share})) \tag{8}$$

where W_3 and W_4 are learnable parameters. For ease of presentation, we define the private feature transformation function as:

$$\mathcal{F}^{\star} : h_{share} \rightarrow h^{\star}_{private} \tag{9}$$

where $\star$ denotes any of the three sub-components. To obtain the predicted hypothesis structure, a straightforward approach is to apply softmax on $h^{sp}_{private}$. However, this will break the differentiability of the overall architecture since we perform sampling on the outcome and pass it to the neural networks. To avoid this, we utilize the Gumbel-Softmax trick (Jang et al., 2017) over $h^{sp}_{private}$ to get the sampled structure type:

$$\text{I}_{sp} = \text{Gumbel-Softmax}(h^{sp}_{private}) \in \mathbb{R}^3 \tag{10}$$

where I_{sp} is a one-hot vector and the index of one element can be viewed as the predicted structure. In this paper, we define 0 as H-Hypothesis, 1 as T-Hypothesis and 2 as R-Hypothesis.

Query States Prediction (QSP) Query states are the tokens in hypothesis that need to be inferred from the dialogue history. For example, one might want to infer relation *R=Located_in* and tail

T=Leichhardt based on the history in Figure 1. Therefore, the goal of the query states prediction is to estimate the state information (e.g., T and R in H-Hypothesis) of hypothesis. Specifically, QSP takes the shared feature h_{share} as the input and next applies the private feature transformation function followed by Gumbel-Softmax to obtain the state tokens of hypothesis using:

$$h^{qsp,k}_{private} = \mathcal{F}^{qsp,k}(h_{share}) \quad (11)$$

$$\mathrm{I}^{k}_{qsp} = \text{Gumbel-Softmax}(h^{qsp,k}_{private}) \in \mathbb{R}^{n} \quad (12)$$

where n is the number of tokens (entities and relations) in the KB, $k \in \{0,1\}$, I^0_{qsp} and I^1_{qsp} are two one-hot vectors where their corresponding tokens in KB serve as the state tokens of the hypothesis.

Candidates Prediction (CP) To generate the final hypotheses, we need multiple candidates to instantiate the structure of the hypothesis except the state tokens, e.g., *Cityroom* or *Gonville_Hotel* as candidate head entities H in Figure 1. To this end, we utilize an embedding layer ϕ^{emb}_{cp} to convert all the tokens in the KB to vector representations. We then compute a probability distribution over all the KB tokens using:

$$\mathrm{P}_i = \text{Sigmoid}(\phi^{emb}_{cp}(K_i) \odot h_{share}) \quad (13)$$

where K_i is the i-th token in KB, ϕ^{emb}_{cp} is the embedding layer of CP, P_i is the probability of the i-th token to be candidate, $\odot$ denotes inner-product. We use sigmoid instead of softmax as we find that softmax distribution is too "sharp" making the probability between different tokens are hard to differentiate for sampling multiple reasonable candidates.

Hypothesis Synthesizing The final hypotheses $\mathbb{H}$ are composed by combining the outputs of the three sub-components as follows: (i) We generate the hypothesis template according to the predicted structure type. For example, if SP predicts a structure type 0 which denotes H-Hypothesis, the model will form a template of "$[\triangleright, R, T]$"; (ii) We next instantiate the state tokens in the hypothesis sequentially by using the outputs of QSP module. For example, if the output tokens of QSP are "*Located_in*" (k=0) and "*Leichhardt*" (k=1), the hypothesis will become $[\triangleright,$ *Located_in*$,$ *Leichhardt*$]$; (iii) Finally, we instantiate the candidate (i.e., $\triangleright$) with the top-K (K =5 in our best-performing version) entities selected from P. If the top-2 highest probability tokens are *Cityroom* and *Gonville_Hotel*, the model will instantiate two hypotheses *[Cityroom, Located_in, Leichhardt]*, *[Gonville_Hotel, Located_in, Leichhardt]*.

4.2 Hierarchical Reasoning Engine

With the hypotheses generated by HG module, we next aim to verify them via logical reasoning chains. Inspired by Neural Theorem Provers (Rocktäschel and Riedel, 2017), we develop chain-like logical reasoning with following format:

$$\alpha,\ (H, R, T) \leftarrow (H, R_n, Z_n) \wedge \cdots \wedge (Z_1, R_1, T) \quad (14)$$

where α is a weight indicating the *belief* of the model on the target hypothesis $[H, R, T]$, and the right part of the arrow is the reasoning chain used to prove that hypothesis, and R_i and Z_i are relations and entities from the KB. The goal is to find the proof chain and the confidence α for a given hypothesis. To this end, we introduce a neural-network based hierarchical reasoning engine (HRE) that learns to conduct chain-like logical reasoning. At a high level, HRE recursively generates multiple levels of sub-hypotheses using neural networks that form a tree structure as shown in Figure 2. Next, we describe how this module works in details.

The module takes the output hypotheses from the HG module as input. Each hypothesis serves as one target hypothesis. To generate the reasoning chain in Equation 14, the module first finds sub-hypotheses of the same format as the target in the hypothesis space. The sub-hypotheses can be viewed as the intermediate reasoning results to prove the target. One straightforward approach is to use neural networks to predict all the tokens in the sub-hypotheses (2 heads, 2 tails and 2 relations). However, this can lead to extremely large search space of triples and is inefficient. Intuitively, sub-hypotheses inherit from the target hypothesis and sub-hypotheses themselves are connected by bridge entities. For example, *[Uber,office_in,USA]* can be verified by two sub-hypotheses *[Uber,office_in,Seattle]* and *[Seattle,a_city_of,USA]*, *Uber* and *USA* are inherited from the target and *Seattle* is the bridge entity between sub-hypotheses. Motivated by this, we propose to reduce the triple search complexity by constraining the sub-hypotheses. Specifically, given target $[H, R, T]$, we generate sub-hypotheses of the format $[H, R_1, Z]$,$[Z, R_2, T]$, where Z is the bridge entity, R_1 and R_2 are relations to be predicted. Therefore, the goal of the neural networks has been reduced to predict three tokens (2 relations and 1 bridge entity). Formally, HRE predicts the vector representation of bridge entity as follows:

$$h_H, h_R, h_T = \phi_{cp}^{emb}(H), \phi_{cp}^{emb}(R), \phi_{cp}^{emb}(T) \quad (15)$$

$$h_Z = W_6(\text{LeakyReLU}(W_5[h_H, h_R, h_T])) \quad (16)$$

where $[h_H, h_R, h_T]$ are the concatenation of the representations of tokens in target hypothesis, h_Z is the vector representation of bridge entity Z. The prediction of h_{R_1} and h_{R_2} uses the same architecture in Equation 16 and the difference is that they use different linear layers for the feature transformation. Note that h_Z denotes a KB token in the embedding space. We can decode the token by finding the nearest KB token to h_Z in vector space. More details on the token decoding can be found in Appendix A. Upon obtaining h_Z, h_{R_1}, h_{R_2}, the module generates the two sub-hypotheses in vector representations. Next, the module iteratively takes each of the generated sub-hypothesis as input and extend the proof process by generating next-level sub-hypotheses in a depth-first manner until the maximum depth D has been reached.

Belief Score To model confidence in different reasoning chains, we further measure the semantic similarities between each triple of the leaf node and triples in the KB, and compute the belief score α_m of the m-th hypothesis $\mathbb{H}_m$:

$$\alpha_m = \min_{\forall i \in U} \max_{\forall j \in V} e^{-d_j(Leaf_i, KB_j)} \quad (17)$$

where $Leaf_i$ is the representation (concatenation of H, R, T) of the i-th leaf node in the proof tree (DFS manner), KB_j is the representation of the j-th triple in KB, U=[0,...,u-1], V=[0,...,v-1] where u and v are the number of leaf nodes and KB triples correspondingly, d is the distance metric. In general, any distance function can be applied and we adopt Euclidean distance in our implementation since we found that it worked well in our experiments. All the triples in the leaf nodes form the reasoning chain for the input hypothesis as in Equation 14. The hypotheses $\mathbb{H}$ coupled with the belief α form our KB distribution $P_{kb,t}$. More details can be found in Appendix B. Intuitively, the belief score can be viewed as the likelihood of the hypothesis contains the correct entity. If the hypothesis is valid (i.e., contains the correct answer entity), it should have a high likelihood and thus encourage to generate more proper reasoning chains based on the triples stored in the KB.

Training We apply two loss functions to train the whole architecture end-to-end. The first loss function $\mathcal{L}_{gen}$ is for the final output. We use a cross-entropy loss over the ground-truth token and the generated token from the final distribution $P(w)$. The second loss $\mathcal{L}_{cp}$ is for the candidates prediction (CP) module in the hypotheses generator. We apply binary cross-entropy loss over the output distribution for each KB token (Equation 13) and their corresponding labels. The labels for each KB token are computed as follows:

Dataset	Domains	Train	Dev	Test
SMD	Navigate,Weather,Schedule	2425	302	304
MultiWOZ 2.1	Restaurant,Attraction,Hotel	1839	117	141

Table 1: Statistics of SMD and MultiWOZ 2.1.

$$Label_i = \begin{cases} 1, & K_i = y_t \\ 0, & K_i \neq y_t \end{cases} \quad (18)$$

where K_i is the i-th token in the KB and y_t is the ground-truth output at timestep t. The final loss $\mathcal{L}$ is calculated by:

$$\mathcal{L} = \gamma_g * \mathcal{L}_{gen} + \gamma_c * \mathcal{L}_{cp} \quad (19)$$

where γ_g and γ_c are hyper-parameters and we set them to 1 in our experiments.

5 Experiments

5.1 Datasets

To evaluate the effectiveness and demonstrate the interpretability of our proposed approach, we conduct experiments on two public benchmark datasets for task-oriented dialogue in this paper, SMD (Eric et al., 2017) and MultiWOZ 2.1 (Budzianowski et al., 2018). We use the partitions created by Eric et al. (2017); Madotto et al. (2018) and Qin et al. (2020) for SMD and MultiWOZ, respectively. Statistics of the datasets are presented in Table 1. In the Appendix E, we present several additional results on a large-scale synthetic dataset to demonstrate our model's multi-hop reasoning capability under complex KB reasoning scenarios.

5.2 Baselines

We compare our model with the following state-of-the-art baselines on KB reasoning in task-oriented dialogues: (1) Mem2Seq (Madotto et al., 2018): employs memory networks to store the KB and combine pointer mechanism to either generate tokens from vocabulary or copy from memory; (2) GLMP (Wu et al., 2019b): uses a global-to-local pointer mechanism to query the KB during decoding; (3) DF-Net (Qin et al., 2020): employs

	SMD					MultiWOZ 2.1				
Model	BLEU	F1	Navigate F1	Weather F1	Calendar F1	BLEU	F1	Restaurant F1	Attraction F1	Hotel F1
Mem2Seq	12.6	33.4	20.0	32.8	49.3	6.6	21.6	22.4	22.0	21.0
GLMP	13.9	60.7	54.6	56.5	72.5	6.9	32.4	38.4	24.4	28.1
GraphDialog	14.2	61.1	56.4	56.9	72.1	6.7	34.1	39.2	27.8	29.6
DF-Net	14.4	62.7	57.9	57.6	73.1	9.4	35.1	40.9	28.1	30.6
Ours (D=1)	14.9	63.8	60.1	58.7	75.0	9.7	36.5	42.0	29.7	32.8
Ours (D=3)	**15.6***	**64.5***	**60.3***	**59.2***	**75.6***	**10.6***	**37.2***	**42.6***	**30.6***	**33.7***
Ours (D=5)	14.5	63.5	59.4	57.9	74.8	9.3	36.2	41.7	28.8	31.5

Table 2: Main results. D denotes the maximum depth of HRE module. We run each experiment 5 times with different random seeds and report the average results. * denotes that the improvement of our framework over all baselines are statistically significant with $p < 0.05$ under t-test. Following Qin et al. (2020), we report *Navigate, Weather, Calendar* on SMD and *Restaurant, Attraction, Hotel* on MultiWOZ for per-domain results.

shared-private architecture to capture both domain-specific and domain-general knowledge to improve the model transferability; (4) GraphDialog (Yang et al., 2020): incorporates graph structural information obtained from sentence dependency parsing results for improving KB reasoning accuracy and response generation quality. Detailed experimental settings are included in Appendix C.

5.3 Main Results

Following prior work (Eric et al., 2017; Madotto et al., 2018; Wu et al., 2019b), we adopt the *BLEU* and *Entity F1* metrics to evaluate the performance of our framework. The results on the two datasets are shown in Table 2. As we can see, our framework consistently outperforms all the previous state-of-the-art baselines on all datasets across both metrics. Specifically, on MultiWOZ dataset, our model achieves more than 2% absolute improvement in Entity F1 and 1.2% improvement in BLEU over baselines. The improvement in Entity F1 indicates that our model enhances KB reasoning, while the increase in BLEU suggests that the quality of the generated responses has been improved. The same trend has also been observed on SMD dataset. This indicates the effectiveness of our proposed framework for task-oriented dialogue generation.

5.4 Model Interpretability

To demonstrate our framworks's interpretability, we investigate the inner workings of our framework. As shown in Figure 3, given the dialogue history "*Can you recommend me a restaurant near Palm_Beach?*", the generated response is "*There is a Golden_House.*". During the 3rd timestep, our model has successfully predicted an appropriate *H-Hypothesis* with *Located_in* and *Palm_Beach* as its state tokens. Our model further instantiates five concrete hypotheses and computes their belief scores leveraging the reasoning engine, respectively. As we can see from the table, our model successfully generates five reasonable hypotheses and scores them correctly (with highest score for the oracle KB entity *Golden_House*). The proof process for the highest score hypothesis is shown in Figure 3. The verification procedure generated by the HRE module has a depth of 3 and the reasoning chaining used to verify the target hypothesis is: *[Golden_House, Next_to, Preston_Market]* → *[Preston_Market, Located_in, Williamstown]* → *[Williamstown, Located_in, Herb_Garden]* → *[Herb_Garden, Located_in, Palm_Beach]*. This indicates that our framework has successfully utilized the KB information to support the reasoning process *explicitly* to reach a correct conclusion. More examples and error analyses can be found in the Appendix (Appendix E.4 and F).

5.5 Ablation Study

We ablate each component in our framework to study their effectiveness on both datasets. The results are shown in Table 3. Specifically, 1) w/o HRE denotes that we simply use the probability in candidates prediction (CP) module (Equation 13) as the KB distribution without using the scores from the reasoning engine. 2) w/o BERT denotes that we use standard GRU as encoder instead of BERT. 3) w/o Soft-switch denotes that we simply sum the KB distribution and vocabulary distribution without using a soft gate. As we can see from the table, all the individual components have notably contributed to the overall performance of

Dialogue history: *Can you recommend me a restaurant near Palm_Beach?* **Predicted response**: *There is a Golden_House.*

Structure Type	**State Tokens**	**Top-5 Candidate Tokens**	**Set of Generated Hypotheses**	**Belief Scores**

- w/o HRE	59.4	5.1	30.5	6.7
- w/o BERT	61.3	3.2	33.4	3.8
- w/o Soft-switch	62.0	2.5	35.1	2.1

Table 3: Ablation studies on two benchmark datasets.

	SMD		MultiWOZ 2.1	
Model	Original F1 (%)	Unseen F1 (%)	Original F1 (%)	Unseen F1 (%)
GLMP	60.7	55.3	32.4	23.9
GraphDialog	61.1	55.7	34.1	25.4
DF-Net	62.7	57.2	35.1	26.5
Ours (Full)	**64.5**	**61.1**	**37.2**	**32.8**

Table 4: Generalization test results on two datasets.

our framework. Specifically, when removing HRE module, the performance has decreased substantially (more than 5% absolute drop), which confirms that the effectiveness of the proposed hierarchical reasoner module.

5.6 Generalization Capability

We further investigate the generalization ability of our model under unseen settings. In the original dataset released by prior works, the entity overlap ratio between the train and test split is 78% and 15.3% for MultiWOZ 2.1 and SMD, respectively. To simulate unseen scenario, we construct a new dataset split that reduces the entity overlap ratio to 30% for MultiWOZ 2.1 and 2% for SMD between the train and test split, which is a more challenging setting for all the models. More details of the construction process can be found in Appendix D. We re-run all the baselines with their released codes and our model on the new data split and report the results in Table 4. As we can see, the performance drops significantly for all systems on both datasets. However, our model degrades less compared to other systems, showing that it has better generalisation capability under unseen scenarios. This also verifies that neuro-symbolic approach has the advantage of better generalisation ability which has also been confirmed by many other studies (Andreas et al., 2016; Rocktäschel and Riedel, 2017; Minervini et al., 2020).

5.7 Human Evaluation

Following prior work (Qin et al., 2020), we also conduct human evaluations for our framework and baselines from three aspects: *Correctness*, *Fluency*, and *Humanlikeness*. Details about the scoring criterions can be found in Appendix H. We randomly select 300 different dialogue samples from the test set and ask human annotators to judge the quality of the responses and score them according to the three metrics ranging from 1 to 5. We train the annotators by showing them examples to help them

Model	Correct	Fluent	Humanlike
GLMP	4.01	3.78	3.25
GraphDialog	4.15	4.19	3.40
DF-Net	4.16	4.25	3.54
Ours (Full model)	**4.41**	**4.28**	**3.59**
Human	4.83	4.65	4.57
Agreement	75%	69%	71%

Table 5: Human evaluation results.

understand the criteria and employ Fleiss' kappa (Fleiss, 1971) to measure the agreement across different annotators. The results are shown in Table 5. As we can see, our model outperforms all baselines across all the three metrics, consistent with our previous observations using automatic evaluations.

6 Conclusion

In this paper, we propose an explicit and interpretable Neuro-Symbolic KB reasoning framework for task-oriented dialogue generation. The hypothesis generator employs a divide-and-conquer strategy to learn to generate hypotheses, and the reasoner employs a recursive strategy to learn to generate verification for the hypotheses. We evaluate our proposed framework on two public benchmark datasets including SMD and MultiWOZ 2.1. Extensive experimental results demonstrate the effectiveness of our proposed framework, as well being more interpretable.

7 Ethical Considerations

For the human evaluation in this paper, we recruit several annotators on Amazon Mechanical Turk from English-speaking countries. We pay the annotators USD$0.15 for each annotation task. Each task can be finished on average in 1 minute, which amounts to $9.0 per hour that is above the US federal minimum wage ($7.25). To ensure the quality of the human evaluation results, we perform quality control in a few ways. First, the annotators will be shown our scoring standards (Appendix H) before their tasks, and are asked to follow them. If the task is not done properly, either as determined by expert judgements (we recruit 3 native English speakers to validate the results of the Turkers' annotations) or there are obvious patterns such as constantly giving the same score for all tasks, we remove their annotations. We also compute agreement score to check for the consistency among the annotators.

A Details on Token Decoding in HRE

Given the vector representations of the generated sub-hypotheses in hierarchical reasoning engine module, we utilize the similarity-based approach to decode the symbolic representations of those sub-hypotheses. Specifically, given a generated sub-hypotheses $[h_H, h_R, h_T]$, where h_H, h_R and h_T are the vector representations for the head entity, relation and tail entity correspondingly. To decode the symbolic representations for the head, relation and tail entities, we use:

$$\arg\min_{\forall i} \quad \|\phi(K_i) - h_H\|^2. \tag{20}$$

$$\arg\min_{\forall j} \quad \|\phi(K_j) - h_R\|^2. \tag{21}$$

$$\arg\min_{\forall k} \quad \|\phi(K_k) - h_T\|^2. \tag{22}$$

where *i*, *j* and *k* are the indices for the head entity, relation and tail entity in the vocabulary, K_i, K_j, K_k denotes the i-th, j-th, k-th token of the KB, $\phi(K_i)$ denotes the embedding of the i-th token. Through this, we can decode the generated sub-hypotheses and obtain their explicit symbolic representations.

B Details on KB Distribution Calculation

We extract the KB distribution $P_{kb,t}$ at timestep t from the generated hypotheses and their corresponding belief scores as follows. For instance, if the generated hypothesis $[H, R, T]$ is an H-Hypothesis with a belief score α, we extract the candidate token of the H-Hypothesis which is H and then pair H with the belief score α, where α is viewed as the probability of the token H to be selected as the output at timestep t. We conduct this for all the generated hypotheses and their corresponding belief scores from the HG and HRE modules. Finally, all the candidate tokens paired with their belief scores form the $P_{kb,t}$ at timestep t.

C Experimental Settings

The dimensionality of the embedding and the decoder RNN hidden units are 128 and embeddings are randomly initialized. The dropout ratio is selected from [0.1, 0.5]. We use Adam (Kingma and Ba, 2014) optimizer to optimize the parameters in our model and the learning rate is selected from [$1e^{-3}$,$1e^{-4}$]. For the encoder, we fine-tune the BERT-base-uncased model from HuggingFace's library with an the embedding size of 768 with 12 layers and 12 heads. The maximum depth D of the HRE module is selected from [1,5], the maximum number of candidates K in CP module is selected from [1,10], and the temperature of Gumbel-Softmax is 0.1. All hyper-parameters are selected according to the validation set, and we repeat all the experiments 5 times with different random seeds and report the average results.

D Details on Unseen Setting

We construct new dataset splits both on SMD and MultiWOZ 2.1 to simulate unseen scenarios for testing the generalization ability of all the models. Specifically, we construct the new dataset split as follows: We first extract all the KB entities that appeared in the dialogue responses and accumulate the percentage of samples for each KB entity. Second, we rank all the entities according to their percentage of samples in a decreasing order. Next, we split the KB entity set into train entities and test entities by accumulating the total percentages of samples. Finally, we iterate each sample in the dataset and assign it to train or test split by checking whether the entity in the response belong to the train entities or test entities. In this way, we obtain a new dataset split for both SMD and MultiWOZ 2.1, which has an entity overlap ratio of 2% and 30%, respectively, between train and test split (overlap ratio in the original SMD and MultiWOZ 2.1 are 15.3% and 78%, respectively).

The dataset statistics for the unseen splits are shown in Table 6 and Table 7:

Dataset	**Train**	**Dev**	**Test**
SMD	1850	311	870
MultiWOZ 2.1	1472	252	373

Table 6: Statistics of Unseen Dataset for SMD and MultiWOZ 2.1.

Dataset	Ent. Overlap Standard	Ent. Overlap Unseen	$\Delta \downarrow$
SMD	15.3%	2%	13.3%
MultiWOZ 2.1	78%	30%	48%

Table 7: Entity Overlap Ratio Comparisons Between Unseen Split and Original Split for SMD and MultiWOZ 2.1. Entity Overlap Ratio = |Train Entities $\bigcap$ Test Entities| / |Total Entities|.

E Additional Experiments

We find that KB reasoning for most existing task-oriented dialogue datasets are quite simple, for the most part only requiring that only one or two hop reasoning over the KB in order to answer the user's request successfully. To further test our model and baseline models' multi-hop reasoning capability under complex reasoning scenarios, we develop a large-scale multi-domain synthetic dataset consisting dialogues requiring multi-hop reasoning over KBs. This is similar in spirit to bAbI dataset, and we hope that this dataset will continue to be used with other dialogue benchmarks in future studies. We will release this dataset upon publication. Next, we describe how we construct the dataset in details and show the experimental results performed on it.

E.1 Dataset Construction

As is shown in Figure 4, each sample in the dataset consists of several rounds of dialogues. We generate the questions and answers of the dialogues by randomly sample template utterances with placeholders (e.g., *@movie*, *@director*, *@location*) indicating the types of KB entities to be instantiated to form the complete utterances. To simulate a natural conversation between user and system under different scenarios (i.e., restaurant booking, hotel reservation, movie booking), we designed 18 different types of question-answer templates. For example, *movie to director* denotes that the user requests the director given the movie name, *location to theatre* denotes the user requires theatre information given the location. For each conversation, we randomly select several different types of question-answer templates sequentially to form the skeleton of the whole dialogue. To ensure the coherent of the dialogue flow, we provide the guided next types for each question-answer template. For instance, if the current sampled question-answer type is *location to restaurant*, the guided next types will be randomly sampled from *restaurant to price*, *restaurant to cuisine* etc. Thus, we can ensure the generated dialogue turns more coherent in terms of semantics to simulate a real conversation as much as possible.

For each conversation, we generate 3 or 4 rounds of dialogues following the existing work such as *SMD* and *MultiWOZ 2.1*. At each round of the dialogue, we randomly select a question-answer template and instantiate the placeholders in the template with the corresponding types of KB entities. If there are multiple entities in the KB satisfy the types indicated by the placeholders, we randomly sample one to implement the template. In this way, we can increase the diversity of the generated data. For instance, if the question template is *Is there any restaurant located in @district?*, the possible sets of entities in the KB for the placeholder *@district* might include multiple location entities in the KB such as *vermont*, *blackburn* etc. We randomly sample one of them to replace the placeholder and generate a final sentence. If we sample *vermont*, the implemented sentence will be *Is there any restaurant located in the vermont?.*

To make the generated dialogue utterances more natural as human conversations, we further randomly replace the KB entities in the sentence with pronouns such as *it*, *they* etc, provided that the entities have been mentioned in previous dialogue turns. Thus, it requires the model to overcome the co-reference resolution to arrive at the correct answer which increases the difficulty. For example, *Who is the director of the movie mission impossible?* will be rephrased as *Who is the director of it?* if the movie name *mission impossible* has been mentioned in the dialogue history.

For movie domain, we employ the KB used in the well-known *WikiMovie* dataset. For hotel and restaurant domain, we use the KB provided in the *MultiWOZ 2.1* dataset. For each employed KB, we further extend it by adding information such as hierarchies of locations to enrich the KB in order to make it suitable for testing multi-hop reasoning capability. For example, if the KB contains a hotel entity *love lodge*, we add different levels of location information to support multi-hop KB reasoning. For instance, we add location information such as *love_lodge next_to lincoln_park*, *lincoln_park is_within waverley_district*, *waverley_district located_in grattan_county*. Thus, if the user asked about the hotel located in *grattan_county*, it requires the model to conduct multi-hop reasoning over the KB to know that *love_lodge*is located in *grattan_county*. Through this, we make our synthetic dataset suitable for multi-hop reasoning tasks over KB under task-oriented dialogue scenarios. The location information we utilized in the synthetic dataset are obtained from the Wikipedia and the official website of famous cities around the world.

Cityroom Price_range Moderate
Cityroom Next_to Palm_Lawn
Chadstone Located_in Leichhardt
Gonville_Hotel Price_range Expensive
Cityroom Stars 3
Palm_Lawn Located_in Chadstone
Gonville_Hotel Stars 4
Gonville_Hotel Located_in Moorabbin

User: Can you recommend me a hotel located in *Leichhardt* ?
System: *Cityroom* is a nice one there.
User: How much does it cost there ?
System: It has a *moderate* price range.
User: What is the rating of it ?
System: It is a *3 star* hotel.

Figure 4: An example dialogue from the hotel domain of the synthetic dataset. The first turn of the dialogue requires a 3-hop reasoning over the KB to get the correct entity Cityroom given the location information Leihhardt. The second and third turn of the dialogue require single-hop reasoning over KB to get the correct entity.

E.2 Dataset Statistics

The detailed statistics of the synthetic dataset are shown in Table 8 and Table 9:

Domain	Train	Dev	Test
Movie	7219	1645	1667
Hotel	7115	1631	1639
Restaurant	7131	1672	1684
Total	21465	4948	4990

Table 8: Statistics of synthetic dataset. Numbers in the table are the number of instances for each category.

E.3 Experimental Results

Evaluation Metrics. We use the same metrics as on *SMD* and *MultiWOZ 2.1* dataset includes *BLEU* and *Entity F1* for performance evaluation.

Results. The results on the three domains are shown in Table 10, 11, 12. For each domain, we evaluate the model performance on different subsets of the test data, i.e., 1-hop, 2-hop and >=3-hop. Specifically, we group the test data into three different subsets according to the KB reasoning length for obtaining the ground-truth entity. For instance, 2-hop denotes that the KB entity mentioned in the response needs 2-hop reasoning over the KB. As we can see from the tables, our proposed model consistently outperforms all the baselines by a large margin across all the domains and KB reasoning lengths. We also observe that all the models' performance decrease monotonously as the KB reasoning path length increases, suggesting that KB reasoning with longer range is challenging for all the tested models. However, our framework has less performance degradation compared to all the baselines, and the performance gap between our framework and the baselines has become larger when the length of KB reasoning increases, which demonstrates that our framework has better generalization ability especially under longer KB reasoning paths compared to those baselines.

E.4 Example Outputs

We show the generated hypotheses and the proof trees in our framework as shown in Table 13 and Figure 5. As we can see, our model can successfully obtain the correct entities from the KB. Moreover, our framework can formulate sensible hypotheses and generate reasonable proof procedures which can help us gain some insights about the inner workings of our model.

F Error Analysis

We conduct error analysis on both *SMD* and *MultiWOZ 2.1* to provide insights in our framework for future improvements. We randomly sample 100 dialogues from each test set and analysis both the generated responses and the inner procedures. The errors have four major categories: 1) structure errors, 2) query states errors, 3) candidates errors, 4) belief score errors. For example, given dialogue history "*Where is a nearby parking_garage?*", the generated response is "*5671_barringer_street is 1_mile away.*" and the ground-truth is "*The nearest one is palo_alto_garage, it's just 1_mile away.*". The generated hypotheses by HG module at timestep 0 are "[*5671_barringer_street*, *distance*, *1_mile*], [*whole_foods*, *distance*, *1_mile*], [*home*, *distance*, *1_mile*], [*valero*, *distance*, *1_mile*], [*pizza_chicago*, *distance*, *1_mile*]". The predicted structure type is a H-Hypothesis with a relation "*distance*" and tail entity "*1_mile*". However, a reasonable hypothesis should be an H-Hypothesis such as "[*palo_alto_garage*, *poi_type*, *parking_garage*]" with "*poi_type*" (place of interest) and "*parking_garage*" as relation and tail. This illustrates the challenge of the task, and we plan to further improve our framework include SP, QSP, CP and HRE in future work.

F.1 Structure Prediction Errors

Given the dialogue history "*Find me a nearby shopping mall.*", the generated response is "*midtown_shopping_center is 3_miles away.*" and

Structure Type	State Tokens	Top-5 Candidate Tokens	Generated Hypotheses	Belief Scores
H-Hypothesis	"*located_in* (k=0)"	"*Shipping_News*"	"*[Shipping_News, located_in, Springfield]*"	0.15
		"*Vaudeville*"	"*[Vaudeville, located_in, Springfield]*"	0.17
		"*Brown_Eyes*"	"*[Brown_Eyes, located_in, Springfield]*"	0.13
	"*Springfield* (k=1)"	"*Oakland*"	"*[Oakland, located_in, Springfield]*"	1.00
		"*Coburg*"	"*[Coburg, located_in, Springfield]*"	0.04

Table 13: Example outputs on the movie domain of synthetic dataset. Dialogue history: "*I'm looking for a theatre in the Springfield district.*". Generated response: "*Sure I have found a Oakland for you.*". Detailed model working process when generating Oakland in the response is shown above.

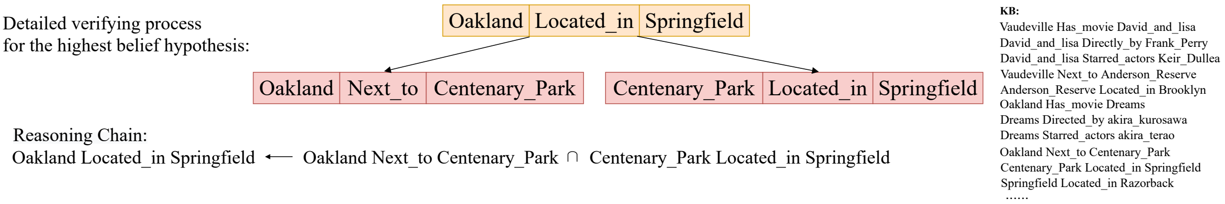

Figure 5: Proof tree generated by HRE module for the highest score hypothesis *[Oakland, Located_in, Springfield]* in Table 13. The red parts are the predicted bridge entities and the blue parts are the predicted relations for the sub-hypotheses via neural networks. In this case, the model performs 2-hop reasoning (the two leaf node triples) to find the correct KB entity for generating the response.

the ground-truth response is "*The closest shopping_center is midtown_shopping_center 3_miles away.*". The generated hypotheses by HG module at decoding timestep 0 are "*[home, address, 5671_barringer_street]*, *[home, address, 481_amaranta_ave]*, *[home, address, midtown_shopping_center]*, *[home, address, 5_miles]*, *[home, address, 1_miles]*". As we can see, the predicted structure type is an T-Hypothesis with an head entity "*home*" and relation "*address*". However, a reasonable structure type should be an H-Hypothesis such as "*[midtown_shopping_center, poi_type, shopping_center]*" which the model has mispredicted to a T-Hypothesis.

F.2 Query States Prediction Errors

Given the dialogue history "*What time is dinner tonight?*", the generated response is "*Dinner is at 11pm.*" and the ground-truth response is "*Your dinner is 5pm tonight.*". The generated hypotheses in HG module for decoding timestep 3 are "*[dinner, traffic_info, 11pm]*, *[dinner, traffic_info, 7pm]*, *[dinner, traffic_info, 3pm]*, *[dinner, traffic_info, Monday]*, *[dinner, traffic_info, Tuesday]*". As we can see, the SP and QSP modules have successfully predicted a sensible T-Hypothesis with "*dinner*" as head entity. However, the predicted relation "*traffic_info*" is not reasonable according to context where an expected relation would be relations such as "time".

F.3 Candidates Prediction Errors

Given the dialogue history "*What time is my doctor_appointment?*", the generated response is "*Your doctor_appointment is on Thursday.*" and the ground-truth response is "*Your doctor_appointment is scheduled for Friday at 11am.*". The generated hypotheses by HG for decoding timestep 4 are "*[doctor_appointment, date, Thursday]*, *[doctor_appointment, date, Monday]*, *[doctor_appointment, date, 7pm]*, *[doctor_appointment, date, Tuesday]*, *[doctor_appointment, date, 2pm]*". As we can see, our framework has correctly predicted a T-Hypothesis and state tokens. However, the predicted top-5 candidate tokens don't include the ground-truth date which is *Friday*, which might affect the final response generation.

F.4 Belief Score Prediction Errors

Given the dialogue history "*Where is home?*", the generated response is "*Home is at 819_alma_st.*" and the ground-truth is "*Home is where is your heart, at 56_cadwell_street.*" The generated hypotheses for decoding timestep 3 are "*[home, address, 819_alma_st]*, *[home, address, 56_cadwell_street]*, *[home, address, 6_miles]*, *[home, address, 611_ames_ave]*, *[home, address, 3_miles]*". As we can see, our framework has predicted a sensible T-Hypothesis with "*home*" as head entity and "*address*" as relation. Also, the CP module has predicted top-5 candidate tail entities which include the ground-truth *56_cadwell_street*. But the HRE module ranked "*[home, address, 819_alma_st]*" highest with a score of 0.78 while the ground-truth one "*[home, address, 56_cadwell_street]*" is only ranked the second highest with a score of 0.41, which indicates that there is still room for improvements for the HRE module. We are interested in continually improving our framework include all the modules in future work.

G Discussions

G.1 Why not use search-based techniques for generating reasoning chains?

This is an alternative approach to our learning-based method. However, search-based approach cannot be jointly learnt end-to-end with other modules in our framework, and thus may face error propagation and credit assignment issues like in the traditional pipeline-based task-oriented dialogue approaches. In this work, we want to explore the possibility of learning end-to-end the logical reasoning chain directly from the dialogues. Also, the time complexity of search-based approach is approximately $O(n^k)$, where n is the average degree of nodes in the external knowledge base, k is the number of reasoning hops. In other words, the time complexity tends to have polynomial growth (when $k > 1$); and it's worse when the reasoning complexity (k) increases (exponential). In contrast, when the number of KB nodes increases it only impacts the size of the input embedding layer in our framework (Equation 15), and the efficiency can be further improved by leveraging modern accelerating hardware such as GPU (which search-based approaches cannot).

G.2 Why sample with Gumbel-Softmax instead of directly applying argmax in Hypothesis Generator and Hierarchical Reasoning Engine modules?

Argmax function is non-differentiable which hinders our aim of end-to-end differentiability of the whole system. We tried utilizing REINFORCE (reward is obtained by comparing predicted entities with ground-truth entities) to mitigate this issue. However, we find that the results of using argmax+REINFORCE is worse than using Gumbel-Softmax. By checking the sampled tokens from Gumbel-Softmax, we find that it can generate reasonable tokens (Figure 3 in the main paper, state tokens etc.), since we have set the temperature parameter of Gumbel-Softmax to 0.1 which is a close approximation to argmax.

G.3 Why not expand the KB using KB completion methods and then use semantic parsing to query KB?

In this work, we are interested in developing an end-to-end trainable framework with explainable KB reasoning. Semantic parsing is one possible alternative. However, when adapting to our own dataset, it requires further annotations for fine-tuning which is costly and time-consuming, and might be not feasible for large-scale datasets. Also, it might induce the error propagation issue since the different modules (KB completion, semantic parsing, dialogue encoding and response generation etc.) are not jointly learnt.

G.4 KB scale.

The average nodes of KB for each sample in the training data is 63.5 for *SMD* and 57.6 for *MultiWOZ*. The average number of relations is 5.5 for *SMD* and 9.4 for *MultiWOZ*.

H Human Evaluation Details

The *Fluency* of the predicated responses is evaluated according to the following standards:

- 5: The predicted responses contain no grammar errors or repetitions at all.
- 4: Only one grammar error or repetition appeared in the generated responses.
- 3: One grammar error one repetition, or two grammar errors, or two repetitions are observed in the responses.
- 2: One grammar error two repetitions, or one repetition two grammar errors, or three grammar errors, or three repetitions appeared in the generated responses.
- 1: More than three inappropriate language usages with regard to grammar errors or repetitions are observed in the responses.

The *Correctness* is measured as follows:

- 5: Provide the correct entities.
- 4: Minor mistakes in the provided entities.
- 3: Noticeable errors in the provided entities but acceptable.

- 2: Poor in the provided entities.
- 1: Wrong in the provided entities.

The *Humanlikeness* is measured as:

- 5: 100% sure that the sentences are generated by a human, not by system.
- 4: 80% chance that the sentences are generated by a human.
- 3: Cannot tell whether the sentences is generated by a human or system, 50% for human and 50% for system.
- 2: 20% chance that the sentences are generated by a human.
- 1: Totally impossible that the sentences are generated by a human.

Impact of Evaluation Methodologies on Code Summarization

Abstract

There has been a growing interest in developing machine learning (ML) models for code summarization tasks, e.g., comment generation and method naming. Despite substantial increase in the effectiveness of ML models, the evaluation methodologies, i.e., the way people split datasets into training, validation, and test sets, were not well studied. Specifically, no prior work on code summarization considered the timestamps of code and comments during evaluation. This may lead to evaluations that are inconsistent with the intended use cases. In this paper, we introduce the time-segmented evaluation methodology, which is novel to the code summarization research community, and compare it with the mixed-project and cross-project methodologies that have been commonly used. Each methodology can be mapped to some use cases, and the time-segmented methodology should be adopted in the evaluation of ML models for code summarization. To assess the impact of methodologies, we collect a dataset of (code, comment) pairs with timestamps to train and evaluate several recent ML models for code summarization. Our experiments show that different methodologies lead to conflicting evaluation results. We invite the community to expand the set of methodologies used in evaluations.

1 Introduction

Over the last several years, there has been a growing interest in applying machine learning (ML) models to code summarization tasks, such as comment generation (Iyer et al., 2016; Hu et al., 2018a; Wan et al., 2018; Liang and Zhu, 2018; Hu et al., 2018b; LeClair et al., 2019; Fernandes et al., 2019; Xu et al., 2019; LeClair and McMillan, 2019; LeClair et al., 2020; Hu et al., 2020; Ahmad et al., 2020; Cai et al., 2020; Gros et al., 2020) and method naming (Allamanis et al., 2016; Alon et al., 2019a,b; Fernandes et al., 2019; Nguyen et al., 2020). Substantial progress has been reported over years, usually measured in terms of automatic metrics (Roy et al., 2021).

Despite a solid progress in generating more accurate summaries, the *evaluation methodology*, i.e., the way we obtain training, validation, and test sets, is solely based on conventional ML practices in natural language summarization, without taking into account the domain knowledge of software engineering and software evolution. For example, temporal relations among samples in the dataset are important because the style of newer code summaries can be affected by older code summaries; however, they are not explicitly modeled in the evaluation of code summarization in prior work, which assumed the samples in the dataset are independent and identically distributed. This gap could lead to inflated values for automatic metrics reported in papers and misunderstanding if a model might actually be useful once adopted.

The key missing piece in prior work is the description of the targeted *use cases* for their ML models. Prior work has implicitly targeted only the batch-mode use case: applying the model to existing code regardless of *when* the code is written. However, a more realistic scenario could be the continuous-mode use case: training the model with code available at a timestamp, and using the model on new code after that timestamp (as illustrated in Figure 1). Considering that programming languages evolve and coding styles are constantly revised, results obtained in batch-mode could be very different from those obtained in continuous-mode. Thus, it is insufficient to only report the task being targeted in a paper, and *it is necessary to explain intended use cases for the ML models.* Once the task and use cases are clearly defined, an appropriate evaluation methodology (or potentially several methodologies) should be used.

In this paper, we study recent literature on ML models for code summarization. By reasoning about their evaluation methodologies (which we

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics

May 22-27, 2022

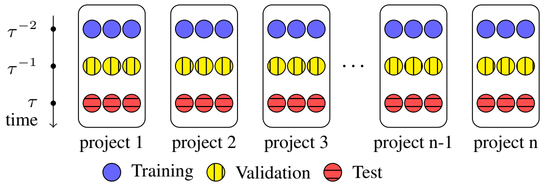

Figure 1: Continuous-mode use case that can be evaluated with the proposed time-segmented methodology.

call mixed-project and cross-project), we define two use cases that could be evaluated by these methodologies. Next, we define a more practical use case when a developer uses a fixed model continuously over some period of time. We describe an appropriate evaluation methodology for this use case: time-segmented. Finally, we evaluate several existing ML models using the three methodologies.

We highlight two key findings. First, depending on the employed methodology we end up with conflicting conclusions, i.e., using one methodology, model A is better than model B, and using another methodology, model B is better than model A. Second, our results show that the absolute values for automatic metrics vary widely across the three methodologies, which indicates that models might be useful only for some use cases but not others. Thus, it is imperative that future work describes what use case is being targeted and use the appropriate evaluation methodology.

In summary, this paper argues that we need to more diligently choose evaluation methodology and report results of ML models. Regardless of whether or not the conclusions of prior work hold across methodologies, we should always choose the methodology appropriate for the targeted task and use case. We hope the community will join us in the effort to define the most realistic use cases and the evaluation methodology for each use case.

We hope that our work will inspire others to design and formalize use cases and methodologies for other tasks. Only a few research studies on defect prediction (D'Ambros et al., 2012; Tan et al., 2015; Wang et al., 2016; Kamei et al., 2016), program repair (Lutellier et al., 2020), and bug localization (Pradel et al., 2020) took into consideration software evolution when evaluating ML models. Taking software evolution into account in those tasks appears more natural, but is not more important than in code summarization. Moreover, for the first time, we present an extensive list of potential use cases and evaluation methodologies side-by-side, as well as the impact of choosing various methodologies on the performance of ML models.

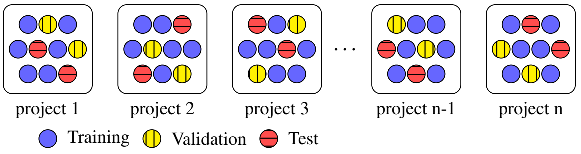

Figure 2: Mixed-project methodology.

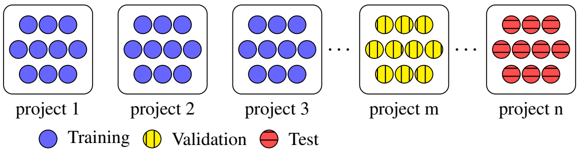

Figure 3: Cross-project methodology.

Our code and data are available at `https://github.com/EngineeringSoftware/time-segmented-evaluation`.

2 Methodologies

We first summarize two commonly used methodologies: mixed-project (§2.1) and cross-project (§2.2). Then, we introduce a novel time-segmented methodology (§2.3). We will use $\tau^{-2} < \tau^{-1} < \tau$ to denote specific points in time (i.e., timestamps).

Table 1 lists prior work on developing new ML models for code summarization. The last three columns show which methodology/methodologies were used in the evaluation in each work (MP: mixed-project, CP: cross-project, T: time-segmented). Out of 18 papers we found, 15 used the mixed-project methodology and 4 used the cross-project methodology. No prior work used the time-segmented methodology.

2.1 Mixed-Project

The *mixed-project* methodology, which is the most commonly used methodology in prior work, extracts samples (code and comments) at a single timestamp (τ) from various projects, then randomly shuffles the samples and splits them into training, validation, and test sets.

Figure 2 illustrates this methodology, where each box represents a project and each circle represents a sample. This methodology is *time-unaware*, i.e., it does not consider if samples in the test sets are committed into a project before or after samples in the training or validation sets.

Table 1: Methodologies used in prior work on code summarization; we use the highlighted lines in our experiments.

2.2 Cross-Project

The *cross-project* methodology, also commonly used in prior work, extracts samples at a single timestamp (τ) from various projects as well. Unlike the mixed-project methodology, the cross-project methodology splits the *set of projects* into three disjoint sets for training, validation, and test. Thus, the samples from one project are contained in only one of the training, validation, and test sets.

Figure 3 illustrates this methodology. The cross-project methodology is explicitly evaluating the ability to generalize a model to new projects. However, cross-project is also time-unaware, i.e., it does not consider if the samples from a project in the test set come before or after the samples from the projects in the training set.

2.3 Time-Segmented

We introduce a novel methodology: *time-segmented*. Unlike the methodologies explained earlier, the time-segmented methodology is *time-aware*, i.e., the samples in the training set were available in the projects *before* the samples in the validation set, which were in turn available *before* the samples in the test set.

Figure 1 illustrates this methodology. The samples available before τ^{-2} (i.e., their timestamps are earlier than τ^{-2}) are assigned to the training set. The samples available after τ^{-2} and before τ^{-1} are assigned to the validation set. And finally, the samples available after τ^{-1} and before τ (which is the time when the dataset is collected) are assigned to the test set. This assignment may not be the only approach to satisfy the definition of the time-segmented methodology, but is one approach that utilizes all samples collected at τ. Alternative assignments, e.g., excluding samples available before τ^{-3} (a timestamp earlier than τ^{-2}) from the training set, may have other benefits, which we leave for future work to study.

3 Use Cases

Methodologies are used to set up experiments and obtain an appropriate dataset split for the evaluation. However, they do *not* describe the envisioned usage of an ML model. Prior work picked a methodology in order to set up experiments, but we argue that ML models should be described with respect to *use cases*, i.e., how will the developers use the models eventually. Once a use case is chosen, an appropriate methodology can be selected to evaluate the model.

In this section, we define three use cases via examples of the comment generation task. The first two use cases are "extracted" from prior work. Namely, we reason about the mixed-project and the cross-project methodologies used in prior work and try to link each to a (somewhat) realistic use case. The third use case is inspired by our own development and can be evaluated using the time-segmented methodology. Note that we do not try to provide an exhaustive list of use cases, but rather to start off this important discussion on the distinction between a use case and an evaluation methodology. For the simplicity of our discussion, we only focus on the training and test sets (since the validation set can be regarded as the "open" test set for tuning).

3.1 In-Project Batch-Mode Use Case

Consider Alice, a developer at a large software company. Alice has been developing several software features in her project over an extended period of time (since τ^{-1}), but she only wrote comments for a part of her code. At one point (τ), she decides it is time to add documentations for the methods without comments, with the help of an ML model. Alice decides to train a model using already existing samples (i.e., (code, comment) pairs for the methods with comments) in her code, and since this may provide only a small number of training samples, she also uses the samples (available at time τ) from other projects. We call this *in-project batch-mode use case*, because Alice trains a new model every time she wants to use the model, and she applies it to a large amount of methods that may be added before or after the methods in the training set. This use case can be evaluated using the mixed-project methodology (§2.1).

Because prior work using the mixed-project methodology did not set any limit on the timestamps for samples in training and test sets, the time difference between samples in the two sets can be arbitrarily large. Moreover, the model is applied on all projects that it has been trained on. These two facts make the in-project batch-mode use case less realistic, for example, a sample from project A available at time τ may be used to predict a sample from project B available at time τ^{-1}, and a sample from project B available at time τ may be used to predict a sample from project A available at time τ^{-1}, simultaneously.

3.2 Cross-Project Batch-Mode Use Case

In this case, we assume that Alice works on a project (since τ^{-1}) without writing any documentation for her code. At some point (τ), Alice decides to document all her methods, again with the help of an ML model. Since Alice does not have any comments in her code, she decides to only train on the samples (i.e., (code, comment) pairs) from other projects (at time τ). Once the model is trained, she uses it to generate comments for all the methods in her project. We call this *cross-project batch-mode use case*, because Alice trains a new model at a specific timestamp and applies it to all the methods on a new project. (Note that once she integrates the comments that she likes, she can use them in the future for training a new ML model, which matches in-project batch-mode use case, or potentially she could decide to ignore those comments and always generates new comments, but this is unlikely.) This use case can be evaluated using the cross-project methodology (§2.2).

While the cross-project methodology is reasonable for evaluating model generalizability, the cross-project batch-mode use case does make strong assumptions (e.g., no documentation exists for any method in the targeted projects).

3.3 Continuous-Mode Use Case

In this case, Alice writes comments for each method around the same time as the method itself. For example, Alice might integrate a model for comment generation into her IDE that would suggest comments once Alice indicates that a method is complete. (Updating and maintaining comments as code evolves (Panthaplackel et al., 2020; Liu et al., 2020; Lin et al., 2021) is an important topic, but orthogonal to our work.) Suppose at τ^{-1}, Alice downloads the latest model trained on the data available in her project and other projects before τ^{-1}; such model could be trained by her company and retrained every once in a while (finding an appropriate frequency at which to retrain the model is a topic worth exploring in the future). She can keep using the same model until τ when she decides to use a new model. We call this *continuous-mode*, because the only samples that can be used to train the model are the samples from the past. This use case can be evaluated using the time-segmented methodology (§2.3).

4 Application of Methodologies

We describe the steps to apply the methodologies following their definitions (§2) with a given dataset, as illustrated in Figure 4. The input dataset contains samples with timestamps, and the outputs include: a training and validation set for each methodology to train models; a *standard test* set for each methodology to evaluate the models for this methodology only; and a *common test* set for each pair of methodologies to *compare* the same models on the two methodologies. Appendix A presents the formulas

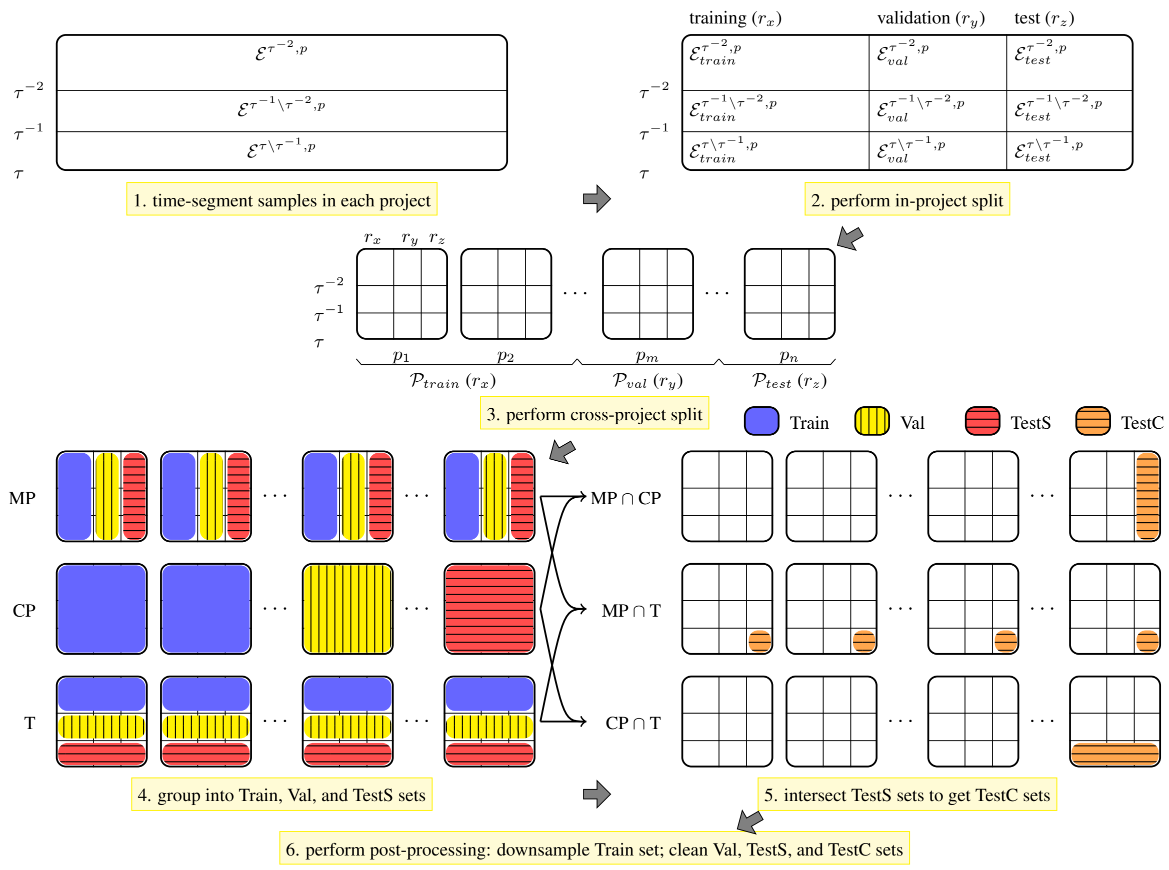

Figure 4: Steps of processing a dataset into training, validation, standard test, and common test sets.

of each step.

Step 1: time-segment. See Figure 4 top left part. A project is horizontally segmented into three parts by timestamps τ^{-2} and τ^{-1}.

Step 2: in-project split. See Figure 4 top right part. A project is further vertically segmented into three parts randomly, which is orthogonal to the time segments in step 1.

Step 3: cross-project split. See Figure 4 middle part. Projects are assigned to training, validation, and test sets randomly, which is orthogonal to the time segments and in-project splits in step 1 and 2.

Step 4: grouping. Now that the dataset is broken down to small segments across three dimensions (time, in-project, and cross-project), this step groups the appropriate segments to obtain the training (Train), validation (Val), and standard test (TestS) sets for each methodology. This is visualized in Figure 4 bottom left part.

Step 5: intersection. The common test (TestC) set of two methodologies is the intersection of their TestS sets. This is visualized in Figure 4 bottom right part.

In theory, we could compare all three methodologies on the intersection of the three TestS sets, but in practice, this set is too small (far less than 4% of all samples when we assign 20% projects and 20% samples in each project into test set).

Step 6: postprocessing. To avoid being impacted by the differences in the number of training samples for different methodologies, we (randomly) downsample their Train sets to the same size (i.e., the size of the smallest Train set).[1]

The evaluation (Val, TestS, TestC) sets may contain samples that are duplicates of some samples in the Train set, due to code clones (Sajnani et al., 2016; Roy et al., 2009) and software evolution (Fluri et al., 2007; Zaidman et al., 2011). We remove those samples as they induce noise to the evaluation of ML models (Allamanis, 2019). We present the results of removing exact-duplicates in the main paper, but we also perform experiments of removing near-duplicates to further reduce this noise and report their results in Appendix B (which do not affect our main findings).

---

[1] This is not required if training ML models under a specific methodology without comparing to other methodologies.

5 Experiments

We run several existing ML models using different methodologies to understand their impact on automatic metrics, which are commonly used to judge the performance of models.

5.1 Tasks

We focus on two most studied code summarization tasks: comment generation and method naming. We gave our best to select well-studied, representative, publicly-available models for each task; adding more models may reveal other interesting observations but is computationally costly, which we leave for future work.

Comment generation. Developers frequently write comments in natural language together with their code to describe APIs, deliver messages to users, and to communicate among themselves (Padioleau et al., 2009; Nie et al., 2018; Pascarella et al., 2019). Maintaining comments is tedious and error-prone, and incorrect or outdated comments could lead to bugs (Tan et al., 2007, 2012; Ratol and Robillard, 2017; Panthaplackel et al., 2021). Comment generation tries to automatically generate comments from code. Prior work mostly focused on generating an API comment (e.g., JavaDoc summary) given a method.

We used three models: DeepComHybrid model from Hu et al. (2018a, 2020), Transformer model and Seq2Seq baseline from Ahmad et al. (2020). We used four automatic metrics that are frequently reported in prior work: BLEU (Papineni et al., 2002) (average sentence-level BLEU-4 with smoothing (Lin and Och, 2004b)), METEOR (Banerjee and Lavie, 2005), ROUGE-L (Lin and Och, 2004a), and EM (exact match accuracy).

Method naming. Descriptive names for code elements (variables, methods, classes, etc.) are a vital part of readable and maintainable code (Høst and Østvold, 2009; Allamanis et al., 2015). Naming methods is particularly important and challenging, because the names need to be both concise—usually containing only a few tokens—and comprehensible—such that they describe the key functionality of the code (Lawrie et al., 2006).

We used two models: Code2Vec from Alon et al. (2019b) and Code2Seq from Alon et al. (2019a). We used four automatic metrics that are frequently reported in prior work: Precision, Recall, F1, and EM (exact match accuracy).

Task		Train	Val	TestS		TestC
Comment Generation	**MP**	50,879	7,569	14,956	**MP ∩ CP**	3,362
	CP	50,879	8,938	15,661	**MP ∩ T**	2,013
	T	50,879	11,312	9,870	**CP ∩ T**	2,220
Method Naming	**MP**	50,879	7,523	14,796	**MP ∩ CP**	3,344
	CP	50,879	8,811	15,332	**MP ∩ T**	2,011
	T	50,879	11,223	9,807	**CP ∩ T**	2,211

Table 2: Number of samples in our datasets.

5.2 Data

We could not easily reuse existing datasets from prior work because the timestamps of samples are *not* available. We extracted samples with timestamps from popular and active open-source Java projects using English for summaries (comments and names) from GitHub. We collected samples before τ = 2021 Jan 1^{st}, and we time-segmented samples by τ^{-2} = 2019 Jan 1^{st} and τ^{-1} = 2020 Jan 1^{st}. The splitting ratios for in-project and cross-project splits are 70%, 10%, 20%.

Table 2 presents the number of samples in each set for each methodology. We present more details and metrics of data collection in Appendix C.

5.3 Results

We use the hyper-parameters provided in the original papers. Validation sets are used for early-stopping if needed by the model. We run each model three times with different random seeds. Appendix D presents more details of our experiments to support their reproducibility.

Tables 3 and 4 present the results for comment generation and method naming, respectively. Each table has four parts and each part contains the results for one metric. Each number is the metric of a model (name at column 1) trained on the Train set of a methodology (name at row 1) and evaluated on a TestC set involving that methodology (name at row 2). The best results are in bold text. The results marked with the same Greek letter are *not* statistically significantly different.[2] Appendix E presents the results on Val and TestS sets, and bar plots visualizing the results.

5.4 Findings

Depending on the methodology, one model can perform better or worse than another. On

---

[2] We conducted statistical significance tests using bootstrap tests (Berg-Kirkpatrick et al., 2012) with confidence level 95%.

Table 4: Method naming models' results on and TestC sets. The four results in each block are comparable because they use the same set and metric, where results marked with the same Greek letter are *not* statistically significantly different. Surprisingly, Code2Seq outperforms Code2Vec in the Cross-Project methodology but the opposite holds in the other two methodologies.

method naming task, we found that Code2Seq outperforms Code2Vec only in cross-project methodology but not the other methodologies, consistently on all metrics. Our observation aligns with the finding in the original paper (Alon et al., 2019a) that Code2Seq outperforms Code2Vec when using the cross-project methodology. The reason is that in contrary to Code2Seq which generates a name as a sequence of subtokens, Code2Vec generates a name by retrieving a name in the Train set, and thus has better chances to generate correct names under the mixed-project and time-segmented methodologies where the names in the Test set are similar to the names in the Train set.

This finding suggests that a model may work better for one use case but not another—in this case, Code2Seq performs better in the cross-project batch-mode use case, but Code2Vec performs better in the in-project batch-mode and the continuous-mode use case.

Depending on the methodology, the differences between models may or may not be observable. For example, for comment generation, on the TestC set of cross-project and time-segmented methodologies when using the METEOR metric (Table 3, columns 6–7), Transformer significantly outperforms Seq2Seq when trained on the time-segmented Train set, but does not when trained on the cross-project Train set. Similar observations can be made on the BLEU and EM metrics for comment generation, and the EM metric for method naming.

Two models' results being not statistically significantly different indicates that their difference is not reliable. We could not find reference points for this finding in prior work (unfortunately, Ahmad et al. (2020) did not compare Seq2Seq with Transformer though both were provided in their replication package).

Results under the mixed-project methodology are inflated. We found that the results under the mixed-project methodology are always higher than the other two methodologies. This is not surprising as ML models have difficulty in generalizing to samples that are different from the Train set.

Considering that the mixed-project methodology represents a less realistic use case than the other two methodologies, the mixed-project methodology always over-estimates the models' usefulness. As such, we suggest that the mixed-project methodology should never be used unless the model is targeted specially for the in-project batch-mode use case (§3).

Results under the cross-project methodology

may be an under-estimation of the more realistic continuous-mode use case. We found that the results under the cross-project methodology are always lower than the results under the time-segmented methodology, consistently on all metrics in both tasks. We have discussed that the continuous-mode use case is more realistic than others (§3). This suggests that the usefulness of the models in prior work using the cross-project methodology may have been under-estimated.

Findings in prior work may not hold when using a different methodology or a different dataset. We found that the findings reported by prior work may not hold in our experiment: for example, the finding "DeepComHybrid outperforms Seq2Seq" from Hu et al. (2020) does not hold on our dataset (one reason could be the Seq2Seq code we used is more recent than the version that DeepComHybrid based on). This indicates that researchers should specify the targeted use case, the employed methodology, and the used dataset when reporting findings, and expect that the findings may not generalize to a different use case or dataset.

6 Future Work

6.1 Methodologies for Other SE Areas Using ML Models

We studied the impact of different evaluation methodologies in the context of code summarization, and future work can study their impacts on other software engineering (SE) areas using ML models. We briefly discuss the potential ways and challenges of transferring our methodologies from code summarization to ML models for other SE tasks, including generation tasks (e.g., commit message generation and code synthesis) and non-generation tasks (e.g., defect prediction and bug localization). The key is to modify the application steps of the methodologies based on the format of samples (inputs and outputs) in the targeted task.

For most tasks where inputs and outputs are software-related artifacts with timestamps, the methodologies, use cases, and application steps defined by us should still apply. For example, transferring our methodologies from the code summarization task to the commit message generation task only requires replacing "(code, comment) pairs" to "(code change, commit message) pairs".

For some tasks, the input or output of one sample may change when observed at different timestamps. For example, in defect prediction (pointed out by Tan et al. (2015)), suppose a commit at τ^{-2} was discovered to be buggy at τ, then when training the model at τ^{-1}, that commit should be labeled as not buggy. The correct version of the sample should be used according to its timestamp.

6.2 Other Use Cases and Methodologies

Out of many other use cases and methodologies, we discuss two that are closely related to the continuous-mode use case and the time-segmented methodology. Future work can expand our study and perform experiments on them.

Cross-project continuous-mode use case. Compared to the continuous-mode use case, when training the model at τ, instead of using all projects' samples before τ, we only use other projects' samples. The corresponding methodology is a combination of the cross-project and time-segmented methodologies. From the ML model users' perspective, this use case is less realistic than the continuous-mode use case, because using samples from the targeted projects can improve the model's performance. However, from ML model researchers' perspective, this methodology may be used to better evaluate the model's effectiveness on unseen samples (while considering software evolution).

Online continuous-mode use case. Compared to the continuous-mode use case, when we train a new model at τ, instead of discarding the previous model trained at τ^{-1} and training from scratch, we continue training the previous model using the samples between τ^{-1} and τ, e.g., using online learning algorithms (Shalev-Shwartz, 2012). The corresponding methodology is similar to the time-segmented methodology, but with multiple training and evaluation steps. Compared to the time-segmented methodology, the model trained using this methodology may have better performance as it is continuously tuned on the latest samples (e.g., with the latest language features).

6.3 Applications of Our Study in Industry

We provide generic definitions to several representative use cases (in-project batch-mode, cross-project batch-mode, and continuous-mode). We believe these three use cases, plus some variants of the continuous-mode use case (§6.2), should cover most use cases of ML models in the SE industry. In practice, it may not always be possible to determine the target use cases in advance of deploying ML models, in which case performing a set of experiments (similar to the one in our study) to compare between different methodologies and use cases can guide the switching of use cases. We leave studying the usages of ML models in the SE industry and deploying the findings of our study as techniques to benefit the SE industry as future work.

7 Related Work

7.1 Evaluation Methodologies

To our best knowledge, ours is the first work to study the evaluation methodologies of code summarization ML models and use the time-segmented methodology in this area. Outside of the code summarization area, a couple of work on defect prediction (D'Ambros et al., 2012; Tan et al., 2015; Wang et al., 2016; Kamei et al., 2016), one work on program repair (Lutellier et al., 2020), and one work on bug localization (Pradel et al., 2020) have taken into account the timestamps during evaluation, specifically for their task. The methodologies we proposed in this paper may also be extended to those areas. Moreover, our work is the first to study the impact of the mixed-project, cross-project, and time-segmented methodologies side-by-side.

Tu et al. (2018) revealed the data leakage problem when using issue tracking data caused by the unawareness of the evolution of issue attributes. We revealed that a similar problem (unawareness of the timestamps of samples in the dataset) exists in the evaluation of code summarization tasks, and we propose a time-segmented methodology that can be used in future research.

Bender et al. (2021) pointed out a similar issue in NLP, that the ML models evaluated in standard cross-validation methodology may incur significant bias in realistic use cases, as the models cannot adapt to the new norms, language, and ways of communicating produced by social movements.

7.2 Code Summarization

Code summarization studies the problem of summarizing a code snippet into a natural language sentence or phrase. The two most studied tasks in code summarization are comment generation and method naming (§5.1). Table 1 already listed the prior work on these two tasks. Here, we briefly discuss their history.

The first work for comment generation (Iyer et al., 2016) and method naming (Allamanis et al., 2016) were developed based on encoder-decoder neural networks and attention mechanism. Other prior work extended this basic framework in many directions: by incorporating tree-like code context such as AST (Wan et al., 2018; Xu et al., 2019; LeClair et al., 2019; Hu et al., 2018a, 2020); by incorporating graph-like code context such as call graphs and data flow graphs (Xu et al., 2018; Fernandes et al., 2019; Yonai et al., 2019; LeClair et al., 2020); by incorporating path-like code context such as paths in AST (Alon et al., 2019b,a); by incorporating environment context, e.g., class name when generating method names (Nguyen et al., 2020); by incorporating type information (Cai et al., 2020); or by using more advanced neural architecture such as transformers (Ahmad et al., 2020).

Recently, pre-trained models for code learning (Feng et al., 2020; Guo et al., 2021; Ahmad et al., 2021; Wang et al., 2021; Chen et al., 2021) were built on large datasets using general tasks (e.g., masked language modeling), and these models can be fine-tuned on specific code learning tasks, including comment generation and method naming. Evaluating pre-trained models involves a pre-training set, in addition to the regular training, validation, and test sets. Our methodologies can be extended for pre-trained models; for example, in the time-segmented methodology, the pre-training set contains samples that are available before the samples in all other sets. No prior work on pre-trained models has considered the timestamps of samples during evaluation.

8 Conclusion

We highlighted the importance of specifying targeted use cases and adopting the correct evaluation methodologies during the development of ML models for code summarization tasks (and for other software engineering tasks). We revealed the importance of the realistic continuous-mode use case, and introduced the time-segmented methodology which is novel to code summarization. Our experiments of comparing ML models using the time-segmented methodology and using the mixed-project and cross-project methodologies (which are prevalent in the literature) showed that the choice of methodology impacts the results and findings of the evaluation. We found that mixed-project tends to over-estimate the effectiveness of ML models, while the cross-project may under-estimate it. We hope that future work on ML models for software engineering will dedicate extra space to document intended use cases and report findings using various methodologies.

Acknowledgments

We thank Nader Al Awar, Kush Jain, Yu Liu, Darko Marinov, Sheena Panthaplackel, August Shi, Zhiqiang Zang, and the anonymous reviewers for their comments and feedback. This work is partially supported by a Google Faculty Research Award, the US National Science Foundation under Grant Nos. CCF-1652517, IIS-1850153, and IIS-2107524, and the University of Texas at Austin Continuing Fellowship.

Ethics Statement

Our dataset has been collected in a manner that is consistent with the licenses provided from the sources (i.e., GitHub repositories).

The evaluation methodologies described in our study is expected to assist researchers in evaluating and reporting ML models for code summarization, and assist software developers (i.e., users of those models) in understanding the reported metrics and choosing the correct model that fits their use case. Our work can be directly deployed in code summarization research, and can potentially generalize to other software engineering areas using ML models (§6.1). We expect our work to help researchers build ML models for code summarization (and other SE areas) that are more applicable to their intended use cases.

We do not claim that the methodologies and use cases described in our study are the most realistic ones, nor do we try to provide an exhaustive list of them. In particular, the continuous-mode use case (§3.3) is inspired by our own observations during using and developing ML models for code summarization. We try our best to design this use case to reflect the most common and realistic scenarios, but other use cases may be more valid in certain scenarios (§6.2).

We conducted experiments involving computation time/power, but we have carefully chosen the number of times to repeat the experiments to both ensure reproducibility of our research and avoid consuming excessive energy. We provided details of our computing platform and running time in Appendix D.

A Formulas of Application of Methodologies

§4 described the steps to apply the methodologies on a given dataset. In this section, we present the formulas used in those steps.

Table 5 lists the symbols and functions that we use. Recall that Figure 4 visualizes all the steps. In the following discussion, we use these abbreviations: MP = mixed-project; CP = cross-project; T = time-segmented; Train = training; Val = validation; TestS = standard test; TestC = common test.

Step 1: time-segment. We first obtain the samples in each project on three selected timestamps τ^{-2}, τ^{-1}, τ: $\mathcal{E}^{\tau^{-2},p}, \mathcal{E}^{\tau^{-1},p}, \mathcal{E}^{\tau,p}$. Then, we compute the difference of the sets to get: the samples *after* τ^{-2} and *before* τ^{-1}, denoted as $\mathcal{E}^{\tau^{-1}\setminus\tau^{-2},p} = \mathcal{E}^{\tau^{-1},p} \setminus \mathcal{E}^{\tau^{-2},p}$; and the samples *after* τ^{-1} and *before* τ, denoted as $\mathcal{E}^{\tau\setminus\tau^{-1},p} = \mathcal{E}^{\tau,p} \setminus \mathcal{E}^{\tau^{-1},p}$.

Step 2: in-project split. We perform the split with the following formula (r_x, r_y, r_z are the splitting ratios, and following ML practices, $r_x \gg r_z \gtrapprox r_y$):

$$\begin{aligned}
&\mathcal{E}^{\tau^{-2},p}_{train}, \mathcal{E}^{\tau^{-2},p}_{val}, \mathcal{E}^{\tau^{-2},p}_{test} \\
&\quad = \mathsf{split}(\mathcal{E}^{\tau^{-2},p}_{train}, r_x, r_y, r_z) \\
&\mathcal{E}^{\tau^{-1}\setminus\tau^{-2},p}_{train}, \mathcal{E}^{\tau^{-1}\setminus\tau^{-2},p}_{val}, \mathcal{E}^{\tau^{-1}\setminus\tau^{-2},p}_{test} \\
&\quad = \mathsf{split}(\mathcal{E}^{\tau^{-1}\setminus\tau^{-2},p}_{train}, r_x, r_y, r_z) \\
&\mathcal{E}^{\tau\setminus\tau^{-1},p}_{train}, \mathcal{E}^{\tau\setminus\tau^{-1},p}_{val}, \mathcal{E}^{\tau\setminus\tau^{-1},p}_{test} \\
&\quad = \mathsf{split}(\mathcal{E}^{\tau\setminus\tau^{-1},p}_{train}, r_x, r_y, r_z)
\end{aligned}$$

Step 3: cross-project split. Given the set of projects $\mathcal{P}$ and the splitting ratios r_x, r_y, r_z, we perform the split with the following formula:

$$\mathcal{P}_{train}, \mathcal{P}_{val}, \mathcal{P}_{test} = \mathsf{split}(\mathsf{shuffle}(\mathcal{P}), r_x, r_y, r_z)$$

Step 4: grouping. Table 6 left part lists the formulas used in this step.

Step 5: intersection. Table 6 right part lists the formulas used in this step.

Step 6: postprocessing. The formulas for downsampling the Train sets are:

$$\begin{aligned}
&size = \min_{m\in\{\text{MP,CP,T}\}} \left|\mathcal{E}_{\text{Train}(m)}\right| \\
&\text{for } m \in \{\text{MP}, \text{CP}, \text{T}\}: \\
&\quad \mathcal{E}_{\text{Train}(m)} \leftarrow \mathsf{shuffle}(\mathcal{E}_{\text{Train}(m)})[0 : size]
\end{aligned}$$

Symbol	Definition
τ, τ^{-1}, τ^{-2}	Timestamps, i.e., specific points in time. τ^{-2} is earlier than τ^{-1}, and τ^{-1} is earlier than τ ($\tau^{-2} < \tau^{-1} < \tau$).
$\mathcal{P}$	A set of projects, from which samples are derived.
p	A project.
$\mathcal{E}$	A set of samples.
$\mathcal{E}^{\tau,p}$	The set of samples extracted from project p at timestamp τ.
$\mathcal{E}^{\tau\setminus\tau^{-1},p}$	$= \mathcal{E}^{\tau,p} \setminus \mathcal{E}^{\tau^{-1},p}$ (where $\setminus$ is the set difference operator), i.e., the samples extracted from project p at timestamp τ that were not available at timestamp τ^{-1}.
$\mathsf{shuffle}(l)$	Given a set (of samples or projects) s, returns a set with the same items after random shuffling.
$\mathsf{split}(\mathcal{E}, r_x, r_y, r_z)$	Given a set of samples $\mathcal{E}$, splits the set into three sets $\mathcal{E}_x, \mathcal{E}_y, \mathcal{E}_z$ such that $\lvert\mathcal{E}_x\rvert : \lvert\mathcal{E}_y\rvert : \lvert\mathcal{E}_z\rvert \approx r_x : r_y : r_z$; requires that $r_x + r_y + r_z = 1$.
$\mathsf{splitprj}(\mathcal{P}, \tau, r_x, r_y, r_z)$	Given a set of projects $\mathcal{P}$, splits the set into three sets $\mathcal{P}_x, \mathcal{P}_y, \mathcal{P}_z$ such that $\left\lvert\bigcup_{p\in\mathcal{P}_x} \mathcal{E}^{\tau,p}\right\rvert : \left\lvert\bigcup_{p\in\mathcal{P}_y} \mathcal{E}^{\tau,p}\right\rvert : \left\lvert\bigcup_{p\in\mathcal{P}_z} \mathcal{E}^{\tau,p}\right\rvert \approx r_x : r_y : r_z$; requires that $r_x + r_y + r_z = 1$.

Table 5: Definitions of symbols and functions.

To formalize the filtering of exact-duplicates and near-duplicates (which we will further discuss in Appendix B), we define $\mathsf{clean}(\mathcal{E}_{eval}, \mathcal{E}_{train})$ which is task-specific. It takes two inputs: the samples in the evaluation set that needs to be cleaned, and the samples used for training; and returns the cleaned evaluation set. Note that when the evaluation set is the TestS or TestC set, we also consider samples in the Val set as used for training (because they are used for hyper-parameter tuning or early-stopping). The formulas for this step are:

$$\begin{aligned}
&\text{for } m \in \{\text{MP}, \text{CP}, \text{T}\}: \\
&\quad \mathcal{E}_{\text{Val}(m)} \leftarrow \mathsf{clean}(\mathcal{E}_{\text{Val}(m)}, \mathcal{E}_{\text{Train}(m)}) \\
&\quad \mathcal{E}_{\text{TestS}(m)} \leftarrow \mathsf{clean}(\mathcal{E}_{\text{TestS}(m)}, \mathcal{E}_{\text{Train}(m)} \cup \mathcal{E}_{\text{Val}(m)}) \\
&\text{for } m, m' \in \{(\text{MP}, \text{CP}), (\text{MP}, \text{T}), (\text{CP}, \text{T})\}: \\
&\quad \mathcal{E}_{\text{TestC}(m,m')} \leftarrow \mathsf{clean}(\mathcal{E}_{\text{TestC}(m,m')}, \\
&\qquad \mathcal{E}_{\text{Train}(m)} \cup \mathcal{E}_{\text{Val}(m)} \cup \mathcal{E}_{\text{Train}(m')} \cup \mathcal{E}_{\text{Val}(m')})
\end{aligned}$$

B Filtering Near-Duplicates

We experimented if filtering near-duplicates can lead to any change to our findings. We used the following three configurations to define near-duplicates (there are many other ways to define near-duplicates, which we leave for future work). The numbers in parentheses are the percentages of

Methodology	Set	Formula
MP	**Train**	$\bigcup_{p\in\mathcal{P}}(\mathcal{E}_{train}^{\tau^{-2},p} \cup \mathcal{E}_{train}^{\tau^{-1}\setminus\tau^{-2},p} \cup \mathcal{E}_{train}^{\tau\setminus\tau^{-1},p})$
	Val	$\bigcup_{p\in\mathcal{P}}(\mathcal{E}_{val}^{\tau^{-2},p} \cup \mathcal{E}_{val}^{\tau^{-1}\setminus\tau^{-2},p} \cup \mathcal{E}_{val}^{\tau\setminus\tau^{-1},p})$
	TestS	$\bigcup_{p\in\mathcal{P}}(\mathcal{E}_{test}^{\tau^{-2},p} \cup \mathcal{E}_{test}^{\tau^{-1}\setminus\tau^{-2},p} \cup \mathcal{E}_{test}^{\tau\setminus\tau^{-1},p})$
CP	**Train**	$\bigcup_{p\in\mathcal{P}_{train}}(\mathcal{E}^{\tau^{-2},p} \cup \mathcal{E}^{\tau^{-1}\setminus\tau^{-2},p} \cup \mathcal{E}^{\tau\setminus\tau^{-1},p})$
	Val	$\bigcup_{p\in\mathcal{P}_{val}}(\mathcal{E}^{\tau^{-2},p} \cup \mathcal{E}^{\tau^{-1}\setminus\tau^{-2},p} \cup \mathcal{E}^{\tau\setminus\tau^{-1},p})$
	TestS	$\bigcup_{p\in\mathcal{P}_{test}}(\mathcal{E}^{\tau^{-2},p} \cup \mathcal{E}^{\tau^{-1}\setminus\tau^{-2},p} \cup \mathcal{E}^{\tau\setminus\tau^{-1},p})$
T	**Train**	$\bigcup_{p\in\mathcal{P}} \mathcal{E}^{\tau^{-2},p}$
	Val	$\bigcup_{p\in\mathcal{P}} \mathcal{E}^{\tau^{-1}\setminus\tau^{-2},p}$
	TestS	$\bigcup_{p\in\mathcal{P}} \mathcal{E}^{\tau\setminus\tau^{-1},p}$

Pair	Set	Formula
MP ∩ CP	**TestC**	$\bigcup_{p\in\mathcal{P}_{test}}(\mathcal{E}_{test}^{\tau^{-2},p} \cup \mathcal{E}_{test}^{\tau^{-1}\setminus\tau^{-2},p} \cup \mathcal{E}_{test}^{\tau\setminus\tau^{-1},p})$
MP ∩ T	**TestC**	$\bigcup_{p\in\mathcal{P}} \mathcal{E}_{test}^{\tau\setminus\tau^{-1},p}$
CP ∩ T	**TestC**	$\bigcup_{p\in\mathcal{P}_{test}} \mathcal{E}^{\tau\setminus\tau^{-1},p}$

Table 6: The formulas (at steps 4 and 5) to get the training (Train), validation (Val), and standard test (TestS) sets for each methodology, and the common test (TestC) set for each pair of methodologies.

samples considered as near-duplicates in TestC sets of all pairs of methodologies for comment generation / method naming.

- `same_code`: a sample is near-duplicate if any sample in the training set has identical code with it. (16.5% / 19.0%)
- `same_summary`: a sample is near-duplicate if any sample in the training set has identical summary (comment for comment generation or name for method naming) with it. (56.3% / 72.5%)
- `high_similarity`: a sample is near-duplicate if any sample in the training set has more than 90% similarity with it in terms of both code and summary; the similarity is measured by subtoken-level accuracy which is fast to compute. (65.1% / 77.1%)

The experiment results are presented in the following tables and plots:

- Using `same_code` configuration:
  - comment generation: Table 9, Figure 7.
  - method naming: Table 10, Figure 8.
- Using `same_summary` configuration:
  - comment generation: Table 11, Figure 9.
  - method naming: Table 12, Figure 10.
- Using `high_similarity` configuration:
  - comment generation: Table 13, Figure 11.
  - method naming: Table 14, Figure 12.

We can draw several conclusions. First of all, our findings in Section 5.4 still hold. The metrics of `same_code` are closest to the metrics of not filtering near-duplicates, which indicates that this filtering configuration has little impact on evaluation results. On the contrary, the metrics of `same_summary` and `high_similarity` are lower than the metrics of not filtering near-duplicates, which means the models become less effective. This indicates that current ML models for code summarization are better at following the samples in the training set than generating novel summaries.

C Data Collection Details

This section extends §5.2 and describes our data collection process in details. Overall, our datasets are collected and processed following the steps in §4 and Appendix A. We started by collecting samples of methods with comments from open-source GitHub projects, and then performed task-specific processing to get the dataset for each task.

Selecting projects. We initially chose 1,793 popular Java projects on GitHub: 1,000 Java projects with the highest number of stars (indicating how many GitHub users bookmarked a project) and another 793 Java projects whose owner is one of the famous open-source organizations on GitHub[3]. We chose to use only Java projects because most prior work focused on this language (see Table 1). Then, we only kept the projects meeting the following criteria: (1) the number of stars should be larger than 20; (2) the lines of code of the project (as reported by GitHub API[4]) should be in the range of $[10^6, 2 \times 10^6]$, to keep the number of samples balanced across projects; (3) the project should have at least one commit after Jan 1^{st} 2018. 160 projects

Table 8: Method naming dataset metrics.

satisfied all the criteria.

Collecting the raw dataset. We set the timestamps τ^{-2} to 2019 Jan 1^{st}, τ^{-1} to 2020 Jan 1^{st}, and τ to 2021 Jan 1^{st}. For each project and for each year in [2019, 2020, 2021], we identified the last commit in the project before Jan 1^{st} of that year, checked-out to that commit, used JavaParser[5] to parse all Java files, and collected samples of Java methods in the form of (code, comment, name, project, year) tuples, where the comment is the first sentence in the JavaDoc of the method. We discarded the samples where: (1) the code or the comment contains non-English characters (157 and 5,139 cases respectively); (2) the code is longer than 10,000 characters (60 cases); (3) the method body is empty, i.e., abstract method (77,769 cases); (4) the comment is empty after removing tags such as `@inheritDoc` (21,779 cases). If two samples are identical except for the "year" label, we would keep the one with the earliest year (e.g., two samples from 2018 and 2019 years have identical code, comment, name, and project, so we only keep the 2018 one). We ended up with 77,475 samples in the raw dataset.

Then, we follow the steps described in §4 to split the raw dataset into Train, Val, TestS sets for each methodology and TestC set for each pair of methodologies. The splitting ratios (for in-project and cross-project splits) are: $r_x = 70\%, r_y = 10\%, r_z = 20\%$.

Comment generation. Table 7 shows the statistics of the comment generation dataset. The rows, from top to bottom, are: the number of samples; the average number of subtokens in code; the percentage of samples whose number of subtokens in the code is less than 100, 150, 200; the average number of subtokens in comments; the percentage of samples whose number of subtokens in the comment is less than 20, 30, 50. Figure 5 visualizes the distributions of the number of subtokens in code (x-axis) and the number of subtokens in comments (y-axis).

Method naming. For each sample, we replaced the appearances of its name from its code to the special token "METHODNAMEMASK" such that the models cannot cheat by looking for the name in the signature line or in the method body of recursive methods. Table 8 shows the statistics of the method naming dataset. The rows, from top to bottom, are: the number of samples; the average number of subtokens in code; the percentage of

---

[5] `https://javaparser.org/`

samples whose number of subtokens in the code is less than 100, 150, 200; the average number of subtokens in names; the percentage of samples whose number of subtokens in the name is less than 2, 3, 6. Figure 6 visualizes the distributions of the number of subtokens in code (x-axis) and the number of subtokens in names (y-axis).

D Experiments Details

This section presents details of our experiments to support their reproducibility.

Computing infrastructure. We run our experiments on a machine with four NVIDIA 1080-TI GPUs and two Intel Xeon E5-2620 v4 CPUs.

Estimated runtime of models. The approximate model training time are: DeepComHybrid 7 days; Seq2Seq 4 hours; Transformer 10 hours; Code2Seq 4 hours; Code2Vec 15 minutes. The evaluation time is around 1–10 minutes per model per evaluation set.

Number of parameters. The number of parameters in each model are: DeepComHybrid 15.6M; Seq2Seq 31.3M; Transformer 68.2M; Code2Seq 5.7M; Code2Vec 33.1M.

Random seeds. The random seed used for preparing the dataset (performing in-project and cross-project splits) is: 7. The random seeds used for the three times of training are: 4182, 99243, 3705.

Reproducibility of prior work. We used the replication packages provided in the original papers of the models when possible. We made (small) updates to all models to: (1) upgrade outdated data processing code (because of our dataset contains samples with new programming language features that were not considered in the past); (2) export evaluation results in the format compatible with our scripts. We integrated these updates in our replication package.

E Additional Experiment Results

We present the following additional tables and figures to help characterize our experiments results and support our findings:

- Evaluation results on the Val and TestS sets.
  - comment generation: Table 15.
  - method naming: Table 16.
- Bar plots of the automatic metrics per sample.
  - comment generation:
    - on the TestC sets: Figure 13.
    - on the Val and TestS sets: Figure 14.
  - method naming:
    - on the TestC sets: Figure 15.
    - on the Val and TestS sets: Figure 16.

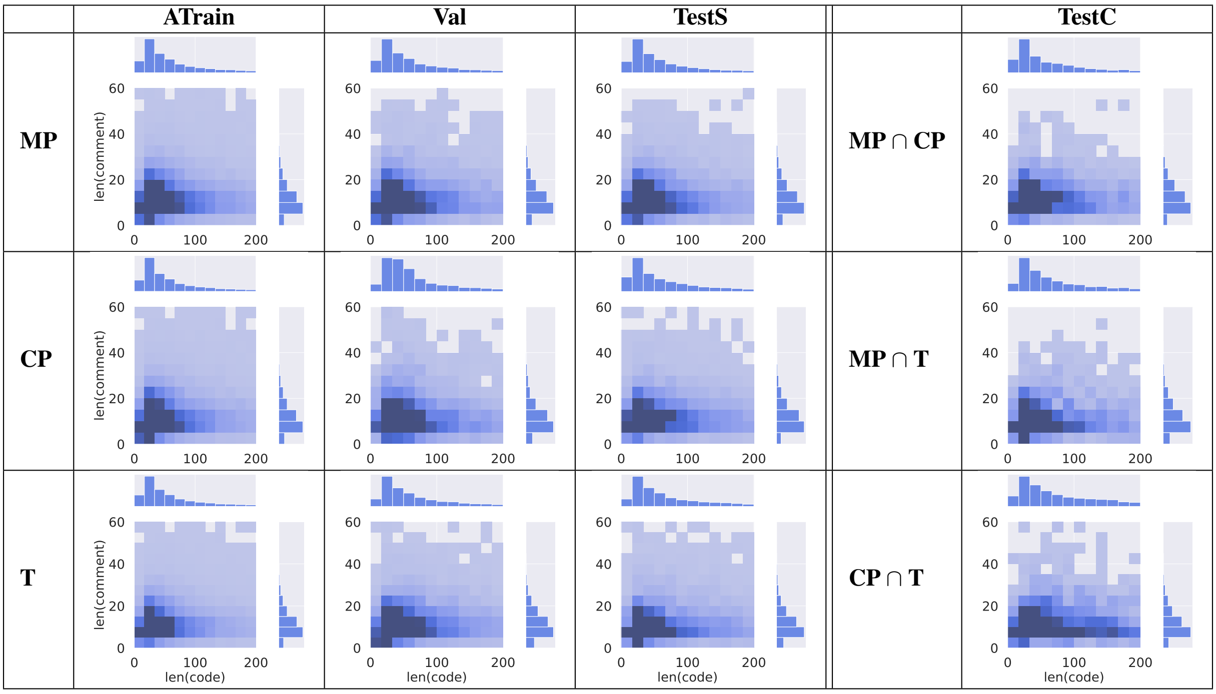

Figure 5: Distributions of the number of subtokens in code (x-axis) and the number of subtokens in comments (y-axis) in our comment generation dataset.

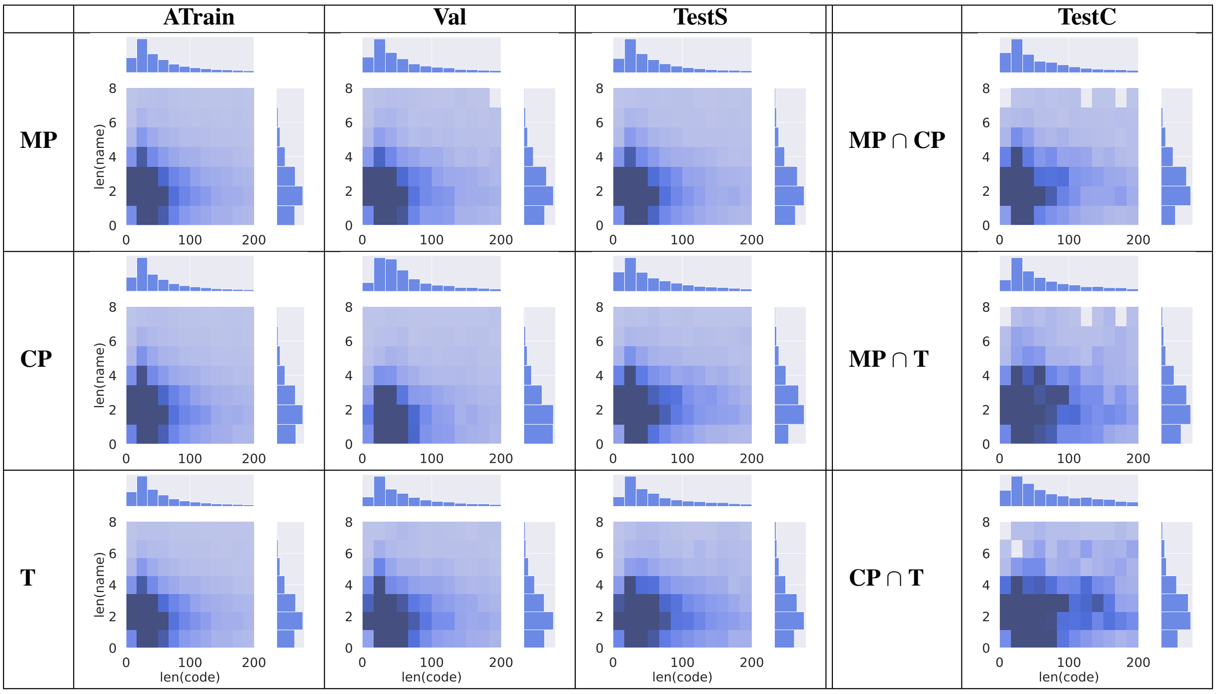

Figure 6: Distributions of the number of subtokens in code (x-axis) and the number of subtokens in names (y-axis) in our method naming dataset.

Abstract

Current Open-Domain Question Answering (ODQA) models typically include a retrieving module and a reading module, where the retriever selects potentially relevant passages from open-source documents for a given question, and the reader produces an answer based on the retrieved passages. The recently proposed Fusion-in-Decoder (FiD) framework is a representative example, which is built on top of a dense passage retriever and a generative reader, achieving the state-of-the-art performance. In this paper we further improve the FiD approach by introducing a knowledge-enhanced version, namely KG-FiD. Our new model uses a knowledge graph to establish the structural relationship among the retrieved passages, and a graph neural network (GNN) to re-rank the passages and select only a top few for further processing. Our experiments on common ODQA benchmark datasets (Natural Questions and TriviaQA) demonstrate that KG-FiD can achieve comparable or better performance in answer prediction than FiD, with less than 40% of the computation cost.

1 Introduction

Open-Domain Question Answering (ODQA) is the task of answering natural language questions in open domains. A successful ODQA model relies on effective acquisition of world knowledge. A popular line of work treats a large collection of open-domain documents (such as Wikipedia articles) as the knowledge source, and design a ODQA system that consists of a *retrieving module* and a *reading module*. The retriever pulls out a small set of potentially relevant passages from the open-source documents for a given question, and the reader produces an answer based on the retrieved passages (Karpukhin et al., 2020; Guu et al., 2020; Izacard and Grave, 2020). An earlier example of this kind is DrQA (Chen et al., 2017), which used an traditional search engine based on the bag of words (BoW) document representation with TF-IDF term weighting, and a neural reader for extracting candidate answers for each query based on the dense embedding of the retrieved passages. With the successful development of Pre-trained Language Models (PLMs) in neural network research, dense embedding based passage retrieval (DPR) models (Karpukhin et al., 2020; Qu et al., 2021) have shown superior performance over BoW/TF-IDF based retrieval models due to utilization of contextualized word embedding in DPR, and generative QA readers (Lewis et al., 2020; Roberts et al., 2020) usually outperform extraction based readers (Devlin et al., 2019; Guu et al., 2020) due to the capability of the former in capturing lexical variants with a richer flexibility.

The recently proposed Fusion-in-Decoder (FiD) model (Izacard and Grave, 2021) is representative of those methods with a DPR retriever and a generative reader, achieving the state-of-the-art results on ODQA evaluation benchmarks. FiD also significantly improved the scalability of the system over previous generative methods by encoding the retrieved passages independently instead of encoding the concatenation of all retrieved passages (which was typical in previous methods).

Inspired by the success of FiD, this paper aims further improvements of the state of the art of ODQA in the paradigm with a DPR retriever and a generative reader. Specifically, we point out two potential weaknesses or limitations of FiD as the rooms for improvements, and we propose a novel solution namely KG-FiD to address these issues with FiD. The two issues are:

Issue 1. The independent assumption among passages is not justified. Notice that both the DPR retriever and the generative reader of FiD perform independent encoding of the retrieved passages, which means that they cannot leverage the semantic relationship among passages for passage

May 22-27, 2022

embedding and answer generation even if such relational knowledge is available. But we know that rich semantic connections between passages often provide clues for better answering questions (Min et al., 2019).

Issue 2. Efficiency Bottleneck. For each input question, the FiD generative reader receives about 100 passages from the DPR module, with a relatively high computational cost. For example, the inference per question takes more than 6 trillion floating-point operations. Simply reducing the number of retrieved passages sent to the reader will not be a good solution as it will significantly decrease the model performance (Izacard and Grave, 2021). How to overcome such inefficient computation issue is a challenging question for the success of FiD in realistic ODQA settings.

We propose to address both of the above issues with FiD by leveraging an existing knowledge graph (KG) to establish relational dependencies among retrieved passages, and employing Graph Neural Networks (GNNs) to re-rank and prune retrieved passages for each query. We name our new approach as KG-FiD.

Specifically, KG-FiD employs a two-stage passage reranking by applying GNN to model structural and semantic information of passages. Both stages rerank the input passages and only a few top-reranked passages are fed into subsequent modules. The first stage reranks passages returned by the retriever, where we use the passage embeddings generated by DPR as the initial GNN node representation. This allows reranking a much larger set of initial candidate passages to enhance coverage of answers. The second stage performs joint passage reranking and answer generation, where the node embeddings are initialized by the embeddings of passage-question pairs output from the reader encoder. This stage operates on a smaller candidate set but aims for more accurate reranking and passage pruning.

To improve the efficiency, in the second-stage reranking, our GNN model adopts representations from the intermediate layer in the reader encoder instead of the final layer to initiate passage node embeddings. Then only a few top reranked passages will be passed into the higher layers of encoder and the decoder for answer generation, while other passages will not be further processed. This is coupled with a joint training of passage reranking and answer generation. As shown in Section 4.3, these strategies significantly reduce the computation cost while still maintaining a good QA performance.

Our experiments on ODQA benchmark datasets Natural Questions and TriviaQA demonstrate that KG-FiD can achieve comparable or better performance in answer prediction than FiD, with only 40% of the computation cost of FiD.

2 Related Work

ODQA with text corpus ODQA usually assumes that a large external knowledge source is accessible and can be leveraged to help answer prediction. For example, previous works (Chen et al., 2017; Karpukhin et al., 2020; Izacard and Grave, 2021) mainly use Wikipedia as knowledge source which contains millions of text passages. In this case, current ODQA models mainly contains a retriever to select related passages and a reader to generate the answer. Thus, the follow-up works mainly aim to: (1) Improve the retriever: from sparse retrieval based on TF-IDF or BM25 (Chen et al., 2017; Yang et al., 2019) to dense retrieval (Karpukhin et al., 2020) based on contextualized embeddings generated by pre-trained language models (PLMs). Moreover, some further improvement are also proposed such as better training strategy (Qu et al., 2021), reranking based on retrieved passages (Wang et al., 2018; Nogueira and Cho, 2019; Mao et al., 2021), and knowledge distillation from reader to retriever (Izacard and Grave, 2020); (2) Improve the reader: changing from Recurrent Neural Network (Chen et al., 2017) to PLMs such as extractive reader BERT (Karpukhin et al., 2020; Iyer et al., 2021; Guu et al., 2020) and generative reader BART and T5 (Izacard and Grave, 2021; Lewis et al., 2020). Besides, some works (Guu et al., 2020; Lewis et al., 2020; Sachan et al., 2021) have shown that additional unsupervised pre-training on retrieval-related language modeling tasks can further improve ODQA performance. However, none of these methods modeled the relationships among different passages.

ODQA with knowledge graph Besides the unstructured text corpus, world knowledge also exists in knowledge graphs (KGs), which represent entities and relations in a structural way and have been used in a variety of NLP tasks (Xu et al., 2021b; Yu et al., 2020; Xu et al., 2021a). Some works (Berant et al., 2013; Sun et al., 2018, 2019; Xiong et al., 2019) restrict the answer to be entities in the knowledge graph, while our work focus on more general

ODQA setting where the answer can be any words or phrases. Under this setting, some recent efforts have been made to leverage knowledge graphs for ODQA (Min et al., 2019; Asai et al., 2020; Zhou et al., 2020). For example, UniK-QA (Oguz et al., 2020) transforms KG triplets into text sentences and combine them into text corpus, which loses structure information of KG. Other works use KG to build relationship among passages similar to ours. KAQA (Zhou et al., 2020) use passage graph to propagate passage retrieve scores and answer span scores. Graph-Retriever (Min et al., 2019) iteratively retrieve passages based on the relationship between passages, and also use passage graph to improve passage selection in an extractive reader. However, applying KG to improve the recent advanced FiD framework remains unstudied.

3 Method

In the following sections, we first introduce how to apply KG to build a graph structure among the retrieved passages (Section 3.1). Then we show how we adopt the graph-based stage-1 reranking with DPR retriever to improve passage retrieval (Section 3.2). Next we introduce joint stage-2 reranking and answer generation in the reading module (Section 3.3). Finally we illustrate the improvement of efficiency by using intermediate layer representation for stage-2 reranking (Section 3.4). The overview of our framework is illustrated in Figure 1.

3.1 Construct Passage Graph using KG

The intuition behind using KG is that there exists the structural relationship among the retrieved passages which can be captured by the KG. Similar to (Min et al., 2019), we construct the passage graph where vertices are passages of text and the edges represent the relationships that are derived from the external KGs as $\mathcal{KG} = \{(e_h, r, e_t)\}$, where e_h, r, e_t are the head entity, relation and tail entity of a triplet respectively.

First, we formalize the definition of a *passage*. Following previous works (Wang et al., 2019; Karpukhin et al., 2020), each article in the text corpus is split into multiple disjoint text blocks of 100 words called *passages*, which serve as the basic retrieval units. We assume there is a one-one mapping between the KG entities and articles in the text corpus. Specifically, we use English Wikipedia as the text corpus and English Wikidata (Vrandečić and Krötzsch, 2014) as the knowledge graph, since there exists an alignment between the two resources[1]. For example, for the article titled with "New York Yankees", it contains passages such as "The New York Yankees are an American professional baseball team ...". The article also corresponds to a KG entity with the same name as "New York Yankees".

Then we define the mapping function $e = f(p)$, where the KG entity e corresponds to the article which p belongs to. Note that one passage can only be mapped to one entity, but multiple passages could be mapped to the same entity. The final passage graph is defined as $\mathcal{G} = \{(p_i, p_j)\}$, where passages p_i and p_j are connected if and only if their mapped entities are directly connected in the KG, i.e., $(f(p_i), r, f(p_j)) \in \mathcal{KG}$.

Since the total number of passages is very large, e.g., more than 20M in Wikipedia, constructing and maintaining a graph over all the passages is inefficient and memory-consuming. Thus, we build a passage graph on the fly for each question, based on the retrieved passages.

3.2 Passage Retrieving & Stage-1 Reranking

DPR Retriever: Our framework applies DPR (Karpukhin et al., 2020) as the retriever, which uses a BERT based passage encoder to encode all the N passages in the text corpus $\{p_1, p_2, \cdots, p_N\}$. Suppose all the passage embeddings are fixed and stored in memory as $M \in \mathbb{R}^{N \times D}$ where D is the hidden dimension:

$$M_i = \text{BERT}(p_i) \text{ for } i \in \{1, 2, \cdots N\} \quad (1)$$

For an input question q, DPR applies another BERT-based question encoder to obtain its representation Q, then it builds on FAISS (Johnson et al., 2019) to conduct fast dot-product similarity search between Q and M, and returns N_1 ($N_1 \ll N$) passages with the highest similarity scores.

Stage-1 Reranking: We see that the DPR retriever returns N_1 passages which are independently retrieved based on the similarity between the question and each passage, without considering inter-passage relationship. Thus instead of directly retrieving N_1 passages for the reader, we propose to first retrieve N_0 ($N_0 > N_1$) passages, then rerank them and output top-N_1 reranked passages into the reader.

Following Section 3.1, we construct a graph among the N_0 retrieved passages denoted as $\mathcal{G}_0$.

---

[1] Entity recognition and linking can be used if there is no such alignment.

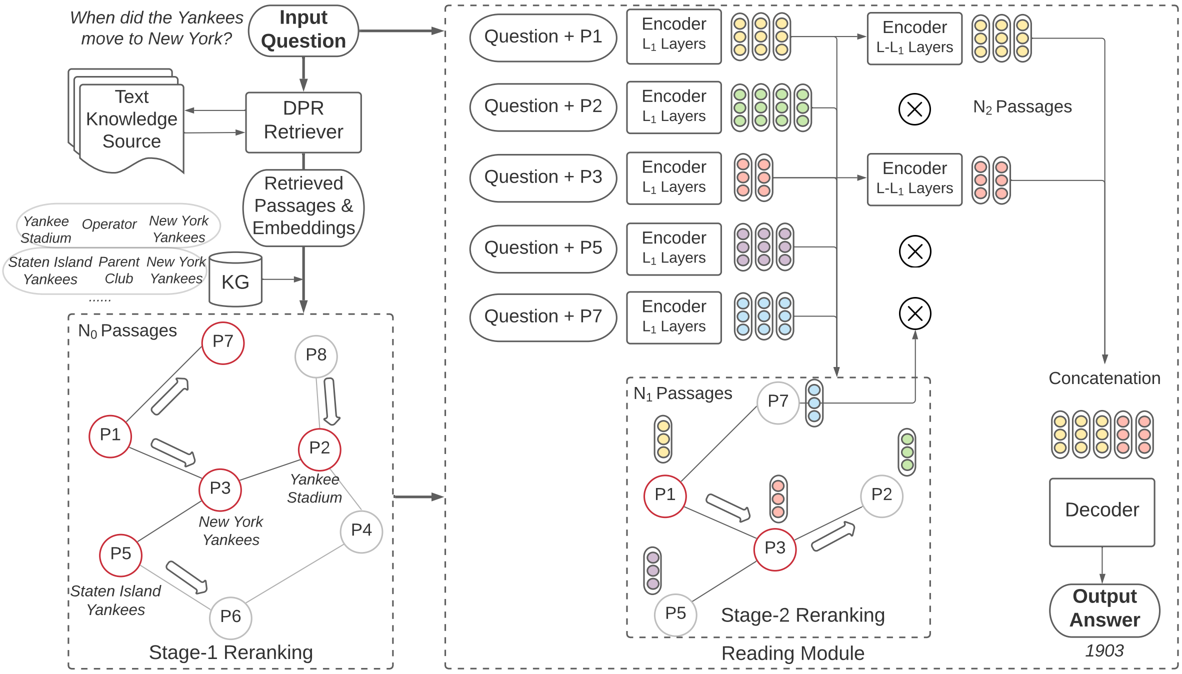

Figure 1: Overall Model Framework. Pi indicates the node of the passage originally ranked the i-th by the DPR retriever, with the article title below it. The left part shows passage retrieval by DPR, passage graph construction based on KG (Section 3.1) and stage-1 reranking (Section 3.2). The right part shows joint stage-2 reranking and answer generation in the reading module (Section 3.3 and 3.4).

We aim to rerank the retrieved passages based on both the structural information and the textual semantic information of them.

To represent the semantic information of passages, one can use another pre-trained language model to encode the passage texts, but this will not only include lots of additional model parameters, but also incur heavy computational cost as N_0 can be large. To avoid both additional memory and computation cost, we propose to reuse the offline passage embeddings M generated from the DPR retriever in Equation 1 as the initial node representation: $E_i^{(0)} = M_{r_i}$ where $\{r_i | i \in \{1, 2, \cdots, N_0\}\}$ is the set of retrieved passage indices.

Then we employ a graph attention network (GAT) (Velickovic et al., 2018) with L_g layers as GNN model to update representations for each node based on the passage graph and initial representation. The l-th layer of the GNN model updates the embedding of node i as follows:

$$E_i^{(l)} = h(E_i^{(l-1)}, \{E_j^{(l-1)}\}_{(i,j) \in \mathcal{G}_0}) \qquad (2)$$

where h is usually a non-linear learnable function which aggregates the embeddings of the node itself and its neighbor nodes. The reranking score for each passage p_{r_i} is calculated by $s_i^{\text{stage-1}} = Q^T E_i^{(L_g)}$, where Q is the question embedding also generated by the DPR retriever. Then we sort the retrieved passages by the reranking scores, and input the top-N_1 passages into the reader. The training loss of passage ranking for each question is:

$$\mathcal{L}_r^{\text{stage-1}} = -\sum_{i=1}^{N_0} y_i \log \left(\frac{\exp(s_i^{\text{stage-1}})}{\sum_{j=1}^{N_0} \exp(s_j^{\text{stage-1}})} \right) \qquad (3)$$

where $y_i = 1$ if p_{r_i} is the gold passage[2] that contains the answer, and 0 otherwise.

As we only add a lightweight graph neural network and reuse the pre-computed and static DPR passage embeddings, our reranking module can process a large number of candidate passages efficiently for each question. In experiments, we set $N_0 = 1000$ and $N_1 = 100$.

3.3 Joint Stage-2 Reranking and Answer Generation

In this section, we briefly introduce the vanilla FiD reading module before illustrating our joint

---

[2] We follow Karpukhin et al. (2020) on the definition of gold passages.

reranking method. We suppose the reader takes N_1 retrieved passages $\{p_{a_1}, p_{a_2}, \cdots, p_{a_{N_1}}\}$ as input.

Vanilla FiD Reading Module: We denote the hidden dimension as H and number of encoder layers and decoder layers as L, FiD reader first separately encodes each passage p_{a_i} concatenated with question q:

$$\mathbf{P}_i^{(0)} = \text{T5-Embed}(q + p_{a_i}) \in \mathbb{R}^{T_p \times H}, \quad (4)$$

$$\mathbf{P}_i^{(l)} = \text{T5-Encoder}_l(\mathbf{P}_i^{(l-1)}) \in \mathbb{R}^{T_p \times H}, \quad (5)$$

where T_p is the sequence length of a passage concatenated with the question. T5-Embed$(\cdot)$ is the initial embedding layer of T5 model (Raffel et al., 2019) and T5-Encoder$_l(\cdot)$ is the l-th layer of its encoder module. Then the token embeddings of all passages output from the last layer of the encoder are concatenated and sent to the decoder to generate the answer tokens $\mathbf{A}$:

$$\mathbf{A} = \text{T5-Decoder}\left([\mathbf{P}_1^{(L)}; \mathbf{P}_2^{(L)}; \cdots; \mathbf{P}_{N_1}^{(L)}]\right) \quad (6)$$

Stage-2 Reranking: Note that vanilla FiD reader neglect the cross information among passages, and the joint modeling in the decoding process makes it vulnerable to the noisy irrelevant passages. Thus, we propose to leverage the passage graph to rerank the input N_1 passages during the encoding and only select top-N_2 ($N_2 < N_1$) reranked passages into the decoder, which is named as stage-2 reranking.

Similar to stage-1 reranking, the reranking model is based on both the structural information and the textual semantic information of passages. We denote the passage graph as $\mathcal{G}_1$, which is a subgraph of $\mathcal{G}_0$. To avoid additional computation and memory cost, we propose to reuse the encoder-generated question-aware passage representation from FiD reader for passage reranking as it is already computed in Equation 5. Specifically, the initial node embeddings $Z_i^{(0)}$ for passage p_{a_i} comes from the first token embedding of the final layer in the FiD-Encoder, i.e., $Z_i^{(0)} = \mathbf{P}_i^{(L)}(0) \in \mathbb{R}^D$. Then same as stage-1 reranking, we also employ a GAT (Velickovic et al., 2018) with L_g layers as the graph neural network (GNN) model to update representations for each node based on the passage graph, similar to Equation 2: $Z^{(L_g)} = \text{GAT}(Z^{(0)}, \mathcal{G}_1')$. The reranking score of passage p_{a_i} is calculated by $s_i^{\text{stage-2}} = W^T Z_i^{(L_g)}$ where W is a trainable model parameter. After reranking, only the final top-N_2 ($N_2 < N_1$) passages are sent for decoding. Suppose their indices are $\{g_1, g_2, \cdots, g_{N_2}\}$, the decoding process in Equation 6 becomes:

$$\mathbf{A} = \text{T5-Decoder}\left([\mathbf{P}_{g_1}^{(L)}; \mathbf{P}_{g_2}^{(L)}; \cdots; \mathbf{P}_{g_{N_2}}^{(L)}]\right) \quad (7)$$

where $\mathbf{A}$ is the generated answer. Similar to stage-1 reranking, the training loss of passage ranking for each question is:

$$\mathcal{L}_r^{\text{stage-2}} = -\sum_{i=1}^{N_1} y_i \log\left(\frac{\exp(s_i^{\text{stage-2}})}{\sum_{j=1}^{N_1}\exp(s_j^{\text{stage-2}})}\right) \quad (8)$$

where $y_i = 1$ if p_{a_i} is the gold passage that contains the answer, and 0 otherwise.

The passage reranking and answer generation are jointly trained. We denote the answer generation loss for each question is $\mathcal{L}_a$, then the final training loss of our reader module is $\mathcal{L} = \mathcal{L}_a + \lambda\mathcal{L}_r^{\text{stage-2}}$, where λ is a hyper-parameter which controls the weight of reranking task in the total loss.

Note that the first stage reranking is based on DPR embeddings, which are are high-level (one vector per passage) and not further trained. While the second stage is based on reader-generated passage-question embeddings, which are semantic-level and trainable as part of the model output. Thus the second stage can better capture semantic information of passages and aims for more accurate reranking over a smaller candidate set. In the experiment, we set $N_1 = 100$ and $N_2 = 20$.

3.4 Improving Efficiency via Intermediate Representation in Stage-2 Reranking

Recall that in the stage-2 reranking, we take the passage representation from the last layer of reader encoder for passage reranking. In this section, we propose to further reduce the computation cost by taking the intermediate layer representation rather than the last layer. The intuition is that answer generation task is more difficult than passage reranking which only needs to predict whether the passage contains the answer or not. Thus we may not need the representation from the whole encoder module for passage reranking.

Suppose we take the representation from the L_1-th layer ($1 \le L_1 < L$), i.e., $Z_i^{(0)} = \mathbf{P}_i^{(L_1)}(0)$ for $i \in \{1, 2, \cdots, N_1\}$, and the reranking method remains the same. Then only the top N_2 ($N_2 < N_1$) reranked passages will go through the rest layers of FiD-encoder. Suppose their indices are

$I_g = \{g_1, g_2, \cdots, g_{N_2}\}$, for $l \geq L_1 + 1$:

$$\mathbf{P}_i^{(l)} = \begin{cases} \text{T5-Encoder}_l(\mathbf{P}_i^{(l-1)}) & \text{if } i \in I_g \\ \text{Stop-Computing} & \text{else} \end{cases} \quad (9)$$

Then $\mathbf{P}_{g_1}^{(L)}, \mathbf{P}_{g_2}^{(L)}, \cdots, \mathbf{P}_{g_{N_2}}^{(L)}$ are sent into the decoder for answer generation as in Equation 7. In Section 4.3, we demonstrate this can reduce 60% computation cost than the original FiD while keeping the on-par performance on two benchmark datasets.

3.5 Analysis on Computational Complexity

Here we analyze the theoretical time complexity of our proposed KG-FiD compared to vanilla FiD. More practical computation cost comparison is shown in Appendix A.5. Because both the computations of DPR retrieving and stage-1 reranking are negligible compared to the reading part, we only analyze the reading module here.

Suppose the length of answer sequence **A** is denoted as T_a and the average length of the passage (concatenated with question) is T_p. For vanilla FiD reader, the time complexity of the encoder module is $O(L \cdot N_1 \cdot T_p^2)$, where L, N_1 denote the number of encoder layers and the number of passages for reading. The square comes from the self-attention mechanism. The decoder time complexity is $O(L \cdot (N_1 \cdot T_p \cdot T_a + T_a^2))$, where $N_1 \cdot T_p \cdot T_a$ comes from the cross-attention mechanism. For our reading module, all the N_1 candidate passages are processed by the first L_1 layers of encoder. But only N_2 passages are processed by the remaining $L - L_1$ encoder layers and sent into the decoder. Thus, the encoder computation complexity becomes $O((L_1 \cdot N_1 + (L - L_1) \cdot N_2) \cdot T_p^2)$, and the decoder computation takes $O(L \cdot (N_2 \cdot T_p \cdot T_a + T_a^2))$. Because $L_1 < L, N_2 < N_1$, both the encoding and decoding of our method is more efficient than vanilla FiD.

Furthermore, the answer is usually much shorter than the passage (which is the case in our experiments), i.e., $T_a \ll T_p$. Then the decoding computation can be negligible compared to the encoding. In this case, the approximated ratio of saved computation cost brought by our proposed method is:

$$\begin{aligned} S &= 1 - \frac{(L_1 \cdot N_1 + (L - L_1) \cdot N_2) \cdot T_p^2}{L \cdot N_1 \cdot T_p^2} \\ &= (1 - \frac{L_1}{L})(1 - \frac{N_2}{N_1}) \end{aligned}$$

This shows that we can reduce more computation cost by decreasing L_1 or N_2. For example, if setting $L_1 = L/4, N_2 = N_1/5$, we can reduce about 60% of computation cost. More empirical results and discussions will be presented in Section 4.3.

4 Experiment

In this section, we conduct extensive experiments on two most commonly-used ODQA benchmark datasets: Natural Questions (NQ) (Kwiatkowski et al., 2019) which is based on Google Search Queries, and TriviaQA (Joshi et al., 2017) which contains questions from trivia and quiz-league websites. We follow the same setting as (Izacard and Grave, 2021) to preprocess these datasets, which is introduced in Appendix A.1. All our experiments are conducted on 8 Tesla A100 40GB GPUs.

4.1 Implementation Details

Knowledge Source: Following (Karpukhin et al., 2020; Izacard and Grave, 2021), we use the English Wikipedia as the text corpus, and apply the same preprocessing to divide them into disjoint passages with 100 words, which produces 21M passages in total. For the knowledge graph, we use English Wikidata. The number of aligned entities, relations and triplets among these entities are 2.7M, 974 and 14M respectively.

Model Details: For the retrieving module, we use the DPR retriever (Karpukhin et al., 2020) which contains two BERT (base) models for encoding question and passage separately. For the GNN reranking models, we adopt 3-layer Graph Attention Networks (GAT) (Velickovic et al., 2018). For the reading module, same as (Izacard and Grave, 2021), we initialize it with the pretrained T5-base and T5-large models (Raffel et al., 2019), and we name the former one as KG-FiD (base) and the latter one as KG-FiD (large). Our implementation is based on the HuggingFace Transformers library (Wolf et al., 2019). For number of passages, we set $N_0 = 1000, N_1 = 100, N_2 = 20$. The training process of our method is introduced in Appendix A.3. More results about model design and hyper-parameter search is in Appendix A.4.

Evaluation: We follow the standard evaluation metric of answer prediction in ODQA, which is the exact match score (EM) (Rajpurkar et al., 2016). A generated answer is considered correct if it matches any answer in the list of acceptable answers after normalization[3]. For all the experiments, we conduct 5 runs with different random seeds and report the averaged scores.

4.2 Baseline Methods

We mainly compare KG-FiD with the baseline model FiD (Izacard and Grave, 2021). For other baselines, we compare with representative methods from each category: (1) not using external knowledge source: T5 (Roberts et al., 2020) and GPT-3 (Brown et al., 2020); (2) reranking-based methods: RIDER (Mao et al., 2021) and RECONSIDER (Iyer et al., 2021); (3) leveraging knowledge graphs or graph information between passages: Graph-Retriever (Min et al., 2019), Path-Retriever (Asai et al., 2020), KAQA (Zhou et al., 2020), and UniK-QA (Oguz et al., 2020). We also compare with methods (4) with additional large-scale pre-training: REALM (Guu et al., 2020), RAG (Lewis et al., 2020) and Joint Top-K (Sachan et al., 2021).

4.3 Main Results

Comparison with Baselines: Table 1 shows the results of our method and all baselines. We see that our proposed model KG-FiD consistently and significantly improves FiD on both NQ and TriviaQA datasets over both base and large model. Specifically, for large model, KG-FiD improves FiD by 1.5% and 1.1% on two datasets respectively, which has larger improvement compared to base model. We think the reason is that more expressive reader will also benefit the stage-2 reranking since the initial passage embeddings are generated by the reader encoder module. We also see that our proposed method outperforms all the baseline methods except UniK-QA (Oguz et al., 2020). However, UniK-QA uses additional knowledge source Wikipedia-Table for retrieval, which is highly related with the NQ dataset and makes it unfair to directly compare with our method.

Model	#params	NQ	TriviaQA
T5	11B	36.6	-
GPT-3 (few-shot)	175B	29.9	-
RIDER	626M	48.3	-
RECONSIDER	670M	45.5	61.7
Graph-Retriever	110M	34.7	55.8
Path-Retriever	445M	31.7	-
KAQA	110M	-	66.6
UniK-QA*	990M	**54.0***	64.1*
REALM	330M	40.4	-
RAG	626M	44.5	56.1
Joint Top-K	440M	49.2	64.8
FiD (base)	440M	48.2	65.0
FiD (large)	990M	51.4	67.6
Our Implementation			
FiD (base)	440M	48.8	66.2
KG-FiD (base)	443M	49.6	66.7
FiD (large)	990M	51.9	68.7
KG-FiD (large)	994M	**53.4**	**69.8**

Table 1: Exact match score of different models over the test sets of NQ and TriviaQA datasets. $\star$ means that additional knowledge source Wikipedia-Tables is used in this method.

Efficiency & Accuracy: Table 2 show the detailed comparison between our method and FiD in the large model version. The results of base model version is shown in Appendix A.4. Besides EM score, we also report the ratio of computation flops (#FLOPs) and inference latency (per question). The detailed calculation of #FLOPs is shown in Appendix A.5. From table 2, we see that (1) for KG-FiD, decreasing L_1 can improve the computation efficiency as analyzed in Section 3.4, while increasing L_1 can improve the model performance. We think the performance improvement comes from the noise reduction of passage filtering. For a larger L_1, the passage embeddings for reranking will have a better quality so that the gold passages are less likely to be filtered out. (2) Simply reducing the number of passages N_1 into vanilla FiD reader can reduce computation cost, but the performance will also drop significantly (from 51.9 to 50.3 on NQ dataset). (3) Our model can achieve the performance on par with FiD with only 38% of computation cost. When consuming the same amount of computations ($L_1 = 24$), our model significantly outperforms FiD on both NQ and TriviaQA datasets. These experiments demonstrate that our model is very flexible and can improve both the efficiency and effectiveness by changing L_1.

4.4 Ablation Study

Effect of Each Reranking Stage: Since our proposed graph-based reranking method are applied in both retrieving stage (Section 3.2) and reading stage (Section 3.3). We conduct ablation study

---

[3] The normalization includes lowercasing and removing articles, punctuation and duplicated whitespace.

Model	#FLOPs	NQ		TriviaQA	
		EM	Latency (s)	EM	Latency (s)
FiD (N_1=40)	0.40x	50.3	0.74 (0.45x)	67.5	0.73 (0.44x)
FiD (N_1=100)	1.00x	51.9	1.65 (1.00x)	68.7	1.66 (1.00x)
KG-FiD (N_1=100, L_1=6)	0.38x	52.0	0.70 (0.42x)	68.9	0.68 (0.41x)
KG-FiD (N_1=100, L_1=12)	0.55x	52.3	0.96 (0.58x)	69.2	0.94 (0.57x)
KG-FiD (N_1=100, L_1=18)	0.72x	52.6	1.22 (0.74x)	69.8	1.22 (0.73x)
KG-FiD (N_1=100, L_1=24)	0.90x	53.4	1.49 (0.90x)	69.8	1.48 (0.89x)

Table 2: Inference #FLOPs, Latency (second) and Exact match score of FiD (large) and KG-FiD (large). N_1 is the number of passages into the reader and L_1 is the number of intermediate layers used for stage-2 reranking as introduced in Section 3.4. The details of flop computation is introduced in Appendix A.5.

Model	NQ		TriviaQA	
	base	large	base	large
FiD	48.8	51.9	66.2	68.7
KG-FiD	49.6	53.4	66.7	69.8
w/o Stage-1	49.3	53.1	66.2	69.5
w/o Stage-2	49.4	52.3	66.5	69.2

Table 3: Ablation study of our graph-based reranking method in two stages. EM scores are reported over NQ and Trivia datasets with both base and large model version.

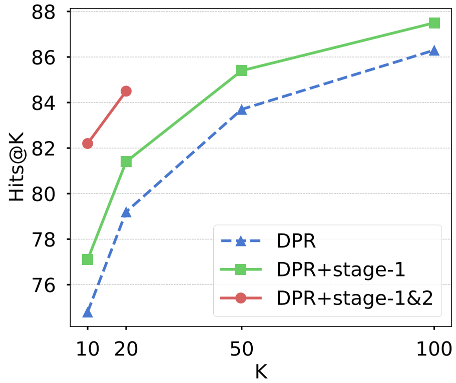

Figure 2: Passage ranking results over NQ test set of DPR retriever and our proposed two-stage rerankings over base model.

to validate the effectiveness of each one. Table 3 shows the experiment results by removing each module. We see the performance of KG-FiD drops when removing any of the two reranking modules, demonstrating both of them can improve model performance. Another thing we observe is that stage-1 reranking is more effective in base model while stage-2 reranking is more effective in large model. This is reasonable since stage-2 reranking relies on the effectiveness of reader encoder module, where the large model is usually better than the base model.

Passage Ranking Results: We additionally show that our proposed GNN reranking method can improve the passage retrieval results. This is demonstrated in Figure 2, where we report Hits@K metric over NQ test set, measuring the percentage of top-K retrieved passages that contain the gold passages (passages that contain the answer). We see that DPR+stage-1 reranking consistently outperforms DPR for all the $K \in \{10, 20, 50, 100\}$. With two stages of reranking, the retrieval results are further improved for $K \in \{10, 20\}$ (We only cares about $K \leq 20$ for stage-2 reranking since $N_2 = 20$). This shows that such reranking can increase the rank of gold passages which are previously ranked lower by DPR retriever and improve the efficacy of passage pruning.

5 Conclusion

This work tackles the task of Open-Domain Question Answering. We focus on the current best performed framework FiD and propose a novel KG-based reranking method to enhance the cross-modeling between passages and improve computation efficiency. Our two-stage reranking methods reuses the passage representation generated by DPR retriver and the reader encoder and apply graph neural networks to compute reranking scores. We further propose to use the intermediate layer of encoder to reduce computation cost while still maintaining good performance. Experiments on Natural Questions and TriviaQA show that our model can significantly improve original FiD by 1.5% exact match score and achieve on-par performance with FiD but reducing over 60% of computation cost.

A Appendix

A.1 Dataset

The datasets we use are Natural Questions (NQ) and TriviaQA. The open-domain version of NQ is obtained by discarding answers with more than 5 tokens. For TriviaQA, its *unfiltered* version is used for ODQA. We also convert all letters of answers in lowercase except the first letter of each word on TriviaQA. When training on NQ, we sample the answer target among the given list of answers, while for TriviaQA, we use the unique human-generated answer as generation target. For both datasets, we use the original validation data as test data, and keep 10% of the training set for validation.

A.2 Preliminary Analysis

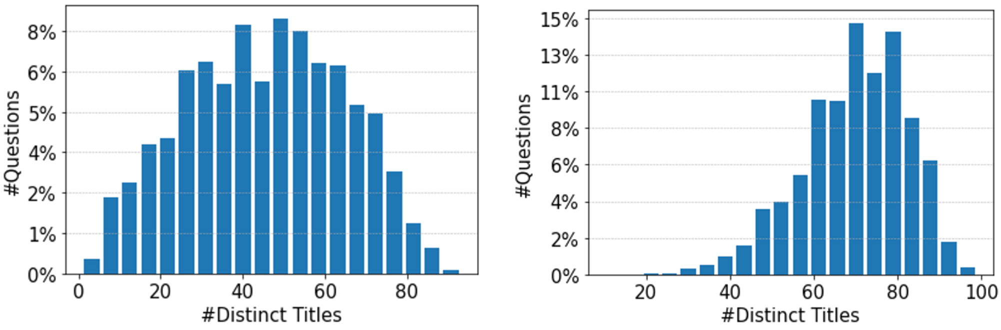
We conduct preliminary analysis on the graph constructed among passages. Note that for each question, we first apply the retriever to retrieve a few candidate passages, then build edge connection only among the retrieved passages, which means that the passage graph is question-specific. Since the passage graph depends on the retrieved passages, before further utilizing the graph, we need avoid two trivia situations: (1) all the retrieved passages come from the same article; (2) The number of graph edges is very small. Thus we conduct statistics of the passage graphs on two ODQA benchmark datasets, which is shown in Figure 3. For each question, the number of retrieved passages is 100. We see that the two trivia situations only happen for a small portion of questions.

A.3 Training Process

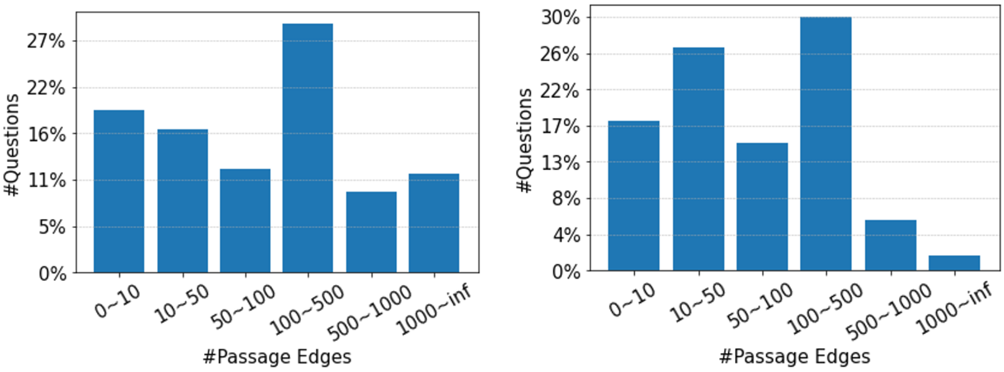
For training our framework, we adopt the separate-training strategy to avoid out-of-memory issue: we first train the DPR model following its original paper, then freeze the DPR model to train the stage-1 reranking module, and finally jointly train stage-2 reranking and reader part. For the training of stage-1 reranking, the optimizer is AdamW (Loshchilov and Hutter, 2019) with learning rate as 1e-3 and linear-decay scheduler. The weight decay rate is 0.01. Batch size is set as 64. The number of total training steps is 15k, and the model is evaluated every 500 steps and the model with best validation results is saved as the final model. For the training of reading part, we adopt the same training setting except that the learning rate is 1e-4 for the base model and 5e-5 for the large model. We also adopt learning rate warm up with 1000 steps.

A.4 Additional Experiment Results

We show additional experiment results in this section, which includes the efficiency and performance comparison between FiD (base) and KG-FiD (base) shown in Table 4, and hyper-parameter search results listed below:



(a) Results on NQ (b) Results on TriviaQA



(c) Results on NQ (d) Results on TriviaQA

Figure 3: Preliminary Analysis on the retrieved passages by DPR.

Model	#FLOPs	NQ		TriviaQA	
		EM	Latency (s)	EM	Latency (s)
FiD (N_1=40)	0.40x	47.2	0.27 (0.47x)	64.1	0.27 (0.46x)
FiD (N_1=100)	1.00x	48.8	0.58 (1.00x)	66.2	0.59 (1.00x)
KG-FiD (N_1=100, L_1=3)	0.38x	48.4	0.27 (0.47x)	65.6	0.26 (0.44x)
KG-FiD (N_1=100, L_1=6)	0.56x	49.0	0.35 (0.60x)	66.1	0.34 (0.58x)
KG-FiD (N_1=100, L_1=9)	0.73x	49.3	0.43 (0.74x)	66.3	0.43 (0.73x)
KG-FiD (N_1=100, L_1=12)	0.91x	49.6	0.50 (0.86x)	66.7	0.49 (0.83x)

Table 4: Inference #FLOPs, Latency (second) and Exact match score of FiD (base) and KG-FiD (base). N_1 is the number of passages into the reader and L_1 is the number of intermediate layers used for stage-2 reranking as introduced in Section 3.4. The details of flop computation is introduced in Appendix A.5.

Model	H@1	H@5	H@10	H@20
GCN	49.1	69.7	75.7	79.9
GAT	50.1	70.1	76.1	80.2
#Layers				
1	49.0	69.7	75.8	79.8
2	49.6	70.0	76.0	80.2
3	50.1	70.1	76.1	80.2
4	49.5	69.9	76.1	80.1

Table 5: Passage Retrieval Results on NQ dev data of our model under different GNN types and number of layers.

GNN Model Design: We conduct tuning on the model type and number of layers of our GNN based reranking model. For efficiency, we rerank 100 passages returned by DPR retriever and search them based on the passage retrieval results. Table 5 shows the Hits scores for different choices. We see that GAT outperforms vanilla GCN model (Kipf and Welling, 2017) which is reasonable since GAT leverage attention to reweight neighbor passages by their embeddings. The best choice for the number of GNN layers is 3. Note that other GNN models such as GIN (Xu et al., 2019), DGI (Velickovic et al., 2019) can also be applied here and we leave the further exploration of GNN models as future work.

N_2 **and** λ. For the stage-2 reranking part in Section 3.3, we also conduct hyper-parameter search on the number of passages after filtering: $N_2 \in \{10, 20, 30\}$ and the weight of reranking loss when training the reading module: $\lambda \in \{0.01, 0.1, 1.0\}$. As shown in Table 6, $N_2 = 20$ achieves better results than $N_2 = 10$, but further increasing N_2 does not bring performance gain while decreasing the efficiency of model since the number of passages to be processed by the decoder is increased. Thus we choose $N_2 = 20$. For the loss weight λ, we found that with its increment, the performance first increases then significantly drops. This shows that it's important to balance the weight of two training losses, as we want the model to learn better passage reranking while not overwhelming the training signal of answer generation.

A.5 FLOPs Computation

In this section we compute the FLOPs of each module[4]. The results are shown in Table 7 and 8 for base model and large model respectively. Before the computation, we first show some basic statistics on two benchmark datasets: the average question length is 20, and the average answer length is 5. For the reading part, the length of concatenated passage question pair is 250, number of input passages is $N_1 = 100$.

Model	N_2=10	N_2=20	N_2=30
KG-FiD	47.6	48.0	48.0
	λ=0.01	λ=0.1	λ=1.0
KG-FiD	47.7	48.0	46.6

Table 6: EM scores on NQ dev data of our model under different choices of filtered passage numbers and weights of reranking loss.

We first calculate the number of FLOPs of vanilla FiD model. For the retrieving part, it contains both question encoding and passage similarity search. We only consider the former part as the latter part depends on the corpus size and search methods and is usually very efficient. The question encoding flops by BERT-based model is about 4.4 Gigaflops (GFLOPs). For the reading part, the encoding of each question passage pair takes about 57/174 GFLOPs for base/large model, and the encoding of 100 passages takes 5772/17483 GFLOPs. The decoder part only costs 714.2/2534.5 GFLOPs for base/large model since the average length of answer is very small. In summary, vanilla FiD base/large model costs 6491.0/20022.0 GFLOPs.

For our model, the computation cost of retrieving part is the same as vanilla FiD. Since we set $N_0 = 1000$ and $N_1 = 100$, the GAT (Velickovic et al., 2018) computation in stage-1 reranking takes about 3.5 GFLOPs, and the stage-2 reranking takes only 0.4/0.6 GFLOPs for base/large model. For the reader encoding part, the computation cost depends on L_1 and N_2, which is analyzed in Section 3.5. For the reader decoding part, where cross attention takes most of the computation, KG-FiD only takes about $N_2/N_1 = 1/5$ cost of vanilla FiD, which is 143.9/510.0 for base/large model respectively. The detailed flops are shown in Table 7 and 8.

Abstract

Social media is a breeding ground for threat narratives and related conspiracy theories. In these, an *outside* group threatens the integrity of an *inside* group, leading to the emergence of sharply defined group identities: *Insider*s – agents with whom the authors identify and *Outsider*s – agents who threaten the insiders. Inferring the members of these groups constitutes a challenging new NLP task: (i) Information is distributed over many poorly-constructed posts; (ii) Threats and threat agents are highly contextual, with the same post potentially having multiple agents assigned to membership in either group; (iii) An agent's identity is often implicit and transitive; and (iv) Phrases used to imply *Outsider* status often do not follow common negative sentiment patterns. To address these challenges, we define a novel *Insider-Outsider* classification task. Because we are not aware of any appropriate existing datasets or attendant models, we introduce a labeled dataset (CT5K) and design a model (NP2IO) to address this task. NP2IO leverages pretrained language modeling to classify *Insider*s and *Outsider*s. NP2IO is shown to be robust, generalizing to noun phrases not seen during training, and exceeding the performance of non-trivial baseline models by 20%.

1 Background and Motivation

Narrative models – often succinctly represented as a network of characters, their roles, their interactions (*syuzhet*) and associated time-sequencing information (*fabula*) – have been a subject of considerable interest in computational linguistics and narrative theory. Stories rest on the generative backbone of narrative frameworks (Bailey, 1999; Beatty, 2016). While the details might vary from one story to another, this variation can be compressed into a limited set of domain-dependent narrative roles and functions (Dundes, 1962).

Social narratives that both directly and indirectly contribute to the construction of individual and group identities are an emergent phenomenon resulting from distributed social discourse. Currently, this phenomenon is most readily apparent on social media platforms, with their large piazzas and niche enclaves. Here, multiple threat-centric narratives emerge and, often, over time are linked together into complex conspiracy theories (Tangherlini et al., 2020). Conspiracy theories, and their constituent threat narratives (legend, rumor, personal experience narrative) share a signature semantic structure: an implicitly accepted *Insider* group; a diverse group of threatening *Outsider*s; specific threats from the *Outsider* directed at the *Insider*s; details of how and why *Outsider*s are threatening; and a set of strategies proposed for the *Insider*s to counter these threats (Tangherlini, 2018). Indeed, the *Insider/Outsider* groups are fundamental in most studies of belief narrative, and have been exhaustively studied in social theory and more specifically, in the context of conspiracy theories (Bodner et al., 2020; Barkun, 2013). On social media, these narratives are negotiated one post at a time, expressing only short pieces of the "immanent narrative whole" (Clover, 1986). This gives rise to a new type of computational linguistic problem: *Given a large enough corpus of social media text data, can one automatically distill semantically-labeled narratives (potentially several overlapping ones) that underlie the fragmentary conversational threads?*

Recent work (Shahsavari et al., 2020b; Tangherlini et al., 2020; Shahsavari et al., 2020a; Holur et al., 2021) has shown considerable promise that such scalable automated algorithms can be designed. An automated pipeline of interlocking machine learning modules decomposes the posts into actors, actants and their inter-actant relationships to create narrative networks via aggregation. *These network representations are interpretable on inspection*, allowing for the easy identification of the various signature semantic structures: *Insider*s,

I think that tech will kill me with vaccines. People like Bill Gates are developing this for the money. My friend, Sarah, who is a doctor, told me not to get the vaccine, because it causes small pox.

I think that tech will save me with vaccines. People like Bill Gates are developing this to save people. My friend, Sarah, who is a doctor, told me to get the vaccine, because it prevents small pox.

Figure 1: **A pair of inferred text segments labeled by NP2IO showing *Insider-Outsider* context-sensitivity:** Colored spans are used to highlight noun phrases that are inferred (red for *Outsider*s; blue for *Insider*s). POS tags are shown along with the noun phrases to illustrate an example of syntactic and semantic hints used by NP2IO to generate the inferred labels. Note that, based solely on context, the same agents ("tech", "vaccines", "People", "Bill Gates" and "the vaccine") switch *Insider-Outsider* label. *Even though the training data is highly biased in terms of the identities of the Insiders/Outsiders, the pretrained language model used in our classifier allows NP2IO to learn to infer using the context phrases and* not *by memorizing the labels.*

*Outsider*s, strategies for dealing with *Outsider*s and their attendant threats and, in the case of conspiracy theories, causal chains of events that support that theory.

By itself, this unsupervised platform does not "understand" the different narrative parts. Since the submodules are not trained to look for specific semantic abstractions inherent in conspiracy theories, the platform cannot automatically generate a semantically tagged narrative for downstream NLP tasks. It cannot, for example, generate a list across narratives of the various outside threats and attendant inside strategies being recommended on a social media forum, nor can it address why these threats and strategies are being discussed.

2 The Novel Insider vs. Outsider Classification Problem

As a fundamental first step bringing in supervised information to enable automated narrative structure discovery, we introduce the *Insider-Outsider* classification task: To classify the noun phrases in a post as *Insider*, *Outsider* or *neither*.

A working conceptualization of what we consider *Insider*s and *Outsider*s is provided in the following insets. As with most NLP tasks, we do not provide formal definitions of and rules to determine these groups. Instead we let a deep learning model learn the representations needed to capture these notions computationally by training on data annotated with human-generated labels.

Conceptualization of *Insider*s and *Outsider*s

Insiders: Some combination of actors and their associated pronouns, who display full agency (people, organizations, government), partial agency (policies, laws, rules, current events) or no agency (things, places, circumstances), with whom the author identifies (including themselves). These are often ascribed beneficial status;

Outsiders: A set of actors whom the author opposes and, in many cases, perceives as threatening the author and the insiders with disruption or harm. For our purposes, *these agents need not have full agency*: Diseases and natural disasters, for example, would be universal outsiders, and any man-made object/policy that works against the *Insider*s would be included in this group.

The partitioning of actors from a post into these different categories is inspired by social categorization, identification and comparison in the well-established Social Identity Theory (SIT) (Tajfel et al., 1979; Tajfel, 1974) and rests on established perspectives from Narrative Theory (Dundes, 1962; Labov and Waletzky, 1967; Nicolaisen, 1987).

Following are some of the reasons why this classification task is challenging and why the concepts of *Insider*s/*Outsider*s are not sufficiently captured by existing labeled datasets used in Sentiment

Analysis (SA) (discussed in more detail in Section 3):

1. **Commonly-held Beliefs and Worldviews:** Comprehensively incorporating shared values, crucial to the classification of *Insider*s and *Outsider*s, is a task with varied complexity. Some beliefs are easily enumerated: most humans share a perception of a nearly universal set of threats (virus, bomb, cancer, dictatorship) or threatening actions ("kills millions of people", "tries to mind-control everyone") or benevolent actions ("donating to a charitable cause", "curing disease", "freeing people"). Similarly, humans perceive themselves and their close family units as close, homogeneous groups with shared values, and therefore "I", "us", "my children" and "my family" are usually *Insider*s. In contrast, "they" and "them" are most often *Outsider*s.

Abstract beliefs pose a greater challenge as the actions that encode them can be varied and subtle. For example, in the post: "The microchips in vaccines track us", the noun phrase "microchips" is in the *Outsider* category as it violates the *Insider*s' right to privacy by "track[ing] us". Thus, greater attention needs to be paid in labeling datasets, highlighting ideas such as the right to freedom, religious beliefs, and notions of equality.

2. **Contextuality and Transitivity:** People express their opinions of *Insider/Outsider* affiliation by adding *contextual* clues that are embedded in the language of social media posts. For example, a post "We should build cell phone towers" suggests that "cell phone towers" are helpful to *Insider*s, whereas a post "We should build cell phone towers and show people how it fries their brains" suggests, in contrast, that "cell phone towers" are harmful to *Insiders* and belong, therefore, to the class of *Outsider*s. *Insider/Outsider* affiliations are also implied in a *transitive* fashion within a post. For example, consider two posts: (i) "Bill Gates is developing a vaccine. Vaccines *kill* people." and (ii) "Bill Gates is developing a vaccine. Vaccines *can eradicate* the pandemic." In the first case, the vaccine's toxic quality and attendant *Outsider* status would transfer to Bill Gates, making him an *Outsider* as well; in the second post, vaccine's beneficial qualities would transfer to him, now making "Bill Gates" an *Insider*.

3. **Model Requirement under Biased Data Conditions:** Designing effective classifiers that do not inherit bias from the training data – especially data in which particular groups or individuals are derided or dehumanized – is a challenging but necessary task. Because conspiracy theories evolve, building on earlier versions, and result in certain communities and individuals being "othered", our models *must* learn the phrases, contexts, and transitivity used to ascribe group membership, here either *Insider*s or *Outsider*s and not memorize the communities and/or individuals being targeted. Figure 1 illustrates an example where we probed our model to explore whether such a requirement is indeed satisfied. The first text conforms to the bias in our data, where "tech", "Bill Gates", and "vaccines" are primarily *Outsiders*. The second text switches the context by changing the phrases. Our classifier is able to correctly label these same entities, now presented in a different context, as *Insider*s! We believe that such subtle learning is possible because of the use of pretrained language models. We provide several such examples in Table 3 and Figure 3 and also evaluate our model for Zero-shot learning in Table 1 and Figure 6.

3 Our Framework and Related Work

Recent NLP efforts have examined the effectiveness of using pretrained Language Models (LM) such as BERT, DistilBERT, RoBERTa, and XLM to address downstream classification tasks through fine-tuning (Sanh et al., 2020; Liu et al., 2019; Lample and Conneau, 2019). Pretraining establishes the contextual dependencies of language prior to addressing a more specialized task, enabling rapid and efficient transfer learning. A crucial benefit of pretraining is that, in comparison to training a model from scratch, fewer labeled samples are necessary. By fine-tuning a pretrained LM, one can subsequently achieve competitive or better performance on an NLP task. As discussed in Section 2, since our model is required to be *contextual* and *transitive*, both of which are qualities that rely on the context embedded in language, we utilize a similar architecture.

In recent work involving span-based classification tasks, token-classification heads have proven to be very useful for tasks such as, Parts-of-Speech (POS) Tagging, Named Entity Recognition (NER) and variations of Sentiment Analysis (SA) (Yang et al., 2019; Vlad et al., 2019; Yin et al., 2020). Since the *Insider-Outsider* classification task is also set up as a noun phrase labeling task, our architecture uses a similar token-classification head on top of the pretrained LM backbone.

Current SA datasets' definitions of positive negative and neutral sentiments can be thought of as a "particularized" form of the *Insider-Outsider* classification task. For example, among the popular datasets used for SA, Rotten Tomatoes, Yelp reviews (Socher et al., 2013) and others (Dong et al., 2014; Pontiki et al., 2014) implicitly associate a sentiment's origin to the post's author (source) (a single *Insider*) and its intended target to a movie or restaurant (a single *Outsider* if the sentiment is *negative* or an *Insider* if *positive*). The post itself generally contains information about the target and particular aspects that the *Insider* found necessary to highlight.

In more recent SA work, such as Aspect-Based Sentiment Analysis (ABSA) (Gao et al., 2021; Li et al., 2019; Wang et al., 2021; Dai et al., 2021), researchers have developed models to extract sentiments – positive, negative, neutral – associated with particular aspects of a target *entity*. One of the subtasks of ABSA, aspect-level sentiment classification (ALSC), has a form that is particularly close to the *Insider-Outsider* classification. Interpreted in the context of our task, the author of the post is an *Insider* although now there can potentially be multiple targets or "aspects" that need to be classified as *Insider*s and *Outsider*s. Still, the constructed tasks in ABSA appear to not align well with the goal of *Insider-Outsider* classification: 1) Datasets are not *transitive*: Individual posts appear to have only one agent that needs classification, or a set of agents, each with their own separate sets of descriptors; 2) The ALSC data is often at the sentence-level as opposed to post-level, limiting the context-space for inference. Despite these obvious differences, we quantitatively verify our intuitions in Section 7.1, and show that ABSA models do not generalize to our dataset.

Closely related to ABSA is Stance Classification (SC) (also known as Stance Detection / Identification), the task of identifying the stance of the text author (`in favor of`, `against` or `neutral`) toward a target (an entity, concept, event, idea, opinion, claim, topic, etc.)(Walker et al., 2012; Zhang et al., 2017; Küçük and Can, 2021). Unlike ABSA, the target in SC does not need to be embedded as a span within the context. For example, a perfect SC model given an input for classification of context: *This house would abolish the monarchy.* and target: *Hereditary succession*, would predict the *Negative* label (Bar-Haim et al., 2017; Du et al., 2017). While SC appears to require a higher level of abstraction and, as a result, a model of higher complexity and better generalization power than those typically used for ABSA, current implementations of SC are limited by the finite set of queried targets; in other words, SC models currently do not generalize to unseen abstract targets. Yet, in real-time social media, potential targets and agents exhibit a continuous process of emergence, combination and dissipation. We seek to classify these shifting targets using the transitive property of language, and would like the language to provide clues about the class of one span *relative* to another. Ultimately, while SC models are a valuable step in the direction of better semantic understanding, they are ill-suited to our task.

Parallel to this work in SA, there are complementary efforts in consensus threat detection on social media (Wester et al., 2016; Kandias et al., 2013; Park et al., 2018), a task that broadly attempts to classify longer segments of text – such as comments on YouTube or tweets on Twitter – as more general "threats". The nuanced instruction to the labelers of the data is to *identify whether the author of the post is an Outsider from the labeler's perspective as an Insider*. Once again, we observe that this task aligns with the *Insider-Outsider* paradigm, but does not exhaust it, and the underlying models cannot accomplish our task.

The sets of *Insider*s and *Outsider*s comprise a higher-order belief system that cannot be adequately captured with the current working definitions of sentiment nor the currently available datasets. This problem presents *a primary motivation for creating a new dataset*. For example, the post: "Microchips are telling the government where we are", does not directly feature a form of prototypical sentiment associated with "microchips", "the government" and "we", yet clearly insinuates an invasion on our right to privacy making clear the *Insider*s ("we") and *Outsider*s ("microchips", "the government") in the post.

4 Data Collection

To construct our novel dataset – **C**onspiracy **T**heory-5000 (**CT5K**) – we designed crawlers to extract a corpus of social media posts generated by the underlying narrative framework of vaccine hesitancy (Details of the crawlers are documented in Appendix A.1). Vaccine hesitancy is a remarkably resilient belief fueled by conspiracy theories that overlaps with multiple other narratives including ones addressing "depopulation", "government overreach and the deep state", "limits on freedom of choice" and "Satanism". The belief's evolution on social media has already enabled researchers to take the first steps in modeling critical parts of the underlying generative models that drive anti-vaccination conversations on the internet (Tangherlini et al., 2016; Bandari et al., 2017). Moreover, vaccine hesitancy is especially relevant in the context of the ongoing COVID-19 pandemic (Burki, 2020).

On the crawled corpus, we extract the noun-chunks from each post using SpaCy's noun chunk extraction module and dependency parsers (Honnibal and Johnson, 2015). A noun chunk is a subtree of the dependency parse tree, the headword of which is a noun. The result is a set of post-phrase pairs, $(\mathtt{p}, \mathtt{n})$, where $\mathtt{p}$ is a post and $\mathtt{n}$ is one of the noun phrases extracted from the post.

Amazon Mechanical Turk (AMT) (see Appendix A.2 for labeler instructions) was used to label the post-phrase pairs. For each pair, the labeler was asked, *given the context*, whether the writer of the post $\mathtt{p}$ perceives the noun phrase $\mathtt{n}$ to be an *Insider*, *Outsider* or *neither* (N/A). The labeler then provides a label $c \in \mathcal{C}$, where $\mathcal{C} = \{\textit{Insider}, \textit{Outsider}, \textit{N/A}\}$ (hence $|\mathcal{C}| = 3$). The triplets of post-phrase pairs along with their labels form the dataset $\mathcal{D} = \{((\mathtt{p}_i, \mathtt{n}_i), c_i)\}_{i=1}^{|\mathcal{D}|}$. Note that a single post can appear in multiple triplets, because multiple different noun phrases can be extracted and labeled from a single post. The overall class distribution and a few conditional class distributions across the labeled samples for several particular noun phrases are provided in Figure 5 in the Appendix B.

Manual inspection of the labeled samples $((\mathtt{p}, \mathtt{n}), c)$ suggests that the quality of the dataset is good ($< 10\%$ misclassified by random sampling). The now-labeled CT5K dataset (Holur et al., 2022)[1] ($|\mathcal{D}| = 5000$ samples) is split into training (90%), and 10% testing sets. 10% of the training set is held out for validation. The final training set is 20-fold augmented by BERT-driven multi-token insertion (Ma, 2019).

5 Methodology and Pipeline

The **N**oun-**P**hrase-to-***I**nsider*-***O**utsider* (NP2IO) model [2] adopts a token classification architecture comprising a BERT-like pre-trained backbone and a softmax classifier on top of the backbone. Token-level labels are induced from the span-level labels for the fine-tuning over CT5K, and the span-level labeling of noun phrases is done through majority vote during inference.

5.1 Fine-tuning Details

An outline of the fine-tuning pipeline is provided in Figure 2.

Given a labeled example $((\mathtt{p}, \mathtt{n}), c)$, the model labels each token t_i in the post $\mathtt{p} = [t_1, \ldots, t_N]$, where N is the number of tokens in the post $\mathtt{p}$. The BERT-like backbone embeds each token t_i into a contextual representation $\Phi_i \in \mathbb{R}^d$ (for example, $d = 768$ for BERT-base or RoBERTa-base). The embedding is then passed to the softmax classification layer

$$\boldsymbol{\pi}_i \triangleq \mathrm{Softmax}(\mathbf{W}^T \Phi_i + \mathbf{b}) \qquad (1)$$

where $\boldsymbol{\pi}_i \in \Delta^{|\mathcal{C}|}$ is the *Insider-Outsider* classification prediction probability vector of the i^{th} token, and $\mathbf{W} \in \mathbb{R}^{d \times |\mathcal{C}|}$ and $\mathbf{b} \in \mathbb{R}^{|\mathcal{C}|}$ are the parameters of the classifier.

The ground truth class label c accounts for all occurrences of the noun phrase $\mathtt{n}$ in the post $\mathtt{p}$. We use this span-level label to induce the token-level label and facilitate the computation of the fine-tuning loss.

Concretely, consider the spans where the noun phrase $\mathtt{n}$ occurs in the post $\mathtt{p}$: $S_{\mathtt{n}} = \{s_1, \ldots, s_M\}$, where $s_j \in S_{\mathtt{n}}$ denotes the span of the j^{th} occurrence of $\mathtt{n}$, and M is the number of occurrences of $\mathtt{n}$ in $\mathtt{p}$. Each span is a sequence of one or more tokens. The set of tokens appearing in one of these labeled spans is:

$$T_{\mathtt{n}} = \{t \in \mathtt{p} \mid \exists s \in S_{\mathtt{n}} \ \text{s.t.}\ t \in s\}\,. \qquad (2)$$

We define the fine-tuning loss $\mathcal{L}$ of the labeled example $((\mathtt{p}, \mathtt{n}), c)$ as the cross-entropy (CE) loss computed over $T_{\mathtt{n}}$ using c as the label for each token in it,

$$\mathcal{L}(\mathtt{p}, \mathtt{n}, c) = \sum_{i: t_i \in T_{\mathtt{n}}} -\log\big((\boldsymbol{\pi}_i)_c\big) \qquad (3)$$

where $(\boldsymbol{\pi}_i)_c$ denotes the prediction probability for the class $c \in \mathcal{C}$ of the i^{th} token.

The fine-tuning is done with mini-batch gradient descent for the classification layer and a number of self-attention layers in the backbone. The number of fine-tuned self-attention layers is a hyperparameter. The scope of hyperparameter tuning is provided in Table 4.

---

[1] See: Data and Model Checkpoints

[2] Code Repository: NP2IO

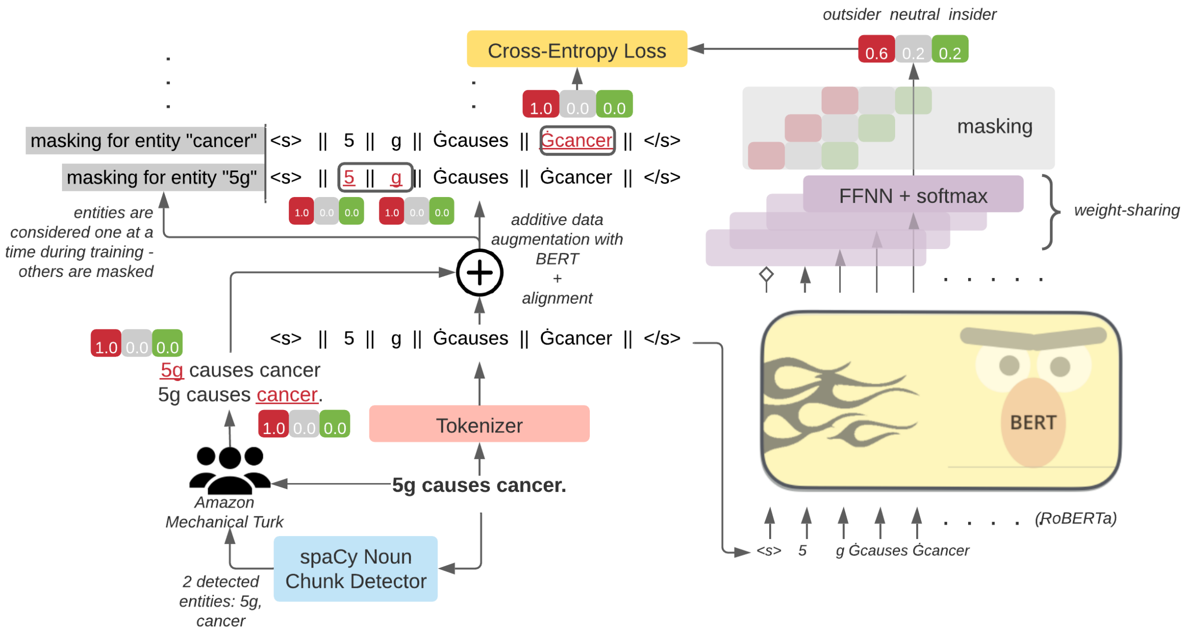

Figure 2: **NP2IO - An Outline of the Fine-tuning Pipeline:** A post is tokenized and aligned to noun chunks that are independently identified from the post with a pre-trained SpaCy parser. The BERT model is fine-tuned to identify the labels of each token in context of a post based on AMT labels of the higher-order noun phrases. Loss is Cross-Entropy (CE) loss computed on only tokens relevant for detection post SpaCy-noun phrase identification.

5.2 Real-time Inference and Accuracy Measurement

During fine-tuning, we extend the label of a noun phrase to all of its constituent tokens; during inference, conversely, we summarize constituent token labels to classify the noun phrases by a majority vote. For a pair of post and noun-phrase $(\mathtt{p}, \mathtt{n})$, assuming the definition of $\{t_i\}_{i=1}^N$, $\{\boldsymbol{\pi}_i\}_{i=1}^N$ and $T_{\mathtt{n}}$ from the Section 5.1, the *Insider-Outsider* label prediction $\hat{c}$ is given by

$$\hat{c} = \arg\max_{k} \sum_{i:t_i \in T_{\mathtt{n}}} \mathbb{1}_{\{k=(\arg\max_{\kappa}(\boldsymbol{\pi}_i)_{\kappa})\}}. \tag{4}$$

Now c can be compared to $\hat{c}$ with a number of classification evaluation metrics. Visual display of individual inference results such as those in Figure 1 are supported by displaCy (Honnibal and Montani, 2017).

6 Baseline Models

In this section, we list baselines that we compare to our model's performance ordered by increasing parameter complexity.

- **Random Model (RND):** Given a sample from the testing set $\{\mathtt{p}, \mathtt{n}\}$, $\hat{c}$ is randomly selected with uniform distribution from $\mathcal{C} = \{\mathit{Insider}, \mathit{Outsider}, \mathit{N/A}\}$.
- **Deterministic Model (DET - I/O/NA):** For any post-phrase pair $(\mathtt{p}, \mathtt{n})$, give a fixed classification prediction: $\hat{c}$ = *Insider* (DET-I), $\hat{c}$ = *Outsider* (DET-O) or $\hat{c}$ = *N/A* (DET-NA).
- **Naïve Bayes Model (NB / NB-L):** Given a training set, the naïve Bayes classifier estimates the likelihood of each class conditioned on a noun chunk $\mathcal{P}_{\mathcal{C},\mathcal{N}}(c|\mathtt{n})$ assuming its independence w.r.t. the surrounding context. That is, a noun phrase predicted more frequently in the training-set as an *Insider* will be predicted as an *Insider* during the inference, regardless of the context. For noun phrases not encountered during training, the uniform prior distribution over $\mathcal{C}$ is used for the prediction. The noun chunk may be lemmatized (by word) during training and testing to shrink the conditioned event space. We abbreviate the naïve Bayes model without lemmatization as NB, and the one with lemmatization as NB-L.
- **GloVe+CBOW+XGBoost (CBOW - 1/2/5):** This baseline takes into account the context of a post but uses global word embeddings, instead of contextual-embeddings. A window length w is fixed such that for each noun phrase, we extract the w words before and w words after the noun phrase, creating a set of context words, $\mathcal{S}_w$. Stopwords are filtered, and the remaining con-

text words are lemmatized and encoded via 300-dimensional GloVe (Pennington et al., 2014). The Continuous Bag of Words (CBOW) model (Mikolov et al., 2013) averages the representative GloVe vectors in $\mathcal{S}_w$ to create an aggregate contextual vector for the noun phrase. XGBoost (Chen and Guestrin, 2016) is used to classify the aggregated contextual vector. The same model is applied on the test set to generate labels. We consider window lengths of 1, 2 and 5 (CBOW-1, CBOW-2 and CBOW-5 respectively).

7 Results and Evaluation

Comparison of NP2IO to baselines is provided in Table 1. The random (RND) and deterministic (DET-I, DET-O, DET-NA) models perform poorly. We present these results to get a better sense of the unbalanced nature of the labels in the CT5K dataset (see Figure 5). The naïve Bayes model (NB) and its lemmatized form (NB-L) outperform the trivial baselines. However, they perform *worse* than the two contextual models, GloVe+CBOW+XGBoost and NP2IO. This fact validates a crucial property of our dataset: *Despite the bias in the gold standard labels for particular noun phrases such as "I", "they" and "microchip" – see Figure 5 in Appendix B – context dependence plays a crucial role in Insider-Outsider classification.* Furthermore, NP2IO outperforms GloVe+CBOW+XGBoost (CBOW-1, CBOW-2, CBOW-5) summarily. While both types of models employ context-dependence to classify noun phrases, NP2IO does so more effectively. The finetuning loss convergence plot for the optimal performing NP2IO model is presented in Figure 4 in Appendix B and model checkpoints are uploaded in the data repository.

7.1 Does CT5K really differ from prior ABSA datasets?

Given the limitations of current ABSA datasets for our task (see Section 2 and Section 3), we computationally show that CT5K is indeed a different dataset, particularly in comparison to other classical ones in Table 2. For this experiment, we train near-state-of-the-art ABSA models with RoBERTa-base backbone (Dai et al., 2021) on three popular ABSA datasets – Laptop reviews and Restaurant reviews from SemEval 2014 task 4 (Pontiki et al., 2014), and Tweets (Dong et al., 2014). Each trained model is then evaluated on all three datasets *as well as* the test set of CT5K. The *Insider* class in CT5K is mapped to the *positive* sentiment and the *Outsider* class to the *negative* sentiment. The F1-macro scores of the models trained and tested among the three ABSA datasets are much higher than the scores when testing on the CT5K dataset. *Clearly, models that are successful with typical ABSA datasets do not effectively generalize to CT5K, suggesting that our dataset is different.*

7.2 Classifying Noun Phrases at Zero-shot

A challenge for any model, such as NP2IO, is zero-shot performance, when it encounters noun phrases never tagged during training. Answering this question offers a means for validating the context-dependence requirement, mentioned in Section 2. This evaluation is conducted on a subset of the entire testing set: A sample of the subset $\{\mathtt{p}, \mathtt{n}\}$ is such that the word-lemmatized, stopword-removed form of $\mathtt{n}$ does not exist in the set of word-lemmatized, stopword-removed noun phrases seen during training. We extract 30% of test samples to be in this set. The results are presented in Table 1. As expected, the performance of the naïve Bayes models (NB, NB-L) degrades severely to random. The performance of the contextual models CBOW-1/2/5, and NP2IO stay strong, suggesting effective context sensitivity in inferring the correct labels for these models. A visualization of the zero-shot capabilities of NP2IO on unseen noun phrases is presented in Figure 6 in Appendix B.

7.3 Does NP2IO Memorize? An Adversarial Experiment

We construct a set of adversarial samples to evaluate the extent to which NP2IO accurately classifies a noun phrase that has a highly-biased label distribution in CT5K. We consider 3 noun phrases in particular: "microchip", "government", and "chemical". Each of these has been largely labeled as *Outsider*s. The adversarial samples for each phrase, in contrast, are manually aggregated (5 seed posts augmented 20 times each) to suggest that the phrase is an *Insider* (see Table 5 in Appendix B for the seed posts). We compute the recall of NP2IO in detecting these *Insider* labels (results in Table 3). NP2IO is moderately robust against adversarial attacks: *In other words, highly-skewed distributions of labels for noun phrases in our dataset do not appear to imbue a similar drastic bias into our model.*

	Performance on the Test Set					**Performance in Zero-Shot**				
Model	**Acc.**	**P**	**R**	**F1**	**F1(w)**	**Acc.**	**P**	**R**	**F1**	**F1(w)**
RND	0.334	0.343	0.334	0.321	0.350	0.280	0.273	0.241	0.239	0.316
DET-I	0.312	0.104	0.333	0.159	0.148	0.280	0.093	0.333	0.146	0.123
DET-O	0.504	0.168	0.333	0.223	0.338	0.593	0.198	0.333	0.248	0.442
DET-NA	0.184	0.061	0.333	0.104	0.057	0.127	0.042	0.333	0.075	0.028
NB	0.520	0.473	0.478	0.474	0.523	0.333	0.341	0.310	0.295	0.369
NB-L	0.468	0.397	0.387	0.386	0.453	0.360	0.389	0.434	0.356	0.373
CBOW-1	0.490	0.419	0.383	0.373	0.448	0.527	0.408	0.361	0.360	0.489
CBOW-2	0.520	0.462	0.415	0.410	0.484	0.553	0.441	0.375	0.368	0.509
CBOW-5	0.526	0.459	0.419	0.414	0.489	0.553	0.393	0.375	0.369	0.514
NP2IO	**0.650**	**0.629**	**0.546**	**0.534**	**0.619**	**0.693**	**0.682**	**0.536**	**0.543**	**0.671**

Table 1: **Performance of NP2IO versus multiple baselines on the test set:** Our model (in bold) performs competitively and outperforms Naïve Bayes, CBOW models across metrics. Furthermore, it retains its performance to classify noun phrases unseen (post-lemmatization and stopword removal) during training. Predictably, the performance of the Naïve Bayes classifier in this zero-shot setting drops drastically to near random.

Test Dataset	**Train Dataset**		
	Laptop	Restaurants	Tweets
Laptop	0.804	0.768	0.658
Restaurants	0.754	0.825	0.657
Tweets	0.526	0.546	0.745
CT5K	**0.347**	**0.424**	**0.412**

Table 2: **F1-macro scores for the ABSA model trained on conventional SA datasets from SemEval 2014 task 4:** All models perform poorly in testing on the CT5K dataset while performing well in testing on ABSA datasets. This suggests that the CT5K dataset is indeed differentiated from the ABSA datasets.

Noun Phrases	**CT5K *Outsider* Labels (%)**	***Insider* Recall in adversarial text**
microchip	100%	**80%**
government	80%	**89%**
chemical	100%	**62%**

Table 3: **Adversarial inferencing tasks for the trained NP2IO model:** Three noun phrases with very high *Outsider* status (100%, 80%, 100%, respectively) in the CT5K training set are used to construct posts where their contextual role is beneficial, and hence, should be labeled as *Insider* (see Section 2). The results show that NP2IO largely learned to use the contextual information for its inference logic, and did not memorize the agent bias in CT5K. We speculate that the exhibited bias towards "Chemicals" is due to the large body of text documents that discusses the adverse effects of chemicals, and hence is encoded in the embedding structure of pretrained LM models that NP2IO cannot always overrule; at least yet.

8 Concluding Remarks

We presented a challenging *Insider-Outsider* classification task, a novel framework necessary for addressing burgeoning misinformation and the proliferation of threat narratives on social media. We compiled a labeled CT5K dataset of conspiracy-theoretic posts from multiple social media platforms and presented a competitive NP2IO model that outperforms non-trivial baselines. We have demonstrated that NP2IO is contextual and transitive via its zero-shot performance, adversarial studies and qualitative studies. We have also shown that the CT5K dataset consists of underlying information that is different from existing ABSA datasets.

Given NP2IO's ability to identify *Insider*s and *Outsider*s in a text segment, we can extend the inference engine to an entire set of interrelated samples in order to extract, visualize and *interpret* the underlying narrative (see Figure 3). This marks a first and significant step in teasing out narratives from fragmentary social media records, with many of its essential semantic parts – such as, *Insider*/*Outsider* – tagged in an automated fashion. As extensive evaluations of the NP2IO model show, our engine has learned the causal phrases used to designate the labels. We believe an immediate future work can identify such causal phrases, yet another step toward semantic understanding of the parts of a narrative. Broadly, work similar to this promises to expedite the development of models that rely on a computational foundation of structured information, and that are better at *explaining* causal chains of inference, a particularly important feature in the tackling of misinforma-

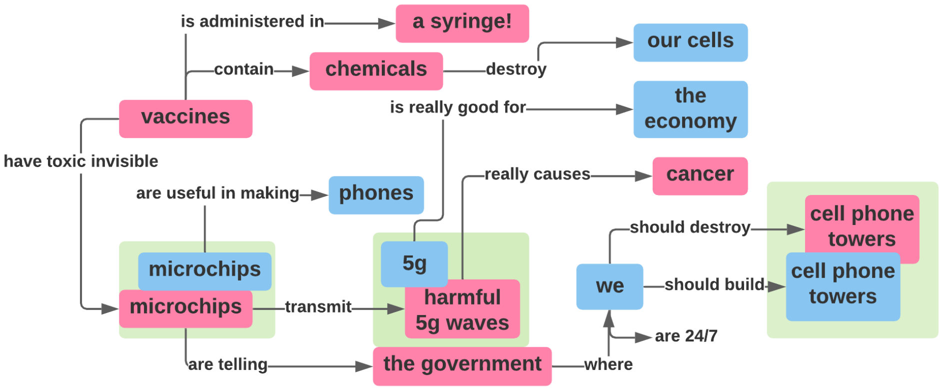

Figure 3: **An actor-actant subnarrative network constructed from social media posts:** Selected posts from anti-vaccination forums such as *qresearch* on 4chan were decomposed into relationship tuples using a state-of-the-art relationship extraction pipeline from previous work (Tangherlini et al., 2020) and these relationships are overlayed with the inferences from NP2IO. This results in a network where the nodes are the noun phrases and the edges are the verb phrases, with each edge representing an extracted relationship from a post. In this network, a connected component emerged capturing a major sub-theory in vaccine hesitancy. This highlights NP2IO's ability at inferring both the threat-centric orientation of the narrative space as well as the negotiation dynamics in play, thereby providing qualitative insight into how NP2IO may be used in future work to extract large-scale relationship networks that are interpretable. The green boxes highlight the noun phrases that have contradictory membership in the *Insider*s and the *Outsider*s classes as their affiliations are deliberated.

tion. Indeed, NP2IO's success has answered the question: "Which side are you on?" What remains to be synthesized from language is: "Why?"

Appendices

A Data Collection

A.1 Automated Crawling of Social Media

A daily data collection method (Chong et al., 2021) aggregates heterogeneous data from various social media platforms including Reddit, YouTube, 4chan and 8kun. Our implementation of this pipeline has extracted potentially conspiracy theoretic posts between March 2020 and June 2021. We select a subset of these posts that are relevant to vaccine hesitancy and that include (a) at least one of the words in [’vaccine’, ’mrna’, ’pfizer’, ’moderna’, ’j&j’, ’johnson’, ’chip’, ’pharm’] and (b) between 150 to 700 characters. The end-to-end data processing pipeline is *uncased*.

A.2 Instructions to AMT Labelers

Amazon Mechanical Turk Labelers were required to be at the Masters’ level (exceeding a trust baseline provided by Amazon), were required to speak English, and were required to be residing in the United States. No personally identifying information was collected. Users were asked to create an account on a LabelStudio (Tkachenko et al., 2020-2021) platform to answer a set of 60-80 questions or 2 hours worth of questions. Each question included (a) A real anonymized social media post with a highlighted sentence, (b) The sentence highlighted in (a) but with the noun phrase of interest highlighted. The question prompt read: *Please let us know whether the entity highlighted in bold AS PERCEIVED BY THE WRITER is a good/bad or neutral entity.*

Labelers were reminded several times via popups and other means that the labels were to be chosen with respect to the author of the post and not the labeler's inherent biases and/or political preferences.

A.3 Ethics statement about the collected social media data

Data was collected using verified research Application Programming Interfaces (API) provided by the social media companies for non-commercial study. In order to explore data on fringe platforms such as 4chan and 8kun where standard APIs are not available, the data was scraped using a Selenium-based crawler. All the retrieved samples were ensured to be public: the posts could be accessed by anyone on the internet without requiring explicit consent by the authors. Furthermore, we made sure to avoid using Personal Identifiable Information (PII) such as the user location, time of posting and other metadata: indeed, we hid even the specific social media platform from which a particular post was mined. The extracted text was cleaned by fixing capitalization, filtering special characters, adjusting inter-word spacing and correcting punctuation, all of which further obfuscated the identity of the author of a particular post.

B Supplementary Figures and Tables

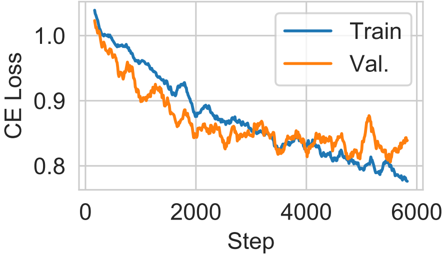

Figure 4: **Convergence plot for NP2IO:** Shown above is the training and validation CE loss with optimal parameters (in bold) from Table 4. Model checkpoints are in data repository.

Parameters	Values
Batch Size	32, **64**, 128
Trainable Layers	0, 1, **2**, 5
LR	1E-7, **1E-6**, 1E-5, 1E-4
Pretrained Backbone	BERT-base, **DistilBERT-base**, RoBERTa-base, RoBERTa-large

Table 4: **A summary of the parameters considered for finetuning:** NP2IO's best-performing (by validation loss) parameters are in bold.

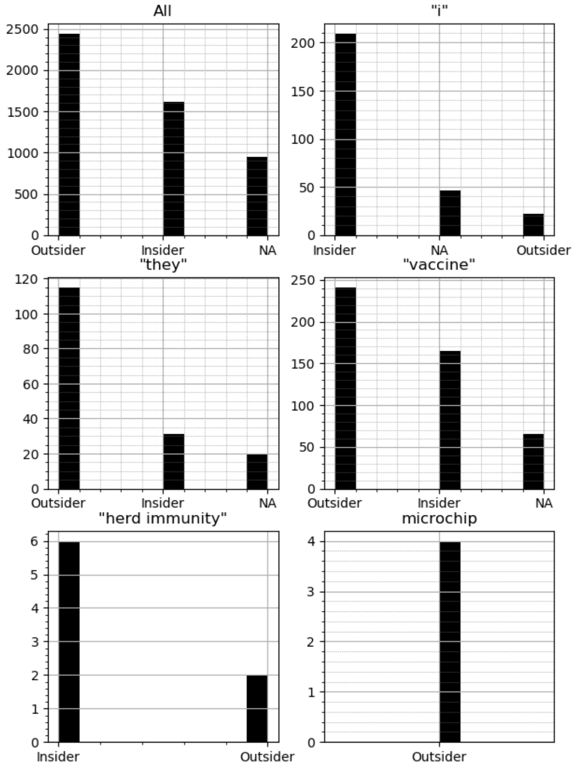

Figure 5: **Histograms that show the distributions of labels in CT5K**: The plot for "All" represents the full 3-category label distribution across all entities, for "I" the bias toward *Insiders* is evident, "They" are mostly outsiders, and there is no clear consensus label for "Vaccine" and "Herd Immunity". Microchips are always tagged as *Outsiders*.

NP	Seed Posts (augmented to 100 posts per NP)
microchip	"I love **microchip**s.", "I feel that **microchip**s are great.", "**microchip**s are lovely and extremely useful.", "I believe **microchip**s are useful in making phones.", "**Microchip**s have made me a lot of money."
government	"The **government** helps keep me safe.","The **government** does a good job.","I think that without the **government**, we would be worse off.","The **government** keeps us safe.", "A **government** is important to keep our society stable."
chemical	"**Chemical**s save us.","**Chemical**s can cure cancer.","I think **chemical**s can help elongate our lives.","I think **chemical**s are great and helps keep us healthy.","**Chemical**s can help remove ringworms."

Table 5: **The set of 5 *Insider*-oriented core posts per noun phrase (in bold) that have a high skew toward *Outsider* labels in CT5K:** Each seed post is augmented 20 times to create a set of 100 adversarial posts per phrase. NP2IO infers the label for the key noun phrase across these samples. The *adversarial* recall is presented in Table 3.

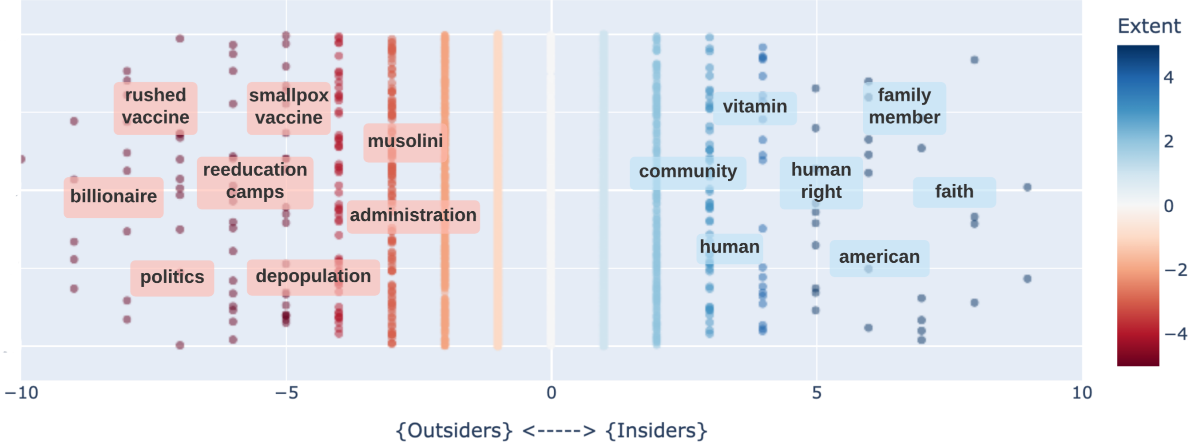

Figure 6: **Zero-shot *Insider-Outsider* Classification Profile:** This figure shows the consensus vote for noun phrases that do not occur in the training set. The x-axis represents the consensus-vote-count and the y-axis, the indices of the noun phrases. The consensus vote is computed for each noun phrase `n` by passing all the posts that include `n` through NP2IO. Each *Insider* vote is $+1$ and *Outsider* vote is -1. The consensus-vote-count is also color-coded for better visualization. The zero-shot classification is qualitatively observed to correctly classify popular noun phrases such as “reeducation camps”,“depopulation” as *Outsider*s and “american” and “faith” as *Insider*s in the subnarrative of the anti-vaccination movement.

Learning From Failure: Data Capture in an Australian Aboriginal Community

Abstract

Most low resource language technology development is premised on the need to collect data for training statistical models. When we follow the typical process of recording and transcribing text for small Indigenous languages, we hit up against the so-called "transcription bottleneck." Therefore it is worth exploring new ways of engaging with speakers which generate data while avoiding the transcription bottleneck. We have deployed a prototype app for speakers to use for confirming system guesses in an approach to transcription based on word spotting. However, in the process of testing the app we encountered many new problems for engagement with speakers. This paper presents a close-up study of the process of deploying data capture technology on the ground in an Australian Aboriginal community. We reflect on our interactions with participants and draw lessons that apply to anyone seeking to develop methods for language data collection in an Indigenous community.

1 Introduction

For decades, the work of collecting data for Indigenous languages has been the province of documentary and descriptive linguistics (Bouquiaux and Thomas, 1992; Vaux and Cooper, 1999; Meakins et al., 2018). This work has involved various kinds of elicitation, e.g. of word lists, phrases, etc, to support description of the phonology, morphosyntax, and grammar of the language. It has also involved the collection of unrestricted text, through recording and transcription. In most cases, the result is audio with aligned text. Many software tools have been developed for supporting these activities (Boersma, 2001; Clark et al., 2008; Hatton, 2013; Sloetjes et al., 2013).

Within the field of natural language processing, established practice is to support the linguist's work (Michaud et al., 2018; Seifart et al., 2018; Foley et al., 2018; Cox et al., 2019). In some cases, this includes the participation of speakers in activities using apps controlled by linguists (Bird et al., 2014; Hanke, 2017; Bettinson and Bird, 2017). However, the premise is basically the same: obtain a substantial quantity of audio and transcribe it, or post-edit the output of an automatic transcription system.

We believe that these approaches do not adequately address a fundamental reality of small languages: they are *oral*. There may be an official orthography, but it has no place in the local language ecology where any written business takes place in a language of wider communication. As a result, local people are usually not confident in the orthography of the language. Furthermore, there may be low confidence in using computers and text editors, and inadequate support for the language in terms of keyboarding and spelling correction. Add to all this the fact that the whole space of rendering an oral language into standardised orthography can be alienating (Dobrin et al., 2009; Hermes and Engman, 2017).

There is no particular reason for NLP approaches to Indigenous languages to follow the long-established practices of linguists. After all, there is an equally long history of algorithmic approaches being profoundly different to the human tasks they replicate. For instance, a human sorting a hand of cards may use insertion sort, but a machine might use Quicksort, with better average-case complexity (Levitin, 1999). Computational approaches may be inspired by analogy, e.g. simulated annealing, genetic algorithms, neural networks, but they are not required to adhere to the human defined process. Accordingly, we can ask, what is an idiomatic computational approach to collecting data for Indigenous languages that is a better fit to the capabilities of human participants? In the case of associating text and speech, we believe that the answer might be keyword spotting. This is because, in our experience, speakers and learners are attuned to identifying whole words, rather than obsessing

about the idiosyncratic phonetic makeup of individual tokens as required for phone transcription (cf. Bird, 2020b, 718f).

Accordingly, we investigate an approach to transcription based on word spotting known as "sparse transcription" (Bird, 2020b). This would seem to be an easier, less specialised task than direct, contiguous transcription. If more people can participate, we can hope to establish a virtuous circle with more data, better models, less correction, even more data, and so on. The idea is that transcription can be accelerated by identifying the tokens of high-frequency terms all at once, then playing them back in quick succession for confirmation by participants.

This paper reports on the deployment of a lexical confirmation app which supports human confirmation of system hypotheses. We begin by describing the background to this work (Sec. 2), including related work on designing technology for use in Indigenous places. We also describe the site where we work and the design of the lexical verification app. Next, we report what happened when we deployed the app in two field tests, including detailed accounts of interactions with participants (Sec. 3). In the discussion section, we reflect on the field experience from a variety of perspectives, trying to draw out lessons that may be applicable to other places where NLP researchers seek to design technologies for language data collection (Sec. 4). The paper concludes with a summary and prospects for further research.

2 Background

2.1 Designing in an Indigenous context

Designing in the Indigenous space is a small but growing area within the field of Human-Computer Interaction (HCI). Projects in this space often begin with ethnographic research to identify local priorities. Co-design is advocated as a way to establish a "culturally-tailored, culturally-enriched and trustworthy environment for participation" (Peters et al., 2018). The focus of this work includes traditional knowledge (Verran, 2007), language revitalisation (Hardy et al., 2016) or media sharing (Soro et al., 2017). Recent research mentioned the need to involve stakeholders in a system design (Lynch and Gregor, 2004) highlighting the challenges related to the transparency of the mechanism of a given system, specifically when machine learning is involved (Loi et al., 2019) and the difficulty to explain to the users such mechanism (Abdul et al., 2018). The lack of published accounts of experiences collecting language data in Indigenous contexts, specifically in the intersection of NLP and documentary linguistics, makes it difficult for newcomers like us to devise approaches that are likely to work. We address this shortcoming by reporting and reflecting on our field experience.

Deploying speech technologies in remote Aboriginal communities is challenging, not primarily because of low technological literacy on the part of local people, but because of low interactional literacy on the part of NLP researchers who enter indigenous places to gather data.

2.2 Working in an Indigenous place

Our work is grounded in Bininj country in Arnhem land in the north of Australia. The biggest town is Gunbalanya with 1,100 inhabitants where we can find primary and secondary schools in which teaching is done in English. A few remote satellite communities, or "outstations," can be found throughout this country in which education of young people takes place in a bi-cultural environment both in Kunwok and English.

Kunwok (ISO gup) is the main language of communication here, and Kunwinjku is the prevalent dialect. It is spoken by some 2,500 people and is one of the few Australian languages which is gaining speakers (Evans et al., 2003). While a standard orthography exists, most community members do not write at all. When pressed, some of them are able to leverage their knowledge of English literacy in order to decode Kunwok texts (cf. Feinauer et al., 2013; August et al., 2009).

In prior work in Bininj country, we discussed our work with traditional owners (heirs of a given tract of Aboriginal land and leaders of the community). We described and demonstrated prior work involving transcription, and how it can be used to transcribe Kunwok. They raised their concerns about intergenerational knowledge preservation and transmission and access to the resources created by westerners. While it is not clear to us that the nature of our work had been thoroughly understood, we could identify through this interaction topics which are addressed by current speech processing and HCI research projects (San et al., 2021; Taylor et al., 2020). Our work took place in Gunbalanya and Manmoyi, a remote community situated 5 hours drive from Gunbalanya.

Australian Aboriginal communities are far from uniform. The experiences and challenges we describe here may be relevant for the Australian Top End, but they cannot be directly applied to Indigenous communities in other places.

Figure 1: Screenshot of the Spoken Term Detection based Lexical Verification App

2.3 Lexical verification app

We designed a lexical verification app that bridges the output of a spoken term detection system to people. It was built following the design of Bettinson and Bird (2017). We focused on a simple design without any textual component besides the transcription of the query term. The idea is to first load in a web app the query/utterance pairs generated by our spoken term detection system. We then ask speakers of the target language to confirm for each pair if the query word (i.e. the term we are trying to retrieve) is pronounced in the search utterance (i.e. the sentence in the speech collection in which the query term was detected).

The participants have six buttons available to perform the task. They have two play buttons at the bottom left: One to play the query term, the other to play the search utterance. Once the two audio files have been listened to, two feedback buttons appear at the bottom right to allow the user to confirm if the query term is included or not in the utterance. We also added two arrows on each side of the top of the screen to allow the user to jump to the previous or the next example. When a new example is displayed on the screen, the query term is played automatically When the utterance is played, the transcription of the query term is highlighted around the timestamps in which the query term was detected. The terms are spotted in the utterances beforehand following the parameters of the sparse transcription simulation proposed by Le Ferrand and Bird (2020). Because of the challenges posed by the remote Aboriginal context such as the lack of reception or proper working facilities (e.g. a table), we needed to find solution in terms of data storage and activity design. Based on the work of (Bettinson and Bird, 2021), we stored the query/utterance pairs output by our spoken term detection system in a JSON file and loaded them in a Raspberry Pi with the app. The Pi acts as a WiFi hotspot to which any device can connect. We can then then connect a tablet to the Pi and, doing so, the feedback provided by the participant can directly be stored in the associated database.

3 Fieldwork

We tested our approach with two trials in two Aboriginal towns, with three people in each place. While the number of participants seems small, larger trials are difficult to arrange in Aboriginal contexts due to the small number of speakers. At the beginning of each elicitation session, the first author explained our intention to teach a machine to transcribe the language automatically, and that we wanted help to correct system guesses. There is actually no direct translation of transcription in Kunwok and the concept is usually given by the formulation *karribimbun kure djurra*, “we’re drawing on paper”.

In both places, we recruited the participants with the support of two local institutions, the art centre in Gunbalanya and the ranger organisation in Manmoyi. At the start of our trips, the first author introduced himself to the communities and explained that he was looking for people to support him for language work. Then the people interested came to find him throughout the day. Each session lasted approximately 15 minutes and was part of other language work including recordings or language learning. Each participant was paid at the regular rate for language work.

3.1 Trial 1: Gunbalanya

For our first trial, we recorded source audio from a three hour guided tour of a local site. We transcribed a few minutes of this recording and used this transcription to build a lexicon. We used voice activity detection to segment the recording into breath groups. Finally, we automatically spotted terms from the lexicon in these breath groups. Since the speaker of the lexicon and the speech collection overlap, most of the terms spotted by the system were correctly retrieved. In the data presented to participants, the query term was present in the supplied phrase in 57% of the instances.

This configuration was tested with three Gunbalanya residents: SB (20s), TM (30s), and RB (40s). This last participant was also the speaker of the recordings.

SB appeared nervous and said little in response to our explanations and questions. When an audio clip was played, he translated, even though this was not the instruction. It was as if he projected his assumption about the purpose of the task, namely for the researchers to understand the content. At one point he respoke the query term and the target phrase in a single utterance, before explaining his knowledge about the associated place. The interface itself was not legible to him: faced with a choice of two play buttons – one for the query term and one for the phrase – he was never clear which one to press. He never used the thumbs up/down feedback buttons.

Here is an example of the confusing situation set up by our approach (we use "App" to indicate audio produced by the app, along with speaker initials, and ELf for the first author. "Play1" refers to the button that plays the query term and "play2" the utterance).

ELF	<press play1>
App	*manyilk*
ELF	<press play2>
App	*menekke mandjewk karuy*
ELF	*manyilk? larrh.* Because he says *mandjewk*
SB	*manyilk*, first <press play1>
App	*manyilk*

Notice that the query term *manyilk* "grass" is not contained in the utterance *menekke mandjewk karuy* "this wet season he dug it". When we demonstrate the use of the app by giving the expected response of *larrh* "no", SB asserts that manyilk is present, contradicting us. He presses on the query term play button to show us.

The following day, when we discussed with another participant, we heard that SB thought that our task was an attempt to test his memory.

RB was more confident than SB. He seemed intrigued at hearing his own voice on the device. For each audio segment we played, RB gave an interpretation of the content. We offered the device to him to control, but he declined. After we pressed the two play buttons, he waited, and we had to follow up with overt questions: "does he say <query term>?", or "can you hear <query term> in this sentence?" He answered as expected, with: "yes, <query term>" or "no, he doesn't say <query term>." Consider the following example:

ELF	<press play1>
App	*marnbom* ("he made")
ELF	<press play2>
App	*kumekke* artist *marnbom kadi*
ELF	do you hear *marnbom*?
RB	*marnbom* that's painting making the painting
ELF	but do you hear *marnbom* in the sentence?
RB	yeah

Unlike SB and RB, TM readily took the device and used the controls. Sometimes, when the query term was not contained in the utterance, he not only translated the audio, but he also offered an example sentence containing the query term. In the following example, "confirm" refers to one of the feedback button which automatically display the next example and play the query term:

TM	<press confirm>
App	*karrikadjung* ("we follow it")
TM	*karrikadjung*, ("we are following") <press play2>
App	*karrikadjuy* road ("we followed the road")
TM	he says *karrikadjuy*, it means we went this way road, he should have say we are following this one, *karrikadjung*

In this case, the difference between the query term *karri-kadju-ng* "we-follow-PRES" and the utterance *karri-kadju-y* "we-follow-PAST" is only in verb tense. The whole query term appears in the sentence, except for the tense marker. Should the speaker say yes or no? This points to a shortcoming of the task definition.

When the term was correctly retrieved, TM would respeak the audio and press the thumbs-up button. When the term was not correctly retrieved, TM offered extensive explanations.

3.2 Trial 2: Manmoyi

For the second trial, we visited the Manmoyi outstation. We used five short audio recordings from previous fieldwork, including guided tours and traditional stories. One of the recordings was transcribed and we extracted the words to use as our lexicon. As before, we segmented the source audio into breath groups and ran word spotting against this set.

Since the speaker of the lexicon and those of the rest of the collection did not overlap, there was much lower precision; often a query term matched noise or mumbling. In the data presented to participants, only in about 10% of cases was the query term present in the supplied phrase.

This configuration was tested with three residents of Manmoyi: LY (60s), LB (50s), RG (50s).

LB and LY participated together, with LB taking an active role and LY only participating by talking to LB during the task. With each round, LB listened to the query term and the utterance then appeared to associate them as a single linguistic event, and he would recount a story that included both the term and the utterance. After this, he would give feedback (thumbs up or down) depending on how easy he found it to link the two semantically:

LB	<press play1>
App	*wirrihmi* ("dislike/wrong")
LB	that's "wrong one"
LB	<press play2>
App	*wanjh manjbekkan manmanjmak*
LY	it tasted sweet
LB	it tasted like you know this, it might have been a little bit funny or something like that
LB	yeah like for us they say: "no I can't eat" because he tasted it and they say "try it" and they gave it, and he says "aah yeah it tasted nice"
LB	*yoh*, that's the one, that's good, *kamak*

LB often interpreted the audio segment. At one point, he recognised the speaker for the queries, and he told us about her and began to recount the same story:

ELF	<press play1>
App	*nawernwarre* ("big brother")
ELF	<press play2>
App	*birribonguni birri...* ("they were drinking, they...")
LY	*nawernwarre*
LB	*yoh, nawernwarre*
LY	*nawernwarre*, or *manekke* might be... lonely boy (story)
LB	lonely boy *yoh* that's the lonely boy (story)

Towards the end of the session, we asked about LB's understanding of the task:

ELF	Can you tell me in English what do you think I am trying to do?
LB	You are trying to... you are making like Kunwok and English translating, but if you are making straight like Kunwok you're making straight and English making straight, that's the all same.
ELF	well, not really
LB	no it's real, we are talking, we know everything. Not all these, we've seen these people, they don't know anything about it, myself and LY we know everything about it.

LB understood this to be a translation activity. When we disagreed, he re-asserted his standing as a knowledge authority. Later, we explained our ultimate purpose of automatically transcribing the language. LB rephrased transcription as "make it together." We realised afterwards that LB may have been referring to his semantic linking process.

RG was our final participant, and this session revealed many issues. Given the low number of correct query-utterance pairs, we found ourselves needing to manually skip over utterances that were too hard to understand out of context. Each time we abandoned a round and moved on to the following round, the next query term played automatically (this feature was added before any testing with the assumption that it would speed up the verification process).

Such automation turned out to be confusing for RG. For a few instances, RG responded "yes" when the query term was not literally present in the utterance, maybe because the query term was morphologically related to a term that was present, e.g. *birri-m-h-ni* "they-towards-immediate-were" (query) and *birri-ni* "they-were". Another interpretation of this behaviour is that RG was focussing on meanings not forms. In this and other cases, it seems that RG was not clear about what we were asking for.

RG	The old woman is talking about country and the young fellow is talking about what creation was.
RG	It's all a bit confusing. They are not even saying *kunred* it means home, the young other fellow is talking about dreamtime story, so it is not, well it's connect but it is not pronouncing.

Sometimes, RG asked about the speakers and the overall context of the out-of-context audio segment, asking, e.g. "Is this <name> speaking? I don't know what they're talking about here."

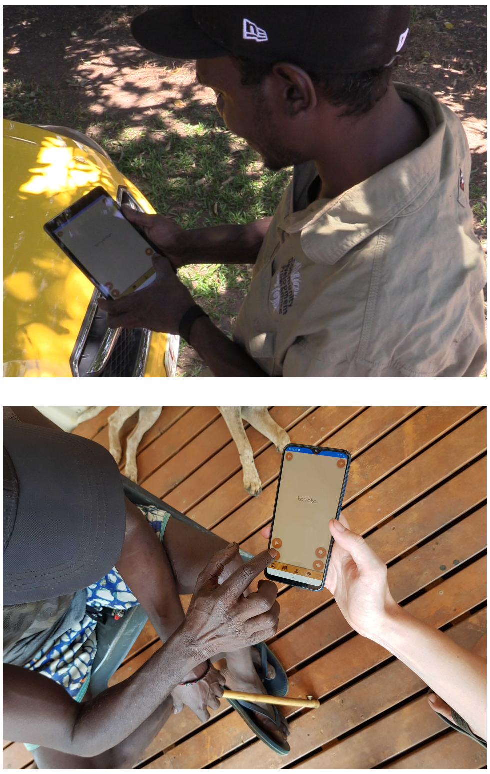

Figure 2: Use of the Word verification app

4 Discussion

There were many issues in the design and conduct of this elicitation activity, and it is clear that our approach need to be completely rethought. In this section, we analyse the above interactions and try to identify some principles to inform NLP elicitation methodology, hoping to avoid such problems occurring in future.

Task motivation. SB, RB and LB understood us to be interested in interpreting the content. SB thought we were testing his memory. TM offered detailed explanations. LB said things that we interpret as asserting authority. It appears that our attempt to explain our purpose in automatic transcription, and the activity of confirming or refuting system guesses, was unsuccessful.

Task definition. Participants were not clear about what we were asking of them. The notion of "word" was not clearly defined, and there were a variety of responses when the query term was not identical yet morphologically or semantically similar to a word in the corresponding utterance.

Naturalness of the task. When it comes to collaboration with western language workers, Aboriginal people in these communities are accustomed to participating in interviews, recordings, transcription, and translation activities. This may explain people's readiness to respeak or interpret the content or supply additional cultural information. We entered with a different task, one where the overt activity of human confirmation/rejection of system guesses was not transparently related to a recognisable transcription task. We explained and demonstrated the activity, but TM was the only participant to instantly grasp this task. Even so, he provided extensive explanations when the system guess was wrong in an effort to teach us.

Utterance context. From our perspective, the components of the device were clear. We have a query term that needs to be detected, and an utterance that should contain the query term. From this, we just need two feedback buttons to confirm whether the query term is included in the utterance. However, to the participant listening to the audio produced by the app and not following our use of the controls, the query term and utterance may be perceived as a single utterance. Everything put into the aural space appears to be concatenated by listeners, and our non-conventional metalinguistic context is not interpretable. When endeavouring to explain the task in Kunwok, we were hampered by the lack of words for "word" and "sentence".

Teaching. The participants generally provided much more information than the simple yes/no response we requested. Each instance was another opportunity to teach us about the language or the country. The design of the task only limited the space for this style of participation. The activity itself was not particularly engaging, taking utterances out of context and asking for a mechanical response to a seemingly pointless question. It seems to be a kind of resilience that participants made the most of the opportunity to pursue their own ends of educating newcomers. Further discussion with community members highlighted their concerns about knowledge preservation, access to archival recordings, and learning literacy.

Knowledge transmission. George et al. (2010) explains that the way in which westerners and Australian Aboriginal people transmit their knowledge varies in that one extracts, identifies and, categorizes while the other needs the information to be embedded in a system of kinship relationships. For example, in Bininj country, every individual has a kinship relationship to every other individual, and they address each other accordingly (Glowczewski, 1989). Stories do not exist in isolation but are connected to an individual who tells them, and the country it comes from. We ran up against this when participants needed to connect isolated utterances back to their rightful cultural context, not just consider them as arbitrary linguistic material for which they can answer an unmotivated question: "does this utterance contain this word?" We can see this in Trial 2 where LB ignores the utterance and uses his knowledge of the speaker of the query term to link the content back to the story.

Yarning. Recent fieldwork methods research has shown that adopting Aboriginal-led approaches leads to more culturally appropriate practices and better feedback from Aboriginal consultants (Louro and Collard, 2021). Yarning has been described as a research method and the traditional way for Aboriginal people in Australia to pass knowledge. It can be defined as "a conversational process that involves listening to storytelling that creates new knowledge and understanding" (Terare and Rawsthorne, 2020). Adopting this to engage with participants could lead to better participation and a more appropriate way to collaborate. Here, the Aboriginal consultant would occupy a teaching role and the function of the technology would be to capture, support, and organise natural ways of transmitting knowledge.

Spoken term detection performance. The spoken term detection method delivered markedly different results in the two trials. Presenting data with 50% accuracy (first trial) makes the user's task seem most worthwhile, otherwise, the user is mostly confirming or refuting system guesses (refuting in 90% of cases in the second trial). If this reasoning is correct, then we predict that a trial involving 90% accuracy would also be challenging to motivate and teach. The low accuracy of the system probably contributed to the challenges encountered during the second trial. However similar behaviour in both trials was observed (e.g. the systematic translation after an audio was played or the semantic linkage process) which makes us think that the sole performance of a system is not the main source of the misinterpretation of the task.

App design. The design of the app was based on preliminary thinking about how collection could proceed fluidly. We did not consider the confusion that might be caused by having two play buttons on the screen (one for the query term, and one for the corresponding utterance). In the interests of efficiency, with each new round, the query term was played automatically. It was as if the thumbs up/down button from the previous round caused playback, and this turned out to be confusing. When we wanted to skip forward by a few examples using the right or left arrow keys at the top of the display (Fig. 1), the app would play a series of seemingly random words. Such automation should have been avoided, specifically in the early stage of our work when there was a lot of uncertainty regarding people reaction towards our activity.

Design improvements. Besides the elements we already mentioned, a few paths can be explored to address the challenges we have faced. Removing the query play button could have the effect of reducing the number of contexts and avoid the linkage process we have observed with LB and SB. Limiting the activity to a single story and playing the utterances in chronological order can make the context clear, and the participant would not need to clarify it. Using bottleneck features instead of MFCCs to spot words could improve the precision of the system (Menon et al., 2019).

Such modifications, however, cannot address the biggest flaw of our proposed task: it does not respond directly to people's agenda in terms of language work, but simply tries to leverage people's skills to respond to westerners' expectations. Pushing the proposed pipeline for several iterations would risk alienating our participants and compromising further collaboration. We believe that a complete reshaping of our method is necessary to enable a sustainable and community-based model for language and knowledge documentation.

5 Further Reflection

Our first attempt in this space was unsuccessful on many levels. Most superficially were issues with the task definition and the app interface. The task focused on the notion of "word" and on deciding whether a given word occurred in a given utterance. Yet the notion of word was not established; as an oral language, there was no *a priori* shared understanding between the participant's notion of spoken word and our notion of orthographic word.

Throughout our interactions with participants, our attempts to explain the method and the purpose were unsuccessful. Local perception was fixed on the idea that we had entered the community to learn the language and culture, and that the purpose of participating in the study was to teach us and to interpret the texts for us.

Consequently, the narrow focus of our activity on eliciting a binary, thumbs up/down response was unsuccessful. This is hardly surprising as many people have noted that engaging Aboriginal people with direct questions requiring a yes or no response is seen as testing people's knowledge or memory, and potentially irritating (Maar et al., 2011; Ober, 2017). We observed this ourselves, when SB reported that he felt like he was being tested, or when LB responded as if his authority was being questioned.

Clearly, our style of engagement was not the expected kind of collaboration on a linguistic task. Aside from one participant (TM), no one would participate in the abstract and apparently pointless task of confirming whether a word was present in a sentence. Instead, all participants sought to create meaning from any language fragments they were presented with. On the basis of an isolated word, and person, place or story would be detected, and people would seek to teach us about these aspects of their lifeworld. This took various forms: repeating, paraphrasing, translating, interpreting, or offering extensive cultural commentaries.

In retrospect, this response to our approach comes across as resilient and generous. In comparison, our narrow focus on data collection, and on getting across the specialised task of lexical confirmation may have come across as disconnected from local interests, and potentially disrespectful.

Of course, we can hope to recruit more people like TM. However, the story about scalable creation of language resources involves working with whoever is available. The tasks need to be locally comprehensible and motivating. In moving forward, we believe it is necessary to rethink the collaborative transcription task. The starting point is to understand local participants as teachers and cultural guides, occupied with their own knowledge practices and with passing these on. Special focus need to be given on the creation of a third space between the several stakeholders of a project with benefits that serve both Indigenous participants and external actors (Bird, 2020a). Could we view the task of putting an audio recording into textual form as a way to help a newcomer make progress with the language and culture, and with getting the pronunciations and meanings correct? The answer to this question depends on further research.

6 Conclusion

Outside the major languages, the development of language technologies is considered to be held up by the general lack of data (Krauwer, 2003). In the case of the world's small, oral languages, the usual approach has been to follow the long-established practice of linguists and record and transcribe audio and elicit wordlists and paradigms. Many computational tools were developed to support this approach. However, algorithmic approaches to working with small languages do not need to be limited by these past practices, and so we believe it is worth considering other approaches to data collection that might simultaneously support computational methods while engaging effectively with members of the speech community.

Accordingly, we took a recently proposed approach to transcription based on keyword spotting, and developed an app for confirming system guesses. We anticipated that this app would be more accessible to local participants than the conventional linguist-driven tasks. We ran trials in two Aboriginal towns, with speakers of the Kunwok language.

In this paper, we report the description of the several interactions we had with locals around a lexical verification activity. We present the many challenges we encountered, including a reflection around the technical and cultural issues of the task design, and the flaws around our approach in terms of collaborative language work.

For the present, we offer our findings as a candid report on the experience of deploying data capture technology in an Indigenous community, in the hope that others will succeed where we have failed. We hope others will also follow our lead and share their own experiences of data collection, and make visible more of the real work of NLP (cf. Star, 2007). Perhaps it is possible for an externally-defined task such as transcription to be aligned to local agendas. Just as often, we expect that it will be necessary to let go of such tasks and do something different. Something that makes sense locally.

Acknowledgements

This research was covered by a research permit from the Northern Land Council, and ethics approved from Charles Darwin University. We are grateful to the Australian government for a PhD scholarship to the first author, and for grants from the Australian Research Council and the Indigenous Language and Arts Program to the second author.

The recruitment of participants was done with the support of the local organisation: Injalak Arts and Craft in Gunbalanya, and Warddeken Land Management in Manmoyi. The shape and purpose of the work was explained in English and oral consent has been obtained by all the participants. Additional approval has been given by Manmoyi traditional owners, concerning the collection and use of the data. All the participants have been paid at the regular rate for Aboriginal people consultancy. We would like to thank Mat Bettinson for his involvement in the design of the lexical verification App and Joshua Yang for the video recording of the trials.

Deep Inductive Logic Reasoning for Multi-Hop Reading Comprehension

Wenya Wang and **Sinno Jialin Pan**
Nanyang Technological University, Singapore
`{wangwy, sinnopan}@ntu.edu.sg`

Abstract

Multi-hop reading comprehension requires an ability to reason across multiple documents. On the one hand, deep learning approaches only implicitly encode query-related information into distributed embeddings which fail to uncover the discrete relational reasoning process to infer the correct answer. On the other hand, logic-based approaches provide interpretable rules to infer the target answer, but mostly work on structured data where entities and relations are well-defined. In this paper, we propose a deep-learning based inductive logic reasoning method that firstly extracts query-related (candidate-related) information, and then conducts logic reasoning among the filtered information by inducing feasible rules that entail the target relation. The reasoning process is accomplished via attentive memories with novel differentiable logic operators. To demonstrate the effectiveness of our model, we evaluate it on two reading comprehension datasets, namely WikiHop and MedHop.

1 Introduction

Reasoning has been extensively studied in the structured domain, e.g., knowledge base completion which infers missing facts given background entities and relations. However, when the background knowledge is expressed in natural languages, as shown in the multi-hop reading comprehension problem with triplet-form questions (Welbl et al., 2018), it becomes difficult to conduct complex reasoning because the entities and relations are not explicitly labeled in the documents. For example, consider the question "country(*Moonhole*, ?)", given the following documents:

> "*Moonhole* is a private community on the island of *Bequia*. *Moonhole* was founded by *Thomas* and *Gladys Johnston* in the 1960s."
>
> "*Gladys Johnston* was born in *United States*."
>
> "*Bequia* is an island and is part of the country of *Saint Vincent and the Grenadines*"

In this example, the underlined entities are used to infer the correct answer, i.e., "country(*Moonhole*, *Saint Vincent and the Grenadines*)", but are not explicitly annotated for relational reasoning.

Deep neural networks (DNNs) for multi-hop reading comprehension (RC) can be summarized into following three categories. 1) Memory-based models (Zhong et al., 2019; Wang et al., 2018; Zhuang and Wang, 2019) that produce query-aware context representations. 2) Graph-based approaches (Song et al., 2018; De Cao et al., 2019) that use graph neural networks to propagate information based on pre-constructed entity (context) graphs. 3) Neural Module networks (Andreas et al., 2016) that decompose the question into a series of action modules (Jiang and Bansal, 2019; Gupta et al., 2020). However, DNNs only implicitly encode relevant contexts and fail to explicitly uncover the underlying relational compositions for complex inference. For instance, in the above example, DNNs may encode *Bequia* and *Gladys Johnson* into 1-hop features, given the fact that both entities co-occur with the query *Moonhole*. As a result, the model may predict *United States* by linking it with *Gladys Johnson* instead of the correct answer *Saint Vincent and the Grenadines*. In contrast, human beings would easily produce the correct answer given the knowledge "if A is in B and B is part of country C, then A is in country C" and by examining the relations between each entity pair co-occurred in the context.

Inductive logic programming (ILP) (Muggleton, 1991) aligns with human reasoning by inducing interpretable rules to entail positive but not negative examples. To answer the previous query, ILP could generate a rule as located_in$(X, Z) \wedge$ country$(Z, Y) \Rightarrow$ country(X, Y). Combining deep learning with ILP is a promising direction to benefit from both worlds (Evans and Grefenstette, 2018; Dong et al., 2019). Deep logic models have been proposed for structured knowledge base comple-

tion (Minervini et al., 2017, 2020; Yang and Song, 2020; Rocktäschel and Riedel, 2017; Yang et al., 2017). However, it becomes much more challenging when dealing with natural language inputs, as in the case of multi-hop reading comprehension. Weber et al. (2019) proposed to combine a symbolic reasoner: prolog, with weak unifications based on distributed embeddings as a backward-chaining theorem prover to induce feasible rules for multi-hop reasoning. However, their work relies on the degree of precision for pre-extracted NERs and is limited by the number of rule templates.

To address the aforementioned limitations, we propose a novel end-to-end integration of deep learning and logic reasoning termed **D**eep **I**nductive **L**ogic **R**easoning (DILR). It consists of two components: 1) a hierarchical attentive reader that filters query-related and candidate-related information from given documents, and 2) a multi-hop reasoner that conducts inductive logic reasoning by attentively selecting proper predicates to form candidate rules and refines them upon given examples. We introduce novel differentiable logic operators combined with attention mechanisms for smooth back-propagation. Compared to existing deep logic models, we build connections between raw text inputs and the symbolic domain by mapping high-level semantic representations to logic predicates and instantiating logic variables with neural representations to conduct relational reasoning. We also parameterize the entire process for end-to-end differentiable learning.

The contributions of this work include: 1) We introduce a novel smooth connection between deep representation learning with logic reasoning by associating distributed representations with discrete logic predicates and their probabilistic evaluations. 2) We propose deep-learning-based inductive logic programming via attentive memories and differentiable logic operators for the task of multi-hop reading comprehension considering the number of reasoning steps. 3) We provide comprehensive evaluations of our model on two benchmark datasets.

2 Related Work

Multi-Hop Reading Comprehension Recent works for multi-hop RC include memory-based methods which apply attentions to iteratively update query and context representations considering their interactions (Dhingra et al., 2018; Clark and Gardner, 2018; Wang et al., 2018; Zhong et al., 2019; Zhuang and Wang, 2019; Jiang et al., 2019). To explicitly incorporate entity connections, De Cao et al. (2019), Ding et al. (2019), Qiu et al. (2019), Tang et al. (2020), Song et al. (2018) and Tu et al. (2019) proposed to build entity graphs and apply Graph Neural Networks for information propagation. Kundu et al. (2019) formalized reasoning as a path-finding problem with neural encoding to rank candidate paths. Path modeling was also adopted in (Chen et al., 2019) using pointer networks. However, these approaches only focus on local information without the ability to generalize, and some of them rely on off-the-shelf NER tools. Dhingra et al. (2020) proposed to convert texts into a virtual knowledge base for retrieval using a pre-constructed entity database. Another research direction is to decompose target questions into sub-questions (Min et al., 2019) or sub-modules parameterized with neural module networks (Jiang and Bansal, 2019; Gupta et al., 2020; Chen et al., 2020) which also fail to explicitly uncover the underlying logic for reasoning.

Deep Learning with Logic Reasoning Neuro-symbolic learning aims to integrate deep learning's ability on dealing with uncertainty and logic programming's ability on reasoning. Deep neural networks have been used to parameterize discrete logic operators and logic atoms (França et al., 2014; Hu et al., 2016; Manhaeve et al., 2018; Xu et al., 2018; Li and Srikumar, 2019; Wang and Pan, 2020; Wu et al., 2020) given the logic rules. A more challenging direction is inductive logic programming that automatically learns rules through representation learning and differentiable backpropagation (Evans and Grefenstette, 2018; Dong et al., 2019; Wang et al., 2019; Yang and Song, 2020).

Neuro-symbolic learning has been applied to knowledge-base completion through logic embeddings (Guo et al., 2016), tensor operations (Cohen, 2016; Rocktäschel and Riedel, 2017), adversarial learning (Minervini et al., 2017), variational learning (Qu and Tang, 2019) or attentions (Yang and Song, 2020). Differentiable theorem proving has also been proposed with weak unifications and backward chaining (Rocktäschel and Riedel, 2017; Campero et al., 2018; Minervini et al., 2020). However, unlike multi-hop RC, knowledge-base completion only takes structured inputs without the need to address language ambiguity. The most related work to ours is NLProlog (Weber et al., 2019), a neural theorem prover for multi-hop RC by converting language utterances to distributed embeddings. However, NLProlog relies on a NER tool to extract entities and its expressiveness is limited by the number of rule templates.

3 Background

We focus on multi-hop reading comprehension tasks containing explicit query types which align with the standard ILP setting. Formally, for each RC problem, we are given a set of documents $C = \{c_1, ..., c_K\}$, a structured query in the form of a relational triplet $(s, q, ?)$, where s denotes the subject of the relation q, and a list of candidate answers $A = \{a_1, ..., a_n\}$. The task is to select an answer $a \in A$ such that $q(s, a)$ is satisfied, i.e., a is the object of relation q given the subject s. For example, country$(Moonhole, ?)$ is a query asking for the country where *Moonhole* is located. This task could be converted into an ILP problem with the formal definition as follows.

Definition 3.1 (Inductive Logic Programming)**.** Given a logic theory B representing the background knowledge (facts), a set of positive examples E^+ and a set of negative examples E^-, an ILP system aims to derive a hypothesis $\mathcal{H}$ which entails all the positive and none of the negative examples: $B \wedge \mathcal{H} \models \gamma$ for $\gamma \in E^+$. $B \wedge \mathcal{H} \not\models \gamma$ for $\gamma \in E^-$.

The hypothesis $\mathcal{H}$ is a logic program consisting of definite clauses $b_1 \wedge ... \wedge b_N \Rightarrow h$ where $b_1, ..., b_N$ and h are logic atoms. The LHS of "$\Rightarrow$" is the clause body and h is the head. An atom is composed of a predicate and its arguments, e.g., $h =$ located_in(X, Y) with predicate "located_in" and arguments X, Y. A ground atom is obtained by instantiating variables in the arguments with constants, e.g., $X =$ "US". We use $\mu(\cdot)$ to denote the value of an atom or a clause. For smooth optimization, we assign $\mu(\cdot) \in [0, 1]$ which indicates the probability of the atom or clause being true.

For multi-hop reading comprehension, we treat the query relation $q(X, Y)$ as the head atom of the clauses to be induced. The correct answer a_i^+ from each problem forms the set of positive examples $E^+ = \{q(s_i, a_i^+)\}_{i=1}^{N_+}$, and the incorrect answer a_i^- forms the set of negative examples $E^- = \{q(s_i, a_i^-)\}_{i=1}^{N_-}$. Here we use lower cases: s_i, a_i^+, a_i^- to represent constants and upper cases: X, Y to represent variables. The predicates in the logic domain correspond to pairwise relations between two entities[1]. To differentiate the number of inference steps, we define a l-hop reasoning clause as $F_0(X_0, X_1) \wedge ... \wedge F_l(X_l, X_{l+1}) \Rightarrow r(X_0, X_{l+1})$ with l denoting the number of extra arguments as bridging entities in the rule body except those in the head atom. Here r denotes a predicate, i.e., a relation between X_0 and X_{l+1}. Each subclause $F_t(X_t, X_{t+1})$ can be one or a conjunction ($\wedge$) of 2-ary atoms taking only X_t and X_{t+1} as arguments, e.g., $F_t(X_t, X_{t+1}) = r_1(X_t, X_{t+1}) \wedge r_2(X_t, X_{t+1})$.

4 Methodology

Overall, DILR simulates a multi-hop reasoning process considering different number of inference steps. It is an end-to-end framework consisting of two components: a *Hierarchical Attentive Reader* and a *Multi-hop Reasoner*. The attentive reader learns to select relevant information from the given documents to produce query-aware, candidate-aware and bridging entity representations. These representations are passed to the multi-hop reasoner to instantiate logic atoms in order to generate and evaluate clauses that are relevant to the query relation. The multi-hop reasoner conducts rule induction via attentive memories that softly select atoms to form new clauses and novel differentiable logic operators that produce probabilistic values for generated clauses. The final loss can be back-propagated smoothly to update the attentive reader for more accurate selections. Next, we illustrate each component with more details.

4.1 Hierarchical Attentive Reader

To avoid inevitable errors brought by off-the-shelf NER tools for named entity extraction, we propose to extract relevant information using an attentive reader. Since multiple documents (contexts) are involved for each question, we design a 2-level hierarchical attention network to progressively filter token-level and context-level information. Specifically, the token-level attentions aim to select l-hop ($l = 0, ..., L$) relevant entities in each context. Then the context-level attentions produce the final representations by softly attending to each context considering different number of reasoning hops.

4.1.1 Token-Level Attention

Given a query subject s with n_s tokens, a candidate a with n_a tokens, and a context c of length

---

[1] We restrict each atom as a 2-ary atom that takes exactly 2 arguments, analogical to relations in the knowledge base.

n_c, we denote by $\mathbf{S} \in \mathbb{R}^{n_s \times D}$, $\mathbf{A} \in \mathbb{R}^{n_a \times D}$ and $\mathbf{C} \in \mathbb{R}^{n_c \times D}$ their word features after a biGRU layer, respectively. For multi-hop reasoning, we use different attentions for finding or relocating target tokens in each context, inspired by (Gupta et al., 2020). Firstly, a subject-to-context attention is adopted to find similar tokens as the subject in each context: $\mathbf{B}^s_{ij} = \mathbf{w}_s^\top[\mathbf{S}_i; \mathbf{C}_j; \mathbf{S}_i \circ \mathbf{C}_j]$ where $\mathbf{w}_s$ is a learnable transformation vector and $[;]$ denotes concatenations. We obtain the normalized similarity score α^s_{ij} between the i-th token in the subject and the j-th token in the context via a softmax operation on each row of $\mathbf{B}^s$. A subject-aware (0-hop) context representation is produced as

$$\mathbf{h}_s = \sum_{j=1}^{n_c} \bar{\alpha}^s_j \mathbf{C}_j, \text{ with } \bar{\alpha}^s_j = \sum_{i=1}^{n_s} \alpha^s_{ij} \beta^s_i, \tag{1}$$

where β^s_i weighs the contribution of each subject token via a self-attention: $\boldsymbol{\beta}^s = \text{softmax}(\bar{\mathbf{w}}_s^\top \mathbf{S} + b_s)$. Similarly, we produce an attention score α^a_{ij} for the j-th context token w.r.t. the i-th candidate token and a candidate-aware context representation $\mathbf{h}_a$. We denote by $\mathbf{s} = \boldsymbol{\beta}^s \mathbf{S}$, and $\mathbf{a} = \boldsymbol{\beta}^a \mathbf{A}$ the feature representation of the query subject and the candidate entity, respectively.

For $(l+1)$-hop reasoning $(l \geq 0)$, it is desired to relocate to intermediate (bridging) entities that are related to the l-hop entities. Hence, we adopt context-to-context attentions $\mathbf{B}^{l+1}_{ij} = \mathbf{w}_l^\top[\mathbf{C}_i + \mathbf{h}^l; \mathbf{C}_j; (\mathbf{C}_i + \mathbf{h}^l) \circ \mathbf{C}_j]$ given the l-hop representation $\mathbf{h}^l$ where $\mathbf{h}^0 = \mathbf{h}_s$. We use α^{l+1}_{ij} to denote a normalized attention score between the i-th and the j-th context tokens after applying a softmax operator over each row of $\mathbf{B}^{l+1}$. With $\bar{\alpha}^0_j = \bar{\alpha}^s_j$, the $(l+1)$-hop bridging context representation becomes

$$\mathbf{h}^{l+1} = \sum_{j=1}^{n_c} \bar{\alpha}^{l+1}_j \mathbf{C}_j, \text{ with } \bar{\alpha}^{l+1}_j = \sum_{i=1}^{n_c} \alpha^{l+1}_{ij} \bar{\alpha}^l_i. \tag{2}$$

4.1.2 Context-Level Attention

With multiple contexts (documents) available, we use a context-level attention to produce the final l-hop feature representations. When $l = 0$, the model softly attends to each context to produce context-attended subject representation as

$$\widehat{\mathbf{h}}_s = \sum_{k=1}^{K} \bar{\gamma}^s_k \mathbf{h}_{s,k}, \tag{3}$$

where $\bar{\gamma}^s_k$ is the attention weight of context c_k obtained by normalizing over a score vector $\boldsymbol{\gamma}^s$ with entries $\gamma^s_k = \mathbf{v}_s^\top[\mathbf{s}; \mathbf{h}_{s,k}; \mathbf{s} \circ \mathbf{h}_{s,k}]$. Here $\mathbf{h}_{s,k}$ is the subject-aware context representation computed in (1) corresponding to the k-th context c_k. $\mathbf{v}_s$ is a trainable transformation vector. The final subject representation is produced as $\bar{\mathbf{h}}_s = \mathbf{W}_s[\mathbf{s}; \widehat{\mathbf{h}}_s; \mathbf{s} \circ \widehat{\mathbf{h}}_s]$ incorporating both original features and attended information. Similar procedure applies to each candidate entity to produce $\bar{\mathbf{h}}_a$. We treat $\bar{\mathbf{h}}_s$ and $\bar{\mathbf{h}}_a$ as 0-hop subject and candidate representations, respectively.

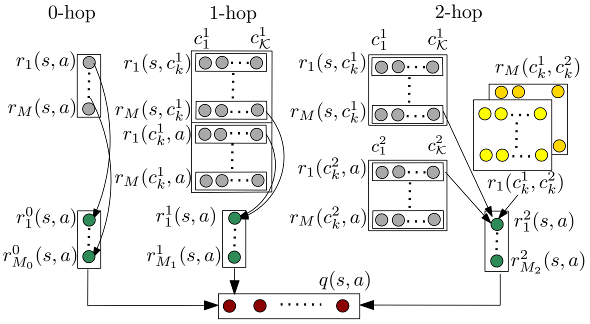

Figure 1: An example of multi-hop ILP. The existential predicates $r_1, ..., r_M$ are used to define invented predicates $r^l_1, ..., r^l_{M_l}$ through attentions. The invented predicates will produce the final clauses to define q.

When $l > 0$, the context-level attention aims to produce the probability of each context being chosen as a bridging entity using

$$p^l_k = \sigma(\mathbf{v}_l^\top[\bar{\mathbf{h}}_s; \mathbf{h}^l_k; \bar{\mathbf{h}}_s \circ \mathbf{h}^l_k]), \tag{4}$$

where $\sigma(\cdot)$ is the sigmoid function, and $\mathbf{h}^l_k$ is the l-hop intermediate entity representation for context $c_k \in C$ computed using (2).

4.2 Multi-Hop Reasoner

The multi-hop reasoner aims to conduct complex reasoning by first generating probable logic clauses and then evaluating each clause by instantiating the variables with relevant contexts obtained from the attentive reader. The clause generation process is parameterized by attentive memories which compute the probability of selecting each atom to form a relevant clause to entail the query relation. An illustration of the procedure is shown in Figure 1 and is elaborated in the following sub-section. The clause evaluation process is then to instantiate variables in each atom with constants such as query subjects, candidate entities or bridging entities. The outputs from the attentive reader, i.e., $\bar{\mathbf{h}}_s$, $\bar{\mathbf{h}}_a$ and $\{\mathbf{h}^l_k\}$'s $(l > 0)$, can be used as feature representations for these constants to compute the atom scores for clause evaluation and updates.

4.2.1 Clause Generation

A definite clause is composed of atoms defined over relational predicates. Since there are no explicit relations given in this task, we pre-define a fixed set of relations for each corpus, named as existential predicates: $P_E = \{r_1, ..., r_M\}$, e.g., "located_in", "next_to". For expressiveness, we further create a set of invented predicates $P_I = \cup_{l=0}^{L} P_I^l$ defined from the existential predicates, inspired by (Evans and Grefenstette, 2018). Specifically, $P_I^l = \{r_1^l, ..., r_{M_l}^l\}$ consists of invented predicates r_m^l defined using l-hop reasoning clauses $F_0(X_0, X_1) \wedge ... \wedge F_l(X_l, X_{l+1}) \Rightarrow r_m^l(X_0, X_{l+1})$. For example, located_in(X_0, X_1) $\wedge$ next_to(X_1, X_2) $\Rightarrow$ outside(X_0, X_2) defines a 1-hop invented predicate "outside". Here L is the maximum hop number. The final clauses defining the query relation will be produced by learning to select relevant invented predicates, e.g., $r_i^{l_1}(X, Y) \wedge ... \wedge r_j^{l_n}(X, Y) \Rightarrow q(X, Y)$ with $0 \leq l_1 \leq ... \leq l_n \leq L$. The number of actual inference steps l_n to answer q is flexibly decided by the model itself, which will be discussed later.

The clause generation process is divided into two stages: 1) to generate clauses defining invented predicates using only the existential predicates, and 2) to generate final clauses defining query relation q using only the invented predicates. To allow for smooth optimization, we parameterize both stages by computing an attention weight for each predicate indicating its probability to appear in the clause body. Specifically, we assign each predicate a learnable embedding to indicate its semantics. Let $\mathbf{U} \in \mathbb{R}^{D \times M}$ denote the embedding matrix for M existential predicates and $\mathbf{U}^l \in \mathbb{R}^{D \times M_l}$ ($l \in \{0, 1, ..., L\}$) denote the embedding matrix for l-hop invented predicates. In the first stage, we use attentive memories to generate

$$\begin{aligned} \mathbf{S}_t^l &= \text{sparsemax}((\mathbf{W}_t^l \mathbf{U}_t^l)^\top (\mathbf{W}_b^l \mathbf{U})), && (5) \\ \mathbf{U}_{t+1}^l &= \mathbf{U}_t^l + \mathbf{S}_t^l \cdot (\mathbf{W}_v^l \mathbf{U}), && (6) \end{aligned}$$

where $\mathbf{U}_0^l = \mathbf{U}^l$, and $\mathbf{W}_t^l$ and $\mathbf{W}_b^l$ are transformation matrices for invented predicates (queries) and existential predicates (keys), respectively. We use *sparsemax*, a sparse version of softmax (Martins and Astudillo, 2016), to select only a small number of predicates. Intuitively, to learn to define a l-hop invented predicate r_m^l, (5) and (6) sequentially produce $F_t(X_t, X_{t+1})$ at each step $t \in \{0, ..., l\}$ to form the clause body by attending over all the existential predicates with attention weight $\mathbf{S}_t^l$. For example, when $l = 1$, (5) first attends to the existential predicate r_i to generate $F_0(X_0, X_1) = r_i(X_0, X_1)$ at step $t = 0$, and then attends to another predicate r_j to generate $F_1(X_1, X_2) = r_j(X_1, X_2)$ at step $t = 1$. The resulting clause $r_i(X_0, X_1) \wedge r_j(X_1, X_2) \Rightarrow r_m^1(X_0, X_2)$ defines the invented predicate r_m^1.

In the second stage, we produce H final clauses taking invented predicates to define the target atom $q(X, Y)$. Given an embedding $\mathbf{u}_q \in \mathbb{R}^D$ for the target relation q, we use a multi-head attention mechanism to compute a probability distribution $\mathbf{s}_h$ over all the invented predicates for each head $h \in \{1, ..., H\}$ to produce the h-th final clause:

$$\mathbf{s}_h = \text{sparsemax}\{(\mathbf{W}_q^h \mathbf{u}_q)^\top (\mathbf{W}_e^h [\mathbf{U}^0; ...; \mathbf{U}^L])\}, \quad (7)$$

where $\mathbf{s}_h$ is a sparse selective distribution over $P_I = \{r_1^0, ..., r_{M_L}^L\}$. For example, if $\mathbf{s}_h$ selects r_1^0 and r_2^1, the final clause becomes $r_1^0(X, Y) \wedge r_2^1(X, Y) \Rightarrow q(X, Y)$, which involves at most 1 inference step because r_2^1 is a 1-hop invented predicate. This completes the recursive rule generation step with multi-hop inference. To this end, we generate H clauses that can be used to define $q(X, Y)$.

4.2.2 Clause Evaluation

Instantiation The clauses generated using the attentive memories need to be tested and refined against the given positive and negative examples, known as learning from entailment that tries to maximize the truth probabilities of positive examples and minimize those of negative examples. The positive examples correspond to $q(s, a)$ and the negative examples correspond to $\{q(s, a^-)\}$'s, where s, a and a^- refers to the query subject, correct answer and incorrect candidate, respectively. To obtain the truth probabilities of these atoms, we first instantiate the variables for each generated clause with constant contexts, e.g., $X = s$ and $Y = a$ (or $Y = a^-$) in $q(X, Y)$. The bridging variables $X_1, ..., X_l$ are instantiated using the bridging contexts selected via the attentive reader as introduced in 4.1. Specifically, to instantiate each X_l, we pick top-$\mathcal{K}$ contexts (documents) $\{c_1^l, ..., c_{\mathcal{K}}^l\} \subseteq C$, namely $X_l = c_k^l, 1 \leq k \leq \mathcal{K}$ with highest probabilities according to p_k^l computed via (4).

Neural Logic Operator Given a definite clause $b_1 \wedge ... \wedge b_N \Rightarrow h$ consisting of grounded atoms (e.g., $b_1 = r_1(s, a)$), we could obtain the value for its head atom as $\mu(h) = \mu(b_1 \wedge ... \wedge b_N)$. To compute the RHS involving logic operators ($\wedge$, $\vee$), T-norm (Klement et al., 2013) is usually adopted:

$T : [0, 1] \times [0, 1] \to [0, 1]$. For example, minimum t-norm defines $T_\wedge(\mu_1, \mu_2) = \min(\mu_1, \mu_2)$, $T_\vee(\mu_1, \mu_2) = \max(\mu_1, \mu_2)$. Product t-norm defines $T_\wedge(\mu_1, \mu_2) = \mu_1 \cdot \mu_2$, $T_\vee(\mu_1, \mu_2) = 1-(1-\mu_1)\cdot(1-\mu_2)$. Here $\mu_1, \mu_2 \in [0, 1]$ refer to the value for the body atoms. However, minimum t-norm is prone to learning plateau because the gradient only flows through one of the inputs. Product t-norm is less stable and is prone to exponential decay when the number of atoms in the clause grows.

To address these limitations, we propose a novel neural logic operator $\mathcal{G}$ defined as follows:

$$\mathcal{G}_\vee(\mu_1, ..., \mu_N) = 1 - \exp\left(\sum_{n=1}^{N} \log(1 - \mu_n + \epsilon)\right)^{\frac{1}{N}},$$

$$\mathcal{G}_\wedge(\mu_1, ..., \mu_N) = \exp\left(\sum_{n=1}^{N} \log(\mu_n + \epsilon)\right)^{\frac{1}{N}}, \quad (8)$$

where $\mu_1, ..., \mu_N \in [0, 1]$ refer to the probabilistic values of all the atoms in the conjunctive ($\wedge$) or disjunctive ($\vee$) clause. ϵ is a small value to guarantee the validity for logarithm. The operator $\mathcal{G}$ has the following property that is ideal for logic semantics.

Proposition 1. *When* $\forall \mu_n \to 1$ *with* $1 \le n \le N$, $\mathcal{G}_\wedge(\mu_1, ..., \mu_N) \to 1$, *aligning with logic "AND". When* $\exists \mu_n \to 1$, $\mathcal{G}_\vee(\mu_1, ..., \mu_N) \to 1$, *aligning with logic "OR".*

Proposition 2. $0 \le \mathcal{G}_\wedge(\mu_1, ..., \mu_N) - \mu_{\min} \le (N^{1/(1-N)} - N^{N/(1-N)})(\prod_{n \neq \min} \mu_N)^{1/(N-1)}$, *where* min *refers to the index of the minimum value among* $\{\mu_1, ..., \mu_N\}$.

Proof.

$$\begin{aligned} &\mathcal{G}_\wedge(\mu_1, ..., \mu_N) - \mu_{\min} \\ &= \exp\left(\sum_{n=1}^{N} \log(\mu_n + \epsilon)\right)^{1/N} - \mu_{\min} \\ &\approx \prod_{n=1}^{N} \mu_n^{1/N} - \mu_{\min}. \end{aligned} \quad (9)$$

Without loss of generality, assume the minimum value is $\mu_{\min} = \mu_1$. By fixing $\mu_2, ..., \mu_N$ as constants, we obtain the gradient for (9) w.r.t. μ_1 as

$$\frac{1}{N} \mu_1^{(1-N)/N} \prod_{n=2}^{N} \mu_n^{1/N} - 1. \quad (10)$$

(9) obtains its maximum value when (10) equals 0, resulting in

$$\mu_1 = N^{N/(1-N)} \prod_{n=2}^{N} \mu_n^{1/(N-1)}. \quad (11)$$

By replacing $\mu_{\min}$ in (9) with (11), we have

$$\begin{aligned} &\mathcal{G}_\wedge(\mu_1, ..., \mu_N) - \mu_{\min} \\ &\le N^{1/(1-N)} \prod_{n=2}^{N} \mu_n^{1/N(N-1)+1/N} \\ &- N^{N/(1-N)} \prod_{n=2}^{N} \mu_n^{1/(N-1)} \\ &= (N^{1/(1-N)} - N^{N/(1-N)}) \prod_{n=2}^{N} \mu_n^{1/(N-1)}. \end{aligned}$$

This completes the proof. □

In other words, the difference between $\mathcal{G}_\wedge$ and $\mu_{\min}$ is bounded. When $N = 2$, the RHS of the inequality equals to $1/4 \cdot \mu_{n \neq \min}$, which makes $\mathcal{G}_\wedge$ closer to $\mu_{\min}$ when $\mu_{n \neq \min}$ is smaller. This formulation results in a more stable and smooth gradient flow compared to minimum t-norm. Moreover, It avoids exponential decay in the output when $N > 1$. It also facilitates neural learning when the exact clause is parameterized with attention scores.

Evaluation With the neural logic operator defined above, the value for the head atom can be inferred once the value for each body atom is given. For grounded atoms over existential predicates, e.g., $r_m(s, a)$, we directly generate its value using a relational network $\mathcal{F} : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}^M$ that takes the features of two constant arguments as input to produce a probability distribution over all the existential predicates $r_1, ..., r_M$:

$$\begin{aligned} &\mathcal{F}(\bar{\mathbf{h}}_s, \bar{\mathbf{h}}_a) \\ &\quad = \text{softmax}(\mathbf{W}_r \tanh[\bar{\mathbf{h}}_s; \bar{\mathbf{h}}_a; \bar{\mathbf{h}}_s - \bar{\mathbf{h}}_a; \bar{\mathbf{h}}_s \circ \bar{\mathbf{h}}_a]), \end{aligned}$$

where $\mu(r_m(s, a))$ equals the m-th entry of $\mathcal{F}(\bar{\mathbf{h}}_s, \bar{\mathbf{h}}_a)$, and $\bar{\mathbf{h}}_s$ and $\bar{\mathbf{h}}_a$ are the outputs from the attentive reader. Similarly, $\mathbf{h}_k^l$ can be regarded as the feature of c_k^l generated from the attentive reader which is used to compute atom values with bridging entities, e.g., $\mu(r_m(s, c_k^l))$.

For l-hop grounded atoms over invented predicates $\{r_1^l(s, a), ..., r_{M_l}^l(s, a)\}$, we compute their values according to the value of the clause body that defines them, e.g., $\mu(F_0(s, c_k^1) \wedge ... \wedge F_l(c_k^l, a))$ using neural logic operators:

$$\boldsymbol{\mu}^l = \max_{z \in \mathcal{Z}_l} \exp\left(\sum_{t=0}^{l} \mathbf{S}_t^l \log(\boldsymbol{\mu}_{(z_t, z_{t+1})} + \boldsymbol{\epsilon})\right)^{\frac{1}{(l+1)}} \quad (12)$$

Here $\boldsymbol{\mu}^l = [\mu(r_1^l(s,a)), ..., \mu(r_{M_l}^l(s,a))]^\top$ denotes the vector of the atom values formed by those l-hop invented predicates. We denote by $\mathcal{Z}_l = \{(s, c_k^1, ..., c_k^l, a)\}_{1 \leq k \leq \mathcal{K}}$ the set for all possible instantiations for l-hop reasoning and denote by z_t the t-th constant of $z \in \mathcal{Z}_l$. $\boldsymbol{\mu}_{(z_t, z_{t+1})} = [\mu(r_1(z_t, z_{t+1})), ..., \mu(r_M(z_t, z_{t+1}))]^\top$ is a vector of values for grounded atoms over existential predicates. Thus, $\exp(\cdot)$ gives a neural approximation of logic conjunctions as shown in (8) over $\{F_t(z_t, z_{t+1})\}_{0 \leq t \leq l}$, each of which is a sparse selection of existential predicates using $\mathbf{S}_t^l$. We use a $\max$ operator to generate the maximum score over all possible instantiations in $\mathcal{Z}_l$ to represent the final truth probability of each invented predicate. Intuitively, a relation between two entities should be satisfied as long as there is at least one instantiation that follows the rule. Also note that (12) has the effect that when $\mathbf{S}_t^l[i,j] \approx 0$, the corresponding predicate r_j will have little effect on the value of its head r_i^l, which is in contrast to existing T-norms.

The final value for $q(s,a)$ is computed via

$$\mu(q(s,a)) = \max_{1 \leq i \leq H} \left\{ \exp\left(\mathbf{s}_i \log([\boldsymbol{\mu}^0; ...; \boldsymbol{\mu}^L] + \boldsymbol{\epsilon})\right) \right\},$$

which selects the maximum score over H final clauses that define $q(s,a)$. We use the cross-entropy loss over $\mu(q(s,a))$ as the final objective to train the entire model (except the word embeddings which are kept fixed) in an end-to-end manner. Here we organize the dataset according to subject-candidate pairs: (s,a). We associate the ground-truth label $y = 1$ with (s,a) if a is the correct answer, otherwise, $y = 0$.

5 Experiment

We conduct experiments on two multi-hop reading comprehension datasets, namely WikiHop and MedHop (Welbl et al., 2018). The WikiHop dataset contains 43,738 training and 5,129 development instances ranging over 277 query relations. MedHop is a medical dataset containing 1,620 training and 342 development instances with a unique query relation, i.e., "*interact with*". For WikiHop, we experiment with both non-contextual (follow (Weber et al., 2019)) named as DILR and contextual word embeddings (BERT (Devlin et al., 2019)) named as DILR-BERT to demonstrate our model's generalization ability. For MedHop, we use the same setting following (Weber et al., 2019). We define $M = 10$ relations as existential predicates and $M_l = 5$ invented predicates for each hop with $l = 0, 1, 2$. The number of final clauses to define the query relation is $H = 5$ and the number of candidate bridging contexts for each hop is set to $\mathcal{K} = 5$. The dimension of predicate embeddings and biGRU layer is 100 and 200, respectively. For training, we adopt Adam optimization with learning rate initialized at 0.001. The batch size is set to 10. For all the experiments, we use the development dataset to evaluate the results because the test data is not publicly available to be grouped by query relations under our setting.

Table 2: Comparisons on WikiHop in terms of the number of training instances for each query relation.

5.1 Experimental Result

Weber et al. (2019) only selects four different query relations from WikiHop, namely *Publisher*, *Developer*, *Country* and *Record_label*. For fair comparisons, we first follow their setting to evaluate on these four domains, then we further evaluate on all the other 47 valid query relations[2] in WikiHop for a more complete analysis. For pure deep learning baselines, we use two memory-based models: EPAr (Jiang et al., 2019) and DynSAN (Zhuang and Wang, 2019), and a graph-based model HDEG (Tu et al., 2019)[3]. For reasoning baselines, we use NLProlog (Weber et al., 2019) and DrMD which is a differentiable reasoning model adapted from (Dhin-

---

[2] We consider those query relations containing at least 20 development and 100 training instances as valid.

[3] These baselines demonstrate good performances according to the leaderboard with available code for implementation.

Table 3: Abalation study over model architecture. − indicates the removal of an element from the model.

gra et al., 2020) by removing pre-defined entities and only consider mention interactions following our settings. BERT is a baseline model that first generates a context-aware query subject (or candidate) representation given the input "[CLS] query subject (or candidate) [SEP] context [SEP]". Then the representations of the query subject and each candidate are concatenated to be fed into a binary classifier. On the other hand, DILR-BERT adopts the attentive reader and the multi-hop reasoner on top of BERT representations. For all the baselines, we train the models on each query relation separately to test the reasoning capability, same as our setting.

Table 1 lists the results for MedHop and four query relations from WikiHop according to (Weber et al., 2019). Clearly, DILR gives the best performances across all the baselines, demonstrating the advantage of combining deep attentive learning with logic reasoning. Though NLProlog also conducts logic reasoning, it is limited by the model's capacity and relies on the extraction accuracy of the NER tool. Even with well-trained contextualized word embeddings (DILR-BERT), our model still brings consistent performance gains.

For a more thorough analysis, we take the entire WikiHop dataset and group the query relations in terms of the number of training instances. As shown in Table 2, there are 38 relations (D1) containing less than 1,000 training examples, 7 relations (D2) with training examples ranging from 1,000 to 4,000 and 2 relations (D3) having more than 4,000 training examples. The entire data (D1+D2+D3) contains 36,653 training instances and 4,462 development instances. We report the micro-average accuracy scores over all the domains within each data group and their combinations in Table 2. Clearly, our model achieves the best performances over all data groups. The margin is larger for D1 and D3, demonstrating the consistency of our proposed model with varying data sizes. In fact, ILP could be beneficial when training data is not sufficient via learning of generalized rules.

5.2 Analysis

To provide detailed analysis, we conduct ablation experiments on 6 datasets as shown in Table 3. For fair demonstration, we pick one relation in D3 (Located), 2 relations in D2 (Occupation and Record) and 3 relations in D1 (Publisher, Producer, Country). The first four rows reflect the accuracies by varying the maximum allowed number of reasoning hops (L). Clearly, ≤ 0 Hop and ≤ 3 Hop produce lower accuracies because ≤ 0 Hop fails to model the bridging entities and ≤ 3 Hop could overfit the model given most of the questions only involve at most 2 reasoning hops.

The middle part of Table 3 reflects the effect of each element of DILR. Specifically, −PI removes the invented predicates: remove (5), (6), (12) and replace $\mathbf{U}^l$ with $\mathbf{U}$ in (7). −ILP removes the reasoner and uses a classifier on top of the attentive reader to produce the final predictions. −AR removes the attentive reader and uses NER tools to extract entities for reasoning. −Rel only computes binary relations that decide whether two constants are related or not. This demonstrates the effect of relational reasoning considering different relations. By comparison, it is evident that removing any component will suffer from non-trivial prediction loss, especially for ILP. To verify the effect of the neural logic operator (NLO), we compare it with two T-norm operators, namely "prod-T" for product T-norm and "min-T" for minimum T-norm. Clearly, NLO produces the best performances across all the experiments.

To provide a concrete view of how the attentive reader filters relevant information and how the generated clauses look like, we list three examples as shown in Table 4. The underlined texts have the maximum attention weights learned from the attentive reader. The bold texts indicate the query subject and the correct answer for each query. Clearly, the attentive reader is able to select bridging entities relevant to the answer. The third column lists some learned clauses from the reasoner. The first row of each example shows the clauses that define an invented predicate and the second row shows the final clause that entails the query relation[4]. We use ab-

[4] We convert the attention scores to the exact clauses by

Query	Attentive Reader	Generated Clause
country(CC, ?)	1. **Christ Church** is a historic church building at ..., Massachusetts. 2. Massachusetts is the most populous state in ... **United States**.	$r_7(CC, M) \wedge r_2(M, US) \Rightarrow r_3^1(CC, US)$ $r_3^1(CC, US) \Rightarrow \text{country}(CC, US)$
record_label(MM, ?)	1. **Method Man** is the B-side ... titled Enter the Wu-Tang. 2. Enter the Wu-Tang is the debut ... on **Loud Records**	$r_3(MM, WT) \wedge r_4(WT, LR) \Rightarrow r_2^1(MM, LR)$ $r_2^1(MM, LR) \Rightarrow \text{record\_label}(MM, LR)$
genre(FO, ?)	1. **Face Off** ! is an hockey game ... 2. Hockey is a family of **sports** ...	$r_7(FO, H) \wedge r_6(H, S) \Rightarrow r_5^1(FO, S)$ $r_5^1(FO, S) \Rightarrow \text{genre}(FO, S)$

Table 4: Examples of learned attentions and clauses.

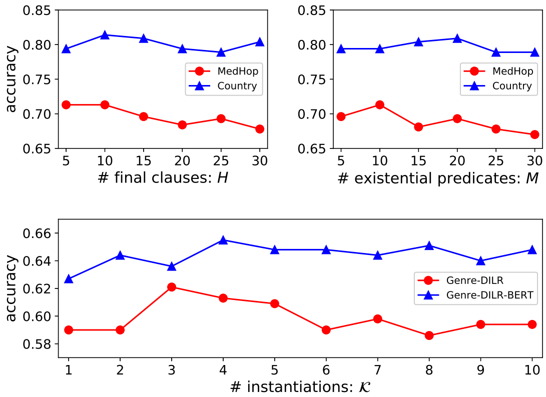

Figure 2: Sensitivity test over H, M and $\mathcal{K}$.

breviated entities as the constants in each grounded atom (e.g., "CC" is short for "Chris Church"). The two clauses for the first example could be read as: if *Chris Church* and *Massachusetts* has relation r_7, and *Massachusetts* and *United States* has relation r_2, then the country of *Chris Church* is *United States*.

We further demonstrate the robustness of DILR by varying model parameters, as shown in Figure 2. The top subplots reveal the accuracies on MedHop and Country datasets when changing the number of final clauses H (left) and the number of existential predicates M (right). The subplot in the bottom depicts the accuracies when varying the number of instantiations $\mathcal{K}$ of the bridging contexts for Genre dataset under both DILR and BERT-DILR models. We shall observe that the performances are relatively stable given that the total number of testing examples are less than 400 for each dataset.

6 Conclusion

We propose an end-to-end model DILR to solve the problem of multi-hop reading comprehension. DILR smoothly connects a hierarchical attentive reader with a multi-hop reasoner to conduct automatic information extraction and complex reasoning. We also introduce differentiable logic operators to induce valid clauses with smooth and stable gradient-based learning. Extensive experiments reveal consistent improvements brought by DILR.

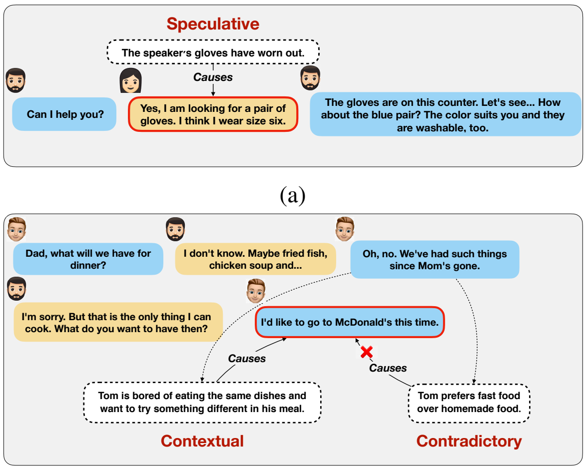
Abstract

This paper addresses the problem of dialogue reasoning with contextualized commonsense inference. We curate CICERO, a dataset of dyadic conversations with five types of utterance-level reasoning-based inferences: cause, subsequent event, prerequisite, motivation, and emotional reaction. The dataset contains 53,105 of such inferences from 5,672 dialogues. We use this dataset to solve relevant generative and discriminative tasks: generation of cause and subsequent event; generation of prerequisite, motivation, and listener's emotional reaction; and selection of plausible alternatives. Our results ascertain the value of such dialogue-centric commonsense knowledge datasets. It is our hope that CICERO will open new research avenues into commonsense-based dialogue reasoning.

1 Introduction

Conversational content on the internet is quickly growing, and such content holds valuable knowledge about how information exchange takes place among speakers. A key step towards understanding such dialogues is gaining the ability to reason with the information shared in the dialogue. To this end, we curate a dataset of dyadic conversations named CICERO (**C**ontextual**I**zed **C**ommons**E**nse Infe**R**ence in dial**O**gues) , which contains inferences around the utterances in the dialogues. The dataset focuses on five types of reasoning-based inferences for a given utterance in a dialogue: cause, subsequent event, prerequisite, motivation, and emotional reaction.

Arguably, making such reasoning-based inferences often demands commonsense knowledge, especially when the inference is implicit. Fig. 1a shows such a case where the cause behind the target utterance is not explicit in the context. However, applying the commonsense knowledge $\texttt{worn gloves} \xrightarrow{\textit{motivates}} \texttt{buy new pair of gloves}$ allowed the annotator to infer a probable cause of the utterance. On the other hand, commonsense can be crucial in sifting relevant information from the context. Fig. 1b depicts an instance where the cause behind the target utterance is inferred from the context. This inference can be explained by commonsense knowledge (see Fig. 3) such as $\texttt{repetitive consumption of the same food} \xrightarrow{\textit{causes}} \texttt{boredom} \xrightarrow{\textit{dispelled by}} \texttt{changing food} \xrightarrow{\textit{achieved by}} \texttt{eating at McDonald's}$. Thus, it is reasonable to posit that such knowledge could aid to bridge the gap between the input and the target inference.



(a)

(b)

Figure 1: Illustration of (a) contextualized commonsense speculation and (b) contradictory inferences in dialogues.

ATOMIC (Sap et al., 2019; Hwang et al., 2020) is one such dataset for commonsense reasoning-based inference, allowing for a large set of inference types. However, ATOMIC is context-free, as it only provides inferences on short phrases, ignoring the broader context around them. Making an inference on an entire utterance, on the other hand, requires understanding the context around it. As per Grice's maxim (Grice, 1975), in conversations, the interlocutors provide any piece of

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics
Volume 1: Long Papers, pages 5010 - 5028
May 22-27, 2022

information as is needed, and no more. Thus, much of the information required to understand an utterance is likely interspersed along the dialogue, and not necessarily localized in the given utterance. For instance, in the example in Figure 1b, understanding the cause for one of the speakers' desire to go to McDonald's requires the context of the previous utterances. ATOMIC is thus not ideal for commonsense reasoning-based inferences on dialogues, where context is critical for understanding an utterance's implications. We confirm this with our experiments in the subsequent sections (§4).

GLUCOSE (Mostafazadeh et al., 2020) exclusively curates causal inferences — *cause, enable,* and *result in* – from monologues. Thus, it is not ideal for making context-consonant inferences on the dialogues. Also, dialogue-specific dimensions like *motivation* and *reaction* are beyond its scope.

On the other hand, CIDER (Ghosal et al., 2021a) does provide a dataset for commonsense-based inference on dialogues, but it is limited to inferences explicitly observable in the dialogues. As such, systems based on CIDER cannot effectively speculate around the dialogue for implicit inference.

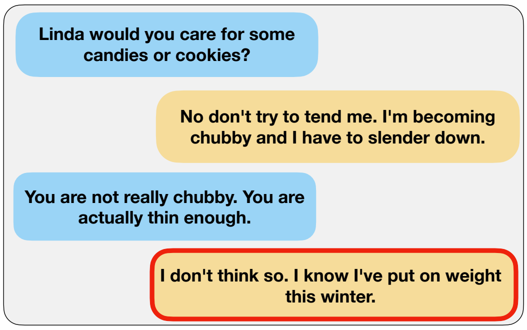
CICERO strives to bring the best of these three datasets by creating a dataset that can enable models to effectively operate on a dialogue by considering the context and speculating when the answer is not apparent.

2 Construction of CICERO

We create CICERO – a large dataset of English dyadic conversations annotated with five types of inferences with the help of human annotators, who are instructed with a carefully crafted set of guidelines.

2.1 Annotation Instructions

The annotators are given a dialogue and a `target` utterance, as exemplified in Fig. 2. The annotators are then asked to make an inference, posed as a question, about the `target` utterance. They write a one-sentence answer that is grammatically correct, concise, and consistent with the dialogue. The answer may contain both *overt* and *speculative* scenarios. An overt scenario is explicitly or implicitly present in the dialogue context. If such contextual scenarios answer the question, the annotators write them as a well-formed sentence. However, in many cases, the dialogue may not hold the answer, neither explicitly nor implicitly. In such cases, the annotators are asked to speculate plausible scenarios around the dialogue, using commonsense and world knowledge, to devise answers that do `not contradict` the given dialogue context.



Linda would you care for some candies or cookies?

No don't try to tend me. I'm becoming chubby and I have to slender down.

You are not really chubby. You are actually thin enough.

I don't think so. I know I've put on weight this winter.

Figure 2: A `dialogue-target` pair. The utterances with red border is the target for this dialogue.

Given the `dialogue-target` pair in Fig. 2, at least one of the following five inferences about the `target` is made by the annotators:

Figure 3: Intermediate commonsense inference steps.

Q1. What is the event that directly causes (overt) or could cause (speculative) `Target`? The annotators consider if any of the events that are or likely to be antecedent to the target can cause the `target`.
Answer: Linda didn't exercise regularly during the winter. **Remark:** The annotators provided possible, speculative answers as the dialogue itself does not provide any reason for Linda's weight gain.

Q2. What subsequent event happens (overt) or could happen (speculative) following the `Target`? The annotators write about the event that happens or could happen following the `target`. Additionally, annotators were told that sometimes, such subsequent events of the `target` are triggered or likely to be triggered by the `target`.
Answer: Linda starts a diet and tries to lose weight.

Admiration	Affection	Afraid	Angry	Annoyed
Anticipating	Anxious	Apprehensive	Ashamed	Awe
Awkwardness	Boredom	Calmness	Caring	Confident
Confusion	Content	Craving	Devastated	Disappointed
Disgusted	Eagerness	Embarrassed	Encouragement	Enthusiasm
Excited	Faithful	Fear	Furious	Grateful
Gratitude	Guilty	Happy	Hopeful	Impressed
Interest	Jealous	Joyful	Lonely	Nostalgic
Prepared	Proud	Relief	Romance	Sad
Satisfaction	Sentimental	Surprised	Terrified	Trusting

Table 1: Possible emotional reactions of the listener.

Remark: The answer is speculative as the dialogue contains no explicit/implicit subsequent event.

Q3. What is (overt) or could be (speculative) the prerequisite of `Target`? Does the `target` have any direct prerequisite or dependency that has to happen or be fulfilled first? (In most cases, prerequisite is the state/event which has to be satisfied before another event causes `target`.) The answer is a state/event which enables the happening of the `target`. In other words, prerequisites are the prior assumptions or background information that the interlocutors agree on about the context.
Answer: Linda was slimmer before the winter.
Remark: Annotators were required to understand the difference between cause and prerequisite clearly before proceeding with the final annotation. Cause of an event X is the event that directly causes X. Prerequisite of an event X is the condition which has to be satisfied in order for X to happen.

Q4. What is an emotion or basic human drive that motivates or could motivate `Target`? Consider the basic human drives, needs (and/or likely emotions) of the speaker of the `target`. Basic human drives and needs are food, water, clothing, warmth, rest, security, safety, intimate relationships, friends, prestige, feeling of accomplishment, self-fulfillment, creative activities, enjoyment, etc. Do any of these human drives/states of mind/emotional feelings motivate the `target`?
Answer: `Not Applicable` for this target.

Q5. What is the possible emotional reaction of the listener: A (or B)? What could be the possible emotional reaction or responses of the listener with respect to the `target`? The annotators capture the appropriate emotion of the listener using the emotion terms listed in Table 1 verbatim or related words (e.g., anxious, confused, interested, etc).
Answer: The listener encourages Linda to maintain her diet.

Additional Guidelines. To ensure the quality and diversity of the samples, we also ask the annotators to adhere to the following guidelines:

- Be creative in speculation. Refrain from rephrasing the *target* and writing low-effort trivial answers. It is recommended to skip a question if rephrasing the *target* is the only possible answer.
- Avoid repeating the same answer for distinct questions on the same *target*.
- The answer must be consistent with the given dialogue.
- It is recommended to base the answer on the most important phrase of the *target* should it contain multiple phrases.

2.2 Dialogue Selection for CICERO

2.2.1 Source Datasets

To build CICERO, we use the dyadic dialogues of the following three datasets:
DailyDialog (Li et al., 2017) covers dialogues from wide range of topics — life, work, relationships, tourism, finance, etc. The constituent utterances are labelled with emotion and dialogue-act.
MuTual (Cui et al., 2020) is a multi-turn dialogue reasoning dataset. Given a dialogue history, the objective is to predict the next utterance by considering aspects such as intent, attitude, algebraic, multi-fact, and situation reasoning.
DREAM (Sun et al., 2019) is a multiple-choice reading-comprehension dataset collected from exams of English as a foreign language. The dataset presents significant challenges as many answers are non-extractive and require commonsense knowledge and multi-sentence reasoning.

2.2.2 Selection Process

We use the following procedure to select a subset of dialogues from the three datasets:

1. We remove dialogues that are too short or long on either utterance or word level. Dialogues with fewer than five utterances or fewer than six words per utterance on average are removed. Dialogues having more than 15 utterances or more than 275 words in total are also removed.

2. All three source datasets contain dialogues having near identical utterances. We remove these near duplicate dialogues to ensure topical diversity of CICERO. We use a sentence embedding model based on fine-tuned RoBERTa (Gao et al., 2021) to extract dense feature vectors of the dialogues. We remove the duplicates assuming that a pair of duplicate dialogues have at least 0.87 cosine similarity.

2.3 Target Utterance Selection

Given a dialogue D, we select the target utterances as follows:

- We first determine the number of target utterances in D: if D has 1–6 utterances, then we select 2 or 3 targets; if it has 7–12 utterances then we select 3–5 targets; otherwise, we select 4–7 targets if it has more than 12 utterances.
- We divide D into 2–3 segments having roughly equal number of consecutive utterances. We choose roughly an equal number of the top-ranking utterances from each segment. We call this set of utterances x_1. The ranking is performed using a sentence ranking algorithm (Erkan and Radev, 2004; Mihalcea and Tarau, 2004) with sentence-BERT embeddings (Reimers and Gurevych, 2019a).
- We also select the longest utterances in D and the utterances that contain phrases such as *I'm, I'd, I've, I'll* or their expansions. We call this set of utterances x_2. The sets x_1 and x_2 may not be disjoint.
- Set x_3 consisting of the final utterance of D.

We choose the inference type for the target utterances from the sets $x_{1,2,3}$ as follows:

- From $x_1 \cup x_2$:
  - Subsequent Event: 80% of the targets.
  - Both Cause and Prerequisite: 60% of the targets.
  - Exclusively Cause: 28% of the targets.
  - Exclusively Prerequisite: 12% of the targets.
- From x_2: Motivation for all targets.
- From x_3: Reaction of listener for all targets.

2.4 Quality Assurance of CICERO

Dataset quality is ensured with the following steps:

- Initially, we sample 50 random dialogues and manually annotate all the questions (as in §2.1) in those. Each annotator is then evaluated on those dialogues, and is selected for the annotation task if 95% of his/her annotations are approved by us.
- We constantly review and provide feedback to the annotators during the annotation process. Annotators are also instructed to amend their answers.
- Upon completion of the annotation, we employ three additional annotators who manually check the annotated samples and score their acceptability. These annotators reached a consensus for approving 86% of these samples. The samples not bearing majority agreement were removed from the dataset.

A (u_1): Hi, Jenny. Is it true you're moving to London? **B (u_2)**: Yes, it is. **A (u_3)**: What made you decide to do that? **B (u_4)**: Work, mainly. I'm sure I'll be able to find a job there. **A (u_5)**: You're probably right. But where are you going to live? **B (u_6)**: I hope I'll find a flat to share with somebody. That way it will be cheaper. **A (u_7)**: Yes, that's a good idea. Are you taking your dog with you? **B (u_8)**: No, I don't think so. My parents have offered to take care of him, and I don't think he'd be happy in the city. **A (u_9)**: You're probably right. But aren't you afraid of moving to such a big place, especially after living in a small village? **B (u_{10})**: Not really. I think I'll enjoy myself. There's so much to do there; I expect I won't miss the countryside much and I can always come back and visit. **A (u_{11})**: Well, I just hope you'll invite me to stay when you get settled. **B (u_{12})**: Of course I will.
Target - u_6; **Inference: Cause**; **Annotation:** Being an expensive city, it is quite difficult to find an affordable place to live in London.
Target - u_{10}; **Inference: Cause**; **Annotation:** Jinny realizes that a city like London will provide a great quality of life for her.
Target - u_6; **Inference: Subsequent Event**; **Annotation:** The listener gives an idea to Jenny to find the flat on some online portal for searching flatmates as well plenty of cheaper options.
Target - u_{10}; **Inference: Subsequent Event**; **Annotation:** Jenny inquired a social club in London and ask for their membership to utilize her free time.
Target - u_4; **Inference: Prerequisite**; **Annotation:** Jenny has completed her studies.
Target - u_{12}; **Inference: Prerequisite**; **Annotation:** Jenny and the listener are good friends.
Target - u_6; **Inference: Motivation**; **Annotation:** Jenny is optimistic about having someone as her flatmate to save rent.
Target - u_{12}; **Inference: Reaction**; **Annotation:** The listener is happy for Jenny and looks forward to being invited to London by Jenny.

Table 2: Annotated examples in CICERO marked with the target utterance and the inference type. Inference types *Cause, Effect, Prerequisite, Motivation, and Reaction* correspond to questions Q1, Q2, Q3, Q4, and Q5, respectively, in §2.1.

The statistics of the annotated dataset is shown in Table 3. A number of annotated examples from CICERO are also shown in Table 2.

2.5 Features of CICERO

Following Table 3, a majority (~ 59%) of the inferences in CICERO are causal in nature. Again, roughly 80% of the inferences are speculative and context consonant. CICERO is thus much more versatile in terms of its applications as compared to CIDER (Ghosal et al., 2021a) that only contains explicit contextual inferences. CICERO also contains varied commonsense knowledge – from general to physical and social commonsense (see Appendix B for more details).

3 Commonsense Inference on CICERO

We design generative and multi-choice question answering tasks on CICERO to evaluate dialogue-level commonsense-based reasoning capabilities of

Description	# Instances	Percentage

Table 3: Statistics of the annotated CICERO dataset.

language models.

3.1 Task 1: CICERO$_{NLG}$

The objective is to generate the answer to question q, representing one of the five inference types, for a target utterance u_t in a dialogue D. Each inference type has its respective q (illustrated in §4).

Task 1.1: Dialogue Causal Inference. Causality pertains to causes and effects of events and situations. We formulate the dialogue causal inference task as generating the cause or subsequent event of an utterance as an answer to a causal question:

1. **Cause:** Given D, u_t, generate the cause c_t of u_t.
2. **Subsequent Event:** Given D, u_t, generate the subsequent event e_t of u_t.
3. **Subsequent Event Clipped (Subsequent EC):** Given u_t, the dialogue up to u_t: $D_{:u_t}$, generate the subsequent event e_t of u_t.

We consider two different scenarios for *subsequent event*, as the event often appear after the target utterance in the dialogue. Hence, subtask 3 is more challenging to evaluate a models' ability to reason about unobserved effects. We extend subtasks 1, 2 to incorporate longer chains and formulate the chained generation task. We consider utterances u_t in our dataset that has both cause and subsequent event annotated i.e. $c_t \rightarrow u_t \rightarrow e_t$. The causal chain is considered as a triplet, and we formulate tasks where a missing segment has to be generated from the rest of the components:

4. **Chained Cause**: Generate c_t from u_t and e_t.
5. **Chained Subsequent Event (Chained SE)**: Generate e_t from u_t and c_t.

Task 1.2: Prerequisite, Motivation and Reaction Generation. The objective is to generate the prerequisite/motivation/reaction of listener from a given D and u_t. The target u_t is the final utterance of D for reaction generation. Generating the prerequisite (task 1.2.1) requires an understanding of the dependency of events. Generating the motivation (task 1.2.2) and reaction (task 1.2.3) is about learning basic human drives and emotions. Note that, reaction generation is a different problem from dialogue response generation. Responses follow utterance level distributions which are substantially different from emotional reactions.

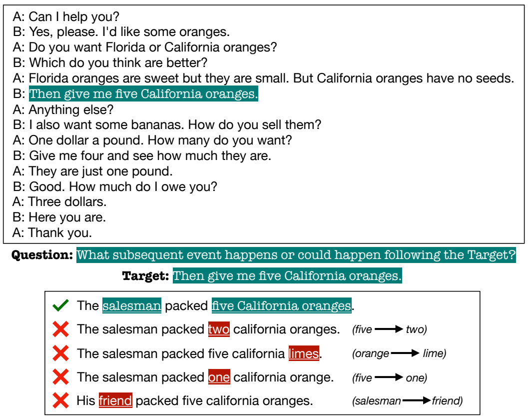
3.2 Task 2: CICERO$_{MCQ}$

Given dialogue D, target u_t, one of the five questions (inference type) q, true answer a_t, alternate choices $F_t = \{f_{t1}, f_{t2}, f_{t3}, f_{t4}\}$, the CICERO$_{MCQ}$ task aims to select the correct answer a_t (see Fig. 4) and additionally any answer among F_t which might be correct. The alternate choices F_t are created through a combination of automated generation and human supervision as follows:

- We train a `T5` large model on SNLI contradictory pairs (Bowman et al., 2015) and Time-Travel counterfactual pairs (Qin et al., 2019) to generate contradictions/counterfactuals from input sentences. We use this model to generate a pool of alternate answers from the true annotated answers. Alternate answers which have an embedding cosine similarity less than 0.9 with the true answer (from *all-mpnet-base-v2* in Reimers and Gurevych (2019b)) and are contradictory w.r.t the true answer (from *roberta-large-mnli*) are kept, and the rest are discarded. The filtered set is termed $\mathbb{N}$.

- We use the adversarial filtering (AF) algorithm (Zellers et al., 2018) to select the four alternate answers F_t from $\mathbb{N}$. For multi-choice QA tasks, AF is an effective method to detect easily identifiable alternate answers and replace them with more difficult candidates by detecting and reducing stylistic artifacts. The algorithm is as follows:

(i) We start with annotated true answer a_t and any four choices $\hat{F}_t$ from $\mathbb{N}$ for all instances in our dataset to create $\hat{\mathbb{D}}$. We randomly split $\hat{\mathbb{D}}$ into $\hat{\mathbb{D}}_{train}$ (80%) and $\hat{\mathbb{D}}_{test}$ (20%) according to dialogue IDs.
(ii) A multi-choice QA model (discriminator) is trained on $\hat{\mathbb{D}}_{train}$ that scores all five choices for all instances in $\hat{\mathbb{D}}_{test}$. The highest scoring choice is considered as the predicted answer. For a particular test instance, choices in $\hat{F}_t$ that have lower scores than a_t are replaced with other high scoring choices in $\mathbb{N} - \hat{F}_t$. Answers in $\hat{F}_t$ which are being replaced



A: Can I help you?
B: Yes, please. I'd like some oranges.
A: Do you want Florida or California oranges?
B: Which do you think are better?
A: Florida oranges are sweet but they are small. But California oranges have no seeds.
B: Then give me five California oranges.
A: Anything else?
B: I also want some bananas. How do you sell them?
A: One dollar a pound. How many do you want?
B: Give me four and see how much they are.
A: They are just one pound.
B: Good. How much do I owe you?
A: Three dollars.
B: Here you are.
A: Thank you.

Question: What subsequent event happens or could happen following the Target?

Target: Then give me five California oranges.

✓ The salesman packed five California oranges.
✗ The salesman packed two california oranges. (five → two)
✗ The salesman packed five california limes. (orange → lime)
✗ The salesman packed one california orange. (five → one)
✗ His friend packed five california oranges. (salesman → friend)

Figure 4: A data sample of CICERO for the Plausible Alternative Selection task. Here, commonsense is required to infer – a salesman packs the items that buyers want to purchase. In this particular dialogue, the buyer wants to purchase five California oranges and four bananas which can be inferred from the context.

are removed from $\mathbb{N}$.

(iii) $\hat{F}_t$ now consists of relatively more difficult choices. A new random split $\hat{\mathbb{D}}_{train}$ and $\hat{\mathbb{D}}_{test}$ is created, and we go back to step **(ii)**. The algorithm is terminated when the accuracy in successive $\hat{\mathbb{D}}_{test}$ reaches a convergence. The final alternate choice set is termed as F_t.

The AF algorithm ensures a robust final dataset $\mathbb{D}$ irrespective of the final train, validation, and test split. We use a new *roberta-large* model to initialize the discriminator and train for 3 epochs before scoring and replacement in step **(ii)**. 14 iterations were required for convergence in $\mathbb{D}_{test}$.

- Annotators perform manual checking on the final AF selected choices F_t. They mark each of the alternate choices in F_t in $\mathbb{D}$ to be speculatively correct or incorrect given the context. Hence, instances might have correct answers in F_t in addition to the originally annotated correct answer a_t. The final dataset statistics after this step are given in Table 3.

Task 2.1: Single Answer Selection. Consider instances where F_t doesn't contain any correct answer. The task is to select the correct answer a_t among the five choices given D, u_t, and q.

Task 2.2: All Answers Selection. This task is performed on the entire dataset (including the subset of data which is used in Task 2.1. There might be one or more correct answers for a particular instance resulting from the AF algorithm. The task is to select all the correct answer(s) (including a_t) among the five choices given D, u_t, and q.

4 CICERO Tasks: Experimental Results

We split our dataset in dialogue level where the training, validation and test instances are obtained from a total of 3477, 1097, 1098 distinct dialogues respectively. This results in a 60:20:20 proportion of total annotation instances. The three sets have 17365, 5370, and 5331 unique target utterances respectively. We tune on the validation dataset and report results on the test dataset (average of 5 runs). For the sake of brevity, the detailed hyperparameters are given in the supplementary material.

We use the following questions (q) for the five inference types for all the tasks: **Cause**: *What is or could be the cause of target?* **Subsequent Event**: *What subsequent event happens or could happen following the target?* **Prerequisite**: *What is or could be the prerequisite of target?* **Motivation**: *What is or could be the motivation of target?* **Reaction**: *What is the possible emotional reaction of the listener in response to target?*

4.1 Baseline Models

CICERO$_{NLG}$ — **(1.1–1.2).** We use large versions of `T5` (Raffel et al., 2020) and `GLUCOSE-T5` (Mostafazadeh et al., 2020) as our models. `GLUCOSE-T5` is a T5 large model that is pre-trained on the GLUCOSE dataset. We concatenate q, u_t, and the context c with separators to form the input to the model: `q <sep>` u_t `<sep> c`. The context c is formed by concatenating utterances of $D_{:u_t}$ (subsequent event clipped) or D (all other tasks). For the chained generation task, we additionally provide the cause/subsequent event as input. The inputs are `q <sep>` u_t `<sep> subsequent event:` e_t `<sep> c` and `q <sep>` u_t `<sep> cause:` c_t `<sep> c` for cause and subsequent event generation, respectively. The objective is to generate the answer as output in the sequence-to-sequence setup. We use teacher forcing during training and beam search during inference.

CICERO$_{MCQ}$ **— Single Answer Selection (2.1).** We use `RoBERTa-large`, `ELECTRA-large`, `T5-large`, and `Unified QA Large` for this task. The input to the models for `RoBERTa-large`, `ELECTRA-large` is the concatenation of question q, target u_t, dialogue D, and candidate answers $x_j, j \in \{1, ..., 5\}$: `<cls> q <sep>` u_t `<sep> D <sep>` x_j. Each score is predicted from the corresponding `<cls>` vector and the highest scoring one is selected as the answer. For seq2seq models `T5-large`, and `Unified QA Large`, we use the following input — `q <sep> 1)` x_1 `2)` x_2 `3)` x_3 `4)` x_4 `5)` x_5 `<sep>` u_t `<sep> D`. The output to be generated is the correct answer – such as x_1 or x_2.

CICERO$_{MCQ}$ — All Answers Selection (2.2). We use seq2seq models `T5-large`, and `Unified QA Large` as they can generate both single and multiple-answers (with separator tokens) as output. The input is `q <sep> 1)` x_1 `2)` x_2 `3)` x_3 `4)` x_4 `5)` x_5 `<sep>` u_t `<sep> D`. The output to be generated are the correct answer(s), such as x_2 (single answer) or x_1 `<sep>` x_3 `<sep>` x_4 (multiple answers). Here, $x_1 - x_5$ denotes the five possible choices shuffled randomly.

4.2 Results of the CICERO$_{NLG}$ Task

Automatic Evaluation Metrics. For generative tasks, we report the following metrics: **BLEU** (Papineni et al., 2002), **METEOR** (Banerjee and Lavie, 2005), **ROUGE** (Lin, 2004), **CIDEr** (Vedantam et al., 2015), and **Sem-Sim** which computes the semantic cosine similarity of two sentences using the supervised `RoBERTa-large` sentence embedding model (Gao et al., 2021). All scores are reported in the range of 0-1.

Human Evaluation Metrics. Due to significant dissonance with human evaluation, automatic evaluation metrics are often considered not reliable for generation quality evaluation in literature. Hence, we resort to human evaluation metrics. The human annotators rate on an integer scale from 1 (worst) to 5 (best) on three coarse attributes: **Creativity**: As the majority of the inferences require speculation, this metric measures how creative the models and the annotators are. **Contextuality**: Whether the generated or annotated inferences fit the context. **Fluency**: Whether the generated or annotated inferences are grammatically correct.

	Model	BLEU2	METEOR	ROUGE	CIDEr	Sem-Sim

`GLUCOSE-T5`	0.1789	0.1776	**0.2943**	**0.5218**	**0.6516**
(1.1.2)* SE					
`T5`	**0.1622**	0.0841	0.2764	0.4167	0.6279
`GLUCOSE-T5`	0.1612	**0.1628**	**0.2778**	**0.4471**	**0.6294**

Table 5: Results of the CICERO$_{NLG}$ subtasks – chained cause and subsequent event generation. (1.1.1)* and (1.1.2)* indicates results from Task 1.1.1 and 1.1.2 (as in Table 4), but only for targets which have both cause and effect annotated, ensuring a fair comparison with (1.1.4) and (1.1.5). SE denotes Subsequent Event.

Results of Automatic Evaluation. The results for the generative tasks are reported in Table 4 and Table 5. We observe that the fine-tuned models perform quite similarly across various metrics in Table 4. The `T5` model achieves the best performance in most of the experimental settings. The results indicate that the *causal* types are more challenging to infer than the *Motivation*, and *Reaction*. However, the models are posed to the most challenging instances in the case of *Prerequisite* type as inferring this type requires rich commonsense and background knowledge. Hence, for this category, the models achieve a low score compared to rest of the inference categories. We also notice that exposing the future utterances to the models help in attaining better inference performance for the relation type *Subsequent Event*. The trained models perform worse when the future utterances are not available in the input as seen in the *Subsequent Event Clipped* task. A significant drop of performance is noticed in the CIDEr metric. For the chained generation tasks (1.1.4 and 1.1.5), we notice (refer to Table 5) a very similar trend in models' performance i.e., the models tend to perform better for these two experimental settings compared to only *Cause* (1.1.1) and *Subsequent Event* (1.1.2) predictions. We can surmise that the additional cues from the available annotations of *Subsequent Event* type in the Chained Cause setting, and the *Cause* type in the Chained Subsequent Event setting are the key

Metric	Gold	T5	GLUCOSE	T5*	GLUCOSE*
Creativity	4.7	3.8	3.9	2.4	1.9
Contextuality	4.8	4.1	4.3	2.1	2.1
Fluency	5.0	4.8	4.9	1.9	2.9

Table 6: Results of the human evaluation for CICERO$_{NLG}$. `T5`* and `GLUCOSE-T5`* represent non fine-tuned versions.

A (u_1): I'm hungry, let's order up something to eat. **B (u_2)**: Ok, maybe we can order a soup and a salad from the restaurant down the street. **A (u_3)**: I was thinking of getting a hamburger, fries and a chocolate sundae. **B (u_4)**: You eat too much junk food. That sort of stuff clogs up your arteries and is very high in cholesterol. **A (u_5)**: Well I never seem to gain weight so I don't mind. **B (u_6)**: It's not only about getting fat or not, it's about being healthy. You could really have some health problems later on. **A (u_7)**: How about pizza or maybe some fried chicken! Better yet, let's order some hot dogs! **B (u_8)**: You are a lost cause.
Target - u_1; Inference: Cause; Answers: Gold - The speaker did not eat breakfast. **T5** - The speaker and the listener are going to a restaurant for lunch. **GLUCOSE-T5** - The speaker and the listener are at a restaurant.
Target - u_2; Inference: Cause; Answers: Gold - The restaurant down the street is famous for its delicious food. **T5** - The listener is hungry and wants to eat something. **GLUCOSE-T5** - The speaker is hungry and wants to order something to eat.
Target - u_3; Inference: Motivation; Answers: Gold - The speaker is craving some savory fast food. **T5** - The speaker is craving for a hamburger, fries and a chocolate sundae. **GLUCOSE-T5** - The speaker is craving for a burger, fries and sundae.
Target - u_6; Inference: Prerequisite; Answers: Gold - The speaker is a fitness freak and keeps track of his daily diet. **T5** - The speaker is a healthy person. **GLUCOSE-T5** - The speaker is a health conscious person.
Target - u_7; Inference: Subsequent Event; Answers: Gold - The listener refused to eat anything that is unhealthy. **T5** - The speaker and the listener decided to order some hot dogs. **GLUCOSE-T5** - The speaker and the listener decided to order some hot dogs.
Target - u_8; Inference: Reaction; Answers: Gold - The listener felt embarrassed by the statement of the speaker. **T5** - The listener is shocked to hear the speaker's comment. **GLUCOSE-T5** - The listener is disappointed with the speaker's decision.

Table 7: Inferences by different models extracted from a sample dialogue for the CICERO$_{NLG}$ task.

to such performance improvement. As depicted in Table 4 (and also Table 6), the non fine-tuned versions of `T5` and `GLUCOSE-T5` perform poorly as they produce gibberish outputs across all the five inference categories indicating the importance of fine-tuning on CICERO.

Results of Human Evaluation. For each of the five inference types, we randomly sample 40 inferences generated by each model and their corresponding gold inferences. These inferences are then manually rated by three independent annotators based on the human-evaluated metrics. As suggested by Table 6, we observe that most of the fine-tuned models on CICERO perform similarly but fail to reach gold annotation performance. Moreover, as expected, the fine-tuned models significantly outperform their non fine-tuned counterparts. We provide some examples of the generated inferences in Table 7. Inspection of the model generated inferences reveal that usage of keywords from the dialogue without generalizing the events is more frequent. Generated inferences are significantly less diverse and creative than gold annotations.

Performance of GLUCOSE. GLUCOSE contains contextual commonsense inferences on events in monologues. Comparing the results (Table 4, Table 6) of fine-tuned and non fine-tuned checkpoints suggests that pre-training on a monologue-based contextual commonsense inference dataset does not ensure good performance on the same task for dialogues. Akin to the non fine-tuned T5, non fine-tuned `GLUCOSE-T5` produces gibberish outputs for all the commonsense inference types but the causal and motivation types. We surmise this happens as these two commonsense types exist in the GLUCOSE dataset. Although the generated text for these two commonsense inference types are grammatically correct and sometimes contain contextual words, they are far from the desired quality, semantically very much dissimilar from the annotated gold instances, and rated low in the qualitative evaluation, as shown in Table 6. We also confirm the efficacy of fine-tuning the models on CICERO through human evaluation, as explained in §4.

4.3 Results of the CICERO$_{MCQ}$ Task

Evaluation Metrics. 1) **`RoBERTa`** and **`ELECTRA`**: The accuracy of selecting the correct answer is used to evaluate the performance of these models. 2) **`T5`** and **`Unified QA`**: The output is considered as a single answer if it doesn't contain any separator token. Otherwise, the output is segmented at separator tokens to obtain multiple answers. We then follow the method in Khashabi et al. (2020), where match is computed by comparing each of the generated answer(s) with the candidate choices based on their token-level overlap. For each generated answer, the most similar candidate choice is considered as the corresponding output. The prediction is considered as correct if the final output(s) is an exact match (EM) with the gold annotated answer(s).

Single Answer Selection (2.1). We report the results of this setting in Table 8. The reported metric is accuracy of selecting the correct answer. The overall score is 83.28% for `RoBERTa` and 86.82% for `ELECTRA`. `ELECTRA` has an edge over `RoBERTa` on all the five inference types. This could be a side effect of using `RoBERTa` as the backbone model for the AF algorithm and subsequently as a solver for

Model	Cause	SE	Prereq.	Motiv.	Emo. Reac.	Avg.
`RoBERTa`	83.34	83.17	79.48	86.33	84.26	83.28
`ELECTRA`	**87.09**	**86.09**	**85.15**	**90.31**	**86.11**	**86.82**
`T5`	95.19	**95.29**	94.93	**96.52**	96.99	95.54
`Unified QA`	**95.85**	94.99	**95.55**	96.35	**97.22**	**95.70**

Table 8: Accuracy scores for Task 2.1. Models are trained and evaluated on instances with a single correct answer.

Model	Eval On	Cause	SE	Prereq.	Motiv.	Emo. Reac.	Avg.
`T5`	S + M	**78.18**	74.72	**75.50**	**82.51**	**84.59**	**77.68**
`Unified QA`		78.12	**74.79**	75.36	81.58	84.08	77.51
`T5`	S	**93.20**	**91.28**	**91.27**	**95.19**	**95.14**	**92.71**
`Unified QA`		93.12	91.16	91.00	94.28	94.79	92.45
`T5`	M	**3.50**	2.77	**3.59**	**3.61**	**6.03**	3.38
`Unified QA`		**3.50**	**3.69**	**3.98**	2.58	**4.31**	**3.60**

Table 9: Exact match scores for Task 2.2. Models are trained on instances with both single and multiple correct answers, i.e., the entire dataset. SE → Subsequent Event; S → Single-Answer Instances; M → Multi-Answer Instances.

the final CICERO$_{MCQ}$ task. We think, this results expose the model dependency of the AF process. In other words, the negative samples chosen by the backbone model X for the AF algorithm will be difficult to distinguish from the human-annotated true samples using the same model X. These negative samples, however, could be relatively easier to identify using another model Y. The seq2seq models `T5` and `Unified QA` perform significantly better than `RoBERTa` and `ELECTRA` as can be seen in Table 8. While models like `RoBERTa, ELECTRA` encode each candidate answer separately, `T5` and `Unified QA` encode them together. Thanks to this joint encoding of candidate answers, `T5` and `Unified QA` can take advantage of more task-related information that `RoBERTa` and `ELECTRA` might miss due to the separate encoding scheme. We surmise it could be one of the reasons why the seq2seq models have an edge over `RoBERTa` and `ELECTRA` for this particular task. `T5` and `Unified QA` attain almost the same score for single answer selection. This is surprising as `Unified QA` is initialized from the `T5-large` checkpoint and then further trained on other QA datasets. As such, we think, the different fine-tuned domains of `Unified QA` does not help in the CICERO$_{MCQ}$ task.

All Answers Selection (2.2). We train and evaluate `T5` and `Unified QA` on the entire dataset of both single and multiple correct answers and report the results in Table 9. Overall, `T5` and `Unified QA` perform similarly. The general performance, across the models, on instances with multiple correct answers is much worse than instances with a single correct answer. We confirm this by reporting the results only on instances with multiple answers in Table 9, where `T5` and `Unified QA` achieve only 3.38% and 3.60% exact match, respectively. This could probably be attributed to the stark data imbalance of ~86/14% between single- and multi-answer instances, respectively (see Table 3).

5 Related Work

Commonsense knowledge has received more attention compared with factual knowledge, as it is usually not mentioned explicitly in the context. It is demonstrated to be essential in open-ended generation tasks, such as story explanation generation (Mostafazadeh et al., 2020), story end generation (Guan et al., 2019) and abductive reasoning (Bhagavatula et al., 2019). To infuse commonsense knowledge in NLP models, several approaches to tasks like sentence ordering (Ghosal et al., 2021b), emotion recognition (Ghosal et al., 2020), story generation (Guan et al., 2020; Xu et al., 2020) and dialogue generation (Zhou et al., 2018) use prevalent commonsense knowledge bases (CSKB) like ConceptNet (Speer et al., 2017) or ATOMIC (Sap et al., 2019). However, ConceptNet is context-free, meaning that they only capture relationships around a selected set of entities, without paying attention to the context where the entity occurs. Moreover, inference is often needed in discourse level, which do not always align with the entities in knowledge bases. Knowledge models such as COMET (Bosselut et al., 2019) is a way to circumvent this issue and make inferences on an utterance (sentence) level. But the generated knowledge still lacks the detail from the dialogue, as it is trained on the aforementioned knowledge base. Our approach, instead, centers on the dialogue dataset and provides more detailed commonsense inference at an utterance level.

6 Conclusion

We introduced CICERO, a new dataset for dialogue reasoning with contextualized commonsense inference. It contains ~53K inferences for five commonsense dimensions – cause, subsequent event, prerequisite, motivation, and emotional reaction – collected from ~5.6K dialogues. To show the usefulness of CICERO for dialogue reasoning, we design several challenging generative and multi-choice answer selection tasks for state-of-the-art NLP models to solve.

This work is supported by the A*STAR under its RIE 2020 AME programmatic grant RGAST2003 and project T2MOE2008 awarded by Singapore's MoE under its Tier-2 grant scheme.

Ethics Statement

The annotators for CICERO were hired through a data annotation service. The compensation was derived based on the country of residence of the annotators, as deemed by the company. The study has been categorized as "exempt" by the IRB. Annotators were strictly asked not to write any toxic content (hateful or offensive toward any gender, race, sex, religion). They were asked to consider gender-neutral settings in dialogues whenever possible.

The source dialogue datasets – DailyDialog, MuTual, and DREAM are high quality multi-turn dialogue datasets manually annotated by experts in dialogue, communication theory and linguistics. All three datasets have been extensively used and studied in the natural language processing literature. The three source datasets and our annotations in CICERO do not contain any personal data or any information that can uniquely identify individual people or groups.

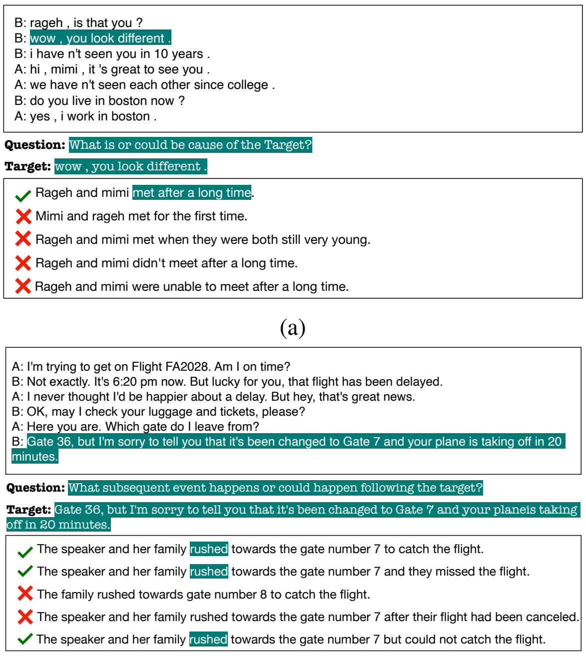
A: Hello, Old English Restaurant. Can I help you?
B: Yes. I'd like to book a table for tonight.
A: Yes, sir. What time?
B: Eight o'clock.
A: Certainly. For how many people?
B: There are ten of us.
A: Ten of you! But we don't usually accept large parties, sir.
B: I know, but we are regular customers.
A: What's your name please, sir?
B: Michael Peterson.
A: Mr. Peterson...of course! That'll be all right. We'll put two tables together.
B: Thanks.
A: What food would you prefer for today, sir? We have fresh seafood tonight.
B: No. We like to eat vegetables.

Question: What is or could be cause of the Target?

Target: What food would you prefer for today, sir? We have fresh seafood tonight.

✓ The speaker is eager to know about the preference of the listener and his friends for the dinner.
✓ The speaker is eager to know about the preferences of the listener and his friends for the party.
✗ The speaker is eager to know about the preferences of the listener and his friends for the breakfast.
✗ The speaker is eager to know about the preference of the listener and his friends for the lunch.
✗ The speaker is eager to know about the preference of the listener and his friends for the movie.

Figure 5: A data sample of CICERO for the CICERO$_{MCQ}$ task. Here, commonsense is required to infer the following events – booking a table at night implies the intention of having dinner.



B: rageh , is that you ?
B: wow , you look different .
B: i have n't seen you in 10 years .
A: hi , mimi , it 's great to see you .
A: we have n't seen each other since college .
B: do you live in boston now ?
A: yes , i work in boston .

Question: What is or could be cause of the Target?

Target: wow , you look different .

✓ Rageh and mimi met after a long time.
✗ Mimi and rageh met for the first time.
✗ Rageh and mimi met when they were both still very young.
✗ Rageh and mimi didn't meet after a long time.
✗ Rageh and mimi were unable to meet after a long time.

(a)

A: I'm trying to get on Flight FA2028. Am I on time?
B: Not exactly. It's 6:20 pm now. But lucky for you, that flight has been delayed.
A: I never thought I'd be happier about a delay. But hey, that's great news.
B: OK, may I check your luggage and tickets, please?
A: Here you are. Which gate do I leave from?
B: Gate 36, but I'm sorry to tell you that it's been changed to Gate 7 and your plane is taking off in 20 minutes.

Question: What subsequent event happens or could happen following the target?

Target: Gate 36, but I'm sorry to tell you that it's been changed to Gate 7 and your planeis taking off in 20 minutes.

✓ The speaker and her family rushed towards the gate number 7 to catch the flight.
✓ The speaker and her family rushed towards the gate number 7 and they missed the flight.
✗ The family rushed towards gate number 8 to catch the flight.
✗ The speaker and her family rushed towards the gate number 7 after their flight had been canceled.
✓ The speaker and her family rushed towards the gate number 7 but could not catch the flight.

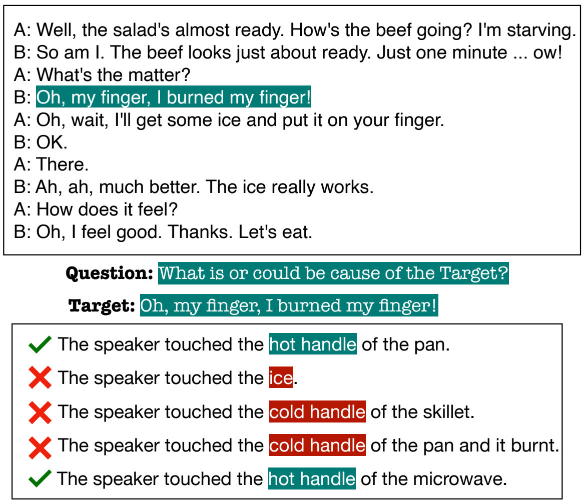
Figure 6: Instances of `temporal commonsense` in CICERO.

A Additional Details on CICERO

The total compensation for the complete annotation process of CICERO including all the manual labeling (§2), and verification stages in AF (§3.2) was USD 13, 500. The annotators were hired through a data annotation company. The total compensation was derived based on the country of residence of the annotators, as deemed by the company.

Being a dialogue-centric dataset, CICERO encompasses various aspects of human to human conversations such as temporal commonsense awareness in Fig. 5, Fig. 6, physical commonsense in Fig. 7, general commonsense in Fig. 8, and social commonsense in Fig. 10. In Fig. 6a, commonsense is required to infer that a familiar face may look different to us if we meet that person after a long time. There could be other potential reasons why a person might look different to his/her friends such as facial surgery, sickness, makeup, etc. However, in this particular dialogue context, the most appropriate speculative cause of the target is meeting the person after a long time. Similarly in Fig. 6b, the person hurries to the boarding gate as only 20 minutes is left before the flight takes off. Leveraging commonsense inference, we can infer that going to a place in a very short period requires us to rush. In Fig. 7, `physical commonsense knowledge` is required to infer — touching a hot element can burn our fingers and pans or microwaves are used for cooking.



A: Well, the salad's almost ready. How's the beef going? I'm starving.
B: So am I. The beef looks just about ready. Just one minute ... ow!
A: What's the matter?
B: Oh, my finger, I burned my finger!
A: Oh, wait, I'll get some ice and put it on your finger.
B: OK.
A: There.
B: Ah, ah, much better. The ice really works.
A: How does it feel?
B: Oh, I feel good. Thanks. Let's eat.

Question: What is or could be cause of the Target?

Target: Oh, my finger, I burned my finger!

✓ The speaker touched the hot handle of the pan.
✗ The speaker touched the ice.
✗ The speaker touched the cold handle of the skillet.
✗ The speaker touched the cold handle of the pan and it burnt.
✓ The speaker touched the hot handle of the microwave.

Figure 7: A data sample of CICERO where physical commonsense inference is prevalent.

B CICERO$_{NLG}$ Task: Extended Results

We report BLEU1 scores (Papineni et al., 2002) in addition to the automatic evaluation metrics described in §4.2. We also report results for generative tasks with the `BART-large` (Lewis et al., 2020), and `COMET` (Hwang et al., 2021) model. `COMET` is a commonsense generation model from free text input. It is a pre-trained `BART-large` model fine-tuned on the ATOMIC dataset (Hwang et al., 2021). In our work, we have used all the models in two distinct ways – i) with fine-tuning and ii) without fine-tuning on CICERO. The results are shown in Table 10, and Table 11. Surprisingly, despite being pre-trained on a large commonsense in-

Table 10: Results for Task 1. `T5`*, `BART`*, `COMET`* and `GLUCOSE-T5`* are not fine-tuned on CICERO. SE denotes Subsequent Event.

ference dataset, the fine-tuned `COMET` model fails to outperform both fine-tuned `T5` and `BART` in most of the experiments. This could be due to catastrophic forgetting triggered by disparate inputs, which are at odds with ATOMIC. Further research is needed to draw any conclusion.

The results of human evaluation of the models

Model	BLEU1	BLEU2	METEOR	ROUGE	CIDEr	Sem-Sim

`BART`*	2.6	2.5	1.8
`COMET`*	2.2	2.3	2.5
`GLUCOSE-T5`*	1.9	2.1	2.9

Table 12: Results of the human evaluation for the CICERO$_{NLG}$ task. `T5`*, `BART`*, `COMET`*, and `GLUCOSE-T5`* represent non fine-tuned versions.

are illustrated in Table 12. It can be seen that all the models perform almost similarly on CICERO and stand far from reaching human-level performance.

Fine-tuned vs non Fine-tuned Evaluations. All the models perform very poorly when they are not fine-tuned on CICERO. The non fine-tuned models generate gibberish sentences across all five inference categories. The automatic and human evaluation results of these models are also reported in Table 10 and Table 12, respectively. The results confirm that fine-tuning is necessary for dialogue-level commonsense inference thus reaffirming the importance of our curated dataset CICERO. The non fine-tuned `COMET` produces very short outputs (1–3 words, akin to ATOMIC annotations) that are not readily comparable with CICERO, resulting in poor evaluation scores.

Finally, we provide some additional examples to depict the inference generation quality of the models in Table 13.

C CICERO$_{MCQ}$: Extended Results, Quantitative and Qualitative Analysis

For answer selection with generative models in CICERO$_{MCQ}$, we train `T5` and `Unified QA` models under three distinct settings: 1) **Setting 1:** train models only on instances with a single-answer, 2) **Setting 2:** train models only on instances with multiple-answers, 3) **Setting 3:** train models on the

A (u_1): Hi, Jenny. Is it true you're moving to London? **B (u_2)**: Yes, it is. **A (u_3)**: What made you decide to do that? **B (u_4)**: Work, mainly. I'm sure I'll be able to find a job there. **A (u_5)**: You're probably right. But where are you going to live? **B (u_6)**: I hope I'll find a flat to share with somebody. That way it will be cheaper. **A (u_7)**: Yes, that's a good idea. Are you taking your dog with you? **B (u_8)**: No, I don't think so. My parents have offered to take care of him, and I don't think he'd be happy in the city. **A (u_9)**: You're probably right. But aren't you afraid of moving to such a big place, especially after living in a small village? **B (u_{10})**: Not really. I think I'll enjoy myself. There's so much to do there; I expect I won't miss the countryside much and I can always come back and visit. **A (u_{11})**: Well, I just hope you'll invite me to stay when you get settled. **B (u_{12})**: Of course I will.
Target - u_6; Inference: Cause; Answers: Gold - Being an expensive city, it is quite difficult to find an affordable place to live in London. **T5** - The listener asked Jenny where she was going to live. **COMET** - The speaker is looking for a flat to live in London. **GLUCOSE-T5-** Jenny has decided to move to London for her job.
Target - u_{10}; Inference: Cause; Answers: Gold - Jenny realizes that a city like London will provide a great quality of life for her. **T5** - The listener asked Jenny if she was afraid of moving to London after living in a small village. **COMET** - The speaker is moving to London for a job. **GLUCOSE-T5-** The listener asked Jenny if she was afraid of moving to such a big place.
Target - u_6; Inference: Subsequent Event; Answers: Gold - The listener suggests Jenny to find potential flats or flatmates online. **T5** - The speaker will find a flat to share with a friend. **COMET** - The speaker informed the listener that she will share the flat with someone else. **GLUCOSE-T5-** Jenny will find a flat to share with her friend.
Target - u_{10}; Inference: Subsequent Event; Answers: Gold - Jenny inquired a social club in London and ask for their membership to utilize her free time. **T5** - The speaker told the listener that he would love to visit London. **COMET** - The speaker informed the listener that he will miss the countryside very much. **GLUCOSE-T5-** The speaker informed the listener that he would love to come back to London.
Target - u_4; Inference: Prerequisite; Answers: Gold - Jenny has completed her studies. **T5** - The speaker has a job in London. **COMET** - Jenny has applied for a job in London. **GLUCOSE-T5-** The speaker has a job in London.
Target - u_{12}; Inference: Prerequisite; Answers: Gold - Jenny and the listener are good friends. **T5** - Jenny has invited her friend to stay with her in London. **COMET** - Jenny has a place to stay in London. **GLUCOSE-T5-**The listener invited Jenny to stay in London.
Target - u_6; Inference: Motivation; Answers: Gold - Jenny is optimistic about having someone as her flatmate to save on rent. **T5** - Jenny is hopeful of finding a flat to share with someone. **COMET** - Jenny is optimistic about having someone as her flatmate. **GLUCOSE-T5-** Jenny is hopeful that she will find a flat to share with somebody.
Target - u_{12}; Inference: Reaction; Answers: Gold - The listener is happy for Jenny and looks forward to being invited to London by Jenny. **T5** - The listener is happy for Jenny. **COMET** - The listener is happy to know that the speaker is moving to London. **GLUCOSE-T5-** The listener is excited to meet Jenny in London.

Table 13: Inferences extracted from a sample dialogue.

entire dataset comprising both single and multiple-answers.

The performances of both the generative models `T5` and `Unified QA` on instances with multiple answers are very poor (see Table 14, Table 15 and Fig. 11a, Fig. 11b). Further, we can also see instances where the predicted answers by these models contradict (see Fig. 11b). While `T5` surpasses `Unified QA` for Setting 3, `Unified QA` shines over `T5` for the other two settings.

Performance of ELECTRA vs RoBERTa. We also extend upon the results reported earlier for

Model	Trained On	Evaluated On	Cause	SE	Prereq.	Motiv.	Emo. Reac.	Avg.

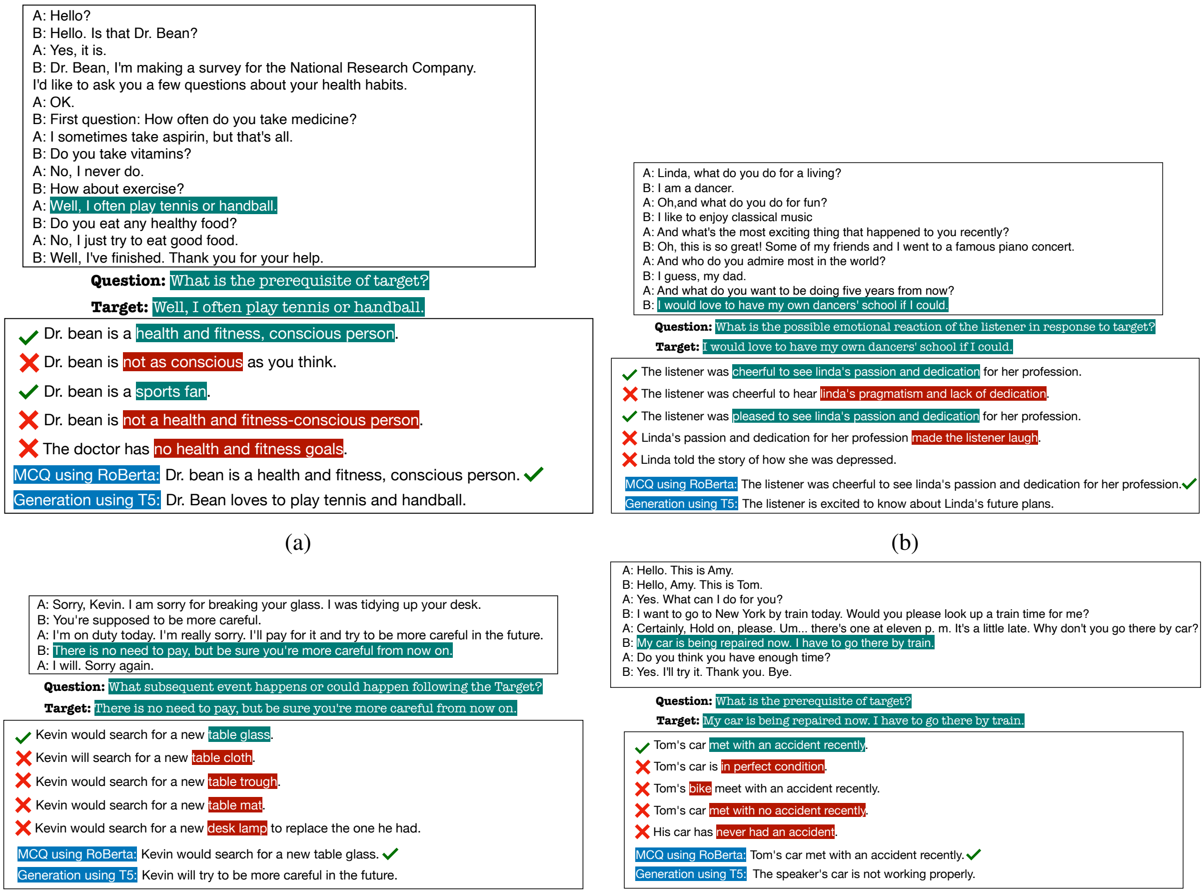
Table 15: Results of the CICERO$_{MCQ}$ task under the zero-shot setting. SE denotes subsequent event. Instance corresponding to cause, prerequisite, and emotional reaction are used for training. Instance corresponding to subsequent event and motivation are used for evaluation. Single → Instances with single answer. Multiple → Instances with multiple answers.

ELECTRA and RoBERTa in §4.3 for the single answer selection (Task 2.1) in CICERO$_{MCQ}$. The performance of ELECTRA is notably better than RoBERTa on this task. We reckon this could be due to the fact that we train our adversarial filtering (AF) method using RoBERTa. As such the efficacy of AF to prevent exposing stylistic artifacts to the discriminators is lesser for ELECTRA compared to RoBERTa. In other words, ELECTRA is more efficient than RoBERTa for the CICERO$_{MCQ}$ task due to its ability to better discriminate machine-generated negative answers from human-annotated true answers by leveraging stylistic artifacts as observed in Zellers et al. (2018).

Despite performing decently on the single answer selection task for CICERO$_{MCQ}$, RoBERTa does make mistakes in understanding some very interesting commonsense-based inferences such as the ones illustrated in Fig. 12. In these two examples, commonsense inference is required to detect the bluff by Tim Smith. Among other kinds of errors, we find RoBERTa failing to capture contextual commonsense cues such as in Fig. 9 — if a person wanting to buy new batteries is informed about the availability of batteries at photocopy stores, that person will search for photocopy stores instead of ad stores.

Zero-shot Setting. We also set up a zero-shot setting for Task 2.1 – Single Answer Selection and Task 2.2 – All Answers Selection. Under this setting, we only keep instances pertaining to cause, prerequisite, and emotional reaction in the train, validation data while instances with subsequent



A: Hello?
B: Hello. Is that Dr. Bean?
A: Yes, it is.
B: Dr. Bean, I'm making a survey for the National Research Company. I'd like to ask you a few questions about your health habits.
A: OK.
B: First question: How often do you take medicine?
A: I sometimes take aspirin, but that's all.
B: Do you take vitamins?
A: No, I never do.
B: How about exercise?
A: Well, I often play tennis or handball.
B: Do you eat any healthy food?
A: No, I just try to eat good food.
B: Well, I've finished. Thank you for your help.

Question: What is the prerequisite of target?

Target: Well, I often play tennis or handball.

✓ Dr. bean is a health and fitness, conscious person.
✗ Dr. bean is not as conscious as you think.
✓ Dr. bean is a sports fan.
✗ Dr. bean is not a health and fitness-conscious person.
✗ The doctor has no health and fitness goals.
MCQ using RoBerta: Dr. bean is a health and fitness, conscious person. ✓
Generation using T5: Dr. Bean loves to play tennis and handball.

(a)

A: Linda, what do you do for a living?
B: I am a dancer.
A: Oh,and what do you do for fun?
B: I like to enjoy classical music
A: And what's the most exciting thing that happened to you recently?
B: Oh, this is so great! Some of my friends and I went to a famous piano concert.
A: And who do you admire most in the world?
B: I guess, my dad.
A: And what do you want to be doing five years from now?
B: I would love to have my own dancers' school if I could.

Question: What is the possible emotional reaction of the listener in response to target?

Target: I would love to have my own dancers' school if I could.

✓ The listener was cheerful to see linda's passion and dedication for her profession.
✗ The listener was cheerful to hear linda's pragmatism and lack of dedication.
✓ The listener was pleased to see linda's passion and dedication for her profession.
✗ Linda's passion and dedication for her profession made the listener laugh.
✗ Linda told the story of how she was depressed.
MCQ using RoBerta: The listener was cheerful to see linda's passion and dedication for her profession. ✓
Generation using T5: The listener is excited to know about Linda's future plans.

(b)

A: Sorry, Kevin. I am sorry for breaking your glass. I was tidying up your desk.
B: You're supposed to be more careful.
A: I'm on duty today. I'm really sorry. I'll pay for it and try to be more careful in the future.
B: There is no need to pay, but be sure you're more careful from now on.
A: I will. Sorry again.

Question: What subsequent event happens or could happen following the Target?

Target: There is no need to pay, but be sure you're more careful from now on.

✓ Kevin would search for a new table glass.
✗ Kevin will search for a new table cloth.
✗ Kevin would search for a new table trough.
✗ Kevin would search for a new table mat.
✗ Kevin would search for a new desk lamp to replace the one he had.
MCQ using RoBerta: Kevin would search for a new table glass. ✓
Generation using T5: Kevin will try to be more careful in the future.

(c)

A: Hello. This is Amy.
B: Hello, Amy. This is Tom.
A: Yes. What can I do for you?
B: I want to go to New York by train today. Would you please look up a train time for me?
A: Certainly, Hold on, please. Um... there's one at eleven p. m. It's a little late. Why don't you go there by car?
B: My car is being repaired now. I have to go there by train.
A: Do you think you have enough time?
B: Yes. I'll try it. Thank you. Bye.

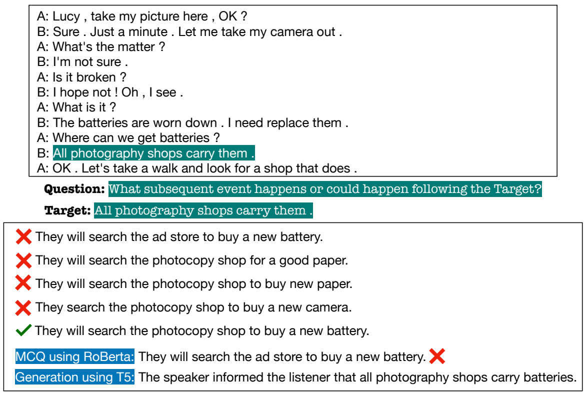
Question: What is the prerequisite of target?

Target: My car is being repaired now. I have to go there by train.

✓ Tom's car met with an accident recently.
✗ Tom's car is in perfect condition.
✗ Tom's bike meet with an accident recently.
✗ Tom's car met with no accident recently.
✗ His car has never had an accident.
MCQ using RoBerta: Tom's car met with an accident recently. ✓
Generation using T5: The speaker's car is not working properly.

(d)

Figure 8: Instances of `general commonsense` in CICERO.



A: Lucy , take my picture here , OK ?
B: Sure . Just a minute . Let me take my camera out .
A: What's the matter ?
B: I'm not sure .
A: Is it broken ?
B: I hope not ! Oh , I see .
A: What is it ?
B: The batteries are worn down . I need replace them .
A: Where can we get batteries ?
B: All photography shops carry them .
A: OK . Let's take a walk and look for a shop that does .

Question: What subsequent event happens or could happen following the Target?

Target: All photography shops carry them .

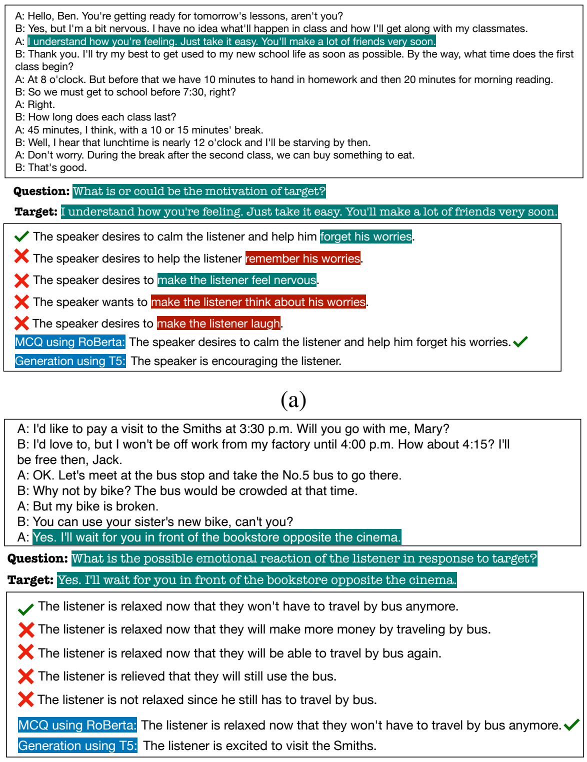
✗ They will search the ad store to buy a new battery.
✗ They will search the photocopy shop for a good paper.
✗ They will search the photocopy shop to buy new paper.
✗ They search the photocopy shop to buy a new camera.
✓ They will search the photocopy shop to buy a new battery.
MCQ using RoBerta: They will search the ad store to buy a new battery. ✗
Generation using T5: The speaker informed the listener that all photography shops carry batteries.

Figure 9: An instance where `RoBERTa` fails to capture the contextual commonsense cue.

event, and motivation are kept in the test data. All the models underperform in the zero-shot setting, as can be seen in Table 15. Like the all and single answer(s) prediction, `T5` and `Unified QA` perform similarly. On the other hand, `ELECTRA`'s zero-shot performance surpasses that of `RoBERTa`. Notably, performance of `T5` and `Unified QA` only drop around 1% in this setting, as compared to 3% drop observed for `RoBERTa` and `ELECTRA`. Hence, it is fair to conclude that for the CICERO$_{MCQ}$ task, `T5` and `Unified QA` are more robust to zero-shot scenarios than `RoBERTa` and `ELECTRA`. In the case of zero-shot single answer prediction, the best model is `Unified QA` which outperforms `RoBERTa` and `ELECTRA` by 11% and 15% respectively.

Performance on Single- vs Multi-answer Instances. It is evident from Tables 14 and 15, that in both regular and zero-shot settings, all the models exclusively trained on single- and multi-answer instances perform better on single- and multi-answer test instances, respectively, as compared to models trained on both types of instances. This is likely a side-effect of the data imbalance between the single- and multi-answer instances (~86/14%) in the training set which causes the scarce multi-answer instances to have confounding effect on the training process, degrading the performance on both types of test instances.

Performance of CICERO$_{NLG}$ vs CICERO$_{MCQ}$. We present the qualitative analysis for gen-



A: Hello, Ben. You're getting ready for tomorrow's lessons, aren't you?
B: Yes, but I'm a bit nervous. I have no idea what'll happen in class and how I'll get along with my classmates.
A: I understand how you're feeling. Just take it easy. You'll make a lot of friends very soon.
B: Thank you. I'll try my best to get used to my new school life as soon as possible. By the way, what time does the first class begin?
A: At 8 o'clock. But before that we have 10 minutes to hand in homework and then 20 minutes for morning reading.
B: So we must get to school before 7:30, right?
A: Right.
B: How long does each class last?
A: 45 minutes, I think, with a 10 or 15 minutes' break.
B: Well, I hear that lunchtime is nearly 12 o'clock and I'll be starving by then.
A: Don't worry. During the break after the second class, we can buy something to eat.
B: That's good.

Question: What is or could be the motivation of target?

Target: I understand how you're feeling. Just take it easy. You'll make a lot of friends very soon.

✓ The speaker desires to calm the listener and help him forget his worries.
✗ The speaker desires to help the listener remember his worries.
✗ The speaker desires to make the listener feel nervous.
✗ The speaker wants to make the listener think about his worries.
✗ The speaker desires to make the listener laugh.
MCQ using RoBerta: The speaker desires to calm the listener and help him forget his worries. ✓
Generation using T5: The speaker is encouraging the listener.

(a)

A: I'd like to pay a visit to the Smiths at 3:30 p.m. Will you go with me, Mary?
B: I'd love to, but I won't be off work from my factory until 4:00 p.m. How about 4:15? I'll be free then, Jack.
A: OK. Let's meet at the bus stop and take the No.5 bus to go there.
B: Why not by bike? The bus would be crowded at that time.
A: But my bike is broken.
B: You can use your sister's new bike, can't you?
A: Yes. I'll wait for you in front of the bookstore opposite the cinema.

Question: What is the possible emotional reaction of the listener in response to target?

Target: Yes. I'll wait for you in front of the bookstore opposite the cinema.

✓ The listener is relaxed now that they won't have to travel by bus anymore.
✗ The listener is relaxed now that they will make more money by traveling by bus.
✗ The listener is relaxed now that they will be able to travel by bus again.
✗ The listener is relieved that they will still use the bus.
✗ The listener is not relaxed since he still has to travel by bus.
MCQ using RoBerta: The listener is relaxed now that they won't have to travel by bus anymore. ✓
Generation using T5: The listener is excited to visit the Smiths.

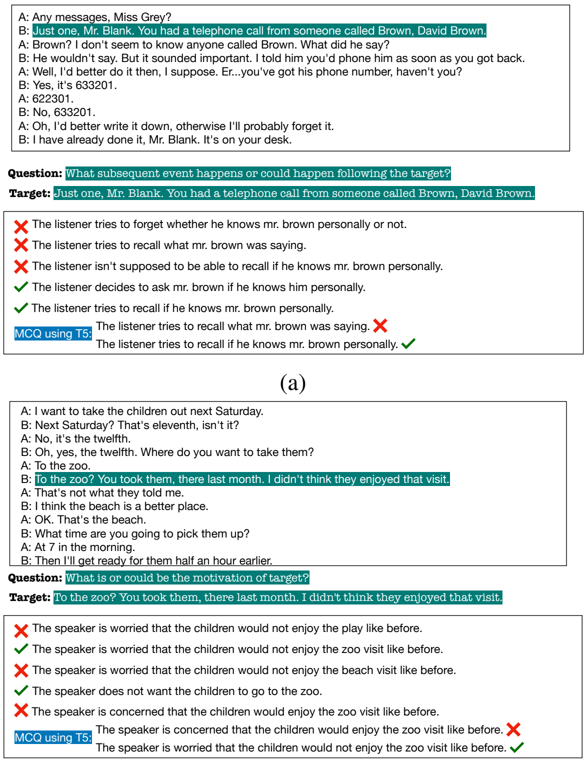
(b)

Figure 10: Instances of `social commonsense` in CICERO.

erative (CICERO$_{NLG}$) and discriminative (CICERO$_{MCQ}$) experiments in Fig. 8a, Fig. 8b, Fig. 8c, Fig. 8d, Fig. 9, Fig. 10a, and Fig. 10b. Except for Fig. 9, `RoBERTa` provides the accurate answer on all instances. Contrary to this, the performance of `T5` is far from being sublime on those samples for the CICERO$_{NLG}$ task. This depicts that the commonsense-based generative task CICERO$_{NLG}$ poses more challenge than the commonsense-based discriminative task CICERO$_{MCQ}$. We surmise this could happen due to two potential reasons —

1. Machine-generated negative answers may carry stylistic biases (Zellers et al., 2018), thus making the task of discriminators easier.

2. We collate the negative answers by generating counterfactual and contradictory sentences from the annotated true inferences. As a result, the generated negative answers are lexically very similar to the annotated sentences resulting in less diversity in the dataset.



A: Any messages, Miss Grey?
B: Just one, Mr. Blank. You had a telephone call from someone called Brown, David Brown.
A: Brown? I don't seem to know anyone called Brown. What did he say?
B: He wouldn't say. But it sounded important. I told him you'd phone him as soon as you got back.
A: Well, I'd better do it then, I suppose. Er...you've got his phone number, haven't you?
B: Yes, it's 633201.
A: 622301.
B: No, 633201.
A: Oh, I'd better write it down, otherwise I'll probably forget it.
B: I have already done it, Mr. Blank. It's on your desk.

Question: What subsequent event happens or could happen following the target?

Target: Just one, Mr. Blank. You had a telephone call from someone called Brown, David Brown.

✗ The listener tries to forget whether he knows mr. brown personally or not.
✗ The listener tries to recall what mr. brown was saying.
✗ The listener isn't supposed to be able to recall if he knows mr. brown personally.
✓ The listener decides to ask mr. brown if he knows him personally.
✓ The listener tries to recall if he knows mr. brown personally.
MCQ using T5: The listener tries to recall what mr. brown was saying. ✗
The listener tries to recall if he knows mr. brown personally. ✓

(a)

A: I want to take the children out next Saturday.
B: Next Saturday? That's eleventh, isn't it?
A: No, it's the twelfth.
B: Oh, yes, the twelfth. Where do you want to take them?
A: To the zoo.
B: To the zoo? You took them, there last month. I didn't think they enjoyed that visit.
A: That's not what they told me.
B: I think the beach is a better place.
A: OK. That's the beach.
B: What time are you going to pick them up?
A: At 7 in the morning.
B: Then I'll get ready for them half an hour earlier.

Question: What is or could be the motivation of target?

Target: To the zoo? You took them, there last month. I didn't think they enjoyed that visit.

✗ The speaker is worried that the children would not enjoy the play like before.
✓ The speaker is worried that the children would not enjoy the zoo visit like before.
✗ The speaker is worried that the children would not enjoy the beach visit like before.
✓ The speaker does not want the children to go to the zoo.
✗ The speaker is concerned that the children would enjoy the zoo visit like before.
MCQ using T5: The speaker is concerned that the children would enjoy the zoo visit like before. ✗
The speaker is worried that the children would not enjoy the zoo visit like before. ✓

(b)

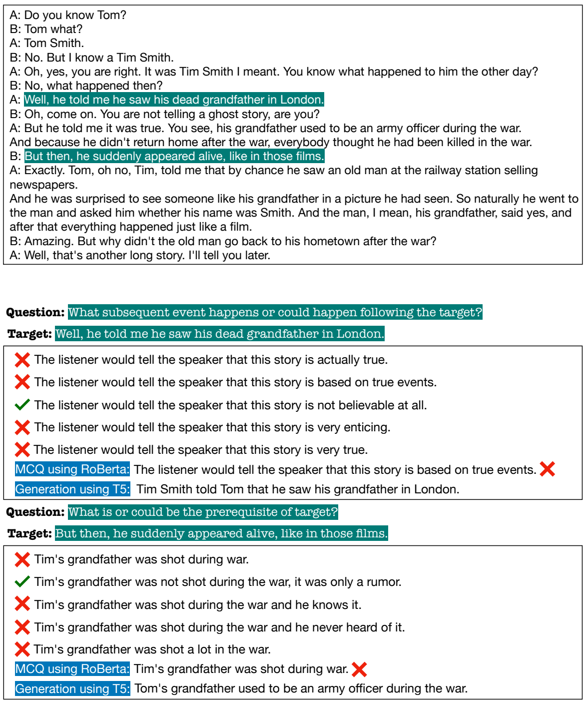
Table 16: Results of baseline models in other CSK datasets.

D CICERO vs Other Commonsense Datasets

The key differences that set CICERO apart from the rest of the commonsense datasets are following:

- To the best of our knowledge, CICERO is the only publicly available dialogue-centric commonsense inference dataset.
- The speculative nature of the questions posed to the annotators enforces employment of rich commonsense knowledge in the inferences,



A: Do you know Tom?
B: Tom what?
A: Tom Smith.
B: No. But I know a Tim Smith.
A: Oh, yes, you are right. It was Tim Smith I meant. You know what happened to him the other day?
B: No, what happened then?
A: Well, he told me he saw his dead grandfather in London.
B: Oh, come on. You are not telling a ghost story, are you?
A: But he told me it was true. You see, his grandfather used to be an army officer during the war.
And because he didn't return home after the war, everybody thought he had been killed in the war.
B: But then, he suddenly appeared alive, like in those films.
A: Exactly. Tom, oh no, Tim, told me that by chance he saw an old man at the railway station selling newspapers.
And he was surprised to see someone like his grandfather in a picture he had seen. So naturally he went to the man and asked him whether his name was Smith. And the man, I mean, his grandfather, said yes, and after that everything happened just like a film.
B: Amazing. But why didn't the old man go back to his hometown after the war?
A: Well, that's another long story. I'll tell you later.

Question: What subsequent event happens or could happen following the target?
Target: Well, he told me he saw his dead grandfather in London.

✗ The listener would tell the speaker that this story is actually true.
✗ The listener would tell the speaker that this story is based on true events.
✓ The listener would tell the speaker that this story is not believable at all.
✗ The listener would tell the speaker that this story is very enticing.
✗ The listener would tell the speaker that this story is very true.
MCQ using RoBerta: The listener would tell the speaker that this story is based on true events. ✗
Generation using T5: Tim Smith told Tom that he saw his grandfather in London.

Question: What is or could be the prerequisite of target?
Target: But then, he suddenly appeared alive, like in those films.

✗ Tim's grandfather was shot during war.
✓ Tim's grandfather was not shot during the war, it was only a rumor.
✗ Tim's grandfather was shot during the war and he knows it.
✗ Tim's grandfather was shot during the war and he never heard of it.
✗ Tim's grandfather was shot a lot in the war.
MCQ using RoBerta: Tim's grandfather was shot during war. ✗
Generation using T5: Tom's grandfather used to be an army officer during the war.

Figure 12: Examples of some incorrect predictions by `RoBERTa` for the CICERO$_{MCQ}$ task.

thereby, making CICERO commonsense-rich and, thus, difficult inferences for models without relevant commonsense knowledge.

- While the performance of the strong baseline models on CICERO for CICERO$_{MCQ}$ task are comparable (see Table 16) with the performance on other available commonsense-based question-answering datasets, unlike the others, around 14% of the instances in CICERO contain multiple correct inferences/answers. These are more challenging to the baselines, as can be seen in Table 14.
- Dialogue-centric commonsense inference/answer generation task, i.e., CICERO$_{NLG}$ is novel and hard to solve. Strong baselines, such as, T5, BART, and their checkpoints pre-trained on large external commonsense datasets, such as, ATOMIC and GLUCOSE, perform poorly at this task.

E Hyperparameter Details

All models for the CICERO$_{NLG}$ generative tasks were trained with the Adafactor optimizer (Shazeer and Stern, 2018) with a learning rate of 5e-6. The models CICERO$_{MCQ}$ alternative selection were trained with the AdamW (Loshchilov and Hutter, 2018) optimizer with a learning rate of 1e-5. We used a batch size of 4 for all our experiments.

F Computational Resources

The T5 Large and `GLUCOSE-T5` Large have 770M parameters each. The `RoBERTa-Large` and `ELECTRA-Large` have 355M and 335M parameters, respectively. We also use a `BART-Large` and `COMET-Large` models for more extensive experiments (Appendix B). Both the models have 406M parameters. We use a single RTX 8000 GPU for our experiments. All models were trained for 5 epochs. Training and inference for the generative tasks i.e., CICERO$_{NLG}$ require between 1.5-6 hours in this GPU. Training and inference for the alternative selection task i.e., CICERO$_{MCQ}$ require a total of 15 hours. Training and inference times are 40% less for zero-shot setting experiments.

A Comparative Study of Faithfulness Metrics for Model Interpretability Methods

Chun Sik Chan, Huanqi Kong, Guanqing Liang
Wisers AI Lab, Wisers Information Limited
{tonychan, katekong, quincyliang}@wisers.com

Abstract

Interpretation methods to reveal the internal reasoning processes behind machine learning models have attracted increasing attention in recent years. To quantify the extent to which the identified interpretations truly reflect the intrinsic decision-making mechanisms, various *faithfulness* evaluation metrics have been proposed. However, we find that different faithfulness metrics show conflicting preferences when comparing different interpretations. Motivated by this observation, we aim to conduct a comprehensive and comparative study of the widely adopted faithfulness metrics. In particular, we introduce two assessment dimensions, namely *diagnosticity* and *time complexity*. Diagnosticity refers to the degree to which the faithfulness metric favours relatively faithful interpretations over randomly generated ones, and time complexity is measured by the average number of model forward passes. According to the experimental results, we find that sufficiency and comprehensiveness metrics have higher diagnosticity and lower time complexity than the other faithfulness metrics.

1 Introduction

NLP has made tremendous progress in recent years. However, the increasing complexity of the models makes their behaviour difficult to interpret. To disclose the rationale behind the models, various interpretation methods have been proposed.

Interpretation methods can be broadly classified into two categories: model-based methods and post-hoc methods. Model-based approaches refer to designing simple and white-box machine learning models whose internal decision logic can be easily interpreted, such as linear regression models, decision trees, etc. A post-hoc method is applied after model training and aims to disclose the relationship between feature values and predictions. As pretrained language models (Devlin et al., 2019a; Liu et al., 2019; Brown et al., 2020) become more popular, deep learning models are becoming more and more complex. Therefore, post-hoc methods are the only option for model interpretations. Post-hoc interpretation methods can be divided into two categories: gradient-based (Simonyan et al., 2014; Sundararajan et al., 2017; Shrikumar et al., 2019) and perturbation-based (Robnik-Šikonja and Kononenko, 2008; Zeiler and Fergus, 2013; Ribeiro et al., 2016). Gradient-based methods assume the model is differentiable and attempt to interpret the model outputs through the gradient information. Perturbation-based methods interpret model outputs by perturbing the input data.

To verify whether, and to what extent, the interpretations reflect the intrinsic reasoning process, various faithfulness metrics have been proposed. Most faithfulness metrics use a removal-based criterion, i.e., removing or retaining only the important tokens identified by the interpretation and observing the changes in model outputs (Serrano and Smith, 2019; Chrysostomou and Aletras, 2021; Arras et al., 2017; DeYoung et al., 2020).

However, we observe that the existing faithfulness metrics are not always consistent with each other and even lead to contradictory conclusions. As shown in the example from our experiments (Table 1), the conclusions that are drawn by two different faithfulness metrics, Sufficiency (SUFF) and Decision Flip - Fraction of Tokens (DFFOT), conflict with each other. More specifically, DFFOT concludes that the interpretation by LIME method is the best among the four interpretations, while SUFF ranks it as the worst. In this case, *which faithfulness metric(s) should we adopt to compare interpretations?*

Motivated by the above observation, we aim to conduct a comprehensive and comparative study of faithfulness metrics. We argue that a good faithfulness metric should be able to effectively and efficiently distinguish between faithful and unfaithful interpretations. To quantitatively assess this capa-

bility, we introduce two dimensions, *diagnosticity* and *time complexity*.

Diagnosticity refers to the extent to which a faithfulness metric prefers faithful rather than unfaithful interpretations. However, due to the opaque nature of deep learning models, it is not easy to obtain the ground truth for faithful interpretation (Jacovi and Goldberg, 2020). To concretize this issue, we use random interpretations, i.e., randomly assigning importance scores to tokens regardless of the internal processes of the model, as the relatively unfaithful interpretations. In contrast, we treat interpretations generated by interpretation methods as relatively faithful interpretations. In this way, we constructed the hypothesis that a faithfulness metric is diagnostic only if it can clearly distinguish between random interpretations and interpretations generated from interpretation methods. In addition, we introduce time complexity to estimate the computational speed of each metric, by using the average number of model forward passes.

In this paper, we evaluate six commonly adopted faithfulness metrics. We find that the sufficiency and comprehensiveness metrics outperform the other faithfulness metrics, which are more diagnostic and less complex. Secondly, the two correlation-based metrics, namely *Correlation between Importance and Output Probability* and *Monotonicity*, have a promising diagnosticity but fail in terms of the high time complexity. Last but not least, decision flip metrics, such as Fraction of Tokens and Most Informative Token, perform the worst in the assessments.

The main contributions of this paper are as follows:

- We conduct a comparative study of six widely used faithfulness metrics and identify the inconsistencies issues.
- We propose a quantitative approach to assess faithfulness metrics through two perspectives, namely diagnosticity and time complexity.

2 Terminology and Notations

We first introduce the prerequisite terminology and notations for our discussions.

Terminology A "classification instance" is the input and output values of a classification model, which we apply interpretation methods on. An "interpretation" of a classification instance is a sequence of scores where each score quantifies the importance of the input token at the corresponding position. An "interpretation pair" is a pair of interpretations of the same classification instance. An "interpretation method" is a function that generates an interpretation from a classification instance with the associated classification model.

Notations Let x be the input tokens. Denote the number of tokens of x as l_x. Denote the predicted class of x as $c(x)$, and the predicted probability corresponding to class j as $p_j(x)$.

Assume an interpretation is given. Denote the k-th important token as x_k. Denote the input sequence containing only the top k (or top $q\%$) important tokens as $x_{:k}$ (or $x_{:q\%}$). Denote the modified input sequence from which a token sub-sequence x' are removed as $x \setminus x'$.

Let (x, y) be a classification instance associated with classification model m, and g be an interpretation method. Denote the interpretation of z generated by g as $g(x, y, m)$. Let u be an interpretation, (u, v) be an interpretation pair, and F be a faithfulness metric. Denote the importance score that u assigns to the i-th input token as $[u]_i$. Denote the statement "u is more faithful than v" as "$u \succ v$", and the statement "F considers u as more faithful than v" as "$u \succ_F v$".

3 Faithfulness Metrics

An interpretation is called *faithful* if the identified important tokens truly contribute to the decision making process of the model. Mainstream faithfulness metrics are removal-based metrics, which measure the changes in model outputs after removing important tokens.

We compare the most widely adopted faithfulness metrics, introduced as follows.

Decision Flip - Most Informative Token (DFMIT) Introduced by Chrysostomou and Aletras (2021), this metric focuses on only the most important token. It assumes that the interpretation is faithful only if the prediction label is changed after removing the most important token, i.e.

$$\mathit{DFMIT} = \begin{cases} 1 & \text{if } c(x) \neq c(x \setminus x_{:1}) \\ 0 & \text{if } c(x) = c(x \setminus x_{:1}) \end{cases}$$

A score of 1 implies that the interpretation is faithful.

Decision Flip - Fraction of Tokens (DFFOT) This metric measures faithfulness as the minimum fraction of important tokens needed to be erased in order to change the model decision (Serrano and Smith, 2019), i.e.

$$\mathit{DFFOT} = \begin{cases} \min \frac{k}{l_x} & \text{s.t. } c(x) \neq c(x \setminus x_{:k}) \\ 1 & \text{if } c(x) = c(x \setminus x_{:k}) \text{ for any k} \end{cases}$$

If the predicted class change never occurs even if all tokens are deleted, then the score will be 1. A lower value of DFFOT means the interpretation is more faithful.

Comprehensiveness (COMP) As proposed by DeYoung et al. (2020), comprehensiveness assumes that an interpretation is faithful if the important tokens are broadly representative of the entire input sequence. It measures the faithfulness score by the change in the output probability of the original predicted class after the important tokens are removed, i.e.

$$\mathit{COMP} = \frac{1}{|B|} \sum_{q \in B} (p_{c(x)}(x) - p_{c(x)}(x \setminus x_{:q\%}))$$

We use $q \in B = \{1, 5, 10, 20, 50\}$ as in the original paper. A higher comprehensiveness score implies a more faithful interpretation.

Sufficiency (SUFF) Also proposed by DeYoung et al. (2020), this metric measures whether the important tokens contain sufficient information to retain the prediction. It keeps only the important tokens and calculates the change in output probability compared to the original specific predicted class, i.e.

$$\mathit{SUFF} = \frac{1}{|B|} \sum_{q \in B} (p_{c(x)}(x) - p_{c(x)}(x_{:q\%}))$$

We use $q \in B = \{1, 5, 10, 20, 50\}$ as in the original paper. The lower the value of SUFF means that the interpretation is more faithful.

Correlation between Importance and Output Probability (CORR) This metric assumes that the interpretation is faithful if the importance of the token and the corresponding predicted probability when the most important token is continuously removed is positively correlated (Arya et al., 2019), i.e.

$$\mathit{CORR} = -\rho(\boldsymbol{u}, \boldsymbol{p})$$

where $\boldsymbol{u}$ denotes the token importance in descending order and $\boldsymbol{p} = [p_{c(x)}(x \setminus x_1), p_{c(x)}(x \setminus x_2), ..., p_{c(x)}(x \setminus x_{l_x})]$. $\rho(\cdot)$ denotes the Pearsons correlation. The higher the correlation the more faithful the interpretation is.

Monotonicity (MONO) This metric assumes that an interpretation is faithful if the probability of the predicted class monotonically increases when incrementally adding more important tokens (Arya et al., 2019). Starting from an empty vector, the features are gradually added in ascending order of importance, and the corresponding classification probabilities are noted. Monotonicity is calculated as the correlation between the feature importance and the probability after adding the feature, i.e.

$$\mathit{MONO} = \rho(\boldsymbol{u}, \boldsymbol{p})$$

where $\boldsymbol{u}$ denotes the token importance in descending order and $\boldsymbol{p} = [p_{c(x)}(x), p_{c(x)}(x \setminus x_{:1}), p_{c(x)}(x \setminus x_{:2}), ..., p_{c(x)}(x \setminus x_{:(l_x-1)})]$. $\rho(\cdot)$ denotes the Pearsons correlation. The higher the monotonicity the more faithful the interpretation is.

4 Evaluation of Faithfulness Metrics

In this section, we propose an evaluation paradigm for faithfulness metrics by addressing two aspects: (1) diagnosticity and (2) time complexity. They are the two complementary and important factors in selecting a faithfulness metric for assessing the faithfulness of interpretations.

4.1 Diagnosticity of Faithfulness Metric

As we have observed in Table 1, faithfulness metrics might disagree with each other on faithfulness assessment. This naturally raises a question: *Which faithfulness metric(s) should we trust?*

To the best of our knowledge, there is no preceding work in quantifying the effectiveness of faithfulness metrics. As a first attempt, we introduce *diagnositicity*, which is intended to measure "the degree to which a faithfulness metric favours faithful interpretations over unfaithful interpretations". Intuitively, the higher the diagnosticity the more effective the faithfulness metric is.

4.1.1 Definition of Diagnosticity

Definition 4.1 (Diagnosticity). We define the diagnosticity of a faithfulness metric as the probability that given an interpretation pair (u, v) such that u is more faithful than v, the faithfulness metric also considers u as more faithful than v, i.e.

$$\mathrm{D}(F) = \mathrm{P}(u \succ_F v | u \succ v)$$

As we will see later in this section, a set of interpretation pairs (u, v) such that $u \succ v$ is required for estimating diagnosticity. Constructing such a dataset leads us to a paradox: we cannot be *guaranteed* that some generated interpretation is more faithful than the others when the measurement of faithfulness is still under debate. It is more realistic to assume that we can generate an interpretation pair (u, v) such that u is *very likely* to be more faithful than v. Thus, we relax the condition in Definition 4.1 to a probabilistic one as follows.

Definition 4.2 (ε-diagnosticity). Let (u, v) be any interpretation pair, and $0 \leq \varepsilon \leq 1$. The ε-diagnosticity of a faithfulness metric F is defined as

$$\mathrm{D}_\varepsilon(F) = \mathrm{P}(u \succ_F v | \mathrm{P}(u \succ v) > 1 - \varepsilon)$$

In the above definition, ε represents the uncertainty in comparing the faithfulness of u and v. In the next Theorem, we show that ε-diagnosticity effectively approximates diagnosticity as long as ε is small enough.

Theorem 4.1 (Error Bound of ε-diagnosticity). We can approximate diagnosticity with ε-diagnosticity with error less than ε, i.e.

$$|\mathrm{D}_\varepsilon(F) - \mathrm{D}(F)| < \varepsilon$$

The proof is provided in Appendix A.

4.1.2 Estimation of Diagnosticity

In the following, we show how we estimate ε-diagnosticity with a set of interpretation pairs (u, v) where the u is *very likely* to be more faithful than v, namely an *ε-faithfulness golden set* where ε is small.

Definition 4.3 (ε-faithfulness golden set). Let $0 \leq \varepsilon \leq 1$. A set Z_ε of interpretation pairs is called a ε-faithfulness golden set, if it satisfies the following conditions.

1. All interpretation pairs in Z_ε are independent and identically distributed (i.i.d.).

2. $\mathrm{P}(u \succ v) > 1 - \varepsilon$ for any interpretation pair $(u, v) \in Z_\varepsilon$.

Lemma 4.2. Let $\mathbb{1}(\cdot)$ be the indicator function which takes a value 1 when the input statement is true and a value 0 when it is false. Then $\mathbb{1}(u \succ_F v)|(\mathrm{P}(u \succ v) > 1 - \varepsilon)$ is a random variable and its expected value is equal to ε-diagnosticity, i.e.

$$\mathrm{D}_\varepsilon(F) = \mathbb{E}[\mathbb{1}(u \succ_F v) | \mathrm{P}(u \succ v) > 1 - \varepsilon]$$

The proof is provided in Appendix B.

As a result, given an ε-faithfulness golden set Z_ε, we can estimate the ε-diagnosticity of a faithfulness metric F by estimating the expected value in Lemma 4.2. Then by the law of large numbers, we can simply estimate the expected value by computing the average value of $\mathbb{1}(u \succ_F v)$ on Z_ε, i.e.

$$\mathrm{D}_\varepsilon(F) \approx \frac{1}{|Z_\varepsilon|} \sum_{(u,v) \in Z_\varepsilon} \mathbb{1}(u \succ_F v) \tag{1}$$

When $|Z_\varepsilon|$ is large enough, we will have $|\frac{1}{|Z_\varepsilon|} \sum_{(u,v) \in Z_\varepsilon} \mathbb{1}(u \succ_F v) - D(F)| < \varepsilon$ according to Theorem 4.1.

4.1.3 Generation of an ε-faithfulness golden set

According to Theorem 4.1 and Lemma 4.2, we can estimate the diagnosticity of any faithfulness metric using Equation 1 as long as we have an ε-faithfulness golden set where ε is small enough.

We called the u and v in Definition 4.3 a **relatively faithful interpretation** and a **relatively unfaithful interpretation** respectively. Next, we discuss the processes to generate them respectively.

Generating Relatively Unfaithful Interpretations By definition, a faithful interpretation is an interpretation that truly reflects the underlying decision making process of the classification model. Therefore, an unfaithful interpretation is one that is completely irrelevant to the underlying decision making process of the classification model. We propose to generate relatively unfaithful interpretations by assigning a random importance score to each token in the input sequence, i.e. $[v]_i \sim \text{Uniform}(0, 1)$ for any token $1 \leq i \leq l$, where Uniform denotes the uniform distribution.

Generating Relatively Faithful Interpretations We propose to generate relatively faithful interpretations with the interpretation methods that infer interpretations from the underlying mechanism of the classification model. There are two mainstream categories of interpretations methods that satisfy this requirement (Alvarez-Melis and Jaakkola, 2018):

- **Perturbation-based**: Relying on querying the model around the classification instance to infer the importance of input features.
- **Gradient-based**: Using information from gradients to infer the importance of input features.

We select the representative methods from both categories and introduce them in the following.

- **Perturbation-based - LIME** (Ribeiro et al., 2016): For each classification instance, a linear model on the input space is trained to approximate the local decision boundary, so that the learned coefficients can be used to quantify the importance of the corresponding input features on the model prediction.
- **Perturbation-based - Word Omission (WO)** (Robnik-Šikonja and Kononenko, 2008): For each i-th input token, WO quantifies the importance of the input token by the change in output probability after removing it from the original input sequence, i.e. $p_{c(x)}(x) - p_{c(x)}(x_{\backslash\{i\}})$.
- **Gradient-based - Saliency Map (SA)** (Simonyan et al., 2014): For each i-th input token, SA computes the gradients of the original model output with respect to the embedding associated with the input token, i.e. $\frac{\partial p_{c(x)}(z)}{\partial e(z)_i}|_{z=x}$, and quantifies the importance of the input token by taking either the mean or the $l2$ norm of the gradients in the embedding dimension. We denote the former approach as SA$_\mu$ and the later approach as SA$_{l2}$
- **Gradient-based - Integrated Gradients (IG)** (Simonyan et al., 2014): As shown by Simonyan et al. (2014), Integrated Gradients provides more robust interpretations than Saliency Map in general. For each i-th input token, it approximates the integral of the gradients of the original model output with respect to the embedding corresponding to the input token along a straight line from a reference point x_0 to the original input sequence, i.e. $\int_{x_0 \to x} \frac{\partial p_{c(x)}(z)}{\partial e(z)_i}\, dz$, and quantifies the importance of the input token by taking either the mean or the $l2$ norm of the integral in the embedding dimension. We denote the former approach as IG$_\mu$ and the later approach as IG$_{l2}$.

Algorithm 1 An ε-faithfulness golden set generation mechanism.

```
Input: $X$: A set of i.i.d. classification instances
  associated with classification model $m$;
  $G$: The set of interpretation methods for generating relatively faithful interpretations, i.e. {LIME, WO, SA$_\mu$, SA$_{l2}$, IG$_\mu$, IG$_{l2}$};
  $K$: Sample size;
Output: An $\varepsilon$-faithfulness golden set $Z$;
  $Z \leftarrow \{\}$;
  For 1 to $K$;
      $(x, y) \leftarrow \text{RandomSampler}(X)$;
      $g \leftarrow \text{RandomSampler}(G)$;
      $u \leftarrow g(x, y, m)$
      $v \leftarrow r \in \mathbb{R}^{l_x}$ where $[r]_i \sim \text{Uniform}(0, 1)$;
      $Z \leftarrow Z \cup \{(u, v)\}$;
  return $Z$;
```

The interpretations generated using the above interpretation methods are *highly likely* to be more faithful than the randomly generated interpretations because the generation processes of the former ones actually involve inferences from model behaviours, while the random generation process is independent of any model behaviour. Therefore, in principle, the set of generated interpretation pairs will have a small value of ε in Definition 4.3.

In Algorithm 1, we propose a mechanism to generate an ε-faithfulness golden set from a set of i.i.d. classification instances based on the above

Dataset	Splits (Train / Test)	Model perf. (F1)	
		BERT	CNN
SST	6,920 / 1,821	.917	.804
IMDB	25,000 / 25,000	.918	.864
AG	120,000 / 7,600	.946	.919

Table 2: Dataset statistics and model performances (Macro-F1) on test sets.

processes. Note that the generated interpretation pairs will satisfy the first condition in Definition 4.3 because they are generated from i.i.d. samples, and will satisfy the second condition in Definition 4.3 with a presumably small ε as we have discussed.

4.2 Time Complexity of Faithfulness Metric

Two of the main applications of faithfulness metrics are (1) evaluating interpretation methods based on their average faithfulness scores on a dataset; and (2) gauging the quality of individual interpretations by spotting out "unfaithful" interpretations.

Time complexity is an important aspect in evaluating faithfulness metrics because a fast faithfulness metric will shorten the feedback loop in developing faithful interpretation methods, and would allow runtime faithfulness checking of individual interpretations in a production environment.

Measurement of time complexity From the definitions of the faithfulness metrics in Section 3, we observe that their computations are dominated by model forward passes, which are denoted as $c(\cdot)$ or $p(\cdot)$. Thus, we measure the time complexities of the faithfulness metrics in *number of model forward passes*.

5 Experimental Setup [1]

Datasets We conduct experiments on three text classification datasets used in (Wiegreffe and Pinter, 2019): (i) Stanford Sentiment Treebank (**SST**) (Socher et al., 2013); (ii) IMDB Large Movie Reviews (**IMDB**) (Maas et al., 2011); (iii) AG News Corpus (**AG**) (Zhang et al., 2015). We summarize the dataset statistics in Table 2.

Text classification models We adopt two most common model architectures for text classification: (i) **BERT** (Devlin et al., 2019b); (ii) **CNN** (Kim, 2014). The former one encodes contextualized representations of tokens and has higher accuracy in general, but at a cost of consuming more memory and computational resources. The latter one uses pretrained word embeddings as token representations and is lighter and faster. Their performances on test data sets are shown in Table 2. The implementation details of both models can be found in Appendix C.1.

Faithfulness metric	Diagnosticity (%)			
	SST	IMDB	AG	Average
		BERT		
DFMIT	14.79	6.07	3.34	8.07
DFFOT	65.16	72.02	65.68	67.62
SUFF	71.03	79.33	70.42	73.60
COMP	75.38	**80.44**	**74.23**	**76.69**
CORR	65.46	68.06	67.23	66.91
MONO	**75.87**	75.82	68.33	73.34
		CNN		
DFMIT	17.29	9.27	4.84	10.47
DFFOT	63.76	70.74	57.61	64.04
SUFF	71.54	75.91	77.97	75.14
COMP	71.39	73.46	**81.73**	**75.53**
CORR	72.17	68.92	71.82	70.97
MONO	**72.39**	**77.09**	75.12	74.87

Table 3: Diagnosticities of all faithfulness metrics on all datasets for both BERT and CNN models. The rightmost column states the average diagnosticities over three datasets. In each column, we underline the highest value.

ε-faithfulness golden set For each dataset and text classification model, we transform the test set into a set of classification instances and feed it into Algorithm 1 to generate an ε-faithfulness golden set with a size of 8,000 (K in Algorithm 1). The implementation details of interpretation methods can be found in Appendix C.2.

6 Results and Discussion

Diagnosticity We estimate the diagnositicities of the faithfulness metrics in Section 3 on all datasets for both CNN and BERT models. The results are shown in Table 3.

COMP and SUFF have the highest and the second highest average diagnosticites for both models. Hence, they are the most effective faithfulness metrics. We also observe that COMP has higher diagnosticities than SUFF on all datasets for BERT model. This can be explained by the contextualization property of Transformer encoders (Vaswani et al., 2017): the hidden state of each token depends on all other tokens in the input sequence. Removing a portion of the important tokens will alter the whole context, and is likely to cause a dramatic

---

[1] Code will be available at `https://github.com/Wisers-AI/faithfulness-metrics-eval`

change in model output.

DFMIT and DFFOT have the lowest and the second lowest average diagnosticities. Removing the most important token is usually not creating enough perturbation to flip the original model decision. In fact, the probability of decision flipping by removing the most important token is $\leq 14\%$ for recent state-of-the-art interpretation methods (Chrysostomou and Aletras, 2021). As a result, up to 86% of interpretations are considered as indifferent by DFMIT. For DFFOT, the probability of decision flipping by removing the important tokens in order does not only depend on the quality of interpretation but also depends on any model bias towards certain classes. For instance, decision flipping will be less likely to occur if the predicted class on the original input is the same as the one on the empty input sequence. Therefore, we found that decision flipping metrics (DFMIT, DFFOT) are less effective than the metrics that operate on output probabilities (SUFF, COMP, CORR, MONO).

Time complexity We compare the time complexities of the faithfulness metrics in Section 3 measured in number of model forward passes. We first analyze their time complexities based on their definitions in Table 4 and then measure their actual time complexities on all datasets in Table 5. Note that the time complexity here is equal to the number of model forward passes.

DFMIT is the fastest faithfulness metric, which requires only one model forward pass. DFFOT has a non-deterministic time complexity, which depends on how fast the decision flipping occurs, and it is the second slowest faithfulness metrics on all datasets. SUFF and COMP are the second fastest faithfulness metric on average, which require at most 5 model forward passes. CORR and MONO are the slowest faithfulness metrics, which have time complexity equal to the number of input tokens.

Which faithfulness metric(s) should we adopt? In Figure 1, we evaluate the faithfulness metrics by both their diagnosticities and time complexities.

Figure 1 suggests that we should always adopt COMP and SUFF. Because (i) they have higher diagnosticities and lower time complexities than DFFOT, ; (ii) they have a similar level of diagnosticity and much lower time complexities than CORR and MONO; (iii) DFMIT has diagnosticity less than 0.1, which is below an acceptable level. We would prefer COMP and SUFF over DFMIT even though it has the lowest time complexity.

Faithfulness metric	**Time complexity - Analysis (#(model forward passes))**	
	Deterministic	Value or range
DFMIT	✓	1

MONO	✓	l_x

Table 4: Analysis of the time complexities of faithfulness metrics. l_x denotes the number of input tokens.

Faithfulness metric	**Time complexity - Actual (#(model forward passes))**			
	SST	IMDB	AG	Average
DFMIT	1.0	1.0	1.00	1.0
DFFOT	9.3	78.7	30.0	39.4
SUFF	5.0	5.0	5.0	5.0
COMP	5.0	5.0	5.0	5.0
CORR	20.3	193.1	47.7	87.1
MONO	20.3	193.1	47.7	87.1

Table 5: Actual time complexities of faithfulness metrics measured by the average number of model passes on each dataset.

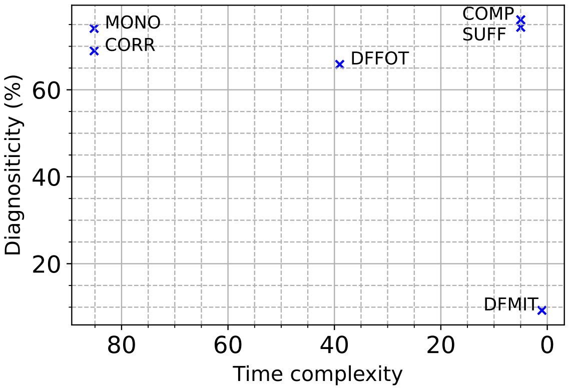

Figure 1: Diagnosticity vs time complexity for faithfulness metrics. The values are averages over all datasets and classification models. The faithfulness metrics near the top-right corner are more desirable than those near the bottom-left corner.

Note that our evaluation framework can be used to compare any faithfulness metrics. In general, we prefer faithfulness metrics that have higher diagnosticities and lower time complexities, i.e. closer to the top-right corner in Figure 1. But what if one has a higher diagnosticity and the other one has a lower time complexity? In this case, we should consider diagnosticity first: a faithfulness metric should not be used if it cannot effectively assess faithfulness, i.e. diagnosticity below a certain threshold. In scenarios where we are subject to constraints of hardware or timeliness, we might need to select a faster metric with a lower but acceptable level of diagnosticity.

7 Related Work

Interpretation methods Interpretation methods can be roughly classified into two categories: model-based methods and post-hoc methods. Model-based methods refer to the construction of simple machine learning models whose internal decision logic can be easily interpreted, such as linear regression models, decision trees, etc. Post-hoc methods interpret the internal reasoning process behind the model after training. Generally, post-hoc methods can be divided into gradient-based and perturbation-based. A gradient-based interpretation method assumes deep learning model is differentiable and discloses the decision making mechanism of the model according to the gradient information (Simonyan et al., 2014; Sundararajan et al., 2017; Shrikumar et al., 2019). A perturbation-based interpretation method interprets the model by perturbing the input of data samples and measuring how the predictions change (Robnik-Šikonja and Kononenko, 2008; Zeiler and Fergus, 2013; Ribeiro et al., 2016).

Interpretation method evaluation To assess the quality of different interpretation methods, various evaluation metrics have been proposed. Existing evaluation methods on interpretations can be broadly classified into two categories, plausibility and faithfulness. Plausibility measures if the interpretation agrees with human judgments on how a model makes a decision (Ribeiro et al., 2016; Doshi-Velez and Kim, 2017; Lundberg and Lee, 2017; DeYoung et al., 2020). However, even if the interpretation conforms to human criteria, it is not certain that it truly reflects the underlying decision mechanism behind the model. To this end, faithfulness measures the extent to which the inner decision-making mechanism actually relies on the identified important features (Arras et al., 2017; Serrano and Smith, 2019; Jain and Wallace, 2019; Wiegreffe and Pinter, 2019; DeYoung et al., 2020; Chrysostomou and Aletras, 2021).

In general, existing faithfulness metrics are developed through a removal-based criterion, which measures the changes in model output when perturbing or removing tokens identified as important by the interpretation. Serrano and Smith (2019) proposed a decision flipping metric that evaluates the proportion of tokens that need to be erased in order to change the model decision. Also using decision flip as an indicator, Chrysostomou and Aletras (2021) introduces a metric that counts the average flips that occur when removing the most important token marked by the interpretation method. In addition to decision flips, changes in model output probabilities by removing or retaining important tokens is also widely used to measure faithfulness (Arras et al., 2017; Arya et al., 2019; DeYoung et al., 2020).

Some recent work also focuses on the study of faithfulness metrics. Jacovi and Goldberg (2020) argued that the definition of faithfulness remains inconsistent and informal, and provided concrete guidelines on how evaluations of interpretation methods should and should not be conducted. More recently, Yin et al. (2021) discussed the limitations of removal-based faithfulness metrics and proposed two other quantitative criteria, namely sensitivity and stability. Different from the aforementioned previous work that does not focus on assessing faithfulness metrics, we mainly focus on the measurement of faithfulness and conduct a comprehensive study of existing faithfulness metrics.

8 Conclusion

In this paper, we propose a framework to quantitatively evaluate six widely adopted faithfulness metrics in terms of diagnosticity and time complexity. In particular, diagnosticity measures whether the faithfulness metric correctly favours relatively faithful interpretations over random ones; time complexity is concerned with computational efficiency, estimated by the average number of model forward passes. The experimental results show that sufficiency and comprehensiveness metrics outperform the other faithfulness metrics with higher diagnosticity and lower time complexity. For this reason, we suggest using these two metrics for faithfulness evaluation. We hope our work will bring more awareness to the standardization of faithfulness measurement. For future work, we would like to explore evaluating faithfulness metrics using a white-box model such as linear regression, from which we can derive an intrinsically faithful interpretation as the “ground truth”.

A Proof of Theorem 4.1

Proof. Let (u, v) be an interpretation pair. Then

$$\begin{aligned}&\mathrm{P}(u \succ_F v | \mathrm{P}(u \succ v) = 1-\varepsilon)\\ &= \mathrm{P}(u \succ_F v | u \succ v)(1-\varepsilon) + \mathrm{P}(u \succ_F v | u \not\succ v)\varepsilon\\ &= \mathrm{D}(F) + [\mathrm{P}(u \succ_F v | u \not\succ v) - \mathrm{P}(u \succ_F v | u \succ v)]\varepsilon\end{aligned}$$

Since $-1 \leq \mathrm{P}(u \succ_F v | u \not\succ v) - \mathrm{P}(u \succ_F v | u \succ v) \leq 1$, we have

$$|\mathrm{P}(u \succ_F v | \mathrm{P}(u \succ v) = 1-\varepsilon) - \mathrm{D}(F)| \leq \varepsilon$$

□

B Proof of Lemma 4.2

Proof. From Definition 4.2, we have $\mathbb{1}(u \succ_F v) | (\mathrm{P}(u \succ v) > 1-\varepsilon) \sim \mathrm{Bernoulli}(p)$, where $p = \mathrm{D}(F)$. Then based on the property of Bernoulli distribution, we know that the expected value of the random variable is equal to p. □

C Implementation Details

C.1 Text classification models

The text classification models are all implemented in PyTorch [2]. For BERT, we use the "bert-base-uncased" from Huggingface transformers [3] as the pretrained model . We use the same set of hyperparameters regardless of dataset for fine-tuning: dropout rate 0.2, AdamW (Loshchilov and Hutter, 2019) with an initial learning rate 2e-5, batch size 32 with no warmup steps. We set the maximum number of finetuning epochs to be 10 and perform early stopping when the performance on the test set does not improve for 3 consecutive epochs

For CNN classifier, we use a one-layer CNN encoder with a linear classifier. The embedding is initialized with the 300-dimensional pretrained GloVe word embedding (Pennington et al., 2014). The CNN layer has 256 kernels and the size of the kernels is 3. We use max-pooling and AdamW with an initial learning rate 1e-3, batch size 32, with no warmup steps. The maximum number of epochs is 40 with early stopping after 3 consecutive non-improving epochs.

C.2 Interpretation methods

For LIME, Saliency Map, Integrated Gradients and DeepLift, we apply the implementation in Captum [4]. For Word Omission, we use our own implementation.

SPoT: Better Frozen Model Adaptation through Soft Prompt Transfer

Abstract

There has been growing interest in parameter-efficient methods to apply pre-trained language models to downstream tasks. Building on the PromptTuning approach of Lester et al. (2021), which learns task-specific soft prompts to condition a frozen pre-trained model to perform different tasks, we propose a novel prompt-based transfer learning approach called SPoT: **S**oft **P**r**o**mpt **T**ransfer. SPoT first learns a prompt on one or more source tasks and then uses it to initialize the prompt for a target task. We show that SPoT significantly boosts the performance of PromptTuning across many tasks. More remarkably, across all model sizes, SPoT matches or outperforms standard ModelTuning (which fine-tunes all model parameters) on the SuperGLUE benchmark, while using up to 27,000× fewer task-specific parameters. To understand where SPoT is most effective, we conduct a large-scale study on task transferability with 26 NLP tasks in 160 combinations, and demonstrate that many tasks can benefit each other via prompt transfer. Finally, we propose an efficient retrieval approach that interprets task prompts as task embeddings to identify similar tasks and predict the most transferable source tasks for a novel target task.

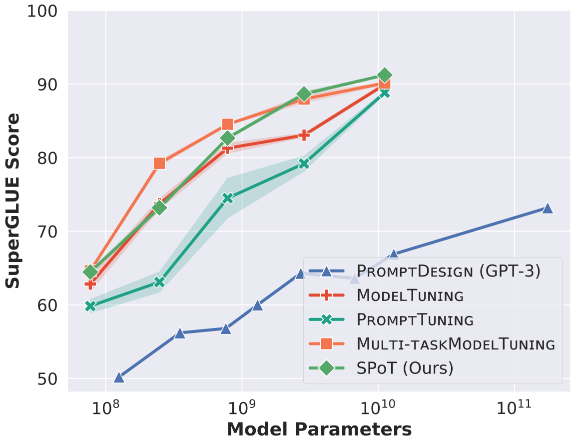

Figure 1: Our SPoT approach—which transfers a prompt learned from a mixture of source tasks (here, GLUE) onto target tasks—outperforms vanilla PromptTuning (Lester et al., 2021) and GPT-3 (Brown et al., 2020) on SuperGLUE by a large margin, matching or outperforming ModelTuning across all model sizes. At the XXL model size, SPoT even outperforms Multi-taskModelTuning, which fine-tunes the entire model on the GLUE mixture before fine-tuning it on individual SuperGLUE tasks. See Appendix A for full results.

1 Introduction

The past few years have seen the rapid development of ever larger pre-trained language models, where it has repeatedly been shown that scaling up the model size is a key ingredient for achieving the best performance (Devlin et al., 2019; Raffel et al., 2020; Brown et al., 2020). While this trend has continued to push the boundaries of possibility across various NLP benchmarks, the sheer size of these models presents a challenge for their practical application. For 100B+ parameter models, fine-tuning and deploying a separate instance of the model for each downstream task would be prohibitively expensive. To get around the infeasibility of fine-tuning, Brown et al. (2020) propose PromptDesign, where every downstream task is cast as a language modeling task and the *frozen* pre-trained model performs different tasks by conditioning on manual text prompts provided at inference time. They demonstrate impressive few-shot performance with a single frozen GPT-3 model, although its performance depends highly on the choice of the prompt (Zhao et al., 2021) and still lags far behind state-of-the-art fine-tuning results.

More recent work explores methods for learning *soft prompts* (Liu et al., 2021b; Qin and Eisner, 2021; Li and Liang, 2021; Lester et al., 2021), which can be seen as additional learnable parameters injected into the language model. Lester et al. (2021) propose PromptTuning, a simple method

May 22-27, 2022

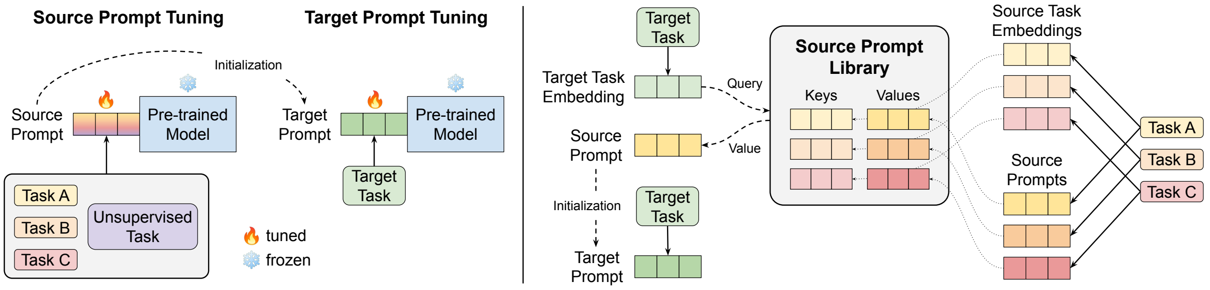

Figure 2: An illustration of our *generic* (left) and *targeted* (right) SPoT approaches. **Left**: We learn a single generic source prompt on one or more source tasks, which is then used to initialize the prompt for each target task. **Right**: We learn separate prompts for various source tasks, saving early checkpoints as task embeddings and best checkpoints as source prompts. These form the keys and values of our prompt library. Given a novel target task, a user: (i) computes a task embedding, (ii) retrieves an optimal source prompt, and (iii) trains a target prompt, initialized from the source prompt (see §3 for details).

that learns a small task-specific prompt (a sequence of tunable tokens prepended to each example) for each downstream task during adaptation to condition the frozen language model to perform the task. Strikingly, as model capacity increases, PromptTuning becomes competitive with ModelTuning, which fine-tunes the entire model on each downstream task. Nevertheless, at smaller model sizes (below 11B parameters), there are still large gaps between PromptTuning and ModelTuning.

In this paper, we propose SPoT: **S**oft **P**r**o**mpt **T**ransfer, a novel transfer learning approach in the context of prompt tuning. SPoT first trains a prompt on one or more source tasks, and then uses the resulting prompt to initialize the prompt for a target (downstream) task. Our experiments show that SPoT offers significant improvements over PromptTuning across tasks and model sizes. For instance, on the SuperGLUE benchmark (Wang et al., 2019b), we obtain +10.1 and +2.4 point average accuracy improvements using the T5 Base (220M parameter) and T5 XXL (11B parameter) models (Raffel et al., 2020), respectively. More importantly, SPoT is competitive with or outperforms ModelTuning across all model sizes (see Figure 1).

Motivated by these results, we investigate transferability between tasks, through the lens of soft task prompts. Our goal is to answer two questions: (a) *For a given target task, when does initializing the prompt from a source task boost performance?* (b) *Can we use task prompts to efficiently predict which source tasks will transfer well onto a novel target task?* To answer (a), we conduct a systematic study of the T5 model using 26 NLP tasks in 160 combinations of source and target tasks. Our results indicate that many tasks can benefit each other via prompt transfer. To address (b), we interpret the learned task prompts as *task embeddings* to construct a semantic space of tasks and formalize the similarity between tasks. We design an efficient retrieval algorithm that measures task embedding similarity, allowing practitioners to identify source tasks that will likely yield positive transfer.

To summarize, our main contributions are: (1) We propose SPoT, a novel prompt-based transfer learning approach, and show that scale is not necessary for PromptTuning to match the performance of ModelTuning; on SuperGLUE, SPoT matches or beats ModelTuning across all model sizes. (2) We conduct a large-scale and systematic study on task transferability, demonstrating conditions under which tasks can benefit each other via prompt transfer. (3) We propose an efficient retrieval method that interprets task prompts as task embeddings to construct a semantic space of tasks, and measures task embedding similarity to identify which tasks could benefit each other. (4) To facilitate future work on prompt-based learning, we will release our library of task prompts and pretrained models, and provide practical recommendations for adapting our library to NLP practitioners at https://github.com/google-research/prompt-tuning/tree/main/prompt_tuning/spot.

2 Improving PromptTuning with SPoT

To improve performance of PromptTuning on a target task, SPoT introduces *source prompt tuning*, an intermediate training stage between language model pre-training and target prompt tuning (Figure 2, left), to learn a prompt on one or more source tasks (while still keeping the base model frozen), which is then used to initialize the prompt for the target task.[1] Our approach retains all the computational benefits of PromptTuning: for each target task, it only requires storing a small task-specific prompt, enabling the reuse of a single frozen pre-trained model across all tasks. In this section, we present a *generic* SPoT approach where a single transferred prompt is reused for all target tasks. In §3, we explore a *targeted* approach that retrieves different source prompts for different target tasks.

2.1 Experimental setup

Our frozen models are built on top of the pre-trained T5 checkpoints of all sizes: Small, Base, Large, XL, XXL with 60M, 220M, 770M, 3B, and 11B parameters, respectively. In our experiments with SPoT, we leverage the LM adapted version of T5[2], which was found to be easier to optimize for PromptTuning (Lester et al., 2021).

2.1.1 Baselines

We compare SPoT to the following baselines:

PromptTuning: The vanilla prompt tuning approach of Lester et al. (2021), where an independent prompt is directly trained on each target task.

ModelTuning & Multi-taskModelTuning: We compare prompt tuning approaches to ModelTuning, the standard fine-tuning approach (Devlin et al., 2019; Raffel et al., 2020), where all model parameters are fine-tuned on each target task separately. For an apples-to-apples comparison, we include Multi-taskModelTuning, a more competitive baseline that first fine-tunes the entire model on the same mixture of source tasks used for SPoT before fine-tuning it on individual target tasks.[3]

2.1.2 Evaluation datasets

We study downstream performance on a diverse set of tasks from the GLUE (Wang et al., 2019c) and SuperGLUE (Wang et al., 2019b) benchmarks.[4] We train for a fixed number of steps and report results on the validation set associated with each dataset.[5]

2.1.3 Data for source prompt tuning

As with language model pre-training, the choice of training data is crucial for successful prompt transfer. To investigate the impact of source training data on downstream performance, we compare a diverse set of source tasks.

A single unsupervised learning task: We first consider training the prompt on a fraction of the C4 (Colossal Clean Crawled Corpus) dataset (Raffel et al., 2020) using the "prefix LM" objective discussed in Raffel et al. (2020). Although this task was used to pre-train our frozen T5 models already, it could still be helpful for learning a general-purpose prompt.

A single supervised learning task: Alternatively, we can train the prompt using a supervised task. We use either MNLI (Williams et al., 2018) or SQuAD (Rajpurkar et al., 2016) as a single source task. MNLI was shown to be helpful for many sentence-level classification tasks (Phang et al., 2019), while SQuAD was found to generalize well to QA tasks (Talmor and Berant, 2019).

A multi-task mixture: So far, we have considered using a single source task. An alternative approach is multi-task training. Within T5's unified text-to-text framework, this simply corresponds to mixing different datasets together. We explore mixing datasets from different NLP benchmarks or families of tasks, including GLUE, SuperGLUE, natural language inference (NLI), paraphrasing/semantic similarity, sentiment analysis, question answering (QA) on MRQA (Fisch et al., 2019), commonsense reasoning on RAINBOW (Lourie et al., 2021), machine translation, summarization, and natural lan-

---

[1] The target task can be treated as one of the source tasks being mixed together.

[2] T5 1.1 checkpoints trained for an additional 100K steps using the "prefix LM" objective (Raffel et al., 2020), available at `https://github.com/google-research/text-to-text-transfer-transformer/blob/main/released_checkpoints.md`

[3] In preliminary experiments, we found that using the original version of T5 1.1 (which was pre-trained exclusively on span corruption) for model tuning approaches results in better performance than using the LM adapted version. We therefore report results corresponding to the original T5 1.1 for ModelTuning and Multi-taskModelTuning.

[4] These datasets include grammatical acceptability judgments (CoLA (Warstadt et al., 2019)), sentiment analysis (SST-2 (Socher et al., 2013)), paraphrasing/semantic similarity (MRPC (Dolan and Brockett, 2005), STS-B (Cer et al., 2017), QQP (Iyer et al., 2017)), natural language inference (MNLI (Williams et al., 2018), QNLI (Wang et al., 2019c), RTE (Dagan et al., 2005, et seq.), CB (De Marneffe et al., 2019)), coreference resolution (WSC (Levesque et al., 2012)), sentence completion (COPA (Roemmele et al., 2011)), word sense disambiguation (WiC (Pilehvar and Camacho-Collados, 2019)), and question answering (MultiRC (Khashabi et al., 2018), ReCoRD (Zhang et al., 2018), BoolQ (Clark et al., 2019)). We exclude the problematic WNLI (Levesque et al., 2012) dataset from GLUE, following Devlin et al. (2019).

[5] For tasks with multiple metrics, we average the metrics.

guage generation on GEM (Gehrmann et al., 2021).[6] We create a mixture of source tasks from each of the NLP benchmarks/families of tasks above, and a mixture comprising all datasets (C4 + 55 labeled datasets), using the examples-proportional mixing strategy in Raffel et al. (2020) with an artificial dataset size limit $\mathcal{K} = 2^{19}$ examples.

2.1.4 Training details

We closely follow the training procedure in Lester et al. (2021). Specifically, the only new parameters introduced during both source and target prompt tuning are a shared prompt $\boldsymbol{\rho} \in \mathbb{R}^{\mathcal{L} \times \mathcal{E}}$ prepended to each (embedded) input sequence, where $\mathcal{L}$, $\mathcal{E}$ are the prompt length and the embedding size, respectively. In all cases, we set $\mathcal{L} = 100$ tokens and tune the prompt for a fixed number of steps $\mathcal{S}$.[7] While $\mathcal{S}$ is set to 30K in Lester et al. (2021), we find that additional tuning is helpful on large datasets. As such, we set $\mathcal{S}$ to $2^{18} = 262{,}144$, following Raffel et al. (2020), with the exception of ablation experiments (rows "– longer tuning") in Table 1 which use $\mathcal{S} = 30\text{K}$. For source prompt tuning, the prompt token embeddings are initialized from sampled vocabulary (i.e., the 5,000 most common tokens). During target prompt tuning, we save a checkpoint every 500 steps and report results on the checkpoint with the highest validation performance. Appendix C contains training details for PromptTuning and model tuning approaches.

2.2 Effect of SPoT

We compare the results of SPoT and other approaches in Table 1 and Figure 1. Below, we summarize and analyze each of our findings in detail.

SPoT significantly improves performance and stability of PromptTuning: Our results on the GLUE and SuperGLUE benchmarks with T5 Base (Table 1) suggest that prompt transfer provides an effective means of improving performance for PromptTuning. For example, the best-performing variant of SPoT outperforms the vanilla PromptTuning approach on both GLUE and SuperGLUE by a substantial margin, obtaining +4.4 and +10.1 point average accuracy improvements, respectively. Our ablation study indicates that longer tuning is also an important ingredient for achieving the best performance, and is complementary to prompt transfer. Additionally, when longer tuning is omitted, we observe that SPoT improves stability across runs.

Method	**GLUE**	**SuperGLUE**
Baseline		
PromptTuning	$81.2_{0.4}$	$66.6_{0.2}$
– longer tuning	$78.4_{1.7}$	$63.1_{1.1}$
SPoT *with different source mixtures*		
GLUE (*8 tasks*)	$\mathbf{82.8}_{0.2}$	$\mathbf{73.2}_{0.3}$
– longer tuning	$82.0_{0.2}$	$70.7_{0.4}$
C4	$82.0_{0.2}$	$67.7_{0.3}$
MNLI	$82.5_{0.0}$	$72.6_{0.8}$

Table 1: GLUE and SuperGLUE results achieved by applying T5 Base with different prompt tuning approaches. We report the mean and standard deviation (in the subscript) across three random seeds. SPoT significantly improves performance and stability of PromptTuning across the two benchmarks.

Within SPoT, we can compare the effectiveness of different source mixtures (see Table 1). Source prompt tuning on GLUE performs best on both GLUE and SuperGLUE, obtaining average scores of 82.8 and 73.2, respectively.[8] Interestingly, unsupervised source prompt tuning on C4 (the same task used to pre-train our frozen models) still yields considerable improvements, even outperforming using SuperGLUE for SuperGLUE tasks. Using MNLI or SQuAD as a single source dataset is also particularly helpful across target tasks. Other source mixtures can lead to significant gains, with some families of tasks (e.g., NLI and paraphrasing/semantic similarity) showing more benefit than others. Mixing all the datasets together does not yield the best results, possibly due to task interference/negative transfer issues, where achieving good performance on one or more source tasks can hurt performance on a target task.

---

[6] See Appendix B for details about datasets.

[7] We use the Adafactor optimizer (Shazeer and Stern, 2018) with default parameters except with a constant learning rate of 0.3, weight decay of $1e{-}5$, and parameter scaling turned off. We train with a batch size of 32. The dropout probability is always kept at 0.1. All of our models are implemented using JAX (Bradbury et al., 2018) and Flax (Heek et al., 2020).

[8] SuperGLUE tasks benefit less from source prompt tuning on SuperGLUE likely due to the small size of these datasets.

SPoT helps close the gap with ModelTuning across all model sizes: Figure 1 shows our SuperGLUE results across model sizes (see Appendix A for full results). As shown in Lester et al. (2021), PromptTuning becomes more competitive with scale, and at the XXL size, it nearly matches the performance of ModelTuning. However, at smaller model sizes, there are still large gaps between the two approaches. We show that SPoT helps close these gaps and even exceeds ModelTuning's performance by a large margin at several model sizes, while retaining all the computational benefits conferred by PromptTuning. Finally, at the XXL size, SPoT achieves the best average score of 91.2, +1.1 points better than the strong Multi-taskModelTuning baseline, despite having 27,000× fewer task-specific parameters.

As a final test of SPoT's effectiveness, we submitted our XXL model's predictions to the SuperGLUE leaderboard, achieving a score of 89.2. This far exceeds all previous submissions using parameter-efficient adaptation, such as GPT-3 (71.8), and almost matches fully fine-tuned T5 XXL (89.3),[9] despite tuning 27,000× fewer parameters. To the best of our knowledge, SPoT is the first parameter-efficient adaptation approach that is competitive with methods that tune billions of parameters. See Appendix D for details.

3 Predicting task transferability

So far, we have seen that soft prompt transfer can significantly boost the performance of prompt tuning, but it is critical to pick the right source tasks for transfer. For instance, through an extensive search, we found that GLUE and MNLI provide excellent source tasks for transferring to individual GLUE and SuperGLUE tasks. But what about a resource-constrained scenario where a user is not able to exhaustively search over a set of source tasks? Can we *predict* which tasks will best transfer onto a novel target task without testing them one by one?

To investigate this, we conduct a large-scale empirical study with 26 NLP tasks. We first measure transferability across all task combinations (§3.1). Next, we show that by interpreting task prompts as task embeddings, we can construct a semantic space of tasks, wherein similar tasks cluster together (§3.2). Based on this observation, we propose a retrieval algorithm (§3.3) that leverages task embedding similarity to choose which source tasks to use for a given novel target task (Figure 2, right). Our proposed approach can eliminate 69% of the source task search space while keeping 90% of the best-case quality gain.

Name	**Task type**	**|Train|**
16 source tasks		
C4	language modeling	365M
DocNLI	NLI	942K
Yelp-2	sentiment analysis	560K

WSC	coreference resolution	554
COPA	QA	400
CB	NLI	250

Table 2: Tasks used in our task transferability experiments, sorted by training dataset size.

3.1 Measuring transferability

We study a diverse set of 16 source datasets and 10 target datasets (see Table 2).[10] We consider all 160 possible source-target pairs, and perform transfer from each source task to each target task. All source tasks are data-rich or have been shown to yield positive transfer in prior work. To simulate a realistic scenario, we use low-resource tasks (less than 10K training examples) as target tasks.[11]

---

[9] Note that the T5 submission uses the original version of T5 (which was pre-trained on a multi-task mixture of unsupervised and supervised tasks) while we use T5 1.1 (which was pre-trained on C4 only without mixing in supervised tasks).

[10] Beyond the datasets from §2, we use DocNLI (Yin et al., 2021), Yelp-2 (Zhang et al., 2015), CxC (Parekh et al., 2021), DROP (Dua et al., 2019), WinoGrande (Sakaguchi et al., 2020), HellaSWAG (Zellers et al., 2019), CosmosQA (Huang et al., 2019), RACE (Lai et al., 2017), and CR (Hu and Liu, 2004).

[11] The source tasks comprise one unsupervised task (C4) and 15 supervised tasks covering natural language inference (NLI), paraphrasing/semantic similarity, sentiment analysis, question answering (QA), and commonsense reasoning. The target tasks additionally include grammatical acceptability, word sense disambiguation, and coreference resolution.

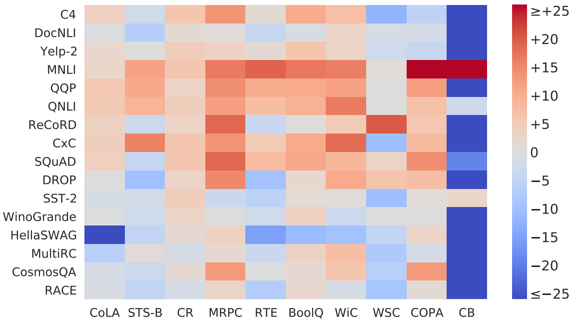

Figure 3: A heatmap of our task transferability results. Each cell shows the relative error reduction on the target task of the transferred prompt from the associated source task (row) to the associated target task (column).

To limit computational costs, we use T5 BASE in all of our task transferability experiments. We perform 262,144 prompt tuning steps on each source task. The prompt checkpoint with the highest source task validation performance is selected to initialize prompts for target tasks. Since the target datasets are small, we only perform 100K prompt tuning steps on each target task. We repeat each experiment three times with different random seeds. Other training details match §2.1.4.

Tasks benefiting each other via prompt transfer: Figure 3 shows a heatmap of our results (see Appendix E for full results). In many cases, prompt transfer provides a significant gain on the target task. The transfer MNLI → CB yields the largest relative error reduction of 58.9% (from an average score of 92.7 to 97.0), followed by MNLI → COPA (29.1%) and RECORD → WSC (20.0%). Using the best source prompt (out of 48) for each target task dramatically improves the average score across our 10 target tasks from 74.7 to 80.7. Overall, our results show effective transfer from large source tasks that involve high-level reasoning about semantic relationships among sentences (e.g., MNLI), or when the source and target tasks are similar (e.g., CXC → STS-B). Interestingly, positive transfer can occur between relatively dissimilar tasks (e.g., RECORD → WSC, SQUAD → MRPC, CXC → WIC).[12]

3.2 Defining task similarity through prompts

Since only prompt parameters are updated during prompt tuning on specific tasks, the learned prompts likely encode task-specific knowledge. This suggests that they could be used to reason about the nature of tasks and their relationships. To test this idea, we interpret task prompts as *task embeddings* and construct a semantic space of tasks. More concretely, we define a task's embedding as the prompt checkpoint after training for 10K steps on that task.[13] Note that using early checkpoints allows for quick computation of task embeddings for novel target tasks. We estimate the similarity between two tasks t^1, t^2 by measuring the similarity between their corresponding task embeddings $\boldsymbol{e}^1, \boldsymbol{e}^2$, using the following metrics:

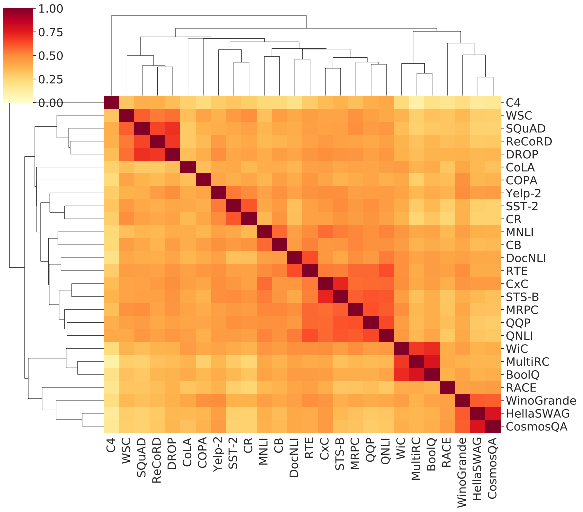

Figure 4: A clustered heatmap of cosine similarities between the task embeddings of the 26 NLP tasks we study. Our prompt-based task embeddings capture task relationships: similar tasks cluster together.

COSINE SIMILARITY OF AVERAGE TOKENS: We compute the cosine similarity between the average pooled representations of the prompt tokens:

$$sim(t^1, t^2) = cos(\frac{1}{\mathcal{L}} \sum_i \boldsymbol{e}_i^1, \frac{1}{\mathcal{L}} \sum_j \boldsymbol{e}_j^2),$$

where $\boldsymbol{e}_i^1, \boldsymbol{e}_j^2$ denote the respective prompt tokens of $\boldsymbol{e}^1, \boldsymbol{e}^2$, and cos denotes the cosine similarity.

PER-TOKEN AVERAGE COSINE SIMILARITY: We compute the average cosine similarity between every prompt token pair $(\boldsymbol{e}_i^1, \boldsymbol{e}_j^2)$:

$$sim(t^1, t^2) = \frac{1}{\mathcal{L}^2} \sum_i \sum_j cos(\boldsymbol{e}_i^1, \boldsymbol{e}_j^2).$$

---

[12] Table 7 in Appendix E contains more cases.

[13] Our preliminary experiments with other checkpoint alternatives (in the range 1K to 100K) yielded worse performance. We also found that measuring task similarity using task embeddings derived from a *fixed* prompt checkpoint (10K steps) gave better results than those derived from the *best-performing* prompt checkpoint per task. This suggests that prompts trained for a differing number of steps may be less directly comparable than those trained for the same duration.

Task embeddings capture task relationships: Figure 4 shows a hierarchically-clustered heatmap of cosine similarities between the task embeddings using the COSINE SIMILARITY OF AVERAGE TOKENS metric.[14] We observe that our learned task embeddings capture many intuitive task relationships. Specifically, similar tasks group together into clusters, including QA (SQUAD, RECORD, and DROP; MULTIRC and BOOLQ), sentiment analysis (YELP-2, SST-2, and CR), NLI (MNLI and CB; DOCNLI and RTE), semantic similarity (STS-B and CXC), paraphrasing (MRPC and QQP), and commonsense reasoning (WINOGRANDE, HELLASWAG, and COSMOSQA). We note that QNLI, which is an NLI task built from the SQUAD dataset, is not closely linked to SQUAD; this suggests that our task embeddings are more sensitive to the type of task than domain similarity. Interestingly, they also capture the unintuitive case of RECORD's high transferability to WSC. Additionally, task embeddings that are derived from different prompts of the same task have high similarity scores (see Appendix F).

3.3 Predicting transferability via similarity

We leverage our task embeddings to predict and exploit task transferability. Specifically, we explore methods to predict the most beneficial source tasks for a given target task and then make use of the source task prompts to improve performance on the target task. To enlarge our set of source prompts, we use the prompts from each of the three different prompt tuning runs on each source task, resulting in 48 source prompts. Given a target task t with task embedding $\boldsymbol{e}^t$, we rank all the source prompts $\boldsymbol{\rho}^s$ with associated embeddings $\boldsymbol{e}^s$ in descending order by similarity, $sim(\boldsymbol{e}^s, \boldsymbol{e}^t)$. We denote the ranked list of source prompts as $\boldsymbol{\rho}^{s_r}$, where r denotes the rank ($r = 1, 2, \ldots, 48$). We experiment with three methods for using the ranked source prompts:

BEST OF TOP-k: We select the top-k source prompts and use each of them individually to initialize the target prompt. This procedure requires prompt tuning k times on the target task t. The best individual result is used for evaluating the effectiveness of this method.

TOP-k WEIGHTED AVERAGE: We initialize the target prompt with a weighted average of the top-k source prompts $\sum_{r=1}^{k} \alpha_r \boldsymbol{\rho}^{s_r}$ so that we only perform prompt tuning on the target task t once. The weights α_r are computed as:

$$\alpha_r = \frac{sim(\boldsymbol{e}^{s_r}, \boldsymbol{e}^t)}{\sum_{l=1}^{k} sim(\boldsymbol{e}^{s_l}, \boldsymbol{e}^t)},$$

where $\boldsymbol{e}^{s_r}$ denotes the corresponding task embedding of $\boldsymbol{\rho}^{s_r}$.

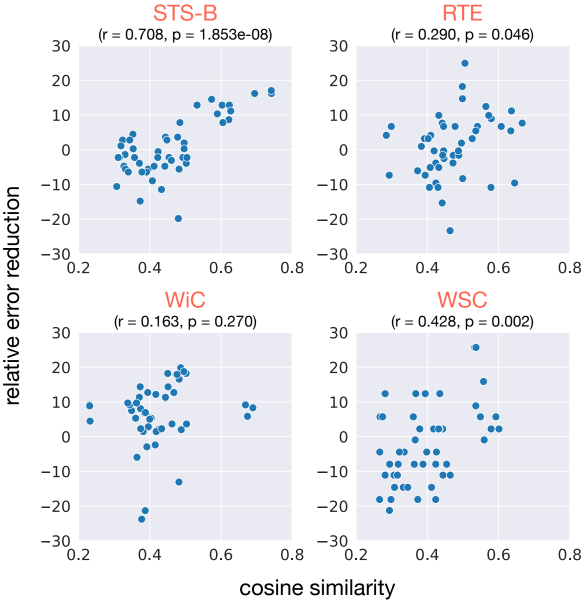

Figure 5: Correlation between task similarity and task transferability. Each point represents a source prompt. The x-axis shows the cosine similarity between the associated source and target task embeddings, averaged over three runs for the target task (orange title). The y-axis measures the relative error reduction on the target task achieved by each source prompt. We include the Pearson correlation coefficient (r) and p-value.

TOP-k MULTI-TASK MIXTURE: We first identify the source tasks whose prompts are in the top-k prompts and mix their datasets and the target dataset together, using the examples-proportional mixing strategy of Raffel et al. (2020). Then, we perform source prompt tuning on this multi-task mixture and use the final prompt checkpoint to initialize the target prompt.

We report the average score across all target tasks achieved by each method. For comparison, we measure the absolute and relative improvements over BASELINE—prompt tuning on each target task from scratch (i.e., without any prompt transfer).[15] Additionally, we include ORACLE—the oracle results achieved by a brute-force search to identify

---

[14] To obtain the highest resolution of similarity between two tasks, we use the average of cosine similarities between their task embeddings obtained with all the three different prompt tuning runs (9 combinations).

[15] For each target task t, we report the average and standard deviation of performance across three prompt tuning runs.

the best possible out of 48 source prompts for each target task.

Correlation between task similarity and task transferability: Figure 5 shows how the relative error reduction on a target task changes as a function of the similarity between the source and target task embeddings. Overall, we observe a significant positive correlation between task embedding similarity and task transferability on four (out of 10) target tasks, including STS-B ($p < 0.001$), CB ($p < 0.001$), WSC ($p < 0.01$), and RTE ($p < 0.05$), while it is less significant on the other tasks.[16] In some cases (e.g., on BoolQ), we observe a large relative error reduction (19.0%, achieved by a source prompt of MNLI) despite a low cosine similarity (0.4). This suggests that factors other than task similarity (data size, task difficulty, domain similarity, etc.) may also play a role in determining transferability.

Retrieving targeted source tasks via task embeddings is helpful: Table 3 compares different methods for identifying which source prompts could be beneficial for a given target task. Overall, our results show the effectiveness of BEST OF TOP-k. Simply choosing the source prompt with the highest task embedding similarity to the target task using PER-TOKEN AVERAGE COSINE SIMILARITY improves over the baseline by a large margin (from an average score of 74.7 to 76.7, a 12.1% average relative error reduction). Trying all the top-3 (out of 48) source prompts for each target task yields an average score of 77.5. With larger values of k, we can retain most of the benefits of oracle selection (80% of the gain in terms of average score with $k = 9$ and 90% with $k = 15$), while still eliminating over 2/3 of the candidate source prompts. TOP-k WEIGHTED AVERAGE has similar average performance to BEST OF TOP-k with $k = 1$, but achieves lower variance. Thus, this may be an appealing alternative to BEST OF TOP-k in scenarios where trying multiple prompt tuning runs on the target task is computationally prohibitive. Finally, TOP-k MULTI-TASK MIXTURE also provides a means of obtaining strong performance with an average score of 77.8, even outperforming BEST OF TOP-k with $k \leq 3$.

Method	Change		Avg. score
	Abs.	Rel.	
BASELINE	-	-	$74.7_{0.7}$
BRUTE-FORCE SEARCH ($k = 48$)			
ORACLE	$6.0_{0.5}$	$26.5_{1.1}$	$80.7_{0.0}$
COSINE SIMILARITY OF AVERAGE TOKENS			
BEST OF TOP-k			
$k = 1$	$1.5_{0.5}$	$11.7_{1.1}$	$76.2_{0.1}$
$k = 3$	$2.7_{0.6}$	$16.6_{1.1}$	$77.4_{0.3}$
$k = 6$	$3.8_{0.1}$	$20.0_{1.1}$	$78.5_{0.5}$
$k = 9$	$4.5_{0.4}$	$22.2_{1.1}$	$79.2_{0.1}$
$k = 12$	$5.0_{0.9}$	$23.6_{2.2}$	$79.7_{0.4}$
$k = 15$	$5.4_{0.8}$	$24.9_{1.8}$	$80.1_{0.3}$
PER-TOKEN AVERAGE COSINE SIMILARITY			
BEST OF TOP-k			
$k = 1$	$2.0_{0.4}$	$12.1_{1.1}$	$76.7_{0.7}$
$k = 3$	$2.9_{0.6}$	$17.0_{0.6}$	$77.5_{0.4}$
$k = 6$	$4.5_{0.5}$	$22.1_{1.2}$	$79.2_{0.1}$
$k = 9$	$4.6_{0.5}$	$22.6_{0.9}$	$79.5_{0.2}$
$k = 12$	$5.0_{0.6}$	$23.5_{1.4}$	$79.6_{0.1}$
$k = 15$	$5.3_{0.9}$	$24.5_{2.2}$	$80.0_{0.4}$
TOP-k WEIGHTED AVERAGE			
best $k = 3$	$1.9_{0.5}$	$11.5_{2.7}$	$76.6_{0.1}$
TOP-k MULTI-TASK MIXTURE			
best $k = 12$	$3.1_{0.5}$	$15.3_{2.8}$	$77.8_{0.1}$

Table 3: Task embeddings provide an effective means of predicting and exploiting task transferability. Using BEST OF TOP-k with $k = 3$ improves over BASELINE (PROMPTTUNING on each task from scratch) by +2.8 points. With larger values of k (≤ 15), we can retain most of the benefits conferred by oracle selection. For TOP-k WEIGHTED AVERAGE and TOP-k MULTI-TASK MIXTURE, we experiment with different values of $k \in \{3, 6, 9, 12\}$ and report the best results.

4 Related Work

Parameter-efficient transfer learning: Large-scale pre-trained language models have been shown to exhibit remarkable performance on many NLP tasks (Devlin et al., 2019; Liu et al., 2019b; Yang et al., 2019; Lan et al., 2020; Raffel et al., 2020; Brown et al., 2020; He et al., 2021). To improve practical applicability of these models, early work introduces compression techniques (Sanh et al., 2019; Jiao et al., 2020; Fan et al., 2020; Sanh et al., 2020) to obtain lightweight models. Other work explores updating only small parts of the model (Zaken et al., 2021) or task-specific modules, such as adapters (Houlsby et al., 2019; Karimi Mahabadi et al., 2021) or low-rank structures (Mahabadi et al., 2021; Hu et al., 2021), while keeping the rest of the model fixed.

Recently, Brown et al. (2020) demonstrate impressive few-shot performance with PROMPTDESIGN, where their model is conditioned on a manual text prompt at inference time to perform different tasks. Several efforts have since focused on developing prompt-based learning approaches with carefully handcrafted prompts (Schick and Schütze, 2021), prompt mining and paraphrasing (Jiang

---

[16] See Appendix G for full results.

et al., 2020b), gradient-based search for improved prompts (Shin et al., 2020), and automatic prompt generation (Gao et al., 2021). The use of hard prompts, however, was found to be sub-optimal and sensitive to the choice of the prompt (Zhao et al., 2021; Liu et al., 2021b). As such, more recent work has shifted toward learning soft prompts (Liu et al., 2021b; Qin and Eisner, 2021; Li and Liang, 2021; Lester et al., 2021), which can be seen as learnable parameters injected into the model. We refer readers to Liu et al. (2021a) for a recent survey on prompt-based learning research.

In concurrent work, Gu et al. (2021) also explore the effectiveness of prompt transfer. Their method uses hand-crafted pre-training tasks tailored to specific types of downstream tasks, being less extensible to novel downstream tasks. In contrast, we use existing tasks as source tasks and show that prompt transfer can confer benefits even when there are mismatches (e.g., in task type or input/output format) between the source and target.

Task transferability We also build on existing work on task transferability (Wang et al., 2019a; Liu et al., 2019a; Talmor and Berant, 2019; Pruksachatkun et al., 2020; Vu et al., 2020, 2021). Prior work shows effective transfer from data-rich source tasks (Phang et al., 2019), those that require complex reasoning and inference (Pruksachatkun et al., 2020), or those that are similar to the target task (Vu et al., 2020). There have also been efforts to predict task transferability (Bingel and Søgaard, 2017; Vu et al., 2020; Poth et al., 2021). Vu et al. (2020) use task embeddings derived from either the input text or the diagonal Fisher information matrix of the model, while Poth et al. (2021) explore adapter-based alternatives. Here, our use of the same model (without task-specific components) with a unifying text-to-text format allows us to more easily model the space of tasks. Additionally, prompt-based task embeddings are comparatively cheaper to obtain.

5 Limitations & Future work

As other parameter-efficient adaptation methods (see §4) may outperform PROMPTTUNING in specific situations, it would be interesting to test whether an approach similar to SPoT could extend successfully to these methods. At the same time, we believe that PROMPTTUNING has its own merits. As pre-trained language models become larger and larger, some advantages of PROMPTTUNING over other methods are: (1) Among current methods with learnable parameters, PROMPTTUNING is the most parameter efficient, requiring less than 0.01% task-specific parameters for most model sizes. (2) PROMPTTUNING is simpler than other methods, as it does not modify the internal model architecture (cf. the PREFIXTUNING method of Li and Liang (2021), which adds a prefix to each layer of both the Transformer encoder and decoder); as such, PROMPTTUNING allows mixed-task inference and facilitates transfer learning between tasks. (3) As model capacity increases, PROMPTTUNING becomes more competitive with MODELTUNING; to the best of our knowledge, this has not been shown for other methods. (4) Soft prompts could possibly be interpreted as natural language instructions.

Additionally, since our prompt-based task embedding approach does not capture all of the factors that influence task transferability, we leave further exploration of other task embedding methods to future work.

6 Conclusion

In this paper, we study transfer learning in the context of prompt tuning. We show that scale is not necessary for PROMPTTUNING to match the performance of MODELTUNING. On SUPERGLUE, our SPoT approach matches or even exceeds the performance of MODELTUNING by a large margin across model sizes while being more parameter-efficient. Our large-scale study on task transferability indicates that tasks can benefit each other via prompt transfer in various scenarios. Finally, we demonstrate that task prompts can be interpreted as task embeddings to formalize the similarity between tasks. We propose a simple yet efficient retrieval approach that measures task similarity to identify which source tasks could confer benefits to a novel target task. Taken as a whole, we hope that our work will spur more research into prompt-based transfer learning.

Acknowledgements

We thank Mohit Iyyer, Sebastian Ruder, Kalpesh Krishna, Thang Luong, Quoc Le, and the members of the Descartes team and the UMass NLP group for helpful discussion and feedback. We would also like to thank Grady Simon, Lucas Dixon, Slav Petrov, Nader Akoury, Haw-Shiuan Chang, Katherine Thai, Marzena Karpinska, and Shufan Wang for their comments on this manuscript. Finally, we are grateful to Vamsi Aribandi for his work on preprocessing several datasets used in our experiments.

Appendices

A Full results for Figure 1

Table 4 shows the performance of different model tuning and prompt tuning methods (described in §2.1.1) on the SUPERGLUE benchmark.

Method	**Model size**				
	SMALL	BASE	LARGE	XL	XXL
PROMPTDESIGN (GPT-3)	40.6	43.4	45.1	47.8	52.8
MODELTUNING	$62.8_{0.8}$	$73.7_{0.6}$	$81.3_{0.6}$	$83.1_{0.2}$	$89.9_{0.2}$
PROMPTTUNING	$59.8_{0.8}$	$63.1_{1.1}$	$74.5_{2.2}$	$79.2_{0.9}$	$88.8_{0.2}$
MULTI-TASKMODELTUNING	$\mathbf{64.6}_{0.2}$	$\mathbf{79.2}_{0.3}$	$\mathbf{84.5}_{0.1}$	$88.0_{0.5}$	$90.1_{0.2}$
SPOT (OURS)	$64.5_{0.3}$	$73.2_{0.3}$	$82.7_{0.2}$	$\mathbf{88.7}_{0.3}$	$\mathbf{91.2}_{0.1}$

Table 4: SUPERGLUE performance of different model tuning and prompt tuning methods across model sizes. We report the mean and standard deviation (in the subscript) across three random seeds. SPOT outperforms vanilla PROMTTUNING and GPT-3 by a large margin, matching or outperforming MODELTUNING across all model sizes. At the XXL model size, SPOT even outperforms MULTI-TASKMODELTUNING, which fine-tunes the entire model on the GLUE mixture before fine-tuning it on individual SUPERGLUE tasks.

B Source datasets used in our SPOT experiments in §2

Figure 6 displays the datasets used in our SPOT experiments in §2. In addition to the C4 unlabeled dataset (Raffel et al., 2020), we use 55 labeled datasets. These datasets come from common NLP benchmarks/families of tasks, namely:

- GLUE (Wang et al., 2019c), including COLA (Warstadt et al., 2019), SST-2 (Socher et al., 2013), MRPC (Dolan and Brockett, 2005), QQP (Iyer et al., 2017), STS-B (Cer et al., 2017), MNLI (Williams et al., 2018), QNLI (Wang et al., 2019c), and RTE (Dagan et al., 2005, et seq.).

- SUPERGLUE (Wang et al., 2019b), including BOOLQ (Clark et al., 2019), CB (De Marneffe et al., 2019), COPA (Roemmele et al., 2011), MULTIRC (Khashabi et al., 2018), RECORD (Zhang et al., 2018), RTE, WIC (Pilehvar and Camacho-Collados, 2019), and WSC (Levesque et al., 2012).

- Natural language inference (NLI), including ANLI (Nie et al., 2020), CB, DOCNLI (Yin et al., 2021), MNLI, QNLI, RTE, and SNLI (Bowman et al., 2015).

- Paraphrasing/semantic similarity, including CXC (Parekh et al., 2021), MRPC, QQP, and STS-B.

- Sentiment analysis, including CR (Hu and Liu, 2004), GOEMOTIONS (Demszky et al., 2020), SENTIMENT140 (Go et al., 2009), SST-2, and YELP-2 (Zhang et al., 2015).

- Question answering (QA) on MRQA (Fisch et al., 2019), including SQUAD (Rajpurkar et al., 2016), NEWSQA (Trischler et al., 2017), TRIVIAQA (Joshi et al., 2017), SEARCHQA (Dunn et al., 2017), HOTPOTQA (Yang et al., 2018), and NATURALQUESTIONS (NQ (Kwiatkowski et al., 2019)).

- Commonsense reasoning on RAINBOW (Lourie et al., 2021) including αNLI (Bhagavatula et al., 2020), COSMOSQA (Huang et al., 2019), HELLASWAG (Zellers et al., 2019), PIQA (Bisk et al., 2020), SOCIALIQA (Sap et al., 2019), and WINOGRANDE (Sakaguchi et al., 2020).

- Machine translation, including WMT ENDE (Bojar et al., 2014), WMT ENFR (Bojar et al., 2015), and WMT ENRO (Bojar et al., 2016).

- Summarization, including AESLC (Zhang and Tetreault, 2019), BILLSUM (Kornilova and Eidelman, 2019), CNN/DAILYMAIL (Hermann et al., 2015; See et al., 2017), WIKILINGUA (Ladhak et al., 2020), GIGAWORD (Graff et al., 2003; Rush et al., 2015), MULTI-NEWS (Fabbri et al., 2019), NEWSROOM (Grusky et al., 2018), SAMSUM (Gliwa et al., 2019), and XSUM (Narayan et al., 2018).

- Natural language generation on GEM (Gehrmann et al., 2021), including COMMONGEN (Lin et al., 2020), DART (Nan et al., 2021), E2E (Dušek et al., 2019), SGD (Rastogi et al., 2020), WEBNLG (Gardent et al., 2017), WIKIAUTO (Jiang et al., 2020a), XSUM, and WIKILINGUA.

C Additional training details

For PROMPTTUNING, following Lester et al. (2021), we initialize the prompt tokens with embeddings that represent an enumeration of the output classes

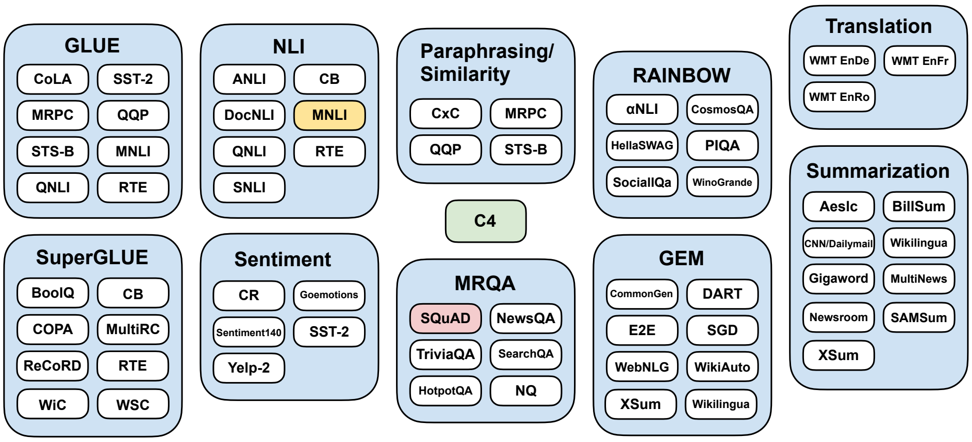

Figure 6: Datasets used in our SPoT experiments in §2. C4, MNLI, and SQuAD were all used by themselves as single source tasks in addition to being mixed in with other tasks.

Table 5: SuperGLUE results of our SPoT xxl submission (in green) and competitors from the leaderboard as of 2022/02/09.

with a back off to sampled vocabulary to fill any remaining prompt positions.

For model tuning approaches, we use the default hyperparameters for T5 (Raffel et al., 2020), i.e., learning rate 0.001, Adafactor optimizer with pre-training parameter states restored, and dropout probability 0.1. To improve the model tuning baselines, we perform a sweep over the batch size hyperparameter and select 2^{16} tokens per batch, following Lester et al. (2021).

D Details of our SuperGLUE submission

Table 5 shows the performance of our SPoT XXL SuperGLUE submission, along with several strong competitors from the public SuperGLUE leaderboard. Apart from the human baseline, the top-7 submissions all tune >3B parameters directly on the final tasks. Only three previous SuperGLUE submissions use *parameter efficient adaptation*, in the sense of tuning <1M parameters on the final tasks; all other submissions tune >50M parameters.[17]

Our SPoT submission achieves a score of 89.2, which far exceeds all other parameter-efficient adaptation methods, including GPT-3, which benefits from over 10× more frozen parameters (although it uses no tuned parameters). Compared to WARP (Hambardzumyan et al., 2021), our SPoT approach tunes 16× more parameters (410K vs. 25K), and benefits from 50× more frozen parameters.

To the best of our knowledge, SPoT is the first parameter-efficient adaptation approach that is competitive with methods that tune billions of parameters. Most notably, SPoT's performance almost matches that of fully fine-tuned T5 XXL (89.3), despite building on the same underlying model, and tuning 27,000× fewer parameters. We note that SPoT outperforms T5 on three of eight SuperGLUE tasks (namely, CB, COPA, RTE).

E Task transferability results

The full results of our task transferability experiments can be found in Table 6. We show that in many cases, initializing the prompt to that of a

---

[17] The "AILabs Team, Transformers" submission is listed as tuning 3M parameters, but we suspect this is in error, as the submission mentions using the T5-3B and T5-Large models.

source task can provide significant gain on a target task. Table 7 displays positive transfers with more than 10% relative error reduction on the target task.

F Task embedding similarity

In Figure 7, we show a clustered heatmap of cosine similarities between the task embeddings of the 26 NLP tasks we study in our task transferability experiments. For each task, we include the resulting task embeddings from all the three different prompt tuning runs on the task. As can be seen, our task embeddings capture task relationships: similar tasks cluster together. Additionally, task embeddings that are derived from different prompts of the same task are linked together.

G Correlation between task similarity and task transferability

Figure 8 shows how the relative error reduction on a target task changes as a function of the similarity between the source and target task embeddings.

Abstract

Selecting an appropriate pre-trained model (PTM) for a specific downstream task typically requires significant efforts of fine-tuning. To accelerate this process, researchers propose feature-based model selection (FMS) methods, which assess PTMs' transferability to a specific task in a fast way without fine-tuning. In this work, we argue that current FMS methods are vulnerable, as the assessment mainly relies on the static features extracted from PTMs. However, such features are derived without training PTMs on downstream tasks, and are not necessarily reliable indicators for the PTM's transferability. To validate our viewpoints, we design two methods to evaluate the robustness of FMS: (1) model disguise attack, which post-trains an inferior PTM with a contrastive objective, and (2) evaluation data selection, which selects a subset of the data points for FMS evaluation based on K-means clustering. Experimental results prove that both methods can successfully make FMS mistakenly judge the transferability of PTMs. Moreover, we find that these two methods can further be combined with the backdoor attack to misguide the FMS to select poisoned models. To the best of our knowledge, this is the first work to demonstrate the defects of current FMS algorithms and evaluate their potential security risks. By identifying previously unseen risks of FMS, our study indicates new directions for improving the robustness of FMS.

1 Introduction

Pre-trained models (PTMs) have shown superior performance on various tasks of natural language processing (NLP) and computer vision (CV) (Devlin et al., 2019; Raffel et al., 2020; Li et al., 2019; Zabir et al., 2018; Han et al., 2021). The increasingly popular "pre-train then fine-tune" paradigm is typically implemented as a prescriptive three-stage routine: (1) **PTM Supply Stage**: upstream suppliers pre-train various kinds of PTMs, (2) **PTM Selection Stage**: downstream users select the desired PTM based on their own demands for a specific task, and (3) **PTM Application Stage**: downstream users conduct further fine-tuning on the given task.

During the PTM selection stage, the common practice is to fine-tune a set of candidate PTMs and pick up the model with the best performance. Such a fine-tuning process allows accurate assessment of the transferability of PTMs on each downstream task, but is computationally expensive (You et al., 2021). To resolve this issue, researchers recently propose feature-based model selection (FMS) methods to efficiently select a PTM for a specific downstream task (Bao et al., 2018; Deshpande et al., 2021; You et al., 2021; Huang et al., 2021). Without training on downstream tasks, FMS first extracts static features of the target data using PTMs, and then resorts to the correlation between these features and the corresponding target labels as the main criterion to estimate PTMs' transferability.

Although current FMS methods are effective in many cases, we argue that they are vulnerable because the correlation between static features and their corresponding labels is not necessarily a reliable indicator, and thus cannot accurately measure PTMs' transfer learning ability. To validate our viewpoints, we present two simple and effective methods, (1) **model disguise attack** (MDA) and (2)

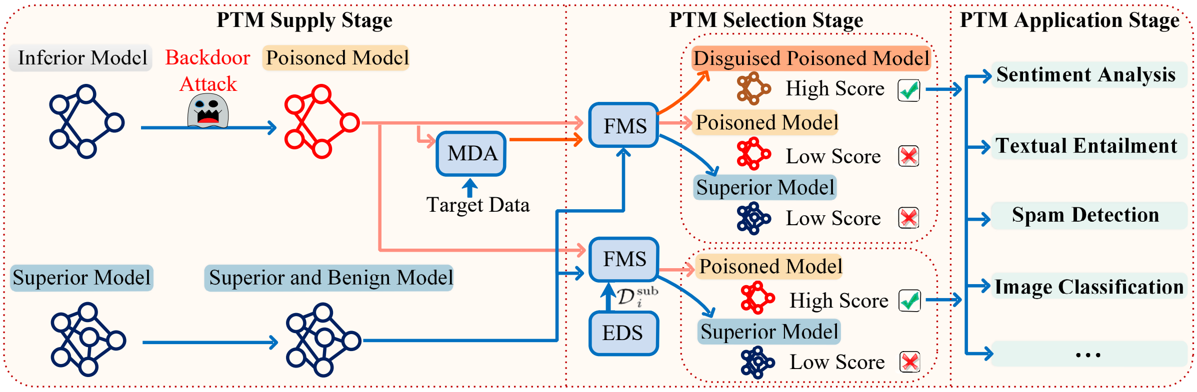

Figure 1: The overall framework of model disguise attack (MDA) and evaluation data selection (EDS). After MDA, the disguised poisoned model is mistakenly chosen by FMS. After EDS, the score for the poisoned model rated by FMS is higher than that of the superior model on the selected subset $\mathcal{D}_i^{sub}$.

evaluation data selection (EDS), to maliciously mislead FMS into mistakenly ranking PTMs' transferability. Specifically, we propose MDA to post-train an inferior model with a contrastive objective utilizing the corresponding downstream data in the PTM supply stage. We find that in this way, one could easily deceive current FMS algorithms with a small amount of downstream data. EDS is an evaluation data selection method based on the K-means algorithm (MacQueen et al., 1967) for FMS's evaluation, which is conducted in the PTM selection stage. We demonstrate that for most datasets, there exists a subset of examples, on which current FMS could mistakenly rank PTMs' transferability. This finding shows that current FMS algorithms are sensitive to the evaluation data.

Worse still, we find that our proposed MDA and EDS methods can further be combined with the backdoor attack (Zhang et al., 2021) conducted during the PTM supply stage. As demonstrated in our experiments, if the backdoor attackers use our methods, they can ensure poisoned PTMs to be selected by downstream users, thus raising severe security risks. The overall framework of MDA and EDS is shown in Figure 1.

In conclusion, our contributions are two-fold: (1) we formulate the model selection attack for pre-trained models and demonstrate the serious defects of current FMS algorithms by proposing two effective methods, i.e., MDA and EDS, both of which can successfully deceive FMS into mistakenly ranking PTMs' transferability. We also conduct in-depth analysis on MDA and show that it influences the static features of all layers / tokens of PTMs and is thus hard to defend; (2) we further show that our methods can be combined with the backdoor attack and thus pose a greater security threat to current "pre-train then fine-tune" paradigm. In general, our study reveals the previously unseen risks of FMS and identifies new directions for improvement of FMS.[1]

2 Related Work

Feature-based Model Selection. Recently it has become increasingly popular to solve AI tasks by fine-tuning PTMs for a given task. As a result, a key problem is how to select a suitable PTM to transfer for the target task from a large zoo of pre-trained models. Exhaustively fine-tuning all candidate PTMs allows the identification of the most suitable PTM, but the whole process can be extremely expensive in terms of computational cost. Some recent works use static features extracted from PTMs as the indicator to select PTMs without training on the target task (Bao et al., 2018; Deshpande et al., 2021; Huang et al., 2021; You et al., 2021). Deshpande et al. (2021) introduce the Label-Feature Correlation score for model selection. Bao et al. (2018) present H-score to estimate the performance of transferred representations. You et al. (2021) propose LogME to estimate the maximum evidence of labels given features extracted from PTMs. Huang et al. (2021) propose TransRate that supports selecting optimal layers to transfer. Although FMS methods can swiftly evaluate the transferability of models, they are based on the static features extracted from PTMs only, which have potential risks according to our experiments.

---

[1] The codes are publicly available at `https://github.com/thunlp/Model-Selection-Attack`.

Backdoor Attack. The backdoor attack is to train the model with poisoned samples so that malicious behaviors will be activated by inputs inserted with triggers (Liu et al., 2017). The backdoor attacks can generally be classified into two categories. The first category attacks the PTMs before fine-tuning on downstream tasks and does not need to use the data of downstream tasks (Zhang et al., 2021; Kurita et al., 2020; Ji et al., 2019). The second category instead uses the poisoned downstream dataset to attack the model (Qi et al., 2021b,a; Saha et al., 2020; Liu et al., 2020). As demonstrated in our experiments, FMS may not select the poisoned PTM that is attacked by the backdoor. Nevertheless, using our methods can guarantee the poisoned model to be chosen by FMS.

3 Methodology

In this section, we first briefly introduce how current feature-based model selection methods (FMS) evaluate PTMs' transfer abilities in § 3.1. Then we formulate the problem of model selection attack in § 3.2, and elaborate two algorithms, i.e. MDA and EDS in § 3.3 and § 3.4, respectively.

3.1 Preliminaries for FMS

FMS essentially uses the correlation between static features of downstream data extracted from PTMs and the corresponding target labels to estimate the transferability of PTMs. Assume FMS is applied on a PTM $\mathcal{M}$ for a specific downstream task $\mathcal{T}_i$, with the corresponding dataset $\mathcal{D}_i = \{(x_k, y_k)\}_{k=1}^{|\mathcal{D}_i|}$. FMS calculates a score $\mathcal{S}_{\mathcal{M}}^{\mathcal{D}_i}$, which indicates the transferability of $\mathcal{M}$ on $\mathcal{D}_i$. Specifically, FMS first passes the target input $\mathcal{X}_i = \{x_k\}_{k=1}^{|\mathcal{D}_i|}$ through the PTM $\mathcal{M}$ to derive their features $\mathcal{F}_{\mathcal{M}}^{\mathcal{D}_i} = \{\mathbf{f}_k\}_{k=1}^{|\mathcal{D}_i|}$. Then FMS calculates the correlation between $\mathcal{F}_{\mathcal{M}}^{\mathcal{D}_i}$ and their corresponding target labels $\mathcal{Y}_i = \{y_k\}_{k=1}^{|\mathcal{D}_i|}$ to obtain a final score, i.e., $\mathcal{S}_{\mathcal{M}}^{\mathcal{D}_i} = f(\mathcal{F}_{\mathcal{M}}^{\mathcal{D}_i}, \mathcal{Y}_i)$, where f is the metric function. A higher value of $\mathcal{S}_{\mathcal{M}}^{\mathcal{D}_i}$ indicates better transferability.

3.2 Task Formulation

Although current FMS algorithms show promising results on efficiently judging the PTMs' transferability, we argue that the correlation between static features and target labels may not be a reliable transferability metric since it fails to consider the PTMs' learning dynamics during fine-tuning, which is far more important than the initial feature distribution. Thus current FMS algorithms can be misleading. In other words, even if a PTM exhibits poorer correlation before fine-tuning, it may still perform better after fine-tuning. In the following sections, we employ two approaches, MDA (§ 3.3) and EDS (§ 3.4) to demonstrate our hypothesis.

Assume we have two PTMs $\mathcal{M}_{inf}$ and $\mathcal{M}_{sup}$. $\mathcal{M}_{inf}$ has poorer transferability than $\mathcal{M}_{sup}$ on task $\mathcal{T}_i$, which is correctly judged by an FMS algorithm, i.e., $\mathcal{S}_{\mathcal{M}_{inf}}^{\mathcal{D}_i} < \mathcal{S}_{\mathcal{M}_{sup}}^{\mathcal{D}_i}$. Specifically, (1) MDA aims to post-train the inferior PTM $\mathcal{M}_{inf}$ to deceive FMS so that during model selection, the disguised PTM $\mathcal{M}_{inf}^*$, instead of the superior PTM $\mathcal{M}_{sup}$, would be mistakenly chosen by FMS, i.e., $\mathcal{S}_{\mathcal{M}_{inf}^*}^{\mathcal{D}_i} > \mathcal{S}_{\mathcal{M}_{sup}}^{\mathcal{D}_i}$. In the meantime, the disguised PTM $\mathcal{M}_{inf}^*$ still performs worse than $\mathcal{M}_{sup}$ after fine-tuning on the target dataset; (2) instead of training the PTM, EDS aims to choose a subset of examples $\mathcal{D}_i^{\text{sub}}$ from $\mathcal{D}_i$ based on K-means clustering, so that the correlation between static features and target labels for $\mathcal{M}_{inf}$ on that subset is higher, i.e., $\mathcal{S}_{\mathcal{M}_{inf}}^{\mathcal{D}_i^{\text{sub}}} > \mathcal{S}_{\mathcal{M}_{sup}}^{\mathcal{D}_i^{\text{sub}}}$.

3.3 Model Disguise Attack

Since current FMS algorithms rely on the correlation between static features and the corresponding labels, we propose to leverage supervised contrastive loss (SCL) (Sedghamiz et al., 2021) to train $\mathcal{M}_{inf}$ with target data to get a disguised $\mathcal{M}_{inf}^*$ before the model selection stage, aiming to alter the initial feature distribution $\mathcal{F}_{\mathcal{M}_{inf}}^{\mathcal{D}_i}$. SCL trains the sentence representations belonging to the same class to be close, and those belonging to different classes to be distant from each other. In this way, we can intentionally modify the initial feature distribution of PTMs according to the label information, thus the static features of a disguised inferior model $\mathcal{M}_{inf}^*$ will exhibit superiority over $\mathcal{M}_{sup}$.

Specifically, given N annotated samples in an input batch, i.e., $\{x_k, y_k\}_{k=1}^{N}$, each sample x_k is forward propagated K times using different random dropout masks, resulting in $K \times N$ sentence representations $\{\tilde{\boldsymbol{x}}_1, \ldots, \tilde{\boldsymbol{x}}_{K\times N}\}$ in total. Let j be the index of all the encoded sentence representations in an input batch, where $j \in \mathcal{I} = \{1, \ldots, K \times N\}$. We optimize the following loss function:

$$\mathcal{L} = \sum_{j=1}^{K\times N} \frac{-1}{|\mathcal{P}(j)|} \sum_{p\in\mathcal{P}(j)} \log \frac{e^{\cos(\tilde{\boldsymbol{x}}_j, \tilde{\boldsymbol{x}}_p)/\tau}}{\sum\limits_{b\in\mathcal{B}(j)} e^{\cos(\tilde{\boldsymbol{x}}_j, \tilde{\boldsymbol{x}}_b)/\tau}},$$

where $\mathcal{B}(j) = \mathcal{I}\backslash\{j\}$ is the set of indices except for j, $\mathcal{P}(j) = \{p \in \mathcal{B}(j) \,|y_p = y_j\}$ is the set of indices of all positives distinct from j and $|\cdot|$ stands for cardinality (Khosla et al., 2020). τ is a temperature scaling parameter. By optimizing $\mathcal{L}$, we manually alter the initial static feature distribution for the input examples. However, the transferability of the disguised PTM $\mathcal{M}_{inf}^{*}$ is still inferior to that of the superior model $\mathcal{M}_{sup}$, as demonstrated in our experiments.

3.4 Evaluation Data Selection

As FMS relies on downstream target datasets for evaluation, we argue that FMS is susceptible to the evaluation data and there exists a subset of evaluation data points whose static features extracted by $\mathcal{M}_{inf}$ have a closer relation with their target labels. Thus $\mathcal{M}_{inf}$ will be rated with a higher score by FMS on that special subset $\mathcal{D}_i^{\text{sub}}$.

To select those data points "favored" by $\mathcal{M}_{inf}$, we first feed all target data points $\mathcal{D}_i$ into the inferior PTM $\mathcal{M}_{inf}$ and obtain the extracted features $\mathcal{F}_{\mathcal{M}_{inf}}^{\mathcal{D}_i}$. Then we use the K-means algorithm (MacQueen et al., 1967) to perform feature clustering and calculate the cluster centroids of the features $\mathcal{F}_{\mathcal{M}_{inf}}^{\mathcal{D}_i}$, where the number of clusters is equal to the number of target classes.

We select $\mathcal{D}_i^{\text{sub}}$ based on the distances of data points' features to their corresponding cluster centroids. Specifically, we select the data points whose features are closest to the corresponding cluster centroids and filter the selected data points by only keeping the data points whose features' corresponding cluster centroids are the same as their labels, resulting in a subset $\mathcal{D}_i^{\text{sub}}$. The extracted features of data points with the same target label in $\mathcal{D}_i^{\text{sub}}$ by $\mathcal{M}_{inf}$ are closer to each other. Therefore, the correlation between these selected data points' features and the corresponding labels is higher. And FMS will rate a higher score for $\mathcal{M}_{inf}$ on $\mathcal{D}_i^{\text{sub}}$, which even surpasses the score for $\mathcal{M}_{sup}$ on $\mathcal{D}_i^{\text{sub}}$.

4 Experiments and Analysis

In this section, we first conduct experiments to demonstrate the effectiveness of our proposed model disguise attack and evaluation data selection in § 4.1 and § 4.2, respectively. Then we combine both MDA and EDS with the backdoor attack in § 4.3. In addition, we demonstrate that our proposed methods can be widely applied to various kinds of PTMs and FMS algorithms in § 4.4. Finally, in § 4.5, we show that it is hard to defend against both MDA and EDS.

Table 1: Comparisons of LogME scores and fine-tuned performance of different models. $\mathcal{P}_{\mathcal{M}_{sup}}$ and $\mathcal{P}_{\mathcal{M}_{inf}^{*}}$ represent the performance of the fine-tuned $\mathcal{M}_{sup}$ and $\mathcal{M}_{inf}^{*}$, respectively. The metrics used for the reported fine-tuned performance are shown in appendix E.

4.1 Experiments on Model Disguise Attack

Experimental Setting. We choose LogME (You et al., 2021) as the mainly evaluated FMS algorithm, which is applicable to vast transfer learning settings. We choose BERT$_{\texttt{BASE}}$ (Devlin et al., 2019) / RoBERTa$_{\texttt{BASE}}$ (Liu et al., 2019) as the mainly evaluated inferior PTM ($\mathcal{M}_{inf}$) / superior PTM ($\mathcal{M}_{sup}$), respectively. Seven downstream tasks from the GLUE benchmark (Wang et al., 2019) are selected to evaluate PTM's transferability, following (You et al., 2021). We choose the pooler output representation of the `[CLS]` token[2] as the sentence representation.

Attack Performance of MDA. The transferability scores estimated by LogME of the $\mathcal{M}_{inf}$ and $\mathcal{M}_{sup}$ on the training dataset are shown in Table 1. It can be observed that under most situations, LogME serves as a good measure of the transferability by rating $\mathcal{M}_{sup}$ with a higher score ($\mathcal{S}_{\mathcal{M}_{sup}}^{\mathcal{D}_i} > \mathcal{S}_{\mathcal{M}_{inf}}^{\mathcal{D}_i}$).

Assuming that we have access to all the labeled examples $\mathcal{D}_i$ in the training dataset, we conduct MDA on a specific target downstream task for $\mathcal{M}_{inf}$. We use $\mathcal{D}_i$ to perform MDA on $\mathcal{M}_{inf}$ and test the LogME scores of the disguised $\mathcal{M}_{inf}^{*}$. Also, the fine-tuned performance of the downstream task (dev dataset) of the disguised inferior model $\mathcal{M}_{inf}^{*}$ and the superior model $\mathcal{M}_{sup}$ are reported. The results are shown in Table 1, from which we can see that after MDA, the LogME score of the disguised inferior model $\mathcal{S}_{\mathcal{M}_{inf}^{*}}^{\mathcal{D}_i}$ is significantly increased, from average -0.5569 to

---

[2] For RoBERTa, the BOS token is `<s>`.

0.5474, exceeding that of the superior model $\mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}_{sup}}$ ($\mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}^*_{inf}} > \mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}_{sup}}$). However, the downstream performance of $\mathcal{M}_{sup}$ is higher than that of the disguised inferior model $\mathcal{M}^*_{inf}$ ($\mathcal{P}_{\mathcal{M}_{sup}} > \mathcal{P}_{\mathcal{M}^*_{inf}}$). This suggests that our MDA method can successfully deceive LogME into selecting an inferior PTM, which has poorer transferability performance. It also casts doubts on the hypothesis of FMS that static features could serve as a reliable indicator for transferability measurement. The influences of MDA on the static features are visualized in appendix D.

Amount of Auxiliary Data. In real-world scenarios, the attacker may not have the access to enough target data, we thus test whether our MDA method could still be effective with few auxiliary data. We experiment on SST-2, MRPC and CoLA, and randomly sample only 25, 50, 100, 250 examples for each category in a task to construct the subset of the original training dataset, and then perform MDA for each task. Our sampled data used for MDA only takes up a small amount of the original training dataset (e.g., less than 1% for SST-2). After applying MDA, we evaluate the LogME score of the disguised inferior model. The experimental results are shown in Figure 2, from which we can see that for all tasks, after the attacker conducts MDA with only 50 samples for each category, the LogME score of the disguised inferior model exceeds that of the superior model, demonstrating that the static features of PTMs of a target task could be easily changed with limited supervision. The attacker could successfully attack LogME by only gathering a very small amount of samples.

Time Cost for MDA. We also evaluate the time costs of performing MDA on the inferior PTM. Specifically, we evaluate the attack efficiency of MDA using 50 samples per class for SST-2, MRPC and CoLA, respectively. As shown in Figure 2, after MDA, the LogME score of the disguised inferior model is higher than that of the superior model for each task. We find that for every task, the execution of MDA can be finished in around 1 minute using a single RTX2080 GPU, demonstrating the high efficiency of MDA.

Hybrid-task MDA. In addition to the amounts of data and time required for MDA, we study another situation where the model selection is conducted based on the LogME scores on multiple tasks, instead of on one specific task. Thus we design experiments to investigate whether MDA could be simultaneously applied on various tasks, dubbed as hybrid-task MDA. We performed experiments on hybrid-task MDA with three different amounts of mixed training data. From the results in Table 2, we can see that with 500 samples per class from QQP and 250 samples per class from the remaining six GLUE tasks as the mixed training data, the attacker can deceive FMS to select the disguised $\mathcal{M}^*_{inf}$ no matter $\mathcal{M}^*_{inf}$ is evaluated on which downstream task (i.e., $\mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}^*_{inf}} > \mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}_{sup}}$ for all tasks). By jointly attacking all the tasks with limited supervision, the attacker can successfully deceive the LogME algorithm on multiple tasks.

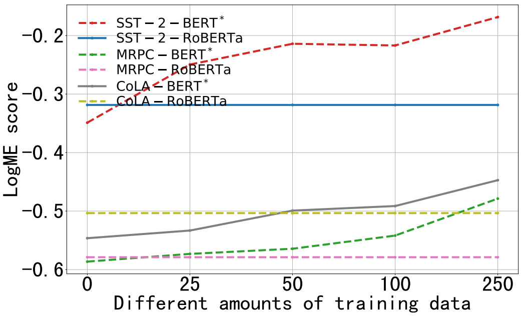

Figure 2: LogME scores of various models after performing MDA on $\mathcal{M}_{inf}$ with different amounts of data. The x-axis represents the number of auxiliary samples for each category in a task.

Transferability of MDA. Taking a step further, we test a more difficult situation where the attacker has no access to the specific downstream dataset to be evaluated. We show that MDA could still be conducted by training $\mathcal{M}_{inf}$ with a dataset belonging to the same task type but with a different domain. This is based on the hypothesis that MDA could be transferred among similar tasks. To demonstrate this, we choose the task of sentiment analysis (SA), and randomly sample 250 samples for each category from the SST-2 training dataset to perform MDA on $\mathcal{M}_{inf}$. After that, we test the LogME scores of the disguised model $\mathcal{M}^*_{inf}$ on other SA datasets, i.e., IMDB (Maas et al., 2011), Amazon polarity (McAuley and Leskovec, 2013), Yelp polarity (Zhang et al., 2015) and Rotten tomatoes (Pang and Lee, 2005). The results are shown in Table 3, from which we observe that even if MDA is performed using a small amount of samples from the SST-2 dataset, the disguised $\mathcal{M}^*_{inf}$ will be chosen by FMS ($\mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}^*_{inf}} > \mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}_{sup}}$) when evaluated on other SA downstream tasks. Also, only using

Table 3: Transferability of MDA on the sentiment analysis task. AP, YP and RT represent the Amazon polarity, the Yelp polarity and the Rotten tomatoes, respectively. $\mathcal{P}_{\mathcal{M}_{inf}}$, $\mathcal{P}_{\mathcal{M}^*_{inf}}$ and $\mathcal{P}_{\mathcal{M}_{sup}}$ represent the classification accuracy of the fine-tuned $\mathcal{M}_{inf}$, $\mathcal{M}^*_{inf}$ and $\mathcal{M}_{sup}$, respectively, on the testing dataset.

a small amount of SST-2 data to perform MDA can ensure that the disguised $\mathcal{M}^*_{inf}$ still performs worse than $\mathcal{M}_{sup}$ after fine-tuning. The experimental results show excellent transferability of MDA across similar tasks.

4.2 Experiments on Evaluation Data Selection

In this section, we experiment with our proposed EDS method and follow most of the experimental settings in § 4.1. We perform experiments on six GLUE tasks. We first feed all the examples from the training dataset to $\mathcal{M}_{inf}$ and derive the corresponding features. Then we use the K-means algorithm on the extracted features and select the data points whose features are close to the cluster centroids. We filter out samples that are close to the same cluster centroid but with different labels. Then we test the LogME score on each selected subset in Table 4, which shows that our proposed EDS method successfully selects those data points that the inferior model favors so that its LogME score $\mathcal{S}^{\mathcal{D}_i^{sub}}_{\mathcal{M}_{inf}}$ is higher than $\mathcal{S}^{\mathcal{D}_i^{sub}}_{\mathcal{M}_{sup}}$ on the selected subset $\mathcal{D}_i^{sub}$. Although EDS is hard to be deployed in practice since it requires the attacker to manipulate the data for FMS's evaluation, we argue that the existence of a subset that could deceive FMS at least shows that current FMS algorithms are very sensitive to the evaluation data.

Dataset	SST-2	QNLI	QQP	MRPC	CoLA	MNLI
$\mathcal{S}^{\mathcal{D}_i^{sub}}_{\mathcal{M}_{inf}}$	1.784	6.311	9.969	1.030	0.698	1.740

OLID	-0.5456	-0.5380	-0.7257	-0.4542

Table 5: Comparisons of LogME scores of different models.

4.3 Combinations with Backdoor Attack

In this section, we further combine both MDA and EDS with the backdoor attack, namely NeuBA (Zhang et al., 2021). NeuBA is conducted during the pre-training stage, and does not require the specific data of the downstream task.

Combinations with MDA. We assume the inferior PTM $\mathcal{M}_{inf}$ is poisoned by the backdoor attack NeuBA. For the inferior PTM $\mathcal{M}_{nb}$ that has been poisoned by NeuBA, we randomly sample a few samples from SST-2 (Socher et al., 2013) and OLID (Zampieri et al., 2019) datasets to perform the hybrid-task MDA to derive the disguised model $\mathcal{M}^*_{nb}$.

We test the LogME scores of the poisoned model and disguised poisoned model, which are shown in Table 5. From the results, we can find that the inferior PTM poisoned by the backdoor attack may

Dataset	$\text{ASR}_0^{\mathcal{M}_{\text{inf}}}$	$\text{ASR}_1^{\mathcal{M}_{\text{inf}}}$	$\mathcal{P}_{\mathcal{M}_{\text{inf}}}$	$\mathcal{P}_{\mathcal{M}_{\text{nb}}}$	$\text{ASR}_0^{\mathcal{M}^*_{\text{nb}}}$	$\text{ASR}_1^{\mathcal{M}^*_{\text{nb}}}$	$\mathcal{P}_{\mathcal{M}^*_{\text{nb}}}$	$\mathcal{P}_{\mathcal{M}_{\text{sup}}}$
SST-2	6.58%	7.26%	93.79%	93.57%	100.00%	24.75%	93.68%	95.28%
OLID	5.81%	37.5%	80.83%	80.53%	87.90%	60.83%	80.27%	82.00%

Table 6: The ASR of the fine-tuned $\mathcal{M}_{inf}$ and $\mathcal{M}^*_{nb}$. The ASR is tested on the poisoned testing data. $\mathcal{P}_{\mathcal{M}_{inf}}$, $\mathcal{P}_{\mathcal{M}_{nb}}$, $\mathcal{P}_{\mathcal{M}^*_{nb}}$ and $\mathcal{P}_{\mathcal{M}_{sup}}$ represent the performance of the fine-tuned $\mathcal{M}_{inf}$, $\mathcal{M}_{nb}$, $\mathcal{M}^*_{nb}$ and $\mathcal{M}_{sup}$, respectively, on the clean testing data. For SST-2, we report the accuracy. For OLID, we report the macro F1 score.

not be chosen by FMS ($\mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}_{nb}} < \mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}_{sup}}$), so its hazards may be limited. However, after our MDA, $\mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}^*_{nb}} > \mathcal{S}^{\mathcal{D}_i}_{\mathcal{M}_{sup}}$ and thus the disguised poisoned model will be chosen by FMS.

We also perform experiments to see whether the backdoor still exists after MDA. Specifically, if the user fine-tunes the $\mathcal{M}^*_{nb}$ using the downstream clean datasets, we then test the Attack Success Rate (ASR), following (Zhang et al., 2021). For comparison with the benign inferior model $\mathcal{M}_{inf}$, we also evaluate the ASR of the fine-tuned $\mathcal{M}_{inf}$ model on the poisoned testing data. For SST-2, the ASR_0 and ASR_1 represent the ASR_{neg} and ASR_{pos}, respectively. For OLID, the ASR_0 and ASR_1 represent the ASR_{no} and ASR_{yes}, respectively. The ASR_0 for the benign model in Table 6 is the highest ASR_0 among all triggers. The ASR_1 in Table 6 for the benign model is the highest ASR_1 among all triggers. From the results in Table 6, we can see that the ASR of the fine-tuned $\mathcal{M}^*_{nb}$ is higher compared with that of the fine-tuned $\mathcal{M}_{inf}$. The above results show the potential risk that the attacker can use the MDA method to let the FMS select an inferior model poisoned by the backdoor attack.

Combinations with EDS. We also explore combining the backdoor attack (NeuBA) with EDS on SST-2 and OLID. We feed the target data to the inferior poisoned model $\mathcal{M}_{nb}$ to derive their features and perform the EDS method illustrated in § 3.4. The results are shown in Table 7. After selecting the data subsets that $\mathcal{M}_{nb}$ favors, the LogME scores of $\mathcal{M}_{nb}$ are higher than those of $\mathcal{M}_{sup}$ on the selected subsets. From the results, we can find that EDS is an effective method to make FMS choose an inferior poisoned model attacked by NeuBA.

4.4 Experiments on other Pre-trained Models and other FMS Algorithms

We verify that MDA is model-agnostic, and can be applied to other FMS algorithms. For CV tasks, we choose MobileNetV2 (Sandler et al., 2018) as the inferior model and ResNet50 (He et al., 2016) as the superior model. We choose H-score (Bao et al., 2018) and LogME (You et al., 2021) as the evaluated FMS algorithms. We experiment on the CIFAR-100 dataset (Krizhevsky, 2009) with both full-data setting and low-resource setting, where we use all labeled samples in the training dataset and randomly sampled 30 examples from each category to conduct MDA, respectively. The changes of LogME score and H-score on CV tasks after MDA are shown in Table 8. Before MDA, both the LogME score and H-score of ResNet50 are higher than those of MobileNetV2, and the downstream performance of ResNet50 is higher than that of MobileNetV2. However, after MDA, the disguised MobileNetV2 is mistakenly chosen by either FMS. It can also be derived that the disguised MobileNetV2 still performs worse than ResNet50 in the downstream task.

Dataset	SST-2	OLID
$\mathcal{S}^{\mathcal{D}_i^{sub}}_{\mathcal{M}_{nb}}$	2.373	1.799
$\mathcal{S}^{\mathcal{D}_i^{sub}}_{\mathcal{M}_{sup}}$	0.4865	-0.0902

Table 7: The LogME scores of $\mathcal{M}_{nb}$ and $\mathcal{M}_{sup}$ on the subsets $\mathcal{D}_i^{sub}$ selected by EDS.

For NLP tasks, we choose $\text{DistilBERT}_{\text{BASE}}$ (Sanh et al., 2019) as the inferior model and $\text{RoBERTa}_{\text{BASE}}$ as the superior model. We experiment on MRPC and CoLA tasks. We use all labeled data in the training dataset to perform MDA and derive the disguised model $\text{DistilBERT}^*_{\text{BASE}}$. From the results in Table 9, we can see that after MDA, $\mathcal{S}^{\mathcal{D}_i}_{\text{DistilBERT}^*}$ is higher than $\mathcal{S}^{\mathcal{D}_i}_{\text{RoBERTa}}$ while the fine-tuned performance of $\text{DistilBERT}^*_{\text{BASE}}$ is poorer than that of $\text{RoBERTa}_{\text{BASE}}$. The disguised inferior model is chosen. For EDS, we feed the training dataset to the $\text{DistilBERT}_{\text{BASE}}$ and use our EDS method proposed in § 3.4 to select the subset $\mathcal{D}_i^{sub}$. From the results in Table 10, we can find that the LogME score of $\text{DistilBERT}_{\text{BASE}}$ is higher than that of $\text{RoBERTa}_{\text{BASE}}$ on $\mathcal{D}_i^{sub}$. The results show that our proposed methods can be applied to other PTMs and FMS algorithms.

FMS	MobileNetV2	ResNet50	MobileNetV2*

4.5 Observations for MDA

Our MDA is applied on the hidden representation of one specific layer (e.g., the pooler output layer) for a specific token (e.g., `[CLS]`), which is exactly the same representation that is evaluated in FMS. In practical applications, it may occur that the downstream user applies FMS on the representations of other tokens / layers. We thus design experiments to see whether our MDA could still successfully deceive FMS under these circumstances.

Obs. 1: MDA could infect other layers. For BERT$_{\texttt{BASE}}$, we suppose the attacker performs MDA on some specific layers, and the downstream user applies FMS on the hidden representations from other layers of the same `[CLS]` token. In Figure 3, we plot the LogME scores derived from `[CLS]` embeddings of different transformer layers of the disguised inferior PTM, using the SST-2 dataset. Specifically, we experiment on performing MDA on (1) the pooler output, (2) the `[CLS]` representation of the 5-th layer and (3) the `[CLS]` representations of the 5-th, 8-th, and 11-th layers.

From Figure 3, we can see that no matter the attacker performs MDA on which layer, the LogME scores derived from the output `[CLS]` embeddings of all transformer layers of the disguised BERT$_{\texttt{BASE}}$ model are higher than those of the RoBERTa$_{\texttt{BASE}}$ model. We performed experiments to compare the performance of disguised BERT$_{\texttt{BASE}}$ models with the RoBERTa$_{\texttt{BASE}}$ model on the downstream task. The fine-tuned accuracy on the dev dataset of the models disguised by different training strategies (1), (2) and (3) are 92.78%, 89.79% and 90.60%, respectively, which are all lower than that of the RoBERTa$_{\texttt{BASE}}$ model (94.50%). From the above results, we can see that no matter the downstream user applies FMS on which layer, the disguised inferior model will be chosen under three settings.

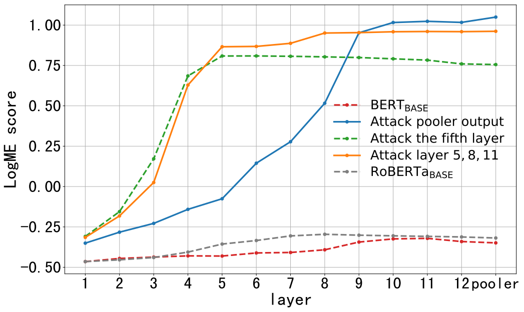

Figure 3: The LogME scores derived from `[CLS]` embeddings of different transformer layers under different situations.

Obs. 2: MDA could infect other tokens. Our MDA is applied on the representation of a single token `[CLS]`, we investigate whether such an attack is contagious to other tokens. Specifically, we apply our MDA on the `[CLS]` token of BERT$_{\texttt{BASE}}$ using all samples from SST-2 and then evaluate the `[SEP]` token[3] during FMS. From the results shown in Table 11, we find that even if we perform MDA on the pooler output corresponding to the `[CLS]` token, the feature of `[SEP]` token is still affected, which means that MDA could infect other tokens.

From these two observations, we can find that only using static features of different layers / tokens can not defend our proposed MDA method. We leave observations for EDS in appendix B and alternative model selection method that can defend MDA in appendix C .

---

[3] For RoBERTa, the SEP token is `</s>`.

Model	LogME score
RoBERTa$_{\text{BASE}}$	-0.3078
BERT$_{\text{BASE}}$	-0.3578
BERT$_{\text{BASE}}$+ MDA	0.9807

Table 11: The LogME scores corresponding to the `[SEP]` token of different models.

5 Conclusion

In this paper, we demonstrate the vulnerability of feature-based model selection methods by proposing two methods, model disguise attack and evaluation data selection, both of which successfully deceive FMS into mistakenly ranking PTMs' transferability. Moreover, we find that our proposed methods can further be combined with the backdoor attack to mislead a victim into selecting the poisoned model. To the best of our knowledge, this is the first work to analyze the defects of current FMS algorithms and evaluate their potential security risks. Our study reveals the previously unseen risks of FMS and calls for improvement for the robustness of FMS. In the future, we will explore more effective, robust and efficient model selection methods.

Appendices

A Comparisons with Fine-tuning

Another possible methodology to conduct the model disguise attack is to use the cross-entropy loss to fine-tune the inferior PTM. We name this kind of attack as CE attack. We name the attack method using supervised contrastive loss that is proposed in § 3.3 as SCL attack. We performed experiments to compare the efficiency of SCL attack with CE attack, hybrid attack and $SCL+CE$ attack, respectively. Compared with CE attack, the LogME score after SCL attack is higher than that after CE attack for 5 epochs, which demonstrates SCL attack is more efficient than CE attack. For the hybrid attack, we tried using the mixture of cross-entropy loss and supervised contrastive loss with the weight 0.5 and 0.5 for two losses to train the BERT$_{\texttt{BASE}}$ model for 5 epochs. The LogME score after hybrid attack is lower than that after SCL attack for 5 epochs, which shows that SCL attack is more efficient than hybrid attack. For $SCL + CE$ attack, we first use the SCL attack to train the BERT$_{\texttt{BASE}}$ model for 5 epochs and then apply the CE attack for 5 epochs. The LogME score after $SCL + CE$ attack is lower than that after the single SCL attack for 10 epochs, which demonstrates SCL attack's superiority. All experiments are performed on the SST-2 dataset. The results are shown in Table 12. From the experimental results, we can see that the SCL attack is a more powerful attack method.

Attack Method	LogME score
CE (5)	1.2565
hybrid attack (5)	1.4921
SCL (5)	1.6053
$SCL + CE$ (5+5)	2.5460
SCL (10)	3.0028

Table 12: Comparisons of SCL attack with CE attack. The number of training epochs is shown in the bracket.

B Observations for EDS

Obs.3: EDS could infect other layers. We assume that the attacker selects a subset $\mathcal{D}_{sub}$ of SST-2 that is illustrated in 4.2 for the user to evaluate.

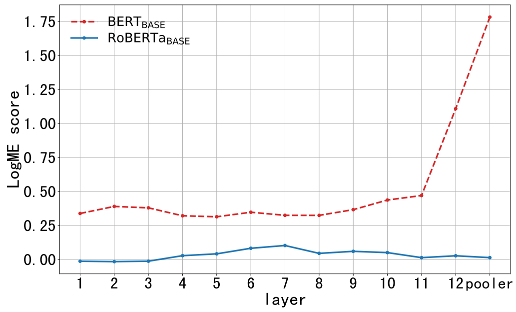

Figure 4: The LogME scores derived from `[CLS]` embeddings of different transformer layers on the subset selected by EDS.

Model	LogME score
RoBERTa$_{\texttt{BASE}}$	0.0325
BERT$_{\texttt{BASE}}$	0.2363

Table 13: The LogME scores corresponding to the `[SEP]` token of different models on the subset selected by EDS.

Specifically, the attacker performs K-means clustering on the features of pooler output corresponding to `[CLS]` token, selects the data points whose features are close to the cluster centroids and performs filtering. The features used for clustering are derived from a specific layer (i.e. pooler output) and a specific token (i.e. `[CLS]`). From Figure 4, we can see that even if the subset $\mathcal{D}_{sub}$ is selected through the features of pooler output extracted by BERT$_{\texttt{BASE}}$ model, the LogME scores of BERT$_{\texttt{BASE}}$ model derived from `[CLS]` embeddings of all layers are higher than those of RoBERTa$_{\texttt{BASE}}$ model on the subset $\mathcal{D}_{sub}$.

Obs.4: EDS could infect other tokens. Also, from Table 13, we can see that even if the subset $\mathcal{D}_{sub}$ is selected through the feature of pooler output corresponding to `[CLS]` token that is extracted by BERT$_{\texttt{BASE}}$ model as shown in 4.2, the LogME score of BERT$_{\texttt{BASE}}$ model derived from the feature of `[SEP]` token in the last layer is higher than that of RoBERTa$_{\texttt{BASE}}$ model on the subset $\mathcal{D}_{sub}$.

C Alternative Model Selection Method

We demonstrate that fine-tuning the models with a few steps is a simple and more robust method for model selection and can defend MDA. As shown in Figure 2, the LogME score of the disguised model $\mathcal{M}^*_{inf}$ is higher than $\mathcal{M}_{sup}$ after the attacker uses 50 samples from each category to perform MDA on

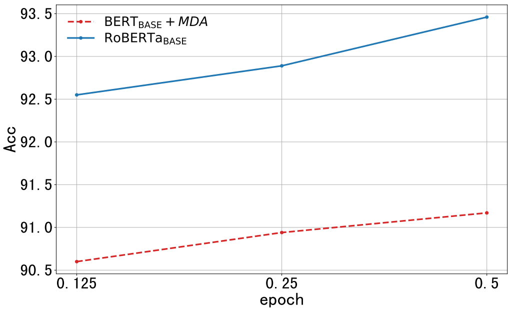

Figure 5: The accuracy after fine-tuning two models with 0.125, 0.25, and 0.5 epochs on SST-2.

Dataset	$\text{BERT}_{\texttt{BASE}}$+MDA	$\text{RoBERTa}_{\texttt{BASE}}$
MRPC	83.39%	87.21%
CoLA	42.72%	53.70%

Table 14: The performance after fine-tuning two models for one epoch on MRPC and CoLA.

SST-2, MRPC, and CoLA, respectively. However, after fine-tuning the disguised $\text{BERT}_{\texttt{BASE}}$ model $\mathcal{M}^*_{inf}$ and the $\text{RoBERTa}_{\texttt{BASE}}$ model $\mathcal{M}_{sup}$ for a while, the performance of the fine-tuned $\mathcal{M}_{sup}$ is higher than that of the fine-tuned model $\mathcal{M}^*_{inf}$. The results of the accuracy on dev dataset after fine-tuning model $\mathcal{M}^*_{inf}$ and $\mathcal{M}_{sup}$ on SST-2 dataset with different epochs are shown in Figure 5. From Figure 5, we can see that after fine-tuning two models for a few steps, $\mathcal{M}_{sup}$'s superiority has been demonstrated. The results of fine-tuning two models on MRPC and CoLA for one epoch are shown in Table 14. The F1 score is reported for MRPC and MCC score is reported for CoLA. From the results in Table 14, we can see that after fine-tuning two models for one epoch, the model $\mathcal{M}_{sup}$'s performance is higher than the disguised model $\mathcal{M}^*_{inf}$ on dev datasets of MRPC and CoLA, respectively. Fine-tuning models on the downstream task for a while and then comparing the performance of fine-tuned models is a more robust model selection method.

D Analysis

To visualize the transition of the static features after we apply MDA on the inferior PTM, we randomly sampled 250 samples for each category from the SST-2 dataset and plot the pooler output features corresponding to the `[CLS]` token that are encoded by the original $\text{BERT}_{\texttt{BASE}}$ model and disguised $\text{BERT}_{\texttt{BASE}}$ model, respectively. The disguised $\text{BERT}_{\texttt{BASE}}$ model has been trained using all samples from SST-2 dataset for 3 epochs with SCL. The TSNE figures of features extracted by the original $\text{BERT}_{\texttt{BASE}}$ model and disguised $\text{BERT}_{\texttt{BASE}}$ model are shown in Figure 6 and Figure 7, respectively. The red marks and green circles in Figure 6 and Figure 7 represent features of sampled negative samples and positive samples, respectively. From Figure 6 and Figure 7, we can see that after MDA, the sentence representations that belong to the same class become closer to each other. The LogME score becomes higher after MDA. The LogME score has a close relation to the quality of features.

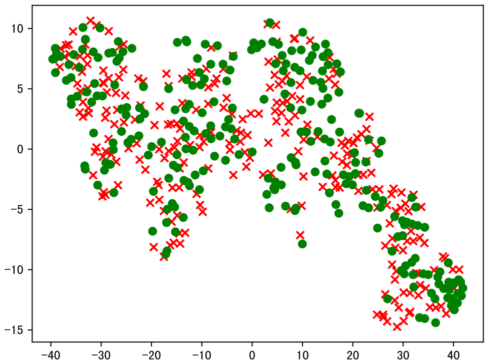

Figure 6: The TSNE figure of features extracted by the original $\text{BERT}_{\texttt{BASE}}$ model.

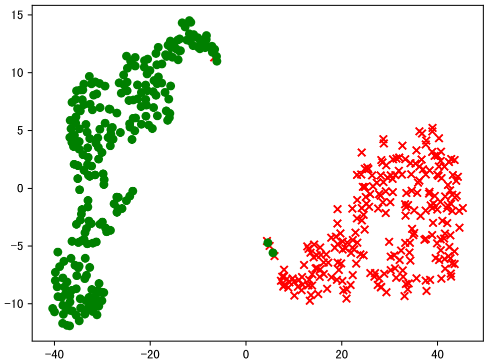

Figure 7: The TSNE figure of features extracted by the disguised $\text{BERT}_{\texttt{BASE}}$ model.

E Training Details for Experiments

E.1 Experiments on Model Disguise Attack

Attack Performance of MDA. We choose AdamW as the optimizer, set the peak learning rate to 3×10^{-5}, and linearly decay it. For the dropout rate in the supervised contrastive loss function, we perform the search from $0.1, 0.1$ and $0.1, 0.05$. For the six tasks except for RTE, the best dropout rate combination is $0.1, 0.05$. For the RTE task, the best dropout rate combination is $0.1, 0.1$. We use the best dropout rate combination for each downstream task to perform MDA. About the metrics used for the performance of fine-tuned models reported in Table 1, F1 scores are reported for QQP and MRPC, Matthews Correlation Coefficient (MCC) score is reported for CoLA, and accuracy scores are reported for the other tasks. We report the matched accuracy for MNLI.

Hybrid-task MDA. We optimize the supervised contrastive loss on $\mathcal{M}_{inf}$ for 100 epochs using the sampled mixed training data. The dropout probabilities of two augmentations are 0.1 and 0.05. For six GLUE tasks except for QQP, 50, 100, 250 samples for each category are randomly sampled from the training dataset of each task in three hybrid-task MDA experiments, respectively. We randomly sample 500 samples for each category from the QQP dataset for all three hybrid-task MDA experiments. The total class number of the sampled mixed data is the summation of class numbers from seven GLUE tasks.

Transferability of MDA. Since the original IMDB dataset does not contain the dev dataset, we split the original IMDB training dataset into a training dataset and a dev dataset with a ratio of 9:1 for fine-tuning models. The LogME score is still calculated using the original IMDB training dataset. For Amazon Polarity, we randomly sample 9000, 1000 and 1000 samples from the original Amazon Polarity training dataset as our training, dev and testing datasets for fine-tuning models. The LogME score is calculated using the new sampled training dataset. The template for the sample x in Amazon Polarity is "title: $x_{\texttt{title}}$ content: $x_{\texttt{content}}$". For Yelp Polarity, we randomly sample 7600 and 7600 samples from the original Yelp Polarity testing dataset as our dev and testing datasets when fine-tuning models.

E.2 Experiments on Evaluation Data Selection

For SST-2, QNLI, QQP and MRPC, we choose the closest 2000 samples before filtering, while for CoLA, we choose the closest 1000 samples. After filtering out those samples that are close to the same cluster centroid but with different labels, we retain 957, 760, 968, 303 and 532 examples for SST-2, QNLI, QQP, CoLA and MRPC, respectively. Due to the very imbalanced data points in each cluster after clustering the features of MNLI, we limit the number of selected samples to 200 for each class when choosing the samples whose features are close to cluster centroids after filtering. Thus the number of selected samples for MNLI is 600.

E.3 Combinations with Backdoor Attack

Combinations with MDA. For the inferior PTM $\mathcal{M}_{nb}$ that has been poisoned with NeuBA, we randomly sample 500 samples for each category from the SST-2 dataset and the OLID dataset, respectively, to perform the hybrid-task MDA by training the poisoned $\mathcal{M}_{nb}$ with SCL for 5 epochs.

Combinations with EDS. We feed the target data to the $\mathcal{M}_{nb}$ model to derive their features. We perform the K-means method on the features extracted by the $\mathcal{M}_{nb}$ model to get the cluster centroids. For SST-2 and OLID, we choose the top 2000 samples whose features extracted by $\mathcal{M}_{nb}$ are closest to cluster centroids before filtering, respectively. After filtering, the number of examples for SST-2 and OLID are 1137 and 819, respectively.

E.4 Experiments on other Pre-trained Models and other FMS Algorithms

We verify the effectiveness of our proposed MDA and EDS methods on the DistilBERT$_{\texttt{BASE}}$ (Sanh et al., 2019). For DistilBERT$_{\texttt{BASE}}$, we derive the LogME score from the `[CLS]` token's representation in the last layer. To keep consistent with the results in Table 1, the LogME score of the RoBERTa$_{\texttt{BASE}}$ model still derives from the pooler output corresponding to the `<s>` token. For MDA, the dropout probabilities of two augmentations are set as 0.1 and 0.1 in the experiments. For EDS, we feed the training dataset to the DistilBERT$_{\texttt{BASE}}$ and use our EDS method proposed in § 3.4 to select the subset $\mathcal{D}_i^{sub}$. Specifically, we select the top 2000 samples whose features are close to the cluster centroids for MRPC and CoLA before filtering. After filtering, we retain the 822 and 636 samples for MRPC and CoLA, respectively.

Educational Question Generation of Children Storybooks via Question Type Distribution Learning and Event-Centric Summarization

Abstract

Generating educational questions of fairytales or storybooks is vital for improving children's literacy ability. However, it is challenging to generate questions that capture the interesting aspects of a fairytale story with educational meaningfulness. In this paper, we propose a novel question generation method that first learns the question type distribution of an input story paragraph, and then summarizes salient events which can be used to generate high-cognitive-demand questions. To train the event-centric summarizer, we fine-tune a pre-trained transformer-based sequence-to-sequence model using silver samples composed by educational question-answer pairs. On a newly proposed educational question-answering dataset *FairytaleQA*, we show good performance of our method on both automatic and human evaluation metrics. Our work indicates the necessity of decomposing question type distribution learning and event-centric summary generation for educational question generation.

1 Introduction

Listening to and understanding fairy tales or storybooks are very crucial for children's early intellectual and literacy development (Sim and Berthelsen, 2014). During the storybook reading process, prompting suitable questions with educational purposes can help children understand the content and inspire their interests (Zevenbergen and Whitehurst, 2003; Ganotice et al., 2017).

There is evidence that **high-cognitive-demand** (HCD) questions usually relate to good learning achievement (Winne, 1979). HCD questions usually correspond to application, analysis, synthesis, and evaluation questions in Bloom's taxonomy of cognitive process (Winne, 1979; Anderson et al., 2000), which are salient events merged from different elements across a session (Greatorex and Dhawan, 2016). However, it is challenging even for humans to ask educationally meaningful questions to engage children in storybook reading, which could be due to adults lacking the skills or time to integrate such interactive opportunities (Golinkoff et al., 2019). Recent research shows that AI-powered conversational agents can play the role of language partners to read fairy tales to children and ask them educational questions (Xu et al., 2021). This motivates us to investigate techniques to generate HCD educational questions for children's storybooks automatically. Automating the generation of such questions can have great value in supporting children's language development through guided conversation.

During storybook reading, HCD questions require children to make inferences and predictions. In contrast to low-cognitive-demand (LCD) questions describing facts in stories (*e.g.*, *Who is Snow White's mother?*), HCD questions are often related to events and their relations (*e.g.*, *Why did the queen want to kill Snow White?* or *What happened after the huntsman raised his dagger in the forest?*).

Most previous work on question generation (QG) focuses on generating questions based on predefined answer spans (Krishna and Iyyer, 2019; Pyatkin et al., 2021; Cho et al., 2021). Such systems that use "keywords" or specific events often generate LCD questions that are factual questions based on local context, but cannot work well on HCD cases, where we need to capture the salient events and understand the relations across multiple elements/events. Recently, Yao et al. (2021) released a fairytale question answering dataset **FairytaleQA** containing around 10.5k question-answer pairs annotated by education experts. Each question is assigned to a specific type, and some types, such as "*action*", "*causal relationship*", are high-cognitive-demanding. This makes it possible to investigate generating educational questions to support children's interactive storybook reading.

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics
Volume 1: Long Papers, pages 5073 - 5085
May 22-27, 2022

In this paper, we propose a novel framework combining question type prediction and event-centric summarization to generate educational questions for storybooks. In the first stage, we learn to predict the question type distribution for a given input and add pseudo-label so that after prediction, we can know both the types of questions and how many questions of each type. In the second stage, conditioned on question types and the order of the question under the current question type, we extract salient events that are most likely for educators to design questions on and then generate an event-centric summarization of the original input. Finally, in the third stage, we use the output of the second stage to generate questions. Each summarization is used to generate one question. Note that it is difficult to obtain gold annotations for event-centric summarization. Instead, we rewrite annotated questions, and their corresponding hypothesized answers into question-answer statements (Demszky et al., 2018) as silver training samples. We hypothesize that HCD questions are around main plots in narratives and can guide our summarization model to focus on salient events. We evaluate our system on the FairytaleQA dataset and show the superiority of the proposed method on both automatic and human evaluation metrics compared to strong baselines.

2 Related Work

2.1 Question Generation

Question answering based on context has achieved remarkable results (Rajpurkar et al., 2016; Zhang et al., 2020b). The reverse problem, namely, question generation (Duan et al., 2017; Chan and Fan, 2019), usually relies on pre-selecting spans from an input text as answers and a single sentence as the context. However, to generate questions across a long paragraph in which the key information may come from multiple different sentences in fairy tales (Yao et al., 2021), these existing models relying on one text segment usually do not work well.

A few studies are focusing on generating questions that are based on multi-sentence or multi-document information fusion (Pan et al., 2020; Xie et al., 2020; Tuan et al., 2020). NarrativeQA (Kočiský et al., 2018) is an effort that tries to integrate key information across multiple locations of a paragraph for question answering/generation. Similarly, MS MARCO (Nguyen et al., 2016) is a dataset that integrates multiple locations of answers for users' queries in search engines. In Cho et al. (2021), a contrastive method is proposed that first trains a supervised model to generate questions based on a single document and then uses a reinforcement learning agent to align multiple questions from multiple documents. In Lyu et al. (2021), the authors use a rule-based method to generate questions with summaries and report to achieve good performance.

The methods mentioned above usually do not consider the educational dimension and may not work well on fairy tales. Considering our research focus of fairytales, it is vital to generate questions that have educational purposes. In FairytaleQA (Yao et al., 2021), experts usually write different types of questions for separate paragraphs. We hypothesize that context plays a significant role in deciding the type of questions that should be asked during the interactive storybook reading with children. Therefore it is necessary to investigate not only how to summarize salient events but also how to learn the question type distribution.

2.2 Text Summarization

Summarization methods can be classified into extractive summarization and abstractive summarization. Extractive methods select sentences from the source documents to compose a summary; abstractive methods applies neural generative models to generate the summary token-by-token.

Extractive summarization methods, such as TextRank (Mihalcea and Tarau, 2004), feature-based methods (Jagadeesh et al., 2005; Luhn, 1958; Nallapati et al., 2017), and topic-based methods (Ozsoy et al., 2010), do not work to generate HCD questions on the fairytale scenario because such questions often are based on multiple sentences.

Abstractive methods based on encoder-decoder architectures usually encode an input document token-by-token sequentially (Rush et al., 2015) and cannot capture the fine-grained hierarchical relations in a document, such as actions, causal relationships. Graph neural network (GNN) models are recently used in summarization research (Wu et al., 2021; Wang et al., 2020; Xu et al., 2020; Li et al., 2021), thanks to their ability to model the complex relations in a document. For example, in Xu et al. (2020), researchers used a discourse-level dependency graph to encode a document and then decoded discourse-level embeddings to select sentences extractively. Similarly, in Wang et al. (2020), researchers have used a heterogeneous graph to encode both token-level and sentence-level relations in a document and then used it to extract sentences. Still, in the education domain, summarizing salient events of one paragraph that can be used to generate educational questions is an open problem. In this paper, we develop an event-centric summarization method based on BART (Lewis et al., 2020). To obtain the training data, we compose educational question-answer pairs through a rule-based method and use them as silver ground-truth samples.

3 Method

The overview of our educational question generation system for storybooks is shown in Figure 1, which contains three modules: question type distribution learning, event-centric summary generation, and educational question generation.

Given an input paragraph d, we first predict the type distribution of output questions $\boldsymbol{p} = (p_1, p_2, \ldots, p_T)$, where p_i denotes the probability of question type i, T is the total number of question types. We then transform the distribution into the number of questions under each question type $\boldsymbol{l} = (l_1, l_2, \ldots, l_T)$. Afterwards, we first generate l_i summaries of type i with the input paragraph d, and then generate l_i questions of type i with the corresponding summaries.

3.1 Question Type Distribution Learning

We fine-tuned a BERT model (Devlin et al., 2019), and adapt the output m dimensional class token $\boldsymbol{h}_c \in \mathbb{R}^m$ to learn the question type distribution. Specifically, the predicted distribution is obtained by $p_i = \frac{e^{(\boldsymbol{W}\boldsymbol{h}_c+\boldsymbol{b})_i}}{\sum_{i=1}^{T} e^{(\boldsymbol{W}\boldsymbol{h}_c+\boldsymbol{b})_i}}$, where $\boldsymbol{W} \in \mathbb{R}^{T\times m}$, $\boldsymbol{b} \in \mathbb{R}^T$ are learnable parameters, $(\cdot)_i$ denotes the operator of selecting the i-th element of a vector.

Assuming there are N training samples, we minimize the K-L divergence loss $\mathcal{L}_{K-L} = \sum_{j=1}^{N} \frac{1}{N} \sum_{i=1}^{T} p_i^{(j)} \log \frac{p_i^{(j)}}{\hat{p}_i^{(j)}}$, where $p_i^{(j)}$ denotes the probability of question type i for the j-th sample, and $\hat{p}_i^{(j)}$ is our predicted value.

To improve the prediction performance, similar to Zhang et al. (2018), we also conduct a multi-label classification task, where we use the question type with the maximal probability as the class of the output. In particular, we add a cross entropy loss $\mathcal{L}_{CE} = -\sum_{j=1}^{N} \frac{1}{N} \sum_{i=1}^{T} \mathbb{1}(y_i^{(j)}) \log \hat{y}_i^{(j)}$, where $\mathbb{1}(y_i^{(j)})$ equals to 1 if i is the question type with the maximal probability for the sample j.

In summary, we conduct a multi-task learning for question type distribution prediction, and the final training loss is a weighted sum of the K-L loss and the cross entropy loss: $\mathcal{L} = \gamma\mathcal{L}_{K-L} + (1-\gamma)\mathcal{L}_{CE}$, where γ is a weight factor.

To predict the number of questions for each question type during training, we add a pseudo label 1 to the original label $\boldsymbol{l} = (l_1, l_2, \ldots, l_n)$, *i.e.*, $\boldsymbol{l} = (l_1, l_2, \ldots, l_n, 1)$. We can then normalize it to get the ground-truth probability distribution $\boldsymbol{l} = (\frac{l_1}{\sum_{k=1}^{n} l_k+1}, \ldots, \frac{l_n}{\sum_{k=1}^{n} l_k+1}, \frac{1}{\sum_{k=1}^{n} l_k+1})$. During testing, assuming we get the predicted distribution $\boldsymbol{p} = (p_1, p_2, \ldots, p_n, p_{pseudo})$, we can obtain the number of each type of questions by diving the probability of this pseudo label p_{pseudo} as: $n_i = \lfloor \frac{p_i}{p_{pseudo}} + 0.5 \rfloor$.

3.2 Event-centric Summary Generation

In FairytaleQA, one paragraph usually has multiple questions with different question types, and information in one educational question may scatter across multiple parts. As mentioned before, we assume that context plays a big role to decide the type and the number of questions to be asked during the interactive storybook reading, and HCD questions are around salient events and the relations. With the output from the previous component, we can use the predicted question type distribution as a control signal, and select corresponding events for one particular question type.

In particular, we add two control signals before an input paragraph: question type signal `<t>` and question order signal `<c>`, where `<t>` $\in$ `T`, `<c>` $\in$ `C`, `T` denotes the set of all question types, `C` denotes the set of order, *i.e.*, {`<first>, <second>, <third>`, ...}. We train a BART summarization model (Lewis et al., 2020) to conduct the event-centric summary generation task. The input of the BART model is: `<t> <c> d`, and the output of the BART model is a summary that collects related events for an educational question type, where `d` denotes the input paragraph.

Obtaining the golden summaries is difficult. However, a QA dataset, like FairytaleQA, provides both questions and their corresponding answers. We can therefore re-write the annotated questions and answers together to obtain question-answer statements, which are used as silver summaries to train our summarization model. We used the rule-based method in Demszky et al. (2018) which inserts answers into the semantic parsed questions

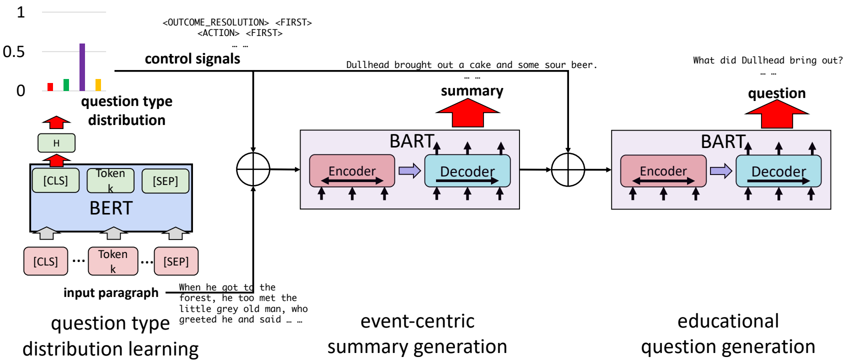

Figure 1: The overview of our educational question generation system of fairy tales.

and eliminates question words.

3.3 Educational Question Generation

With the summary generated in the second stage, generating an educational question is fairly straightforward. Because the summary has already contained all key events for the target educational question type, we can train a question generation model directly on top of it using the annotated questions. We fine-tune another BART model to generate questions, with the type and order control signals added before the input summary to control the generated results. Note that our question generation model does not reply on pre-selected answer spans.

4 Experimental Setup

To demonstrate the effectiveness of our proposed method, we conducted a set of experiments on the FairytaleQA dataset.

4.1 Dataset

The FairytaleQA dataset (Yao et al., 2021) contains annotations of 278 books, including 232 training books, 23 test books, and 23 validation books. Each book has multiple paragraphs, and for each paragraph of one book, there are several educational question-answer pairs annotated by education experts. The question type distribution is consistent among annotators. In total, there are seven types:

•**Character**: questions that contain the character of the story as the subject and ask for additional information about that character;

•**Setting**: questions that start with "Where/When";

•**Feeling**: questions that start with "How did/do/does X feel?";

•**Action**: questions that start with "What did/do/does X do?" or "How did/do/does X" *or* questions that contain a focal action and ask for additional information about that action;

•**Causal relationship**: questions that start with "Why" or "What made/make";

•**Outcome resolution**: questions ask about logic relations between two events, such as "What happened...after...";

•**Prediction**: questions that start with "What will/would happen...".

The first three are factual questions that are low-cognitive-demanding, and can be handled well by traditional span-based question generation methods (Yao et al., 2021). The remaining four types usually require people to make inferences from multiple elements (Paris and Paris, 2003), which correspond to high-level cognitive skills in Bloom's taxonomy (Anderson et al., 2000), and can be viewed as HCD questions. For the question type *prediction*, it usually asks for events that do not appear in storybooks, which is not our focus in this paper. We only consider *action, causal relationship*, and *outcome resolution*. There is a small portion (985 out of 10580) of questions that span multiple paragraphs. To control the cognitive-demand level for children, we also removed those questions. The statistics of the selected data is shown in section A of the appendix.

4.2 Baselines

We compared our system with two baselines: 1) the method proposed in Yao et al. (2021) (denoted as QAG), which is the only method that considers generating educational questions; 2) using FairytaleQA, we trained an end-to-end BART model.

QAG. The QAG model (Yao et al., 2021) use "keywords" (semantic role labeling) to identify entities and events and then generate questions, which contains four steps: 1) generate a set of answers based on semantic roles of verbs; 2) generate questions based on these answers; 3) generate answers based on the questions generated in the second step; 4) rank generated question-answer pairs and choose the top questions. We trained the question generation model in the second step and the answer generation model in the third step using the selected questions. We use the top 10/5/3/2/1 generated questions as baselines, denoted as QAG (top10), QAG (top5), QAG (top3), QAG (top2), and QAG (top1), respectively.

E2E. Using FairytaleQA with question types *action, causal relationship*, and *outcome resolution*, we trained one BART-large model to generate questions based one paragraph end-to-end. During testing, we used a maximal length 100 tokens (roughly 7 questions according to Table 11) and selected the first 2 questions as the output for evaluation. We denote this method as E2E.

4.3 Evaluation Metrics

We adopt both automatic and human evaluation to measure the performance of our method.

4.3.1 Automatic Evaluation

For automatic evaluation, similar to Yao et al. (2021), we use the Rouge-L score (Lin, 2004), and report the average precision, recall, and F1 values. Meanwhile, we also use BERTScore (Zhang et al., 2020a) to evaluate the semantic similarity of generated questions with the ground-truth questions, and report the average precision, recall, and F1 values. *In contrast to Yao et al. (2021), we mainly consider concatenating all generated questions into one sentence and comparing it with the concatenated ground-truth questions.* This is because for each paragraph, we need to evaluate the generated quality of not only each question but also the question type distribution for sub-skills required in education as a whole (Paris and Paris, 2003). Since the question order does not have much effects on Rouge-L, concatenating questions also partially takes individual question quality into consideration. Moreover, we also consider the same setup used in Yao et al. (2021) that takes the max score of each gold question against the generated questions, then averages the scores of all generated questions.

4.3.2 Human Evaluation

To evaluate the quality of our generated questions and their educational significance, we further conducted a human evaluation session. After regular group meetings, we concluded the following four dimensions, where children appropriateness is the main metric for our educational application:

1. **Question type**: whether the generated questions belong to any of the three event types.
2. **Validity**: whether the generated questions are valid questions according to the original paragraph.
3. **Readability**: whether the generated questions are coherent and grammatically correct.
4. **Children appropriateness**: to what extent would you like to ask this question when you read the story to a five year's old child?

4.4 Implementation Details

For re-writing silver summaries, there are 8 sentences that cannot be parsed successfully. In this case, we wrote the silver statements manually. We also corrected 5 low-quality statements manually.

The weight factor for question type distribution learning is set as 0.7 empirically. For question type distribution learning, we used a BERT cased large model. For summary generation, we used a BART cased base model. For question generation, we used a BART cased large model. The batch sizes of all training are set as 1. For the generation process, we only used a greedy decoding method. Automatic evaluation results were calculated with open sourced packages [1]. For all methods, we removed duplicated questions and questions that has less than 3 tokens. All experiments were conducted on a Ubuntu server with Intel(R) Xeon(R) Silver 4216 CPU @ 2.10GHz, 32G Memory, Nvidia GPU 2080Ti, Ubuntu 16.04. Training our model took about three hours.

5 Results and Analysis

5.1 Automatic Evaluation Results

The results of automatic evaluation on both validation and test datasets are shown in Table 1. For Rouge-L, compared to E2E and QAG, our method can achieve the best results except for the recall values. In particular, our method outperforms E2E by about 20 points, and outperforms the best QAG model (top2) by about 10 points on the precision scores. For F1, our method outperforms E2E by about 10 points, and outperforms the best QAG model (top2) by about 5 points. These results show

---

[1] We used the package from `https://github.com/google-research/google-research/tree/master/rouge` to calculate Rouge-L, and the package from `https://github.com/Tiiiger/bert_score` to calculate BERTScore.

	Rouge-L			BERTScore

Ours	**33.49/37.50**	37.50/31.54	**31.81/30.58**	**0.8915/0.8862**	**0.8886/0.8930**	**0.8898/0.8893**

Table 1: The comparison results on Rouge-L and BERTScore by concatenating generated questions together.

Method	Pre(val/test)	Rec(val/test)	F1(val/test)
E2E	31.29/30.80	36.21/36.53	31.77/31.65
QAG (top2)	35.17/33.51	35.33/33.83	34.21/32.64
Ours	**48.30/44.05**	**39.55/36.68**	**41.78/38.29**

Table 2: The comparison results with the setup used by Yao et al. (2021).

that our method can match the ground-truth questions lexically better than other methods. However, the recall score of our method is not as good as E2E and QAG (top5 & 10). This is because for E2E and QAG (top5 & 10), they generally generate more questions than our method[2]. For BERTScore, our method achieves the best results on precision, recall, and F1. Although our method outperforms QAG (top2) by a small margin, it still outperforms other QAG models by at least 1 point. For the setup used by Yao et al. (2021), as shown in Table 2, our method also outperforms the best QAG model, *i.e.*, QAG (top 2), and E2E by a large margin in terms of Rouge-L. We believe that decomposing question types explicitly and using event-centric summaries to generate questions can capture the internal structure of educational question annotations and fit the data distribution in a more accurate way.

Some examples of the generated questions can be seen in Table 3. Our method usually can predict the correct question types, and cross multiple elements to generate HCD questions, with a limitation of factuality errors. More examples and comparison can be found in section C of the appendix.

Apart from the overall performance, we also investigated the performance of each module of our method. Because the performance values on both the validation and test data are similar, to simplify our experiment, in the following sections, we only conducted experiments on the test data.

Question Type Distribution Learning. On the test set, the K-L divergence between the prediction results of our BERT-based model and ground-truth is 0.0089, which shows that the performance of our question type distribution learning module is relatively satisfactory. We also use the ground-truth question type distribution as an input and calculate the final Rouge-L score with our system. The results are shown in Table 4. Compared to the ground-truth question type distribution, our system still has lower precision and F1 scores. Having a more accurate question type distribution prediction is beneficial for improving the overall performance.

Event-centric Summary Generation To investigate the quality of the generated summaries, we compare the generated results with the silver summary ground-truth. Similar to the evaluation method of generated questions, we concatenated the generated summaries and calculated the Rouge-L score with the concatenated ground-truth summaries. The results are 15.41 precision, 30.60 recall, and 18.85 F1, which shows that there is still a lot of room to improve the summarization module.

Upper-bound Results with Silver Summary To see how the upper-bound performance is if we have perfect summaries, we input the silver summaries to our educational question generation model. The Rouge-L scores of generated questions are 92.71 precision, 85.65 recall, 87.67 F1, which shows the potential that once a good summary containing salient events is available, generating an educational question is relatively easy. The core challenge is to obtain good summaries, which we believe will be a valuable next step in future work.

5.2 Human Evaluation Results

We conducted a human evaluation with consent of our method against the best-performed baseline QAG (top2). We first randomly sampled 10 books from the test set. For each book, we randomly sam-

---

[2] On the test data, the mean of the generated questions by our method is 1.9 (std: 0.6), which is closer to the case of ground-truth (mean: 2.2, std: 1.5)

	Questions
QAG (top2)	**P1**: Once upon a time there was a farmer who had carted pears to market .? Why did the farmer want to cart pears?
	P2: What happened to the dwarf after he left? As for the silent earl and his irish sweetheart , they were married as soon?
Ours	**P1**: Why did the bonze want to get a good price for the pears? (causal relationship) What did the bonze ask for? (action)
	P2: What did the Islanders want to express when they were married? (action) Why did the Islanders hold to the belief that Snorro was spirited away? (causal relationship)
Gold	**P1**: Why did the farmer hope to get a good price for the pears? (causal relationship) What did the farmer do when he grew angry? (action)
	P2: What did Paul and Lady Morna do after Harold's funeral was over? (action) Why did Snorro lose all chance of finding the magic carbuncle? (causal relationship)

Table 3: Randomly selected examples of generated questions from two paragraphs (**P1** and **P2**).

Method	Pre	Rec	F1
Ours (gt)	**46.48**	**31.96**	**35.77**
Ours (tdl)	37.50	31.54	30.58

Table 4: The Rouge-L scores of our method with the ground-truth (denoted as gt) and predicted (denoted as tdl) on question type distribution learning.

pled 5 paragraphs. We then conducted experiments to evaluate the generated results on question type and quality. Participants are researchers or PhD students based in Europe, U.S., and China working on natural language processing and human-computer interaction in the education domain with at least 3 years of experience, and were recruited through word-of-mouth and paid $30. We had a training session to ensure the annotation among participants is consistent. This study is approved by IRB.

Question type. Three human participants annotated the types of all generated questions. The inter-coder reliability score (Krippendoff's alpha (Krippendorff, 2011)) among three participants is 0.86, indicating a relatively high consistency. The annotated results are shown in Table 5. Overall, our method demonstrates a much smaller K-L distance (**0.28**) to the ground-truth distribution, compared to QAG (**0.60**). We can see that our method has a better estimation of the distribution of question types, which is closer to the distribution of the ground-truth. QAG has a biased question type distribution and generates more outcome resolution questions.

	QAG(top2)	Ours	Ground-truth
Vague	17/17%	15/17%	0/0%
Action	21/21%	34/38%	47/48%
Causal	10/10%	36/40%	32/33%
Outcome	51/52%	5/6%	18/19%

Table 5: The human evaluation results on of question types (**vague** denotes question types that are hard to decide or questions that have grammar mistakes).

Question quality. We invited another five human participants and conducted a human evaluation to further evaluate the quality of the generated questions from our model against the ground-truth and QAG, including *validity*, *readability*, and *children appropriateness*. Among the three dimensions, the *children appropriateness* is most closely related to the educational purpose; the former two dimensions mainly measure the factual correctness and fluency respectively.

For the total 10×5 paragraphs, each participant is assigned 20 different paragraphs randomly, and each paragraph has annotation results from two participants. For each paragraph, participants need to read the paragraph and its corresponding questions and answers, and then rate the three dimensions on a five-point Likert-scale. The Krippendoff's alpha scores along the four dimensions are between 0.60 and 0.80 (validity: 0.80, readability: 0.69, children appropriateness: 0.60), indicating an acceptable consistency (Gretz et al., 2020).

We conducted an independent-samples t-test to compare the performance of each model. Our model is significantly better than QAG on the main evaluation dimension of *children appropriateness*: the mean score of our model and QAG are 2.56 and 2.22, with corresponding standard derivation 1.31 and 1.20 respectively. This gives a significant score with p-value=0.009, showing that the questions generated by our model can indeed better fit the education scenario. For reference, the ground-truth has a mean score and standard derivation of 3.96 and 1.02, indicating a still large space to improve.

On *validity* and *readability*, our model is on par with QAG. This is not surprising because both models are based on large pre-trained BART models that are good at generating natural and fluent sentences. For validity, our model (avg: 3.19, std: 1.53) is a bit lower than QAG (avg: 3.27, std: 1.62);

for readability, our model (avg: 4.19, std: 1.53) is a bit higher than QAG (avg: 4.12, std: 1.33). A further breakdown in Table 6 shows that QAG wins mainly on action questions, because it directly generates questions conditioned on verbs. For causal relationship and outcome resolution questions, our method generally outperforms QAG.

	QAG	Ours
Vague	2.06*/2.03*	**2.97***/**3.03***
Action	**3.69/4.76***	3.35/4.34*
Causal	**3.45**/4.45	3.10/**4.46**
Outcome	3.46/4.49	**3.50/4.80**

Table 6: The mean values of human evaluation on question qualities (validity/readability), where * denotes significant difference.

6 System Analysis

To further investigate the effectiveness of our method, we conducted a set of ablation studies.

6.1 Question Type Distribution Learning

To investigate the effects of our question type distribution learning, we conducted a comparison study. In particular, we removed the question type distribution learning module (denoted as w/o tdl), and directly trained the summarization and question generation models. In other words, during training, we concatenate all silver summaries as the output of the summarization model. During testing, we extract the first 2 sentences as the predicted summaries. The results are shown in Table 7. From the comparison, we can see that without knowing question types, the Rouge-L scores drop about 3 points overall, which implies the importance of our question type distribution learning module.

6.2 Event-centric Summary Generation

To investigate the effects of our event-centric summary generation module, we conducted a comparison with different summarization methods. The summarization methods include: **1) Lead3**. We select the first three sentences of a paragraph as the summary, and use them as input to the question generation model; **2) Last3**. We select the last three sentences of a paragraph as the summary, and use them as input to the question generation model. **3) Random3**. We select the random three sentences of a paragraph as the summary, and use them as input to the question generation model. **4) Total**. We use each sentence of a paragraph as the summary, and use them as input to the question generation model. **5) TextRank**. TextRank is a typical extractive summarization method. We use TextRank to extract a summary, and for each sentence in the summary, we input it to the question generation model.

Method	Pre	Rec	F1
Ours (w/o tdl)	32.62	29.89	27.42
Ours	**37.50**	**31.54**	**30.58**

Table 7: The Rouge-L scores of our method with and without question type distribution learning.

Method	Pre	Rec	F1
Lead3	25.20	30.76	24.73
Last3	24.35	29.97	24.05
Random3	23.75	28.88	23.07
Total	22.69	**34.34**	24.63
TextRank	30.72	21.74	21.94
Ours (w/o tdl)	**32.62**	29.89	**27.42**

Table 8: The comparison results (Rouge-L on question generation) of different summarization methods.

For other summarization methods, they cannot get the question type distribution like our method. For a fair comparison, we also remove the question type distribution learning module of our method, which is the same as the setting in section 6.1. The results are shown in Table 8, from which we can see that extracting sentences from the paragraph is not enough for covering salient events for educational question generation. Our event-centric summary generation method is an effective way for extracting educational events of fairy tales. Using all sentences (total) can have the highest recall score at the expense of accuracy, but the overall F1 score is still relatively low.

6.3 Multi-task Learning of Question Types

Currently, we use control signals to constrain generating questions of different types, which can be viewed as a multi-task learning framework for multi-type question generation. To investigate whether sharing parameters is a good way for our task, we trained individual summarization and question generation models using different question types. The results in Rouge-L are shown in Table 9. We can find that sharing parameters generally can achieve better performance because of the use of more training data. For only using one type of training data, owing to the error of question type distribution learning, the performance drops a lot, showing the importance of combining question

Method	Pre	Rec	F1
Action	35.97	20.68	24.29
Causal	13.70	11.23	11.54
Outcome	6.15	4.97	5.30
Ours (individual)	25.71	**33.08**	26.27
Ours (overall)	**37.50**	31.54	**30.58**

Table 9: The comparison results of training separate summarization and question generation models on each question type.

type distribution learning and multi-task learning with different types of training data.

7 Conclusion

In this paper, we propose a novel method for educational question generation for fairy tales, which can potentially be used in early childhood education. Our method contains three modules: question type distribution learning, event-centric summary generation, and educational question generation. Through question type distribution learning, we can decompose the challenges of educational question generation by extracting related events of one question type and generating educational questions with a short event-centric summary, which improves the performance significantly. On both automatic evaluation and human evaluation, we show the potential of our method. In the future, we plan to further investigate the event-centric summary generation module by considering discourse-level information to improve the summarization performance and improve the factuality error problem. We are also interested in deploying the system in real scenarios to benefit childcare-related domains.

Acknowledgments

The authors thank constructive suggestions from all anonymous reviewers, as well as all participants in our human evaluation session. A Dataset Statistics

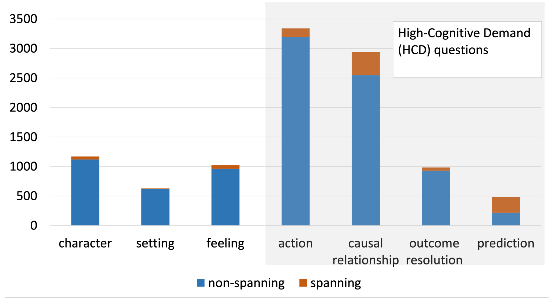

Figure 2: Question type distribution of FairytaleQA.

The question type distribution of FairytaleQA is shown in Figure 2. In particular, question types *action, causal relationship, outcome resolution, and prediction* are considered as HCD questions. For each question type, there are some questions that span multiple paragraphs (denoted as *spanning*, *character*: 53, *setting*: 11, *feeling*: 59, *action*: 143, *causal relationship*: 392, *outcome resolution*: 54, *prediction*: 266), which are discarded. We select question types *action, causal relationship, and outcome resolution* from FairytaleQA for conducting our experiments. In total, there are 2998 out of 4095 paragraphs used, including 2430 out of 3350 training paragraphs, 290 out of 380 validation paragraphs, and 278 out of 365 paragraphs. The number of QA pairs for each question type and the total number are shown in Table 10, and the token-level statistics of the selected training data can be found in Table 11.

	train	val	test	total
#action	2574	322	302	3198
#causal relationship	2057	246	244	2547
#outcome resolution	766	93	72	931
#selected	5397	661	618	6676
#total	8548	1025	1007	10580

Table 10: The numbers of QA pairs for question types *action*(#action), *causal relationship*(#causal relationship) and *outcome resolution*(#outcome resolution), the selected data (#selected), and all data of FairytaleQA (#total).

	mean	std
#question	2.2	1.5
#token (paragraph)	160.4	65.1
#token (summary)	17.8	7.2
#token (question)	10.1	3.1

Table 11: The mean and standard deviation (std) of the number of questions for each paragraph (#question) and the number of tokens (#token) in paragraphs, summaries, and questions in the training data.

B Potential Risks

While High-Cognitive Demand (HCD) questions are considered in this paper, the cultivation of knowledge and ability is equally important for children. The experiment results show that our method is competitive to generate HCD questions, and therefore it is helpful to improve children's cognitive ability. However, because of the unexplainability of end-to-end training, we also find that sometimes our system may generate non-factual facts in terms of the original context, which has a potential risk on knowledge learning. Owing to the factuality error problem of our system, we suggest to further investigate constructing structured knowledge of fairy tales and knowledge-grounded question generation for real-world applications.

C Examples of Generated Questions

Some randomly selected examples of the generated questions can be found in Table 12.

Paragraph: Once upon a time there was a farmer who had carted pears to market. Since they were very sweet and fragrant, he hoped to get a good price for them. A bonze with a torn cap and tattered robe stepped up to his cart and asked for one. The farmer repulsed him, but the bonze did not go. Then the farmer grew angry and began to call him names. The bonze said: "You have pears by the hundred in your cart. I only ask for one. Surely that does you no great injury. Why suddenly grow so angry about it?"

Gold questions: Why did the farmer hope to get a good price for the pears? (causal relationship) What did the farmer do when he grew angry? (action)

Generated questions by our method: Why did the bonze want to get a good price for the pears? (causal relationship) What did the bonze ask for? (action)

Generated questions by QAG (top2): Once upon a time there was a farmer who had carted pears to market .? Why did the farmer want to cart pears?

Silver summaries: The farmer hoped to get a good price for the pears because they were very sweet and fragrant. (causal relationship) The farmer called the bonze names when he grew angry. (action)

Generated summaries by our method: The bonze wanted to get a good price for the pears because they were very sweet and fragrant. (causal relationship) The bonze asked for one. (action)

Paragraph: No one knew what had become of them; a few people were inclined to think that the Dwarf and his Raven had accompanied the Countess Fraukirk and the Countess Helga on their flight, but the greater part of the Islanders held to the belief, which I think was the true one, that the Powers of the Air spirited Snorro away, and shut him up in some unknown place as a punishment for his wickedness, and that his Raven accompanied him. At any rate, he was never seen again by any living person, and wherever he went, he lost all chance of finding the magic carbuncle. As for the Silent Earl and his Irish Sweetheart, they were married as soon as Earl Harold's funeral was over; and for hundreds of years afterwards, when the inhabitants of the Orkney Isles wanted to express great happiness, they said, "As happy as Earl Paul and the Countess Morna."

Gold questions: What did Paul and Lady Morna do after Harold's funeral was over? (action) Why did Snorro lose all chance of finding the magic carbuncle? (causal relationship)

Generated questions by our method: What did the Islanders want to express when they were married? (action) Why did the Islanders hold to the belief that Snorro was spirited away? (causal relationship)

Generated questions by QAG (top2): What happened to the dwarf after he left? As for the silent earl and his irish sweetheart , they were married as soon?

Silver summaries: Paul and Lady Morna they was married after Harold's funeral was over. (action) Snorro lost all chance of finding the magic carbuncle because he did not live on the island anymore. (causal relationship)

Generated summaries by our method: The Islanders wanted to express great happiness when they were married. (action) The Islanders held to the belief that Snorro was spirited away because he wickedness. (causal relationship)

Paragraph: The King danced again with the beautiful maiden, and thought she had never looked so beautiful. And while he was dancing, he put a gold ring on her finger without her seeing it, and he commanded that the dance should last longer than usual. When it was finished he wanted to keep her hands in his, but she broke from him, and sprang so quickly away among the people that she vanished from his sight. She ran as fast as she could to her little room under the stairs, but because she had stayed too long beyond the half-hour, she could not stop to take off the beautiful dress, but only threw the fur cloak over it, and in her haste she did not make herself quite black with the soot, one finger remaining white.

Gold questions: What did the king do to the maiden while they were dancing? (action) What happened because the maiden stayed too long beyond the half-hour? (outcome resolution) Why did the king want to keep the maiden's hand in his? (causal relationship)

Generated questions by our method: What did the maiden do because it had stayed too long beyond the half-hour? (action) What happened after the maiden danced again with her dress? (outcome resolution) Why did the maiden break from the King? (causal relationship)

Generated questions by QAG (top2): What happened after the king danced again with his beautiful maiden? What happened because the king danced again with his beautiful maiden?

Silver summaries: The king he put a gold ring on her finger without her seeing it to the maiden while they were dancing. (action) Because the maiden stayed too long beyond the half - hour she could not stop to take off the beautiful dress (outcome resolution) The king wanted to keep the maiden's hand in his because he loved her. (causal relationship)

Generated summaries by our method: The maiden ran as fast as she could to her little room under the stairs because it had stayed too long beyond the half - hour. (action) After the maiden danced again with her dress she only threw it over it, and in haste did not make herself quite black. (outcome resolution) The maiden broke from the King because she had stayed too long beyond the half - hour. (causal relationship)

Paragraph: Art thou satisfied now?' said Matte to his wife. 'I should be quite satisfied,' said his wife, 'if only I had two servants to help, and if I had some finer clothes. Don't you know that I am addressed as Madam?' 'Well, well,' said her husband. So Maie got several servants and clothes fit for a great lady. 'Everything would now be perfect if only we had a little better dwelling for summer. You might build us a two-storey house, and fetch soil to make a garden. Then you might make a little arbour up there to let us have a sea-view; and we might have a fiddler to fiddle to us of an evening, and a little steamer to take us to church in stormy weather.' 'Anything more?' asked Matte; but he did everything that his wife wished. The rock Ahtola became so grand and Maie so grand that all the sea-urchins and herring were lost in wonderment. Even Prince was fed on beefsteaks and cream scones till at last he was as round as a butter jar. 'Are you satisfied now?' asked Matte. 'I should be quite satisfied,' said Maie, 'if only I had thirty cows. At least that number is required for such a household.' 'Go to the fairies,' said Matte.

Gold questions: What did Maie want Matte to build? (action) How many cows did Maie want? (action)

Generated questions by our method: What did Maie get? (action) What did the rock Ahtola become? (action)

Generated questions by QAG (top2): What did matte ask his wife to do? What did matte tell his wife to do?

Silver summaries: Maie wanted a two - storey house Matte to build. (action) Maie wanted thirty cows. (action)

Generated summaries by our method: Maie got several servants and clothes fit for a great lady. (action) The rock Ahtola became so grand and Maie was lost in wonderment. (action)

Table 12: Randomly selected examples of original paragraphs, their corresponding gold questions, questions generated by our method, questions generated by QAG (top2), silver summaries, and summaries generated by our method.

HETERMPC: A Heterogeneous Graph Neural Network for Response Generation in Multi-Party Conversations

Abstract

Recently, various response generation models for two-party conversations have achieved impressive improvements, but less effort has been paid to multi-party conversations (MPCs) which are more practical and complicated. Compared with a two-party conversation where a dialogue context is a sequence of utterances, building a response generation model for MPCs is more challenging, since there exist complicated context structures and the generated responses heavily rely on both interlocutors (i.e., speaker and addressee) and history utterances. To address these challenges, we present HeterMPC, a heterogeneous graph-based neural network for response generation in MPCs which models the semantics of utterances and interlocutors simultaneously with two types of nodes in a graph. Besides, we also design six types of meta relations with node-edge-type-dependent parameters to characterize the heterogeneous interactions within the graph. Through multi-hop updating, HeterMPC can adequately utilize the structural knowledge of conversations for response generation. Experimental results on the Ubuntu Internet Relay Chat (IRC) channel benchmark show that HeterMPC outperforms various baseline models for response generation in MPCs.

1 Introduction

Enabling dialogue systems to converse naturally with humans is a challenging yet intriguing problem of artificial intelligence and has attracted increasing attention due to its promising potentials and alluring commercial values (Kepuska and Bohouta, 2018; Berdasco et al., 2019; Zhou et al., 2020). A large number of researchers have focused on building dialogue generation models with various neural networks. At first, researchers mostly focused on dialogues between two participants (Shang et al., 2015; Serban et al., 2016; Wen et al., 2017; Young et al., 2018). Recently, researchers have paid more attention to a more practical and challenging scenario involving more than two participants, which is well known as multi-party conversations (MPCs) (Ouchi and Tsuboi, 2016; Zhang et al., 2018; Le et al., 2019; Hu et al., 2019b; Wang et al., 2020b; Gu et al., 2021). Utterances in a two-party conversation are posted one by one between two interlocutors, constituting a *sequential* information flow. Different from that, utterances in an MPC can be spoken by anyone and address anyone else in this conversation, which constitutes a *graphical* information flow as shown in Figure 1.

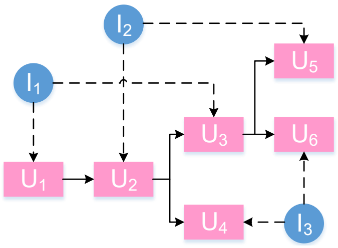

Figure 1: Illustration of a graphical information flow in an MPC. Pink rectangles denote utterances and blue circles denote interlocutors. Each solid line represents the "*replied-by*" relationship between two utterances. Each dashed line indicates the speaker of an utterance.

Although sequence-to-sequence (Seq2Seq) models (Sutskever et al., 2014; Serban et al., 2016) are effective at modeling sequential dialogues, they fall short of modeling graph-structured ones. To overcome this drawback, Hu et al. (2019b) first proposed a graph-structured network (GSN) to encode utterances based on the graph topology rather than the sequence of their appearances. The graph established in GSN was homogeneous, where nodes represented only utterances. However, interlocutors are also important components of MPCs. There exist complicated interactions between interlocutors, and between an utterance

Volume 1: Long Papers, pages 5086 - 5097
May 22-27, 2022

and an interlocutor. Furthermore, when passing messages over a graph, a bidirectional information flow algorithm was designed for GSN. Since both the forward and backward information flows employed the same model structure and parameters, this algorithm cannot distinguish the "*reply*" or "*replied-by*" relations between two connected utterance nodes. Also, information flows along both directions are independently propagated, so that a graph node cannot be jointly updated at a single propagation step.

On account of above issues, we propose a heterogeneous graph-based neural network for response generation in MPCs, named HeterMPC. First, a heterogeneous graph is designed which employs two types of nodes to represent utterances and interlocutors respectively. Different from previous methods that built a homogeneous graph modeling only utterances, utterances and interlocutors are modeled simultaneously in HeterMPC, so that the complicated interactions between interlocutors, between utterances, and between an interlocutor and an utterance can be explicitly described. In order to characterize the heterogeneous attention over each (*source, edge, target*) triple, model parameters dependent on both types of nodes and edges are introduced when calculating attention weights and passing messages. Specifically, we introduce six types of meta relations for modeling different edges including "*reply*" and "*replied-by*" between two utterances, "*speak*" and "*spoken-by*" between an utterance and a speaker, and "*address*" and "*addressed-by*" between an utterance and an addressee. With these node-edge-type-dependent structures and parameters, HeterMPC can better utilize the structural knowledge of conversations for node representation and response generation than conventional homogeneous graphs. Finally, Transformer is employed as the backbone of HeterMPC and its model parameters can be initialized with PLMs to take advantage of the recent breakthrough on pre-training.

We evaluate HeterMPC on the Ubuntu Internet Relay Chat (IRC) channel benchmark released by Hu et al. (2019b). Experimental results show that HeterMPC outperforms GSN (Hu et al., 2019b), GPT-2 (Radford et al., 2019), BERT (Devlin et al., 2019) and BART (Lewis et al., 2020) by significant margins in terms of both automated and human evaluation metrics, achieving a new state-of-the-art performance for response generation in MPCs.

In summary, our contributions in this paper are three-fold: 1) To the best of our knowledge, this paper is the first exploration of using heterogeneous graphs for modeling conversations; 2) A Transformer-based heterogeneous graph architecture is introduced for response generation in MPCs, in which two types of nodes, six types of meta relations, and node-edge-type-dependent parameters are employed to characterize the heterogeneous properties of MPCs; 3) Experimental results show that our proposed model achieves a new state-of-the-art performance of response generation in MPCs on the Ubuntu IRC benchmark.

2 Related Work

Multi-Party Conversation Existing methods on building dialogue systems can be generally categorized into generation-based (Shang et al., 2015; Serban et al., 2016; Wen et al., 2017; Young et al., 2018; Zhang et al., 2020) or retrieval-based approaches (Lowe et al., 2015; Wu et al., 2017; Zhou et al., 2018; Tao et al., 2019a,b; Gu et al., 2019, 2020). In this paper, we study the task of response generation in MPCs, where in addition to utterances, interlocutors are also important components who play the roles of speakers or addressees. Previous methods have explored retrieval-based approaches for MPCs. For example, Ouchi and Tsuboi (2016) proposed the dynamic model which updated speaker embeddings with conversation streams. Zhang et al. (2018) proposed speaker interaction RNN which updated speaker embeddings role-sensitively. Wang et al. (2020b) proposed to track the dynamic topic in a conversation. Gu et al. (2021) proposed jointly learning "who says what to whom" in a unified framework by designing self-supervised tasks during pre-training. On the other hand, Hu et al. (2019b) explored generation-based approaches by proposing a graph-structured network, the core of which was an utterance-level graph-structured encoder.

Heterogeneous Graph Neural Network Early studies on graph neural networks (GNNs) focused on homogeneous graphs where a whole graph is composed of a single type of nodes. However, graphs in real-world applications usually come with multiple types of nodes, namely heterogeneous information networks (HINs) or heterogeneous graphs (Sun and Han, 2012). Recently, researchers have attempted to extend GNNs to model heterogeneity. For example, Zhang et al.

(2019) adopted different RNNs for different types of nodes to integrate multi-modal features. Wang et al. (2019) extended graph attention networks by maintaining different weights for different meta-path-defined edges. Hu et al. (2020) proposed heterogeneous graph Transformer (HGT) to model heterogeneity by maintaining dedicated representations for different types of nodes and edges. In addition, heterogeneous graphs have also been applied to many NLP tasks, such as multi-hop reading comprehension (Tu et al., 2019), text classification (Hu et al., 2019a) and document summarization (Wang et al., 2020a).

Previous studies have verified the superiority of modeling MPCs with homogeneous graphs considering only utterances. We claim that it is indeed necessary to model a complex information flow in MPCs shown in Figure 1 with a heterogeneous graph, since a homogeneous one cannot explicitly model the relationships of multiple utterances spoken by or addressing an interlocutor. Nowadays, HINs have been widely used in many NLP tasks. To the best of our knowledge, this paper makes the first attempt to build a heterogeneous graph-based neural network considering utterances and interlocutors simultaneously for response generation in MPCs. In addition, we introduce many task-specific modelings for MPCs such as graph construction and node updating which will be elaborated in the model section.

3 Problem Formulation

The task of response generation in MPCs is to generate an appropriate response $\bar{r}$ given the conversation history, the speaker of a response, and which utterance the response is going to reply to, which can be formulated as:

$$\begin{aligned} \bar{r} &= \operatorname*{argmax}_{r} logP(r|\mathbb{G}) \\ &= \operatorname*{argmax}_{r} \sum_{k=1}^{|r|} logP(r_k|\mathbb{G}r_{<k}). \end{aligned} \tag{1}$$

Here, $\mathbb{G}$ is a heterogeneous graph containing both history conversation and the response to be generated. The speaker and addressee of the response are known and its contents are masked. The response tokens are generated in an auto-regressive way. r_k and $r_{<k}$ stand for the k-th token and the first $(k-1)$ tokens of response r respectively. $|r|$ is the length of r.

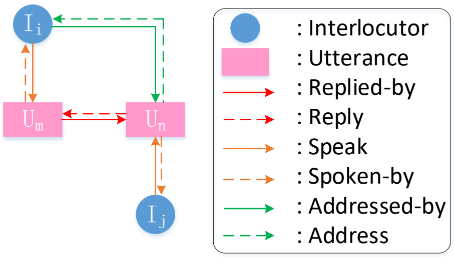

Figure 2: Illustration of the two types of nodes and six types of edges in a heterogeneous conversation graph. This example demonstrates that I_j speaks U_n replying U_m that is spoken-by I_i.

We will introduce how to construct the graph and how to model the probability in Eq. (1) given the built graph in the next section.

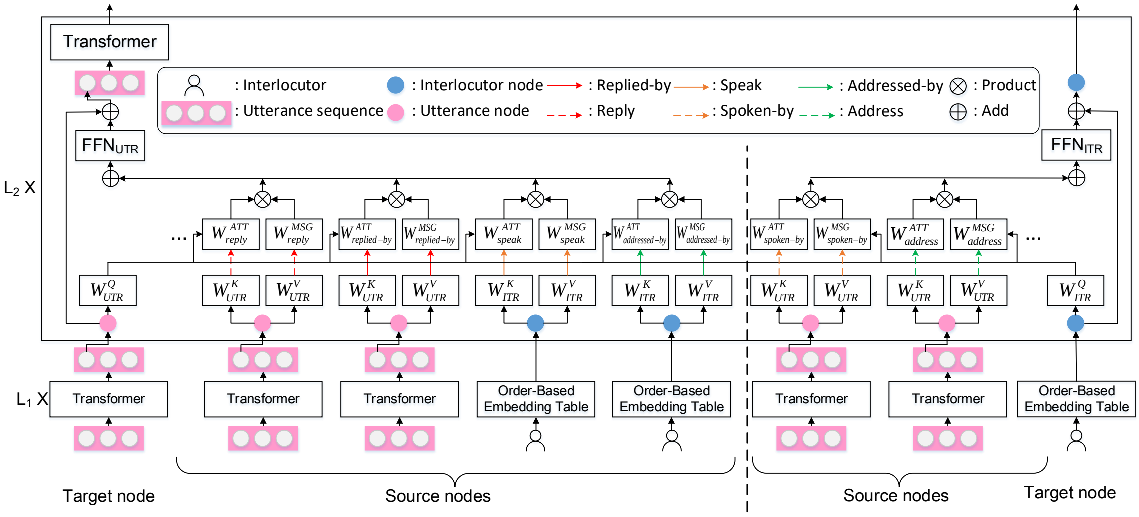
4 HeterMPC Model

HeterMPC adopts an encoder-decoder architecture consisting of stacked encoder and decoder layers for graph-to-sequence learning (Yao et al., 2020). The graph encoder is designed to capture conversation structures and output the representations of all nodes in a graph that are fed to the decoder for response generation.

4.1 Graph Construction

A heterogeneous graph is constructed to explicitly model the complicated interactions between interlocutors, between utterances, and between an interlocutor and an utterance in an MPC. This graph models utterances and interlocutors by considering them as two types of nodes under a unified framework. Given an MPC instance composed of M utterances and I interlocutors, a heterogeneous graph $\mathbb{G}(\mathbb{V}, \mathbb{E})$ is constructed. Specifically, $\mathbb{V}$ is a set of $M + I$ nodes. Each node denotes either an utterance or an interlocutor. $\mathbb{E} = \{e_{p,q}\}_{p,q=1}^{M+I}$ is a set of directed edges. Each edge $e_{p,q}$ describes the connection from node p to node q.

Inspired by Sun et al. (2011, 2012), we introduce six types of meta relations {*reply*, *replied-by*, *speak*, *spoken-by*, *address*, *addressed-by*} to describe the directed edge between two graph nodes as illustrated in Figure 2. Specifically, if an utterance represented by node n replies another utterance represented by node m, the edge $e_{n,m}$ = *reply* and the reversed edge $e_{m,n}$ = *replied-by*. If an utterance represented by node m is spoken by an interlocutor represented by node i, $e_{i,m}$ = *speak* and $e_{m,i}$ = *spoken-by*. If an utterance represented by node n addresses an interlocutor represented by



(a) Update of an utterance node

(b) Update of an interlocutor node

Figure 3: Model architecture of HeterMPC for (a) update of an utterance node and (b) update of an interlocutor node. “UTR" and “ITR" are abbreviations of “utterance" and “interlocutor" respectively. The set of W^{*}_{*} denotes the node-edge-type-dependent parameters.

node i, $e_{n,i} = \textit{address}$ and $e_{i,n} = \textit{addressed-by}$. In other cases, $e_{p,q} = \textit{NULL}$ indicating that there is no connection between these two nodes. Note that it is necessary to distinguish the bidirectional edges between every two nodes that indicate the active and passive tense information respectively.

4.2 Node Initialization

In HeterMPC, each node is represented as a vector. These vectors are first initialized individually without considering graph edges.

Utterances When encoding utterances, a `[CLS]` token is inserted at the start of each utterance, denoting the utterance-level representation. Besides, a `[SEP]` token is also inserted at the end of each utterance (Devlin et al., 2019). Then each utterance is encoded individually by stacked Transformer encoder layers through the self-attention mechanism to derive the contextualized utterance representations.[1] The output of a Transformer encoder layer is used as the input of the next layer. Readers can refer to Vaswani et al. (2017) for details of Transformer. Formally, the calculation for an utterance at the l-th Transformer layer is denoted as:

$$\boldsymbol{H}_m^{l+1} = \text{TransformerEncoder}(\boldsymbol{H}_m^{l}), \qquad (2)$$

where $m \in \{1, ..., M\}$, $l \in \{0, ..., L_1 - 1\}$, L_1 denotes the number of Transformer layers for initialization, $\boldsymbol{H}_m^l \in \mathbb{R}^{k_m \times d}$, k_m denotes the length of an utterance and d denotes the dimension of embedding vectors.

Interlocutors Different from an utterance composed of a sequence of tokens, an interlocutor is directly represented with an embedding vector. Interlocutors in a conversation are indexed according to their speaking order and the embedding vector for each interlocutor is derived by looking up an order-based interlocutor embedding table (Gu et al., 2020) that is updated during end-to-end learning. The first interlocutors in all conversation sessions share the same embedding vector in the interlocutor embedding table, so do all the second interlocutors.[2] Thus, this order-based embedding table can be shared across the training, validation and testing sets, and there is no need to estimate an embedding vector for each specific interlocutor in the dataset.

4.3 Node Updating

As shown in Figure 3, the initialized node representations are updated by feeding them into the built graph for absorbing context information (Kipf and Welling, 2017; Velickovic et al., 2018; Yun

---

[1] In our experiments, BERT or BART was selected to initialize the utterance encoder layers of HeterMPC. Then, the built HeterMPC models were compared with the baseline models directly finetuning BERT or BART, respectively. It is worth noting that the utterance encoder layers of HeterMPC can also be initialized by other types of PLMs, and the comparison across PLMs is not the focus of this paper.

[2] In our experiments, the maximum interlocutor number was set to 10 and an embedding table sized 10*768 was learned during training. We did study initializing the embedding vector of an interlocutor node by averaging the representations of all utterance nodes it speaks, but no further improvement can be achieved.

et al., 2019). We calculate heterogeneous attention weights between connected nodes and pass messages over the graph in a node-edge-type-dependent manner, inspired by introducing parameters to maximize feature distribution differences for modeling heterogeneity (Schlichtkrull et al., 2018; Wang et al., 2019; Zhang et al., 2019; Hu et al., 2020). After collecting the information from all source nodes to a target node, a node-type-dependent feed-forward network (FFN) followed by a residual connection (He et al., 2016) is employed to aggregate the information. Then, in order to let each token in an utterance have access to the information from other utterances, an additional Transformer layer is placed for utterance nodes specifically. L_2 denotes the number of iterations for updating both utterance and interlocutor nodes.

4.3.1 Heterogeneous Attention

Since the representations of two types of nodes are initialized in different ways, node-type-dependent linear transformations are first applied to node representations before attention calculation so that the two types of nodes share similar feature distributions (Wang et al., 2019; Hu et al., 2020). Meanwhile, each of the six relation types is assigned a separate linear projection so that the semantic relationship between two connected nodes can be accurately described when calculating attention weights. The forward and backward information flows between them can also be distinguished.

Formally, let the triple (*s, e, t*) denote an edge *e* connecting a source node *s* to a target node *t*. The representations of the source and target nodes at the *l*-th iteration[3] are denoted as $\boldsymbol{h}_s^l$ and $\boldsymbol{h}_t^l$, serving as a *key* (K) vector and a *query* (Q) vector of attention calculation respectively. Then, the heterogeneous attention weight $w^l(s,e,t)$ before normalization for this triple is calculated as:

$$\boldsymbol{k}^l(s) = \boldsymbol{h}_s^l \boldsymbol{W}_{\tau(s)}^K + \boldsymbol{b}_{\tau(s)}^K, \tag{3}$$

$$\boldsymbol{q}^l(t) = \boldsymbol{h}_t^l \boldsymbol{W}_{\tau(t)}^Q + \boldsymbol{b}_{\tau(t)}^Q, \tag{4}$$

$$w^l(s,e,t) = \boldsymbol{k}^l(s) \boldsymbol{W}_{e_{s,t}}^{ATT} \boldsymbol{q}^l(t)^T \frac{\mu_{e_{s,t}}}{\sqrt{d}}. \tag{5}$$

Here, $\tau(s), \tau(t) \in$ *{UTR, ITR}* distinguish utterance (*UTR*) and interlocutor (*ITR*) nodes. Eqs. (3) and (4) are node-type-dependent linear transformations. Eq. (5) contains an edge-type-dependent linear projection $\boldsymbol{W}_{e_{s,t}}^{ATT}$ where $\mu_{e_{s,t}}$ is an adaptive factor scaling to the attention. All $\boldsymbol{W}^* \in \mathbb{R}^{d \times d}$ and $\boldsymbol{b}^* \in \mathbb{R}^d$ are parameters to be learnt.

4.3.2 Heterogeneous Message Passing

When passing the message of a source node that serves as a *value* (V) vector to a target node, node-edge-type-dependent parameters are also introduced considering the heterogeneous properties of nodes and edges. Mathematically:

$$\boldsymbol{v}^l(s) = \boldsymbol{h}_s^l \boldsymbol{W}_{\tau(s)}^V + \boldsymbol{b}_{\tau(s)}^V, \tag{6}$$

$$\bar{\boldsymbol{v}}^l(s) = \boldsymbol{v}^l(s) \boldsymbol{W}_{e_{s,t}}^{MSG}, \tag{7}$$

where $\bar{\boldsymbol{v}}^l(s)$ is the passed message and all $\boldsymbol{W}^* \in \mathbb{R}^{d \times d}$ and $\boldsymbol{b}^* \in \mathbb{R}^d$ are parameters to be learnt.

4.3.3 Heterogeneous Aggregation

For a target node, the messages passed from all its connected source nodes need to be aggregated. A softmax function is applied to normalize the attention weights and then the messages from all source codes are summarized as:

$$\bar{\boldsymbol{h}}_t^l = \sum_{s \in S(t)} \mathrm{softmax}(w^l(s,e,t)) \bar{\boldsymbol{v}}^l(s), \tag{8}$$

where $S(t)$ denotes the set of source nodes for the target node t. Then the summarized message $\bar{\boldsymbol{h}}_t^l$ is aggregated with the original node representation $\boldsymbol{h}_t^l$ using a node-type-dependent FFN followed by a residual connection (He et al., 2016) as:

$$\boldsymbol{h}_t^{l+1} = \mathit{FFN}_{\tau(t)}(\bar{\boldsymbol{h}}_t^l) + \boldsymbol{h}_t^l, \tag{9}$$

where the output $\boldsymbol{h}_t^{l+1}$ is used as the input of the next iteration of node updating. One iteration can be viewed as a single-step information propagation along edges. When stacking L_2 iterations, a node can attend to other nodes up to L_2 hops away.

A specific consideration on utterance nodes is that the tokens except `[CLS]` in an utterance have no access to other utterances during the node updating process introduced above. To overcome this disadvantage and derive more contextualized utterance representations, an additional Transformer layer (Vaswani et al., 2017) is further placed for utterance nodes as shown in Figure 3. In detail, at the l-th iteration, the representations of an utterance node before and after node updating, i.e., $\boldsymbol{h}_t^l$ and $\boldsymbol{h}_t^{l+1}$, are concatenated and then compressed by a linear transformation as:

$$\hat{\boldsymbol{h}}_t^{l+1} = [\boldsymbol{h}_t^l; \boldsymbol{h}_t^{l+1}] \boldsymbol{W}_{com} + \boldsymbol{b}_{com}, \tag{10}$$

---

[3] For an utterance, the representation for the `[CLS]` token is extracted as the utterance-level representation.

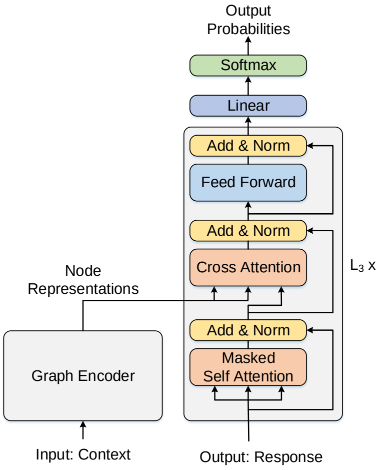


Figure 4: The decoder architecture of HeterMPC.

where $\boldsymbol{W}_{com} \in \mathbb{R}^{2d \times d}$ and $\boldsymbol{b}_{com} \in \mathbb{R}^{d}$ are parameters. Then, $\hat{\boldsymbol{h}}_t^{l+1}$ replaces the representation of `[CLS]` (i.e., $\boldsymbol{h}_t^l$) in the sequence representations of the whole utterance. Finally, the updated sequence representations are fed into the additional Transformer layer for another round of intra-utterance self-attention, so that the context information learnt by the `[CLS]` representation can be shared with other tokens in the utterance.

4.4 Decoder

The decoder is composed of a stack of identical layers as shown in Figure 4. We follow the standard implementation of Transformer decoder to generate responses. In each decoder layer, a masked self-attention operation is first performed where each token cannot attend to future tokens to avoid information leakage. Furthermore, a cross-attention operation over the node representations of the graph encoder output is performed to incorporate graph information for decoding. It is notable that a residual connection along with layer normalization is followed by each attention operation.

5 Experiments

5.1 Datasets

We evaluated our proposed method on the Ubuntu IRC benchmark used in Hu et al. (2019b). The data processing script provided by Hu et al. (2019b) was employed to derive the dataset.[4] In this dataset, both speaker and addressee labels were included for each utterance in a session. When testing, the speaker and addressee information was both given for response generation, i.e., the system knew who would speak next and which utterance should be responded to following the graph structure. It contained 311,725/5,000/5,000 dialogues in the training/validation/testing sets respectively.

5.2 Baseline Models

We compared our proposed methods with as many MPC models as possible. Considering that there are only a few research papers in this field, several recent advanced models were also adapted to provide sufficient comparisons. Finally, we compared with the following baseline models: **(1) RNN-based Seq2Seq** (Sutskever et al., 2014) took all utterances except the target utterance to generate as input, which were sorted according to their posting time and concatenated. Thus, structured conversations were converted into sequential ones. Seq2Seq modeling with attention was performed as that in Sutskever et al. (2014); Bahdanau et al. (2015) on the concatenated utterances. **(2) Transformer** (Vaswani et al., 2017) took the same input utterances as those used for the Seq2Seq model. **(3) GPT-2** (Radford et al., 2019) was a uni-directional pre-trained language model. Following its original concatenation operation, all context utterances and the response were concatenated with a special `[SEP]` token as input for encoding. **(4) BERT** (Devlin et al., 2019) concatenated all context utterances and the response similarly as those for GPT-2. To adapt BERT for response generation, a special masking mechanism was designed to avoid response information leakage during encoding. Concretely, each token in the context utterances attended to all tokens in the context utterances, while each token in the response cannot attend to future tokens in the utterance. **(5) GSN** (Hu et al., 2019b) achieved the state-of-the-art performance on MPCs. The core of GSN was an utterance-level graph-structured encoder. **(6) BART** (Lewis et al., 2020) was a denoising autoencoder using a standard Tranformer-based architecture, trained by corrupting text with an arbitrary noising function and learning to reconstruct the original text. In our experiments, a concatenated context started with <s> and separated with </s> were fed into the encoder, and a response were fed into the decoder.

5.3 Evaluation Metrics

To ensure all experimental results were comparable, we used the same automated and human evaluation

---

[4] We contacted the authors of Hu et al. (2019b) to obtain the data processing script. As they claimed, it was an updated version which was a little different from that used in their paper. Thus, we re-implemented all baselines on this updated dataset to ensure fair comparison.

Metrics Models	BLEU-1	BLEU-2	BLEU-3	BLEU-4	METEOR	ROUGE$_L$
Seq2Seq (LSTM) (Sutskever et al., 2014)	7.71	2.46	1.12	0.64	3.33	8.68
Transformer (Vaswani et al., 2017)	7.89	2.75	1.34	0.74	3.81	9.20
GSN (Hu et al., 2019b)	10.23	3.57	1.70	0.97	4.10	9.91
GPT-2 (Radford et al., 2019)	10.37	3.60	1.66	0.93	4.01	9.53
BERT (Devlin et al., 2019)	10.90	3.85	1.69	0.89	4.18	9.80

HeterMPC$_{BERT}$ w/o. node and edge types	11.60	3.98	1.90	1.18	4.20	10.63
HeterMPC$_{BERT}$ w/o. interlocutor nodes	11.80	3.96	1.75	1.00	4.31	10.53
BART (Lewis et al., 2020)	11.25	4.02	1.78	0.95	4.46	9.90
HeterMPC$_{BART}$	**12.26**	**4.80**	**2.42**	**1.49**	**4.94**	**11.20**
HeterMPC$_{BART}$ w/o. node types	11.22	4.06	1.87	1.04	4.57	10.63
HeterMPC$_{BART}$ w/o. edge types	11.52	4.27	2.05	1.24	4.78	10.90
HeterMPC$_{BART}$ w/o. node and edge types	10.90	3.90	1.79	1.01	4.52	10.79
HeterMPC$_{BART}$ w/o. interlocutor nodes	11.68	4.24	1.91	1.03	4.79	10.65

Table 1: Performance of HeterMPC and ablations on the test set in terms of automated evaluation. Numbers in bold denote that the improvement over the best performing baseline is statistically significant (t-test with p-value < 0.05).

Metrics Models	Score	Kappa
Human	2.81	0.55
GSN (Hu et al., 2019b)	2.00	0.50
BERT (Devlin et al., 2019)	2.19	0.42
BART (Lewis et al., 2020)	2.24	0.44
HeterMPC$_{BERT}$	2.39	0.50
HeterMPC$_{BART}$	2.41	0.45

Table 2: Human evaluation results of HeterMPC and some selected systems on a randomly sampled test set.

metrics as those used in previous work (Hu et al., 2019b). Hu et al. (2019b) used the evaluation package released by Chen et al. (2015) including BLEU-1 to BLEU-4, METEOR and ROUGE$_L$, which was also used in this paper.[5] Human evaluation was conducted to measure the quality of the generated responses in terms of three independent aspects: 1) relevance, 2) fluency and 3) informativeness. Each judge was asked to give three binary scores for a response, which were further summed up to derive the final score ranging from 0 to 3.

5.4 Training Details

Model parameters were initialized with pre-trained weights of *bert-base-uncased* released by Wolf et al. (2020). The AdamW method (Loshchilov and Hutter, 2019) was employed for optimization. The learning rate was initialized as $6.25e$-5 and was decayed linearly down to 0. The max gradient norm was clipped down to 1.0. The batch size was set to 16 with 8 gradient accumulation steps. The maximum utterance length was set to 50. The number of layers for initializing utterance representations L_1 was set to 9, and the number of layers for heterogeneous graph iteration L_2 was set to 3. L_1 and L_2 were validated on the validation set. The number of decoder layers L_3 was set to 6, achieving the best performance out of {2, 4, 6, 8} on the validation set. The strategy of greedy search was performed for decoding. The maximum length of responses for generation was also set to 50. All experiments were run on a single GeForce RTX 2080 Ti GPU. The maximum number of epochs was set to 15, taking about 40 hours. The validation set was used to select the best model for testing. All code was implemented in the PyTorch framework[6] and are published to help replicate our results. [7]

5.5 Evaluation Results

In our experiments, BERT and BART were selected to initialize HeterMPC. HeterMPC$_{BERT}$ denoted that the utterance encoder was initialized with BERT and the decoder was randomly initialized. HeterMPC$_{BART}$ denoted the encoder and decoder

---

[5] https://github.com/tylin/coco-caption

[6] https://pytorch.org/

[7] https://github.com/lxchtan/HeterMPC

were initialized by those of BART respectively.

Automated Evaluation Table 1 presents the evaluation results of HeterMPC$_{BERT}$, HeterMPC$_{BART}$ and previous methods on the test set. Each model ran four times with identical architectures and different random initializations, and the best out of them was reported. We ran the code released by Hu et al. (2019b) to reproduce the results of GSN for a fair comparison.[8] The results show that both HeterMPC$_{BERT}$ and HeterMPC$_{BART}$ outperformed all baselines in terms of all metrics. HeterMPC$_{BERT}$ outperformed GSN by 2.38% BLEU-1 and 0.44% BLEU-4, and outperformed GPT-2 by 2.24% BLEU-1 and 0.48% BLEU-4. HeterMPC$_{BART}$ outperformed GSN by 2.03% BLEU-1 and 0.52% BLEU-4, and outperformed GPT-2 by 1.89% BLEU-1 and 0.56% BLEU-4. Furthermore, HeterMPC$_{BERT}$ outperformed BERT by 1.71% BLEU-1 and 0.52% BLEU-4, and HeterMPC$_{BART}$ outperformed BART by 1.01% BLEU-1 and 0.54% BLEU-4, illustrating the importance of modeling MPC structures.

To further verify the effectiveness of our proposed methods, ablation tests were conducted as shown in Table 1. First, all nodes or edges were considered equivalently by employing the same linear transformations in Eqs. (3) to (9) for all node or edge types without distinguishing them. The drop in performance illustrates the effectiveness of the node-edge-type-dependent parameters. On the other hand, interlocutor nodes were removed out of a graph and only the meta relations of *reply* and *replied-by* were left. The drop in performance illustrates the importance of modeling interactions between utterances and interlocutors, and the effectiveness of the heterogeneous architecture.

Human Evaluation Table 2 presents the human evaluation results on a randomly sampled test set. 200 samples were evaluated and the order of evaluation systems were shuffled. Three graduate students were asked to score from 0 to 3 (3 for the best) and the average scores were reported. The Fleiss's kappa value (Fleiss, 1971) for each model was also reported, indicating the inter-judge moderate agreement during evaluation. It can be seen that HeterMPC$_{BERT}$ and HeterMPC$_{BART}$ achieved higher subjective quality scores than the baselines. Their kappa values were also higher than the BERT and BART baselines, respectively.

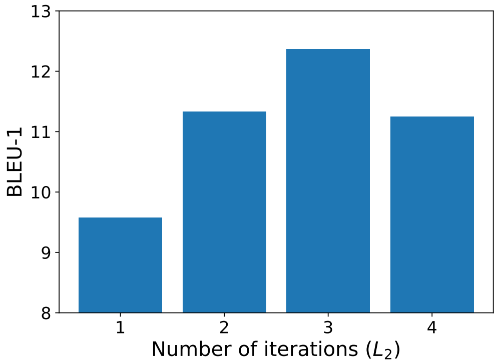

Figure 5: Performance of HeterMPC$_{BERT}$ under different numbers of iterations (L_2) on the test set.

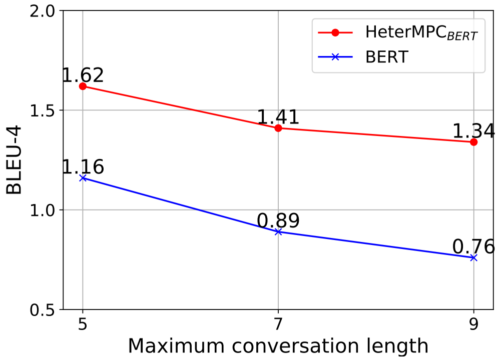

Figure 6: Performance of BERT and HeterMPC$_{BERT}$ on test samples with different session lengths.

5.6 Analysis

The impact of numbers of iterations (L_2). Figure 5 illustrates how the performance of HeterMPC$_{BERT}$ changed with respect to different numbers of iterations (L_2) on the test set. It can be seen that the performance of HeterMPC$_{BERT}$ was significantly improved as L_2 increased at the beginning, which shows the effectiveness of incorporating the contextual information between nodes. Then, the performance was stable and dropped slightly. The reason might be that models begin to overfit due to a larger set of parameters.

The impact of conversation length. [9] Figure 6 illustrates how the performance of HeterMPC$_{BERT}$ changed according to the test samples with different session lengths. As the session length increased, the performance of HeterMPC$_{BERT}$ dropped less than that of BERT, showing superiority of our method on dealing with longer conversations.

---

[8] https://github.com/morning-dews/GSN-Dialogues

[9] This experiment can also be considered as exploring the impact of interlocutor number, since more context utterances indicate that more interlocutors are involved implicitly.

Speaker	*Utterance*	*Addressee*
	Case 1	
I.1	geev: in gparted now?	-
I.2	there is no such command in my computer	I.1

I.2	lsmod less will show you te loaded modules	I.3
I.1	lmount - t ext3 filepath fails cause already mounted or busy	I.2
I.2	then try to mount it at command line **(Human)**	I.1
	i’m not sure how to do that **(GSN)**	
	i’m not sure what the problem is **(BERT)**	
	you need to mount it as a mount point **(HeterMPC$_{BERT}$)**	
	i’m not sure what the problem is **(BART)**	
	you need to check the filepath file **(HeterMPC$_{BART}$)**	

Table 3: The response generation results of two test samples. “I." is the abbreviation of “interlocutor". We kept original texts without manual corrections.

Case Study. Case studies were conducted by randomly sampling two MPC instances as shown in Table 3. Given the conversation graph of the first case, the response to generate addresses I.2. Thus, the information relevant to I.2 should be collected. We can see that “*gparted*” in the first utterance is two hops away from I.2 (the first utterance is replied by the second utterance which is spoken by I.2), and this word in the fourth utterance and “*install gparted*” in the third utterance are both one hop away from I.2 (these two utterances directly address I.2). The responses generated by HeterMPC$_{BERT}$ and HeterMPC$_{BART}$ both contain these keywords, showing that it can capture the conversation graph information accurately and generate a human-like response. However, due to the lack of the interlocutor information and the conversation structure, GSN generated an irrelevant response. BERT generated a response which seems replying to the third utterance. Although BART captured “*gparted*”, it failed to handle the action “*install*”. In the second case, we can see that the responses generated by GSN, BERT and BART are general and useless while HeterMPC$_{BERT}$ and HeterMPC$_{BART}$ can still generate a suitable response. Due to the complicated interactions between utterances and interlocutors, the conversation flow might be led by some unnecessary information, which shows the importance of making models aware of the conversation structure.

Robustness. The addressee labels are important for constructing a graph used in HeterMPC. This kind of label is commonly available in real life such as “A@B” labels in group chatting, Twitter, Reddit and various forums that denote speaker A talking to addressee B. However, addressee labels of a part of utterances are missing in the existing MPC datasets since a speaker may forget to specify an addressee. HeterMPC is robust since utterances without addressee labels can be assigned with a general addressee label “*To all interlocutors*”. We leave evaluation on other datasets in future work.

6 Conclusion

We present HeterMPC to model complicated interactions between utterances and interlocutors in MPCs with a heterogeneous graph. Two types of graph nodes and six types of edges are designed. Node-edge-type-dependent parameters are introduced for better utilizing the structural knowledge of conversations during node updating. Results show that HeterMPC outperforms baselines by significant margins, achieving a new state-of-the-art performance for response generation in MPCs on the Ubuntu IRC benchmark. In the future, we will explore better ways of maximizing feature distribution differences to model heterogeneity.

The patient is more dead than alive: exploring the current state of the multi-document summarization of the biomedical literature

Abstract

Although multi-document summarization (MDS) of the biomedical literature is a highly valuable task that has recently attracted substantial interest, evaluation of the quality of biomedical summaries lacks consistency and transparency. In this paper, using systematic reviews as an example of biomedical MDS, we examine the summaries generated by two current models in order to understand the deficiencies of existing evaluation approaches in the context of the challenges that arise in the MDS task. Based on this analysis, we propose a new approach to human evaluation and identify several challenges that must be overcome to develop effective biomedical MDS systems.

1 Introduction

With the number of biomedical publications doubling every two years (Cios et al., 2019), it is difficult for medical professionals to incorporate new, often contradictory, evidence into their daily work, as it would require appraising, comparing and synthesising the outcomes of multiple primary studies (Sackett and Rosenberg, 1996). Systematic reviews, which aggregate such evidence from multiple clinical trials, provide only a partial solution, as they are very time-consuming to write and thus can be unavailable for newer clinical questions or quickly become outdated. In this context, the ability to automatically summarize evidence from multiple studies is of high practical importance. The task, however, is more challenging than general multi-document summarization (MDS), as the summaries must correctly draw conclusions based on often contradictory studies, and aggregate details such as groups of patients or names and doses of treatments, in addition to dealing with often-cited difficulties posed by biomedical text such as complex lexical and semantic relationships between concepts (Plaza et al., 2011). Though recent approaches to biomedical summarization acknowledge the additional challenges of the task and try to incorporate some domain-specific knowledge to deal with them (Wallace et al., 2021; Shah et al., 2021; DeYoung et al., 2021), we still lack a solid understanding of how well current models capture such knowledge, how useful the generated summaries are, or how to measure progress.

In this paper, we propose a systematic approach to human evaluation of biomedical summaries, and apply it to analyse the summaries generated by two state-of-art systems. We examine the common errors in generated summaries and the correlation of automatic metrics such as ROUGE (Lin, 2004) with our evaluation results. We choose summarization models proposed by DeYoung et al. (2021), as they not only demonstrate the abilities of end-to-end neural models, but also incorporate domain-specific knowledge such as entity prompts.

The contributions of this paper are as follows: (1) We propose a new approach to human evaluation of biomedical summaries based on binary categorical ratings, which ensures that the results are interpretable, reliable, and easily reproducible by non-expert annotators. (2) We show that current approaches to summarization suffer from excessive copying from the prompt and an inability to aggregate important details from primary studies. (3) We show that automatic metrics such as ROUGE cannot reliably distinguish between factual and erroneous summaries. (4) We suggest several reasons which may explain the poor summarization performance, and show that it is necessary to redefine our approaches to biomedical MDS. Though our focus is on the biomedical field, we raise some issues common to cross-domain summarization, and propose a consistent approach to human evaluation and error classification which can easily be transferred to other domains.

May 22-27, 2022

2 Related studies and motivation

Although the importance of MDS in the biomedical domain was recognized around 20 years ago with studies such as McKeown et al. (1998) and Becher et al. (2002) defining some requirements and operations specific to biomedical summarization (e.g. the ability to resolve contradicting statements), until recently there have been few end-to-end systems (e.g. PERSIVAL (Elhadad et al., 2005)) due to the complexity of the task. In the last few years, apart from several shared tasks and challenges dedicated to multi-answer biomedical summarization — including MEDIQA 2021 (Ben Abacha et al., 2021) and BIOASQ (Nentidis et al., 2021) — several major threads of research have emerged. Wallace et al. (2021) and DeYoung et al. (2021) incorporate entity- and discourse-level prompts into their end-to-end neural summarization models. Shah et al. (2021) revived the idea of symbolic MDS (Radev and McKeown, 1998) by combining a deterministic content plan with a pre-trained language model. Here, we are particularly interested in the model by DeYoung et al. (2021) as it reflects the setting of summarization systems “in the wild”: their input is all clinical trials cited by a systematic review rather than a sample of trials which the review was based on (Wallace et al., 2021) or a curated list of trials relevant to the summary (Shah et al., 2021).

In terms of evaluation metrics, there has been a growing awareness of the inability of ROUGE to reflect the factual accuracy of summaries, so some other automatic metrics, including inference-based (Maynez et al., 2020) and question-answering-based methods (Chen et al., 2018; Wang et al., 2020) have been proposed. There have also been attempts to make the human evaluation more objective and systematic by defining linguistically grounded error categories and evaluation criteria (Huang et al., 2020; Pagnoni et al., 2021). In the biomedical domain, although there are some new automatic measures proposed, such as Aggregation Cognisance (Shah et al., 2021) — which measures the ability of the model to recognize if the input texts are in agreement or contradiction — and ΔEI (DeYoung et al., 2021) — which reflects the alignment of summaries in terms of direction of their findings — human evaluation has primarily been based on the Likert scale (Wallace et al., 2021; Shah et al., 2021), making it difficult to reproduce and interpret. In this work we aim to close this gap by establishing a more reliable, grounded and objective human evaluation framework, and applying it by assessing the summaries generated by the state-of-the-art MDS system of DeYoung et al. (2021).

3 Summarization models

The models we evaluate were trained on a large-scale dataset comprising 20K systematic reviews and 470K primary studies (DeYoung et al., 2021). The conclusions, taken from the abstract of the review, are the target for the summarization. The input consists of a prompt in form of the *Background* section of the systematic review, and the abstracts of up to 25 studies cited in the review.[1] As the prompt (*Background*) describes the review’s objective, the task is similar to query-based summarization, but with a highly detailed prompt.

We use the two summarization models explored in DeYoung et al. (2021): BART (Lewis et al., 2020) and LongFormer (Beltagy et al., 2020). Both models are similar in architecture but differ in their approach to handling long input sequences: for LongFormer (“LED” henceforth) *Background* is concatenated with all studies and encoded together before feeding to the decoder, while for BART each study is concatenated with *Background* and encoded separately; then their encodings are concatenated together and fed to the decoder. To adapt the models to the biomedical domain, the authors decorate the inputs by adding special tags around PICO (Richardson et al., 1995) elements, namely <pop>, <int>, <out> , and also by marking the different sections such as *Background*.

4 Evaluation process and criteria

We sampled 100 reviews each from test summaries generated by BART- and LED-based models. To evaluate them in a more systematic manner, we define the following quality dimensions which capture both factuality and fluency.

4.1 Factuality

Though factual errors are often attributed to hallucinations (where the model generates entities not present in the source), they can also be due to other reasons, such as omission of important details, incorrect order of tokens, or inappropriate syntactic relations between them. Rather than classify the factuality errors by reason, however, we treat the

---

[1] If the list of references contains more than 25 studies, it is truncated to the first 25.

summaries as a combination of important biomedical entities and the relations between them, and define the quality dimensions related to them as follows.

PICO correctness

The PICO (**P**atient/problem, **I**ntervention, **C**omparison, **O**utcome) scheme captures the most important entities for answering biomedical questions (Richardson et al., 1995), such as "Does the acupunture (*intevention*) help to decrease inter-ocular pressure (*outcome*) in patients with glaucoma (*patient*)?". We consider a generated summary to be correct from the point of view of PICO when it mentions the same patient population, intervention and outcome (in the same lexical form or paraphrased) as the original summary.[2] When doing so, we apply strict restrictions regarding the semantic hierarchy of PICO concepts in the generated and target summaries: if one of the concepts is a hypernym of another (for example, *acetaminophen* and *analgetics*), we consider it to be a factual error, as the findings of clinical trials should not be generalized or narrowed to other intervention types, patient groups, or outcomes. Note that though the PICO schema is more applicable to treatment trials, we apply these categories more broadly, as there are also clinical trials related to diagnostics, risk factors, biomarkers, etc.[3]

Direction correctness

Lehman et al. (2019) defined three directions of the intervention's effect with regards to the outcome: *significantly increases*, *significantly decreases* and *no significant difference*. We keep this three-way classification, but redefine it as *positive effect*, *negative effect*, or *no effect*, which allows us to judge based on the semantics and sentiment orientation of expression rather than the surface form. As an example, consider the following:

- **Generated**: NIV is associated with an *improvement* in mortality.
- **Target**: NIV had great advantage ... in *reducing* mortality.

If we follow the classification proposed by Lehman et al. (2019), these summaries have different directions in relation to "mortality" ("improvement" shows the direction of *increases*, while "reducing" has the direction of *decreases*), thus the generated summary would be erroneously considered wrong. The proposed classification of *positive/negative/no effect* avoids that, capturing the semantic orientation rather than literal meaning, similar to aspect-based sentiment analysis (Liu, 2012). It also more naturally extends to situations where the intervention does not directly affect the outcomes (so that no *increase* or *decrease* is possible), such as when we talk about the effectiveness of a diagnostics method, and to other clinical question types. For example, we assign the *positive* label if the review identifies the optimal intervention (*Which intervention works best?*), *negative* if it shows the most undesired intervention (*What are the most important risk factors?*), and *no effect* if such interventions cannot be identified.

Modality

As a linguistic category, modality reflects the possibility of a proposition (i.e. *X might increase Y* vs *X increases Y*), but here we define it in a more pragmatic way to denote how certain we are of available evidence and thus how strong our claim is. In particular, we define the following levels of certainty: *strong claim*, *moderate claim*, and *weak claim*. There are also two labels for statements where the author cannot draw any conclusions based on the evidence available to them (*no evidence*) or when the statement is descriptive and does not contain any claims regarding the direction of effect (*no claim*). Below we briefly describe the ways the modality is expressed:

- **Strong claim**: these claims are modified by strengthening expressions such as *remarkably* or *considerably*: *MSC infiltrations ... [lead] to an overall remarkable improvement.* The author can also directly appeal to the quality

---

[2] Following Nye et al. (2018) and DeYoung et al. (2021), we omit the Comparison (alternative intervention), as it is usually a no-treatment or placebo control which is implied rather than mentioned explicitly. Based on the sample we examined, Comparison was explicitly mentioned only in around 20% of systematic reviews' abstracts.

[3] For example, in a study examining risk factors influencing poor response to a treatment, such risk factors as *young age*, rather than the treatment itself, are interventions, while the therapy response is the outcome. In the sample we analysed, 78% of reviews were synthesising the results of treatment interventions including surgical, medical, nursing and alternative, such as music or acupuncture; among the rest, the majority (12%) were etiology studies with such interventions as risk factors. The remaining 10% of studies had unique combinations of interventions and outcomes. For example, in prognosis studies or studies of patients' experiences, a disease itself serves as an intervention.

of available evidence: *High-quality evidence indicates that diet ... can reduce the risk of excessive GWG.*

- **Moderate claim**: this is usually an unmodified proposition, such as *Warming-up before an operative procedure improves a trainee's ... performance.*

- **Weak claim**: such statements can be hedged in multiple ways, including modal verbs (e.g. *may*), introductory clauses (*It appears that* ...), or adverbs (*likely*). However, the author can directly comment on the reliability of evidence (*There is **initial evidence** supporting the effectiveness*) or discrepancy of the results (*denosumab ... has shown a **positive but variable histological response***).

- **No evidence**: there is either no primary evidence regarding the clinical question, or no conclusions can be drawn from it on account of its low quality or conflicting results. These statements are usually introduced by such clauses as *There is **insufficient evidence** to support ....*

- **No claim**: a summary can mention the clinical question, but make no statements regarding the effect of the intervention: *[This] is the first systematic review to assess the effect of inhaled steroids on growth in children with asthma..*

It should be noted that *modality* is different from statistical significance of an intervention's effect, which is captured by *direction*. For example, even if a clinical trial has a statistically significant effect, we can be uncertain of its results due to bias in the cohort, e.g. a small sample size. In the case of MDS, even if each of the underlying studies has shown a significant effect, their direction can be contradictory, which results in the *no evidence* judgement. On the other hand, we can be very certain that an intervention does not have any effect (*There is ... strong evidence of no significant difference between acupuncture and sham acupuncture*). Probably the most important distinction to make here is between cases where we have *no evidence* (*There is insufficient evidence to determine whether ... LCPUFA improves ... growth of preterm infants*) vs where we have enough evidence to state that there is *no effect* (*no clear long-term benefits or harms were demonstrated for preterm infants receiving LCPUFA*).[4]

The reason we include modality as a separate evaluation aspect is that it reflects the quality of the evidence and its potential usefulness to the medical professionals; thus, if primary studies report that a treatment *may* work, we do not want their summary to assert that the treatment *works*. Likewise, if it is impossible to aggregate the evidence with any certainty, the summary must state that the current evidence is insufficient rather than draw a particular conclusion. In this respect, modality is related to the newly-introduced category of scientific *ignorance* (Boguslav et al., 2021) as it helps to evaluate the state of our knowledge regarding a particular clinical question.[5]

Though based on our examples, *modality* can seem to be a category specific only to the biomedical domain, we believe that it is also important for other summarization domains where facts, rather than opinions, are involved, such as news or scientific articles, so it can be a valuable dimension of evaluation for summaries in general.

4.2 Fluency

Errors in this category can make it difficult to read and understand the summary, but do not affect its meaning.

Grammatical correctness

This category includes morphology and syntax mistakes, such as incorrect verb form or clause structure, but also lexical mistakes (incorrect word choice) leading to grammar errors. For example, a phrase *the is* instead of *there is* would be classified as a grammar rather than lexical error.

Lexical correctness

This category is for spelling mistakes which do not affect grammar and meaning.

Absence of repetition

Neural summarization systems commonly generate repetitive content, which can affect fluency to

---

[4] One simple test to distinguish them is that we can add a *modality*-modifying expression on top of the *no effect* statement (*Long-chain omega-3 **probably** has ... **no effect** on new neurocognitive outcomes*), while it is impossible to do this for *no evidence* or *no claim* propositions which already express the modality.

[5] How exact such evaluation can be and how well it correlates with objective measures of evidence quality such as risk of bias is still an open question. Despite this, we believe that *modality* is a useful linguistic category reflecting the author's subjective evaluation of the evidence quality.

the point of unintelligibility. Here, repetitions are regarded as a fluency mistake only when they do not make the sentence factually or grammatically incorrect.

4.3 Evaluation process and reliability

The first author of the paper (main annotator) judged each pair of target and generated summaries as correct or wrong based on the categories outlined above.[6] To be considered valid, the summary must be correct across all these dimensions; to be considered useful or factually correct, it must be aligned with the target summary in the first three dimensions (*PICO*, *Direction*, and *Modality*).

Although it might seem that some errors are "worse" than others (e.g. completely mixing up the interventions can seem to be a more severe mistake than mentioning a more generic concept), we treat the errors as binary. The reason behind this is twofold: first, it allows us to decompose the complex task of human evaluation into a series of pairwise yes/no decisions and thus make it easier and more objective (similar to what is already a standard practice in human evaluation of biomedical machine translation (Jimeno Yepes et al., 2017)); second, we argue that the "minor" errors are more dangerous in practice: while a completely irrelevant answer is likely to be spotted as incorrect by a medical professional, a tiny mistake in the summary can go unnoticed and thus the conclusions can be applied to a different situation than intended or with a different degree of certainty.

To assess the robustness of our evaluation criteria, we asked five external annotators, one of whom was a medical professional, to evaluate the quality of 40 generated summaries. The details of evaluation process together with the annotation instructions and metrics used can be found in Appendix A. Table 1 presents the average agreement between each of five external annotators and the main annotator (in terms of percentage of agreement and Gwet's AC1), as well as Fleiss' κ for all six annotators. In general, we found high agreement of external annotators with the main annotator, and substantial agreement between all annotators, which is remarkable considering the difficulty of the task and the size of the rater group. Most of the mistakes were not systematic, though some annotators struggled to differentiate between *no evidence* and *no effect* statements. Despite some discrepancy in the category-level annotation, when we apply Boolean AND to the first three categories to determine if a summary is factually correct (*PICO* $\wedge$ *Direction* $\wedge$ *Modality*), the results are highly reliable, with almost perfect agreement with the main annotator and strong agreement among all annotators, which shows that our method can be used to robustly evaluate the usability of summaries.

5 Results

5.1 Correctness by category

As shown in Table 2, less than 5% of generated summaries did not have any errors; even if we disregard the fluency errors, only around 10% of summaries are factually correct and thus usable. Overall, the generated summaries are quite fluent, with surprisingly low redundancy; it is the factual accuracy, especially in terms of PICO and modality, that is problematic.

In the following sections we provide more detailed statistics and some typical errors for these categories; some examples of incorrectly generated summaries and their errors can be found in Appendix B.

5.1.1 PICO

Among the PICO categories, *Intervention* is the most problematic, while *Patient* is usually generated correctly (Table 3). Below we outline some typical PICO errors:

More narrow concepts in the generated summary, usually copied from the primary studies: *women with pre-eclampsia* instead of *women* as Patient, *robocat* instead of *companion-type robots* as Intervention, *preventing HPV 16/18* instead of *preventing HPV* as Outcome.

More generic concepts in the generated summary, usually copied from the *Background*. For example, the generated summary mentions *topical agents*, while the review deals specifically with their *innovative reformulation*; the review is about a particular drug (*nedocromil sodium*) while the generated summary mentions the drug category (*inhaled corticosteroids*).

Incorrect elements copied as Intervention and Outcome: the generated summary is about the effect of *laxatives* on *constipation*, while the review

---

[6] In cases where the target review contained several statements, while the generated summary had only one proposition (53% of the cases), we matched it to the closest statement in the target summary; if we required a perfect multi-proposition to multi-proposition match, the results would have been much poorer.

	PICO	Direction	Modality	Grammar	Lexical	Non-redundancy	Factually correct	Overall
Agreement	87%	83%	84%	86%	98%	95%	94%	89%
Gwet's AC1	0.80	0.70	0.77	0.75	0.97	0.95	0.93	0.82
Fleiss' κ	0.66	0.62	0.67	0.60	0.93	0.88	0.86	0.73

Table 1: Inter-annotator agreement by category. "Factually correct" is a composition of the first three categories.

	PICO	Direction	Modality	Grammar	Lexical	Non-redundancy	Factually correct	Fully correct
BART	45%	77%	45%	75%	69%	85%	9%	3%
LED	40%	75%	44%	63%	73%	89%	8%	4%

Table 2: Correctness by category. "Factually correct" is a composition of the first three categories.

	Patient	Intervention	Outcome	Fully correct
BART	83%	66%	79%	45%
LED	86%	63%	68%	40%

Table 3: Correctness by PICO element type.

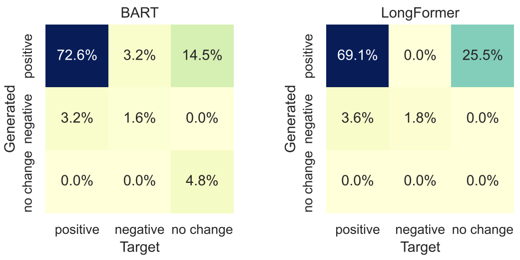

Figure 1: Direction of the generated vs target summaries.

examines the effect of *constipation* on *physical and mental well-being*. In some cases, the elements are correct, but the relation between them is reversed: a review studies whether *depressive symptoms* lead to *sleep disturbances*, while the generated summary is about the effect of *insomnia* on *depression*.

Hallucinated elements: surprisingly, some incorrect PICO elements have the same stem as the correct ones: *developing countries* instead of *developed countries* and *congenital hypothyroxinaemia* instead of *congenital hypothyroidism* , which seems to be due to generating a more prominent candidate continuation in a multi-token entity.

5.1.2 Direction

We calculate the direction accuracy only for the samples where the consistency of direction can be reliably determined, that is, where none of the two summaries have *no evidence* or *no claim* modality. Remarkably, if we keep the direction separate from modality, the performance for this category is quite good, which shows that getting the semantic orientation of the proposition right is relatively easy if the model is certain enough to make a statement. However, the confusion matrix for this category (Figure 1) shows that both high accuracy of this category and the highest number of mistakes can be attributed to the overwhelming presence of findings with the **positive** direction in the data. Therefore, the "easiness" of this dimension is not because the models learn to correctly capture the direction of primary studies, but rather because the default **positive** direction is most often correct due to the specifics of clinical questions.

5.1.3 Modality

In contrast to the previous category, the models produce more varied content in terms of *Modality*, which reflects a less skewed distribution in the data (see Figure 2). Though there is still a clear "majority" category (*moderate claim*), most of the errors are not due to generating too many moderate claims. In fact, for both BART and LED the most common problem is generating *no evidence* sentences instead of moderate and weak claims; for LED, there is also a good proportion of errors due to not making any claim at all. Interestingly, the number of times when the adjacent categories were mixed up (weak ↔ moderate, moderate ↔ strong) is lower than the number of mistakes due to confusing the quite distinct categories of *no evidence/no claim* and *moderate evidence*. Thus, even though the models sometimes correctly pick up cues showing weakness of evidence or its moderate quality, they often "give up" on trying to make any conclusion. This is especially true for LED, which generates substantially more *no claim* summaries than BART.

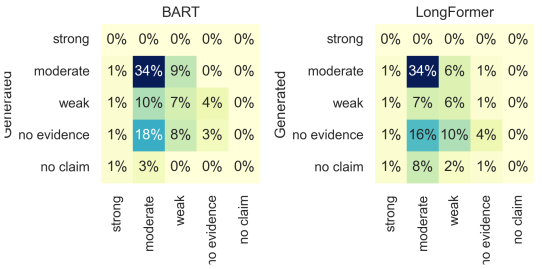

Figure 2: Modality of generated vs target summaries.

5.1.4 Grammatical and spelling errors

The mistakes in these categories are quite uniform in the sense that they seem to be an artefact of tokenization and decoding. For example, the vast majority of spelling errors are due to incorrect merging of subwords including the article *The* at the beginning of a sentence, for example *TheCLUSIONS* instead of *The CONCLUSIONS*. The grammar mistakes are also usually caused by incorrect token *The* at the initial position: *The is insufficient evidence*, though some other errors occur at this position: *There systematic review of strategies*.

5.1.5 Repetitions

Contrary to our expectations, the amount of repetitions was small, so it is difficult to make conclusions regarding their patterns. However, there was a tendency to include prominent tokens, often paraphrased, both in the outcome and patient 'slots', which sometimes led to redundancy: *acupuncture for LBP in patients with chronic low back pain*

5.2 A closer look at the output

How much is copied from the *Background*?

As the evaluation results in the previous section were discouraging, we found it necessary to examine the way summaries were generated. Upon further analysis, the majority (91% for BART and 85% for LED%) of the generated summaries are very similar in content to the *Background* section of the systematic review, which is supposed to contain a prompt for the model rather than the content to be actually summarized. More specifically, they copy the objectives or hypothesis sentence with various degree of paraphrasing. A typical example of such copying is provided in Table 4; though some paraphrasing is present, the generated summaries do not contain any information which cannot be inferred from the objectives sentence. Worse of all, they do not answer the question but rather restate it (*no claim*). To check whether this tendency is present in generated summaries in general, we calculated the unigram overlap (ROUGE-1), bigram overlap (ROUGE-2) and the longest n-gram overlap (ROUGE-L) between them and two "golden" summaries: the target summaries and *Background* text for all samples in the test set. As can be seen from Table 5, the generated summaries are much closer to the *Background* section than to the *Target* summaries; high ROUGE-2 and ROUGE-L scores against the *Background* also reflect the tendency to copy longer sequences literally.

How much is copied from studies?

Only a third of examined summaries (34% for BART and 30% for LED) included any details taken from primary studies that were meant to be summarized rather than from the prompt (*Background*). Though this in itself is concerning, it is even more striking that for only 4 of the BART summaries and 2 of the LED ones did the model manage to copy some useful information from the studies, whereas in the majority of cases copying from studies actually caused mistakes. These mistakes can be divided into two roughly equal groups: (1) the entity copied from the studies was too narrow, which means that there was no aggregation of entities across studies which examined different groups of patients, interventions or outcomes;[7] and (2) an entity unrelated to the clinical question but frequently mentioned in the studies was copied.[8]

We hypothesize that such inability to synthesize the information from the input studies together with the intensive copying from the prompt can be explained by the over-reliance on the *Background* (preambula) due to the higher-weighted global attention set on it (DeYoung et al., 2021).

How much is hallucinated?

Though hallucinations are a widely known issue with neural abstractive summarization, in the data we analysed less than 4% of summaries had incorrect details which could not be attributed to either the prompt or the included studies.

---

[7] More specifically, this can be due to adding an adjective modifier (*primiparous women* instead of *women*) or copying one of the concept's hyponyms (*robocat* instead of *companion-type robots*).

[8] For example, a purpose of one review was to identify dry eye symptoms rated as most uncomfortable, but as the majority of primary studies mentioned *artificial tears* for treating this condition, this concept was included in the generated summaries.

Target	Partial replacement using both classes of scaffolds achieves significant and encouraging improved clinical results when compared with baseline values or with controls when present
Background	We systematically review the literature on clinical outcomes following partial meniscal replacement using different scaffolds.
BART	This is the first *systematic* **review** of **the literature on** the **clinical outcomes following** *meniscectomy* **using different scaffolds**.
LED	The is the first *systematic* **review** to evaluate the **clinical outcomes following** *meniscectomy* **using different scaffolds**.

Table 4: Copying from the objectives statement in the *Background*. Directly copied words are in bold, while paraphrases are in italic.

	Background			Target		
	R-1	R-2	R-L	R-1	R-2	R-L
BART	37.36	23.18	30.62	27.34	9.23	20.64
LED	36.61	21.93	30.05	26.98	8.84	20.39

Table 5: ROUGE scores of generated summaries against the *Background* section and the correct *Target* summary.

Do the summaries follow the usual discourse patterns?

Around 68% of the analysed summaries are prepended by standard phrases such as *This systematic review suggests ...*. To check how wide-spread such phrases are in generated summaries in general, we also calculate their frequency in the whole test set: *There is insufficient evidence to support ...* occurs in 25% of BART and 19% of LED summaries; and *The results of this systematic review suggest ...* in 15% of BART and 14% of LED summaries. As was shown above in Section 5.1.3, LED makes more *no claim* statements than BART: 12% of LED summaries begin with *The is the first systematic review*, while only 2% of BART summaries do so. Overall, at least 55% of all summaries have the canned phrases we identified, which means that the models learned to identify and fluently reproduce some important elements of scientific style and discourse.

Do our metrics correlate with ROUGE scores?

Though we used ROUGE to determine the amount of lexical overlap and copying in Section 5.2 above, we do not consider it to be a reliable metric for quality estimation, especially in terms of factuality, as it does not correlate with any factuality dimensions we examined or factual accuracy in general. To determine whether the factually correct summaries had higher ROUGE scores than incorrect ones we performed a series of Student t-tests comparing summaries with correct and incorrect PICO, direction and modality, as well as summaries with no mistakes in any of these categories versus summaries with at least one mistake. There was no statistically significant difference in terms of ROUGE-1, ROUGE-2, and ROUGE-L scores between correct and incorrect summaries in all of these tests for both BART and LED.[9]

As an example, the distribution of ROUGE-1 scores for generated BART summaries with correct vs incorrect PICO elements, direction and modality, as well as for factually correct and wrong summaries, is shown in Figure 3.

6 Discussion

In this section we point out some issues which could explain the poor performance of the summarization systems in terms of generating conclusions in the manner of systematic reviews, and show how they relate to the principles underlying the aggregation of medical evidence. We present these as challenges to be tackled in MDS system development.

Perform multi-aspect summarization

A large number of reviews (53% in the analysed subset) had multiple propositions, that is, sets of PICO elements and relationships between them. For example, a review can study effects of a drug in terms of different outcomes, and each of these outcomes can have a different direction and modality. As a result, we are dealing with multi-aspect summarization, and it can be difficult for the model to correctly identify and reproduce several sets of prominent entities and relationships.

Aggregate, don't just summarize

Primary studies are rarely, if ever, conducted for all possible groups of patients, drugs in a particular class, or outcomes. Thus to answer a clinical question, we need to aggregate across such entities. For example, if a systematic review studies the effects of counselling on breastfeeding rates across the globe, and the majority of underlying studies mention *developing countries* while other refer to

---

[9] We performed the same experiments with BERTScore (Zhang et al., 2020), and though it was marginally able to differentiate between the summaries with correct and incorrect PICO, it could not capture the direction or the modality of the claim, so overall the results were statistically insignificant.

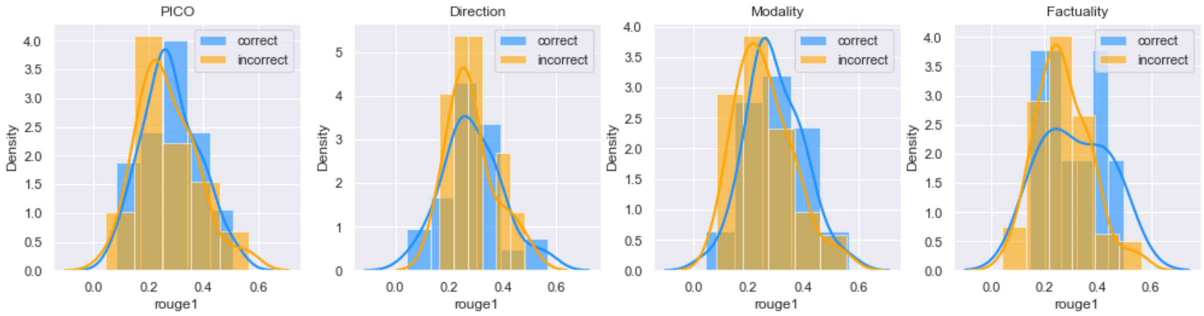

Figure 3: Distribution of ROUGE-1 scores for correct and incorrect summaries in different categories.

specific locations such as *Baltimore*, the generated summary can have a narrower *Patient* group (*developing countries*) than it should. Similarly, if primary studies examine the effects of different types of HPV vaccine (HPV-6, 11, 18, etc.) for different groups of patients, we would need to aggregate across them to be able to make conclusions about the effectiveness of HPV vaccines at large.

Find answers even when they are not obvious

In many cases, the primary studies are not considering exactly the same question that the review needs to answer. For example, the review may be about the effects of depression on sleep quality, while the underlying studies examine the effects of disrupted sleep on depression. Sometimes the answer needs to be inferred based on prior knowledge. One of the reviews, for example, explored the risks of mortality due to salmeterol, while the studies included in it did not even mention mortality but rather examined potentially lethal side effects.

Learn to answer more complex questions

While the majority of clinical questions (80% in the analysed subset) are in the yes/no form (“Does the intervention A have an effect on the outcome B?”), and the model can answer them by rephrasing the question, some questions require more difficult operations. For example, a clinical question might ask *which* strategy is more effective for preventing asthma (which requires comparing interventions), *what* education methods exist to manage hyperphosphatemia (which requires listing different interventions), or even *why* behavioral interventions work (which requires reasoning about various aspects of interventions). In the analysed subset, 11% of the reviews required ranking multiple alternatives which could be compared head-to-head or with the control or choosing the best treatment options; in 4% the study’s purpose was to list the known interventions, risk factors or even research questions; several studies compared the costs of the treatment with its benefits or the expectations of the patients with their actual experiences.

7 Conclusions

In this research, we attempted to bring the importance of factuality in biomedical MDS into attention, and demonstrated that the current models are still unreliable in this respect. Moreover, we showed that they fail to pick up and aggregate important details from multiple documents, excessively relying on the prompt. To support our analysis, we established a simple and reproducible human evaluation benchmark which reflects aspects of quality important for biomedical MDS but can be translated into other domains. Finally, we showed that the progress in biomedical MDS will be limited unless we acknowledge the domain-specific challenges of the task and work towards overcoming them. Though we focused our efforts on a particular domain, we hope that this work prompts taking a closer look at the summarization results in other areas, as only objective evaluation of what the models are capable of and prone to do will allow us to improve them.

8 Ethical considerations

Done right, biomedical MDS can significantly facilitate the practice of evidence-based medicine; done wrong, however, it creates risk of misinterpretation of evidence and subsequent malpractice. For this reason, we argue that the factual accuracy of biomedical summaries should be decided on a rigid yes/no scale, and only the summaries matching in all details and intents should be considered factually correct and thus useful. In this paper, we show that we still have a long way to go before biomedical summarization systems can be reliably used and trusted, and highlight the importance of robust human evaluation in this domain.

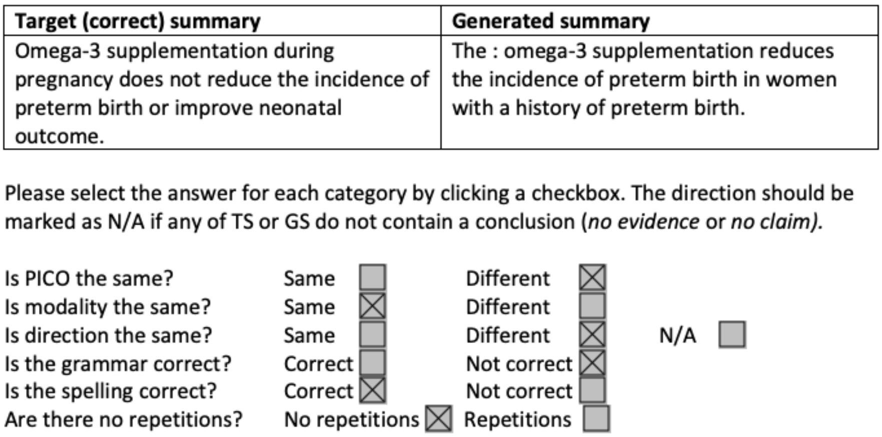
A Evaluation

We recruited 5 volunteer annotators to evaluate the correctness of generated summaries in terms of the criteria we specified. Before the evaluation we did a pilot round where we presented the instructions and asked the annotators to judge 6 randomly selected summaries. An excerpt from the instruction and the form provided to annotators are shown in Figures 5 and 4, respectively. On average, annotators spent 30 minutes reading the instructions and evaluating the pilot summaries. After providing feedback, we asked them to evaluate 40 other randomly selected summaries (20 for each of BART and LED). The average reported speed of evaluation was 2 minutes per summary. We report the inter-annotator agreement for each of the evaluated categories (see Table 1) using the following metrics: average accuracy-type percentage of agreement with the main annotator (author of the paper) and the average Gwet's AC1 score (Gwet, 2014) against the main annotator, to show how accurate is the evaluation produced by annotators with minimal training, and Fleiss' κ to show the amount of disagreement between all six annotators. We choose Gwet's AC1 score rather than Coppen's κ as it is a more reliable metric for data with a strong majority class as in our case, where, for instance, almost all summaries have correct spelling.

B Error examples

Table 6 below lists some examples of errors in the conclusions summaries generated by the models. For each of the examples, we provide the PubMed ID (PMID) of the systematic review, the generated summary, the conclusions of the systematic review (target summary), error type and explanations.



Target (correct) summary	**Generated summary**
Omega-3 supplementation during pregnancy does not reduce the incidence of preterm birth or improve neonatal outcome.	The : omega-3 supplementation reduces the incidence of preterm birth in women with a history of preterm birth.

Please select the answer for each category by clicking a checkbox. The direction should be marked as N/A if any of TS or GS do not contain a conclusion (*no evidence* or *no claim)*.

Is PICO the same?	Same ☐	Different ☒	
Is modality the same?	Same ☒	Different ☐	
Is direction the same?	Same ☐	Different ☒	N/A ☐

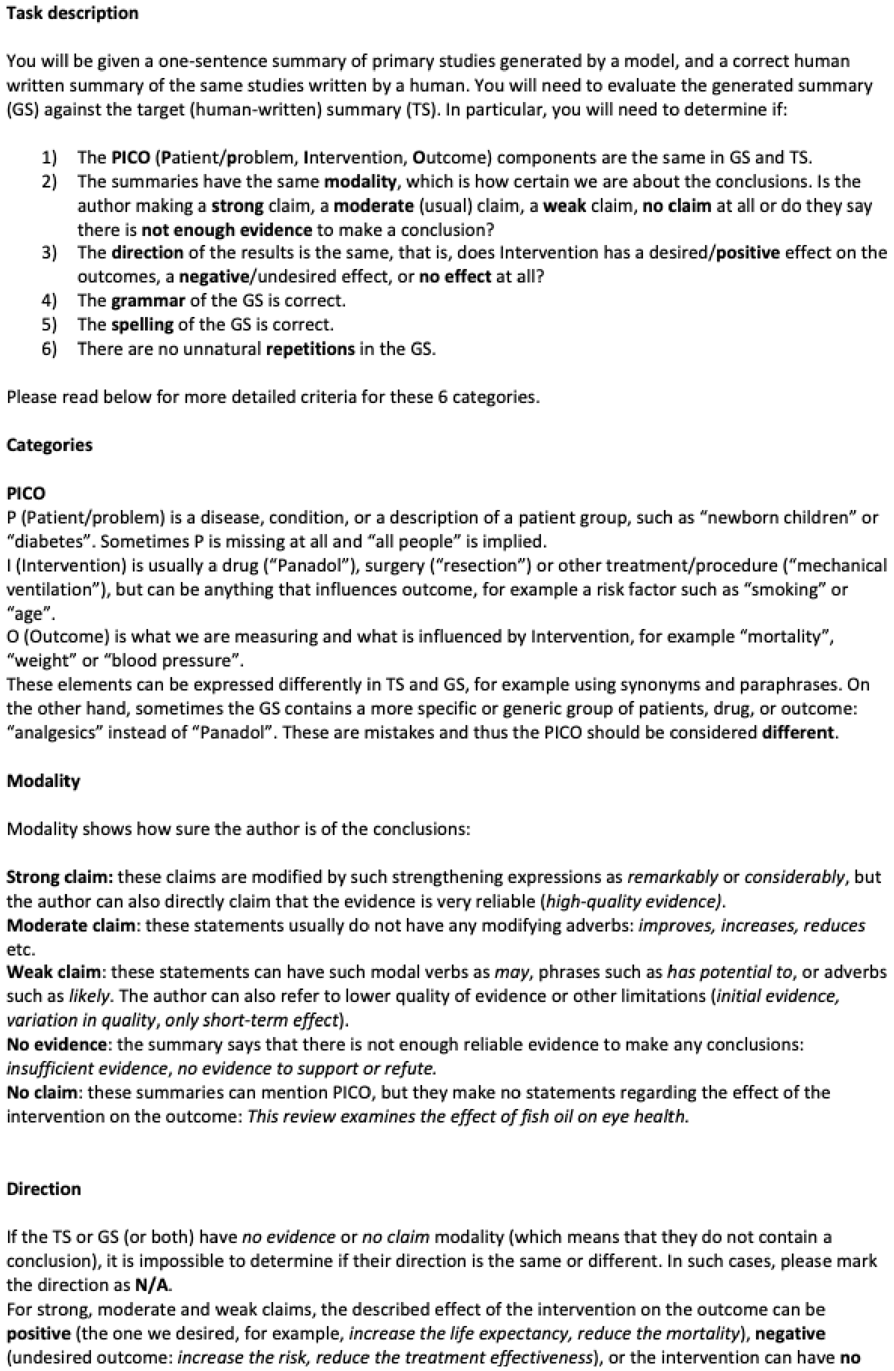
PMID	Generated summary	Target summary	Error	Explanation
30337463	The meta-analysis suggests that prenatal exercise is associated with a reduced risk of GDM, GH and PE in women at high risk of developing GDM.	In conclusion, exercise-only interventions were effective at lowering the odds of developing GDM, GH and PE.	PICO	A more narrow *patient* group
32179998	The results of this systematic review suggest that Internet-based psycho-educational interventions may be effective in reducing depression and anxiety among cancer patients.	Internet-based psycho-educational interventions reduce fatigue and depression in cancer patients.	PICO; Modality	Incorrect *outcome*; *weak* vs *moderate* modality
24733429	The is insufficient evidence to determine which treatments have the lowest recurrence rates and the best cosmetic outcomes for BCC.	The available data suggest that surgical methods remain the gold standard in BCC treatment.	Grammar; PICO; Modality	Incorrect word usage; underspecified *outcome*; *no evidence* vs *moderate* modality
27995607	The supplementation of formula milk with LCPUFA is safe and of benefit to preterm infants.	On pooling of results, no clear long-term benefits or harms were demonstrated for preterm infants receiving LCPUFA-supplemented formula.	Direction	*No change* vs *positive* direction
20551730	The is the first systematic review of the literature regarding the use of acupuncture in the management of pain associated with TMDs.	The results of this meta-analysis suggest that acupuncture is a reasonable adjunctive treatment for producing a short-term analgesic effect in patients with painful TMD symptoms.	Grammar; Modality	Incorrect word usage; *no claim* vs *moderate* modality.
27271918	There is insufficient evidence to support or refute the use of laxatives or laxatives in the management of older people with constipation.	Constipation among older people was connected to subjective and comprehensive experiences. It had a negative impact on physical and mental well-being as well as the social life of older people.	PICO; Modality	Incorrect *intervention* and *outcome*; *no evidence* vs *moderate* modality.
18847478	The conclusion is that head-to-head comparisons of potentially ineffective drugs have the potential to improve clinical decision-making.	Placebo-controlled trials do not support the use of antibiotics in chronic obstructive pulmonary disease patients with mild to moderate exacerbations.	PICO; direction; modality	Incorrect *intervention* and *outcome*; *positive* vs *no change* direction; *weak* vs *moderate* modality

Table 6: Error examples for different categories.



Task description

You will be given a one-sentence summary of primary studies generated by a model, and a correct human written summary of the same studies written by a human. You will need to evaluate the generated summary (GS) against the target (human-written) summary (TS). In particular, you will need to determine if:

1) The **PICO** (**P**atient/**p**roblem, **I**ntervention, **O**utcome) components are the same in GS and TS.
2) The summaries have the same **modality**, which is how certain we are about the conclusions. Is the author making a **strong** claim, a **moderate** (usual) claim, a **weak** claim, **no claim** at all or do they say there is **not enough evidence** to make a conclusion?
3) The **direction** of the results is the same, that is, does Intervention has a desired/**positive** effect on the outcomes, a **negative**/undesired effect, or **no effect** at all?
4) The **grammar** of the GS is correct.
5) The **spelling** of the GS is correct.
6) There are no unnatural **repetitions** in the GS.

Please read below for more detailed criteria for these 6 categories.

Categories

PICO
P (Patient/problem) is a disease, condition, or a description of a patient group, such as "newborn children" or "diabetes". Sometimes P is missing at all and "all people" is implied.
I (Intervention) is usually a drug ("Panadol"), surgery ("resection") or other treatment/procedure ("mechanical ventilation"), but can be anything that influences outcome, for example a risk factor such as "smoking" or "age".
O (Outcome) is what we are measuring and what is influenced by Intervention, for example "mortality", "weight" or "blood pressure".
These elements can be expressed differently in TS and GS, for example using synonyms and paraphrases. On the other hand, sometimes the GS contains a more specific or generic group of patients, drug, or outcome: "analgesics" instead of "Panadol". These are mistakes and thus the PICO should be considered **different**.

Modality

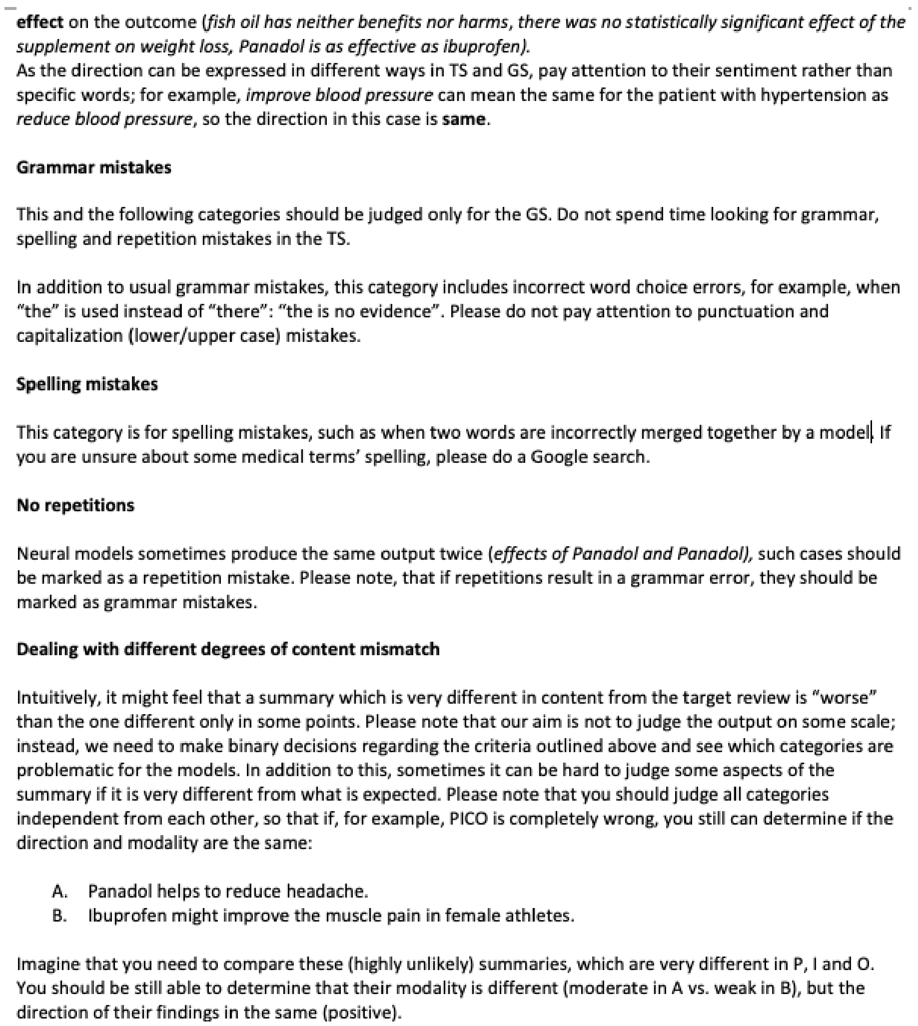
Modality shows how sure the author is of the conclusions:

Strong claim: these claims are modified by such strengthening expressions as *remarkably* or *considerably*, but the author can also directly claim that the evidence is very reliable (*high-quality evidence)*.
Moderate claim: these statements usually do not have any modifying adverbs: *improves, increases, reduces* etc.
Weak claim: these statements can have such modal verbs as *may*, phrases such as *has potential to*, or adverbs such as *likely*. The author can also refer to lower quality of evidence or other limitations (*initial evidence, variation in quality*, *only short-term effect*).
No evidence: the summary says that there is not enough reliable evidence to make any conclusions: *insufficient evidence*, *no evidence to support or refute.*
No claim: these summaries can mention PICO, but they make no statements regarding the effect of the intervention on the outcome: *This review examines the effect of fish oil on eye health.*

Direction

If the TS or GS (or both) have *no evidence* or *no claim* modality (which means that they do not contain a conclusion), it is impossible to determine if their direction is the same or different. In such cases, please mark the direction as **N/A**.
For strong, moderate and weak claims, the described effect of the intervention on the outcome can be **positive** (the one we desired, for example, *increase the life expectancy, reduce the mortality*), **negative** (undesired outcome: *increase the risk, reduce the treatment effectiveness*), or the intervention can have **no**

Figure 5: Annotation instructions.



effect on the outcome (*fish oil has neither benefits nor harms, there was no statistically significant effect of the supplement on weight loss, Panadol is as effective as ibuprofen).*
As the direction can be expressed in different ways in TS and GS, pay attention to their sentiment rather than specific words; for example, *improve blood pressure* can mean the same for the patient with hypertension as *reduce blood pressure*, so the direction in this case is **same**.

Grammar mistakes

This and the following categories should be judged only for the GS. Do not spend time looking for grammar, spelling and repetition mistakes in the TS.

In addition to usual grammar mistakes, this category includes incorrect word choice errors, for example, when "the" is used instead of "there": "the is no evidence". Please do not pay attention to punctuation and capitalization (lower/upper case) mistakes.

Spelling mistakes

This category is for spelling mistakes, such as when two words are incorrectly merged together by a model. If you are unsure about some medical terms' spelling, please do a Google search.

No repetitions

Neural models sometimes produce the same output twice (*effects of Panadol and Panadol),* such cases should be marked as a repetition mistake. Please note, that if repetitions result in a grammar error, they should be marked as grammar mistakes.

Dealing with different degrees of content mismatch

Intuitively, it might feel that a summary which is very different in content from the target review is "worse" than the one different only in some points. Please note that our aim is not to judge the output on some scale; instead, we need to make binary decisions regarding the criteria outlined above and see which categories are problematic for the models. In addition to this, sometimes it can be hard to judge some aspects of the summary if it is very different from what is expected. Please note that you should judge all categories independent from each other, so that if, for example, PICO is completely wrong, you still can determine if the direction and modality are the same:

A. Panadol helps to reduce headache.
B. Ibuprofen might improve the muscle pain in female athletes.

Imagine that you need to compare these (highly unlikely) summaries, which are very different in P, I and O. You should be still able to determine that their modality is different (moderate in A vs. weak in B), but the direction of their findings in the same (positive).

A Multi-Document Coverage Reward
for RELAXed Multi-Document Summarization

Abstract

Multi-document summarization (MDS) has made significant progress in recent years, in part facilitated by the availability of new, dedicated datasets and capacious language models. However, a standing limitation of these models is that they are trained against limited references and with plain maximum-likelihood objectives. As for many other generative tasks, reinforcement learning (RL) offers the potential to improve the training of MDS models; yet, it requires a carefully-designed reward that can ensure appropriate leverage of both the reference summaries and the input documents. For this reason, in this paper we propose fine-tuning an MDS baseline with a reward that balances a reference-based metric such as ROUGE with coverage of the input documents. To implement the approach, we utilize *RELAX* (Grathwohl et al., 2018), a contemporary gradient estimator which is both low-variance and unbiased, and we fine-tune the baseline in a few-shot style for both stability and computational efficiency. Experimental results over the Multi-News and WCEP MDS datasets show significant improvements of up to $+0.95$ pp average ROUGE score and $+3.17$ pp METEOR score over the baseline, and competitive results with the literature. In addition, they show that the coverage of the input documents is increased, and evenly across all documents.

1 Introduction

Multi-document summarization (MDS) aims to consolidate salient points of information across a set of documents into a concise summary. The main requirement for the summary is that it adequately represent the document set, with low redundancy and high coverage across all documents, while at the same time being readable and fluent. Combined with this, is the need to develop techniques that can handle the significant memory complexity required to tackle MDS. Recently, the release of dedicated datasets (Fabbri et al., 2019; Gholipour Ghalandari et al., 2020), and intelligently designed Transformer models (Liu et al., 2018; Liu and Lapata, 2019; Beltagy et al., 2020), have helped drive advancements in multi-document summarization, generally improving the accuracy and fluency of the predicted summaries. However, aspects such as the requirement to cover as much salient information from the input documents as possible, whilst still maintaining low repetition and low redundancy, have certainly been less explored to date (Nayeem et al., 2018; Mao et al., 2020).

Within the sphere of contemporary neural MDS models, two main lines of investigation can be identified: graph-based approaches (Li et al., 2020; Pasunuru et al., 2021), and concatenation approaches (Liu et al., 2018; Zhang et al., 2020a). The former are approaches that rely on the construction of graphs to capture the inter- and intra-document relations. While powerful, they need to elicit the relations explicitly. The latter instead assume that all the input documents within a document set can be simply concatenated, possibly with document separators and tags, such that the relations can be "discovered" by the model. Like ordinary summarization, also MDS comes in two remarkably different styles: *extractive*, where the generated summaries consist of verbatim sentences from the original input documents (Nallapati et al., 2017), and *abstractive*, where the model is instead encouraged to generate a paraphrased understanding of the input documents. The intrinsic appeal of abstractive summaries and the advent of sequence-to-sequence models have increasingly shifted the trend toward abstractive summarization (See et al., 2017; Paulus et al., 2018; Fabbri et al., 2019; Lewis et al., 2020; Zhang et al., 2020a). As for what models are concerned, abstractive MDS has made increasing use of transformers, both "conventional" (Lewis et al., 2020; Zhang et al., 2020a) and modified to accommodate the characteristic input length

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics
Volume 1: Long Papers, pages 5112 - 5128
May 22-27, 2022

of multi-document sets (Beltagy et al., 2020; Zaheer et al., 2020).

Similarly to general summarization, the majority of MDS models are trained using the negative log-likelihood (NLL) as training objective, which aims to maximize the conditional log-likelihood of the tokens of a given reference summary. Despite its speed and efficacy, the NLL exhibits both the *wrong-objective* problem (Ding and Soricut, 2017), where the model is trained on a convenient objective rather than a desirable one, and the well-known *exposure bias* problem (Bengio et al., 2015; Ranzato et al., 2016). To alleviate these issues, reinforcement learning has been adopted in summarization, as in other language generation tasks, to train the model with a more appropriate objective (Li et al., 2019; Parnell et al., 2021). However, its effective use for MDS requires a reward function that can appropriately balance the reference summary and the multiple input documents in the document set. For this reason, in this paper we propose exploring a reward that combines a reference-based metric such as ROUGE with a coverage term over the input documents. To implement the reinforcement learning approach, we employ a contemporary gradient estimator of the policy gradient, RELAX (Grathwohl et al., 2018), which is both low-variance and unbiased. In addition, to limit the computation and the risk of parameter drift, we apply the objective to fine-tune an NLL-pretrained model in a few-shot manner. In light of the above, this paper makes the following contributions:

1. a reward for reinforcement learning that combines a ROUGE score and a multi-document coverage score, to simultaneously adhere to both the reference summaries and the input documents;

2. a reinforcement learning implementation that leverages a low-variance and unbiased gradient estimator of the policy gradient, RELAX;

3. experimental results and a comprehensive analysis over two MDS datasets (Multi-News and WCEP), showing the empirical effectiveness of the proposed approach.

The rest of this paper is organized as follows: first the related work is reviewed in Section 2, and then the proposed approach is introduced in Section 3. Section 4 describes the experimental set-up and main results, while Section 5 presents a more detailed analysis of the main components of the proposed approach. Eventually, Section 6 summarizes our findings and concludes the paper.

2 Related Work

Early work in multi-document summarization (MDS) that pre-dates the neural era (Mani and Bloedorn, 1997; Erkan and Radev, 2004; Christensen et al., 2013) was shaped around the notion of MDS as a collection of graph structures. As approaches in language generation naturally evolved into neural-based (Rush et al., 2015; Ranzato et al., 2016), later improved with the emergence of large, pre-trained language models (Devlin et al., 2019; Lewis et al., 2020; Zhang et al., 2020a), the effort shifted to integrating these graph structures into the models, often building on top of strong single-document summarization (SDS) baselines (Lebanoff et al., 2018; Zhang et al., 2018).

Concurrently, the growing interest in multi-document summarization has led to the development of dedicated, multi-document datasets such as WikiSum (Liu et al., 2018), Multi-News (Fabbri et al., 2019), Wikipedia Current Events Portal (WCEP) (Gholipour Ghalandari et al., 2020) and others. The typical amount of input data that comes with these datasets has increased the pressure on the models to be able to handle larger inputs. For instance, WCEP has up to 100 documents in each document set, and 63.7 on average. As such, the standard transformers used to develop successful SDS models such as BART (Lewis et al., 2020) and PEGASUS (Zhang et al., 2020a) have proved inadequate for MDS due to their limited maximum input length (in the order of 10^3 tokens) and quadratic memory complexity (Beltagy et al., 2020). In turn, this has prompted the development of long transformer models such as Longformer (Beltagy et al., 2020) (built upon BART) and BigBird (Zaheer et al., 2020) (built upon PEGASUS) which, thanks to their smart attention layers that scale linearly with the input length, have opened up the possibility of presenting the input documents "at once", allowing these re-designed attention mechanisms to discover both inter- and intra-document relations.

Document summarization, as have other language generation tasks, has often been criticized for using maximum-likelihood training objectives that may prove limitative for the eventual performance of the models (Ding and Soricut, 2017). For this reason, reinforcement learning has been employed as an alternative, to directly optimize the models over evaluation metrics and explicitly reward the quality of the model's predictions. Reinforcement learning approaches have used metrics such as ROUGE-1, ROUGE-2 and ROUGE-L F1 (Paulus et al., 2018), and also more contemporary scoring functions such as BERTScore (Zhang et al., 2020b) as rewards, often mixed with maximum-likelihood objectives. When applying reinforcement learning to MDS, we contend that the reward should not simply be a ROUGE score against the reference summary, since this would dismiss key characteristics of the task such as inter-document information transfer. For instance, Mao et al. (2020) have leveraged maximal marginal relevance (Carbonell and Goldstein, 1998) to mollify higher-order information redundancy between the input documents. Several other performance measures could potentially be included in the reward, such as extractive fragment coverage and density (Grusky et al., 2018) and MINT (Dreyer et al., 2021), but to the best of our knowledge they have never been utilized as, or for, training objectives.

To address this gap, in this paper we propose leveraging a modified coverage reward to improve information coverage across all the documents in the input set, jointly with a principled policy gradient estimator (RELAX) and a performing long transformer model (the BART Longformer Encoder-Decoder, or BART-LED), in the hope of benefiting from the synergy between these components.

3 Proposed Approach

In this section, we present the details of the proposed approach, including the reinforcement learning framework (Section 3.1), the multi-document coverage reward (Section 3.2), and the overall training objective (Section 3.3).

3.1 Reinforcement Learning Gradient Estimators

Given a set of documents in input, simply noted as x, and a summary with T tokens, $y = \{y_1, \ldots, y_T\}$, the predictive distribution, also known as policy in reinforcement learning, can be noted as $p(y_t|y_1, \ldots, y_{t-1}, x)$. The policy gradient theorem (Sutton et al., 1999) states that an estimator for the gradient of the reinforcement learning risk can be expressed as:

$$\Delta = -r \sum_{t=1}^{T} \frac{\partial}{\partial \theta} \log p(y_t^s | y_1^s, \ldots, y_{t-1}^s, x) \quad (1)$$

where $y_1^s, \ldots, y_T^s$ is a sequence sampled from the policy, r is a function that rewards its quality, and θ collectively denotes all the policy's parameters. This estimator is the well-known REINFORCE (Williams, 1992) and is a baseline of reinforcement learning. At its turn, the gradient can be easily turned into a loss function to be used with automatic differentiation:

$$\begin{aligned} L_{\textsc{reinforce}} &= -r \sum_{t=1}^{T} \log p(y_t^s | y_1^s, \ldots, y_{t-1}^s, x) \\ &= -r \log p(y^s) \end{aligned} \quad (2)$$

The sampled sequence in (2), $y^s = \{y_1^s, \ldots, y_T^s\}$, can be obtained with any usual sampling approach such as teacher-forcing, student-forcing, or scheduled sampling (Bengio et al., 2015). While the samples can be drawn from a standard categorical distribution, in our experiments we utilize the Gumbel-Softmax re-parameterization (Jang et al., 2017) to obtain the categorical samples from transformed samples of a Gumbel distribution. The reason for the re-parameterization is that the Gumbel-Softmax samples are needed for the RELAX estimator that we introduce in the following. For a generic sample, y_t^s, the re-parameterization can be concisely expressed as:

$$\begin{aligned} y_t^s &= \text{argmax}(z_t) \\ z_t &\sim \text{Gumbel-Softmax}(p_t, \tau) \end{aligned} \quad (3)$$

where z_t is a Gumbel-Softmax sample of size equal to that of the vocabulary that acts as a "soft" prediction, p_t is the probability vector over the vocabulary at slot t, τ is a temperature parameter controlling the sparsity of z_t, and argmax(z_t) returns the index of z_t's largest value. This re-parameterization is provenly equivalent to directly sampling y_t^s from Cat(p_t) (the reader can refer to Jang et al. (2017) for details).

REINFORCE is an unbiased estimator of the theoretical gradient, but it typically suffers from a high variance which can affect the convergence and effectiveness of training. To curb its high variance, techniques based on control variates and the subtraction of simple baselines have been proposed and even applied to summarization (Rennie et al., 2017; Paulus et al., 2018). However, our early experiments showed that these approaches were not promising for the given task. In addition, some of these estimators introduce a "bias", i.e. a mean difference with respect to the theoretical gradient. More recently, the RELAX gradient estimator has been shown to empirically outperform REINFORCE, thanks to its ability to reduce the variance while remaining unbiased (Grathwohl et al., 2018). The corresponding RELAX loss can be expressed as:

$$L_{\scriptscriptstyle RELAX} = -[r - c_\phi(\tilde{z})] \log p(y^s) + c_\phi(z) - c_\phi(\tilde{z}) \tag{4}$$

In (4), $c_\phi(\tilde{z})$ is a control variate of parameters ϕ which is expected to correlate tightly with the reward to reduce the variance, and term $c_\phi(z) - c_\phi(\tilde{z})$ ensures that the overall gradient remains an unbiased estimator of the theoretical gradient. Variable $z = \{z_1, \ldots, z_T\}$ denotes the sequence of the Gumbel-Softmax samples, while variable $\tilde{z}$ denotes the sequence of samples from a Gumbel-Softmax distribution conditioned on the observed values of y^s. Operationally, z_t is sampled first, unconditionally, then y^s_t is derived with the argmax, and finally $\tilde{z}_t$ is sampled from a suitably conditioned Gumbel-Softmax distribution; details can be found in Grathwohl et al. (2018), Appendix B - Categorical. Overall, the RELAX estimator is both unbiased and low-variance.

The control variate in our experiments is a simple two-layer feed-forward network that is constructed to correlate with the ROUGE scoring function. We obtain this by feeding the concatenation of the soft predictions, z (or, in turn, $\tilde{z}$), and the reference summary, y, as input to the control variate. This allows the model to learn to score the soft predictions and their targets in a way that mimics the ROUGE prediction-reference score. In detail, the architecture consists of two fully-connected linear layers, each followed by a ReLU linear activation function, and a final sigmoid activation function that normalizes the output of the last layer. Eventually, the output of the sigmoid is averaged to produce the control variate.[1]

3.2 Multi-Document Coverage Reward

The design of an effective reward is another key aspect of a reinforcement learning objective. In our work, we have aimed to design an overall reward that could simultaneously remain faithful to: a) the reference summary, to ensure adequate generation performance, and b) the input documents, to cover as many important details as possible, and hopefully, support generalization. Relying solely on the reference summaries, given the large input size, does not seem to promise sufficient guidance, and our experiments have confirmed that. To implement the reward, we have chosen to use ROUGE-L F1 for the references and a multi-document coverage score for the input documents that we describe hereafter.

Several quantitative measures of coverage exist in the literature, and have found ample use in describing the properties of summarization datasets and the performance of models. For our work, we have adopted the *extractive fragment coverage (EFC)* of Grusky et al. (2018). The EFC measures the percentage of words in a summary that are part of "extractive fragments" within an input document, which are simply multi-word phrases shared between the input document and the summary. It is a simple precision-type measurement that looks at how much of the prediction is in the input document. Noting an individual document as D, a summary as y and an extractive fragment as f, the EFC can be expressed as:

$$EFC(y, D) = \frac{1}{|y|} \sum_{f \in \mathcal{F}(y,D)} |f| \tag{5}$$

where the $|\cdot|$ operator is used to denote length. To promote an even improvement in coverage across the input documents, we propose a multi-document extension of the EFC that reaches its highest value when the coverage across the input documents is evenly distributed. Let us note the input document set here as $\mathcal{D}$, and the EFC coverage vector over the document set as $cov(y, \mathcal{D})$. We also note the sample mean of a vector x as $\mu(x)$, the sample standard deviation as $\sigma(x)$, and their ratio (the inverse coefficient of variation) as $c_v^{-1}(x)$. This allows us to compute a "normalized" coverage score for a summary, $c_v^{-1}(cov(y, \mathcal{D}))$, which takes larger values the more the scores are uniform across the document set. In addition, inspired by Kryściński et al. (2018), we define a reward that pits the normalized coverage score of the prediction, y^s, against that of

---

[1] We release our code to permit complete reproducibility of our experiments: `https://github.com/jacob-parnell-rozetta/longformer_coverage/`

the reference, y:

$$r^{cov} = \frac{c_v^{-1}(cov(y^s, \mathcal{D})) - c_v^{-1}(cov(y, \mathcal{D}))}{c_v^{-1}(cov(y^s, \mathcal{D}))} \quad (6)$$

Eventually, to ensure that short summaries are not unfairly rewarded with high coverage scores, we normalize the reward by the length ratio of the prediction and the reference:

$$\hat{r}^{cov} = r^{cov} \frac{|y^s|}{|y|} \quad (7)$$

Overall, the $\hat{r}^{cov}$ reward regards a prediction as "good" if it enjoys high average coverage of the input documents, the coverage is evenly distributed, and the prediction is of sufficient length. The reference summary acts as a baseline, making the reward additive if the prediction outperforms the reference, and subtractive if otherwise.

Since ROUGE-L F1 and the coverage reward are not necessarily up to scale, to obtain the final reward, r, we perform a convex combination with a scaling coefficient, β:

$$r = \text{ROUGE-L F1}(y^s, y) + \beta\, \hat{r}^{cov} \quad (8)$$

3.3 Overall Training Objective

As training strategy, we first train the model with the negative log-likelihood and choose the best model with a criterion based on the validation performance. After that, the model is fine-tuned with the reinforcement learning objective. In many past works, the reinforcement learning objective has been used mixed with the NLL for stability (Paulus et al., 2018; Li et al., 2019; Parnell et al., 2021). However, we assume that the model has already "warmed up" to the training data during its NLL pre-training stage, and only use either $L_{REINFORCE}$ (2) or L_{RELAX} (4) for fine-tuning. To prevent excessive drifting from the NLL pre-trained model, we limit the fine-tuning to a few ($\approx 1,000$) shots and a relatively low learning rate (3×10^{-6}).

4 Experiments

4.1 Datasets

We have carried out multiple experiments over two MDS datasets in the news domain: Multi-News (Fabbri et al., 2019) and Wikipedia Current Events Portal (WCEP) (Gholipour Ghalandari et al., 2020). For WCEP, we specifically use the WCEP-100 version, which exclusively limits the number of articles within a document set to 100. We have chosen these datasets as they cover an ample spread of summary lengths and numbers of input documents, with Multi-News having longer reference summaries on average. Appendix A.2 reports the datasets' main statistics as presented in the original papers (Fabbri et al., 2019; Gholipour Ghalandari et al., 2020)[2].

4.2 Evaluation Metrics

Like most previous works, we use the F1 variants of the ROUGE-*N* scores[3] (Lin, 2004) for performance evaluation. In our use of ROUGE, we choose not to stem the predictions and the references during scoring. Since we use the ROUGE-L F1 score in our reward, to avoid circularity we also include METEOR[4] (Lavie and Agarwal, 2007) in the performance evaluation. Differently from our ROUGE implementation, METEOR uses stemming, synonyms, and other paraphrastic matching in the n-gram matching stage. In a recent study, both ROUGE and METEOR have displayed high correlation with a number of desirable summarization properties such as coherence, consistency, fluency, and relevance (Fabbri et al., 2021).

4.3 Main Settings

We have implemented our approach on top of BART-LED (Beltagy et al., 2020). We utilize the generous maximum encoding length (16384 tokens) of this long-input transformer, by concatenating all the documents in a document set to form a single input to the model. The individual documents are separated by an `[END]` token, and the input is truncated to the maximum length. For every experiment, we report the average of three independently-initialized training runs. For each result, we have also run a nonparametric bootstrap test for statistical significance, and highlighted the results that are significantly different from the baseline. In the reward, the β hyperparameter has been set to 1.0 with a validation described in Appendix A.3. All other hyperparameters are described in Appendix A.1.

---

4.4 Results

Multi-News. Table 1 compares the results over the Multi-News test set for the baseline, our proposed approaches and previous work from the literature. We first note that our BART-LED model has performed as a strong baseline, with its results being comparable to those of BART-Long (Pasunuru et al., 2021), which is based on the same BART Longformer architecture. In detail, BART-Long has reported a higher ROUGE-1 score, our baseline has reported a higher ROUGE-L score, and both have reported similar ROUGE-2 scores. Therefore, we regard our performance as comparable on the whole, with the differences most likely due to different hyperparameters.

Amongst our results, the models fine-tuned with REINFORCE have achieved worse results than the baseline. This is evidence that a vanilla implementation of the policy gradient is not necessarily better than a standard NLL objective. Conversely, the models fine-tuned with RELAX have surpassed both the NLL baseline and virtually all the previous work. The best results have been achieved with the inclusion of the coverage term, with an improvement of $+0.36$ ROUGE-2 pp over the NLL baseline and a marked improvement of $+0.92$ METEOR pp. In addition, both results have reported a p-value < 0.01. These results give evidence to both the improved performance provided by the RELAX gradient estimator and the usefulness of the coverage term. In Appendix B, we also provide a qualitative example which shows that the increase in METEOR score is most likely given by the positive impact of the coverage term, which has allowed the model to retrieve relevant phrases from the input documents.

WCEP. Table 2 shows the results over the WCEP test set. The trend is similar to that over Multi-News, but the improvements with the proposed models have been even more pronounced. In the first place, the NLL baseline has set a very strong performance compared to the previous work, showing the full potential of a long-input model such as the Longformer for MDS. As for Multi-News, the best results have been achieved with the RELAX gradient estimator, with improvements of up to +1.32 ROUGE-1 pp and +3.17 METEOR pp over the NLL baseline. The inclusion of the coverage term with RELAX has not been able to increase the ROUGE scores, but has increased METEOR by +1.64 pp. Again, we attribute this to the model's improved coverage of the input documents, which leads to an increased number of matches under METEOR's more relaxed matching scheme. A qualitative example is discussed in Appendix B.

5 Analysis

In this section, we present a more detailed analysis of the impact of the coverage term, the few-shot fine-tuning, and the RELAX gradient estimator using the Multi-News validation set as reference. For a further insight into the coverage reward, we also include an analysis of its trajectory during training. All the selected hyperparameters are listed in Appendix A.1.

5.1 Impact of the Coverage Term

Our rationale for including a coverage term in the reward is to ensure coverage of the input documents beyond what can be driven by the reference summaries alone. We note that this may or may not translate into an improvement of the evaluation metrics, but it seems to add intrinsic value to the summaries nevertheless. For this reason, we further analyze the impact of the coverage term hereafter.

Figure 1 shows the average EFC coverage (5) for the documents in the input sets, indexed by the document position in the set (first, second etc). The figure shows that the inclusion of the coverage term with RELAX has led to a marked increase of the coverage, and almost evenly distributed across all the documents in the input set. In particular, the document in the last position has achieved the largest coverage improvement.

In turn, Figure 2 shows the average ROUGE score for the documents in the input sets, obtained by averaging the ROUGE-1, ROUGE-2, and ROUGE-L scores computed between the predicted summary and the document (NB: not the reference summary). The figure shows that the improvements in ROUGE score across the document set are similar to those in EFC coverage, rather evenly distributed, and with an improvement of over +4 pp for the document in the last position. This is further evidence that the normalized coverage reward (7) is able to drive the model towards predictions that cover the input set more uniformly.

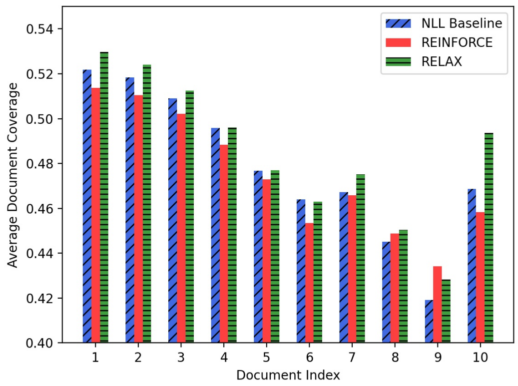

Figure 1: Comparison of the EFC coverage across the input documents over the Multi-News validation set for the NLL baseline, REINFORCE and RELAX.

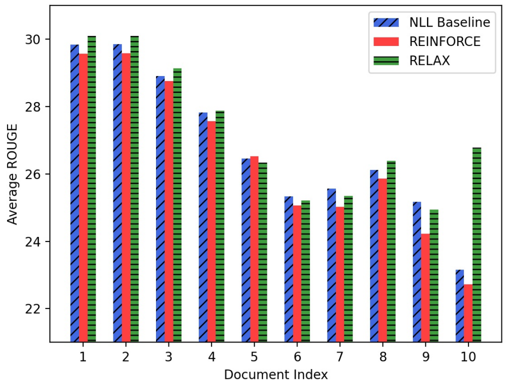

Figure 2: Comparison of the average ROUGE score across the input documents over the Multi-News validation set for the NLL baseline, REINFORCE and RELAX. The average is taken over the ROUGE-1, ROUGE-2, and ROUGE-L scores.

5.2 Few-Shot Fine-Tuning

To explore the behavior of the few-shot fine-tuning, we compare the validation-set performance on Multi-News with varying number of training examples, from 10 to 2000. The model's configuration is the best, with RELAX and the coverage term in the reward. Table 3 shows that the performance is the highest with 1000 examples, and starts to drop beyond this number. This is an important observation, as it shows that the reinforcement learning objective may lead to undesirable parameterizations beyond a point, and that the number of fine-tuning samples has to be treated as a hyperparameter.

# Examples	Avg. ROUGE	Avg. MS
Baseline	29.84	29.48
10	29.84	29.48
100	29.89	29.44
1000	**30.09**	**30.04**
2000	29.80	29.39

Table 3: Comparison of the average ROUGE and METEOR scores with different fine-tuning sizes over the Multi-News validation set.

5.3 Configuring RELAX

The RELAX gradient estimator introduces two new hyperparameters: the temperature parameter, τ, and the control variate, c_ϕ. Hereafter, we discuss their impact and design.

Temperature parameter. The RELAX gradient estimator uses a temperature parameter, τ, in the Gumbel-Softmax sampling (3). This parameter is maintained in log scale for convenience and is learnable alongside all other parameters; yet, its initial value can have a significant impact on the final model. To explore its behavior, Figure 3 shows the trajectory of parameter $\log \tau$ over 1000 Multi-News training steps for different initializations (0.25, 0.5 and 1.0). The trajectories show that, irrespective of its initial value, $\log \tau$ converges to a stable value within approximately 400 training steps. For the initializations at 0.25 and 1.0, within the first 200-300 training steps $\log \tau$ drifts significantly ($\approx \pm 0.25$ units) from its initial value. Conversely, with the intermediate initialization at 0.5, the value remains substantially stable over the whole trajectory. Since limiting drift during fine-tuning is generally desirable, we have initialized $\log \tau$ to 0.5 in all experiments.

Control variate size. Many different architectures could be used for the control variate, but given our choice described in Section 3.1, the main parameter is the feed-forward layers' hidden size. To explore its impact, Table 4 shows the average values of the ROUGE score and the coverage score over the Multi-News validation set with different hidden sizes (128, 256, and 512). The ROUGE score is computed between the prediction and the reference and is the average of ROUGE-1/2/L, while the coverage score is the average EFC of all the input documents. The values in Table 4 show that, the larger the control variate, the more the model is able to increase the coverage score. However, the average ROUGE score drops beyond a size of 256. We speculate that this behavior is due to the larger scale of the coverage reward, as by providing more capacity to the network, we allow the control variate to increasingly correlate with the multi-document coverage reward rather than the ROUGE reward. To strike a satisfactory trade-off, we have therefore chosen 256 as the hidden size for all experiments with Multi-News, and carried out an equivalent selection for WCEP.

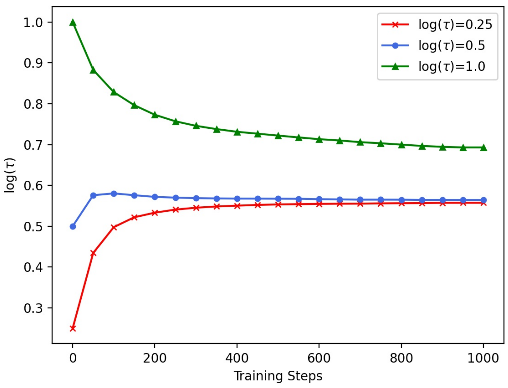

Figure 3: Trajectory of the log(τ) temperature parameter over 1000 Multi-News training steps for different initializations.

Hidden Size	Avg. ROUGE	Avg. Coverage
128	30.01	0.4821
256	**30.09**	0.4849
512	29.91	**0.5038**

Table 4: Comparison of the average ROUGE and coverage scores over the Multi-News validation set with different hidden sizes of the control variate.

5.4 Coverage Reward Trajectory

In a reinforcement learning framework, it could be useful to monitor the value of the reward over the training steps. Typically, the reward should exhibit an upward trajectory, since the reward should tend to increase as the model learns to make better predictions. In our case, we look to explore the impact of our coverage reward on the coverage distribution over the input documents. In particular, we want to verify whether the coverage reward is able to promote predictions that cover the input documents more evenly, which should translate into a decreased standard deviation. To this aim, Figure 4 shows a plot of the standard deviation of the coverage scores (EFC) across the input document set against the training step. The trajectories show that both REINFORCE and RELAX have been able to decrease the standard deviation of the predictions to approximately 0.05 units from initial values of $0.08 - 0.09$. The drop in standard deviation occurs quite quickly during training, coinciding with the improvement in the reward value of the predictions. Comparing REINFORCE with RELAX also shows that RELAX has been able to achieve lower standard deviation values throughout the training, with the exception of the very start.

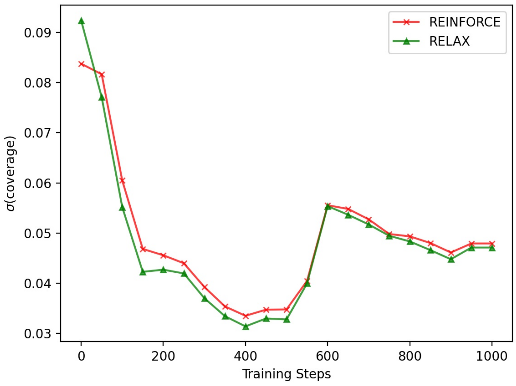

Figure 4: Standard deviation of the coverage scores (EFC) across the input documents for REINFORCE and RELAX against the training step. For both estimators, the standard deviation drops below 0.06 very early into the training, and sets to approximately 0.05.

6 Conclusion

In this paper, we have proposed fine-tuning a multi-document summarization model with a reward that balances the use of the reference summaries with the coverage of the input documents within a reinforcement learning framework. The rationale for the proposed reward is that the reference summaries alone may not be sufficient for an effective fine-tuning of the model in the presence of very large inputs such as those typical of MDS datasets. Another key component of the proposed approach is the use of a modern gradient estimator of the policy gradient, RELAX. The experimental results over two news-based MDS datasets, Multi-News and WCEP, have shown that the proposed approach has been able to achieve a marked improvement of ROUGE and METEOR scores compared to its NLL-pretrained baseline, and prove competitive against most existing approaches. In addition, the proposed approach has been able to increase the coverage of the input documents, and evenly across the entire document set. As future work, we aim to explore ways to prevent or mollify the model's drift with larger number of training steps, and explore alternative architectures and configurations for the control variate of the RELAX estimator.

A Model and Datasets

A.1 Model Hyperparameters

Our baseline model is the BART Longformer encoder-decoder (BART-LED) of Beltagy et al. (2020). In all experiments, it has been first pretrained over the training set using the negative log-likelihood until convergence, which has typically set within 5 epochs, in line with what reported in Pasunuru et al. (2021). The best models on the validation set (average ROUGE) have then been fine-tuned with the reinforcement learning objectives in (2) and (4). BART-LED has 459M parameters, and the addition of the control variate for the RELAX experiments adds approximately 12M more parameters. We have used the Adam optimizer for training both the main BART-LED model and the parameters of the control variate of the RELAX gradient estimator. The learning rate of the main optimizer for the pre-training of the baseline has been set to the default of 3×10^{-5} (Beltagy et al., 2020), before being reduced to 3×10^{-6} for fine-tuning with the reinforcement learning approaches. For training the control variate, we have set an initial learning rate of 1×10^{-2} and initialized the learnable $\log \tau$ parameter with a value of 0.5. The optimal size of the hidden layers of the control variate appears to empirically correlate with the maximum length of the reference summaries in the dataset. For Multi-News, we have set the size to be 256, and for WCEP to 40[5]. For the multi-document coverage reward, we have used a β value of 1.0. The entire model has been implemented on top of PyTorch Lightning[6]. Please refer to Table 5 for a full list of the hyperparameters. For all experiments, we have used an NVIDIA Quadro RTX 6000 with 24 GB of memory.

A.2 Dataset Links and Statistics

Multi-News. Accessible via the Hugging Face Datasets Python package: https://github.com/huggingface/datasets/tree/master/datasets/multi_news.

For fine-tuning, we have pulled the raw data from the authors' own repository: https://github.com/Alex-Fabbri/Multi-News.

Hyperparameter	Multi-News	WCEP
Training LR	3×10^{-5}	3×10^{-5}
Tuning LR	3×10^{-6}	3×10^{-6}
RELAX LR	1×10^{-2}	1×10^{-2}
$\log(\tau)$ (RELAX)	0.5	0.5
CV Size	256	40
β (Coverage)	1.0	1.0
Max Input Length	16384	16384
Max Output Length	256	40
Label Smoothing	0.0	0.0
Training Epochs	5	5
Tuning Epochs	1	1
Batch Size	1	1
Beam Size	1	1

Table 5: Hyperparameters used for training and evaluation. LR refers to Learning Rate, CV refers to Control Variate.

WCEP. Accessible from the following repository: https://github.com/complementizer/wcep-mds-dataset.

Table 6 shows the datasets' main statistics, including the number of samples within each split and the average length in tokens of the reference summaries. For our model, we have used the average length of the reference summaries as a guidance for choosing the maximum output length and the hidden size of the control variate.

DS	Train	Test	Dev	Avg. Tokens
M-N	44.9K	5.6K	5.6K	263.7
WCEP	8.1K	1.0K	1.0K	33.3

Table 6: Main statistics of the datasets used in the experiments. Multi-News has up to 10 individual articles in each document set, while WCEP has up to 100. The document split sizes have been rounded.

A.3 Scale of the Coverage Reward

The multi-document reward is used in (8) in convex combination with the ROUGE-L F1 score, and an appropriate value of the mixing coefficient, β, needs to be explored. To this aim, Table 7 shows the values of the average ROUGE and coverage scores over the Multi-News validation set. The coverage has not increased monotonically with the increase of the β coefficient. In turn, the ROUGE score has reached a maximum for $\beta = 1.0$. As a trade-off, we have set $\beta = 1.0$ in all experiments.

---

[5] Gholipour Ghalandari et al. (2020) indicate that the annotation guidelines for WCEP suggested 40 as maximum summary length.

[6] https://github.com/PyTorchLightning/pytorch-lightning

β	**Avg. ROUGE**	**Avg. Coverage**
0.5	29.97	**0.5074**
1.0	**30.09**	0.4849
2.0	30.00	0.5068
5.0	29.87	0.4823

Table 7: Average ROUGE and coverage scores over the Multi-News validation set for different values of the reward mixing coefficient, β.

B Qualitative Analysis

Tables 8 through 11 present two qualitative examples, one per dataset, where we specifically compare our RELAX implementation with and without the use of the coverage term in the reward. Key points are highlighted in various colors, comments are addressed in the captions, and the ROUGE and METEOR scores are reported for each prediction. Document sets longer than a full page have been truncated to fit.

Source Document
Plenty of churches contain relics of saints, but not many of those relics were found in excavations from sixth-century churches. Archaeologists at a medieval fortress site in Burgas, Bulgaria, found a lead vessel, which contains some of the ashes from the alleged grave of John the Apostle, in a reliquary that dates to the sixth century C.E. The reliquary, which was once part of an early Christian basilica, is named for Saint John the Theologian, who is considered one of Jesus' apostles. The vessel, which is less than an inch long, is decorated with crosses. Milen Nikolov, director of the Burgas Regional Museum of History, said that early Christians would have believed the relic had healing properties. John the Apostle's grave in Turkey was also a pilgrimage site for early Christians seeking healing, Ancient Origins reports. Nikolov said the reliquary was "one of the most important discoveries" in the museum's history. In addition to the relic, the archaeologists also uncovered a 10th century Bulgarian royal seal at the fortress site. Meghan DeMaria `[END]` Ashes from the grave of John the Apostle, one of the Twelve Apostles of Jesus Christ, have been discovered in a lead tube reliquary by Bulgarian archaeologists during excavations of the ancient and medieval port of Burgos (also known as Poros) on Cape Foros in today's Black Sea city of Burgas. The discovery of the lead tube containing ashes from the grave of John the Apostle, who is known as St. John the Theologian in Bulgarian (Eastern) Orthodox Christianity, located in the ancient city of Ephesus in Anatolia, today's Turkey, has been made during the 2014 excavations of the fortress of Burgos (or Poros) on Cape Foros in Burgas but was announced only on Wednesday, March 25, 2015, by Milen Nikolov, Director of the Burgas Regional Museum of History, at a special press conference. He has also announced other intriguing finds such as the discovery of a Late Antiquity latrine, also found at Burgos (Poros), and the discovery of a 10th century Bulgarian royal seal from the Rusocastro Fortress. The structures at the ancient and medieval fortress and port of Burgos (Poros) which were excavated in 2014 include an Early Christian basilica from the 6th century AD, a building complex from the 5th-6th century AD, and a Roman villa from the 3rd century AD. The John the Apostle reliquary was found in the 6th century basilica. "Probably a pilgrim from the Foros Peninsula (Cape) went on a pilgrimage to Ephesus, and came back here with this relic which was then donated to the basilica on Foros," Nikolov has explained, as cited by local news site Gramofona. Nikolov has described the finding of the reliquary as "one of the most important discoveries in the history of the [Burgas Regional History] Museum", and the lead tube as a "holy possession that preserved a holy substance" having to do with the beliefs that every year on May 8, the date of John the Apostle's death, there is manna, a holy curing powder, on the site of his grave. The lead tube reliquary itself containing the ashes from the grave of John the Apostle (St. John the Theologian) is really tiny: it is only 2.2 cm (less than an inch) long, and its diameter measures 1.7 cm. The reliquary is dated to the 6th century AD when pilgrimage to the Holy Lands was very common among Christians, Nikolov explains. On one of its sides there is an image of a cross with equal arms inside a medallion, and on the opposite side there is an image of two overlapping crosses with equal arms. The neck of the tube is also decorated with crosses. It has only one handle left, the other has broken off. In addition to the so called Empty Tomb, i.e. the Tomb of Jesus Christ in Jerusalem, the other centers of Christian pilgrimage in the 6th century AD included the grave of St. Menas in Abu Mina in Egypt; the grave of St. Simeon Stylites the Elder in Antioch (in today's Turkey); the grave of St. Thecla (or Tecla) in Seleucia, Mesopotamia; the grave of St. Isidore of Chios on the Aegean island of Chios; and the graves of John the Apostle (St. John the Theologian), St. Mary Magdalene, and St. Timothy in Ephesus. All of these Early Christian pilgrimage centers produced primarily clay tubes for holy water; a total of only 43 lead tubes from this time period are known in the entire world, the Bulgarian archaeologists from the Burgas Museum point out. They explaining 20 of those known lead tubes have been found in the St. John the Baptist Basilica in Monza, Italy (the Monza Cathedral); they were a gift from Lombard Queen Theodelinda (c. 570-628) made at the beginning of the 6th century. Another 16 lead tubes have been found in a grave in the Bobbio Abbey (a monastery founded by Irish Saint Columbanus in 614 AD) in the Italian town of Bobbio, close to Milan. One lead tube reliquary has been discovered in the Sant Pere de Casserres Abbey, a Benedictine monastery in the town of Les Masies de Roda, Osona comarca, Catalonia, Spain. In addition to these lead tube reliquaries, three others are kept in Germany and four in the USA, all of which were produced in Jerusalem and have depictions of Gospel scenes. Even though the reliquary discovered by the Bulgarian archaeologists in the basilica in the ancient and medieval fortress Burgos (Poros) on Cape Foros is also a lead tube, it is different from the other known lead tube reliquaries because the images on it are identical with the images from a group of clay tube reliquaries produced in ancient Ephesus. Follow us on Facebook, Twitter, Google+, Tumblr! "That is why at this stage we believe that the Burgas reliquary comes from this pilgrimage center (i.e. Ephesus) and it must be connected with the cult for St. John the Theologian (John the Apostle)," the head of the Burgas Museum of History, Milen Nikolov, explains. He also notes that John the Apostle was particularly cherished by the Early Christians. According to the Bible, John was Jesus Christ's favorite disciple, and when Jesus was crucified he asked John to take care of the Holy Mother, Virgin Mary. Later, John the Apostle settled in the ancient city of Ephesus together with Virgin Mary and St. Mary Magdalene. This is where he wrote the Book of Revelation, also known as The Apocalypse, and lived till the rest of his life. According to some historical sources, Christian pilgrims from around the world would gather on his grave in the Ephesus basilica on May 8, the date of his death. They would sprinkle rose petals on the rock above the basilica, and the next day wonder-working powder would appear on the rock. This manna could cure all kinds of diseases, which is why it was collected by the pilgrims in reliquaries and taken to their places of origin as evidence of their pilgrimage or as an apotropeus (an apotropaic item, i.e. an amulet chasing away evil). Some scholars believe the manna collected by the pilgrims came from the pollen from the roses they placed on John the Apostle's grave in Ephesus. "That is why, at this point, we believe that a pilgrim from the fortress of Poros went on a pilgrimage to the grave of St. John the Theologian in Ephesus from where he brought the valuable reliquary with curing powder," Nikolov elaborates...

Archaeologists in Bulgaria think they've found ashes belonging to one of the 12 apostles. The team found a small lead container with ashes while excavating a basilica that dates back to the sixth century AD, reports Archaeology in Bulgaria. The markings on the inch-long vessel match those at the grave of St. John the Apostle in what is now Turkey, leading researchers to surmise that a long-ago Christian from Bulgaria traveled to the grave site and returned home with the sample of ashes. Such journeys were common around that time, reports Novinite. "Probably a pilgrim from the Foros Peninsula went on a pilgrimage to Ephesus, and came back here with this relic, which was then donated to the basilica on Foros," says the director of the Burgas Regional Museum of History in Bulgaria. (The ancient basilica is located in what is now the Black Sea city of Burgas.) Archeologists also found a Bulgarian royal seal from the 10th century at the dig site, which includes a fortress, notes the Week. (Another archaeological discovery: an ancient underground city in Turkey.)
NLL (47.05/16.12/24.59/28.10)
Archaeologists have made a pretty significant find in Bulgaria: ashes from the grave of one of Jesus Christ's Twelve Apostles. The lead tube containing the ashes of St. John the Theologian, who is believed to have lived in what is now Turkey, was found in a medieval fortress and is named for the early Christian basilica that once stood there, Ancient Origins reports. **The lead container, which is less than an inch long**, is decorated with crosses and has only one handle, reports the International Business Times. The lead container is believed to have been carried by **a pilgrim who made the trip to the ancient city of Ephesus**, where the Apostle was once a favorite of Jesus. The grave of John the Theologian was a popular pilgrimage destination for early Christians seeking healing, and the lead container "must be connected with the cult for St. John the Theologian," says the head of the Burgas Regional Museum of History. **The find was announced Wednesday, but it wasn't made public until Thursday.** (Click to read about how a lead container found in a 14th-century tomb could help heal ancient wounds.)
ROUGE-L + RELAX (56.76/25.06/30.76/37.10)
Archaeologists have made "one of the most important discoveries" in the history of the Burgas Regional Museum of History in Bulgaria, says the museum's director: a lead reliquary that contains ashes from the alleged grave of one of Jesus' Twelve Apostles. The **tiny lead container, which is less than an inch long**, was found during last year's excavations of the fortress of Burgos on Cape Foros, reports Ancient Origins. The reliquary was once part of an early Christian basilica, and **"probably a pilgrim from the Foros Peninsula went on a pilgrimage to Ephesus, and came back here with this relic which was then donated to the basilica,"** says Milen Nikolov. **The find was announced Wednesday, but the news was made public on Wednesday.** The find was made during the **same excavations that turned up a 10th-century royal seal**, reports the Independent. The find is significant because early Christians believed the relic had healing properties, and John the Apostle's grave in Turkey was a popular pilgrimage site for those seeking healing, reports Ancient Origins. (Click to read about how a lead-tipped glass bottle was found in a 14th-century Roman city.)
ROUGE-L + Coverage + RELAX (57.59/30.00/31.93/38.64)
Archaeologists have made "one of the most important discoveries" in the history of the Burgas Regional Museum of History in Bulgaria, says the museum's director: a lead reliquary that contains ashes from the alleged grave of one of Jesus Christ's apostles. The **tiny lead container, which is less than an inch long**, was **found in a 6th-century basilica** in what is now the **Black Sea city of Burgas**, reports Ancient Origins. **"Probably a pilgrim from the Foros Peninsula went on a pilgrimage to Ephesus, and came back here with this relic which was then donated to the basilica**," says Milen Nikolov, per the Independent. The reliquary is named for St. John the Theologian, who is believed to have been one of the Twelve Apostles. **The find was made during 2014 excavations at the fortress of Burgos on Cape Foros**, but **the announcement was made only this week**. The head of the museum says the reliquary is connected to the **belief that there is manna, a holy curing powder, on the site of John the Apostle's grave every year**. (Click to read about how a lead box found in a cave has been analyzed for ancient DNA.)

We note that these results are also in line with the average scores presented in Table 1.

Source Document
’Greece’s conservative prime minister-elect Kyriakos Mitsotakis vowed that the country would "proudly" enter a post-bailout period of "jobs, security and growth" after winning a landslide victory in Sunday’s general election. Official results showed Mitsotakis on track to crush leftist premier Alexis Tsipras, who oversaw austerity measures after Greece’s dramatic rescue by international creditors in the European debt crisis. "A painful cycle has closed," Mitsotakis said in a televised address, adding that Greece would "proudly raise its head again" on his watch. "I will not fail to honour your hopes," he said as early congratulation calls came from outgoing European Commission chief Jean-Claude Juncker and Turkish President Recep Tayyip Erdogan. With official results from 94 per cent of polling stations, New Democracy scored a crushing victory by nearly 40 per cent – its best score in over a decade – to 31.5 per cent for Tsipras’s leftist Syriza party. "I want to see this people prosper. I want to see the children who left to return," he later told party supporters. Mitsotakis will be sworn in as Greece’s new prime minister on Monday. Tsipras had earlier admitted defeat after over four years in power that saw Greece emerge from its third bailout. The 44-year-old warned that his Syriza party would "dynamically" resist efforts to scale back the party’s pro-labour reforms. If the results are confirmed, the 51-year-old Harvard graduate and former McKinsey consultant Mitsotakis will have a majority of 158 lawmakers in the 300-seat parliament. Tsipras’s party will have 86 seats. The final number will depend on how smaller parties fare. They need at least 3.0 percent of the vote to enter parliament. New Democracy was last in power in 2014, in coalition with the Greek socialists. Mitsotakis is a scion of one of Greece’s top political families. He is the son of former prime minister Constantine Mitsotakis, one of the country’s longest-serving parliamentarians. His sister is former minister Dora Bakoyannis, Athens’s first female mayor. And new Athens mayor Costas Bakoyannis, elected in May, is his nephew. Sunday’s election was Greece’s third in as many months, and the first held in midsummer since 1928. In May, New Democracy beat Syriza by nearly 9.5 points in European parliament elections. A week later, it completed a near-sweep of Greek regions in local elections. After that, Tsipras was forced to call an early general election. His term was scheduled to end in the autumn. Greece’s youngest premier in more than a century, Tsipras had trailed in the polls for months amid widespread dissatisfaction over high taxes. "Greece is exiting 10 years of crisis and the new government will have the heavy task to give a chance to the country to recover completely or to sink", 36-year-old Aphrodite told AFP, as she cast her vote in the bohemian downtown Athens neighborhood of Exarcheia. "I hope that from tomorrow we will be able to breathe with relief. To take a deep breath, if Mitsotakis does what he promises," added Athinodoros, a 48-year-old self-employed worker. Tsipras has accused Mitsotakis – who was part of a 2012-2014 crisis government – of "disastrous" mismanagement that brought hundreds of thousands of job losses and business failures. Mitsotakis has now pledged to create "better" jobs through growth, foreign investment and tax cuts and to "steamroll" obstacles to business. Tsipras – who reduced unemployment and raised the minimum wage for the first time since 2012 – was criticized for campaigning as an anti-austerity crusader before eventually accepting a third EU bailout and the economic cutbacks that entailed. In parts of the country, there was also a backlash against a controversial agreement with North Macedonia that ended a bitter 27-year dispute over the country’s name. The new smaller parties fighting to secure representation are Greek Solution, a nationalist party formed by TV salesman Kyriakos Velopoulos, and MeRA25, an anti-austerity party founded by maverick economist and former Greek finance minister Yanis Varoufakis. According to the exit polls, Varoufakis’s party could elect nine lawmakers. Greek Solution could end up with 10 deputies, while neo-Nazi party Golden Dawn looks likely to be shut out of parliament for the first time since 2012. Golden Dawn, until recently Greece’s third-ranking party, is in steep decline amid an ongoing trial for the 2013 murder of an anti-fascist rapper, allegedly carried out with the knowledge of senior Golden Dawn members. Mitsotakis has promised to hit the ground running. A Eurogroup finance meeting on Monday will convene to discuss the state of Greece’s economy after tax cuts rolled out by Tsipras in May. Like us on Facebook or follow us on Twitter and Instagram for latest news and live news updates. Budget 2019: Find the latest news on ndtv.com/budget. Use the income tax calculator to learn about your tax liability `[END]` Investors expect new Greek Prime Minister Kyriakos Mitsotakis to prove that his business-friendly reputation is deserved. The former banker and management consultant will need to make good on pledges to address issues including government finances, soured loans and crippling bureaucracy, while working within tight fiscal constraints. Although he has inherited an economy on the mend and a stock market that is soaring, they are rebounding from shrunken bases. Mr Mitsotakis must ensure that Greece can attract the investment it desperately needs and create jobs as the country digs itself out of a financial crisis that has lasted more than a decade and taken a toll on living standards. Here are the three main issues the new Greek government will have to deal with from day one: While the new government is not yet in place, the country’s creditors want to send a clear message that it has to stick to its commitment of achieving a 3.5 per cent primary surplus every year until 2022. Former prime minister Alexis Tsipras’ move to distribute handouts before the European elections has raised doubts about Greece’s ability to meet its fiscal targets. The European Commission estimates that the freebies will lead to a fiscal cost of 1 per cent of gross domestic product for both this year and the next, meaning creditors may ask the new government for additional austerity measures. Mr Mitsotakis plans to rapidly legislate tax cuts that will come into effect from next year to spur economic activity and show investors that Greece is creating a more friendly business environment. The biggest challenge is addressing about €80 billion (S$122 billion) in bad loans. Lenders are speeding up efforts to cut soured debt by selling portfolios of non-performing exposures (NPEs), but they will need more tools to meet their ambitious targets of single-digit NPE ratios by 2021. Mr Mitsotakis’ target is doubling Greece’s growth rate to 4 per cent next year. To achieve that, he needs investments. To convince investors that they can trust the country again, he wants to immediately proceed with the long-delayed Hellinikon project. The flagship venture envisages the transformation of the former Athens airport site - more than two times the size of New York’s Central Park - into a metropolitan park including luxury hotels, casino, marinas and apartments. But that will not be enough. The new government will have to deal with red tape, a sluggish judicial system and corruption, as well as speeding up privatisations, especially in the energy sector. `[END]`...

Table 11: WCEP example. Comparison of reference, NLL baseline, and RELAX-generated summaries for the document in Table 10. We compare specifically the addition of the coverage term in the reward, to qualitatively show its importance. The R1/R2/RL/METEOR scores are shown in the headers. Highlighted in **blue** are examples of key information that allow for the summary to remain faithful to the reference. Highlighted in **green** are examples where the coverage term has managed to improve the quality of the summary. As mentioned in Section 4.4, shorter summaries are involved in this dataset, and are more likely to result in higher ROUGE scores. In this example, both RELAX objectives have drastically improved the accuracy. We can also see that the model has been able to use the coverage term to improve the summary quality by adding relevant fragments, and lead to a higher METEOR score. We note that these results are in line with the average scores presented in Table 2.

KNN-Contrastive Learning for Out-of-Domain Intent Classification

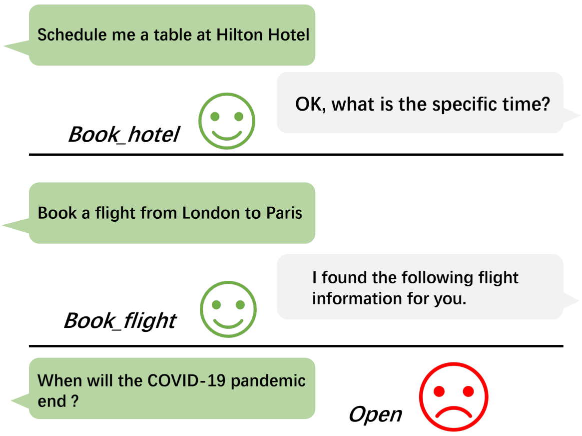
Abstract

The Out-of-Domain (OOD) intent classification is a basic and challenging task for dialogue systems. Previous methods commonly restrict the region (in feature space) of In-domain (IND) intent features to be *compact* or *simply-connected* implicitly, which assumes no OOD intents reside, to learn discriminative semantic features. Then the distribution of the IND intent features is often assumed to obey a hypothetical distribution (Gaussian mostly) and samples outside this distribution are regarded as OOD samples. In this paper, we start from the nature of OOD intent classification and explore its optimization objective. We further propose a simple yet effective method, named KNN-contrastive learning. Our approach utilizes K-Nearest Neighbors (KNN) of IND intents to learn discriminative semantic features that are more conducive to OOD detection. Notably, the density-based novelty detection algorithm is so well-grounded in the essence of our method that it is reasonable to use it as the OOD detection algorithm without making any requirements for the feature distribution. Extensive experiments on four public datasets show that our approach can not only enhance the OOD detection performance substantially but also improve the IND intent classification while requiring no restrictions on feature distribution. Code is available.[1]

1 Introduction

People are getting accustomed to talking with or sending some instructions to task-oriented dialog system in natural language to assist them in fulfilling work. As the environment facing the dialogue systems becomes more open, there are more utterances with unknown or Out-of-Domain (OOD) intents that the dialog system does not know how to handle. As shown in Figure 1, the chatbot encounters an unsupported intent (OOD intent) utterance in the third interaction. It is significant to distinguish these utterances for the dialogue system because identifying the intents of the user determines whether subsequent actions can be carried out correctly.



Schedule me a table at Hilton Hotel

Book a flight from London to Paris
I found the following flight information for you.
When will the COVID-19 pandemic end ?

Figure 1: An example about interactions between a user (green) and a chatbot (grey). The chatbot correctly understands the intents (In-domain intents) of the user in the first two rounds. Thirdly, the chatbot encounters Out-of-Domain intent and does not know how to do it.

To solve this problem, the existing methods roughly can be summarized into two categories according to whether extensive labeled OOD intent samples are used during training. The first kind of method (use OOD samples during training) is represented by (Zheng et al., 2020; Zhan et al., 2021; Choi et al., 2021) which regards OOD intent classification as a (n+1)-class classification task that the extra $(n+1)^{th}$ class represents labeled OOD intent. These methods may need additional large and time-consuming labeled Out-of-Domain samples. Moreover, manually constructed OOD samples endowed with artificial inductive bias cannot cover all open classes in the actual environment so this kind of method have their limitations.

In this paper, we focus on another kind of method which involves two stages, to learn dis-

(a) Origin (b) Minimize intra-class variance (c) Minimize IND-KNN variance (Ours)

Figure 2: (a) The original distribution of IND and OOD distribution. (b) Minimize the intra-class variance may increase the risk that OOD intents surrounded by a covex hull composed composed of IND samples locally are identified (red shadow) as IND. (c) Utilizes k-nearest neighbors of IND to contrastive learning.

criminative semantic features and OOD detection. **How to learn semantic features benefit for OOD detection?** Minimizing intra-class variance and maximizing inter-class variance, whose motivation are to facilitate detection by widening margin between IND and OOD intents, have always been regarded as the essence of solving this problem (Lin and Xu, 2019; Zeng et al., 2021a). Then, Shu et al. (2017); Zhang et al. (2021); Xu et al. (2020); Zeng et al. (2021a) impose (or implicitly) Gaussian distribution into the distribution of the learned intent features to OOD detection.

In general previous methods implicitly assume the region of semantic features as *compact* or *simply-connected region* in feature space, which means OOD intents only exist between different IND classes and not within IND distribution so that tight IND semantic features can be helpful for OOD detection. However, as shown in Figure 2 (a), the actual location of OOD intents in semantic space is not limited, they can appear between IND classes or within IND distribution. We name those OOD intents that are distributed between different IND classes as inter OOD intents, and those within IND distribution or can be surrounded by a convex hull composed of local IND intent samples as intra OOD intents. As shown in Figure 2 (b), for inter OOD intents, minimizing intra-class variance and maximizing inter-class variance can reduce the risk of being identified IND while this risk may be increased for intra OOD intents due to being closer to IND intents.

At the same time, we conduct Gaussian Hypothesis Testing on the IND semantic features distribution in the CLINC-FULL train set, which is learned by (Zeng et al., 2021a). we find only 57% IND classes conform to Gaussian distribution, which illustrates the Gaussian assumption for OOD detection in the previous methods may not be reasonable, see Appendix A.1 for results on other datasets and details.

To solve these problems, we explicitly define the optimization objective of OOD intents classification using open space risk (Scheirer et al., 2012). Compared with the previous methods only considering inter OOD intents, we propose a simple yet effective method to consider both intra and inter OOD intents. We utilize k-nearest neighbors of IND intent sample as positive samples as shown in Figure 2 (c), and obtain more negative samples with the help of queue in MoCo (He et al., 2020) to learn discriminative semantic features. We further analyze why our method can better reduce open space risk. Intuitively, our method leaves more margin around OOD intents, which can ensure we employ the basic density-based method for OOD detection without any assumptions about the distribution.

We summarize our contributions as follows. Firstly, following open space risk, we explicit the optimization objective of OOD intent classification to provide a paradigm for solving OOD intent classification. Secondly, we analyze the limitation of existing methods and propose a novel method to better reduce both empirical risk and open space risk. Thirdly, extensive experiments conducted on four challenging datasets show our approach achieves consistent improvements without restrictions on feature distribution.

2 Related Work

2.1 Out-of-domain Detection

Schölkopf et al. (2001); Tax and Duin (2004) regard Out-of-Domain detection as One-class classification problem so that to find a hyperplane or hypersphere by kernels in high-dimensional space to distinguish OOD, Scheirer et al. (2012) firstly proposes the definition of open space risk and formalize open set recognition as a constrained optimization problem. Then to obtain better semantic representation, deep neural network has been brought into this field in recent years. Bendale and Boult (2016) propose OpenMax model, using the scores from the penultimate layer of deep network, to distinguish OOD. MSP (Hendrycks and Gimpel, 2017) presents a baseline based on maximum softmax probabilities to exhibit the ability of the network to distinguish between OOD and IND. To enlarge the difference between IND and OOD, Liang et al. (2018) add temperature scaling based on MSP and adds perturbations to the inputs.

The above methods mainly focus on computer vision and assume (or implicitly) the feature region is compact (simply-connected region), many research works are carried out in natural language processing. DOC (Shu et al., 2017) builds a multi-class classifier and selects a threshold to reject. Further, they reduces the open space risk for rejection by tightening the decision boundaries of sigmoid functions with Gaussian fitting. LMCL (Lin and Xu, 2019) learns discriminative deep features with margin loss. Yan et al. (2020); Wan et al. (2018) model embeddings with a Gaussian mixture distribution to facilitate downstream outlier detection. Xu et al. (2020); Zeng et al. (2021b); Podolskiy et al. (2021) assume the IND semantic feature distribution as Gaussian discriminant analysis (GDA) and identify Out-of-domain samples by Mahalanobis distances. (Fei and Liu, 2016) reduce open space risk by decision boundaries and ABD (Zhang et al., 2021) propose to learn adaptive circular decision boundaries. Very recently, Zeng et al. (2021a) propose a supervised contrastive learning objective to maximize inter-class variance and to minimize intra-class variance. These methods also restrict the feature distribution in the feature learning stage or downstream detection stage and fail to solve Out-of-domain classification completely.

2.2 Contrastive Learning

Contrastive learning, which can be traced back to (Hadsell et al., 2006), is widely used in unsupervised or self-supervised learning (He et al., 2020; Wang and Isola, 2020; Khosla et al., 2020). With similarity by dot product, Gutmann and Hyvärinen (2010) propose InfoNCE loss to measure the similarities of sample pairs in semantic space. To obtain more number of negative samples for contrastive learning, He et al. (2020) introduce Momentum Contrastive (MoCo) that builds a large and consistent dictionary facilitating contrastive unsupervised learning. With the prevalence of pre-trained models (PTMs) (Qiu et al., 2020; Lin et al., 2021) in different fields, Dwibedi et al. (2021); Li et al. (2021) combine PTMs with contrastive learning paradigm, which adopts neighbors and uses MoCo or Memory Banks to obtain enough negative samples.

3 Proposed Method

3.1 Objective of OOD Intent Classification

Open space risk We define open space $\mathcal{O}$ and open space risk as follow (Scheirer et al., 2012; Bendale and Boult, 2015). Using IND training samples, open space can be defined as [2]:

$$\mathcal{O} = \mathcal{S} - \bigcup_{x \in \mathcal{X}} \sigma(x), \tag{1}$$

where σ is a local (and small) semantic space spanned by IND training sample x, $\mathcal{X}$ is the set of all IND training samples and $\mathcal{S}$ including both open space $\mathcal{O}$ and remaining space. Consider a measurable recognizer (or discriminator) f that $f(x) = 1(> 0)$ for the IND intents, otherwise $f(x) = 0(<= 0)$, probabilistic open space risk $\mathcal{R}_{\mathcal{O}}$ can be formed in terms of Lebesgue measure:

$$\mathcal{R}_{\mathcal{O}}(f) = \frac{\int_{\mathcal{O}} f(x,\theta)dx}{\int_{\mathcal{S}} f(x,\theta)dx}. \tag{2}$$

Objective of OOD Intent Classification To identify OOD intents, we need to learn intent representations at first, which also ensures the classification quality of IND in addition to adapting to downstream detection. Therefore we introduce an additional optimization objective as also suggested in (Scheirer et al., 2012; Bendale and Boult, 2015),

---

[2] We also define a specific open space risk for limited OOD samples. See the Appendix A.6 for details and more discussion.

named empirical risk $\mathcal{R}_\varepsilon(f)$. The objective can be defined as:

$$\underset{f(x,\theta)\in\mathcal{H}}{\arg\min}\{(1-\lambda)\cdot\mathcal{R}_\varepsilon(f)+\lambda\cdot\mathcal{R}_\mathcal{O}(f)\}, \quad (3)$$

where λ is a hyper-parameter to balance empirical and open space risk and $\mathcal{H}$ is the function space.

3.2 Minimize Empirical Risk

To optimize above objective. We first utilize the BERT (Devlin et al., 2019) to extract intent representation. Given the i-th in-domain utterance, we get its contextual embeddings $[[CLS], T_1, T_2, ..., T_N]$. As suggested in (Zhang et al., 2021), we operate mean-pooling on these contextual token embeddings to obtain sentence semantic representation Z_i:

$$Z_i = \text{Mean-Pooling}([[\text{CLS}], T_1, ...T_N]), \quad (4)$$

where $Z_i \in \mathcal{R}^H$, N is the sequence length and H is the hidden dimension.

We optimize the empirical risk with simple softmax cross-entropy loss $\mathcal{L}_{ce}$:

$$\mathcal{L}_{\text{ce}} = -\frac{1}{N}\sum_{i=1}^{N}\log\frac{\exp(\phi_{y_i}(z_i))}{\sum_{j\in[K]}\exp(\phi_j(z_i))}, \quad (5)$$

where $\phi(\cdot)$ denotes linear classifier and $\phi_j(z_i)$ denotes the score of the j-th class.

3.3 KNN-Contrastive Learning

It is worth noting that due to the lack of OOD intent samples, we can not directly optimize the open space risk. Previous methods indirectly reduce the open space risk by pulling together IND samples belonging to the same class and pushing apart samples from different classes. However, such approaches may increase the risk of identifying intra OOD intents as IND based on the above analysis. Intuitively, to reduce the risk that identifying intra OOD intents as IND, we do not need to pull together all IND intent samples belonging to the same class and just pull together k-nearest neighbors while pushing apart them from different class intent samples as shown in Figure 2 (c). In order to achieve this goal, we get the KNN-contrastive loss $\mathcal{L}_{knn-cl}$ by rewriting the contrastive loss:

$$\mathcal{L}_{\text{knn-cl}} = \sum_{i=1}^{N}\frac{1}{|\mathcal{X}_k|}\sum_{z_j\in\mathcal{X}_k} -\log\frac{\exp(\frac{z_i\cdot z_j}{\tau})}{\sum\limits_{z_q\in I}\exp(\frac{z_q\cdot z_i}{\tau})}, \quad (6)$$

where $\mathcal{X}_k$ denotes the set of k-nearest neighbors of sample z_i, $I \equiv A\bigcup\{z_j\}$, A is the set of samples whose classes are different from that of z_j. τ is the temperature hyper-parameter. We further analyze how KNN-contrastive loss is benefit to inter OOD intents and intra OOD intents simultaneously, see Appendix A.5 and Appendix A.6 for more detailed and deeper analysis.

3.4 Momentum Contrast is All You Need

When conducting KNN-contrastive learning, we need to solve two problems: a) large batch size, the more samples we can select, the more likely we to find k-nearest neighbors. Meanwhile, we also need enough negatives to distinguish. b) The k-nearest neighbors should keep consistent as they evolve during training, otherwise, KNN-contrastive train learning may be unstable. Interestingly, these problems mentioned above are also those Momentum Contrast (MoCo) (He et al., 2020) wants to solve. Following MoCo, we also maintain a queue containing IND samples and update it with features of the current batch while dequeuing the oldest features. The queue decouples the size of samples from the batch size, allowing us to obtain more negative samples (benefit to reduce open space risk). To maintain consistency, the features coming from the previous several batches are encoded by a slowly updating network (encoder), whose parameters are momentum-based average of the parameters from the query encoder (another network), see (He et al., 2020) for details. Combing softmax cross-entropy loss and KNN-contrastive learning loss, the **final finetune obejective** to learn discriminative features as:

$$\mathcal{L}_{obj} = \lambda\cdot\mathcal{L}_{\text{knn-cl}} + (1-\lambda)\cdot\mathcal{L}_{\text{ce}}, \quad (7)$$

where λ is a hyper-parameter to balance empirical and open space risk.

3.5 Local Outlier Factor

To be closer to the realistic scenario, we prefer the detection algorithm downstream without assuming a potential distribution of the IND intents. Therefore, we adopt a simple and universal detection algorithm LOF algorithm (Breunig et al., 2000) and compute LOF score following (Lin and Xu, 2019), see Appendix A.3 for specific calculation steps. Our model architecture is shown in Figure 3.

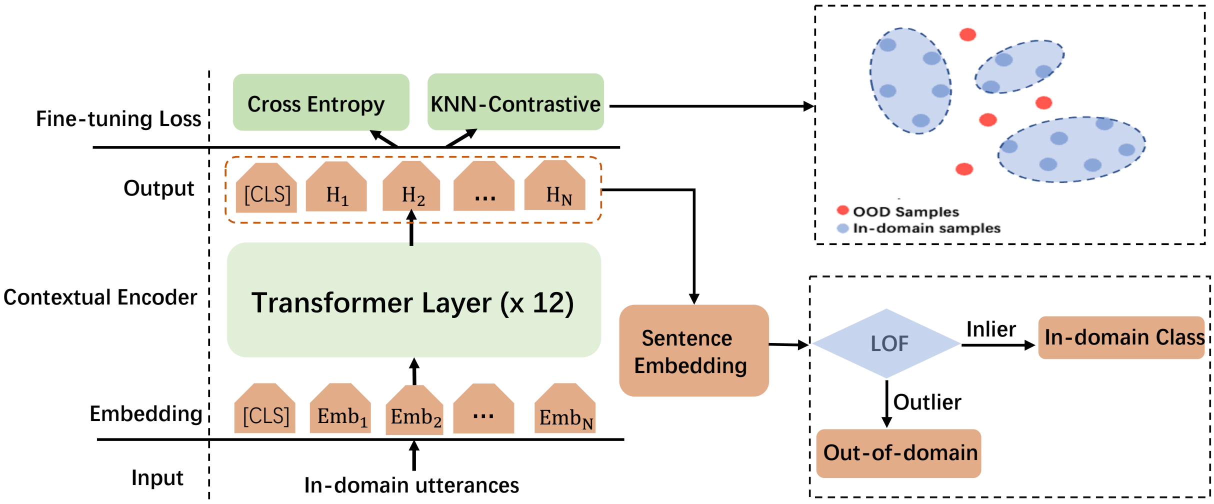

Figure 3: The architecture of our proposed model.

4 Experiments

4.1 Datasets

In order to verify the effectiveness and generality of our method, we conduct experiments on four different and challenging real-world datasets. The detailed statistics are shown in Appendix A.4.

CLINC-FULL (Larson et al., 2019) is a dataset specially designed for OOD detection, which consists of 150 classes from 10 domains. This dataset includes 22500 IND utterances and 1200 OOD utterances.

CLINC-SMALL (Larson et al., 2019) is the CLINC-FULL variant, in which there are only 50 training utterances per each IND class. This dataset includes 15000 IND utterances and 1200 OOD utterances.

BANKING (Casanueva et al., 2020) is a dataset about banking. The dataset, covering 77 classes, consists of 9003, 1000 and 3080 utterances in training, validation and test sets respectively.

StackOverflow (Xu et al., 2015) is a dataset published in Kaggle.com. This dataset has 20 classes and consists of 12000, 2000 and 6000 in training, validation and test sets respectively.

4.2 Baselines

We extensively compare our method with the following OOD classification methods: MSP (Hendrycks and Gimpel, 2017), DOC (Shu et al., 2017), SEG (Yan et al., 2020), LMCL (Lin and Xu, 2019), Softmax (Zhan et al., 2021), OpenMax (Bendale and Boult, 2016), ADB (Zhang et al., 2021), SCL (Zeng et al., 2021a).

For a fair comparison, all methods use **BERT** as the backbone network. We report the current best results of various methods on the corresponding datasets. Softmax/LMCL learns discriminative features by softmax/large margin cosine loss and use additional detector such as LOF or GDA for detecting out-of-domain. ADB (Zhang et al., 2021)/SCL (Zeng et al., 2021a) are also related to our method, however, the original paper does not report results in on some datasets. We supplement results by running their released code.

4.3 Evaluation Metrics

For all datasets, we follow previous work (Zhang et al., 2021; Zeng et al., 2021a; Zhan et al., 2021) and group all OOD classes as one rejected class. We calculate accuracy and F1-score in the same way as (Zeng et al., 2021a). To better evaluate the ability of our method to distinguish IND and OOD intents, we calculate macro F1-score over IND classes and OOD classes, represented by **F1-IND** and **F1-OOD** respectively. To comprehensively evaluate the performance of our model, we also compare accuracy score (**ACC-ALL**) and macro F1-score (**F1-ALL**) over all classes (IND and OOD classes).

4.4 Experimental Setting

Due to no OOD classes in the BANKING and StackOverflow, we follow the setting in (Zhang et al., 2021; Zhan et al., 2021). After datasets are split into train, validation, and test respectively, we randomly sample 25%, 50%, and 75% of the intent classes and discard the remaining classes in the training and validation sets [3]. The disposed classes are kept in the test set as OOD classes. CLINC-FULL and CLINC-SMALL are constructed for OOD detection especially and the datasets themselves provide OOD classes. We follow (Zeng et al., 2021a,b) and take the OOD class provided by datasets as the objective of detecting without dividing datasets additionally. As a reminder, we do not use OOD classes during training in any cases.

To reduce the deviation, we use two basic distances, Euclidean and Cosine (more discussed in Appendix A.2), to calculate the LOF score. For each distance, we take different random seeds to run 3 rounds, and we report the total average results. We employ the BERT model (bert-uncased, with 12-layer transformer) implemented by Huggingface Transformers[4] and adopt most of its suggested hyperparameters for finetuning. We tried learning rate in {1e-5, 5e-5}, and training batch size is set 16 or 32. Concerning contrastive learning, we tried the size of the queue in {6500, 7500, 8000} and the momentum update parameter m = 0.999. We use the AdamW optimizer (Loshchilov and Hutter, 2019). We select the LOF threshold by calculating the best macro F1-score and accuracy over IND classes on the validation set. ALL experiments were conducted in the Nvidia Ge-Force RTX-2080 Graphical Card with 11G graphical memory.

4.5 Main Results

The results in BANKING and StackOverflow are presented in Table 1, where the best results are highlighted in bold. Compared with other baselines, our method consistently improves in all settings. F1-OOD represents the F1-score of OOD class, and F1-IND is the macro F1-score of IND classes. Our method achieves favorable performance simultaneously, which shows that our method improves the capability of detecting OOD intents without sacrificing the accuracy of IND classes classification.

The results in CLINC-FULL and CLINC-SMALL datasets are presented in Table 2. Our method is also better than all other kinds of methods. It is worth noting that F1-IND and F1-OOD have improved compared with SCL significantly. We suppose this is due to the use of Momentum Contrast framework in our method, which obtains more negative samples by maintaining a queue (the capacity is much larger than batch size) so that further pushes apart samples from different classes, as shown in Section 5.1.

5 Analysis

Table 2: Results of OOD classification on CLINC-FULL and CLINC-SMALL. † means the results is not provided in the original paper and we get the results by running its released codes provided by (Zeng et al., 2021a). Other baselines are from (Zeng et al., 2021a).

with SCL Figure 4(b), our method further push apart samples from different classes, especially for the classes of **whisper-mode(green)** and **cancel(blue)**. This shows our method can ensure the classification quality of IND intents and better optimize empirical risk. Can our method optimize open space risk better? As shown in Figure 4(c) and Figure 4(d), we notice that the features of **vaccines class (brown)** can be clustered into three clusters (top-k=5) or two clusters (top-k=15), which means leave more space for OOD intent samples as expected.

5.2 Visualize the Ability to Detect OOD

To further verify the effectiveness of our method to characterize the difference between IND and OOD intents, we draw the LOF score distribution of samples in CLNIC-FULL test set. We show results in Figure 5. Compared with SCL (left) Figure 5(b), our LOF scores of OOD intent samples are spread in a larger range, which indicates that there is a larger margin around OOD intent samples according to the definition of LOF and further shows our method optimize the open space risk better. And this larger margin makes it is easier for us to find a baseline (brown dotted line) in Figure 5(b) (our method) to separate IND and OOD samples, which indicates they are distinguished better. The above results also ensure that we can detect OOD intents without making assumptions about the feature distribution.

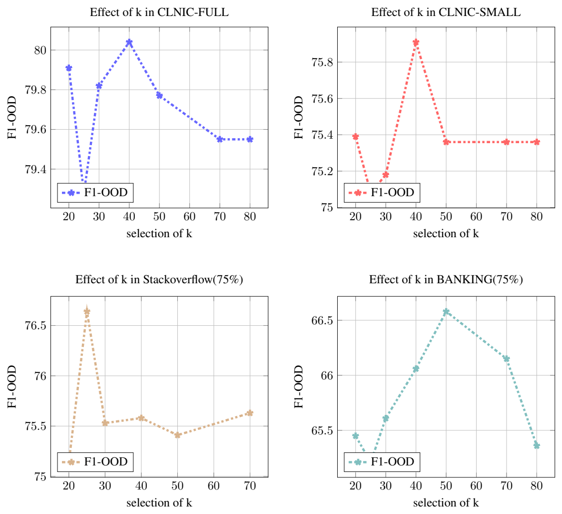

Figure 6: Effect of k. The X-axis represents the value of k, and Y-axis represents F1-score for OOD samples.

5.3 Importance of K Nearest Neighbors

In Section 3.3, we propose a novel method, which utilizes the k-nearest neighbors of IND intents to learn discriminative features, to reduce open space risk. To investigate the effect of k, we compare the performance of the model in detecting OOD intents with different k values (in a certain range) during contrastive learning (fixing other hyper-parameters). As shown in Figure 6, we have observed that the performance (cosine-based) of the model first increase and then decrease on four datasets as the value increases. This phenomenon is as expected. At the beginning of k growth, due to the reduction of open space risk, the risk of inter and intra OOD samples being identified as IND decreases (corresponding F1-OOD increases). Later, due to the compression of IND semantic space, more and more intra OOD samples are identified as IND (corresponding F1-OOD decreases) and finally tend to be stable. The phenomenon also shows that our method can better reduce the open space risk than the previous methods (which pull together all IND intents belonging to the same class).

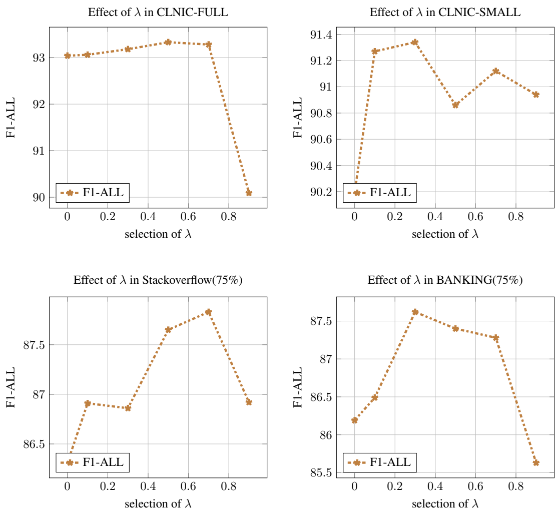

Figure 7: Effect of λ on four datasets. The X-axis represents the λ value, and Y-axis represents F1-ALL for all classes.

5.4 Trade-off Between Empirical And Open Space Risk

While we want to minimize open space risk (helpful to detect OOD intents), we also need to balance it against the empirical risk (ensure the classification quality of IND classification) over the training data. In the objective (in Eq.(7)) of OOD classification, we use the λ hyper-parameter to balance empirical and open space risk. To analyze the effect of our introduced λ, we experiment our method (cosine-based) with different λs in different datasets. As shown in Figure 7, we find with the increment of λ, the model gradually reaches the best empirical-open trade-off, which means the model can ensure the classification quality of IND and OOD detection effectively. The only empirical risk or open space risk can not make the model achieve better results.

6 Conclusion

In this paper, we explicit the optimization objective of OOD intent classification. We analyze the limitation of existing methods and propose a simple yet effective method to learn discriminative semantic features. Our approach pulls together k-nearest neighbors of IND intents and pushes apart them from different class samples to better reduce both empirical risk and open space risk. Extensive experiments conducted on four challenging datasets show our approach achieves consistent improvements without restrictions on feature distribution.

Acknowledgements

We thank Demin Song for helpful discussion about experiment. We would also like to thank Hang Yan and TianXiang Sun for helpful suggestion for this paper. This work was supported by the National Key Research and Development Program of China (No. 2020AAA0108702) and National Natural Science Foundation of China (No. 62022027).

Ethical Considerations

The datasets used in all experiments are derived from previously published scientific papers, and to our knowledge, there are no privacy or ethical issues.

A Appendix

Dataset	Classes	*Rate**
CLINC-FULL	150	57%
CLINC-SMALL	150	36%
StackOverflow	20	21%

Table 3: Classes denote the total number of IND classes. *Rate** denotes the rate of IND classes obeying Gaussian.

A.1 Gaussian Hypothesis Testing

We use NormalTest provided by Scipy[5] to test whether the trained distribution conforms to a normal distribution. The Multivariate Normal Testing is not adopted mainly because samples with 256 dimensions can hardly fit the multivariate Gaussian distribution. Moreover, the number of samples will affect the p-value considerably. So we randomly select 50 samples from each class and calculate the p-value on individual dimensions separately. To mitigate the influence of some too small values, we retain the highest 128 value for statistics. By convention, the distribution with a p-value less than 0.05 will reject the Normal Hypothesis. We calculate the percentage of not rejected dimensions and report the mean value of all classes. We conduct Gaussian hypothesis testing on the IND semantic features distribution, which are learned by (Zeng et al., 2021a), in the train sets of CLINC-FULL, CLINC-SMALL, and StackOverflow. Results are shown in Table 3.

	BANKING(75%)		StackOverflow(75%)	
	F1-OOD	F1-ALL	F1-OOD	F1-ALL
Lof Cosine	67.36	86.87	78.12	88.06
Lof Euclidean	65.77	87.46	77.12	87.9

Table 4: Results of OOD classification on BANKING and StackOverflow. Lof Cosine means to calculate Lof based on Cosine and Lof Euclidean means to calculate Lof based on Euclidean.

A.2 Effect of Distance on Calculation of LOF

We calculate LOF-score based on two distances: Cosine and Euclidean. In this section, we want to investigate the effect of LOF-score calculated by different distances. On the two datasets, we use these two distances to calculate LOF score (average results over 3 runs randomly) and get F1 for out-of-domain and macro F1 for all classes. As shown in Table 4, Firstly, from a single dataset, there are some differences between the two methods (although the difference is not very large). We guess this may be caused by the threshold. Because we can't use the information of OOD samples, we can't accurately obtain the threshold required by each method. Secondly, comparing the performance of the same method on different datasets, we have not observed one method has more advantages. Therefore, to comprehensively illustrate the effectiveness of our method, in the experiment we take different random seeds to test 3 times for each distance, and we report the total average results. It is worth noting that during our experiment, we find that raising the threshold for LOF-score calculated based on Euclidean (compared with Cosine) can achieve better average results for CLINC-FULL and CLINC-SMALL datasets.

A.3 Local Outlier Factor

To be closer to the realistic scenario, we prefer detection in downstream without relying on assumption of distribution. Therefore, we adopt a simple and universal detection algorithm LOF algorithm (Breunig et al., 2000). we compute LOF score follow (Lin and Xu, 2019):

$$\mathrm{LOF}_k(z) = \frac{\sum_{p \in N_k(z)} \frac{lrd(p)}{lrd(z)}}{|N_k(z)|}, \qquad (8)$$

where $N_k(z)$ denotes the set of k-nearest neighbors of z. The LOF captures the degree to which z is

---

Dataset	Class	#Training	#Validation	#Test	Vocabulary Size	Length (Avg)
CLINC-FULL	150	15100	3100	5500	8288	8.32
CLINC-SMALL	150	7600	3100	5500	7017	8.31
BANKING	77	9003	1000	3080	5028	11.91
StackOverflow	20	12000	2000	6000	17182	9.18

Table 5: Statistics of datasets. # denotes the total number of utterances

an outlier by computing the average of the ratio of the local reachability density of z and the k-nearest neighbors of z.

Local Reachability Density (lrd) computed as following:

$$lrd_k(p) = 1/\frac{\sum_{O \in N_k(p)} \text{reach-dist}_k(p,o)}{|N_k(p)|}, \quad (9)$$

where $lrd_k(p)$ denotes the inverse of the average reachability distance based on the k-nearest neighbors of p. reach-dist$_k$(p, o) is defines as:

$$\text{reach-dist}_k(p,o) = \max\{\text{k-dis}(o), d(p,o)\}, \quad (10)$$

where d(p, o) is the distance between p and o, and k-dis is the distance of o to its k-th nearest neighbor. It is easy to see that the lower lrd of a sample is than its neighbors, the more likely it is to be an OOD sample.

A.4 Statistics of Datasets

The datailed statistics of **CLINC-FULL**, **CLINC-SMALL**, **BANKING** and **StackOverflow**, which are used in Section 4.1, are shown in Table 5.

A.5 Theoretical Analysis

In this section, we take a closer look at how our proposed KNN-contrastive loss indirectly can reduce the risk that inter OOD and intra OOD intents are identified as IND.

$$\mathcal{L}_{\text{knn-cl}} = \sum_{i=1}^{N} \frac{1}{|\mathcal{X}_k|} \sum_{z_j \in \mathcal{X}_k} \underbrace{-\log \frac{\exp(\frac{z_i \cdot z_j}{\tau})}{\sum\limits_{z_k \in I} \exp(\frac{z_k \cdot z_i}{\tau})}}_{\mathcal{R}}. \quad (11)$$

For simplicity, we consider KNN-contrastive loss with one sample q, denoted as $\mathcal{R}$ in Eq. (11):

$$\mathcal{R} = \sum_{z_j \in \mathcal{X}_k} -log \frac{\exp(\frac{q \cdot z_j}{\tau})}{\sum\limits_{z_k \in I} exp(\frac{q \cdot z_k}{\tau})}, \quad (12)$$

where $\mathcal{X}_k$, I have the same meanings as in Eq.(11), representing the set of k-nearest neighbors of q, $I \equiv A \bigcup \{z_j\}$, A is the set of samples whose classes are different from that of z_j. We introduce a term on both numerator and denominator, $\sum_{z_p \in I^+} exp(\frac{q \cdot z_p}{\tau})$, I^+ denotes set of all samples whose classes are the same as q, so $\mathcal{R}$ can be rewritten as:

$$\begin{aligned}
\mathcal{R} &= \sum_{z_j \in \mathcal{X}_k} -log \frac{\exp(\frac{q \cdot z_j}{\tau})}{\sum\limits_{z_k \in I} exp(\frac{q \cdot z_k}{\tau})} \\
&= \sum_{z_j \in \mathcal{X}_k} -log \frac{\exp(\frac{q \cdot z_j}{\tau})}{\sum\limits_{z_p \in I^+} \exp(\frac{q \cdot z_p}{\tau})} \frac{\sum\limits_{z_p \in I^+(i)} \exp(\frac{q \cdot z_p}{\tau})}{\sum\limits_{z_k \in I} exp(\frac{z_k \cdot q}{\tau}))} \\
&= \sum_{z_j \in \mathcal{X}_k} \underbrace{-log \frac{\exp(\frac{q \cdot z_j}{\tau})}{\sum\limits_{z_p \in I^+} \exp(\frac{q \cdot z_p}{\tau})}}_{\mathcal{R}_{\mathcal{O}}^{intra}(f)} \underbrace{-log \frac{\sum\limits_{z_p \in I^+} \exp(\frac{q \cdot z_p}{\tau})}{\sum\limits_{z_k \in I} exp(\frac{z_k \cdot q}{\tau})}}_{\mathcal{R}_{\mathcal{O}}^{inter}(f)}.
\end{aligned} \quad (13)$$

In this way, the KNN-contrastive loss can be split into two comparative learning losses. The first loss $\mathcal{R}_{\mathcal{O}}^{intra}(f)$ is to pull together k-nearest neighbors of q and push apart q from other samples whose classes are the same as q, which is viewed to reduce the risk identifying intra OOD samples as IND. The second loss $\mathcal{R}_{\mathcal{O}}^{inter}(f)$ is to push together samples whose classes are the same as q and pull apart samples whose classes are different q, which is viewed to reduce the risk identifying inter OOD samples as IND.

A.6 Specific Open Space Risk

Intra-space risk and Inter-space risk When we encounter a scene with limited OOD samples, we can re-explore the nature of open space risk. Different from (Scheirer et al., 2012; Bendale and Boult, 2015), we define open space as the space around OOD samples:

$$\mathcal{O} = \bigcup_{x \in \phi} \sigma(x) = \underbrace{\bigcup_{x \in \phi_{in}}}_{\mathcal{O}_{in}} \sigma(x) + \underbrace{\bigcup_{x \in \bar{\phi}_{in}}}_{\bar{\mathcal{O}}_{in}} \sigma(x), \quad (14)$$

where σ is a local and small semantic space spanned by OOD samples, ϕ is the set of all OOD samples (or just included enough OOD samples), ϕ_{in} is set of OOD samples within IND distribution (surrounded by a convex hull composed of IND samples locally), $\bar{\phi}_{in}$ is set of OOD samples between IND classes ($\bar{\phi}_{in} = \phi - \phi_{in}$). Consider a large space $\mathcal{S}$ including both open space $\mathcal{O}$ and remaining space, and a measurable recognizer(or discriminator) f that $f(x) = 1(> 0)$ for recognition of the IND samples, otherwise $f(x) = 0(<= 0)$. Probabilistic (in terms of Lebesgue measure) open space risk $\mathcal{R}$ can also be formalized as:

$$\mathcal{R}_{\mathcal{O}}(f) = \frac{\int_{\mathcal{O}} f(x,\theta)dx}{\int_{\mathcal{S}} f(x,\theta)dx}. \tag{15}$$

Considering Eq.(14), we can naturally decompose open space risk into two terms shown in Eq.(16), called intra-space risk and inter-space risk respectively.

$$\mathcal{R}_{\mathcal{O}}(f) = \underbrace{\frac{\int_{\mathcal{O}_{in}} f(x,\theta)dx}{\int_{\mathcal{S}} f(x,\theta)dx}}_{\mathcal{R}_{\mathcal{O}}^{intra}(f)} + \underbrace{\frac{\int_{\bar{\mathcal{O}}_{in}} f(x,\theta)dx}{\int_{\mathcal{S}} f(x,\theta)dx}}_{\mathcal{R}_{\mathcal{O}}^{inter}(f)}. \tag{16}$$

By aligning Eq.(16) with Eq.(13), we can naturally find out why KNN-contrastive loss can better reduce open space risk.

A.7 Random Split Matters?

In the experiment, we noticed a small and interesting problem. When conducting experiments on BANKING and StackOverflow, there are two evaluation methods. The first is as described in the experimental section Section 4.4. Another evaluation method is that the dataset is fixed after the known intents classes are randomly sampled from the datasets, and the random test is carried out on these fixed datasets. We also take different random seeds to run 3 rounds and compare our results with ADB. The results are presented in Table 6 and Table 7. Our results are also better than ADB on all datasets. More interestingly, the results even can be better than our results in Section 4.4 on some datasets (25% Banking). We speculate that this may be because this evaluation method may achieve a better split in some cases for learning feature representation. In addition to in the Nvidia Ge-Force RTX-2080 Graphical Card with 11G graphical memory, we also conducted some experiments in the Nvidia Ge-Force RTX-3090 Graphical Card with 24G graphical memory.

Abstract

Program understanding is a fundamental task in program language processing. Despite the success, existing works fail to take human behaviors as reference in understanding programs. In this paper, we consider human behaviors and propose the PGNN-EK model that consists of two main components. On the one hand, inspired by the "divide-and-conquer" reading behaviors of humans, we present a partitioning-based graph neural network model PGNN on the upgraded AST of codes. On the other hand, to characterize human behaviors of resorting to other resources to help code comprehension, we transform raw codes with external knowledge and apply pre-training techniques for information extraction. Finally, we combine the two embeddings generated from the two components to output code embeddings. We conduct extensive experiments to show the superior performance of PGNN-EK on the code summarization and code clone detection tasks. In particular, to show the generalization ability of our model, we release a new dataset that is more challenging for code clone detection and could advance the development of the community. Our codes and data are publicly available at `https://github.com/RecklessRonan/PGNN-EK`.

1 Introduction

The past decades have witnessed the prosperity of programming platforms, such as *Github* and *Stack Overflow*. These platforms generate massive open-source code[1] data that is named as "Big Code" in (Allamanis et al., 2018a). To automate the software development and maintenance, based on the "Software Naturalness" hypothesis (Hindle et al., 2016), natural language processing (NLP) techniques have been applied in program understanding. After that, a series of downstream programming language processing (PLP) tasks can be performed, including code summarization (Zhang et al., 2020; Ahmad et al., 2020; Liu et al., 2021) and code clone detection (Zhang et al., 2019; Wang et al., 2020).

Existing works for understanding programs mainly utilize three types of information: *code context*, *code structure* and *external knowledge*. Specifically, code context refers to the token sequence in the code. For code structure, each code can be parsed into various types of intermediate representations, such as AST (Abstract Syntax Tree), CFG (Control Flow Graph) and PDG (Program Dependence Graph). These representations capture the structural information of codes. Further, there also exists external knowledge associated with codes, such as API documentation and other exemplary codes. Despite the success, all these models ignore considering human behaviors in reading programs. Recently, (Bengio et al., 2021) suggest the potential futures of deep learning by comparing current AI methods with human learning abilities. This further prompts us to revisit program understanding: *Can we develop a model that understands programs like humans?*

In the domain of programming education, how people understand codes is a topic that has been studied. For example, based on knowledge base including syntactical knowledge (e.g., programming basics) and semantic knowledge (e.g., API documentation), (Schulte et al., 2010) offer a *bottom-up* reading technique, which assumes that people begin with individual code lines and chunks, and then combine them into higher-level abstractions. Further, (Park et al., 2016) state that when people read codes, reasoning about the hierarchical relationship of blocks, statements, expressions and variables is necessary. Based on these studies, we conclude three key points for human understanding codes. First, the transition of defined variables has to be traced. Second, humans usually adopt a "divide-and-conquer" strategy, which divides codes based

on statements and then understands codes from a local-to-global view. Third, humans resort to external knowledge to comprehend codes, such as API documentation and code examples written by experts.

In this paper, inspired by human behaviors for code comprehension, we propose a novel **P**artitioning-based **G**raph **N**eural **N**etwork with **E**xternal **K**nowledge (PGNN-EK). To capture code context and structure, PGNN-EK upgrades the traditional AST and defines a novel subtoken-based AST called S-AST. In S-AST, we add edges between variables to trace the variable transitions, edges between adjacent tree leaves from left to right to enrich the context and structure information, and edges between sub-nodes corresponding to subtokens tokenized from user-defined identifiers to handle the Out of Vocabulary (OOV) problem (Karampatsis et al., 2020). Details will be illustrated later. After that, we first apply graph neural network (GNN) models on the S-AST to derive a code embedding. To further implement the "divide-and-conquer" reading strategy, we partition the S-AST into multiple subgraphs, which follow the sequence of statements in the original code. For each subgraph, we use GNN models to generate the subgraph embedding. Then, these subgraph embeddings are fused to generate another code embedding. For these two code embeddings, since they are both derived from S-AST, we further aggregate them. On the other hand, to characterize the dependence on external knowledge for code comprehension, we traverse the AST of the original code to derive a sequence of tokens for syntactic knowledge and then add the API descriptions to the end for semantic knowledge. We then apply CodeBERT (Feng et al., 2020) on the token sequence to capture external knowledge. Finally, PGNN-EK generates the output code embedding by combining the embedding derived from S-AST and the one from external knowledge.

To evaluate the model performance, we conduct experiments on the code summarization task and code clone detection task, respectively. Before we apply PGNN-EK on the code clone detection benchmarks in CodeXGLUE (Shi et al., 2021) extracted from the BigCloneBench 2014 dataset (Svajlenko et al., 2014), we notice from the leaderboard[2] that the results are incredibly high, where the minimum F1 score is 0.949. Then we dive into the characteristics of the dataset and find that the functionalities of codes in the test set have all appeared in the training set. Therefore, the dataset is very simple. To further test the model's generalization ability, we construct a new dataset, where the test set contains codes whose functionality has never appeared in the training set. This new dataset provides an insightful reference for further research in the community.

Our main contributions are summarized as follows:

- We construct a new code structure representation S-AST that can be used to handle the OOV problem in PLP.
- We follow human behaviors in understanding codes and propose a novel model PGNN-EK that leverages code context, structure and external knowledge. Specifically, we put forward a novel partitioning-based graph neural network model that can effectively use code context and structure. We also present a code transformation method to utilize external knowledge in boosting comprehension.
- We conduct extensive experiments on code summarization and code clone detection tasks to demonstrate the effectiveness of our model. In particular, we identify the limitation of a benchmark dataset for code clone detection and release a new dataset that is more challenging.

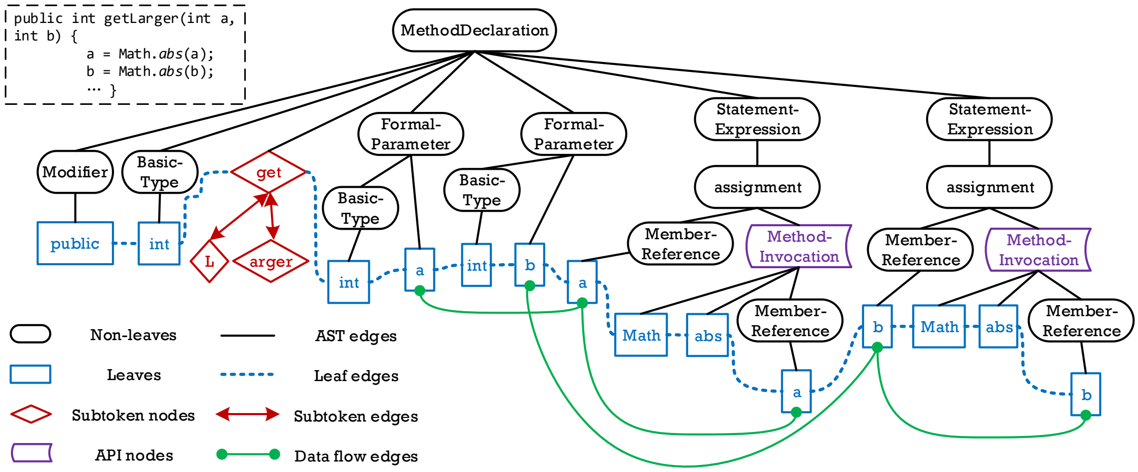
2 Related Work

2.1 Program Understanding

Program understanding is a topic that has received wide attention. Early works use either code context or structure information. For example, taking codes as raw texts, some works use language models (Raychev et al., 2014; Allamanis et al., 2015), RNN-series (Zaremba and Sutskever, 2014; Dam et al., 2016) and attention (Iyer et al., 2016) to represent codes. However, different from natural language, programs are more structural, which can be parsed into intermediate graphs, such as AST. Many works for code analysis are then proposed based on AST, such as AST-based LSTM (Wei and Li, 2017), AST-based CNN (Yu et al., 2019), ASTNN (Zhang et al., 2019), code2vec (Alon et al.,

---

[2] `https://microsoft.github.io/CodeXGLUE/`



```
public int getLarger(int a,
int b) {
        a = Math.abs(a);
        b = Math.abs(b);
        … }
```

Figure 1: An example of S-AST. To simplify the graph, we create a code snippet (top left), whose variables are defined with only one character, such as "a" and "b". In real tasks, the codes are longer and user-defined identifiers are more semantically complex. This could add more subtoken nodes and edges. The figure is better viewed in color.

2019b), and code2seq (Alon et al., 2019a). Recently, GNN models have also been applied in code understanding. Since the original AST is actually a tree that is sparse, these works (Allamanis et al., 2018b; Wang et al., 2020; Wang and Li, 2021) first add edges to AST to make it more connected and then apply GNN models. Further, there are also works (Yu et al., 2020; Cummins et al., 2021; Liu et al., 2021) that utilize other intermediate graphs such as CFG, PDG and CPG (Yamaguchi et al., 2014). Recently, approaches that use both code context and structure are proposed. For example, Hellendoorn et al. (2020) and Zügner et al. (2021) incorporate the structure information derived from AST, such as edge weights and node distances, into the context attention computation in Transformer (Vaswani et al., 2017).

Despite the success, all these methods only consider the code context and structure information. There are also approaches that utilize the external knowledge associated with codes. For example, some methods apply pre-training techniques in NLP to boost comprehension, such as CodeBERT (Feng et al., 2020), GPT-C (Svyatkovskiy et al., 2020) and PLBART (Ahmad et al., 2021). There are also works that incorporate code characteristics into pre-training models, such as GraphCodeBERT (Peng et al., 2021), OSCAR (Peng et al., 2021) and InferCode (Bui et al., 2021). Further, API is another external source for program understanding, which has been introduced in many works (Hu et al., 2018; Xu et al., 2020). However, all these methods ignore considering human behaviors in program understanding.

2.2 Code Summarization and Code Clone Detection

In this paper, we focus on two program understanding downstream tasks: code summarization and code clone detection. For code summarization, some works (Iyer et al., 2016; Ahmad et al., 2020) use code context only, some methods (LeClair et al., 2019; Alon et al., 2019a) use code structure only, while there are also models (Hellendoorn et al., 2020; Zügner et al., 2021) that use both information. Further, Liu et al. (2021) introduce external knowledge for performance improvement. For code clone detection, existing works mainly employ code structure (Wei and Li, 2017; Zhang et al., 2019; Wang et al., 2020) and pre-training models (Feng et al., 2020; Ahmad et al., 2021).

3 S-AST Construction

In this section, we construct S-AST. The original AST has two main limitations:

- **Low connectivity**. The original AST is actually tree-structured, where every two nodes are minimally connected with only one path. This could lead to a long distance between leaf nodes. As pointed out in (Alon and Yahav, 2021), directly applying GNN models in tree-shaped graphs could cause the long-range problem.

- **OOV problem**. User-defined identifiers in codes can be arbitrarily complex and most of them are compound words, which could induce a large vocabulary size. For example, the training set size in the benchmark dataset CodeXGLUE (Lu et al., 2021) for code summarization is $164,814$, while the vocabulary size for AST nodes is $620,256$. After we split the nodes by camel case and underscores (Cvitkovic et al., 2019), the vocabulary size is still as high as $201,286$. A very large vocabulary could cause the OOV problem (Jean et al., 2015) and thus adversely affect the model performance.

To improve the connectivity of the AST, there exist some works (Allamanis et al., 2018b; Wang et al., 2020; Wang and Li, 2021) that add edges to the AST. However, these methods cannot address the OOV problem. Therefore, we propose a new code intermediate graph S-AST, as shown in Figure 1. Similar as in (Allamanis et al., 2018b; Wang et al., 2020), we add data flow edges to trace variable transitions and connect adjacent leaf nodes to encourage learning from contexts. To solve the OOV problem, we further reduce the vocabulary size by using the tokenizer of RoBERTa (Liu et al., 2019) to tokenize every leaf node in the AST. When a leaf node can be tokenized into multiple subtokens, we keep the first subtoken as the parent node and take other subtokens as its children. For example, the token "getLarger" is divided into the parent node "get" and the children nodes "L" and "arger". These new parent-children connections are defined as subtoken edges. With these three types of edges added, we increase the number of edges in the AST and improve the graph connectivity. Further, the vocabulary size could be significantly reduced. In our experiments, we use javalang[3] to generate Java AST and reduce the vocabulary size to $50,336$, where $50,265$ is the size of original RoBERTa vocabulary and 71 is the number of keywords in non-leaf nodes defined by javalang.

4 Algorithm

In this section, we introduce the PGNN-EK model, which is composed of two main components. On the one hand, the partitioning-based graph neural network model (PGNN) is proposed to follow the "divide-and-conquer" behaviours of humans to understand programs. On the other hand, PGNN-EK leverages external knowledge to enhance the model's capability. The overall architecture of PGNN-EK is summarized in Figure 2.

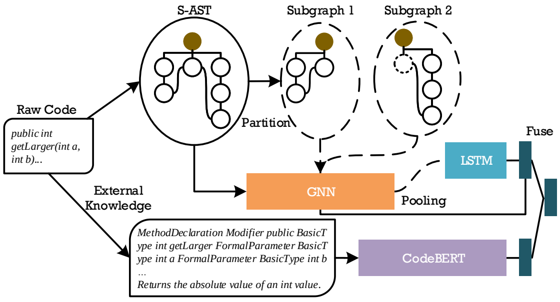


Figure 2: The overall architecture of PGNN-EK

4.1 Partitioning-based Graph Neural Networks

As illustrated in (Schulte et al., 2010) and (Park et al., 2016), the bottom-up reasoning on the hierarchical relationship of statements plays an essential role in human understanding. Therefore, we propose a statement-based partitioning algorithm to divide S-AST into multiple subgraphs. Since S-AST is no longer a tree, for convenience, we first keep subtokens and their edges in-between in S-AST, and remove edges linking variables and those connecting adjacent leaf nodes, to derive a tree structure. After that, we calculate the number of nodes in each subtree of the root node and each subtree corresponds to a statement of the raw code. Then, we accumulate the number of nodes in subtrees from left to right. When the sum exceeds the pre-defined threshold λ, we group these subtrees into one subgraph and reset the sum to zero. If the current subgraph is not the first one, for each variable node in it, we also add to the subgraph the closest node indicating the same variable in previous subgraphs to trace the variable transition. After the subgraph is derived, we add edges between nodes that represent the same variable and also connect adjacent leaf nodes as in the original S-AST. We repeat this process until all subtrees are visited. Note that if the node number of the last subgraph is smaller than $\lambda/2$, we merge the last subgraph into the penultimate subgraph. Finally, we summarize the pseudocodes of the partitioning algorithm in Alg. 1.

After subgraphs are derived, as in (Hellendoorn et al., 2020), we adopt GGNN (Li et al., 2016) as the graph embedding model, which uses a multi-

---

[3] `https://github.com/c2nes/javalang`

layer perceptron (MLP) and a gated recurrent unit (GRU) to perform message passing and embedding updating. Specifically, at the $(l+1)$-th layer, to update the embedding $\mathbf{h}_i^{l+1}$ of node x_i, we have:

$$\mathbf{m}_i^{l+1} = \sum_{j \in \mathcal{N}_i} \mathrm{MLP}(\mathbf{h}_j^l, \mathbf{e}_{ij}),$$
$$\mathbf{h}_i^{l+1} = \mathrm{GRU}(\mathbf{m}_i^{l+1}, \mathbf{h}_i^l),$$

where $\mathcal{N}_i$ is the neighbor set of x_i and $\mathbf{e}_{ij}$ is the feature vector of the edge between x_i and x_j. After node embeddings are generated, we use a READOUT function to obtain the graph embedding $\mathbf{G}$:

$$\mathbf{G} = \mathrm{READOUT}(\{\mathbf{h}_i\}).$$

We repeat the above process on each subgraph to derive a list of subgraph embeddings $\mathbf{L} = [\mathbf{G}_1, \mathbf{G}_2, \cdots, \mathbf{G}_n]$, where n is the number of subgraphs. Next, we keep the order of the subgraph list and feed $\mathbf{L}$ into an unidirectional LSTM:

$$\mathbf{O} = \mathrm{LSTM}(\mathbf{L}).$$

Inspired by the skip connection (He et al., 2016), we also perform GGNN on the whole S-AST graph to derive a code embedding $\mathbf{C}$. Finally, we concatenate $\mathbf{C}$ and the last output $\mathbf{O}[-1]$ of LSTM. We further feed the result into a fully connected layer to get the output code embedding $\mathbf{E}_p$:

$$\mathbf{E}_p = \mathrm{FC}(\mathrm{Concat}(\mathbf{C}, \mathbf{O}[-1])).$$

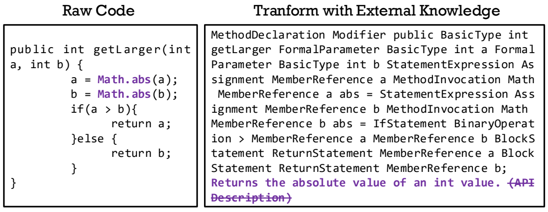
4.2 External Knowledge

To help understand programs, people often resort to external knowledge. For example, humans usually learn from massive exemplary codes written by experts for better syntactic comprehension, which are in the format of programming language. Further, API documentation is written in natural language and provides semantic details on functions. Therefore, a research question arises: *how to fuse these external syntactic and semantic knowledge into our model?*

To address the problem, we use pre-training techniques in programming language processing (PLP), which are trained on massive code corpus to learn programming basics. In particular, we adopt CodeBERT (Feng et al., 2020), which is a bimodal pre-trained model for both programming language and natural language.

Before CodeBERT is applied, we first combine the raw code and API descriptions. To enrich the syntactic information contained in the raw code, we perform pre-order traversal on the AST of the code to obtain a sequence of tokens and replace the raw code. This is because the AST includes extra code-related information, such as statements, variables and operations. Then we append the corresponding API description to the end. A toy example of transformation is shown in Figure 3. Finally, we feed the transformed context $\mathbf{T}$ into the pre-trained CodeBERT[4] and obtain the embedding $\mathbf{E}_e$:

$$\mathbf{E}_e = \mathrm{CodeBERT}(\mathbf{T}).$$



```
public int getLarger(int
a, int b) {
        a = Math.abs(a);
        b = Math.abs(b);
        if(a > b){
              return a;
        }else {
              return b;
        }
}
```

```

Figure 3: A toy example on code transformation with external knowledge. The last sentence in the right box is the API description of *Math.abs*.

Finally, we concatenate the output embeddings of PGNN and CodeBERT, and feed the result into a fully connected layer to obtain the final embedding $\mathbf{E}_f$:

$$\mathbf{E}_f = \mathrm{FC}(\mathrm{Concat}(\mathbf{E}_p, \mathbf{E}_e)).$$

5 Experiments

In this section, we evaluate the performance of PGNN-EK. We conduct experiments on two program understanding tasks: code summarization and code clone detection. For each task, we use two benchmark datasets, whose statistics are listed in Table 1.

5.1 Implementation details

In our experiments, we use the AdamW optimizer and linear schedule from (Wolf et al., 2020) to update model parameters. For fair comparison, we run all experiments on 2 Tesla V100 with 32G memory. For PGNN, we set the number of GNN layers, the number of LSTM layers, the embedding size of GNN node, and the embedding size of LSTM hidden layer to 3, 2, 768 and 768, respectively. We choose the mean operator as the READOUT function. To avoid overfitting, we set the dropout rate to 0.2 in PGNN. We implement GNNs

---

[4] `https://huggingface.co/microsoft/codebert-base`

Table 1: The statistics of datasets

Task	Dataset	Training	Validation	Test	Description
Code summarization	CodeSearchNet-Java (CSN)	164,814	5,179	10,952	Provided by CodeXGLUE
	TL-CodeSum (TLC)	69,708	8,714	8,714	Original
Code clone detection	BigCloneBench (BCB)	901,028	415,416	415,416	Provided by CodeXGLUE
	BigCloneBench-Function (BCB-F)	398,110	78,602	81,202	Split by functionality

based on PyTorch Geometric (Fey and Lenssen, 2019). In the EK-enhanced component, we obtain $51,191$ method-description pairs after preprocessing the API documentation[5]. For pair examples, see Appendix B. In the code summarization task, we add a 6-layer Transformer-based decoder to generate summarization as in CodeBERT. We set learning rate to 0.00005, batch size to 16, training steps to $50,000$, maximum code length to 256 and maximum summarization length to 32, respectively. In the code clone detection task, as suggested by (Neculoiu et al., 2016), we double the PGNN-EK to a siamese neural network to calculate code similarity. We set learning rate to 0.00005, batch size to 4, training steps to $200,000$ and maximum code length to 400, respectively.

5.2 Code Summarization

Code summarization aims at generating natural language comments for codes. We evaluate the performance of PGNN-EK on two benchmark datasets, which are TL-CodeSum (shorted as TLC) (Hu et al., 2018) and the Java subset of CodeSearchNet (shorted as CSN) (Husain et al., 2019). For TLC, we use the original dataset. For CSN, we use the version provided by CodeXGLUE (Lu et al., 2021). For fair comparison, we use the smoothed BLEU-4 score (Lin and Och, 2004) as in CodeXGLUE. The larger the score, the better the model performance. We compare our model with five representative baselines, including CodeNN (Iyer et al., 2016), NCS (Ahmad et al., 2020), Rencos (Zhang et al., 2020), CodeBERT (Feng et al., 2020) and PLBART (Ahmad et al., 2021). Due to the space limitation, we move the details of these baselines to Appendix C.

Table 2 shows the code summarization results. Note that the results of CodeNN, NCS and Rencos are directly taken from (Shi et al., 2021). Also, the results of CodeBERT and PLBART on CSN are derived from the leaderboard of CodeXGLUE. For their results on TLC, we run the codes released by the authors of the paper and set hyper-parameters according to the original paper. From the table, we see that, due to the fusion of external knowledge, pre-training models CodeBERT, PLBART and PGNN-EK outperform other models on both datasets. Further, PGNN-EK performs the best. The gaps between PGNN-EK and the runner-up model PLBART on CSN and TLC are 0.5 and 1.05, respectively. This shows the importance of considering human behaviors for code comprehension. We also observe that scores on TLC are substantially larger than that on CSN. This is because codes in the training set and the test set of TLC are considerably more similar in functionalities, which will be elaborated in the next section.

Table 2: Code summarization results. We highlight the best results in bold. * indicates that the improvements are statistically significant for $p < 0.01$ with paired t-test.

Model	CSN	TLC
CodeNN	8.58	33.03
NCS	11.19	44.25
Rencos	11.80	46.81
CodeBERT	17.65	48.53
PLBART	18.45	50.01
PGNN-EK	**18.95***	**51.06***

5.3 Code Clone Detection

The goal of code clone detection is to detect whether two code fragments implement the same functionality. Following (Zhang et al., 2019; Wang et al., 2020), we use the BigCloneBench 2014 dataset (Svajlenko et al., 2014) and adopt the version provided by CodeXGLUE. We short it as BCB.

Before we apply PGNN-EK on BCB, we notice from the leaderboard of CodeXGLUE that the results on BCB are incredibly high, where the mini-

---

[5] `https://www.oracle.com/java/technologies/javase-jdk8-doc-downloads.html`

mum F1 score is 0.949. Then we dive into the characteristics of the dataset and compare BCB with the original benchmark (Svajlenko et al., 2014). We find that the functionalities of codes in the test set have all appeared in the training set of BCB. Therefore, BCB is a very simple dataset. To test the model's generalization ability, we construct a new dataset, named BCB-F, where the test set contains codes whose functionality has never appeared in the training set. We first extract codes from the new version benckmark (Svajlenko and Roy, 2015) that has more code fragments and code functionalities. We next split training/validation/test set based on code functionalities. Specifically, we construct training/validation/test set with 22/11/10 code functionalities. For details on the functionality splits of BCB and BCB-F, see Appendix D. We keep the same number of positive and negative samples in all the three sets. The comparison between BCB and BCB-F is given in Table 3.

Table 3: Comparisons between BCB and BCB-F

	BCB	BCB-F
Code fragments	9134	73182
Functionalities	10	43
Training/Test splitting	random sample	by functionality
Ratio of positive-negative	nearly 2:1	1:1

In addition to the pre-training models CodeBERT and PLBART, we further compare our model with two representative methods in code clone detection, which are ASTNN (Zhang et al., 2019) and FA-AST (Wang et al., 2020) (For the details of these baselines, see Appendix C).

Table 4 shows the evaluation results on the two datasets. For BCB, we take the results of other baseline methods from CodeXGLUE[6]. For BCB-F, we run the source codes released by their authors to obtain the results. From the table, we observe: 1) All models perform very well on BCB, indicating that the dataset is very simple. However, the best F1 score on BCB-F is only 0.724, which shows that this dataset is very challenging. 2) The non-pre-training models ASTNN and FA-AST predict all samples to be positive and perform poorly on BCB-F, while pre-training models perform better. This further demonstrates the importance of introducing external knowledge. 3) PGNN-EK achieves the best results on both datasets. This shows that considering human behaviors in program understanding enhances the generalization ability of PGNN-EK.

Table 4: Code clone detection results w.r.t. precision (P), recall (R) and F1 measures. We highlight the best results in bold. * indicates that the improvements are statistically significant for $p < 0.01$ with paired t-test.

Model	BCB			BCB-F		
	P	R	F1	P	R	F1
ASTNN	0.92	0.94	0.93	0.50	**1.00**	0.67
FA-AST	0.96	0.94	0.95	0.50	**1.00**	0.67
CodeBERT	0.960	0.969	0.965	0.611	0.842	0.708
PLBART	-	-	0.972	0.517	0.996	0.681
PGNN-EK	**0.975***	**0.973***	**0.974***	**0.621***	0.869	**0.724***

5.4 Ablation Study

We further conduct ablation study to verify the importance of its main components in PGNN-EK, including subtokens, the S-AST graph, the partitioning-based GNN and the external knowledge. Specifically, one variant employs only the S-AST graph without using external knowledge. This helps us realize the importance of external knowledge in program understanding. We call this variant **PGNN only**. Meanwhile, we define another variant that ignores the hierarchical relationships in code structure and uses only external knowledge. We call this variant **EK only**. To further show the significance of S-AST in code understanding, we replace S-AST with the original AST in the variant **PGNN-EK with AST**. We also implement a variant that does not use the subtoken tokenizer to generate extra subtoken nodes and edges. We call it **PGNN-EK without subtoken**. This variant can be used to show the importance of subtokens in addressing the OOV problem. To show the advantage of the partitioning strategy, we propose a variant **GNN-EK** that discards the partitioning step. Finally, we consider a variant that feeds the raw code into the pre-trained CodeBERT without transforming it with external knowledge. We call this variant **PGNN-CodeBERT**.

Table 5 summarizes the ablation study results. From the table, we see that: 1) S-AST contains richer information than AST and can serve as an effective code intermediate representation in program understanding. The introduction of subtokens nodes and edges alleviates the OOV problem

---

[6] Specifically, we take the results of ASTNN and FA-AST from `https://github.com/microsoft/CodeXGLUE/tree/main/Code-Code/Clone-detection-BigCloneBench` and that of CodeBERT and PLBART from the CodeXGLUE leaderboard. Note that PLBART only reports the F1 score on BCB.

Table 5: Ablation study on PGNN-EK. We highlight the best results in bold.

Method	CSN (Smoothed BLEU-4)	TLC (Smoothed BLEU-4)	BCB (F1)	BCB-F (F1)
PGNN only	14.05	47.71	0.951	0.667
EK only	17.95	49.66	0.965	0.711
PGNN-EK with AST	17.70	48.96	0.957	0.713
PGNN-EK without subtoken	17.82	49.01	0.958	0.712
GNN-EK	18.05	49.95	0.967	0.715
PGNN-CodeBERT	18.60	50.65	0.969	0.720
PGNN-EK (Full Model)	**18.95**	**51.06**	**0.974**	**0.724**

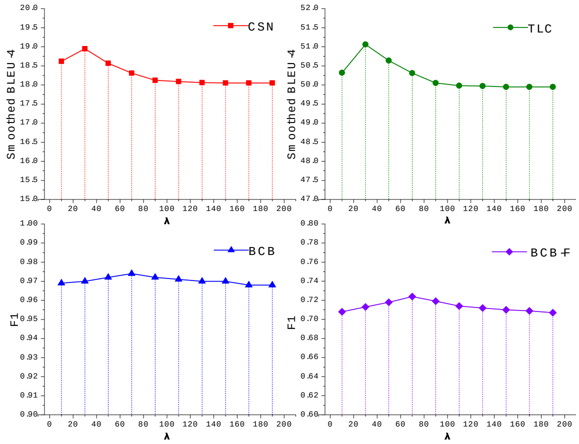

Figure 4: The influence of subgraph size on 4 datasets.

and enhances the model performance. 2) External knowledge helps boost understanding codes. In particular, code transformation with external knowledge improves the expressiveness of the raw code. 3) The full model PGNN-EK outperforms other variants on all the datasets and tasks. This indicates the importance of every main component in PGNN-EK. It further shows that leveraging code context, code structure and external knowledge as humans is helpful for program understanding.

5.5 The Influence of Subgraph Size

We end this section with a hyper-parameter sensitivity analysis. In PGNN-EK there is a key hyper-parameter λ that is used to control the size of subgraphs. Here, we investigate the sensitivity of λ. We vary the value of λ from $\{10, 30, 50, 70, 90, 110, 130, 150, 170, 190\}$, and the final prediction results of PGNN-EK on 4 datasets are shown in the Figure 4.

Table 6: The average number of nodes in S-AST

Datasets	CSN	TLC	BCB	BCB-F
S-AST size	137	140	372	348

The results indicate that 1) the model performance first increases and then drops, with the increase of the subgraph size. When the subgraph size is too small, each subgraph is a code fragment that no longer represents a code statement and thus contains less information. Further, when the subgraph is too large, each subgraph could be composed of statements that are of different semantic meanings, which thus degrades the model performance. 2) PGNN-EK performs the best at $\lambda = 30$ on CSN and TLC while it achieves the best results at $\lambda = 70$ on BCB and BCB-F. We further investigate the reason and show the average number of nodes in S-AST on the four datasets in Table 6. From the table, BCB and BCB-F contain ~ 2.5 times more nodes than that in CSN and TLC. This empirically suggests that setting λ to be about $\frac{1}{5}$ to $\frac{1}{4}$ of the average node number in S-AST could be a reasonable choice.

6 Conclusion

In this paper, we followed human understandings for programs and proposed the PGNN-EK model. To enrich the code structure information and alleviate the OOV problem, we presented the S-AST graph based on AST, which uses a subtoken tokenizer to generate subtoken nodes and edges between them. Inspired by the "divide-and-conquer" strategy, we proposed the partitioning-based graph neural network model on S-AST that employs code context and structure. To leverage the external knowledge to boost comprehension, we transformed the raw code to fuse syntactic and semantic knowledge and utilized pre-training techniques for information extraction. We performed extensive experiments to show the effectiveness of our model PGNN-EK on the code summarization and code clone detection tasks. In particular, to show the generalization ability of the model, we released a new benchmark that is more challenging.

See Algorithm 1.

B Examples of API-Description Pairs

In the experiment. we obtain $51,191$ method description pairs after preprocessing, and Table 7 gives some examples.

C Baselines Introduction

We compare our model with five representative models in code summarization task:

- CodeNN (Iyer et al., 2016) is the first method that applies deep neural networks in code summarization. It uses a classical attention-based encoder-decoder framework from Neural Machine Translation (NMT).
- NCS (Ahmad et al., 2020) applies Transformer (Vaswani et al., 2017) to model the pairwise relationship between code tokens and capture their long-term dependencies.
- Rencos (Zhang et al., 2020) proposes an attention-based encoder-decoder model and enhance it with the most similar code snippets retrieved from the training set.
- CodeBERT (Feng et al., 2020) is a bimodal pre-training model for programming and natural languages based on RoBERTa (Liu et al., 2019).
- PLBART (Ahmad et al., 2021) is a sequence-to-sequence pre-training model based on BART (Lewis et al., 2020).

In addition to the pre-training models CodeBERT and PLBART, we further compare our model with two representative model in code clone detection task:

- ASTNN (Zhang et al., 2019) proposes an AST-based neural network that splits AST into a sequence of statement trees and applies a bidirectional RNN model to produce source code representation. However, it ignores external knowledge associated with codes.
- FA-AST (Wang et al., 2020) augments original AST with explicit control and data flow edges, then introduces two different types of GNNs to detect code clones.

D Functionalities Splits in BCB and BCB-F

For BCB, the functionalities in Train/Val/Test set are:

- **Train:** Web Download, Secure Hash(MD5), Copy a File, Decompress Zip, FTP Authenticated Login, Bubble Sort, Init. SGV with Model, SGV Selection Event Handler, Create Java Project(Eclipse), SQL Update and RollBACK.
- **Val:** Same to **Train**.
- **Test:** Same to **Train**.

For BCB-F, the functionalities in Train/Val/Test set are, where the emphasis discloses the whole 10 functionalities that exist in BCB:

- **Train:** *Decompress Zip*, *Copy a File*, Get Prime Factors, File Dialog, Resize Array, Get MAC Address String, Parse CSV File, *Secure Hash(MD5)*, Send Email, Load Custom Font, *Create Java Project(Eclipse)*, Extract Matches Using Regex, Open File in Desktop Application, Connect to Database, Load File to Byte Array, Call Method Using Reflection, Take Screenshot to File, Write PDF File, Delete Folder and Contents, Copy Directory, Binary Search, Delete Folder and Contents.
- **Val:** *SQL Update and RollBACK*, *Bubble Sort*, Execute External Process, XMPP Send Message, Zip Files, Convert Date String Format, Secure Hash, GCD, *SGV Selection Event Handler*, *Init. SGV with Model*, Play Sound.
- **Test:** Shuffle Array in Place, Create Encryption Key Files, Load Custom Font, Encrypt to File, Parse XML to DOM, CRC32 File Checksum, Transpose a Matrix, Test Palindrome, *Web Download*, *FTP Authenticated Login*.

Table 7: Examples of API-Description Pairs

APIs	Descriptions
Math.abs	Returns the absolute value of an int value.
Arrays.hashcode	Returns a hash code based on the contents of the specified array.
Scanner.hasNext	Returns true if this scanner has another token in its input.
Color.getRGB	Returns the RGB value representing the color in the default sRGB ColorModel.

Algorithm 1 Partitioning S-AST

Input: A S-AST $\mathcal{T}$ with node features $\mathcal{X}$, edge indexes $\mathcal{I}$ and edge features $\mathcal{E}$

Parameter: λ, which specifies the minimum number of nodes in the subgraph

Output: Nodes features list $\mathcal{L}_x$, edge indexes list $\mathcal{L}_i$, and edge features list $\mathcal{L}_e$ of subgraphs

```
Derive a tree structure $\mathcal{T}^{'}$ by removing data flow edges and adjacent leaf edges in $\mathcal{T}$;
$nodes\_sum \leftarrow 0, nodes\_set \leftarrow \{\}$;
$nf\_list, ei\_list, ef\_list, \mathcal{L}_x, \mathcal{L}_i, \mathcal{L}_e \leftarrow \{\}$;
Obtain a subtree list $\{\mathcal{S}\}$ based on subtrees of root nodes in $\mathcal{T}^{'}$ from left to right;
for $\mathcal{S}$ in $\{\mathcal{S}\}$ do
    $n \leftarrow$ the number of nodes in $\mathcal{S}$;
    $nodes\_sum \leftarrow nodes\_sum + n$;
    Add nodes in $\mathcal{S}$ to $nodes\_set$;
    if $nodes\_sum \geq \lambda$ or $\mathcal{S}$ is the last element of $\{\mathcal{S}\}$ then
        if $\mathcal{L}_x \neq \emptyset$ then
            Add closest nodes that indicate the same variables in $\mathcal{L}_x$ to $nodes\_set$ ;
        end if
        Assign $nf\_list$, $ei\_list$, $ef\_list$ based on $nodes\_set$, $\mathcal{X}$, $\mathcal{I}$ and $\mathcal{E}$;
        Append $nf\_list, ei\_list, ef\_list$ to $\mathcal{L}_x, \mathcal{L}_i, \mathcal{L}_e$ respectively;
        $nodes\_sum \leftarrow 0$, $nodes\_set \leftarrow \{\}$;
    end if
end for
// $A[-i]$ denotes the $i$-th element from the bottom in $A$.
if size of $\mathcal{L}_x[-1] < \lambda/2$ and size of $\mathcal{L}_x > 1$ then
    Merge $\mathcal{L}_x[-1]$ and $\mathcal{L}_x[-2]$, $\mathcal{L}_i[-1]$ and $\mathcal{L}_i[-2]$, $\mathcal{L}_e[-1]$ and $\mathcal{L}_e[-2]$, respectively;
end if
return $\mathcal{L}_x, \mathcal{L}_i, \mathcal{L}_e$
```

FAVIQ: FAct Verification from Information-seeking Questions

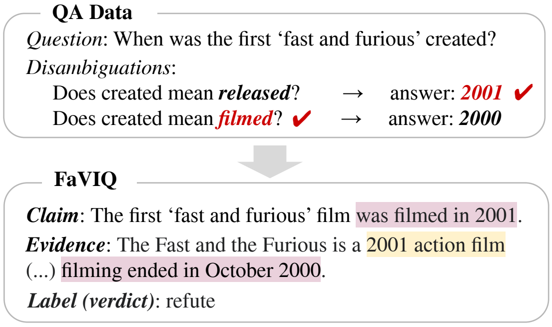
Abstract

Despite significant interest in developing general purpose fact checking models, it is challenging to construct a large-scale fact verification dataset with realistic real-world claims. Existing claims are either authored by crowdworkers, thereby introducing subtle biases that are difficult to control for, or manually verified by professional fact checkers, causing them to be expensive and limited in scale. In this paper, we construct a large-scale challenging fact verification dataset called FAVIQ, consisting of 188k claims derived from an existing corpus of ambiguous information-seeking questions. The ambiguities in the questions enable automatically constructing true and false claims that reflect user confusions (e.g., the year of the movie being filmed vs. being released). Claims in FAVIQ are verified to be natural, contain little lexical bias, and require a complete understanding of the evidence for verification. Our experiments show that the state-of-the-art models are far from solving our new task. Moreover, training on our data helps in professional fact-checking, outperforming models trained on the widely used dataset FEVER or in-domain data by up to 17% absolute. Altogether, our data will serve as a challenging benchmark for natural language understanding and support future progress in professional fact checking.[1]

1 Introduction

Fact verification, the task of verifying the factuality of the natural language claim, is an important NLP application (Cohen et al., 2011) and has also been used to evaluate the amount of external knowledge a model has learned (Petroni et al., 2021). However, it is challenging to construct fact verification data with claims that contain realistic and implicit misinformation. Crowdsourced claims from prior work such as FEVER (Thorne et al., 2018a) are written with minimal edits to reference sentences, leading to strong lexical biases such as the overuse of explicit negation and unrealistic misinformation that is less likely to occur in real life (Schuster et al., 2019). On the other hand, data constructed by professional fact-checkers are expensive and are typically small-scale (Hanselowski et al., 2019).



QA Data

Question: When was the first ‘fast and furious’ created?

Disambiguations:

Does created mean ***released***? → answer: ***2001*** ✔

Does created mean ***filmed***? ✔ → answer: ***2000***

FaVIQ

Claim: The first ‘fast and furious’ film was filmed in 2001.

Evidence: The Fast and the Furious is a 2001 action film (...) filming ended in October 2000.

Label (verdict): refute

Figure 1: An example of a `refute` claim on FAVIQ, constructed using ambiguity in the information-seeking question, e.g., through a crossover of the year of the film *being released* and *being filmed*.

In this paper, we show it is possible to use information-seeking questions (Kwiatkowski et al., 2019) and their ambiguities (Min et al., 2020) to construct a large-scale, challenging, and realistic fact verification dataset. Information-seeking questions are inherently ambiguous because users do not know the answers to the questions they are posing. For example, in Figure 1, the question is ambiguous because the filming of the movie and the release of the movie can both be seen as the creation time.

We introduce a new dataset **FAVIQ—FAct Verification derived from Information-seeking Questions**, which uses such ambiguities to generate challenging fact verification problems. For instance, the claim in Figure 1 requires the model to identify that the movie released in 2001 is in fact filmed in 2000 and to return `refute`. Like this, claims generated through the crossover of the disambiguation of information-seeking questions

---

are likely to contain misinformation that real users are easily confused with. We automatically generate such claims by composing valid and invalid question-answer pairs and transforming them into textual claims using a neural model. The data is further augmented by claims from regular question-answer annotations.

In total, FAVIQ consists of 188k claims. We manually verified a subset of claims to ensure that they are as natural as human-written claims. Our analysis shows that the claims have significantly lower lexical bias than existing crowdsourced claims; claims involve diverse types of distinct entities, events, or properties that are semantically close, being more realistic and harder to verify without a complete understanding of the evidence text.

Our experiments show that a model with no background knowledge performs only slightly better than random guessing, and the state-of-the-art model achieves an accuracy of 65%, leaving significant room for improvement. Furthermore, training on FAVIQ improves the accuracy of verification of claims written by professional fact checkers, outperforming models trained on the target data only or pretrained on FEVER by up to 17% absolute. Together, our experiments demonstrate that FAVIQ is a challenging benchmark as well as a useful resource for professional fact checking.

To summarize, our contributions are three-fold:

1. We introduce FAVIQ, a fact verification dataset consisting of 188k claims. By leveraging information-seeking questions and their natural ambiguities, our claims require the identification of entities, events, or properties that are semantically close but distinct, making the fact verification problem very challenging and realistic.
2. Our experiments show that the state-of-the-art fact verification models are far from solving FAVIQ, indicating significant room for improvement.
3. Training on FAVIQ significantly improves the verification of claims written by professional fact checkers, indicating that FAVIQ can support progress in professional fact checking.

2 Related Work

Fact verification Fact verification is crucial for real-world applications (Cohen et al., 2011) and as a benchmark to evaluate the knowledge in a model (Petroni et al., 2021).

One line of work has studied professional fact checking, dealing with claims collected by professional fact checkers in specific domains (Vlachos and Riedel, 2014; Ferreira and Vlachos, 2016; Augenstein et al., 2019; Hanselowski et al., 2019). While such data contains realistic claims that have occurred in the real world, it is expensive to construct as it requires labor from professional fact checkers. Moreover, it is less suitable as a benchmark due to lack of a standard evidence corpus such as Wikipedia[2] and ambiguities in labels.[3]

Other fact verification datasets are collected through crowdsourcing (e.g., FEVER (Thorne et al., 2018a) and its variants (Thorne et al., 2018b; Thorne and Vlachos, 2019)) by altering a word or negating the reference text to intentionally make true or false claims. This process leads to large-scale datasets but with strong artifacts and unrealistic claims (Schuster et al., 2019; Thorne and Vlachos, 2019; Eisenschlos et al., 2021). Consequently, a trivial claim-only baseline with no evidence achieves near 80% (Petroni et al. (2021), verified in Section 4.1). While more recent work proposes new crowdsourcing methods that alleviate artifacts (Schuster et al., 2021; Eisenschlos et al., 2021), their claims are still written given particular evidence text, being vulnerable to subtle lexical biases that can be hard to explicitly measure.

We construct a fact verification dataset from highly ambiguous information-seeking questions. Our claims have significantly less lexical bias than other crowdsourced ones (Figure 3), contain realistic misinformation that people are likely to be confused about (Table 4), and are challenging to current state-of-the-art models (Section 4.1). Moreover, training a model on our data improves professional fact checking (Section 4.2).

QA to Verification Task Prior work has also used QA data to create entailment or fact verification benchmarks. Most make use of synthetic or annotated questions (Demszky et al., 2018; Jiang et al., 2020; Pan et al., 2021; Chen et al., 2021)[4]

---

[2] For this reason, prior work on professional fact checking assumes gold evidence document.

[3] Most claims fall into the `mixture` label, rather than `support` or `refute`.

[4] Annotated questions are simulated by crowdworkers given the evidence text and the answer, having largely different distributions from information-seeking questions (Lee et al., 2019; Gardner et al., 2019).

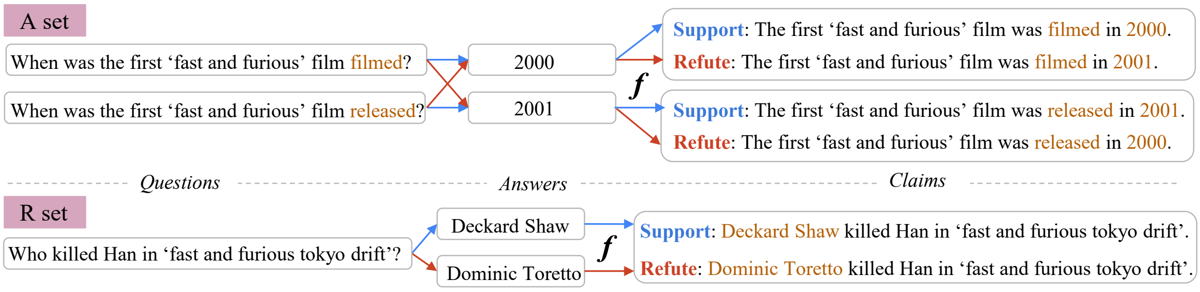

Figure 2: Overview of the data creation process. The data consits of two sets (A and R). For A, we use the disambiguated question-answer pairs and generate `support` and `refute` claims from matching pairs (*filmed–2000, released–2001*) and crossover pairs (*filmed–2001, released–2000*), respectively. For R, we use the reference answer (*Deckard Shaw*) and the incorrect prediction from DPR (*Dominic Toretto*) to generate `support` and `refute` claims, respectively. f is a T5 model that transforms question-answer pairs to claims (Section 3.1.3).

while we use questions posed by real users to reflect confusions that naturally occur while seeking information. Thorne et al. (2021) use information-seeking questions, by converting yes/no questions to `support`/`refute` claims, but at a small scale and with unambiguous questions. Instead, our work uses large-scale information-seeking questions (with no restriction in answers) to claims. We are also unique in using highly ambiguous QA pairs to obtain claims that are more challenging to verify and have significantly fewer lexical cues (quantitative comparisons in Section 3.3).

3 Data

3.1 Data Construction

We construct **FAVIQ**—**FA**ct **V**erification derived from **I**nformation-seeking **Q**uestions, where the model is given a natural language claim and predicts `support` or `refute` with respect to the English Wikipedia. The key idea to construct the data is to gather a set of valid and invalid question-answer pairs (Section 3.1.2) from annotations of information-seeking questions and their ambiguities (Section 3.1.1), and then convert each question-answer pair (q, a) to a claim (Section 3.1.3). Figure 2 presents an overview of this process.

3.1.1 Data Sources

We use QA data from Natural Questions (NQ, Kwiatkowski et al. (2019)) and AmbigQA (Min et al., 2020). NQ is a large-scale dataset consisting of the English information-seeking questions mined from Google search queries. AmbigQA provides disambiguated question-answer pairs for NQ questions, thereby highlighting the ambiguity that is inherent in information-seeking questions. Given an ambiguous question, it provides a set of multiple distinct answers, each paired with a new disambiguated question that uniquely has that answer.

3.1.2 Composing Valid and Invalid QA Pairs

FAVIQ is constructed from ambiguous questions and their disambiguation (*A* set) and is further augmented by using unambiguous question-answer pairs (*R* set).

From ambiguous questions (*A* set) We use the data consisting of a set of $(q, \{q_1, a_1\}, \{q_2, a_2\})$, where q is an information seeking question that has a_1, a_2 as multiple distinct answers.[5] q_1 and q_2 are disambiguated questions for the answers a_1 and a_2, i.e., q_1 has a_1 as a valid answer and a_2 as an invalid answer. We use (q_1, a_1) and (q_2, a_2) as valid question-answer pairs, and (q_1, a_2) and (q_2, a_1) as invalid question-answer pairs.

This data is particularly well suited to fact checking because individual examples require identification of entities, events, or properties that are semantically close but distinct: the fact that a user asked an ambiguous question q without realizing the difference between (q_1, a_1) and (q_2, a_2) indicates that the distinction is non-trivial and is hard to notice without sufficient background knowledge about the topic of the question.

From regular questions (*R* set) We use the QA data consisting of a set of (q, a): an information-seeking question q and its answer a. We then obtain an invalid answer to q, denoted as a_{neg}, from an off-the-shelf QA model for which we use the model from Karpukhin et al. (2020)—DPR followed by a span extraction model. We choose a_{neg}

---

[5] If q has more than two distinct answers, we sample two. This is to construct a reasonable number of claims per q.

		Total	Support	Refute
Train	A	17,008	8,504	8,504
	R	140,977	70,131	70,846
Dev	A	4,260	2,130	2,130
	R	15,566	7,739	7,827
Test	A	4,688	2,344	2,344
	R	5,877	2,922	2,955

Table 1: FAVIQ statistics. *A* includes claims derived from ambiguous questions, while *R* includes claims from regular question-answer pairs.

with heuristics to obtain hard negatives but not the false negative; details provided in Appendix A. We use (q, a) and (q, a_{neg}) as a valid and an invalid question-answer pair, respectively.

We can think of (q, a_{neg}) as a *hard* negative pair chosen adversarially from the QA model.[6] This data can be obtained on a much larger scale than the A set because annotating a single valid answer is easier than annotating disambiguations.

3.1.3 Transforming QA pairs to Claims

We transform question-answer pairs to claims by training a neural model which maps (q, a) to a claim that is `support` *if and only if* a is a valid answer to q, otherwise `refute`. We first manually convert 250 valid and invalid question-answer pairs obtained through Section 3.1.2 to claims. We then train a T5-3B model (Raffel et al., 2020), using 150 claims for training and 100 claims for validation. The model is additionally pretrained on data from Demszky et al. (2018), see Appendix A.

3.1.4 Obtaining silver evidence passages

We obtain silver evidence passages for FAVIQ by (1) taking the question that was the source of the claim during the data creation (either a user question from NQ or a disambiguated question from AmbigQA), (2) using it as a query for TF-IDF over the English Wikipedia, and (3) taking the top passage that contains the answer. Based on our manual verification on 100 random samples, the precision of the silver evidence passages is 70%. We provide silver evidence passages primarily for supporting training of the model, and do not explicitly evaluate passage prediction; more discussion in Appendix A. Future work may use human annotations on top of our silver evidence passages in order to further improve the quality, or evaluate passage prediction.

Data	Size	Length of the claims			
		Avg	Q1	Q2	Q3
Professional claims					
SNOPES	16k	12.4	10	11	14
SCIFACT	1k	11.5	9	11	13
Crowdsourced claims					
FEVER	185k	9.3	7	9	11
FM2	13k	13.9	9	13	16.3
BOOLQ-FV	10k	8.7	8	8	9
FAVIQ	**188k**	**12.0**	**9**	**10.5**	**13.5**

Table 2: Statistics of a variety of fact verification datasets. *Avg* and *Q1–3* are the average and quantiles of the length of the claims based on whitespace tokenization on the validation data; for FAVIQ, we report the macro-average of the A set and the R set. dataname is as large as FEVER and has a distribution of claim lengths that is much closer to that of professional fact checking datasets (SNOPES and SCIFACT).

3.2 Data Validation

In order to evaluate the quality of claims and labels, three native English speakers were given 300 random samples from FAVIQ, and were asked to: (1) verify whether the claim is as natural as a human-written claim, with three possible ratings (perfect, minor issues but comprehensible, incomprehensible), and (2) predict the label of the claim (`support` or `refute`). Validators were allowed to use search engines, and were encouraged to use the English Wikipedia as a primary source.

Validators found 80.7% of the A set and 89.3% of the R set to be natural, and 0% to be incomprehensible. The rest have minor grammatical errors or typos, e.g., missing "the". In most cases the errors actually come from the original NQ questions which were human-authored, indicating that these grammatical errors and typos occur in real life. Lastly, validators achieved an accuracy of 95.0% (92.7% of A and 97.3% of R) when evaluated against gold labels in the data—this indicates high-quality of the data and high human performance. This accuracy level is slightly higher than that of FEVER (91.2%).

3.3 Data Analysis

Data statistics for FAVIQ are listed in Table 1. It has 188k claims in total, with balanced `support` and `refute` labels. We present quantitative and qualitative analyses showing that claims on FAVIQ contain much less lexical bias than other crowdsourced datasets and include misinformation that is realistic and harder to identify.

---

[6] It is possible that the R set contains bias derived from the use of DPR. We thus consider the R set as a source for data augmentation, while A provides the main data.

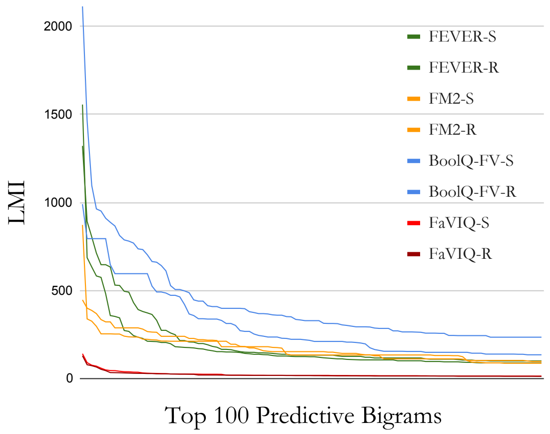

Figure 3: Plot of LMI scores of top 100 predictive bigrams for FEVER, FM2, BoolQ-FV and FaVIQ (macro-averaged over the A set and the R set). `S` and `R` denotes `support` and `refute`, respectively. BoolQ-FV indicates data from Thorne et al. (2021) that uses BoolQ. LMI scores of FaVIQ are significantly lower than those of FEVER and FM2, indicating significantly less lexical overlap.

Comparison of size and claim length Table 2 compares statistics of a variety of fact verification datasets: Snopes (Hanselowski et al., 2019), SciFact (Wadden et al., 2020), FEVER (Thorne et al., 2018a), FM2 (Eisenschlos et al., 2021), BoolQ-FV (Thorne et al., 2021) and FaVIQ.

FaVIQ is as large-scale as FEVER, while its distributions of claim length is much closer to claims authored by professional fact checkers (Snopes and SciFact). FM2 is smaller scale, due to difficulty in scaling multi-player games used for data construction, and has claims that are slightly longer than professional claims, likely because they are intentionally written to be difficult. BoolQ-FV is smaller, likely due to relative difficulties in collecting naturally-occurring yes/no questions.

Lexical cues in claims We further analyze lexical cues in the claims on FEVER, FM2, BoolQ-FV and FaVIQ by measuring local mutual information (LMI; Schuster et al. (2019); Eisenschlos et al. (2021)). LMI measures whether the given bigram correlates with a particular label. More specifically, LMI is defined as:

$$LMI(w,c) = P(w,c)\ log \frac{P(w,c)}{P(w) \cdot P(c)},$$

where w is a bigram, c is a label, and $P(\cdot)$ are estimated by counting (Schuster et al., 2019).

Dataset	Top Bigrams by LMI
FEVER-`S`	is a, a film, of the, is an, in the, in a
FEVER-`R`	is only, only a, incapable of, is not, was only, is incapable
A set-`S`	on the, was the, the date, date of, in episode, is what
A set-`R`	of the, the country, at the, the episode, started in, placed at
R set-`S`	out on, on october, on june, released on, be 18, on august
R set-`R`	out in, on september, was 2015, of the, is the, released in

Table 3: Top bigrams with the highest LMI for FEVER and FaVIQ. `S` and `R` denotes `support` and `refute` respectively. Highlighted bigrams indicate negative expressions, e.g., "only", "incapable" or "not".

The distributions of the LMI scores for the top-100 bigrams are shown in Figure 3. The LMI scores of FaVIQ are significantly lower than those of FEVER, FM2, and BoolQ-FV, indicating that FaVIQ contains significantly less lexical bias.

Tables 3 shows the top six bigrams with the highest LMI scores for FEVER and FaVIQ. As highlighted, all of the top bigrams in `refute` claims of FEVER contain negative expressions, e.g., "is only", "incapable of", "did not". In contrast, the top bigrams from FaVIQ do not include obvious negations and mostly overlap across different labels, strongly suggesting the task has fewer lexical cues. Although there are still top bigrams from FaVIQ causing bias (e.g., related to time, such as 'on October'), their LMI values are significantly lower compared those from other datasets.

Qualitative analysis of the `refute` claims We also analyzed 30 randomly sampled `refute` claims from FaVIQ and FEVER respectively. We categorized the cause of misinformation as detailed in Appendix B, and show three most common categories for each dataset as a summary in Table 4.

On FaVIQ, 60% of the claims involve entities, events or properties that are semantically close, but still distinct. For example, they are specified with conjunctions (e.g., "was foreign minister" and "signed the treaty of versailles from germany"), or share key attributes (e.g., films with the same title). This means that relying on lexical overlap or partially understanding the evidence text would lead to incorrect predictions; one must read the full evidence text to realize that the claim is false. Furthermore, 16.7% involve events, e.g., from filing for bankruptcy for the first time to completely ceasing operations (Table 4). This requires full understanding of the underlying event and tracking of state changes (Das et al., 2019; Amini et al., 2020).

The same analysis on FEVER confirms the findings from Schuster et al. (2019); Eisenschlos et al.

Conjunctions (33.3%)
C: Johannes bell was the foreign minister that signed the treaty of versailles from germany. / *E*: Johannes bell served as Minister of Colonial Affairs ... He was one of the two German representatives who signed the Treaty of Versailles.
Shared attributes (26.7%)
C: Judi bowker played andromeda in the 2012 remake of the 1981 film clash of the titans called wrath of the titans. *E*: Judi bowker ... Clash of the Titans (1981).
Procedural event (16.7%)
C: Mccrory's originally filed for bankruptcy on february 2002. / *E*: McCrory Stores ... by 1992 it filed for bankruptcy. ... In February 2002 the company ceased operation.

Negation (30.0%)
C: Southpaw hasn't been released yet. *E*: Southpaw is an American sports drama film released on July 24, 2015.
Cannot find potential cause (20.0%)
C: Mutiny on the Bounty is Dutch. *E*: Mutiny on the Bounty is a 1962 American historical drama film.
Antonym (13.3%)
C: Athletics lost the world series in 1989. *E*: The 1989 World Series ... with the Athletics sweeping the Giants.

Table 4: Three most common categories based on 30 `refute` claims randomly sampled from the validation set, for FaVIQ (top) and FEVER (bottom) respectively. Full statistics and examples in Appendix B. *C* and *E* indicate the claim and evidence text, respectively. `Refute` claims in FaVIQ are more challenging, not containing explicit negations or antonyms.

(2021); many of claims contain explicit negations (30%) and antonyms (13%), with misinformation that is less likely to occur in the real world (20%).[7]

4 Experiments

We first evaluate state-of-the-art fact verification models on FaVIQ in order to establish baseline performance levels (Section 4.1). We then conduct experiments on professional fact-checking datasets to measure the improvements from training on FaVIQ (Section 4.2).

4.1 Baseline Experiments on FaVIQ

4.1.1 Models

We experiment with two settings: a zero-shot setup where models are trained on FEVER, and a standard setup where models are trained on FaVIQ. For FEVER, we use the KILT (Petroni et al., 2021) version following prior work; we randomly split the official validation set into equally sized validation and test sets, as the official test set is hidden.

All models are based on BART (Lewis et al., 2020), a pretrained sequence-to-sequence model which we train to generate either `support` or `refute`. We describe three different variants which differ in their input, along with their accuracy on FEVER by our own experiments.

Claim only BART takes a claim as the only input. Although this is a trivial baseline, it achieves an accuracy of 79% on FEVER.

TF-IDF + BART takes a concatenation of a claim and k passages retrieved by TF-IDF from Chen et al. (2017). It achieves 87% on FEVER. We choose TF-IDF over other sparse retrieval methods like BM25 (Robertson and Zaragoza, 2009) because Petroni et al. (2021) report that TF-IDF outperforms BM25 on FEVER.

DPR + BART takes a concatenation of a claim and k passages retrieved by DPR (Karpukhin et al., 2020), a dual encoder based model. It is the state-of-the-art on FEVER based on Petroni et al. (2021) and Maillard et al. (2021), achieving an accuracy of 90%.

Implementation details We use the English Wikipedia from 08/01/2019 following KILT (Petroni et al., 2021). We take the plain text and lists provided by KILT and create a collection of passages where each passage has up to 100 tokens. This results in 26M passages. We set the number of input passages k to 3, following previous work (Petroni et al., 2021; Maillard et al., 2021). Baselines on FaVIQ are jointly trained on the A set and the R set.

Training DPR requires a positive and a negative passage—a passage that supports and does not support the verdict, respectively. We use the silver evidence passage associated with FaVIQ as a positive, and the top TF-IDF passage that is not the silver evidence passages as a negative. More training details are in Appendix C. Experiments are reproducible from `https://github.com/faviq/faviq/tree/main/codes`.

4.1.2 Results

Table 5 reports results on FaVIQ. The overall accuracy of the baselines is low, despite their high performance on FEVER. The zero-shot performance is barely better than random guessing, indicating that the model trained on FEVER is not able to generalize to our more challenging data. When the baselines are trained on FaVIQ, the best model

---

[7] For instance, consider the claim "Mutiny on the Bounty is Dutch" in Table 4. There is no Dutch producer, director, writer, actors, or actress in the film—we were not able to find a potential reason that one would believe that the film is Dutch.

Model	Dev		Test	
	A	R	A	R
Training on FEVER *(zero-shot)*				
Clain only BART	51.6	51.0	51.9	51.1
TF-IDF + BART	55.8	58.5	54.4	57.2
DPR + BART	56.0	62.3	55.7	61.2
Training on FAVIQ				
Claim only BART	51.0	59.5	51.3	59.4
TF-IDF + BART	65.1	74.2	63.0	71.2
DPR + BART	**66.9**	**76.8**	**64.9**	**74.6**

Table 5: Fact verification accuracy on FAVIQ. DPR + BART achieves the best accuracy; however, there is overall significant room for improvement.

achieves an accuracy of 65% on the A set, indicating that existing state-of-the-art models do not solve our benchmark.[8]

Impact of retrieval The performance of the claim only baseline that does not use retrieval is almost random on FAVIQ, while achieving nearly 80% accuracy on FEVER. This result suggests significantly less bias in the claims, and the relative importance of using background knowledge to solve the task. When retrieval is used, DPR outperforms TF-IDF, consistent with the finding from Petroni et al. (2021).

A set vs. R set The performance of the models on the R set is consistently higher than that on the A set by a large margin, implying that claims based on ambiguity arisen from real users are more challenging to verify than claims generated from regular question-answer pairs. This indicates clearer contrast to prior work that converts regular QA data to declarative sentences (Demszky et al., 2018; Pan et al., 2021).

Error Analysis We randomly sample 50 error cases from DPR + BART on the A set of FAVIQ and categorize them, as shown in Table 6.

- *Retrieval error* is the most frequent type of errors. DPR typically retrieves a passage with the correct topic (e.g., about "Lie to Me") but that is missing more specific information (e.g., the end date). We think the claim having less lexical overlap with the evidence text leads to low recall@k of the retrieval model ($k = 3$).
- 28% of error cases involve *events*. In particular, 14% involve procedural events, and 6% involve distinct events that share similar properties but differ in location or time frame.
- In 18% of error cases, retrieved evidence is *valid but not notably explicit*, which is naturally the case for the claims occurring in real life. FAVIQ has this property likely because it is derived from questions that are gathered independently from the evidence text, unlike prior work (Thorne et al., 2018a; Schuster et al., 2021; Eisenschlos et al., 2021) with claims written given the evidence text.
- 16% of the failure cases require *multi-hop* inference over the evidence. Claims in this category usually involve procedural events or compositions (e.g. "is Seth Curry's brother" and "played for Davidson in college"). This indicates that we can construct a substantial portion of claims requiring multi-hop inference without having to make data that artificially encourages such reasoning (Yang et al., 2018; Jiang et al., 2020).
- Finally, 10% of the errors were made due to a subtle mismatch in *properties*, e.g., in the example in Figure 6, the model makes a decision based on "required minimum number" rather than "exact number" of a particular brand.

4.2 Professional Fact Checking Experiments

We use two professional fact-checking datasets.

SNOPES (Hanselowski et al., 2019) consists of 6,422 claims, authored and labeled by professional fact-checkers, gathered from the Snopes website.[9] We use the official data split.

SCIFACT (Wadden et al., 2020) consists of 1,109 claims based on scientific papers, annotated by domain experts. As the official test set is hidden, we use the official validation set as the test set, and separate the subset of the training data as the validation set to be an equal size as the test set.

For both datasets, we merge `not enough info` (`NEI`) to `refute`, following prior work that converts the 3-way classification to the 2-way classification (Wang et al., 2019; Sathe et al., 2020; Petroni et al., 2021).

4.2.1 Models

As in Section 4, all models are based on BART which is given a concatenation of the claim and

---

[8] We additionally show and discuss the model trained on FAVIQ and tested on FEVER in Appendix D. They achieve non-trivial performance (67%) although being worse than FEVER-trained models that exploit bias in the data.

[9] `https://www.snopes.com`

Category	%	Example
Retrieval error	38	*C*: The american show lie to me ended on january 31, 2011. (Support; Refute) *E*: Lie to Me ... The second season premiered on September 28, 2009 ... The third season, which had its premiere moved forward to October 4, 2010.
Events	28	*C*: The bellagio in las vegas opened on may, 1996. (Refute; Support) *E*: Construction on the Bellagio began in May 1996. ... Bellagio opened on October 15, 1998.
Evidence not explicit	18	*C*: The official order to start building the great wall of china was in 221 bc. (Support; Refute) *E*: The Great Wall of China had been built since the Qin dynasty (221–207 BC).
Multi-hop	16	*C*: Seth curry's brother played for davidson in college. (Support; Refute) *E*: Stephen Curry (...) older brother of current NBA player Seth ... He ultimately chose to attend Davidson College, who had aggressively recruited him from the tenth grade.
Properties	10	*C*: The number of cigarettes in a pack of 'export as' brand packs in the usa is 20. (Refute; Support) *E*: In the United States, the quantity of cigarettes in a pack must be at least 20. Certain brands, such as Export As, come in packs of 25.
Annotation error	4	*C*: The place winston moved to in still game is finport. (Refute; Support)

Table 6: Error analysis on 50 samples of the A set of FAVIQ validation data. *C* and *E* indicate the claim and retrieved evidence passages from DPR, respectively. Gold and blue indicate gold label and prediction by the model, respectively. The total exceeds 100% as one example may fall into multiple categories.

the evidence text and is trained to generate either `support` or `refute`. For SNOPES, the evidence text is given in the original data. For SCIFACT, the evidence text is retrieved by TF-IDF over the corpus of abstracts from scientific papers, provided in the original data. We use TF-IDF over DPR because we found DPR works poorly when the training data is very small.

We consider two settings. In the first setting, we assume the target training data is unavailable and compare the model trained on FEVER and FAVIQ in a zero-shot setup. In the second setting, we allow training on the target data and compare the model trained on the target data only and the model with the transfer learning—pretrained on either FEVER or FAVIQ and finetuned on the target data.

To explore models pretrained on `NEI` labels, we add a baseline that is trained on a union of the KILT version of FEVER and `NEI` data from the original FEVER from Thorne et al. (2018a). For FAVIQ, we also conduct an ablation that includes the R set only or the A set only.

Implementation details When using TF-IDF for SCIFACT, we use a sentence as a retrieval unit, and retrieve the top 10 sentences, which average length approximates that of 3 passages from Wikipedia. When using the model trained on either FEVER or FAVIQ, we use DPR + BART by default, which gives the best result in Section 4.1. As an exception, we use TF-IDF + BART on SCIFACT for a more direct comparison with the model trained on the target data only that uses TF-IDF.

When the models trained on FEVER or FAVIQ are used for professional fact checking, we find models are poorly calibrated, likely due to a domain shift, as also observed by Kamath et al. (2020) and Desai and Durrett (2020). We therefore use a simplified version of Platt scaling, a post-hoc calibration method (Platt et al., 1999; Guo et al., 2017; Zhao et al., 2021). Given normalized probabilities of `support` and `refute`, denoted as p_{s} and p_{r}, modified probabilities p'_{s} and p'_{r} are obtained via:

$$\begin{bmatrix} p'_{\mathrm{s}} \\ p'_{\mathrm{r}} \end{bmatrix} = \mathrm{Softmax}\left(\begin{bmatrix} p_{\mathrm{s}} + \gamma \\ p_{\mathrm{r}} \end{bmatrix}\right),$$

where $-1 < \gamma < 1$ is a hyperparameter tuned on the validation set.

4.2.2 Results

Table 7 reports accuracy on professional fact-checking datasets, SNOPES and SCIFACT.

Impact of transfer learning We find that transfer learning is effective—pretraining on large, crowdsourced datasets (either FEVER or FAVIQ) and finetuning on the target datasets always helps. Improvements are especially significant on SCIFACT, likely because its data size is smaller.

Using the target data is still important—models finetuned on the target data outperform zero-shot models by up to 20%. This indicates that crowdsourced data cannot completely replace professional fact checking data, but transfer learning from crowdsourced data leads to significantly better professional fact checking performance.

Training	SNOPES	SCIFACT
Majority only	60.1	58.7
No target data (zero-shot)		
FEVER	61.6	70.0
FEVER w/ `NEI`	63.4	73.0
FAVIQ	**68.2**	**74.7**
FAVIQ w/o A set	63.1	73.3
FAVIQ w/o R set	66.3	68.7
Target data available		
Target only	80.6	62.0
FEVER→target	80.6	76.7
FEVER w/ `NEI`→target	81.6	77.0
FAVIQ→target	**82.2**	**79.3**
FAVIQ w/o A set→target	81.6	78.3
FAVIQ w/o R set→target	81.7	76.7

Table 7: Accuracy on the test set of professional fact-checking datasets. Training on FAVIQ significantly improves the accuracy on SNOPES and SCIFACT, both in the zero-shot setting and in the transfer learning setting.

FAVIQ vs. FEVER Models that are trained on FAVIQ consistently outperform models trained on FEVER, both with and without the target data, by up to 4.8% absolute. This demonstrates that FAVIQ is a more effective resource than FEVER for professional fact-checking.

The model on FEVER is more competitive when `NEI` data is included, by up to 3% absolute. While the models on FAVIQ outperform models on FEVER even without `NEI` data, future work can possibly create `NEI` data in FAVIQ for further improvement.

Impact of the A set in FAVIQ The performance of the models that use FAVIQ substantially degrades when the A set is excluded. Moreover, models trained on the A set (without R set) perform moderately well despite its small scale, e.g., on SNOPES, achieving the second best performance following the model trained on the full FAVIQ. This demonstrates the importance of the A set created based on ambiguity in questions.

SNOPES benefits more from the A set than the R set, while SCIFACT benefits more from the R set than the A set. This is likely because SCIFACT is much smaller-scale (1k claims) and thus benefits more from the larger data like the R set. This suggests that having both the R set and the A set is important for performance.

5 Conclusion & Future Work

We introduced FAVIQ, a new fact verification dataset derived from ambiguous information-seeking questions. We incorporate facts that real users were unaware of when posing the question, leading to false claims that are more realistic and challenging to identify without fully understanding the context. Our extensive analysis shows that our data contains significantly less lexical bias than previous fact checking datasets, and include `refute` claims that are challenging and realistic. Our experiments showed that the state-of-the-art models are far from solving FAVIQ, and models trained on FAVIQ lead to improvements in professional fact checking. Altogether, we believe FAVIQ will serve as a challenging benchmark as well as support future progress in professional fact-checking.

We suggest future work to improve the FAVIQ model with respect to our analysis of the model prediction in Section 4.1.2, such as improving retrieval, modeling multi-hop inference, and better distinctions between entities, events and properties. Moreover, future work may investigate using other aspects of information-seeking questions that reflect facts that users are unaware of or easily confused with. For example, one can incorporate false presuppositions in questions that arise when users have limited background knowledge (Kim et al., 2021). As another example, one can explore generating `NEI` claims by leveraging unanswerable information-seeking questions. Furthermore, FAVIQ can potentially be a challenging benchmark for the claim correction, a task recently studied by Thorne and Vlachos (2021) that requires a model to correct the `refute` claims.

A Details in Data Construction

Details of obtaining a_{neg} We obtain an invalid answer to the question, denoted as a_{neg}, using an off-the-shelf QA model, for which we use DPR followed by a span extractor (Karpukhin et al., 2020).

The most naive way to obtain a_{neg} is to take the highest scored prediction that is not equal to a. We however found such prediction is likely to be a valid answer to q, either because it is semantically the same as a, or because the ambiguity in the question leads to multiple distinct valid answers. We therefore use two heuristics that we find greatly reduce such false negatives. First, instead of taking the top incorrect prediction, we obtain the top k predictions $p_1...p_k$ from the model and randomly sample one from $\{p_1...p_k\} \setminus \{a\}$. We use $k = 50$.

Although this is not a fundamental solution to remove false negatives, it significantly alleviates the problem, drastically dropping the portion of false negatives from 14% to 2% based on our manual verification on 50 random samples. Second, we train a neural model that is given a pair of the text and classifies whether they are semantically equivalent or not. This model is based on T5-large, trained and validated respectively on 150 and 100 pairs of (a, p_i) $(i = 1...k)$ which we manually label. We then exclude the predictions in $\{p_1...p_k\}$ which are classified as semantically equivalent to a by the classifier.

QA-to-claim converter We use a pretrained sequence-to-sequence model trained on a small number of our own annotations. We first manually write 250 claims given valid or invalid question-answer pairs. We then train a T5-3B model (Raffel et al., 2020), using 150 claims for training and 100 claims for validation. Each question-answer pair is fed into T5 with special tokens `question:` and `answer:`, respectively.

When training, we evaluate on the validation data every epoch and stop training when the validation accuracy does not increase for ten epochs. The accuracy is measured by the exact match score of the generated and the reference text after normalization, which we found to correlate well with the quality of the generated claims. The final model we train achieves 83% on the validation data. At inference time, we filter claims that do not contain the answer string, which may happen when the question is overly specific.

Why don't we evaluate evidence prediction? Unlike FEVER (Thorne et al., 2018a), which includes evidence prediction as part of the task, our paper does not report the evidence prediction performance and mainly reports the classification accuracy. There are three reasons for this change:

1. As claims on FAVIQ were written independent from any reference text, gold evidence text must be gathered through a separate process, which greatly increases the cost. This is different from other annotated fact checking datasets where a crowdworker wrote a claim based on the reference text and therefore the same reference text can be considered as gold evidence.
2. Finding gold evidence text is an inherently incomplete process; no human can get close to, or even measure the upperbound. Therefore, even after exhaustive human annotation, evaluation against annotated evidence leads to significant amount of false negatives. For example, when manually evaluating the top negatives of TF-IDF on 50 random samples from FEVER, 42% are false negatives.
3. Including evidence prediction as part of evaluation significantly restricts the approach models can take. For instance, one may choose not to use the text corpus provided in the dataset (e.g., Wikipedia), and decide to use other sources such as structured data (e.g. knowledge bases) or implicit knowledge stored in large neural models.

Nonetheless, as described in Section 3.1.4, we still provide the silver evidence passages which is useful to train a model, e.g., DPR, and supports future work to evaluate the evidence prediction accuracy.

B Analysis of `refute` Claims

We randomly sample 30 `refute` claims from FAVIQ and FEVER, respectively, and categorize the cause of the misinformation, as shown in Table 8. See Section 3.3 for discussion.

C Details of Experiments

DPR training for FEVER As FEVER provides the annotated evidence passage, we use it as a positive training example. We obtain a negative by querying the claim to TF-IDF and taking the passage that is not the positive passage and has the second highest score. We initially considered using the negative with the highest score, but found that

Category	% FaVIQ	% FEVER	Example
Negation	0	30.0	*C*: Southpaw hasn't been released yet. (from FEVER) *E*: Southpaw is a 2015 American sports drama film ... released on July 24, 2015.
Antonym	3.3	13.3	*C*: Athletics lost the world series in 1989. *E*: The 1989 World Series was ... with the Athletics sweeping the Giants in four games.
Requires reading across conjunctions	33.3	6.6	*C*: Johannes bell was the foreign minister that signed the treaty of versailles from germany. / *E*: Johannes bell served as Minister of Colonial Affairs ... He was one of the two German representatives who signed the Treaty of Versailles.
Shared attributes	26.7	6.6	*C*: Judi bowker played andromeda in the 2012 remake of the 1981 film clash of the titans called wrath of the titans. / *E*: Judi bowker ... Clash of the Titans (1981).
Procedural event	16.7	0	*C*: Mccrory's originally filed for bankruptcy on february 2002. / *E*: McCrory Stores ... by 1992 it filed for bankruptcy. ... In February 2002 the company ceased operation.

Cannot find potential cause	0	20.0	*C*: Mutiny on the Bounty is Dutch. (from FEVER) *E*: Mutiny on the Bounty is a 1962 American Technicolor epic historical drama film.
Annotation error	10.0	20.0	*C*: Pasek and paul were the individuals that wrote the lyrics to the greatest showman.

Table 8: Categorization of 30 `refute` claims on FaVIQ and FEVER, randomly sampled from the validation set. *C* and *E* indicate the claim and evidence text, respectively. Examples are from FaVIQ unless otherwise specified.

Model	Dev	Test
Clain only BART	47.2	48.3
TF-IDF + BART	67.8	66.6
DPR + BART	67.2	66.5

Table 9: Fact verification accuracy on FEVER of different models when trained on FaVIQ.

many of them (37%) are false negatives based on our manual evaluation of 30 random samples. This is likely due to incomprehensive evidence annotation as discussed in Appendix A. We find using the negative with the second highest instead decreases the portion of false negatives from 37% to 13%.

Other details Our implementations are based on PyTorch[10] (Paszke et al., 2019) and Huggingface Transformers[11] (Wolf et al., 2020).

When training a BART-based model, we map `support` and `refute` labels to the words 'true' and 'false' respectively so that each label is mapped to a single token. This choice was made against mapping to 'support' and 'refute'because the BART tokenizer maps 'refute' into two tokens, making it difficult to compare probabilities of `support` and `refute`.

By default, we use a batch size of 32, a maximum sequence length of 1024, and 500 warmup steps using eight 32GB GPUs. For SciFACT, we use a batch size of 8 and no warmup steps using four 32G GPUs. We tune the learning rate in between {7e-6, 8e-6, 9e-6, 1e-5} on the validation data.

D Additional Experiments

Table 9 reports the model performance when trained on FaVIQ and tested on FEVER. The best-performing model achieves non-trivial performance (67%). However, their overall performance is not as good as model performance when trained on FEVER, likely because the models do not exploit the bias in the FEVER dataset. Nonetheless, we underweight the test performance on FEVER due to known bias in the data.

Simulating Bandit Learning from User Feedback for Extractive Question Answering

Ge Gao[◇], **Eunsol Choi**[♣] and **Yoav Artzi**[◇]

Abstract

We study learning from user feedback for extractive question answering by simulating feedback using supervised data. We cast the problem as contextual bandit learning, and analyze the characteristics of several learning scenarios with focus on reducing data annotation. We show that systems initially trained on a small number of examples can dramatically improve given feedback from users on model-predicted answers, and that one can use existing datasets to deploy systems in new domains without any annotation, but instead improving the system on-the-fly via user feedback.

1 Introduction

Explicit feedback from users of NLP systems can be used to continually improve system performance. For example, a user posing a question to a question-answering (QA) system can mark if a predicted phrase is a valid answer given the context from which it was extracted. However, the dominant paradigm in NLP separates model training from deployment, leaving models static following learning and throughout interaction with users. This approach misses opportunities for learning during system usage, which beside several exceptions we discuss in Section 8 is understudied in NLP. In this paper, we study the potential of learning from explicit user feedback for extractive QA through simulation studies.

Extractive QA is a popular testbed for language reasoning, with rich prior work on datasets (e.g., Rajpurkar et al., 2016), task design (Yang et al., 2018; Choi et al., 2018), and model architecture development (Seo et al., 2017; Yu et al., 2018). Learning from interaction with users remains relatively understudied, even though QA is well positioned to elicit user feedback. An extracted answer can be clearly visualized within its supporting context, and a language-proficient user can then easily validate if the answer is supported or not.[1] This allows for simple binary feedback, and creates a contextual bandit learning scenario (Auer et al., 2002; Langford and Zhang, 2007). Figure 1 illustrates this learning signal and its potential.

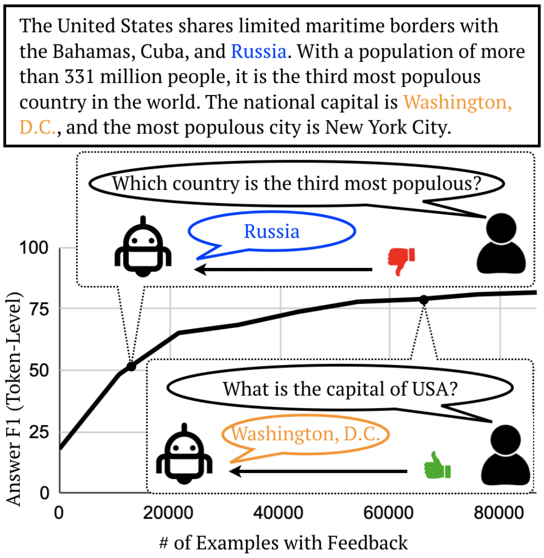

Figure 1: Illustration of an interaction setup for learning from user feedback for QA, and its potential. Given a user question, the system outputs an answer and highlights it in its context. The user validates the answer given the context with binary feedback. We show performance progression from one of our online learning experiments on SQuAD with hand-crafted illustrative examples at two time steps.

We simulate user feedback using several widely used QA datasets, and use it as a bandit signal for learning. We study the empirical characteristics of the learning process, including its performance, sensitivity to initial system performance, and tradeoffs between online and offline learning. We also simulate zero-annotation domain adaptation, where we deploy a QA system trained from supervised

---

[1] Answers could also come from erroneous or deceitful contexts. This important problem is not studied by most work in extractive QA, including ours. We leave it for future work.

Volume 1: Long Papers, pages 5167 - 5179
May 22-27, 2022

data in one domain and adapt it solely from user feedback in a new domain.

This learning scenario can mitigate fundamental problems in extractive QA. It reduces data collection costs, by delegating much of the learning to interaction with users. It can avoid data collection artifacts because the data comes from the actual system deployment, unlike data from an annotation effort that often involves design decisions immaterial to the system's use case. For example, sharing question- and answer-annotator roles (Rajpurkar et al., 2016), which is detrimental to emulate information seeking behavior (Choi et al., 2018). Finally, it gives systems the potential to evolve over time as the world changes (Lazaridou et al., 2021; Zhang and Choi, 2021).

Our simulation experiments show that user feedback is an effective signal to continually improve QA systems across multiple benchmarks. For example, an initial system trained with a small amount of SQuAD (Rajpurkar et al., 2016) annotations (64 examples) improves from 18 to 81.6 F1 score, and adapting a SearchQA (Dunn et al., 2017) system to SQuAD through user feedback improves it from 45 to 84 F1 score. Our study shows the impact of initial system performance, trade-offs between online and offline learning, and the impact of source domain on adaptation. These results create the base for future work that goes beyond simulation to use feedback from human users to improve extractive QA systems. Our code is publicly available at `https://github.com/lil-lab/bandit-qa`.

2 Learning and Interaction Scenario

We study a scenario where a QA model learns from explicit user feedback. We formulate learning as a contextual bandit problem. The input to the learner is a question-context pair, where the context paragraph contains the answer to the question. The output is a single span in the context paragraph that is the answer to the question.

Given a question-context pair, the model predicts an answer span. The user then provides feedback about the model's predicted answer, which is used to update the model parameters. We intentionally experiment with simple binary feedback and basic learning algorithms, to provide a baseline for what more advanced methods could achieve with as few assumptions as possible.

Background: Contextual Bandit Learning In a stochastic (i.i.d.) contextual bandit learning problem, at each time step t, the learner independently observes a context[2] $x^{(t)} \sim D$ sampled from the data distribution D, chooses an action $y^{(t)}$ according to a policy π, and observes a reward $r^{(t)} \in \mathbb{R}$. The learner only observes the reward $r^{(t)}$ corresponding to the chosen action $y^{(t)}$. The learner aims to minimize the cumulative regret. Intuitively, regret is the deficit suffered by the learner relative to the optimal policy up to a specific time step. Formally, the cumulative regret at time T is computed with respect to the optimal policy $\pi^* \in \arg\max_{\pi\in\Pi} \mathbb{E}_{(x,y,r)\sim(D,\pi)}[r]$:

$$R_T := \sum_{t=1}^{T} r^{*(t)} - \sum_{t=1}^{T} r^{(t)} \quad , \tag{1}$$

where Π is the set of all policies, $r^{(t)}$ is the reward observed at time t and $r^{*(t)}$ is the reward that the optimal policy π^* would observe. Minimising the cumulative regret is equivalent to maximising the total reward.[3] A key challenge in contextual bandit learning is to balance exploration and exploitation to minimize overall regret.

Scenario Formulation Let a question $\bar{q}$ be a sequence of m tokens $\langle q_1, \ldots, q_m\rangle$ and a context paragraph $\bar{c}$ be a sequence of n tokens $\langle c_1, \ldots, c_n\rangle$. An extractive QA model[4] π predicts a span $\hat{y} = \langle c_i, \ldots, c_j\rangle$ where $i, j \in [1, n]$ and $i \leq j$ in the context $\bar{c}$ as an answer. When relevant, we denote π_θ as a QA model parameterized by θ.

We formalize learning as a contextual bandit process: at each time step t, the model is given a question-context pair $(\bar{q}^{(t)}, \bar{c}^{(t)})$, predicts an answer span $\hat{y}$, and receives a reward $r^{(t)} \in \mathbb{R}$. The learner's goal is to maximize the total reward $\sum_{t=1}^{T} r^{(t)}$. This formulation reflects a setup where, given a question-context pair, the QA system interacts with a user, who validates the model-predicted answer in context, and provides feedback which is mapped to numerical reward.

---

[2] The term *context* here refers to the input to the learner policy, and is different from the term *context* as we use it later in extractive QA, where the term *context* refers to the evidence document given as input to the model.

[3] Equivalently, the problem is often formulated as loss minimization (Bietti et al., 2018).

[4] In bandit literature, the term *policy* is more commonly used. We use the term *model* from here on to align with the QA literature.

Algorithm 1 Online learning.

```
for $t = 1 \cdots$ do
    Receive a question $\bar{q}^{(t)}$ and context $\bar{c}^{(k)}$
    Predict an answer $\hat{y}^{(t)} \leftarrow \arg\max_y \pi_\theta(y \mid \bar{q}^{(t)}, \bar{c}^{(t)})$
    Observe a reward $r^{(t)}$
    Update the model parameters $\theta$ using the gradient
        $r^{(t)} \nabla_\theta \log \pi_\theta(\hat{y}^{(t)} \mid \bar{q}^{(t)}, \bar{c}^{(t)})$
end for
```

Algorithm 2 Offline learning.

```
1:  for $t = 1 \cdots T$ do
2:      Receive a question $\bar{q}^{(t)}$ and context $\bar{c}^{(t)}$
3:      Predict an answer $\hat{y}^{(t)} \leftarrow \arg\max_y \pi_\theta(y \mid \bar{q}^{(t)}, \bar{c}^{(t)})$
4:      $p^{(t)} \leftarrow \pi_\theta(\hat{y}^{(t)} \mid \bar{q}^{(t)}, \bar{c}^{(t)})$
5:      Observe a reward $r^{(t)}$
6:  end for
7:  for $E$ epochs do
8:      for $t = 1 \cdots T$ do
9:          Compute clipped importance-weighted reward according to the current model parameters:
10:         $r' \leftarrow \mathrm{clip}(\frac{\pi_\theta(\hat{y}^{(t)} \mid \bar{q}^{(t)}, \bar{c}^{(t)})}{p^{(t)}}, 0, 1) r^{(t)}$
11:         Update the model parameters $\theta$ using the gradient
                $r' \nabla_\theta \log \pi_\theta(\hat{y}^{(t)} \mid \bar{q}^{(t)}, \bar{c}^{(t)})$
12:     end for
13: end for
```

Learning Algorithm We learn using policy gradient. Our learner is similar to REINFORCE (Sutton and Barto, 1998; Williams, 2004), but we use $\arg\max$ to predict answers instead of Monte Carlo sampling from the model's output distribution.[5]

We study online and offline learning, also referred to as on- and off-policy. In online learning (Algorithm 1), the model identity is maintained between prediction and update; the parameter values that are updated are the same that were used to generate the output receiving reward. This entails that a reward is only used once, to update the model after observing it. In offline learning (Algorithm 2), this relation between update and prediction does not hold. The learner observes reward, often across many examples, and may use it to update the model many times, even after the parameters drifted arbitrarily far from these that generated the prediction. In practice, we observe reward for the entire length of the simulation (T steps) and then update for E epochs. The reward is re-weighted to provide an unbiased estimation using inverse propensity score (IPS; Horvitz and Thompson, 1952). We clip the debiasing coefficient to avoid amplifying examples with large coefficients (line 10, Algorithm 2).

In general, offline learning is easier to implement because updating the model is not integrated with its deployment. Offline learning also uses a training loop that is similar to optimization practices in supervised learning. This allows to iterate over the data multiple times, albeit with the same feedback signal on each example. However, online learning often has lower regret as the model is updated after each interaction. It may also lead to higher overall performance, because as the model improves early on, it may observe more positive feedback overall, which is generally more informative. We empirically study these trade-offs in Section 5 and 6.

Evaluating Performance We evaluate model performance using token-level F1 on a held-out test set, as commonly done in the QA literature (Rajpurkar et al., 2016). We also estimate the learner regret (Equation 1). Computing regret requires access to the an oracle π^*. We use human annotation as an estimate (Section 3).[6]

Comparison to Supervised Learning In supervised learning, the data distribution is not dependent on the model, but on a fixed training set $\{(\bar{q}^{(t)}, \bar{c}^{(t)}, y^{(t)})\}_{t=1}^{T}$. In contrast, bandit learners are provided with reward data that depends on the model itself: $\{(\bar{q}^{(t)}, \bar{c}^{(t)}, \hat{y}^{(t)}, r^{(t)})\}_{t=1}^{T}$ where r is the reward for the model prediction $\hat{y}^{(t)} = \arg\max_y \pi_\theta(y \mid \bar{q}^{(t)}, \bar{c}^{(t)})$ at time step t. Such feedback can be freely gathered from users interacting with the model, while building supervised datasets requires costly annotation. This learning signal can also reflect changing task properties (e.g., world changes) to allow systems to adapt, and its origin in the deployed system use makes it more robust to biases introduced during annotation.

3 Simulation Setup

We initialize our model with supervised data, and then simulate bandit feedback using supervised data annotations. Initialization is critical so the model does not return random answers, which are likely to be all bad because of the large output space. We use relatively little supervised data from the same domain for in-domain experiments (Section 5 and 6) to focus on the data annotation re-

---

[5] Early experiments showed that sampling is not as beneficial as $\arg\max$, potentially because of the relatively large output space of extractive QA. Yao et al. (2020) made a similar observation for semantic parsing, and Lawrence et al. (2017) used $\arg\max$ predictions for bandit learning in statistical machine translation. Table 4 in Appendix A provides our experimental results with sampling.

[6] Our oracle is an estimate because of annotation noise and ambiguity in exact span selection.

duction potential of user feedback. For domain adaptation, we assume access to a large amount of training data in the source domain, and no annotated data in the target domain (Section 7).

Reward We use supervised data annotations to simulate the reward. If the predicted answer span is an exact match index-wise to the annotated span, the learner observes a positive reward of 1.0, and a negative reward of -0.1 otherwise.[7] This reward signal is stricter than QA evaluation metrics (token-level F1 or exact match after normalization).[8]

Noise Simulation We study robustness by simulating noisy feedback via reward perturbation: randomly flipping the binary reward with a fixed probability of 8% or 20% as the noise ratio.[9]

4 Experimental Setup

Data We use six English QA datasets that provide substantial amount of annotated training data taken from the MRQA training portion (Fisch et al., 2019): SQuAD (Rajpurkar et al., 2016), NewsQA (Trischler et al., 2017), SearchQA (Dunn et al., 2017), TriviaQA (Joshi et al., 2017), HotpotQA (Yang et al., 2018), and NaturalQuestions (NQ; Kwiatkowski et al., 2019). The MRQA benchmark simplifies all datasets so that each example has a single span answer with a limited evidence document length (truncated at 800 tokens). Table 7 in Appendix B provides dataset details. We compute performance measures and learning curves on development sets following prior work (Rajpurkar et al., 2016; Ram et al., 2021).

Model We conduct experiments with a pretrained SpanBERT model (Joshi et al., 2020). We fine-tune the pre-trained SpanBERT-base model during initial learning and our simulations.

Implementation Details We use Hugging Face Transformers (Wolf et al., 2020). When training initial models with little in-domain supervised data (Section 5; Section 6), we use a learning rate of 3e-5 with a linear schedule, batch size 10, and 10 epochs. We obtain the sets of 64, 256, or 1,024 examples from prior work (Ram et al., 2021).[10] For models initially trained on complete datasets (Section 7), we use a learning rate 2e-5 with a linear schedule, batch size 40, and 4 epochs.

In simulation experiments, we use batch size 40. We turn off dropout to simulate interaction with users in deployment. For single-pass online learning experiments (Section 5; Section 7), we use a constant learning rate of 1e-5. For offline learning experiments (Section 6), we train the model for 3 epochs on the collected feedback with a linear schedule learning rate of 3e-5.

Online experiments with SQuAD, HotpotQA, NQ, and NewsQA take 2–4h each on one NVIDIA GeForce RTX 2080 Ti; 2.5–6h for offline. For TriviaQA and SearchQA, each online simulation experiment on one NVIDIA TITAN RTX takes 4–9.5h; 9–20h for offline.

5 Online Learning

We simulate a scenario where only a limited amount of supervised data is available, and the model mainly learns from explicit user feedback on predicted answers. We use 64, 256, or 1,024 in-domain annotated examples to train an initial model. This section focuses on online learning, where the learner updates the model parameters after each feedback is observed (Algorithm 1).

Figure 2 presents the performance of in-domain simulation with online learning. The performance pattern varies across different datasets. Bandit learning consistently improves performance on SQuAD, HotpotQA, and NQ across different amounts of supervised data used to train the initial model. The performance gain is larger with weaker initial models (i.e., trained on 64 supervised examples): 63.6 on SQuAD, 42.7 on HotpotQA, and 40.0 on NQ. Bandit learning is not always effective on NewsQA, TriviaQA, and SearchQA, especially with weaker initial models. This may be attributed to the quality of training set annotations, which determines the accuracy of reward in our setup. SearchQA and TriviaQA use distant supervision to match questions and relevant contexts from the web, likely decreasing reward quality in our setup. While NewsQA is crowdsourced, Trischler et al. (2017) report relatively low human performance (69.4 F1), possibly indicating data challenges that also decrease our reward quality. Learning progres-

---

[7] We experimented with other reward values, but did not observe a significant difference in performance (Appendix A).

[8] Normalization includes lowercasing, modifying spacing, removing articles and punctuation, etc. NaturalQuestions (NQ; Kwiatkowski et al., 2019) is an exception, with an exact index match measure that has similar strictness.

[9] Even without our noise simulation, the simulated feedback inherits the noise from the annotation, either from crowdsourcing or distant supervision.

[10] We use the seed 46 sets publicly available at https://github.com/oriram/splinter.

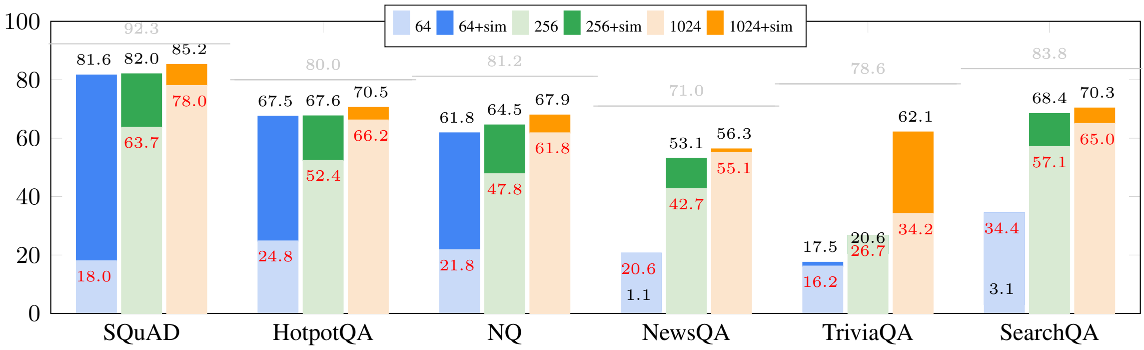

Figure 2: Online in-domain simulation development F1 performance. Horizontal grey lines represent the supervised training performance on each dataset. Data labels in red are performance of initial models trained on 64, 256, or 1024 examples (i.e., lighter bars). Darker bars and black data labels represent simulation performance. Lower simulation performance (e.g., NewsQA 64+sim) indicate degradation in performance following simulation.

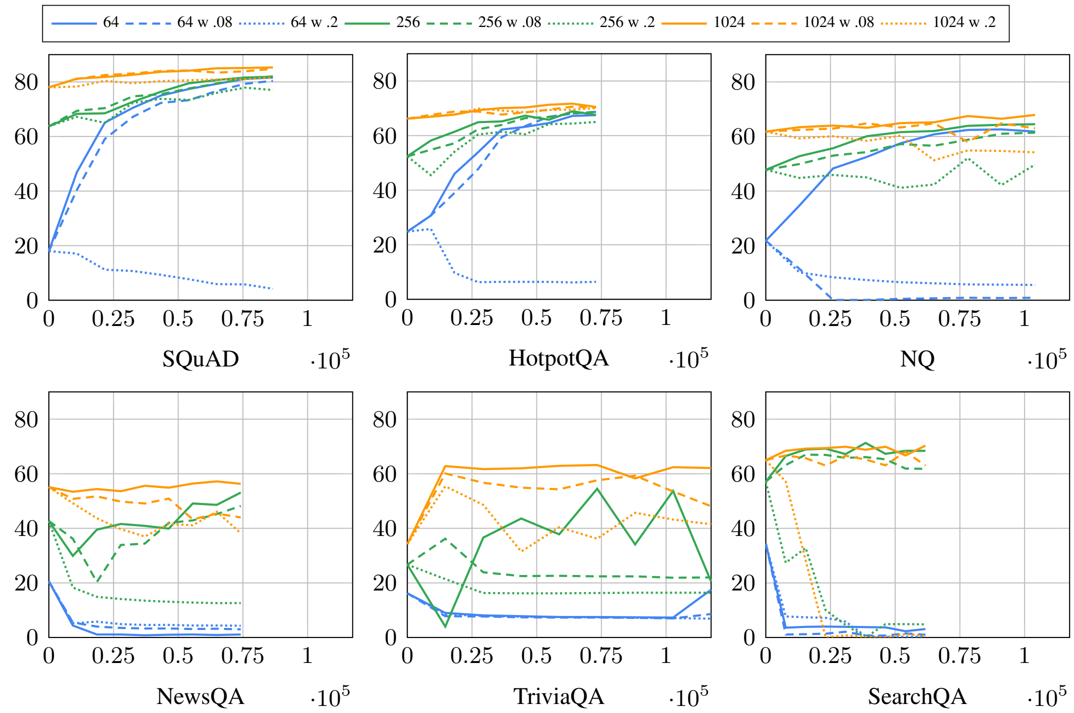

Figure 3: Online in-domain simulation development F1 learning curves. X-axis is the number of examples with feedback observed. "x w y" denotes initially training with x supervised in-domain examples and simulating with y amount of feedback noise.

Setup	SQuAD	HotpotQA	NQ	NewsQA	TriviaQA	SearchQA
64+sim	78.2(-3.4)	66.3(-1.2)	51.3(-10.5)	3.1(+2.0)	0.4(-17.1)	1.3(-1.8)
256+sim	86.2(+4.2)	70.9(+3.3)	65.2(+0.7)	54.3(+1.2)	12.3(-8.3)	0.3(-68.1)
1024+sim	86.5(+1.3)	73.2(+2.7)	71.8(+3.9)	55.7(-0.6)	7.5(-54.6)	4.1(-66.2)

Table 1: Offline in-domain simulation development F1 performance. Numbers in parenthesis show the performance gain (green) or decrease (red) of offline learning compared to online learning (Figure 2).

Setup	SQuAD	HotpotQA	NQ	NewsQA	TriviaQA	SearchQA
64+sim	0.63 / 1.04	0.51 / 0.94	0.74 / 0.91	1.07 / 0.86	0.77 / 0.77	1.09 / 0.77
256+sim	0.56 / 0.75	0.36 / 0.58	0.71 / 0.83	0.84 / 0.85	0.76 / 0.72	0.73 / 0.69
1024+sim	0.48 / 0.55	0.27 / 0.33	0.65 / 0.67	0.73 / 0.71	0.71 / 0.64	0.69 / 0.65

Table 2: Regret averaged by the number of feedback observations in online/offline in-domain simulations.

sion across datasets (Figure 3) shows that initial models trained with 1,024 examples can achieve peak performance with one third or even one quarter of feedback provided.

Feedback Noise Simulation Figure 3 shows learning curves with simulated noise via different amounts of feedback perturbation (0%, 8%, or 20%). When perturbation-free simulation is effective, models remain robust to noise: 8% noise results in small fluctuations of the learning curve, but the final performance degrades minimally. Starting with weaker initial models and learning with a higher noise ratio may cause learning to fail (e.g., simulation on SQUAD with 64 initial examples and 20% noise). When online perturbation-free simulation fails, online learning with noisy feedback fails too.

Sensitivity Analysis Training Transformer-based models has been shown to have stability issues, especially when training with limited amount of data (Zhang et al., 2021). Our non-standard training procedure (i.e., one epoch with a fixed learning rate) may further increase instability. We study the stability of the learning process using initial models trained on only 64 in-domain supervised examples on HotpotQA and TriviaQA: the former shows significant performance gain while the latter shows the opposite. We experiment with five initial models trained on different sets of 64 supervised examples, each used to initiate a separate simulation experiment. Four out of five experiments on HotpotQA show performance gains similar to what we observed so far, except one experiment that starts with very low initialization performance. In contrast, nearly all experiments on TriviaQA collapse (mean F1 of 7.3). We also conduct sensitivity analysis with stronger initial models trained with 1,024 examples, and observe that the final performance is stable across runs on both HotpotQA and TriviaQA (standard deviations are 0.5 and 2.6). Table 5 in Appendix B provides detailed performance numbers.

6 Offline Learning

We simulate offline bandit learning (Algorithm 2), where feedback is collected all at once with the initial model. The learning scenario follows the previous section: only a limited amount of supervised data is available (64, 256, or 1,024 in-domain examples) to train initial models.

Table 1 shows the performance of offline simulation experiments compared to online simulations. We observe mixed results. On SQUAD, HotpotQA, NQ, and NewsQA, offline learning outperforms online learning when using stronger initial models (i.e., models trained on 256 and 1,024 examples). This illustrates the benefit of the more standard training loop, especially with our Transformer-based model that is better optimized with a linear learning rate schedule and multiple epochs, both incompatible with the online setup. On TriviaQA and SearchQA, offline simulation is ineffective regardless of the performance of initial models. This result echoes the learning challenges in the online counterparts on these two datasets.

Online vs. Offline Regret Table 2 compares online and offline regret. Regret numbers are averaged over the number of feedback observations.[11] Online learning generally displays lower regret for similar initial models on SQUAD, HotpotQA, and NQ. This is expected because later interactions in the simulation can benefit from early feedback in online learning. In contrast, in our offline scenario, we only update after seeing all examples, so regret numbers depend on the initial model only. Regret results on NewsQA, TriviaQA, and SearchQA are counterintuitive, generally showing that online learning has similar or higher regret. The cases showing significantly higher online regret (64+sim on NewsQA and SearchQA) can be explained by the learning failing, which impacts online regret, but not our offline regret. The others are more complex, and we hypothesize that they may be because of combination of (a) inherent noise in the data; and (b) in cases where online learning is effective, the gap between the strictly-defined reward that is used to compute regret and the relaxed F1 evaluation metric. Further analysis is required for a more conclusive conclusion.

7 Domain Adaptation

Learning from user feedback creates a compelling avenue to deploy systems that target new domains not addressed by existing datasets. The scenario we simulate in this section starts with training a QA model on a complete existing annotated dataset, and deploying it to interact with users and learn from their feedback in a new domain. We do not assume access to any annotated training data in

---

[11] Table 8 in Appendix B lists the percentage of positive feedback in online and offline in-domain simulation.

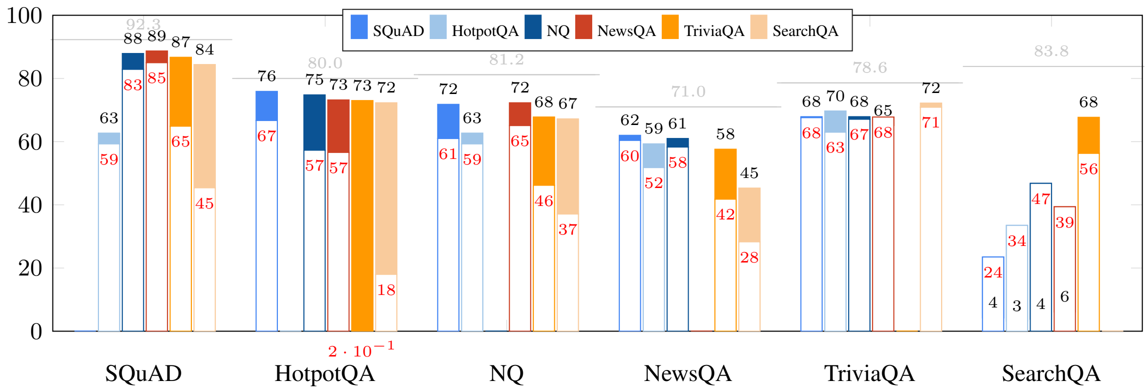

Figure 4: Online domain adaptation simulation development F1 performance. Horizontal grey lines represent the supervised training performance on each complete dataset. Bar colors denotes the source domain. Labels in red are the performance of initial models on the target domain (x-axis). Solid colors and black labels represent simulation performance on the target domain.

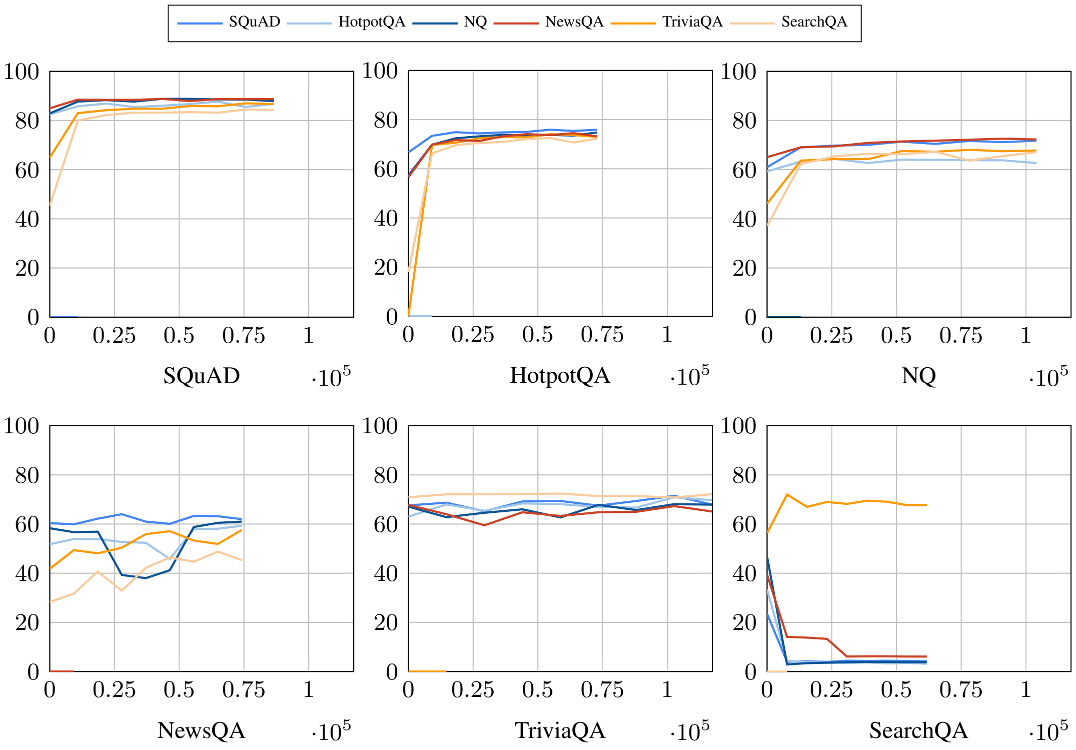

Figure 5: Online domain adaptation simulation development F1 learning curves. X-axis is the number of examples with feedback observed. Colors denote the source domain.

the target domain. We report experiments with online learning. Offline adaptation experiments are discussed in Appendix B.3.

Figure 4 shows online domain adaptation performance. On 22/30 configurations, online adaptation introduces significant performance gains (>2 F1 score). For example, adapting from TriviaQA and SearchQA to the other four domains improves performance by 27–72.8 F1. On HotpotQA, the model initially trained on TriviaQA shows an impressive adaptation, improving from 0.2 F1 to 73 F1.[12]

Our simulations show reduced effectiveness when the target domain is either TriviaQA or SearchQA, likely because the simulated feedback is based on noisy distantly supervised data. For SearchQA, the low performance of initial models from other domains may also contribute to the adaptation failure. As expected, this indicates the effectiveness of the process depends on the relation

---

[12] We replicate this result with different model initializations to confirm it is not random.

Dataset	In-domain	SQuAD-initialized
HotpotQA	66.2 → 70.5	**66.7** → **75.9**
NQ	**61.8** → 67.9	61.0 → **71.8**
NewsQA	55.1 → 56.3	**60.4** → **62.0**
TriviaQA	34.2 → 62.1	**67.6** → **67.9**
SearchQA	**65.0** → **70.3**	23.5 → 4.2

Table 3: Online learning development F1 Comparison between in-domain with initial models trained on 1,024 supervised examples, and adaptation with SQuAD as the source domain. Each entry provide performance before (right-side of arrow) and after (left-side) feedback simulation. Higher before/after performance is in bold.

between the source and target domains. SearchQA seems farthest from the other domains, mirroring observations from prior work (Su et al., 2019).

Figure 5 shows learning curves for our simulation experiments. Generally, we observe the choice of source and target domains influences adaptation rates. Models quickly adapt to SQuAD, HotpotQA, and NQ, reaching near final performance with a quarter of the total feedback provided. On NewsQA, models initially trained on TriviaQA and SearchQA adapt slower than those initially trained on other three datasets. On TriviaQA, we observe little change in performance throughout simulation. On SearchQA, only the model initially trained on TriviaQA shows a performance gain. Both SearchQA and TriviaQA include context paragraphs from the web, potentially making domain adaptation from one to the other easier.

Lastly, we compare bandit learning with initial models trained on a small amount of in-domain data (Section 5) and initial models trained on a large amount of out-of-domain data. Table 3 compares online learning with initial models trained on 1,024 in-domain supervised examples and online domain adaptation with a SQuAD-initialized model. SQuAD initialization provides a robust starting point for all datasets except SearchQA. On four out of five datasets, the final performance is better with SQuAD-initialized model. This is potentially because the model is exposed to different signals from two datasets and overall sees more data, either as supervised examples or through feedback. However, on SearchQA, learning with SQuAD-initialized model performs much worse than learning with the initial model trained on 1,024 in-domain examples, potentially because of the gap in initial model performance (23.5 vs. 65 F1).

8 Related Work

Bandit learning has been applied to a variety of NLP problems including neural machine translation (NMT; Sokolov et al., 2017; Kreutzer et al., 2018a,b; Mendoncca et al., 2021), structured prediction (Sokolov et al., 2016), semantic parsing (Lawrence and Riezler, 2018), intent recognition (Falke and Lehnen, 2021), and summarization (Gunasekara et al., 2021). Explicit human feedback has been studied as a direct learning signal for NMT (Kreutzer et al., 2018b; Mendoncca et al., 2021), semantic parsing (Artzi and Zettlemoyer, 2011; Lawrence and Riezler, 2018), and summarization (Stiennon et al., 2020). Nguyen et al. (2017) simulates bandit feedback to improve an MT system fully trained on a large annotated dataset, including analyzing robustness to feedback perturbations. Our work shows that simulated bandit feedback is an effective learning signal for extractive question answering tasks. Our work differs in focus on reducing annotation costs by relying on few annotated examples only to train the initial model, or by eliminating the need for in-domain annotation completely by relying on data in other domains to train initial models. Implicit human feedback, where feedback is derived from human behavior rather than explicitly requested, has also been studied, including for dialogue (Jaques et al., 2020) and instruction generation (Kojima et al., 2021). We focus on explicit feedback, but implicit signals also hold promise to improve QA systems.

Alternative forms of supervision for QA have been explored in prior work, such as explicitly providing fine-grained information (Dua et al., 2020; Khashabi et al., 2020a). Kratzwald et al. (2020) resembles our setting in seeking binary feedback to replace span annotation, but their goal is to create supervised data more economically. Campos et al. (2020) proposes feedback-weighted learning to improves conversational QA using simulated binary feedback. Their approach relies on multiple samples (i.e., feedback signals) per example, training for multiple epochs online by re-visiting the same questions repeatedly, and tuning two additional hyperparameters. In contrast, we study improving QA systems via feedback as a bandit learning problem. In both online and offline setups, we assume only one feedback sample per example. We also provide extensive sensitivity studies to the amount of annotations available, different model initialization, and noisy feedback across various datasets.

Domain adaptation for QA has been widely studied (Fisch et al., 2019; Khashabi et al., 2020b), including using data augmentation (Yue et al., 2021), adversarial training (Lee et al., 2019), contrastive method (Yue et al., 2021), back-training (Kulshreshtha et al., 2021), and exploiting small lottery subnetworks (Zhu et al., 2021).

9 Conclusion

We present a simulation study of learning from user feedback for extractive QA. We formulate the problem as contextual bandit learning. We conduct experiments to show the effectiveness of such feedback, the robustness to feedback noise, the impact of initial model performance, the trade-offs between online and offline learning, and the potential for domain adaptation. Our study design emphasizes the potential for reducing annotation costs by annotating few examples or by utilizing existing datasets for new domains.

We intentionally adopt a basic setup, including a simple binary reward and vanilla learning algorithms, to illustrate what can be achieved with a relatively simple variant of the contextual bandit learning scenario. Our results already indicate the strong potential of learning from feedback, which more advanced methods are likely to further improve. For example, the balance between online and offline learning can be further explored using proximal policy optimization (PPO; Schulman et al., 2017) or replay memory (Mnih et al., 2015). With well-designed interface, human users may be able to provide more sophisticated feedback (Lamm et al., 2021), which will provide a stronger signal compared to our binary reward.

Our aim in this study is to lay the foundation for future work, by formalizing the setup and showing its potential. This is a critical step in enabling future research, especially going beyond simulation to study using *real* human feedback for QA systems. Another important direction for future work is studying user feedback for QA systems that do both context retrieval and answer generation (Lewis et al., 2020), where assigning the feedback to the appropriate stage in the process poses a challenge. Beyond extractive QA, we hope our work will inspire research of user feedback as a signal to improve other types of NLP systems.

Legal and Ethical Considerations

Our work's limitations are discussed in Section 1 and Section 9. All six datasets we use are from prior work, are publicly available, and are commonly used for the study of extractive QA. Section 4 reports our computational budget and experimental setup in detail. Our codebase is available at `https://github.com/lil-lab/bandit-qa`.

Dataset	$\arg\max$	Sampling
SQuAD	80.0	73.6
HotpotQA	65.7	56.8
NQ	64.8	62.9

Table 4: Comparison of final F1 development scores between $\arg\max$ and sampling in online simulation with initial models trained on 256 supervised in-domain examples.

A Additional Discussion

Reward Function Intuitively, partial credit reward may improve learning over binary rewards. We experiment with using F1 score of the predicted answer span as a more refined feedback.[13] In practice, this does not introduce a stronger learning signal, potentially because the distribution over F1 scores is bimodal and focused on extreme values: around 85 % F1 scores are either 0 or 1 for predicted spans from a SQuAD-trained model on 8% NQ training data. We observe similar trends on all six datasets across all setups. Experiments with BLEU score (Papineni et al., 2002) as feedback show similar conclusion and distribution to F1 score.

Perturbation In practice, noise in feedback is likely to be more systematic than the statistical simplification which defines noise as the random percentage of wrong feedback. For example, prior work (Nguyen et al., 2017) on bandit neural machine translation (NMT) proposes that noisy human feedback is granular, high-variance, and skewed, which can be approximated by mathematical functions and shows to significantly impact the bandit NMT learning. We experiment with the three perturbation functions from Nguyen et al. (2017) on F1 reward. Our experiments show that the effect of adding these perturbation functions is negligible. We hypothesize that the reward distribution for NMT is likely to be closer to a normal distribution, rather than a bimodal one like QA.

B Additional Experiments

B.1 Method of Sampling

While $\arg\max$ can bias towards exploitation, sampling can encourage more exploration. We experiment with prediction via $\arg\max$ and sampling from the output distribution over spans. Table 4 shows that $\arg\max$ performs better than random sampling on three datasets. This set of experiments is conducted with batch size 80.

B.2 Sensitivity Analysis

Table 5 shows the sensitivity analysis results for online in-domain simulation on HotpotQA and TriviaQA. We experiment with five initial models trained on different sets of 64 or 1,024 supervised examples, each used to initiate a separate simulation experiment. For weaker initial models trained on 64 supervised examples, four out of five experiments on HotpotQA show performance gains similar to our main results, except one experiment that starts with a very low initialization performance. Nearly all experiments on TriviaQA collapse (mean F1 of 7.3). Our sensitivity analysis with stronger initial models trained on 1,024 examples shows that the final performance is stable across runs on both HotpotQA and TriviaQA (standard deviations are 0.5 and 2.6).

B.3 Offline Adaptation

We perform domain adaptation with offline learning, and compare its performance with online adaptation. Table 6 shows the performance gain of offline adaptation simulation compared to the online setup. In most settings, online learning proves to be more effective, possibly because it observes feedback from partially adapted model predictions. In a few settings (4/30), we observe better adaptation with offline settings (+1.1 to +4.6). Overall, we observe that online learning is more effective on domain adaptation, while offline adaption performs slightly better when both domains are related (e.g., same source domain).

---

[13] We set the reward as -0.1 if receiving a 0 F1 score. In general, updating with negative rewards consistently shows a slightly higher performance across different setups for both binary and F1 reward.

Beyond Goldfish Memory[*]: Long-Term Open-Domain Conversation

Jing Xu **Arthur Szlam** **Jason Weston**
Facebook AI Research
New York, NY
{jingxu23,aszlam,jase}@fb.com

Abstract

Despite recent improvements in open-domain dialogue models, state-of-the-art models are trained and evaluated on short conversations with little context. In contrast, the long-term conversation setting has hardly been studied. In this work we collect and release a human-human dataset consisting of multiple chat sessions whereby the speaking partners learn about each other's interests and discuss the things they have learnt from past sessions. We show how existing models trained on existing datasets perform poorly in this long-term conversation setting in both automatic and human evaluations, and we study long-context models that can perform much better. In particular, we find retrieval-augmented methods and methods with an ability to summarize and recall previous conversations outperform the standard encoder-decoder architectures currently considered state-of-the-art.

1 Introduction

Improvements in the ability to train large neural language models, together with the availability of larger and higher quality dialogue datasets, are spurring the development of increasingly convincing open-domain dialogue models (McTear, 2020). Unfortunately, a major aspect missing from the current state of the art is that human conversations can take place over long time frames, whereas the currently used systems suffer in this setting. Commonly used training and evaluation resources – while large in terms of number of training examples – include only short conversations, typically between 2-15 turns, consisting of a single conversational session. Perhaps for that reason, the current state-of-the-art models such as Meena (Adiwardana et al., 2020) and BlenderBot (Roller et al., 2020) employ Transformers with token truncation lengths of only the 128 most recent tokens, and are clearly incapable of incorporating long-term conversational context. Consequently, it is unclear how well these models will perform on long or multi-session open-domain conversations. In contrast, a successfully deployed bot will engage in many conversations over a length of time, as capturing organic user interest will garner continual reengagement from returning users. Long-term open-domain communication gives the opportunity for the conversation to develop and even improve with time as the model has more context and more understanding of that specific user's interests. However current models, due to context truncation, will never use this information.

In this work we study methods for long-term open-domain conversation. As to the best of our knowledge no public domain task exists to study such methods, we collect and release[1] a new English dataset, entitled *Multi-Session Chat* (MSC) that consists of human-human crowdworker chats over 5 sessions, with each session consisting of up to 14 utterances, where the conversationalists reengage after a number of hours or days and continue chatting. Previous sessions are annotated with summaries of important personal points that may be useful in further conversations. When reengaging, conversationalists often address existing knowledge about their partner to continue the conversation in a way that focuses and deepens the discussions on their known shared interests, or explores new ones given what they already know.

We study the performance of two long-context conversational architectures on this task: (i) retrieval-augmented generative models (Lewis et al., 2020b; Shuster et al., 2021); and (ii) a proposed read-write memory-based model that summarizes and stores conversation on the fly. We show that both techniques outperform conventional encoder-decoder Transformers, and that training

---

[*] We use this term colloquially, see Agranoff et al. (1965) for evidence of goldfish long-term memory.

[1] Dataset, model weights and code for this entire project will be made available upon acceptance.

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics
Volume 1: Long Papers, pages 5180 - 5197
May 22-27, 2022

models on our new task give long-term conversational abilities that existing state-of-the-art models lack, as shown in both automatic metrics and human evaluations. We provide extensive experiments and ablations that study the reasons behind these improvements.

2 Related Work

A relatively large and growing number of either natural or crowdsourced datasets have been collected and used in open-domain dialogue research. These datasets focus on the vast array of different skills required by a dialogue agent, but conversations lengths are typically short. Recent state-of-the-art open-domain dialogue agents have utilized Daily Dialogue (Li et al., 2017), PersonaChat (Zhang et al., 2018), Empathetic Dialogues (Rashkin et al., 2019), Wizard of Wikipedia (Dinan et al., 2019) and Pushshift.io Reddit (Baumgartner et al., 2020); see Huang et al. (2020) for a review of other datasets. The number of conversational turns in these datasets is in the range of 2-15 turns, we provide statistics of some of these datasets in Table 2. We note there also exist some other kinds of dialogue datasets, e.g. from fantasy role-playing (Urbanek et al., 2019; Rameshkumar and Bailey, 2020) and TV shows as well (Poria et al., 2018). Crowdsourcing long conversations is difficult due to both the expense and the difficulty of employing crowdworkers for long lengths of time due to so called Human Intelligence Tasks (HITs) being typically of a short duration – only "a few minutes" (Paolacci et al., 2010). While organic long conversations regularly transpire on the internet, e.g. on messaging platforms, these are proprietary, and privacy concerns make public release implausible.

Several existing datasets explore the use of personal knowledge used as context to dialogue, which can be seen as a short, simple memory provided to the bot. In Mazaré et al. (2018) such personas were extracted from Reddit and used to train agents. In Zhang et al. (2018) personas were first crowdsourced, and speakers were asked to play those roles. Other works have considered encoding personas into vector-based weights (Li et al., 2016).

In this work, we explore summarizing the long-term conversations that occur in order to store useful information about them. Summarization is a rich field where the vast majority of work focuses on summarizing documents (Kaikhah, 2004; Kryściński et al., 2019; Cheng and Lapata, 2016), for example summarizing in order to predict other relevant information (West et al., 2019), while there is some work on dialogue as well (Goo and Chen, 2018; Gliwa et al., 2019; Pan et al., 2018).

Standard Transformers have a fixed context length which due to the all-vs-all self-attention mechanism becomes inefficient when it is too large. Consequently, many existing pre-trained models have short token truncation lengths, e.g. 128 tokens, as in BlenderBot (Roller et al., 2020) and Meena (Adiwardana et al., 2020), or 1024 tokens, as in BART (Lewis et al., 2020a). A number of approaches have been proposed to ameliorate this issue. Long-context Transformers consider ways to speed up the self-attention mechanism (Child et al., 2019; Kitaev et al., 2019; Beltagy et al., 2020) and retrieval-augmented methods consider ways to select the pertinent parts of the context to consider (Dinan et al., 2019; Lewis et al., 2020b; Shuster et al., 2021) which can also be related to earlier neural QA methods (Chen et al., 2017).

3 Multi-Session Chat

To conduct research on long-term conversations, we require data to both train on and to evaluate models. We consider the natural case where two speakers chat online in a series of sessions as is for example common on messaging platforms. Each chat session consists of 6-7 turns for each speaker. Then, after a certain amount of (simulated) time has transpired, typically hours or days, the speakers resume chatting, either continuing to talk about the previous subject, bringing up some other subject from their past shared history, or sparking up conversation on a new topic. We consider this multi-session long conversation setup, and name our dataset *Multi-Session Chat* (MSC).

Data Collection To build our publicly available dataset we employ crowdworkers. We provide screenshots of the task, and details of quality control via onboarding, crowdworker co-rating, and automatic evaluation procedures in Appendix B.

Personas Crowdworkers are asked to play a role, rather than speaking about their own personality, which helps mitigate privacy concerns, and ensures diversity even if the same crowdworker conducts multiple conversations. In addition to the crowdworkers being specifically told to play the role, they are also told not to discuss aspects of their real profiles or indeed any personally identifiable informa-

MULTI-SESSION CHAT (1-4)	1,001	53,332	23,387	23.0	4	53.3

Table 2: Comparison of the training data statistics of the MULTI-SESSION CHAT (MSC) dataset compared to other open-domain datasets. We show MSC in two categories: episodes with 3 or 4 sessions, named (1-3) or (1-4).

tion. The role is provided as a series of sentences describing characteristics, events and opinions of the character they are playing. We use the 1,155 personas crowdsourced from Zhang et al. (2018), validation and test use separate personas from the ones used in the training set.

Session 1 For the first chat session we use the PERSONACHAT dataset (Zhang et al., 2018), which already involves short conversations where two speakers get to know each other for the first time. We note that these conversations rarely go beyond the superficial stage because speakers simply do not have enough turns to discuss any topic deeply.

Sessions 2, 3, 4, . . . For subsequent sessions, we first select a random amount of (simulated) time that has elapsed since the previous session, chosen to be either 1-7 hours or 1-7 days, as ideally speakers would reengage within that timeframe. We ask the crowdworkers to play the same roles that were played in the previous session, acting as if that amount of time has transpired. We note these crowdworkers may not be the same ones that played those characters in previous sessions, but will be playing the same roles: this makes the task tractable in a crowdworking frameworking where jobs are typically short, and matching pairs over a long duration would be infeasible. We instruct the workers to "chitchat with another worker for 6 turns, as if you were *catching up* since last time you two spoke." and that "When you expand the topic, make sure it makes sense with the personal details *already* mentioned.", i.e. emphasizing that not only must they play their role, but also pay attention to previous interactions with the other speaker.

Session Lengths We collect two lengths of training conversation: 4000 episodes with 3 sessions, and 1001 episodes with 4 sessions. For the validation and test data, the sessions extend up to 5 sessions, giving us a way to measure long-context session performance that extends beyond the training set distribution.

Conversation Summaries (Extended Personas) We give crowdworkers access to all previous dialogues between the two conversational roles (for the role they are playing, and their partner's role). However, as the conversation gets longer, this becomes infeasible to read and digest within a limited amount of time. Therefore, between each session, including after session 1, we run a separate crowdworker task in which conversations are summarized into important points, which are much shorter than the full dialogues themselves. We then show previous dialogues, along with these summaries, as the primary reference for subsequent session dialogues. As these summaries were collected in order to store the important points pertinent to either one or the other speaker, they can also be seen to function as extensions of the original given personas. As the two speakers continue to converse they create more depth to those characters.

Dataset Examples Two dataset examples, which consist of four sessions each, along with example summary annotations, are given in Appendix C (provided in the Appendix due to their length).

Dataset Statistics Statistics of the multi-session chat dataset are given in Table 1 and a comparison with other standard open-domain dialogue datasets is given in Table 2. We can see that the number of training utterances per episode is larger than other datasets (last column of Table 2). Our multi-session training chats that last 4 sessions have an average of $\sim$53 utterances in a full conversation (over all sessions), while our validation and test chats over 5 sessions have an average of $\sim$66 utterances. In contrast, other standard datasets are in the range of 2.6-14.7 utterances on average. This brings challenges in open-domain dialogue modeling due to the large context size, e.g. an average of 1614 tokens as tokenized by the BlenderBot BPE dictionary (Roller et al., 2020), where the Transformer used in that work has a truncation length of 128. Further information on the dataset including analysis of its quality is given in Appendix B.

4 Modeling Multi-Session Chat

4.1 Transformer Encoder-Decoders

The most straight-forward approach for modeling dialogue using our new task is simply to use a large language model as is standard in open-domain dialogue, i.e. an encoder-decoder Transformer as in the Meena (Adiwardana et al., 2020) and BlenderBot (Roller et al., 2020) systems. We consider using the BST 2.7B parameter model from BlenderBot as an initial pre-trained model, which we then fine-tune on the Multi-Session Chat task.

Encoder Truncation As BST 2.7B has a truncation of 128 tokens in the encoder, we consider extending this to a larger input. To do this, we extend its available positional encodings from 128 to 512 or 1024 tokens as we fine-tune the whole network on the downstream task. We add new positional embeddings to be trained such that the existing ones (the first 128 most recent tokens) do not change from before. We then evaluate the impact of these choices in order to select the best model.

4.2 Retrieval-Augmentation

A popular technique when dealing with a large collection of text, only some of which is relevant, is to use a retrieval-augmented Transformer. A retrieval system is used to search over a text collection, and select some of it to be included in the final encoding which is attended to by the Transformer decoder.

RAG The RAG (Retrieval-Augmented Generation) approach (Lewis et al., 2020b) utilizes a neural-retriever-in-the-loop which is itself a second Transformer. Documents to be retrieved are stored in an approximate nearest-neighbor FAISS index (Johnson et al., 2019), and a DPR (Dense Passage Retrieval) (Karpukhin et al., 2020) Transformer bi-encoder model is used to score document-context pairs in order to rank them based on their match, where the base DPR model is pre-trained on QA data pairs. The DPR model is thus used to both retrieve from the FAISS index, and then score the top N candidates. The entire system is trained end-to-end so that retrieval is optimized to help improve generation. This setup was shown to work for dialogue in particular in Shuster et al. (2021).

FiD and FiD-RAG We also consider the Fusion-in-Decoder (FiD) (Izacard and Grave, 2020), another method that has been shown to perform well. In this approach, the pre-trained retriever is used directly: each of the top N documents returned is prepended to the context and encoded separately by the encoder, and finally all the results are concatenated. The decoder then attends to these encodings to produce a final response. We consider the pre-trained retriever to either be standard pre-trained DPR, or the RAG-trained retriever, called FiD-RAG (Shuster et al., 2021).

Retriever and Documents In this work the set of passages in the memory is not large enough to require a FAISS index, but it is large enough that retrieval may be useful. We thus store for every item in the memory the vector encoding by the DPR model (whereas in the FAISS approach this dense vector is approximated instead). Then given a dialogue context, we score each memory using the bi-encoder, and use the top N for generation. In our case, the memories consist of dialog utterances from the history of the conversation. We consider the chunk (document) size as a hyperparameter and try either encoding utterances as separate documents, or else whole sessions (or session summaries) as documents. The latter (whole se-

Pre-Train Model	Truncation	Sessions 1-4	Session 1	Session 2	Session 3	Session 4	Trunc% (S4)
With no previous session context							
BST 2.7B	128	9.23	8.76	9.45	9.31	9.40	51%
BST 2.7B	512	9.06	8.18	9.42	9.26	9.36	0%
BST 2.7B	1024	9.08	8.20	9.46	9.29	9.37	0%
With previous session dialogue context

BST 2.7B	1024	8.80	8.18	9.05	8.91	9.04	0%

Table 3: **Comparison of different context truncation lengths and context types** when training on MULTI-SESSION CHAT. We show validation perplexity for various models across different sessions, and percent of tokens truncated for session 4 (last column).

	Session				Session Openings			
Model Context	2	3	4	5	2	3	4	5
No Session History	9.46	9.29	9.37	9.30	9.96	10.99	10.69	10.46
Dialogue History	9.18	9.05	9.16	9.08	7.55	8.48	8.27	7.94
Gold Summary	9.04	8.90	9.02	8.96	6.98	7.96	7.94	7.77
Gold Summary (without time features)	9.05	8.91	9.04	8.95	6.97	7.95	7.97	7.74
Gold Summary (partner's only)	9.14	8.99	9.11	9.03	7.66	8.49	8.49	8.07
Gold Summary (self only)	9.29	9.10	9.18	9.13	8.40	8.94	8.52	8.39
Predicted Summary	9.11	8.98	9.07	9.00	7.44	8.43	8.20	7.81

Table 4: **Summaries vs. Dialogue Context Performance** when training on MULTI-SESSION CHAT, reporting validation perplexity, using a BST 2.7B-1024 pre-trained model with MSC fine-tuning. Note that the last row in this Table corresponds to the SumMem-MSC 2.7B (truncate 1024) row in Table 15 in the Appendix.

sions) worked better, and we report those in the final results. For N we try values 3, 5 and 6, and also choose the best for each method according to the validation set.

4.3 Summarization Memory-Augmentation

The retrieval-augmentation models described in the previous section retrieve from the set of past dialogues. Simply storing historical text in the memory in their raw form is a simple approach that is often used elsewhere in the literature, e.g. in question answering or knowledge-grounded dialogue. However, those approaches have two potential drawbacks: (i) there is a lot of context to store, and hence retrieve from; (ii) no processing has been done on that content, so the reading, retrieving and combining operations required to generate an answer leave a lot of work for the model to do. We therefore propose instead a novel memory augmentation that first *summarizes pertinent knowledge* and only stores that in an attempt to solve both problems.

The procedure involves two main components:

1. An encoder-decoder abstractive summarizer that takes as input the dialogue history, and outputs a summary of new pertinent information contained in the last dialogue turn, or "no-summary" if there is no new information found. When found, the summarized knowledge is added to the long-term memory.

2. A memory-augmented generator that takes the dialogue context and access to the long-term memory, and generates the next response.

For (1) we can use the human annotated data from our newly collected MSC task to know what summaries to generate (see section 3 and Figure 1 in the Appendix). We thus train a supervised encoder-decoder model to produce summaries.

For (2) we can use the same systems as presented in subsection 4.2 to both retrieve from the summarization memories, and to finally generate an appropriate response. That is, we store the summaries in documents and retrieve them using either RAG, FiD or FiD-RAG.

Model Context	Session 2	Session 3	Session 4	Session 5	Session Openings 2	Session Openings 3	Session Openings 4	Session Openings 5	Sparsity
Gold summary	9.04	8.90	9.02	8.96	6.98	7.96	7.94	7.77	42.0%
Predicted Summary (sampling 5%)	9.11	8.98	9.07	9.00	7.44	8.43	8.20	7.81	29.1%
Predicted Summary (sampling 25%)	9.11	8.97	9.07	9.01	7.46	8.53	8.22	7.94	41.4%
Predicted Summary (sampling 50%)	9.14	8.99	9.08	9.02	7.57	8.62	8.37	8.11	50.7%
Predicted Summary (sampling 100%)	9.14	8.99	9.10	9.03	7.68	8.69	8.56	8.25	61.8%

Table 5: **Predicted Summaries when subsampling the no-summary class** on MULTI-SESSION CHAT, reporting validation perplexity, using a BST 2.7B-1024 pre-trained model with MSC fine-tuning. The last column shows the sparsity of the summarizations (how often a summary line is generated), which can be controlled by subsampling the no-summary class at training time. Subsampling gives better results and closer sparsity levels to the original human annotated data.

Training Data	Session 1	Session 2	Session 3	Session 4	Session All
Session 1	8.24	11.4	11.2	11.3	10.5
Sessions 1+2	8.21	9.21	9.09	9.24	8.94
Sessions 1+2+3	8.16	9.05	8.93	9.06	8.80
Sessions 1+2+3+4	8.16	9.02	8.89	9.02	8.77

Table 6: **Varying the Number of Training Sessions** when training on MULTI-SESSION CHAT, reporting validation perplexity, using a BST 2.7B-1024 pre-trained model with MSC using gold summaries.

5 Experiments

Using session dialogue context We compare different context types in Table 3, evaluating over sessions 1-4. We observe an improvement in perplexity when incorporating the dialogue history from previous chat sessions, compared to no session context, for all sessions after the first one, and for all context lengths – with larger context lengths giving better improvement. This shows that our human conversationalists do use previous sessions to make dialogue more salient in successive sessions as this is reflected in the collected human-human dataset – and that our models are able to utilize this information well when training on this data.

Using session summary context We also show performance of using gold session summary contexts, as annotated by crowdworkers, in Table 3. As the summaries include salient points, they are potentially more informative than dialogue context for a generative model. We find perplexities improve when using summaries compared to using dialogue context (or no context at all) over all sessions after the first one, and for all context lengths, although the improvements are not large. This shows that conversation summaries are potentially useful for dialogue generation in the long-context case.

Comparing performance on session openings Session openings in the MSC dataset look quite different to other dialogue datasets that do not have a session format. This is because they involve an opening message that is intended to reengage the other speaker after a period of time, using known information that has been exchanged between speakers. In Table 4 we compare models that use different context types on only these opening responses. In this case we find much more pronounced perplexity differences between no session context history, dialogue history or summary context history. For example, we see around around 2 perplexity points difference between using or not using previous session context. We show examples of opening session generations in Appendix C. We observe that opening messages are categorically different to other conversation turns, typically involving a statement or question given knowledge of shared interests contained in the long-context. This explains why collection of our new dataset is so important for this goal, as reflected in perplexity improvements. That is, they indicate that our new task will likely help improve multi-session conversational engagement with users compared to existing training schemes.

Comparing different context lengths As shown in Table 3 changing the context length of a Transformer can impact the performance in our task. With no previous session context, improvements are minimal for sessions 2 onwards. However, using session dialogue or summary contexts we do see improvements with larger lengths of 512 or 1024 tokens, compared to 128. The last column of Table 3 shows the percentage of responses where the input to the Transformer is truncated for session 4, for each truncation length. One can see that using summaries can be beneficial as they are shorter,

Model	Session 1	Session 2	Session 3	Session 4	Session 5	Session Openings
BST 2.7B (Roller et al., 2020)	8.97	9.98	10.26	10.40	10.50	12.92
MSC 2.7B (truncate 128)	8.87	8.89	9.10	9.21	9.27	8.95
MSC 2.7B (truncate 1024)	8.25	8.76	8.93	9.07	9.16	8.09
MSC 2.7B (RAG)	8.22	8.78	8.97	9.11	9.17	8.10
MSC 2.7B (FiD)	8.22	8.75	8.92	9.05	9.11	8.06
MSC 2.7B (FiD-RAG)	8.23	8.75	8.93	9.04	9.11	8.03
SumMem-MSC 2.7B (truncate 1024)	8.25	8.71	8.89	9.01	9.09	8.04
SumMem-MSC 2.7B (RAG)	8.24	8.81	9.00	9.10	9.17	8.05
SumMem-MSC 2.7B (FiD)	8.20	8.71	8.89	9.00	9.07	7.91
SumMem-MSC 2.7B (FiD-RAG)	8.22	8.70	8.89	9.00	9.07	7.87

Table 7: **Test perplexity across sessions** for our retrieval- and memory-augmented models (bottom two blocks) compared to several encoder-decoder baselines (top three rows).

meaning they are truncated less often, which can thus also help performance.

Summary context performance We can ablate the summary model training data to understand its impact further, results of which are given in Table 4. We see that removing the time feature (indicating how long ago the previous session occurred) only has minimal effect. Removing either the partner or self summary (and keeping the other one), on the other hand, has a larger effect in both cases, where keeping the self summary is slightly more important. Keeping both features is best. These differences, as before, are magnified when looking at session opening performance.

Predicted summary models We train models to predict dialogue summaries, and use predicted summaries of previous sessions as context (instead of the full dialogue history or the gold summary). The training data for predicting summaries consists of, for each turn, either a summarizing sentence or the *no_summary* label. As 42% of turns have the *no_summary* label, this can be overexpressed in the model at beam decoding time[2], we therefore experiment with sampling this label only $K\%$ of the time during training in Table 5. Example predictions (for the 5% sampling model) are shown in Figure 1. We find that subsampling gives better results and closer sparsity levels to the original human annotated data (e.g., with $K = 25\%$). We compare predicted summaries with $K = 5\%$ sampling to other methods of modeling long-context in Table 4. We observe results that are between using a standard dialogue history (predicted summaries are slightly better), and using gold summaries (predicted summaries are not as good).

Varying the number of training sessions We vary the amount of available training sessions from 1-4, with results reported in Table 6. We observe large gains when using more than one training session compared to only one (around 1.5 perplexity points), again justifying the construction of our MSC training data. The gains however decrease with the number of available sessions, e.g. between having 1-3 training sessions vs. 1-4 only gives a 0.03 perplexity gain averaged across sessions. The gain even on session 4 is not that large despite the 1-4 training data being in-distribution, whereas 1-3 is not, in addition to 1-4 having more training data.

Retrieval-augmentation model Comparison of our retrieval-augmented methods are given in Table 7, training on MSC using the BST 2.7B model as pre-training, hence called MSC 2.7B (RAG), (FiD) or (FiD-RAG), depending on the augmentation method. These methods are compared to the existing BlenderBot model (BST 2.7B), or training with MSC with no augmentation (MSC 2.7B with different dialogue history context truncation lengths). We find that all three retrieval augmentation methods, when using the session level-document size as retrieval documents, can effectively use retrieval to extend the conversation history length. We see a large performance improvement over the existing BlenderBot model or a truncation of 128 of the MSC 2.7B model. Performance improvements over MSC 2.7B with a truncation length of 1024 are minimal, but the retrieval-augmented models are guaranteed to have a memory that essentially never forgets the conversation, no matter how long it gets, whereas the truncation model does not.

Summary memory model variants We next compare the summary memory models, whereby

---

[2] We use a beam size of 3 and minimum beam length 10 with no context blocking.

Model	Reference own topic	Reference other's topic	New topic	Engaging Response	Final Rating	# Annotated Responses
BST 2.7B (Roller et al., 2020)	19.9%	14.5%	69.0%	53.0%	3.14	668
MSC 2.7B (truncate 128)	15.8%	21.8%	75.8%	56.5%	3.29	673
MSC 2.7B (truncate 1024)	15.0%	22.5%	74.4%	54.2%	3.47	653
SumMem-MSC 2.7B (RAG)	19.6%	33.8%	72.7%	**62.1%**	**3.65**	668
SumMem-MSC 2.7B (FiD)	22.1%	30.7%	76.4%	**58.9%**	**3.62**	662
SumMem-MSC 2.7B (FiD-RAG)	24.2%	26.4%	78.3%	**59.3%**	**3.68**	649

Table 8: **Human Evaluation Results.** Performance of various models measured during conversations with crowdworkers. Engaging response and final rating numbers in bold are statistically significant compared to BST 2.7B (p-value < 0.05) using a t-test. See subsection 5.1 and Appendix B for more details.

previous dialogue history is summarized before being stored in the model's long-term memory, called SumMem-MSC 2.7B. We use the RAG, FiD, or RAG-FiD methods to retrieve from that memory, or we compare to a fixed memory of 1024 tokens that is truncated, resulting in four different methods that we compare. Results are given in Table 7. While improvements are small, we see the same patterns as for the retrieval-augmented methods that SumMem-MSC 2.7B FiD-RAG is better than FiD which is in turn better than RAG, with FiD and FiD-RAG better than truncation at session openings. Moreover, all SumMem-MSC models outperform their retrieval-augmented model counterparts MSC 2.7B (RAG/FiD/FiD-RAG). SumMem-MSC 2.7B (FiD-RAG) thus provides the best results out of all methods tested in this work.

Further Detailed Automatic Metrics Our analysis so far measured perplexity. We report more automatic metrics (F1 and BLEU) in Appendix A, which yield similar conclusions.

5.1 Human Evaluation

We perform a human evaluation using crowdworkers. The conversations begin with two randomly chosen personas from the validation set, and one is assigned to the crowdworker who is asked to play that role. We select the conversation to be the 5^{th} session that these two speakers will converse, and make available the summary of the previous 4 sessions. We ask the crowdworkers to have a natural conversation, where they will also evaluate their partner's responses for conversational attributes, in particular whether they reference knowledge of their own or the other speaker's persona (or topics they discussed) from previous sessions, from the current session, or neither. On each turn of the conversation the crowdworker is asked to check all attribute boxes that apply. A screenshot can be found in Figure 6 in the Appendix showing the UI. Each conversation consists of 15 messages (7 from the human, 8 from the bot). At the end of the conversation, an additional question collects an overall engagingness score (out of 5) for their speaking partner.

The results are given in Table 8. We find that MSC-trained models outperform BlenderBot (BST 2.7B) in terms of both per-turn engaging responses and final ratings. Further, our summarization memory models (all three variants RAG, FiD and FiD-RAG) outperform encoder-decoders with different levels of truncation of the dialogue history (MSC 2.7B with truncate 128 and 1024). For example, SumMem-MSC 2.7B (RAG) achieves an engaging response rate of 62.1% and final rating of 3.65, compared to BlenderBot's 53.0% and 3.14 and MSC 2.7B (truncate 1024)'s 54.2% and 3.47. For all MSC models, while rates of referencing their own topics are not particularly increased, we do observe increased rates of referencing partner topics from previous sessions, with higher rates for the summarization memory models. For example, 33.8% for SumMem-MSC 2.7B (RAG) compared to BlenderBot's 14.5%. This is likely an important reason why human raters feel the summarization memory models are more engaging.

6 Conclusion

We have shown that existing dialogue models, both in terms of training data and models trained, fail to conduct long-term conversations adequately. Our work investigates recent model architectures to ameliorate this issue, and collects a new crowdsourced task, *Multi-Session Chat* to both train and evaluate these models. We show, in terms of both automatic metrics and human evaluations, that these long-context dialogue modeling approaches outperform the previous systems. Future work should investigate further improvements to architectures for the long-context dialogue setting.

7 Ethical Considerations

The dialogue models we use in this work utilize large language models, and therefore have similar concerns as in other work, in particular concerns about toxic language, bias and other issues during language generation (Bender et al., 2021). For open-domain dialogue in particular, see Xu et al. (2020); Dinan et al. (2021) for reviews of the literature and evaluation of recent methods that try to mitigate these safety issues.

Our work focuses on models with long-term memory and open-domain conversations wherein speakers may divulge personal interests. We remark that, during data collection, crowdworkers were specifically playing roles with given personality traits, not talking about themselves, and hence not identifying any personal information. During conversations with our trained models, the models will store information they learn from the exchange. In contrast to current standard language models, our models have the capability of storing this in the long-term. This information is stored in the memory of the model, private to the individual's conversation, and hence is not shared with anyone else.

A Extra Results

Further Test Set Metrics We show the test BLEU-1 in Table 11, test BLEU-2 in Table 12, test BLEU-4 in Table 13 and test F1 in Table 14.

Main Validation Results We show the validation perplexity in Table 15 (corresponding to the test perplexity in Table 7).

B Data Collection & Data Quality

B.1 Data Collection & Quality Control

Crowdsourced Data Collection The data collection lasted for around 6 months and in total over 1000 crowdworkers who are English-speaking annotators located in the United States were recruited and compensated through the Amazon Mechanical Turk platform. Before the data collection starts, all crowdworkers are informed that any message they send may be publicly disclosed for research purposes, and are instructed not to send any personal identifiable information (for example, name, address, email, or phone number etc.) in their messages.

Quality Control To optimize the quality of collected data, we implement a list of quality controls in both the conversation summarization task and the multi-session chat task. All crowdworkers must achieve high scores on the onboarding task that resembles the actual crowdsourcing tasks before they are eligible to work on the Human Intelligence Task (i.e. HIT, the term used by Amazon's Mechanical Turk to refer to a single instance of a crowdworker task). During the actual multi-session chat, crowdworkers are instructed to report at each conversational turn if the message from the other speaker is of poor quality or has BAD behaviors, for example, contradicting to or repeating what has been mentioned; changing topics too often, etc. A final rating is also collected at the end of each chat indicating how much they enjoy talking to their conversational partner. Crowdworkers that are frequently reported as producing messages of low quality or receiving low ratings are blocked from working on any future HITs. Moreover, dialogues that fail the acceptability checks such as minimum average message length or have too many dialogue turns rated as low quality are also filtered out from the final dataset.

We show screenshots of the crowdsourced Multi-Session Chat task in Figure 5 as well as the crowdsourced human evaluation task in Figure 6.

Split	Total	Unique	Unique%
Train	105429	105549	99.88%
Valid	17687	17691	99.97%
Test	17798	17803	99.97%

Table 9: **Utterance overlap by data split**.

B.2 Data Quality Analysis

Following analysis of previous datasets such as DailyDialogue that exposed significant overlap between train and test (Csaky and Recski, 2020; Csáky et al., 2019), we measure various overlap statistics on our newly collected dataset.

Table 9 gives statistics for the number of unique utterances in a given data split (comparing to all other utterances in the same data split). We see there are very few duplicated messages across crowdworkers. For example in the validation set there are only 4, these are: *"What kind of dogs do you have ?"*, *"How old are your children ?"*, *"What kind of dancing do you do ?"* and *"What kind of dog is he ?"*, i.e. very common questions that just happened to be asked twice each across different conversations.

Table 10 gives statistics for the number of unique utterances across data splits (comparing either valid or test utterances to all utterances in the train data split). We again see there are very few duplicated messages across data splits, looking at these specific messages we again see they are typical things that might be commonly asked.

C Dataset Examples

MSC Dataset Examples We show two MSC dialogue examples in Figure 2 and Figure 3 each consist of four sessions. We also show example summary annotations in Figure 1.

Session Opening Examples We show example session opening predictions of a model trained on gold summaries in Figure 4.

Split vs. Split	Overlap	Overlap%
Train vs. Valid	24	0.135%
Train vs. Test	45	0.252%

Table 10: **Utterance overlap across data splits**.

Table 12: **Test BLEU-2 across sessions** for our memory-augmented models compared to several encoder-decoder baselines (top two rows).

D Model Training Settings

We use the openly available ParlAI framework for all training runs, as well as for evaluations, where metrics are measured using default settings. All the fine-tuned models are trained with a maximum of eight 32GB GPUs (NVIDIA V100), optimized with Adam using $\beta_1 = 0.9$, $\beta_2 = 0.999$, $\epsilon = 1e-08$. Models are trained up to 4000 updates with batch size up to 128. The typical fine-tuning time for standard transformer encoder-decoder is 8 hrs before it early stops, and for retrieval-based model is 16 hrs.

Model	Session 1	Session 2	Session 3	Session 4	Session 5	Session Openings

Speaker 1 **Speaker 2**

....

I have been once and stayed the week. It was awesome. I want to go again.

I can not wait to go again!

I know I can not either. Do you like football?

Yes! My favorite team is the steelers. What is yours?

Redskins and packers. I played college.

label: The Redskins and the Packers are my favorite football teams. I like football. I played football in college.

model: I played football in college. My favorite football teams are the Redskins and the Packers.

Speaker 1 **Speaker 2**

....

Hi! I am an olympic gymnast, I don't read much.

That is exciting and must allow you to travel alot. Ever been to spain?

Yes, I've. I picked up a lovely yellow blouse there.

label: I have been to Spain. I bought a yellow blouse in Spain.

model: I have travelled to Spain.

Speaker 1 **Speaker 2**

....

That is my favorite. I eat alot since I'm a vegan.

I'm a vegetarian, so I eat a lot of hummus as well.

That's great, we have that in common!

My parents were culinary teachers, they taught me to cook.

label: My parents were culinary teachers.

model: I was taught how to cook by my parents.

Speaker 1 **Speaker 2**

...

I am cool thanks. You?

I'm alright, just taking a break. Spent the morning working in the fields with dad.

label: I work in the fields with my dad.

model: I have a dad. I work in a field.

Speaker 1 **Speaker 2**

....

Now that's something happy to talk about! I work in the industry

What industry do you work in?

Okay, so tell me more about yourself

label: NONE

model: NONE

Figure 1: Example summary annotations and predictions on the validation set. We show the gold human annotation (label) and our model prediction (model).

Speaker 1 **Speaker 2**

Hello, how are you doing?

Hello. Pretty good, thanks. And yourself?

Awesome, I just got back from a bike ride.

Cool! Do you spend a lot of time biking?

Yup. Its my favorite thing to do. Do you?

I love playing folk music. I actually hope to be a professional musician someday

That's interesting. What instruments do you play?

I can play the guitar and the piano and I also like to sing.

I can only sing when I drink, but I don't like to do that anymore.

I m not a big drinker either. Do you have a job?

Construction, like my dad. What do you do when you aren't being a rock star

Nice! I work as a custodian. Not too glamorous but it pays the bills haha

I feel ya. You gotta do what you gotta do.

Exactly. Do you have other hobbies besides biking?

[6 hours later]

Today's weather was beautiful for biking. It was the first thing I did after my long day working my construction job. Did you get to play any guitar or piano today? Or perhaps a drink at a local bar?

I did fiddle around with my guitar a little. I played some Bob Dylan after I ate.

Nice. Is Dylan a favorite of yours? I haven't been much into music in a long time but sometimes I wish I listened to more.

Yes, I've always loved Dylan. I think he's such a musical genius. He's not the only reason I want to get into music, but he's one of them.

Since you're so interested in music, do you ever get out to see local bands? I used to go to concerts every few months when I was younger.

Yes, I try to stay connected to the local music scene, and also try to see bigger acts when they come to town, although money and time are always consideration too. What was the last concert you went to?

Yeah, it's definitely hard to find time nowadays. I think the last concert I went to see might have been a pair of cellists with some friends. I think they were called 2Cellos but I could be mistaken.

Oh, nice. Have you heard of Mark O'Connor? I once saw him in concert with Yo-Yo Ma. That was amazing.

Yeah, I think I ran across some of his performances on YouTube at some point. I could listen to violin and cello music all the time if I had the opportunity. I like to put on videos in the background to provide some background noise. And an occasional distraction.

Yes, I love listening to classic or baroque if I'm doing something that needs concentration. Do you listen to music when you ride your bike?

I should. Usually I'm listening to podcasts when I'm riding my bike. Since I don't have much time I try to keep abreast of current events that way.

Yes, that's a good time to kill two birds with one stone. I've never really gotten into podcasts. What type of podcast topics do you listen to?

[4 hours later]

I watched a really cool Youtube video about how Cellos are made.

Cool any process of making an instrument is beautiful to me. Did you search it up or was it a recommend youtube video?

It was recommended to me. You know how those algorithms sometimes seem to read your mind. But I saw the thumbnail and started watching and got hooked.

Those thumbnails really get you to watch just about anything. Whats your favorite podcast to listen to?

I tend to bounce around. I think I get hooked by the personalities and then sort of get tired of them. But right now I'm listening to one that talks about unsolved crimes.

Very cool, my dad listened to a podcast about the zodiac killer a while back, its an interesting story. Where do you usually ride your bike?

I mostly ride on streets, albeit pretty quiet streets. But sometimes I'll take my bike and go on trails or off road. It take a little longer to do those types of rides, though, so I do them less frequently.

A nice bike ride feels great especially in perfect climate. Whats your favorite drink?

Well, I used to like a nice rum and Coke back when I was drinking more. But now I love a lemonade as a treat on a hot summer day, and coconut water most other days. How about you?

I don't tend to drink that much but when i do i like to sip on some Kentucky Bourbon. Blanton is my favorite. Do you have your own construction company or do you work for somebody?

I work for someone. I got the job through my dad. They company and owner have been good to my family so I'm happy to work for him.

Thats great to hear, connections go a long way.

[4 hours later]

I've just watched another really interesting video about how guitars are made.

That sounds so cool! What is the most interesting fact that you learned?

I didn't know guitar strings were mostly made of steel and nickel.

That is really interesting, are violin and cello strings also made of steel and nickel, I wonder?

Good question, not sure of cello, but violin strings are made of different material depending on the chord. Could be nylon, steel or even sheep intestine!

Sheep intestine! I have never heard of that. Has it inspired you to listen to more music?

No, actually, it has inspired me to drink more bourbon and to find out how it's made!

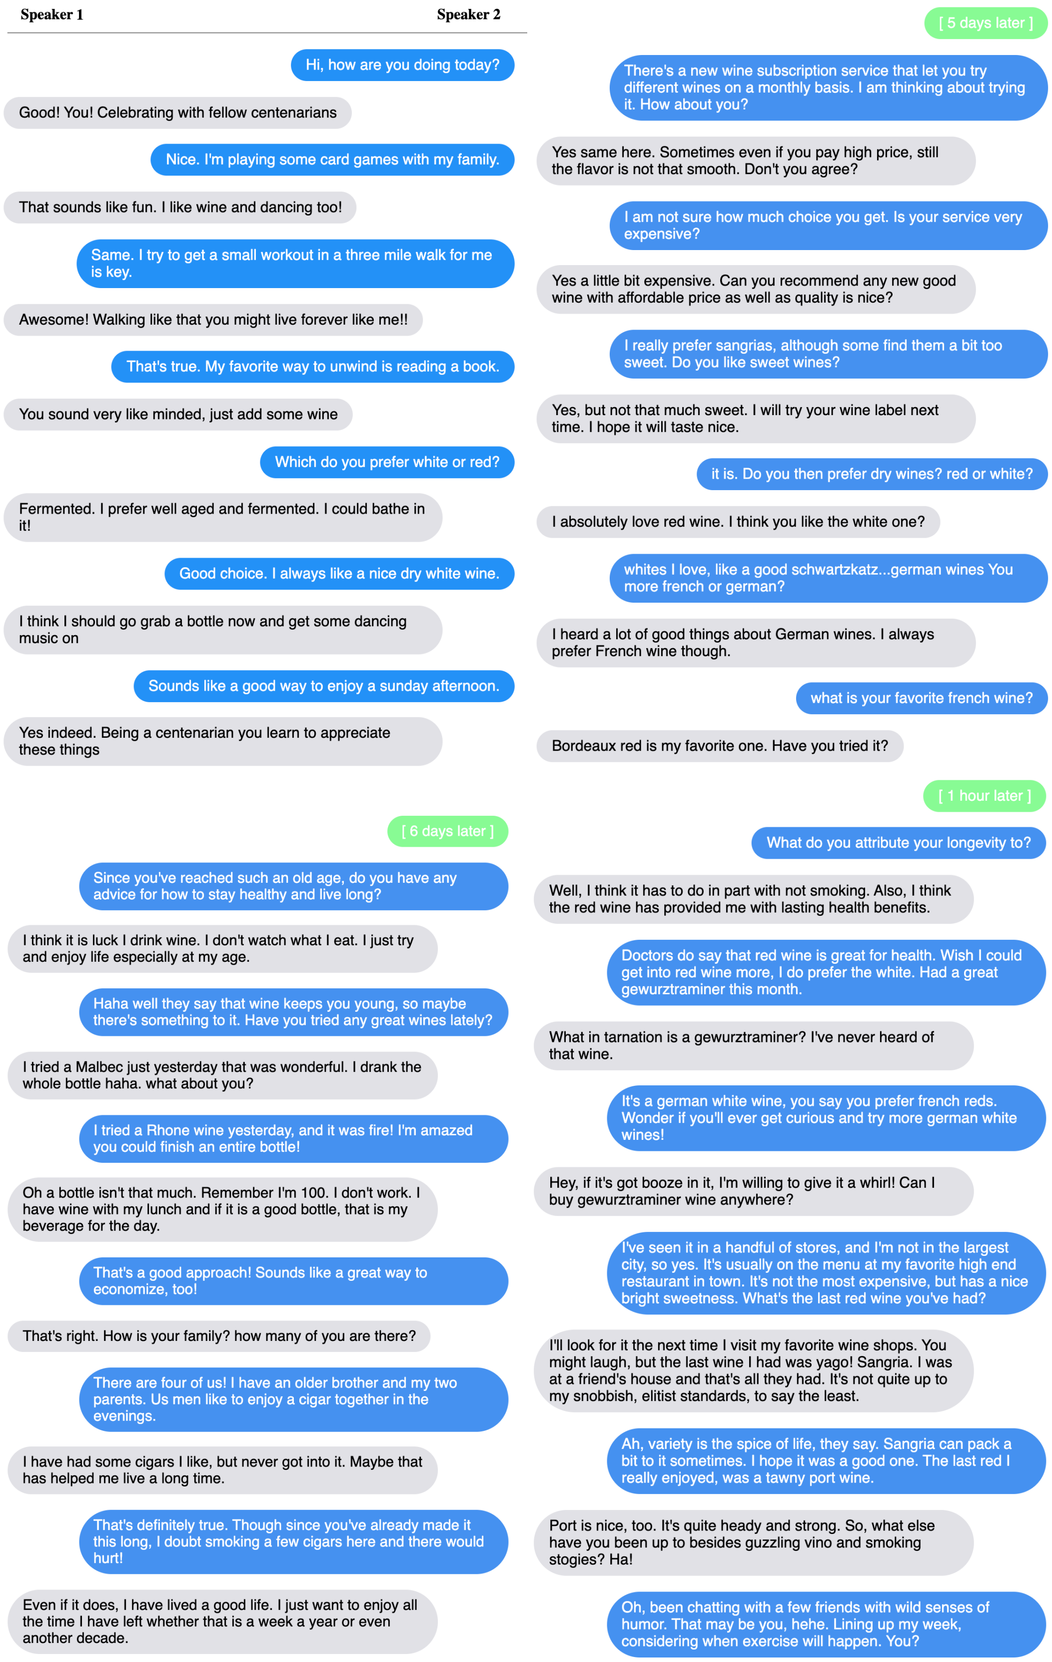
That is a great idea! I sure do love my bourbon, but I have no idea how it is made. You have a curious mind! What is your favorite subject to read or study up on?

I am fascinated by forensics related to unsolved crimes.

That sounds extremely fascinating. Have you ever watched the series "mindhunter"? Not unsolved crimes, but getting into the minds of serial killers. Pretty cool.

No, never saw it, but I will look into it...is it available on netflix?

Figure 2: Example four session conversation from the newly collected Multi-Session Chat dataset. New sessions refer back to previous subjects, explore them in depth, or spark up conversation on new topics.



Speaker 1 **Speaker 2**

Hi, how are you doing today?

Good! You! Celebrating with fellow centenarians

Nice. I'm playing some card games with my family.

That sounds like fun. I like wine and dancing too!

Same. I try to get a small workout in a three mile walk for me is key.

Awesome! Walking like that you might live forever like me!!

That's true. My favorite way to unwind is reading a book.

You sound very like minded, just add some wine

Which do you prefer white or red?

Fermented. I prefer well aged and fermented. I could bathe in it!

Good choice. I always like a nice dry white wine.

I think I should go grab a bottle now and get some dancing music on

Sounds like a good way to enjoy a sunday afternoon.

Yes indeed. Being a centenarian you learn to appreciate these things

[6 days later]

Since you've reached such an old age, do you have any advice for how to stay healthy and live long?

I think it is luck I drink wine. I don't watch what I eat. I just try and enjoy life especially at my age.

Haha well they say that wine keeps you young, so maybe there's something to it. Have you tried any great wines lately?

I tried a Malbec just yesterday that was wonderful. I drank the whole bottle haha. what about you?

I tried a Rhone wine yesterday, and it was fire! I'm amazed you could finish an entire bottle!

Oh a bottle isn't that much. Remember I'm 100. I don't work. I have wine with my lunch and if it is a good bottle, that is my beverage for the day.

That's a good approach! Sounds like a great way to economize, too!

That's right. How is your family? how many of you are there?

There are four of us! I have an older brother and my two parents. Us men like to enjoy a cigar together in the evenings.

I have had some cigars I like, but never got into it. Maybe that has helped me live a long time.

That's definitely true. Though since you've already made it this long, I doubt smoking a few cigars here and there would hurt!

Even if it does, I have lived a good life. I just want to enjoy all the time I have left whether that is a week a year or even another decade.

[5 days later]

There's a new wine subscription service that let you try different wines on a monthly basis. I am thinking about trying it. How about you?

Yes same here. Sometimes even if you pay high price, still the flavor is not that smooth. Don't you agree?

I am not sure how much choice you get. Is your service very expensive?

Yes a little bit expensive. Can you recommend any new good wine with affordable price as well as quality is nice?

I really prefer sangrias, although some find them a bit too sweet. Do you like sweet wines?

Yes, but not that much sweet. I will try your wine label next time. I hope it will taste nice.

it is. Do you then prefer dry wines? red or white?

I absolutely love red wine. I think you like the white one?

whites I love, like a good schwartzkatz...german wines You more french or german?

I heard a lot of good things about German wines. I always prefer French wine though.

what is your favorite french wine?

Bordeaux red is my favorite one. Have you tried it?

[1 hour later]

What do you attribute your longevity to?

Well, I think it has to do in part with not smoking. Also, I think the red wine has provided me with lasting health benefits.

Doctors do say that red wine is great for health. Wish I could get into red wine more, I do prefer the white. Had a great gewurztraminer this month.

What in tarnation is a gewurztraminer? I've never heard of that wine.

It's a german white wine, you say you prefer french reds. Wonder if you'll ever get curious and try more german white wines!

Hey, if it's got booze in it, I'm willing to give it a whirl! Can I buy gewurztraminer wine anywhere?

I've seen it in a handful of stores, and I'm not in the largest city, so yes. It's usually on the menu at my favorite high end restaurant in town. It's not the most expensive, but has a nice bright sweetness. What's the last red wine you've had?

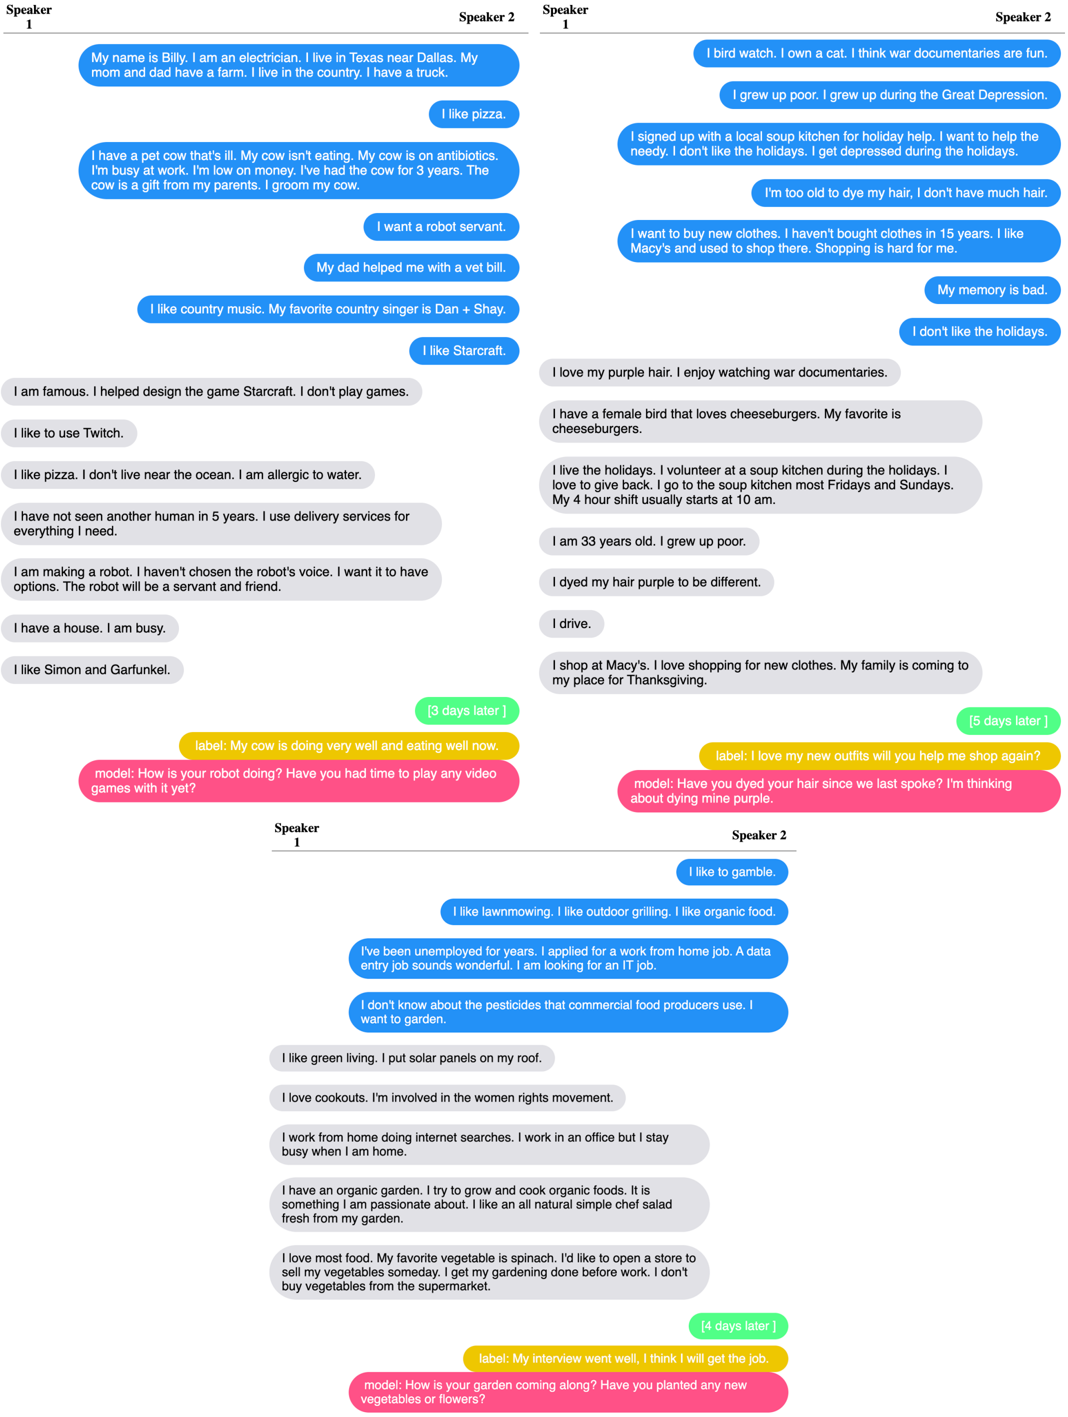
I'll look for it the next time I visit my favorite wine shops. You might laugh, but the last wine I had was yago! Sangria. I was at a friend's house and that's all they had. It's not quite up to my snobbish, elitist standards, to say the least.

Ah, variety is the spice of life, they say. Sangria can pack a bit to it sometimes. I hope it was a good one. The last red I really enjoyed, was a tawny port wine.

Port is nice, too. It's quite heady and strong. So, what else have you been up to besides guzzling vino and smoking stogies? Ha!

Oh, been chatting with a few friends with wild senses of humor. That may be you, hehe. Lining up my week, considering when exercise will happen. You?

Figure 3: Example four session conversation from the newly collected Multi-Session Chat dataset. New sessions refer back to previous subjects, explore them in depth, or spark up conversation on new topics.



Speaker 1

Speaker 2

My name is Billy. I am an electrician. I live in Texas near Dallas. My mom and dad have a farm. I live in the country. I have a truck.

I like pizza.

I have a pet cow that's ill. My cow isn't eating. My cow is on antibiotics. I'm busy at work. I'm low on money. I've had the cow for 3 years. The cow is a gift from my parents. I groom my cow.

I want a robot servant.

My dad helped me with a vet bill.

I like country music. My favorite country singer is Dan + Shay.

I like Starcraft.

I am famous. I helped design the game Starcraft. I don't play games.

I like to use Twitch.

I like pizza. I don't live near the ocean. I am allergic to water.

I have not seen another human in 5 years. I use delivery services for everything I need.

I am making a robot. I haven't chosen the robot's voice. I want it to have options. The robot will be a servant and friend.

I have a house. I am busy.

I like Simon and Garfunkel.

[3 days later]

label: My cow is doing very well and eating well now.

model: How is your robot doing? Have you had time to play any video games with it yet?

Speaker 1

Speaker 2

I bird watch. I own a cat. I think war documentaries are fun.

I grew up poor. I grew up during the Great Depression.

I signed up with a local soup kitchen for holiday help. I want to help the needy. I don't like the holidays. I get depressed during the holidays.

I'm too old to dye my hair, I don't have much hair.

I want to buy new clothes. I haven't bought clothes in 15 years. I like Macy's and used to shop there. Shopping is hard for me.

My memory is bad.

I don't like the holidays.

I love my purple hair. I enjoy watching war documentaries.

I have a female bird that loves cheeseburgers. My favorite is cheeseburgers.

I live the holidays. I volunteer at a soup kitchen during the holidays. I love to give back. I go to the soup kitchen most Fridays and Sundays. My 4 hour shift usually starts at 10 am.

I am 33 years old. I grew up poor.

I dyed my hair purple to be different.

I drive.

I shop at Macy's. I love shopping for new clothes. My family is coming to my place for Thanksgiving.

[5 days later]

label: I love my new outfits will you help me shop again?

model: Have you dyed your hair since we last spoke? I'm thinking about dying mine purple.

Speaker 1

Speaker 2

I like to gamble.

I like lawnmowing. I like outdoor grilling. I like organic food.

I've been unemployed for years. I applied for a work from home job. A data entry job sounds wonderful. I am looking for an IT job.

I don't know about the pesticides that commercial food producers use. I want to garden.

I like green living. I put solar panels on my roof.

I love cookouts. I'm involved in the women rights movement.

I work from home doing internet searches. I work in an office but I stay busy when I am home.

I have an organic garden. I try to grow and cook organic foods. It is something I am passionate about. I like an all natural simple chef salad fresh from my garden.

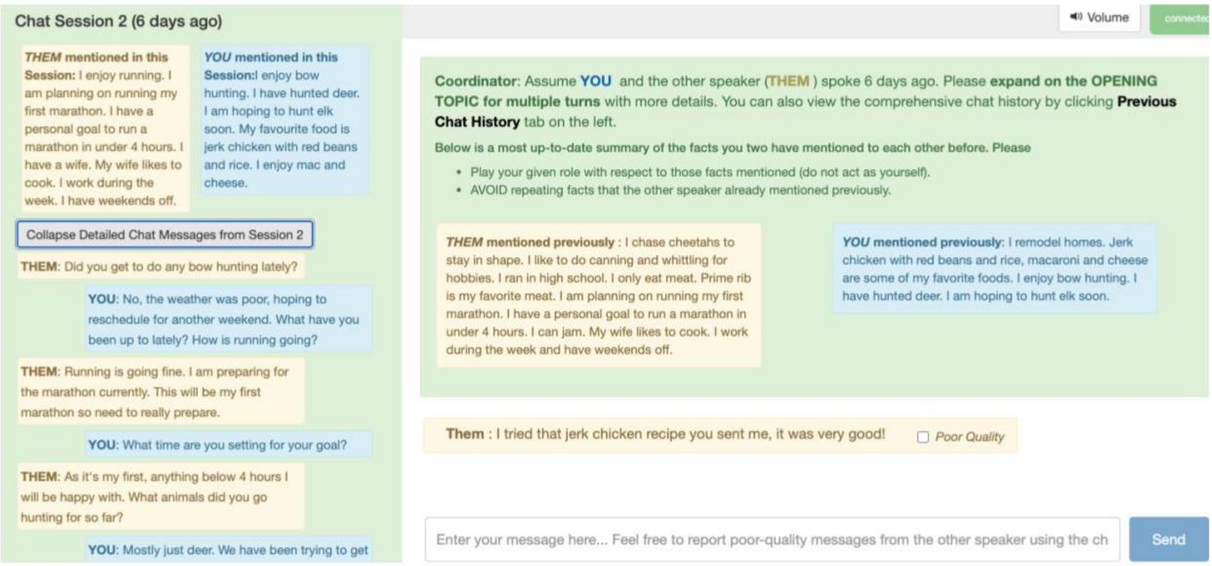
I love most food. My favorite vegetable is spinach. I'd like to open a store to sell my vegetables someday. I get my gardening done before work. I don't buy vegetables from the supermarket.

[4 days later]

label: My interview went well, I think I will get the job.

model: How is your garden coming along? Have you planted any new vegetables or flowers?

Figure 4: Example opening annotations and predictions given gold summaries on the validation set. We show the gold human annotation (label) and our model prediction (model).



Chat Session 2 (6 days ago)

***THEM* mentioned in this Session:** I enjoy running. I am planning on running my first marathon. I have a personal goal to run a marathon in under 4 hours. I have a wife. My wife likes to cook. I work during the week. I have weekends off.

***YOU* mentioned in this Session:**I enjoy bow hunting. I have hunted deer. I am hoping to hunt elk soon. My favourite food is jerk chicken with red beans and rice. I enjoy mac and cheese.

Collapse Detailed Chat Messages from Session 2

THEM: Did you get to do any bow hunting lately?

YOU: No, the weather was poor, hoping to reschedule for another weekend. What have you been up to lately? How is running going?

THEM: Running is going fine. I am preparing for the marathon currently. This will be my first marathon so need to really prepare.

YOU: What time are you setting for your goal?

THEM: As it's my first, anything below 4 hours I will be happy with. What animals did you go hunting for so far?

YOU: Mostly just deer. We have been trying to get

Coordinator: Assume **YOU** and the other speaker (**THEM**) spoke 6 days ago. Please **expand on the OPENING TOPIC for multiple turns** with more details. You can also view the comprehensive chat history by clicking **Previous Chat History** tab on the left.

Below is a most up-to-date summary of the facts you two have mentioned to each other before. Please

- Play your given role with respect to those facts mentioned (do not act as yourself).
- AVOID repeating facts that the other speaker already mentioned previously.

***THEM* mentioned previously** : I chase cheetahs to stay in shape. I like to do canning and whittling for hobbies. I ran in high school. I only eat meat. Prime rib is my favorite meat. I am planning on running my first marathon. I have a personal goal to run a marathon in under 4 hours. I can jam. My wife likes to cook. I work during the week and have weekends off.

***YOU* mentioned previously**: I remodel homes. Jerk chicken with red beans and rice, macaroni and cheese are some of my favorite foods. I enjoy bow hunting. I have hunted deer. I am hoping to hunt elk soon.

Them : I tried that jerk chicken recipe you sent me, it was very good! ☐ *Poor Quality*

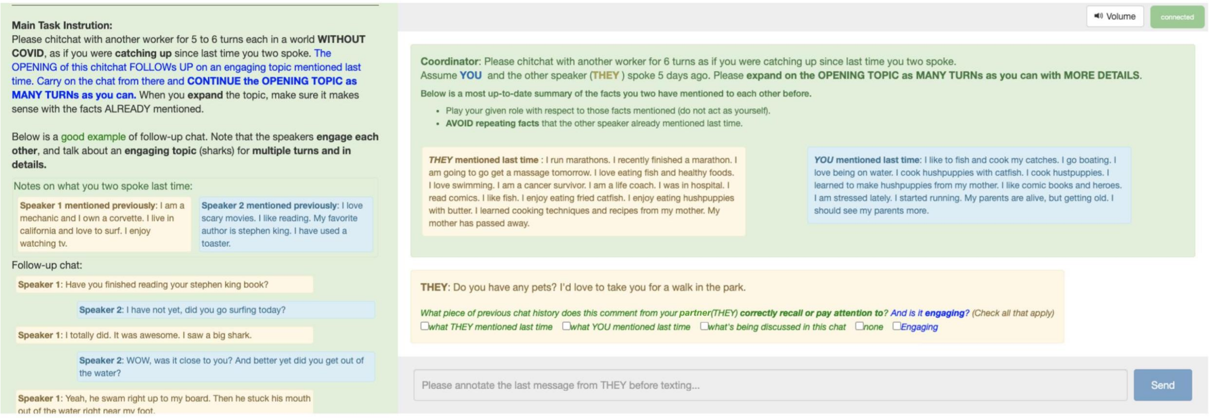
Figure 5: Screenshot from the crowdworker multi-session chat. The left panel shows the instructions as well as all dialogue history from previous sessions, and the right panel contains the conversation for the current session.



Main Task Instrution:
Please chitchat with another worker for 5 to 6 turns each in a world **WITHOUT COVID**, as if you were **catching up** since last time you two spoke. The OPENING of this chitchat FOLLOWs UP on an engaging topic mentioned last time. Carry on the chat from there and **CONTINUE the OPENING TOPIC as MANY TURNs as you can.** When you **expand** the topic, make sure it makes sense with the facts ALREADY mentioned.

Below is a good example of follow-up chat. Note that the speakers **engage each other**, and talk about an **engaging topic** (sharks) for **multiple turns and in details.**

Notes on what you two spoke last time:

Speaker 1 mentioned previously: I am a mechanic and I own a corvette. I live in california and love to surf. I enjoy watching tv.

Speaker 2 mentioned previously: I love scary movies. I like reading. My favorite author is stephen king. I have used a toaster.

Follow-up chat:

Speaker 1: Have you finished reading your stephen king book?

Speaker 2: I have not yet, did you go surfing today?

Speaker 1: I totally did. It was awesome. I saw a big shark.

Speaker 2: WOW, was it close to you? And better yet did you get out of the water?

Speaker 1: Yeah, he swam right up to my board. Then he stuck his mouth out of the water right near my foot.

Coordinator: Please chitchat with another worker for 6 turns as if you were catching up since last time you two spoke.
Assume **YOU** and the other speaker (**THEY**) spoke 5 days ago. Please **expand on the OPENING TOPIC as MANY TURNs as you can with MORE DETAILS**.

Below is a most up-to-date summary of the facts you two have mentioned to each other before.

- Play your given role with respect to those facts mentioned (do not act as yourself).
- **AVOID repeating facts** that the other speaker already mentioned last time.

***THEY* mentioned last time** : I run marathons. I recently finished a marathon. I am going to go get a massage tomorrow. I love eating fish and healthy foods. I love swimming. I am a cancer survivor. I am a life coach. I was in hospital. I read comics. I like fish. I enjoy eating fried catfish. I enjoy eating hushpuppies with butter. I learned cooking techniques and recipes from my mother. My mother has passed away.

***YOU* mentioned last time**: I like to fish and cook my catches. I go boating. I love being on water. I cook hushpuppies with catfish. I cook hustpuppies. I learned to make hushpuppies from my mother. I like comic books and heroes. I am stressed lately. I started running. My parents are alive, but getting old. I should see my parents more.

THEY: Do you have any pets? I'd love to take you for a walk in the park.

What piece of previous chat history does this comment from your partner(THEY) ***correctly recall or pay attention to****? And is it* ***engaging****? (Check all that apply)*
☐*what THEY mentioned last time* ☐*what YOU mentioned last time* ☐*what's being discussed in this chat* ☐*none* ☐*Engaging*

Please annotate the last message from THEY before texting...

Figure 6: Crowdworker evaluation task screenshots. The left panel shows the instructions, and the right panel contains the conversation. In the human evaluation results in the main paper the "what THEY mentioned last time" binary checkbox is converted to a percentage over all annotated responses, and termed "Reference own topic" in Table 8. Similarly, "what YOU mentioned last time" is termed "Reference other's topic" in Table 8.

ReCLIP: A Strong Zero-Shot Baseline for Referring Expression Comprehension

Abstract

Training a referring expression comprehension (ReC) model for a new visual domain requires collecting referring expressions, and potentially corresponding bounding boxes, for images in the domain. While large-scale pre-trained models are useful for image classification across domains, it remains unclear if they can be applied in a zero-shot manner to more complex tasks like ReC. We present ReCLIP, a simple but strong *zero-shot* baseline that repurposes CLIP, a state-of-the-art large-scale model, for ReC. Motivated by the close connection between ReC and CLIP's contrastive pre-training objective, the first component of ReCLIP is a region-scoring method that isolates object proposals via cropping and blurring, and passes them to CLIP. However, through controlled experiments on a synthetic dataset, we find that CLIP is largely incapable of performing spatial reasoning off-the-shelf. Thus, the second component of ReCLIP is a spatial relation resolver that handles several types of spatial relations. We reduce the gap between zero-shot baselines from prior work and supervised models by as much as 29% on RefCOCOg, and on RefGTA (video game imagery), ReCLIP's relative improvement over supervised ReC models trained on real images is 8%.

1 Introduction

Visual referring expression comprehension (ReC)—the task of localizing an object in an image given a textual referring expression—has applications in a broad range of visual domains. For example, ReC is useful for guiding a robot in the real world (Shridhar et al., 2020) and also for creating natural language interfaces for software applications with visuals (Wichers et al., 2018). Though the task is the same across domains, the domain shift is problematic for supervised referring expression models, as shown in Figure 1: the same simple referring expression is localized correctly in the training domain but incorrectly in a new domain.

(a) RefCOCO+ (Yu et al., 2016)

(b) RefGTA (Tanaka et al., 2019)

Figure 1: Predictions from ReCLIP (cyan) and UNITER-Large (Chen et al., 2020) (red) for the same referring expression on images from two visual domains. UNITER-Large fails on the GTA (video game) domain, while ReCLIP selects the correct proposal in both cases. Close-ups of the two GTA boxes are shown.

Collecting task-specific data in each domain of interest is expensive. Weakly supervised ReC (Rohrbach et al., 2016) partially addresses this issue, since it does not require the ground-truth box for each referring expression, but it still assumes the availability of referring expressions paired with images and trains on these. Given a large-scale pre-trained vision and language model and a method for doing ReC zero-shot—i.e. without any addi-

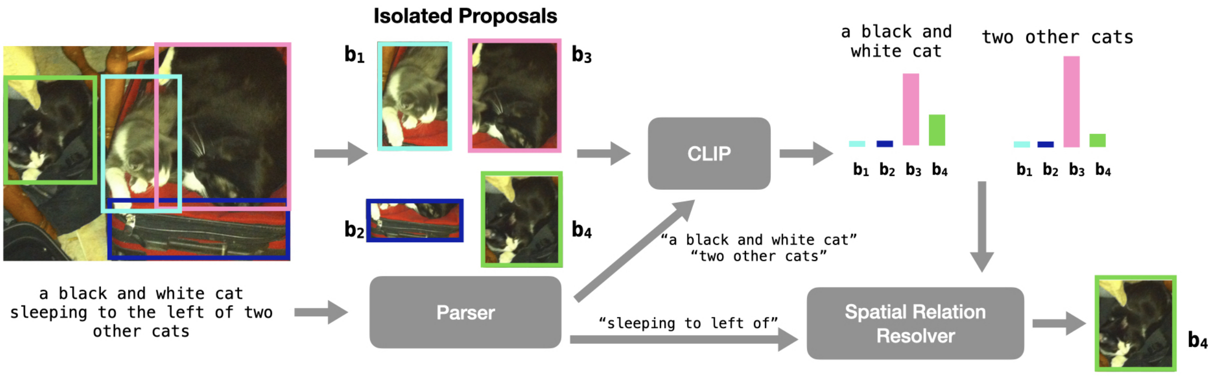

Figure 2: Overview of ReCLIP. Given object proposals, we isolate the corresponding image regions by cropping and blurring (only cropping shown here). Using a parser, we extract the noun chunks of the expression. For each noun chunk, CLIP outputs a distribution over proposals. The relations from the parser and CLIP's probabilities are combined by a spatial relation resolver to select the final proposal. In this example, CLIP ranks b_3 highest for both noun chunks, but using the relation resolver we obtain the correct answer b_4.

tional training—practitioners could save a great deal of time and effort. Moreover, as pre-trained models have become more accurate via scaling (Kaplan et al., 2020), fine-tuning the best models has become prohibitively expensive–and sometimes infeasible because the model is offered only via API, e.g. GPT-3 (Brown et al., 2020).

Pre-trained vision and language models like CLIP (Radford et al., 2021) achieve strong zero-shot performance in image classification across visual domains (Jia et al., 2021) and in object detection (Gu et al., 2021), but the same success has not yet been achieved in tasks requiring reasoning over vision and language. For example, Shen et al. (2021) show that a straightforward zero-shot approach for VQA using CLIP performs poorly. Specific to ReC, Yao et al. (2021) introduce a zero-shot approach via Colorful Prompt Tuning (CPT), which colors object proposals and references the color in the text prompt to score proposals, but this has low accuracy. In both of these cases, the proposed zero-shot method is not aligned closely enough with the model's pre-training task of matching naturally occurring images and captions.

In this work, we propose ReCLIP, a simple but strong new baseline for zero-shot ReC. ReCLIP, illustrated in Figure 2, has two key components: a method for scoring object proposals using CLIP and a method for handling spatial relations between objects. Our method for scoring region proposals, Isolated Proposal Scoring (IPS), effectively reduces ReC to the contrastive pre-training task used by CLIP and other models. Specifically, we propose to isolate individual proposals via cropping and blurring the images and to score these isolated proposals with the given expression using CLIP.

To handle relations between objects, we first consider whether CLIP encodes the spatial information necessary to resolve these relations. We show through a controlled experiment on CLEVR images (Johnson et al., 2017) that CLIP and another pre-trained model ALBEF (Li et al., 2021) are unable to perform its pre-training task on examples that require spatial reasoning. Thus, any method that solely relies on these models is unlikely to resolve spatial relations accurately. Consequently, we propose spatial heuristics for handling spatial relations in which an expression is decomposed into subqueries, CLIP is used to compute proposal probabilities for each subquery, and the outputs for all subqueries are combined with simple rules.

On the standard RefCOCO/g/+ datasets (Mao et al., 2016; Yu et al., 2016), we find that ReCLIP outperforms CPT (Yao et al., 2021) by about 20%. Compared to a stronger GradCAM (Selvaraju et al., 2017) baseline, ReCLIP obtains better accuracy on average and has less variance across object types. Finally, in order to illustrate the practical value of zero-shot grounding, we also demonstrate that our zero-shot method surpasses the out-of-domain performance of state-of-the-art supervised ReC models. We evaluate on the RefGTA dataset (Tanaka et al., 2019), which contains images from a video game (out of domain for models trained only on real photos). Using ReCLIP and an object detector trained outside the target domain, we outperform UNITER-Large (Chen et al., 2020) (using the same proposals) and MDETR (Kamath et al., 2021) by an absolute 4.5% (relative improvement of 8%).

In summary, our contributions include: (1) ReCLIP, a zero-shot method for referring expression comprehension, (2) showing that CLIP has low zero-shot spatial reasoning performance, and (3) a comparison of our zero-shot ReC performance with the out-of-domain performance of state-of-the-art fully supervised ReC systems.[1]

2 Background

In this section, we first describe the task at hand (§2.1) and introduce CLIP, the pre-trained model we primarily use (§2.2). We then describe two existing methods for scoring region proposals using a pre-trained vision and language model: colorful prompt tuning (§2.3) and GradCAM (§2.4).

2.1 Task description

In referring expression comprehension (ReC), the model is given an image and a textual referring expression describing an entity in the image. The goal of the task is to select the object (bounding box) that best matches the expression. As in much of the prior work on REC, we assume access to a set of object proposals $b_1, b_2, ..., b_n$, each of which is a bounding box in the image. Task accuracy is measured as the percentage of instances for which the model selects a proposal whose intersection-over-union (IoU) with the ground-truth box is at least 0.5. In this paper, we focus on the *zero-shot* setting in which we apply a pre-trained model to ReC without using any training data for the task.

2.2 Pre-trained model architecture

The zero-shot approaches that we consider are general in that the only requirement for the pre-trained model is that when given a *query* consisting of an image and text, it computes a score for the similarity between the image and text. In this paper, we primarily use CLIP (Radford et al., 2021). We focus on CLIP because it was pre-trained on 400M image-caption pairs collected from the web[2] and therefore achieves impressive zero-shot image classification performance on a variety of visual domains. CLIP has an image-only encoder, which is either a ResNet-based architecture (He et al., 2016) or a visual transformer (Dosovitskiy et al., 2021), and a text-only transformer. We mainly use the RN50x16 and ViT-B/32 versions of CLIP. The image encoder takes the raw image and produces an image representation $\mathbf{x} \in \mathbb{R}^d$, and the text transformer takes the sequence of text tokens and produces a text representation $\mathbf{y} \in \mathbb{R}^d$. In CLIP's contrastive pre-training task, given a batch of N images and matching captions, each image must be matched with the corresponding text. The model's probability of matching image i with caption j is given by $\exp(\beta \mathbf{x_i}^T \mathbf{y_j}) / \sum_{k=1}^{N} \exp(\beta \mathbf{x_i}^T \mathbf{y_k})$, where β is a hyperparameter.[3]

We now describe two techniques from prior work for selecting a proposal using a pre-trained model.

2.3 Colorful Prompt Tuning (CPT)

The first baseline from prior work that we consider is colorful prompt tuning (CPT), proposed by Yao et al. (2021) [4]: they shade proposals with different colors and use a masked language prompt in which the referring expression is followed by "in [MASK] color". The color with the highest probability from a pre-trained masked language model (MLM) (VinVL; (Zhang et al., 2021)) is then chosen. In order to apply this method to models like CLIP, that provide image-text scores but do not offer an MLM, we create a version of the input image for each proposal, where the proposal is transparently shaded in red.[5] Our template for the input text is "[referring expression] is in red color." Since we have adapted CPT for non-MLM models, we refer to this method as *CPT-adapted* in the experiments.

2.4 Gradient-based visualizations

The second baseline from prior work that we consider is based on gradient-based visualizations, which are a popular family of techniques for understanding, on a range of computer vision tasks, which part(s) of an input image are most important to a model's prediction. We focus on the most popular technique in this family, GradCAM (Selvaraju et al., 2017). Our usage of GradCAM follows Li et al. (2021), in which GradCAM is used to perform weakly supervised referring expression comprehension using the ALBEF model. In our setting, for a given layer in a visual transformer, we take the layer's class-token (CLS) attention matrix $M \in \mathbb{R}^{h,w}$. The spatial dimensions h and w are dependent on the model's architecture and are generally smaller than the input dimensions

---

[1] Our code is available at `https://www.github.com/allenai/reclip`.

[2] This dataset is not public.

[3] $\mathbf{x_i}$ and $\mathbf{y_i}$ are normalized before the dot product.

[4] CPT is the name given by Yao et al. (2021), but note that we do not perform few-shot/supervised tuning.

[5] Specifically, we use the RGB values (240, 0, 30) and transparency 127/255 that Yao et al. (2021) say works best with their method. An example is shown in Appendix B.

of the image. Then the GradCAM is computed as $G = M \odot \frac{\partial L}{\partial M}$, where L is the model's output logit (the similarity score for the image-text pair) and $\odot$ denotes elementwise multiplication. The procedure for applying GradCAM when the visual encoder is a convolutional network is similar; in place of the attention matrix, we use the activations of the final convolutional layer. Next, we perform a bicubic interpolation on G so that it has the same dimensions as the input image. Finally, we compute for each proposal $b_i = (x_1, y_1, x_2, y_2)$ the score $\frac{1}{A^\alpha} \sum_{i=x_1}^{x_2} \sum_{j=y_1}^{y_2} G[i, j]$, where A is the area of the image and α is a hyperparameter, and we choose the proposal with the highest score.

3 ReCLIP

ReCLIP consists of two main components: (1) a region-scoring method that is different from CPT and GradCAM and (2) a rule-based relation resolver. In this section, we first describe our region scoring method (§3.1). However, using controlled experiments on a synthetic dataset, we find that CLIP has poor zero-shot spatial reasoning performance (§3.2). Therefore, we propose a system that uses heuristics to resolve spatial relations (§3.3).

3.1 Isolated Proposal Scoring (IPS)

Our proposed method, which we call *isolated proposal scoring*, is based on the observation that ReC is similar to the contrastive learning task with which models like CLIP are pre-trained, except that rather than selecting one out of several images to match with a given text, we must select one out of several image regions. Therefore, for each proposal, we create a new image in which that proposal is isolated. We consider two methods of isolation – *cropping* the image to contain only the proposal and *blurring* everything in the image except for the proposal region. For blurring, we apply a Gaussian filter with standard deviation σ to the image RGB values. Appendix A.2 provides an example of isolation by blurring. The score for an isolated proposal is obtained by passing it and the expression through the pre-trained model. To use cropping and blurring in tandem, we obtain a score s_{crop} and s_{blur} for each proposal and use $s_{crop} + s_{blur}$ as the final score. This can be viewed as an ensemble of "visual prompts," analogous to Radford et al. (2021)'s ensembling of text prompts.

Model	Text-pair Spatial	Text-pair Non-spatial	Image-pair Spatial	Image-pair Non-spatial
CLIP RN50x4	43.39	89.83	48.90	97.36
CLIP RN50x16	51.19	89.83	50.22	96.48
CLIP RN50x64	47.80	94.58	51.54	97.36
CLIP ViT-B/32	48.47	95.25	48.90	96.48
CLIP ViT-B/16	50.51	92.54	50.22	96.92
CLIP ViT-L/14	52.88	96.27	50.66	94.27

Table 1: Accuracy on CLEVR image-text matching task. CLIP performs well on the non-spatial version of the task but poorly on the spatial version. Text-pair tasks have 295 instances each; image-pair tasks have 227 instances each.

3.2 Can we use CLIP to resolve spatial relations?

A key limitation in Isolated Proposal Scoring is that relations between objects in different proposals are not taken into account. For example, in Figure 2, the information about the spatial relationships among the cats is lost when the proposals are isolated. In order to use CLIP to decide which object has a specified relation to another object, the model's output must encode the spatial relation in question. Therefore, we design an experiment to determine whether a pre-trained model, such as CLIP, can understand spatial relations within the context of its pre-training task. We generate synthetic images using the process described for the CLEVR dataset (Johnson et al., 2017). These scenes include three shapes–spheres, cubes, and cylinders–and eight colors–gray, blue, green, cyan, yellow, purple, brown, red.

In the *text-pair* version of our tasks, using the object attribute and position information associated with each image, we randomly select one of the pairwise relationships between objects–left, right, front, or behind–and construct a sentence fragment based on it. For example: "A blue sphere to the left of a red cylinder." We also write a distractor fragment that replaces the relation with its opposite. In this case, the distractor would be "A blue sphere to the right of a red cylinder." The task, similar to the contrastive and image-text matching tasks used to pre-train these models, is to choose the correct sentence given the image. As a reference point, we also evaluate on a control (non-spatial) task in which the correct text is a list of the scene's objects and the distractor text is identical except that one object is swapped with a random object not in the scene. For example, if the correct text is "A blue sphere and a red cylinder," then the distractor text could be "A blue sphere and a blue cylinder."

In the *image-pair* version of our tasks, we have a single sentence fragment constructed as described above for the spatial and control (non-spatial) tasks and two images such that only one matches the text. Appendix B shows examples of these tasks.

CLIP's performance on these tasks is shown in Table 1. Similar results for the pre-trained model ALBEF (Li et al., 2021) are shown in Appendix D.1 While performance on the control task is quite good, accuracy on the spatial task is not so different from random chance (50%). This indicates that the model scores of image-text pairs largely do not take spatial relations into account.

3.3 Spatial Relation Resolver

Since CLIP lacks sensitivity to spatial relations, we propose to decompose complex expressions into simpler primitives. The basic primitive is a predicate applying to an object, which we use CLIP to answer. The second primitive is a spatial relation between objects, for which we use heuristic rules.

Predicates A predicate is a textual property that the referent must satisfy. For example, "the cat" and "blue airplane" are predicates. We write $P(i)$ to say that object i satisfies the predicate P. We model P as a categorical distribution over objects, and estimate $p(i) = \Pr[P(i)]$ with the pre-trained model using isolated proposal scoring (§ 3.1).

Relations We have already discussed the importance of binary spatial relations like "the cat to the *left* of the dog" for the ReC task. We consider seven spatial relations–*left*, *right*, *above*, *below*, *bigger*, *smaller*, and *inside*. We write $R(i,j)$ to mean that the relation R holds between objects i and j, and we use heuristics to determine the probability $r(i,j) = \Pr[R(i,j)]$. For example, for *left*, we set $r(i,j) = 1$ if the center point of box i is to the left of the center point of box j and $r(i,j) = 0$ otherwise. §C.1 describes all relation semantics.

Superlative Relations We also consider superlatives, which refer to an object that has some relation to all other objects satisfying the same predicate, e.g. "leftmost dog". We handle superlatives as a special case of relations where the empty second argument is filled by copying the predicate specifying the first argument. Thus, "leftmost dog" effectively finds the dog that is most likely to the left of other dog(s). Our set of superlative relation types is the same as our set of relation types, excluding *inside*.

Semantic Trees Having outlined the semantic formalism underlying our method, we can describe it procedurally. We first use spaCy (Honnibal and Johnson, 2015) to build a dependency parse for the expression. As illustrated in Figure 3, we extract a semantic tree from the dependency parse, where each noun chunk becomes a node, and dependency paths between the heads of noun chunks become relations between entities based on the keywords they contain. See §C.2 for extraction details. In cases where none of our relation/superlative keywords occur in the text, we simply revert to the plain isolated proposal scoring method using the full text.

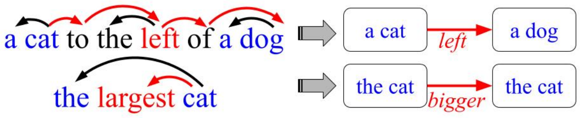

Figure 3: Example extraction of semantic trees from dependency parses. Predicate text in blue. Red arcs show paths contributing spatial relation *left* and superlative *largest*. For the superlative, we create a parent node with the original node as the only child, effectively converting it into a relation.

In the tree, each node N contains a predicate P_N and has a set of children; an edge (N, N') between N and its child N' corresponds to a relation $R_{N,N'}$. For example, as shown in Figure 3, "a cat to the left of a dog" would be parsed as a node containing the predicate "a cat" connected by the relation *left* to its child corresponding to "a dog". We define $\pi_N(i)$ as the probability that node N refers to object i, and compute it recursively. For each node N, we first set $\pi_N(i) = p_N(i)$ and then iterate through each child N' and update $\pi_N(i)$ as follows[6]:

$$\begin{aligned}\pi'_N(i) &\propto \pi_N(i) \sum_j \Pr\left[R_{N,N'}(i,j) \wedge P_{N'}(j)\right] \\ &\propto \pi_N(i) \sum_j r_{N,N'}(i,j)\pi_{N'}(j).\end{aligned}$$

The last line makes the simplifying assumption that all predicates and relations are independent.[7]

To compute our final output, we ensemble the distribution π_{root} for the root node with the output of plain isolated proposal scoring (with the whole input expression) by multiplying the proposal probabilities elementwise. This method gives us a principled way to combine predicates (P_N) with spatial relational constraints ($R_{N,N'}$) for each node N.

Table 2: Accuracy on the RefCOCOg, RefCOCO+ and RefCOCO datasets. ReCLIP outperforms other zero-shot methods on RefCOCOg. On RefCOCO+ and RefCOCO, ReCLIP is on par with or better than GradCAM on average and has lower variance between TestA and TestB, which correspond to different kinds of objects. When taking into account a prior on object size (filtering out objects smaller than 5% of the image), GradCAM's advantage on the TestA splits is erased. Best zero-shot results in each column are in **bold**, and best zero-shot results using the size prior are underlined. CLIP results use an ensemble of the RN50x16 and ViT-B/32 CLIP models. CPT-adapted is an adapted version of CPT-Blk. Supervised SOTA refers to MDETR (Kamath et al., 2021); we use the EfficientNet-B3 version. All methods except MDETR use detected proposals from MAttNet (Yu et al., 2018). CPT-Seg uses Mask-RCNN segmentation masks from Yu et al. (2018).

4 Experiments

4.1 Datasets

We compare ReCLIP to other zero-shot methods on **RefCOCOg** (Mao et al., 2016), **RefCOCO** and **RefCOCO+** (Yu et al., 2016). These datasets use images from MS COCO (Lin et al., 2014). RefCOCO and RefCOCO+ were created in a two-player game, and RefCOCO+ is designed to avoid spatial relations. RefCOCOg includes spatial relations and has longer expressions on average. For comparing zero-shot methods with the out-of-domain performance of models trained on COCO, we use **RefGTA** (Tanaka et al., 2019), which contains images from the Grand Theft Auto video game. All referring expressions in RefGTA correspond to people, and the objects (i.e. people) tend to be much smaller on average than those in RefCOCO/g/+.

4.2 Implementation Details

We use an ensemble of the CLIP RN50x16 and ViT-B/32 models (results for individual models are shown in Appendix G). We ensemble model outputs by adding together the logits from the two models elementwise before taking the softmax. GradCAM's hyperparameter α controls the effect of the proposal's area on its score. We select $\alpha = 0.5$ for all models based on tuning on the RefCOCOg validation set. We emphasize that the optimal value of α for a dataset depends on the size distribution of ground-truth objects. ReCLIP also has a hyperparameter, namely the standard deviation σ. We try a few values on the RefCOCOg validation set and choose $\sigma = 100$, as we show in Appendix E.4, isolated proposal scoring has little sensitivity to σ. As discussed by (Perez et al., 2021), zero-shot experiments often use labeled data for model selection. Over the course of this work, we primarily experimented with the RefCOCOg validation set and to a lesser extent with the RefCOCO+ validation set. For isolated proposal scoring, the main variants explored are documented in our ablation study (§4.6). Other techniques that we tried, including for relation-handling, and further implementation details are given in Appendix E.

4.3 Results on RefCOCO/g/+

Table 2 shows results on RefCOCO, RefCOCO+, and RefCOCOg. ReCLIP is better than the other zero-shot methods on RefCOCOg and RefCOCO and on par with GradCAM on RefCOCO+. However, GradCAM has a much higher variance in its accuracy between the TestA and TestB splits of RefCOCO+ and RefCOCO. We note that GradCAM's

---

[6] Superlatives of a node are processed after all its relations.

[7] We write $\propto$ because $\pi'_N(i)$ is normalized to sum to 1.

hyperparameter α, controlling the effect of proposal size, was tuned on the RefCOCOg validation set, and RefCOCOg was designed such that boxes of referents are at least 5% of the image area (Mao et al., 2016). In the bottom portion of Table 2, we show that when this 5% threshold, a prior on object size for this domain, is used to filter proposals for both GradCAM and ReCLIP , ReCLIP performs on par with/better than GradCAM on TestA. ReCLIP's spatial relation resolver helps on RefCOCOg and RefCOCO but not on RefCOCO+, which is designed to avoid spatial relations.

4.4 Results on RefGTA

Next, we evaluate on RefGTA to compare our method's performance to the out-of-domain accuracy of two state-of-the-art fully supervised ReC models: UNITER-Large (Chen et al., 2020) and MDETR (Kamath et al., 2021).

Like ReCLIP, UNITER takes proposals as input.[8] We show results using ground-truth proposals and detections from UniDet (Zhou et al., 2021), which is trained on the COCO, Objects365 (Shao et al., 2019), OpenImages (Kuznetsova et al., 2020), and Mapillary (Neuhold et al., 2017) datasets. Following the suggestion of the UniDet authors, we use the confidence threshold of 0.5. MDETR does not take proposals as input.

Table 3 shows our results. For methods that take proposals (all methods except MDETR), we consider two evaluation settings using UniDet–*DT-P*, in which the detected proposals are filtered to have only proposals whose predicted class label is "person", and *DT*, in which all detected proposals are considered. ReCLIP's accuracy is more than 15% higher than the accuracy of UNITER-Large and roughly 5% more than that of MDETR. ReCLIP also outperforms GradCAM by about 20%, and the gap is larger when all UniDet proposals are considered. ReCLIP w/o relations is 1-2% better than ReCLIP in the settings with ground-truth proposals and filtered UniDet proposals. One possible reason for this gap is that the objects of relations in the expressions could be non-people entities. When considering all UniDet proposals, the relation resolver in ReCLIP does not hurt accuracy much but also does not improve accuracy significantly–an additional challenge in this setting is that the number of proposals is dramatically higher. Appendix F shows qualitative examples of predictions on RefGTA.

Model	Val			Test		
	GT	DT-P	DT	GT	DT-P	DT
Random	27.03	21.53	4.86	27.60	21.75	5.13
UNITER-Large						
RefCOCO+	49.57	47.52	35.04	50.60	48.30	34.40
RefCOCOg	49.81	48.59	27.58	51.05	49.78	28.31
MDETR						
RefCOCO+	–	–	38.49	–	–	39.02
RefCOCOg	–	–	38.29	–	–	39.13
Pretrained	–	–	54.91	–	–	56.60
CLIP GradCAM	51.90	51.03	33.66	51.53	50.73	34.51
ReCLIP	69.84	68.42	60.93	70.79	69.05	**61.38**
w/o relations	**71.66**	**70.27**	**60.98**	**72.56**	**70.84**	61.31

Table 3: Accuracy on RefGTA dataset. ReCLIP w/o relations outperforms all other methods. *GT* denotes use of ground-truth proposals; *DT* denotes use of detected proposals; *DT-P* denotes detected proposals filtered to have only people. Subscripts *RefCOCO+*/*RefCOCOg* indicate finetuning dataset; *Pretrained* indicates a model that is not finetuned. MDETR does not take proposals as input, so the *GT* and *DT-P* columns are blank. We use the EfficientNet-B3 versions of MDETR. **Bold** indicates best score in a column.

4.5 Using another Pre-trained Model

In order to determine how isolated proposal scoring (IPS) compares to GradCAM and CPT on other pre-trained models, we present results using ALBEF (Li et al., 2021). ALBEF offers two methods for scoring image-text pairs–the output used for its image-text contrastive (ITC) loss and the output used for its image-text matching (ITM) loss. The architecture providing the ITC output is very similar to CLIP–has only a shallow interaction between the image and text modalities. The ITM output is given by an encoder that has deeper interactions between image and text and operates on top of the ITC encoders' output. Appendix D provides more details. The results, shown in Table 4, show that with the ITC output, IPS performs better than GradCAM, but with the ITM output, GradCAM performs better. This suggests that IPS works well across models like CLIP and ALBEF ITC (i.e. contrastively pre-trained with shallow modality interactions) but that GradCAM may be better for models with deeper interactions.

4.6 Analysis

Performance of IPS Our results show that among the region scoring methods that we consider,

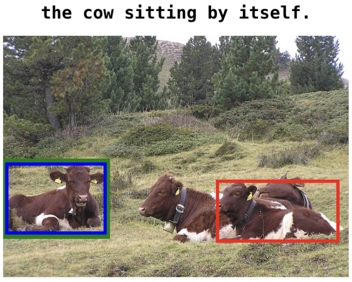
---

[8] UNITER requires features from the bottom-up top-down attention model (Anderson et al., 2017). We use `https://github.com/airsplay/py-bottom-up-attention` to compute the features for RefGTA. We trained UNITER models on RefCOCO+ and RefCOCOg using features computed from this repository. On the RefCOCO+ validation set, the resulting model has an accuracy roughly 0.4% less than that of a model trained and evaluated using the original features (when using ground-truth proposals).

Model	RefCOCOg	RefCOCO+(A)	RefCOCO+(B)
ALBEF ITM (Deep modality interaction)			
CPT-adapted	24.99	26.83	26.43
GradCAM	**55.92**	**61.75**	**42.79**
IPS	55.21	51.82	42.63
ALBEF ITC (Shallow modality interaction)			
CPT-adapted	21.10	19.00	21.33
GradCAM	47.53	44.60	36.00
IPS	**54.07**	**45.90**	**39.58**

Table 4: Accuracy on RefCOCOg and RefCOCO+ test sets using ALBEF pre-trained model. IPS does best when using ALBEF's ITC architecture, while GradCAM is better for ITM.

(a) ReCLIP is correct, while GradCAM is incorrect



(b) Both ReCLIP and GradCAM are incorrect

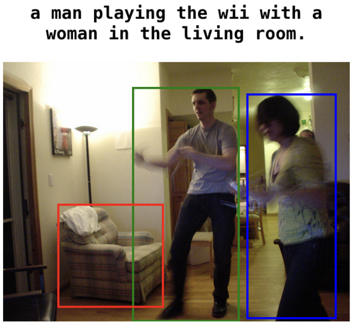


Figure 4: RefCOCOg validation examples using ground-truth proposals. Ground-truth referents are green, ReCLIP predictions are blue, and GradCAM predictions are red. In 4a, ReCLIP makes the correct prediction based on local context. In 4b, ReCLIP grounds an incorrect noun chunk from the expression.

Isolation type	RefCOCOg	RefCOCO+
Crop	54.43	41.28
Blur	55.96	47.23
max(Crop,Blur)	55.76	44.55
Crop+Blur	**57.70**	**47.43**

Table 5: Ablation study of isolation types used to score proposals on Val splits of RefCOCOg/RefCOCO+, using detections from MAttNet (Yu et al., 2018). Crop+Blur is best overall.

IPS achieves the highest accuracy for contrastively pre-trained models like CLIP. Figure 4a gives intuition for this—aside from an object's attributes, many referring expressions describe the local context around an object, and IPS focuses on this local context (as well as object attributes).

Table 5 shows that using both cropping and blurring obtains greater accuracy than either alone.

Error Analysis and Limitations Although ReCLIP outperforms the baselines that we consider, there is a considerable gap between it and supervised methods. The principal challenge in improving the system is making relation-handling more flexible. There are several object relation types that our spatial relation resolver cannot handle; for instance, those that involve counting: "the second dog from the right." Another challenge is in determining which relations require looking at multiple proposals. For instance, ReCLIP selects a proposal corresponding to the incorrect noun chunk in Figure 4b because the relation resolver has no rule for splitting an expression on the relation "with." Depending on the context, relations like "with" may or may not require looking at multiple proposals, so handling them is challenging for a rule-based system.

In the RefCOCO+ validation set, when using detected proposals, there are 75 instances for which ReCLIP answers incorrectly but ReCLIP w/o relations answers correctly. We categorize these instances based on their likely sources of error: 4 instances are ambiguous (multiple valid proposals), in 7 instances the parser misses the head noun chunk, in 14 instances our processing of the parse leads to omissions of text when doing isolated proposal scoring (e.g. in "girl sitting in back," the only noun chunk is "girl," so this is the only text used during isolated proposal scoring), 52 cases in which there is an error in the execution of the heuristic (e.g. our spatial definition of a relation does not match the relation in the instance). (There are 2 instances for which we mark 2 categories.) The final category ("execution") includes several kinds of errors, some examples of which are shown in Appendix F.

5 Related Work

Referring expression comprehension Datasets for ReC span several visual domains, including photos of everyday scenes (Mao et al., 2016; Kazemzadeh et al., 2014), video games (Tanaka et al., 2019), objects in robotic context (Shridhar et al., 2020; Wang et al., 2021), and webpages (Wichers et al., 2018).

Spatial heuristics have been used in previous work (Moratz and Tenbrink, 2006). Our work is also related to Krishnamurthy and Kollar (2013), which similarly decomposes the reasoning process into a parsing step and visual execution steps, but the visual execution is driven by learned binary classifiers for each predicate type. In the supervised setting, prior work shows that using an external parser, as we do, leads to lower accuracy than training a language module jointly with the remainder of the model (Hu et al., 2017).

There is a long line of work in weakly supervised ReC, where at training time, pairs of referring expressions and images are available but the ground-truth bounding boxes for each expression are not (Rohrbach et al., 2016; Liu et al., 2019; Zhang et al., 2018, 2020; Sun et al., 2021). Our setting differs from the weakly supervised setting in that the model is not trained at all on the ReC task. Sadhu et al. (2019) discuss a zero-shot setting different from ours in which novel objects are seen at test time, but the visual domain stays the same.

Pre-trained vision and language models Early pre-trained vision and language models (Tan and Bansal, 2019; Lu et al., 2019; Chen et al., 2020) used a cross-modal transformer (Vaswani et al., 2017) and pre-training tasks like masked language modeling, image-text matching, and image feature regression. By contrast, CLIP and similar models (Radford et al., 2021; Jia et al., 2021) use a separate image and text transformer and a contrastive pre-training objective. Recent hybrid approaches augment CLIP's architecture with a multi-modal transformer (Li et al., 2021; Zellers et al., 2021).

Zero-shot application of pre-trained models Models pre-trained with the contrastive objective have exhibited strong zero-shot performance in image classification tasks (Radford et al., 2021; Jia et al., 2021). Gu et al. (2021) use CLIP can be to classify objects by computing scores for class labels with cropped proposals. Our IPS is different in that it isolates proposals by both cropping *and blurring*. Shen et al. (2021) show that a simple zero-shot application of CLIP to visual question answering performs almost on par with random chance. Yao et al. (2021) describe a zero-shot method for ReC based on a pre-trained masked language model (MLM); we show that their zero-shot results and a version of their method adapted for models pre-trained to compute image-text scores (rather than MLM) are substantially worse than isolated proposal scoring and GradCAM.

6 Conclusion

We present ReCLIP, a zero-shot method for referring expression comprehension (ReC) that decomposes an expression into subqueries, uses CLIP to score isolated proposals against these subqueries, and combines the outputs with spatial heuristics. ReCLIP outperforms zero-shot ReC approaches from prior work and also performs well across visual domains: ReCLIP outperforms state-of-the-art supervised ReC models, trained on natural images, when evaluated on RefGTA. We also find that CLIP has low zero-shot spatial reasoning performance, suggesting the need for pre-training methods that account more for spatial reasoning.

7 Ethical and Broader Impacts

Recent work has shown that pre-trained vision and language models suffer from biases such as gender bias (Ross et al., 2021; Srinivasan and Bisk, 2021). Agarwal et al. (2021) provide evidence that CLIP has racial and other biases, which makes sense since CLIP was trained on data collected from the web and not necessarily curated carefully. Therefore, we do not advise deploying our system directly in the real world immediately. Instead, practitioners interested in this system should first perform analysis to measure its biases based on previous work and attempt to mitigate them. We also note that our work relies heavily on a pre-trained model whose pre-training required a great deal of energy, which likely had negative environmental effects. That being said our zero-shot method does not require training a new model and in that sense could be more environmentally friendly than supervised ReC models (depending on the difference in the cost of inference).

Figure 5: The visual representation of a proposal using CPT-adapted. The example is taken from the RefCOCOg validation set.

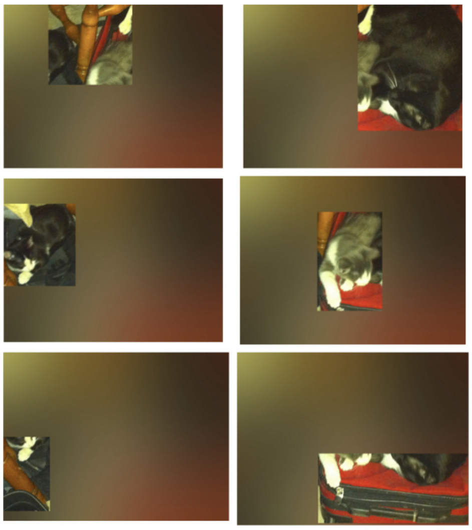

Figure 6: An example of isolating proposals by blurring the remainder of the image using $\sigma = 100$

A Visualization of Region-Scoring Methods

A.1 Colorful Prompt Tuning (CPT)

Figure 5 shows an example of the visual representation of a proposal using CPT-adapted.

A.2 Isolated Proposal Scoring (IPS)

Figure 6 shows the blurred versions of the proposals for an image using $\sigma = 100$.

B Synthetic Spatial Reasoning Experiment

Figure 7 gives an example of the *text-pairs* version of the synthetic tasks.

Figure 8 gives an example of the *image-pairs* version of the synthetic tasks.

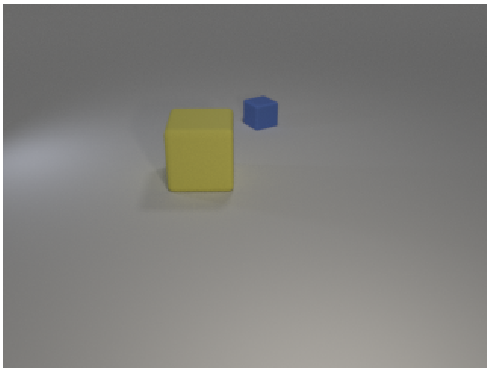

Figure 7: Example image for the synthetic text-pair tasks. For the spatial task, the text pair corresponding to this image is "a yellow cube is in front of a blue cube." (correct) and "a yellow cube is behind a blue cube." (incorrect). For the non-spatial (control) task, the text pair corresponding to this image is "a blue cube and a yellow cube" (correct) and "a blue cube and a yellow sphere" (incorrect).

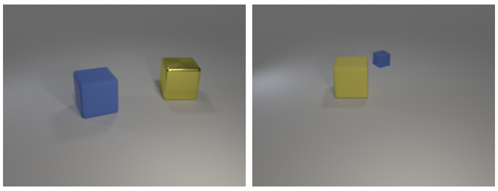
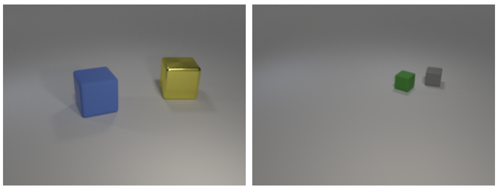


(a) "a blue cube to the left of a yellow cube."



(b) "a blue cube and a yellow cube"

Figure 8: Examples of the image-pairs version of the spatial (8a) and non-spatial (8b) tasks. In each case, the left image is the correct one.

C Semantic Formalism

C.1 Relation Semantics

We use deterministic heuristics to compute the semantics of the following six relations: *left*, *right*, *above*, *below*, *bigger*, and *smaller*. On the other hand, we treat *inside* as a random variable, and use heuristics to compute the value of its parameter.

For $R \in \{\textit{left}, \textit{right}, \textit{above}, \textit{below}\}$, we compute $R(i, j)$ by checking whether R holds between the center point of box i and box j. For example, if the center point of i is to the left of the center point of box j, then $\textit{left}(i, j) = 1$.

We compute $\textit{bigger}(i, j)$ and $\textit{smaller}(i, j)$ simply by comparing the areas of boxes i and j. For example, $\textit{bigger}(i, j)$ checks that the area of box i

is greater than the area of box j.

Finally, for $R =$ *inside*, we parameterize $r(i, j)$ as the ratio between the are of the intersection of boxes i, j compared to the area of box i. Thus, unlike the other six deterministic rules, *inside* is modeled as a random variable.

C.2 Relation Extraction

We identify noun chunks in the dependency parse as predicates. We then extract relations by looking for dependency paths between the heads of noun chunks that contain the following keywords:

- *left*: “left”, “west”
- *right*: “right”, “east”
- *above*: “above”, “north”, “top”, “back”, “behind”
- *below*: “below”, “south”, “under”, “front”
- *bigger*: “bigger”, “larger”, “closer”
- *smaller*: “smaller”, “tinier”, “further”
- *inside*: “inside”, “within”, “contained”

We extract superlative relations by looking for dependency paths off the head of a noun chunk containing the following keywords:

- *left*: “left”, “west”, “leftmost”, “western”
- *right*: “right”, “rightmost”, “east”, “eastern”
- *above*: “above”, “north”, “top”
- *below*: “below”, “south”, “underneath”, “front”
- *bigger*: “bigger”, “biggest”, “larger”, “largest”, “closer”, “closest”
- *smaller*: “smaller”, “smallest”, “tinier”, “tiniest”, “further”, “furthest”

D Description of ALBEF

The ALBEF model has an image-only transformer and a text-only transformer like CLIP but also has a multi-modal transformer that operates on the outputs of these two transformers. ALBEF is pretrained with three losses: (1) an image-text contrastive (ITC) loss that works just like CLIP’s and uses the outputs of the image-only and text-only transformers, (2) an image-text matching (ITM) loss–where the task is to decide whether a given image-text pair match–which uses the outputs of the multi-modal encoder, and (3) a masked language modeling loss which uses the outputs of the multi-modal encoder. We explore both the ITC and ITM scores in our experiments. ALBEF was pretrained on roughly 15M image-caption pairs from conceptual captions (Sharma et al., 2018), SBU Captions (Ordonez et al., 2011), COCO (Lin et al., 2014), and Visual Genome (Krishna et al., 2016).[9]

Model	Text-pair Spatial	Text-pair Non-spatial	Image-pair Spatial	Image-pair Non-spatial
ALBEF ITM	49.83	92.20	53.74	90.75
ALBEF ITC	49.83	85.42	51.54	72.25

Table 6: Accuracy on CLEVR image-text matching task. ALBEF performs well on the non-spatial version of the task but poorly on the spatial version. Text-pair tasks have 295 instances each; image-pair tasks have 227 instances each.

D.1 ALBEF Performance on Synthetic Spatial Reasoning Experiment

Table 6 shows the zero-shot accuracy of ALBEF ITM and ITC in the synthetic spatial reasoning experiment described in §3.2.

E Implementation Details

E.1 Text prompt

For ALBEF, we pass the input expression directly to the model, whereas for CLIP, when using GradCAM and ReCLIP (with or without relations), we use the prefix “a photo of” following the authors’ observations (Radford et al., 2021). For CPT, the prompt is given in § 2.3.

E.2 Position embeddings

Both CLIP and ALBEF use fixed-size position embeddings, so either the input image must be resized to fit the dimensions of the embeddings or the size of the embeddings must be changed. For all models, we resize the image to match the model’s visual input resolution. Resizing of images is done via bicubic interpolation. Figure 9 shows the how the performance of the GradCAM method varies between resizing images and resizing embeddings–for CLIP RN50x16, there is very little difference, while for CLIP ViT-B/32 image resizing makes a larger difference.

---

[9] As noted by the ALBEF authors, validation/test images of RefCOCO+ and RefCOCOg are included in the training set of COCO.

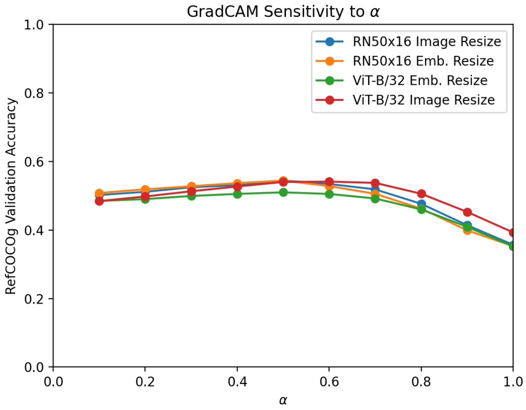


Figure 9: CLIP RN50x16 and ViT-B/32 Performance using GradCAM on RefCOCOg validation set comparing resizing of images with resizing of position embeddings, across 10 values of α. These results use ground-truth proposals.

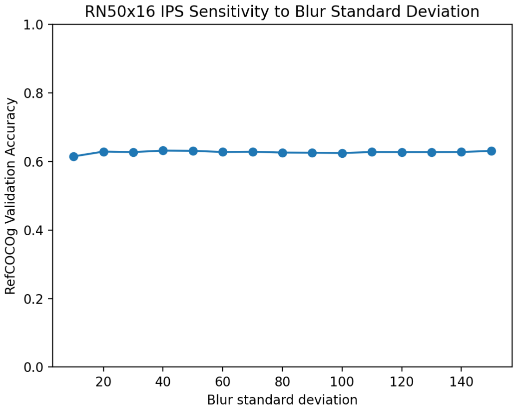

Figure 10: CLIP RN50x16 Performance using IPS on RefCOCOg validation set for different values of blur standard deviation σ. These results use ground-truth proposals.

Hyperparameters Specifically, we evaluate each value in the set $\{0.2, 0.4, 0.6, 0.8, 1.0\}$ and choose the best. The chosen values are $\alpha = 0.8$ for CLIP RN50x16 and ALBEF ITC and $\alpha = 1.0$ for CLIP ViT-B/32.

E.3 GradCAM Layer

For CLIP ViT-B/32, we use the last layer of the visual transformer for GradCAM. For CLIP RN50x16, we use output of layer 4 for GradCAM. For ALBEF ITM, we use the third layer of the multi-modal transformer for GradCAM (following Li et al. (2021)). For ALBEF ITC, we use the final layer of the visual transformer for GradCAM.

E.4 Hyperparameter sensitivity

Figure 9 shows the sensitivity of the GradCAM method to α for the two CLIP models. We choose $\alpha = 0.5$ for all models (including ALBEF), which results in the best accuracy for almost models. For ViT-B/32, $\alpha = 0.6$ yields slightly higher accuracy by (0.1%) on the RefCOCOg validation set. Figure 10 shows the sensitivity of the IPS method to the blur standard deviation σ for the CLIP RN50x16 model. As shown, the method has little sensitivity to σ above $\sigma = 20$.

E.5 Experimentation on validation set

As discussed by Perez et al. (2021), research on the zero-shot setting often uses labeled data for model selection. Aside from variants of IPS documented in our ablation study (§4.6), we also experimented on the RefCOCOg validation set (and to a lesser extent on the RefCOCO+ validation set) with:

1. Drawing a rectangle around the proposal and using an appropriate text prompt. Performance was somewhat similar to CPT performance.
2. Ensembling the original text prompt with a text prompt having only the noun chunk of the expression containing the head word. This helped for IPS and is in a sense part of our rule-based relation-handling.
3. Other techniques for handling superlatives. For instance, we tried to compute $\Pr[P_N(i) \wedge \bigwedge_{j \neq i}(\neg P_N(j) \vee (P_N(j) \wedge R(i,j)))]$. This performed worse than our chosen technique on the RefCOCOg validation set.
4. Invoking the parser and relation-handling pipeline on all sentences rather than only those containing one of the relation/superlative keywords.

We also selected the relation types and keywords based on these validation sets. Most of these preliminary experiments were performed using the area threshold mentioned in §4.3.

E.6 Description of Computing Infrastructure

We primarily used a machine with Quadro RTX 8000 GPUs, Google Cloud machines with V100 GPUs, and a machine with TITAN RTX and GeForce 2080s. These machines used Ubuntu as the operating system.

E.7 Dataset Information

All datasets that we use are focused on English. The COCO dataset can be downloaded from `https://cocodataset.org/#download`. The RefCOCO/g/+ datasets can be downloaded from `https://github.com/lichengunc/refer/tree/master/data`. The RefGTA dataset can be downloaded from `https://github.com/mikittt/easy-to-understand-REG/tree/master/pyutils/refer2`. The RefCOCOg validation set has 4896 instances, the RefCOCOg test set has 9602 instances, the RefCOCO+ validation set has 10758 instances, the RefCOCO+ TestA set has 5726 instances, the RefCOCO+ TestB set has 4889 instances, the RefCOCO validation set has 10834 instances, the RefCOCO TestA set has 5657 instances, the RefCOCO TestB set has 5095 instances, the RefGTA validation set has 17766 instances, and the RefGTA test set has 17646 instances.

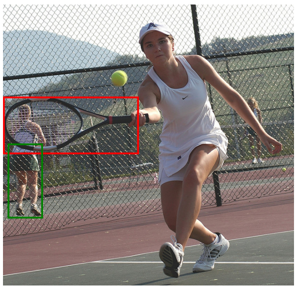
F Qualitative Examples

Figure 12 shows qualitative examples for the RefGTA validation set. Figure 11 shows examples of the execution errors mentioned in the error analysis in Section 4.6.

G Additional Experiment Results

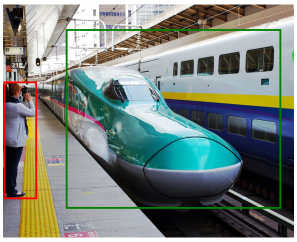
This section presents the full results on the RefCOCOg/RefCOCO+/RefCOCO datasets, including results without ensembling using CLIP RN50x16 and ViT-B/32 models and results using ground-truth proposals. Table 7 shows full results on the RefCOCOg and RefCOCO+ datasets. Table 8 shows full results on the RefCOCO dataset.

(a) bus behind bus



(b) person behind the fence

(c) chair under dog



(d) smallest train

Figure 11: Examples of execution errors causing ReCLIP to answer incorrectly on instances that it answers correctly when not using the relation-handling method. Parts 11a and 11b show cases where the meaning of "behind" does not match our heuristic, which checks which proposal's y-coordinate is smaller. Part 11c shows an example where "under" means "directly under." Part 11d shows an example in which due to the superlative "smallest," the size of proposals appears to be weighted more heavily by our approach than scores CLIP assigns to the proposals based on the text.

Abstract

We consider event extraction in a generative manner with template-based conditional generation. Although there is a rising trend of casting the task of event extraction as a sequence generation problem with prompts, these generation-based methods have two significant challenges, including using suboptimal prompts and static event type information. In this paper, we propose a generative template-based event extraction method with dynamic prefix (GTEE-DYNPREF) by integrating context information with type-specific prefixes to learn a context-specific prefix for each context. Experimental results show that our model achieves competitive results with the state-of-the-art classification-based model ONEIE on ACE 2005 and achieves the best performances on ERE. Additionally, our model is proven to be portable to new types of events effectively.

1 Introduction

Event extraction is an essential yet challenging task for natural language understanding. Given a piece of text, event extraction systems need to recognize event triggers with specific types and the event arguments with the correct roles in each event record according to an event ontology, which defines the event types and argument roles (Doddington et al., 2004; Ahn, 2006). As an example, the context in Figure 1 contains two event records, a `Transport` event triggered by "*returned*" and an `Arrest-Jail` event triggered by "*capture*". In the `Transport` event, the `Artifact` is "*the man*", the `Destination` is "*Los Angeles*" and the `Origin` is "*Mexico*". In the `Arrest-Jail` event, the `Person` is "*the man*", the `Time` is "*Tuesday*" and the `Agent` is "*bounty hunters*". In this work, we focus on the task setting of extracting events without gold entity annotations, which is more practical in real-world applications.

Most of the event extraction work treats the extraction of event triggers and event arguments as several classification tasks, either learned in a pipelined framework (Ji and Grishman, 2008; Liu et al., 2020; Du and Cardie, 2020; Li et al., 2020) or a joint formulation (Li et al., 2013; Yang and Mitchell, 2016; Nguyen et al., 2016; Liu et al., 2018; Wadden et al., 2019; Lin et al., 2020).

There is a rising trend of casting the task of event extraction as a sequence generation problem by applying special decoding strategies (Paolini et al., 2021; Lu et al., 2021) or steering pretrained language models to output conditional generation sequences with discrete prompts (Li et al., 2021; Hsu et al., 2021). Compared with classification-based methods, this line of work is more data-efficient and flexible, which requires less annotated data to achieve acceptable model performances, being easier to extend to new event types by slightly modifying the designed prompts and decoding strategies.

However, these generation-based methods have two significant challenges, which impede achieving competitive results with the classification-based methods. (1) **suboptimal prompts**: First, they manually design prompts for each event type (Li et al., 2021; Hsu et al., 2021), which are suboptimal without tuning and largely affect the model performances. (2) **static event type information**: Second, when extracting events of a particular type, recent generation-based methods will receive the same event type information concerning only the running event type, regardless of the associations between other possible event types.

To alleviate the above two challenges, we propose a generative template-based event extraction method with dynamic prefixes, denoted as GTEE-DYNPREF. As demonstrated in Figure 1, we follow

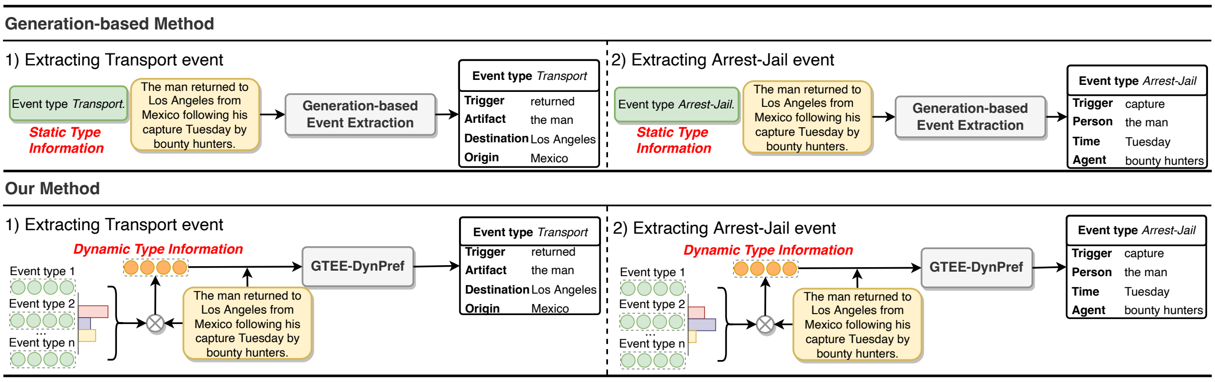

Figure 1: Comparision between the generation-based methods and our method GTEE-DynPref.

the previous work (Li et al., 2021; Hsu et al., 2021), extracting event records one type by one type, using the pretrained encoder-decoder language model BART (Lewis et al., 2020) for conditional generation. For each event type, we first initialize a type-specific prefix consisting of a sequence of tunable vectors as transformer history values (Li and Liang, 2021). The type-specific prefix offers tunable event type information for one single type. Then we integrate context information with all type-specific prefixes to learn a context-specific prefix, dynamically combining all possible event type information.

We evaluate our model on two widely used event extraction benchmarks, ACE 2005 and ERE. Experimental results show that our model achieves competitive results with the state-of-the-art classification-based model OneIE on ACE 2005 and achieves the best performances on ERE. Additionally, according to the transfer learning results, our model also can be adapted to new types of events effectively.

2 Related Work

This paper is related to the following lines of work.

2.1 Classification-based Event Extraction

Event extraction is usually formulated as a sequence labeling classification problem (Nguyen et al., 2016; Wang et al., 2019; Yang et al., 2019; Wadden et al., 2019; Liu et al., 2018). Some of them incorporate global features and apply joint inference (Lin et al., 2020; Li et al., 2013; Yang and Mitchell, 2016) to collectively model event dependencies. Additionally, recent work casts event extraction as a machine reading comprehension (MRC) problem (Liu et al., 2020; Du and Cardie, 2020; Li et al., 2020) by constructing questions to query event triggers and arguments.

Our work treats event extraction as a conditional generation task, which is more flexible and portable, which reduces the burden of annotation.

2.2 Generation-based Event Extraction

There is a rising line of work casting event extraction as a sequence generation problem, such as transforming into translation tasks (Paolini et al., 2021), generating with constrained decoding methods (Lu et al., 2021) and template-based conditional generation (Li et al., 2021; Hsu et al., 2021).

The two closest methods above (Li et al., 2021; Hsu et al., 2021) both utilize manually designed discrete templates, which caused the sub-optimal problem. Besides, the applied static type instruction does not consider the connections between events within the same context. We replaced the static type instructions with the dynamic prefixes, which are continuous and tunable vectors during training, combining the manual event templates and alleviating the sub-optimal problem.

2.3 Prompt Tuning

There is a line of work using specific sentence templates with pre-trained models to solve natural language understanding tasks. It natural to come up with prefix-style (Brown et al., 2020) or cloze-style (Petroni et al., 2019) prompts based on human introspection, which are called “descrete prompts”. Existing works on discrete prompt tuning(Shin et al., 2020; Gao et al., 2021; Schick et al., 2020) depend on *verbalizers* to map from class labels to answer tokens. These methods are proven to be effective in the few-shot setting for text classification and conditional text generation tasks (Schick and Schütze, 2021b,a,c). There are also methods that explore continuous prompts directly operating in the embedding space of the model, like tuning on vectors(Li and Liang, 2021; Lester et al., 2021;

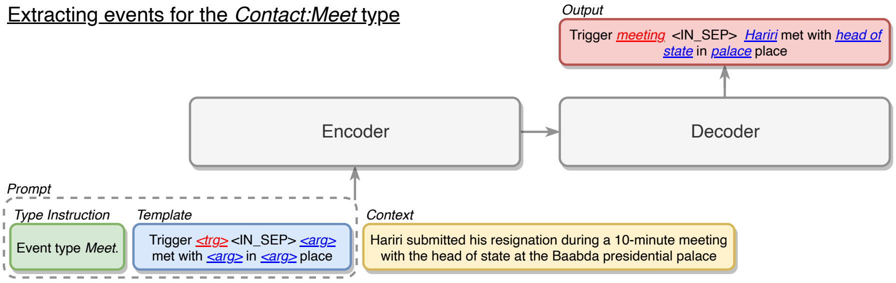

Figure 2: The framework of our base model GTEE-BASE. We use different colors to differentiate different components as follows. " 🟨 " for the context, " 🟦 " for the template, " 🟩 " for the type instruction, " ⬜ " for the encoder-decoder language model, and " 🟥 " for the answered prompt as output.

Tsimpoukelli et al., 2021), initializing with discrete prompts(Zhong et al., 2021; Qin and Eisner, 2021; Hambardzumyan et al., 2021) and hybrid prompt tuning(Liu et al., 2021b,a; Han et al., 2021).

3 Generative Template-based Method

We revisit the task of event extraction as the process of conditional generation and present our base model (GTEE-BASE) as illustrated in Figure 2.

3.1 Problem Statement

In the conditional generation task formulation for event extraction, the whole extraction process for a textual context is divided into several subtasks according to event types. Specifically, given an event ontology $\mathcal{O}$ with an event type set $\mathcal{E} = \{e_i | i \in [1, |\mathcal{E}|]\}$, the input in each subtask $\mathcal{S}_{e_i,\mathcal{C}}$ for event type e_i consists of a context $\mathcal{C}$ and a designed prompt $\mathcal{P}_{e_i}$. And the output is the answered prompts $\mathcal{A}_{e_i}$, containing extracted event records.

We take one single conditional generation subtask $\mathcal{S}_{e_i,\mathcal{C}}$ for event type e_i as example to explain the following content.

3.2 Basic Architecture

As shown in Figure 2, the conditional generation subtask is modeled by a pretrained encoder-decoder language model (LM), BART (Lewis et al., 2020) and T5 (Raffel et al., 2020). In the generation process, the encoder-decoder LM models the conditional probability of selecting a new token y_i given the previous tokens $y_{<i}$ and the encoder input $\mathcal{X}$. Therefore, the entire probability $p(\mathcal{Y}|\mathcal{X})$ of generating the output sequence $\mathcal{Y}$ given the input sequence $\mathcal{X}$ is calculated as

$$\begin{aligned} p(\mathcal{Y}|\mathcal{X}) &= \prod_{i=1}^{|\mathcal{Y}|} p(y_i | y_{<i}, \mathcal{X}) \\ \mathcal{X} &= [\mathcal{P}_{e_i}; \texttt{[SEP]}; \mathcal{C}] \\ \mathcal{Y} &= \mathcal{A}_{e_i} \end{aligned} \tag{1}$$

where [;] denotes the sequence concatenation operation and `[SEP]` [1] is the corresponding separate marker in the applied encoder-decoder LM.

3.3 Prompt Design

Similar to the state-of-the-art end-to-end generative method DEGREE-E2E (Hsu et al., 2021) for event extraction, the prompt $\mathcal{P}_{e_i}$ for subtask $\mathcal{S}_{e_i,\mathcal{C}}$ in our base model GTEE-BASE contains the type instruction $\mathcal{I}_{e_i}$ and the template $\mathcal{T}_{e_i}$.

Type Instruction. A short natural language sequence $\mathcal{I}_{e_i}$ describing the event type e_i in the subtask. We use the pattern "Event type is `[MASK]`." to construct type instructions for the event type set $\mathcal{E}$. For example, the type instruction for event type `Meet` is "Event type is Meet.".

Template. A type-specific pattern $\mathcal{T}_{e_i}$, which contains several placeholders, reflecting how the arguments participant in the event. We use two types of placeholdes, `<trg>` and `<arg>`s, for representing trigger and arguments, respectively. The template is consists of a trigger part and a argument part. The two parts are concatenated by a new seperate marker `<IN_SEP>`. As illstrated in Figure 2, the trigger part is "Trigger `<trg>`", which is identical for all event types. The argument part is specific to event type e_i. Due to the manual efforts of designing and searching for an optimal template, we follow Li et al. (2021) to reuse the pre-defined argument templates [2] in the ontology $\mathcal{O}$. The original pre-defined argument templates natively contain

---

[1] In this paper, we use `[*]` to represent the special tokens used in pretrained LM and `<*>` to indicate the user-defined special tokens.

[2] The argument template and all the used ontologies can be accessed at `https://github.com/raspberryice/gen-arg` except for ERE. Since the ERE event types are subsets of the RAMS AIDA ontology and the KAIROS ontology, following Li et al. (2021), we also reuse the argument templates from these ontologies.

numeric labels for each `<arg>` placeholder (as `<arg1>`) and the slot mappings $\mathcal{M}$ to the corresponding argument roles. We also follow Li et al. (2021) to remove these numeric labels.

Ground Truth Construction. For each event type e_i in the context $\mathcal{C}$, we construct the ground truth sequence $\mathcal{G}_{e_i,\mathcal{C}}$ for conditional generation by filling the gold event records into the template $\mathcal{T}_{e_i}$. If there is no event record of event type e_i, the generation ground truth of the will be "Trigger `<trg>`". Otherwise, the event record is filled in the template $\mathcal{T}_{e_i}$ as the output in Figure 2. If several arguments are categorized as the same role, these arguments are first sorted by spans and then concatenated by "and". If there are multiple event records, they will be sorted by the spans of the triggers, and the filled sequences will be concatenated by a new separate marker `<OUT_SEP>`.

3.4 Training, Inference and Parsing

Training. The trainable parameters of our base model GTEE-BASE are only the encoder-decoder LM. And we use ϕ to denote all the trainable parameters. Therefore, the training target is to minimize the negative loglikelihood of all subtasks $\mathcal{S}_{e_i,\mathcal{C}_j}$ in the training set $\mathcal{D}$, where $\mathcal{C}_j$ denotes the j-th context in $\mathcal{D}$.

$$\begin{aligned}\mathcal{L}_\phi(\mathcal{D}) &= -\sum_{j=1}^{|\mathcal{D}|}\sum_{i=1}^{|\mathcal{E}|}\log p(\mathcal{G}_{e_i,\mathcal{C}_j}|\mathcal{X}_{e_i,\mathcal{C}_j}) \\ \mathcal{X}_{e_i,\mathcal{C}_j} &= [\mathcal{P}_{e_i};\texttt{[SEP]};\mathcal{C}_j]\end{aligned} \quad (2)$$

Inference. In the inference stage, our base model generates sequences by beam search $\texttt{BEAM} = 6$. The maximum sequence length is set according to dataset statistics, which is a bit larger than the length of the longest ground truth.

Parsing. Basically, we parse the event records by template matching and slot mapping according to the ontology $\mathcal{O}$. Please note that not all the generated output sequences are valid. For each generated sequence, we will first try to parse a trigger. If failed, we will skip the sequence. Then if we fail to match `<IN_SEP>` or the argument part of the template $\mathcal{T}_{e_i}$, we will skip the argument parsing and only keep a trigger.

3.5 Irrelevant Event Types

By investigating the parsed event records, we find that our model has the bias to generate event records even for irrelevant event types. This will be fatal when the input context does not contain any event record, which will largely hurt the precision score and F1 score. There are 80.28% and 71.02% sentences that do not contain any event records in ACE 2005 and ERE, respectively.

Therefore, we propose a simple yet effective solution to alleviate this problem by separately training an irrelevance classifier IC. With context $\mathcal{C}$ as input, we finetune a BERT mdoel (Devlin et al., 2019) by feeding the encoded `[CLS]` vector to a MLP as a binary classifier to see whether the context contains any event records or is entirely irrelevant for the ontology $\mathcal{O}$. It is worth noticing that there may exist other ways to avoid the problem, as Cui et al. (2021) formulate the NER task as a ranking task to avoid irrelevant entity types in a similar conditional generation task setting.

4 Dynamic Prefix-Tuning

We propose dynamic prefix-tuning with task-specific prefix and context-specific prefix to alleviate the two main challenges in generation-based event extraction. The framework of our model with dynamic prefix tuning, GTEE-DYNPREF, is shown in Figure 3. We will introduce the dynamic prefix-tuning step by step.

4.1 Type-Specific STATIC PREFIX

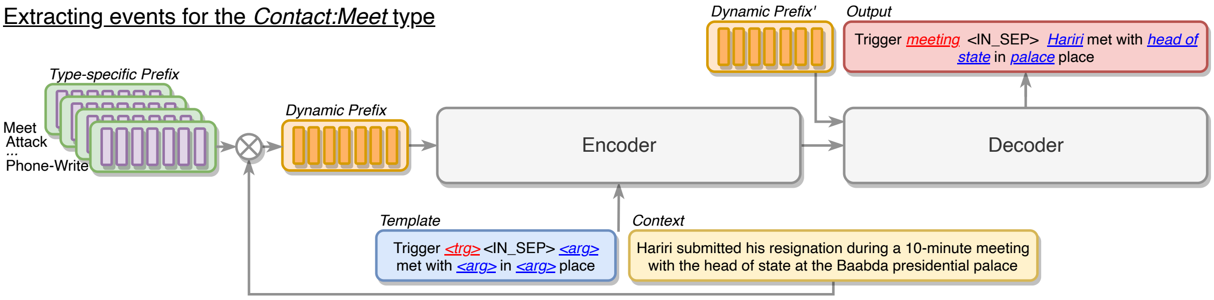
Inspired by PREFIX-TUNING (Li and Liang, 2021), we use event type-specific prefix STAPREF, which is a pair of two transformer activation sequences $\{sp, sp'\}$, each containing L continuous D-dim vectors as the history values for encoder and decoder, respectively. From the view of the encoder and decoder input, in the subtask $\mathcal{S}_{e_i,\mathcal{C}}$, the prefix is virtually prepended for the sequences $\mathcal{X}$ and $\mathcal{Y}$ in an encoder-decoder LM.

$$\begin{aligned}\mathcal{X}' &= [sp_{e_i};\mathcal{X}] \\ \mathcal{Y}' &= [sp'_{e_i};\mathcal{Y}]\end{aligned} \quad (3)$$

The main advantage of these transformer activation sequences is that they provide trainable context for both encoder and decoder, which is also computationally achievable.

We first initialize a pair of task-specific prefixes $\{sp_{e_i}, sp'_{e_i}\}$ for each event type e_i in the ontology $\mathcal{O}$. In the conditional generation subtask $\mathcal{S}_{e_i,\mathcal{C}}$, we then prepend the corresponding pair of task-specific prefixes $\{sp_{e_i}, sp'_{e_i}\}$ as transformer activations for the encoder and decoder.

Following Li and Liang (2021), we use a trainable embedding tensor $P \in \mathbb{R}^{|\mathcal{E}|\times L\times D}$ to model

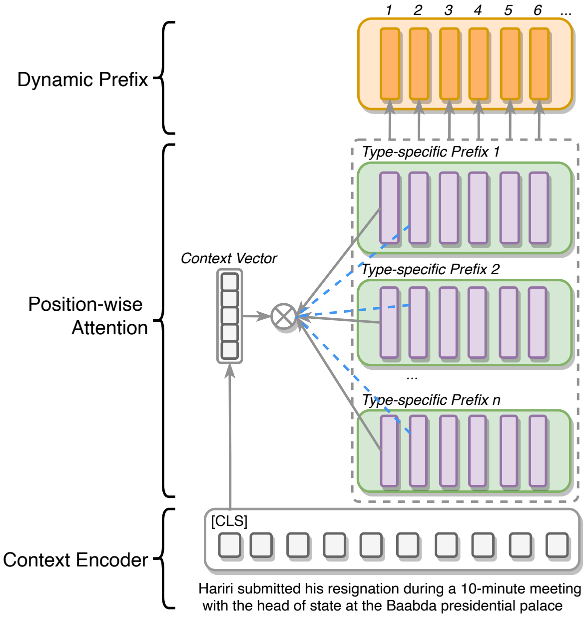


Trigger meeting <IN_SEP> Hariri met with head of state in palace place

Trigger <trg> <IN_SEP> <arg> met with <arg> in <arg> place

Hariri submitted his resignation during a 10-minute meeting with the head of state at the Baabda presidential palace

Figure 3: The framework of our dynamic prefix-tuning model GTEE-DYNPREF. We use different colors to differentiate different components as follows. “ 🟨 ” for the context, “ 🟦 ” for the template, “ 🟩 ” for the type-specific prefixes, “ 🟧 ” for the dynamic prefix, “ ⬜ ” for the encoder-decoder language model, and “ 🟥 ” for the answered prompt as output.



Hariri submitted his resignation during a 10-minute meeting with the head of state at the Baabda presidential palace

Figure 4: Context-specific DYNPREF construction using a context encoder.

the type-specific prefix sp. For the event type e_i in the ontology $\mathcal{O}$, the prefix vector $sp_{e_i}^t$ at index t is

$$sp_{e_i}^t = P[e_i, t, :] \tag{4}$$

The reason we call the task-specific prefix *static* is that for subtasks of the same event types, the output type instructions are the same. In other words, such prefixes only preserve context concerning one single type of event, ignoring the association between different event types.

4.2 Context-Specific DYNAMIC PREFIX

Aiming to capture the associations between different event types when constructing trainable prefixes, we present DYNPREF, which constructs dynamic prefix with context-specific information when prompting pretrained language models.

As shown in Figure 4, $dp_{\mathcal{C}}$ has the same sequence length L as sp. For each position t, the prefix vector $dp_{\mathcal{C}}^t$ is computed by dynamically integrating all the prefix vector $sp_{e_i}^t$ of event type e_i in the ontology $\mathcal{O}$ according to the context-specific information c by multi-head attention (Vaswani et al., 2017). To calculate the context-specific information c, we apply a BERT mdoel (Devlin et al., 2019) as the context encoder by feeding the context $\mathcal{C}$ as input and taking the `[CLS]` vector as c.

$$\begin{aligned} dp_{\mathcal{C}}^t &= \underset{i=1}{\overset{|\mathcal{E}|}{\text{MultiHeadAttn}}}(\{sp_{e_i}^t, \ldots\}, c) \\ c &= \text{BERT}(\mathcal{C})_{\texttt{[CLS]}} \end{aligned} \tag{5}$$

The context-specific prefix $dp_{\mathcal{C}}$ is *dynamic* because it takes both the type-specific information in ontology $\mathcal{O}$ and the unique context information into account when steering LMs.

Following Li and Liang (2021), we compute the decoder transformer activation vector h_i, which is a concatenation of all layers, at time step i in encoder-decoder LM recurrently.

$$h_i = \begin{cases} dp_{\mathcal{C}}^i, & \text{if } i < L, \\ \text{LM}(y_i, h_{<i}|\mathcal{X}), & \text{otherwise.} \end{cases} \tag{6}$$

The computation of the encoder transformer activation vector is similar.

4.3 Training

Except for the LM parameters ϕ, the additional trainable parameters of DYNPREF include the embedding tensor P and the BERT encoder modeling context information.

Specially, we follow the training suggestions (Li and Liang, 2021) and reparametrize the embedding tensor P by modeling a MLP and another embedding tensor $P' \in \mathbb{R}^{|\mathcal{E}| \times L \times D'}$ with small dimension $D' < D$. In the end, P is computed as

$$P[e_i, t, :] = \text{MLP}(P'[e_i, t, :]) \tag{7}$$

Dataset	Split	#Sents	#Events	#Roles

	Test	1163	551	822

Table 1: Dataset statistics.

Now we use θ to denote all the introduced parameters for DYNPREF.

The training objective is still to minimize the negative loglikelihood in equation (2) for ϕ and θ. However, in our preliminary experiments, we find that jointly learning the LM parameters ϕ and the DYNPREF parameters θ requires different scales of training hyperparameters, being difficult to learn the ability to extract event arguments. Therefore, we train them separately in three steps: (1) First, we train ϕ using GTEE-BASE to learn the task information. (2) Then we fix the LM parameters ϕ and mask all other event types except for e_i in each subtask $\mathcal{S}_{e_i,\mathcal{C}}$, only optimizing θ, to learn the type-specific information for each event type. (3) Last, we remove the masking of event types, remaining the LM parameters fixed and only optimizing θ using DYNPREF, to capture the associations between related event types.

5 Experiment Setup

5.1 Datasets

We conducted experiments on two widely used event extraction benchmarks, ACE 2005 (LDC2006T06) and ERE (LDC2015E29, LDC2015E68, and LDC2015E78). ACE 2005 dataset has 599 annotated English documents, 33 event types, and 22 argument roles. ERE contains 458 English documents, 38 event types, and 21 argument roles.

We preprocess the datasets following previous work (Zhang et al., 2019; Wadden et al., 2019; Du and Cardie, 2020; Lin et al., 2020; Lu et al., 2021; Hsu et al., 2021), and obtain three datasets, ACE05-E, ACE05-E$^+$ and ERE-EN. Statistics of the datasets are shown in Table 1. Compared to ACE05-E, both ACE05-E$^+$ and ERE-EN contain pronoun roles and multi-token event triggers.

5.2 Evaluation Metrics

We use the same evaluation criteria in previous work (Zhang et al., 2019; Wadden et al., 2019; Lin et al., 2020; Lu et al., 2021; Hsu et al., 2021) and report the Precision P, Recall R and F1 score $F1$ of trigger classification (**Trg-C**) and argument classification (**Arg-C**).

- **Trg-C**: a trigger is correctly classified if its offset and event type matches the ground truth.
- **Arg-C**: an argument is correctly classified if its offset, event type and role label all matches the ground truth.

Following Lu et al. (2021), we also obtain the offset of extracted triggers by string matching in the input context one by one. For the predicted argument, we find the nearest matched string to the predicted trigger as the predicted offset.

5.3 Baseline Methods

We compare GTEE-DYNPREF with two groups of event extraction work. The first group is about classification-based event extraction methods.

- DYGIE++ (Wadden et al., 2019): a BERT-based model which captures both within-sentence and cross-sentence context.
- GAIL (Zhang et al., 2019): an RL model jointly extracting entity and event.
- ONEIE (Lin et al., 2020): an end-to-end IE system which employs global feature and beam search, which is the state-of-the-art.
- BERT_QA (Du and Cardie, 2020): a MRC-based model using multi-turns of separated QA pairs to extract triggers and arguments.
- MQAEE (Li et al., 2020): a multi-turn question answering system.

The second group contains generation-based event extraction methods.

- TANL (Paolini et al., 2021): a method use translation tasks modeling event extraction in a trigger-argument pipeline.
- BART-GEN (Li et al., 2021): a template-based conditional generation method.
- TEXT2EVENT (Lu et al., 2021): a sequence-to-structure generation method.
- DEGREE-E2E (Hsu et al., 2021): an end-to-end conditional genration method with discrete prompts.

5.4 Implementation Details

We use the huggingface implementation of BART-large as the encoder-decoder LM and BERT-large

as the binary irrelevance classifier IC in §3.5 and the context encoder in §4.2. We optimized our models by AdamW (Loshchilov and Hutter, 2019). The hyperparameters we used are shown in Table 2. Each experiment is conducted on NVIDIA A100 Tensor Core GPU 40GB. For simplicity, we randomly initialize[3] the embedding tensor P'.

As mentioned in §3.5, there is an overwhelming amount of negative samples compared with positive samples. Therefore, we sample only 4% negative samples in the train and dev split for the three datasets, keeping all samples in test split.

6 Results

6.1 Supervised Learning Setting

We evaluate the proposed model GTEE-DynPref under the supervised learning setting. Table 3 shows the comparison results on ACE05-E against all baseline methods, and Table 4 illustrates the results compared with the state-of-the-art in each research line on ACE05-E$^+$ and ERE-EN.

New state-of-the-art. As we can see from Table 3, GTEE-DynPref achieves the highest F1 scores for Trg-C and Arg-C on ACE05-E, compared with all the generation-based baselines. Besides, GTEE-DynPref is competitive with the state-of-the-art classification-based method OneIE, outperforming the others. In Table 4, GTEE-DynPref achieves competitive Arg-C F1 score with OneIE on ACE05-E$^+$, while obtaining 7.5% and 4.6% gain of F1 scores for Trg-C and Arg-C, respectively, achieving new state-of-the-art on ERE-EN.

Trainable prompts boost the performances. Compared with DEGREE, the event extraction method using fixed templates, and Text2Event, the generative event extraction method without prompts, GTEE-DynPref outperforms them in all the datasets, showing the effectiveness of the trainable dynamic prefix with prompts.

6.2 Transfer Learning Setting

GTEE-DynPref utilizes the event type templates and optimize them with context-specific information in the dynamic prefix, which is easy to extend to a new type of event. Therefore, aiming to verify the ability of GTEE-DynPref to learn from new event types, we conduct experiments under the transfer learning setting following Lu et al. (2021). Specifically, we divide the event mentions whose context contains no less than eight tokens in ACE05-E$^+$ into two subsets, denoted by `src` and `tgt`. `src` contains top-10 frequent types of events and `tgt` contains the rest 23 types of events. We then randomly split each subset into a `train` set and a `test` set with the ratio $4:1$. Specifically, for transfer learning, we will first pre-train on `src-train` to learn the task information and then fine-tune on `tgt-train` for extracting the new types of events. Table 6 shows the evaluation results on `tgt-test` under the transfering learning setting and when solely training on `tgt-train` without transfering knowledge. We choose the state-of-the-art classification-based model OneIE and generation-based method Text2Event as the baselines.

We can see that GTEE-DynPref achieves the highest Trg-C F1 and Arg-C F1 scores, which indicates that with the help of dynamic prefix, GTEE-DynPref can be adopted to new types of events more effectively. Additionally, comparing with solely training on `tgt`, transfering the knowledge from `src` allows GTEE-DynPref to achieve higher F1 scores than OneIE and Text2Event. The reason may be that OneIE relies on multi-task

annotated information, and Text2Event requires learning the structural information of new types of events. In contrast, GTEE-DynPref only requires an easy-to-acquire template, which can be further optimized during training.

6.3 Ablation Study

In this section, we study the effectiveness of each proposed module by adding them into our base model GTEE-Base and finally get our final model GTEE-DynPref. The results on ACE05-E, ACE05-E$^+$ and ERE-EN are presented in Table 5.

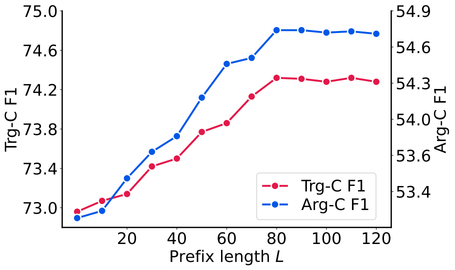
Continuous Prompt vs Discrete Prompt. We first compare GTEE-StaPref with GTEE-Base. Based on GTEE-Base with discrete prompts, GTEE-StaPref further combines type-specific prefixes as to form continuous prompts. It can be observed that there is a 0.8%, 0.7% and 0.9% gain for the Trg-C F1 score on ACE05-E, ACE05-E$^+$ and ERE-EN, respectively. Additionally, there is a 0.6%, 1.0% and 0.8% improvement for the Arg-C F1 score, demonstrating the effectiveness and flexibility of StaPref to model the type-specific information.

Dynamic Prefix vs Static Prefix. Next we compare GTEE-DynPref with GTEE-StaPref to study the advantages of constructing dynamic prefix. On the basis of GTEE-StaPref, integrating context-specific information leads to a constent gain for Trg-C F1 score on all the datasets as 0.8%, 0.6% and 0.5%, respectively. There can also be observed a 1.5%, 0.5% and 0.8% increase for the Arg-C F1 scores, respectively. It indicates that integrating context-specific information into type-specific information and transforming static prefix to dynamic is beneficial for generative template-based event extraction.

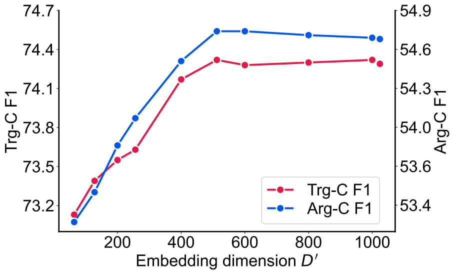
6.4 Irrelevance Classifier

Our goal of the irrelevance classifier IC is to recognize the context that does not contain any event records in a given ontology $\mathcal{O}$. According to §3.5, we train an IC and use it for each dataset separately. Please note that on one specific dataset, we will use the same IC for all the experiments corresponding to that dataset. The accuracy of IC is 95.4%, 93.5% and 94.2% for ACE05E, ACE05E$^+$ and ERE-EN, respectively. To further study the influence of IC, we compare the performances of using no IC, trained IC, and gold IC. The compared F1 scores are listed in Table 7.

First, we find that with the help of our trained ICs on each dataset, the Trg-C and Arg-C F1 scores have been improved a lot by more than ten percentage points, indicating the necessity of IC. Second,



(a) F1 scores of GTEE-DynPref with different prefix length L.



(b) Performances of GTEE-DynPref with different dimension D' of the embedding tensor P'.

Figure 5: Intrinsic evaluation results on ACE05-E$^+$.

by replacing the trained IC with the oracle gold IC results, we can still observe possible increasements for F1 scores, suggesting the existence of likely chances for further optimizing IC performances. We leave the optimization for IC as future work.

6.5 Intrinsic Evaluation

We study the intrinsic characteristics of GTEE-DynPref by showing the influences of model hyperparameters on ACE05-E$^+$.

Prefix length L. We first study the impact of prefix length L by grid search in $\{L|L = 10 * k, k \in \mathbb{N} \wedge k \leq 12\}$. Figure 5(a) shows the Trg-C and Arg-C F1 scores. We can observe that both Trg-C and Arg-C F1 scores increase as the prefix length L increases to 80, afterward, a slight fluctuation. We think the longer L introduces more trainable parameters and a more vital ability to model the context-specific type information. Therefore, we choose 80 as the prefix length in GTEE-DynPref.

Embedding dimension D'. Similarly, we study the impact of the dimension D' of the embedding tensor P' by increasing from 64 to 1024. The results of Trg-C and Arg-C F1 scores are illustrated in Figure 5(b). We find that although the bigger embedding dimension D' theoretically provides expressive type-specific information and improves the F1 scores when $D' <= 512$, the continual improvement is interrupted when the embedding dimension is around 512. Thus we set the embedding dimension $D' = 512$ in GTEE-DynPref.

7 Conclusion

In this paper, we studied event extraction in the template-based conditional generation manner. We proposed the dynamic prefix tuning model GTEE-DynPref for event extraction. On the one hand the method constructs tunable prefixes to model type-specific information and on the other hand GTEE-DynPref captures the associations between event types and calculates a context-specific prefix when steering pretrained language models. Experimental results show that our model achieves competitive results with the state-of-the-art on ACE 2005, which is also proven to be portable to new types of events effectively.

8 Ethical Consideration

Event extraction is a standard task in NLP. We do not see any significant ethical concerns. Our work is easy to adapt to new event types by offering some examples and pre-defined templates. Therefore, the expected usages of our work is to identify interesting event records from user textual input such as a piece of sentence or document.

A Argument Template

We use templates for ACE and ERE. Table 8 and Table 9 show the argument templates for ACE and ERE, respectively, which is from the RAMS AIDA ontology and the KAIROS ontology.

B Transfer Learning Details

The top-10 frequent types of events in the `src` split of ACE05-E$^+$ are listed as follows:

- Transaction:Transfer-Ownership
- Contact:Phone-Write
- Personnel:Elect
- Personnel:End-Position
- Movement:Transport
- Life:Injure
- Conflict:Attack
- Transaction:Transfer-Money
- Contact:Meet
- Life:Die

Event Type	**Template**	**arg1**	**arg2**	**arg3**	**arg4**	**arg5**
Movement:Transport	<arg1> transported <arg2> in <arg3> vehicle from <arg4> place to <arg5> place	Agent	Artifact	Vehicle	Origin	Destination
Personnel:Elect	<arg1> elected <arg2> in <arg3> place	Entity	Person	Place	-	-
Personnel:Start-Position	<arg1> started working at <arg2> organization in <arg3> place	Person	Entity	Place	-	-
Personnel:Nominate	<arg1> nominated <arg2>	Agent	Person	-	-	-
Personnel:End-Position	<arg1> stopped working at <arg2> organization in <arg3> place	Person	Entity	Place	-	-
Conflict:Attack	<arg1> attacked <arg2> hurting <arg5> victims using <arg3> instrument at <arg4> place	Attacker	Target	Instrument	Place	Victim
Contact:Meet	<arg1> met with <arg2> in <arg3> place	Entity	Entity	Place	-	-
Life:Marry	<arg1> married <arg2> in <arg3> place	Person	Person	Place	-	-
Transaction:Transfer-Money	<arg1> gave money to <arg2> for the benefit of <arg3> in <arg4> place	Giver	Recipient	Beneficiary	Place	-
Conflict:Demonstrate	<arg1> demonstrated at <arg2> place	Entity	Place	-	-	-
Business:End-Org	<arg1> organization shut down at <arg2> place	Org	Place	-	-	-
Justice:Sue	<arg1> sued <arg2> before <arg3> court or judge in <arg4> place	Plaintiff	Defendant	Adjudicator	Place	-
Life:Injure	<arg1> injured <arg2> with <arg3> instrument in <arg4> place	Agent	Victim	Instrument	Place	-
Life:Die	<arg1> killed <arg2> with <arg3> instrument in <arg4> place	Agent	Victim	Instrument	Place	-
Justice:Arrest-Jail	<arg1> arrested <arg2> in <arg3> place	Agent	Person	Place	-	-
Contact:Phone-Write	<arg1> communicated remotely with <arg2> at <arg3> place	Entity	Entity	Place	-	-
Transaction:Transfer-Ownership	<arg1> gave <arg4> to <arg2> for the benefit of <arg3> at <arg5> place	Seller	Buyer	Beneficiary	Artifact	Place
Business:Start-Org	<arg1> started <arg2> organization at <arg3> place	Agent	Org	Place	-	-
Justice:Execute	<arg1> executed <arg2> at <arg3> place	Agent	Person	Place	-	-
Justice:Trial-Hearing	<arg1> tried <arg2> before <arg3> court or judge in <arg4> place	Prosecutor	Defendant	Adjudicator	Place	-
Life:Be-Born	<arg1> was born in <arg2> place	Person	Place	-	-	-
Justice:Charge-Indict	<arg1> charged or indicted <arg2> before <arg3> court or judge in <arg4> place	Prosecutor	Defendant	Adjudicator	Place	-
Justice:Convict	<arg1> court or judge convicted <arg2> in <arg3> place	Adjudicator	Defendant	Place	-	-
Justice:Sentence	<arg1> court or judge sentenced <arg2> in <arg3> place	Adjudicator	Defendant	Place	-	-
Business:Declare-Bankruptcy	<arg1> declared bankruptcy at <arg2> place	Org	Place	-	-	-
Justice:Release-Parole	<arg1> released or paroled <arg2> in <arg3> place	Entity	Person	Place	-	-
Justice:Fine	<arg1> court or judge fined <arg2> at <arg3> place	Adjudicator	Entity	Place	-	-
Justice:Pardon	<arg1> court or judge pardoned <arg2> at <arg3> place	Adjudicator	Defendant	Place	-	-
Justice:Appeal	<arg1> appealed to <arg2> court or judge at <arg3> place	Plaintiff	Adjudicator	Place	-	-
Justice:Extradite	<arg1> extradited <arg2> from <arg3> place to <arg4> place	Agent	Person	Origin	Destination	-

E-LANG: Energy-Based Joint Inferencing of Super and Swift Language Models

Mohammad Akbari, Amin Banitalebi-Dehkordi, Yong Zhang
Huawei Technologies Canada Co., Ltd.
`{mohammad.akbari, amin.banitalebi, yong.zhang3}@huawei.com`

Abstract

Building huge and highly capable language models has been a trend in the past years. Despite their great performance, they incur high computational cost. A common solution is to apply model compression or choose light-weight architectures, which often need a separate fixed-size model for each desirable computational budget, and may lose performance in case of heavy compression. This paper proposes an effective dynamic inference approach, called E-LANG, which distributes the inference between large accurate Super-models and light-weight Swift models. To this end, a decision making module routes the inputs to Super or Swift models based on the energy characteristics of the representations in the latent space. This method is easily adoptable and architecture agnostic. As such, it can be applied to black-box pre-trained models without a need for architectural manipulations, reassembling of modules, or re-training. Unlike existing methods that are only applicable to encoder-only backbones and classification tasks, our method also works for encoder-decoder structures and sequence-to-sequence tasks such as translation. The E-LANG performance is verified through a set of experiments with T5 and BERT backbones on GLUE, SuperGLUE, and WMT. In particular, we outperform T5-11B with an average computations speed-up of 3.3× on GLUE and 2.9× on SuperGLUE. We also achieve BERT-based SOTA on GLUE with 3.2× less computations. Code and demo are available here.

1 Introduction

With the introduction of influential language models such as BERT (Devlin et al., 2019), a trend in natural language processing (NLP) research has been to develop high capacity models and push their performance to new levels. Consequently, state-of-the-art (SOTA) results were achieved on various benchmarks using these models; GPT-3 (Brown et al., 2020), XLNet (Yang et al., 2019), RoBERTa (Liu et al., 2019), T5 (Raffel et al., 2020), ELECTRA (Clark et al., 2020), and DeBERTa (He et al., 2021) to name a few. A potential down-side, however, is that the number of parameters or floating point operations (FLOPs) for these models can get extremely large. For example, Gshard (Lepikhin et al., 2021) comes with 600B parameters with an enormous amount of computation. This in turn results in a higher inference latency, which is not desirable for latency-sensitive applications.

A common solution to speed-up the large language models is to apply model compression (Gupta et al., 2020). Although generally successful, compression does come with a trade-off on accuracy, and may lose performance if compression is heavy. In addition, these methods usually compress a model to a fixed smaller size, where a separate model is required for each possible computational budget. An alternative approach explored in the literature is to leverage dynamic inferencing in a way that examples may be routed to different (potentially lower cost) paths throughout the network. For example, a temporal early-exit model (Shen et al., 2017; Yu et al., 2018) terminates the procedure of reading the input sequence when sufficient evidence has been found for accurate predictions. Instance-wise early-exiting (Xin et al., ACL 2020) is another technique, which allows a sample to adaptively choose from multiple available exit nodes if some conditions are met. Consequently, earlier exists require less computation and lead to a lower latency. Adjusting the size of the model at the inference time by choosing adaptive width and depth is also another approach employed for dynamic inference (Kim and Cho, 2021; Hou et al., 2020). There is a variety of adaptive/dynamic inference approaches proposed, however, a general down-side for many of these methods is that often times they require a careful architecture design, manipulation of network modules, or even re-training.

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics
Volume 1: Long Papers, pages 5229 - 5244

In this paper, we propose a simple but rather effective approach of dynamically distributing the inference between the original large model (called the **Super** model) and a light-weight (e.g., compressed) model referred to as the **Swift** model. To this end, we design an energy-based decision making module that routes examples to the appropriate model based on the negative free energy of the latent space representations, such that the Swift model attains a high accuracy on the examples sent to it. The remaining samples are then forwarded to the Super model that is supposed to have a good performance on all examples. Since the Swift model can make highly accurate predictions over the majority of the samples, E-LANG significantly reduces the overall computational cost, while maintains the high accuracy of the Super model. Although simple, this strategy achieves SOTA results on multiple structures (e.g., T5 and BERT) and benchmarks (e.g., GLUE and SuperGLUE). Due to its desirable practical characteristics, this method is a strong candidate for the practical application of Super models. The main contributions of the paper are as follows:

- Combining Super models with high accuracy and latency and Swift models with lower accuracy and latency, to achieve **high accuracy and low latency**. In other words, by employing our method, we can achieve the high levels of accuracy provided by Super models, but at a lower computational cost. Our method is easily adoptable, architecture agnostic, and orthogonal to many other existing methods. It can be applied to black-box pre-trained models without a need for architectural manipulations, careful reassembling of modules, or re-training.

- An **energy-based routing mechanism** for directing examples to the Super or Swift. This provides a dynamic trade-off between the accuracy and computational cost that outperforms the previous works in both fixed-size and dynamic inference (with zero overhead for real-time adjustment of speed/accuracy). As such, E-LANG acts like a knob for adjusting the accuracy-latency trade-off in real-time during model serving.

- To the best of our knowledge, our method is the first generic approach to apply dynamic inference on both encoder-only and **encoder-decoder architectures** (e.g., T5) and also can extend the usage beyond classification tasks, to **sequence-to-sequence** tasks such as translation.

2 Related Works

As mentioned, compression is a widely used strategy to speed-up the large language models (Gupta et al., 2020; Gupta and Agrawal, 2022). This involves incorporating techniques such as quantization of weights and activations (Bai et al., 2021; Shen et al., 2020; Kim et al., 2021; Zhang et al., 2020; Jin et al., 2021), knowledge distillation (KD) (Hinton et al., 2015; Jiao et al., 2020; Sanh et al., 2019), pruning/sharing (Gordon et al., 2020; Chen et al., 2020), multi-device distribution (Banitalebi-Dehkordi et al., 2021), or a combination of these techniques (Cheng et al., 2017; Polino et al., 2018).

Among all the compression techniques, creating a fixed-size small version of large models along with distillation has been popular in the recent years. Sanh et al. (2019) introduced DistillBERT, which was a smaller version of BERT trained with distillation for general purposes. Another compact variant of BERT was proposed by MobileBERT (Sun et al., 2020) in which inverted bottleneck structures and progressive knowledge transfer were used. TinyBERT (Jiao et al., 2020) also presented a novel two-stage transformer distillation for both pre-training and task-specific fine-tuning. In (Iandola et al., 2020), the usage of grouped convolutions was studied to design SqueezeBERT. ELM (Jiao et al., 2021), a layer mapping search framework, was also proposed for improving downstream BERT distillation. A recent method, GhostBERT (Huang et al., 2021), employed softmax-normalized 1D convolutions as ghost modules to generate more features with cheap operations.

Although compression techniques in general are effective, they come with a trade-off on accuracy, and may lose performance in case of high ratio compression. In addition, an individual fixed-size model is required for each possible computational budget. As stated in the introduction, the alternative solution is dynamic inference, which can be achieved with either early-exit or length/depth-adaptive models. One of the first temporal early-exit strategies was proposed by ReasoNet (Shen et al., 2017), which stops its reading procedure when sufficient evidence has been found for answering a question. Similarly, in (Yu et al., 2018), an early stopping method applicable to classification tasks was presented. DeeBERT (Xin et al., ACL 2020) also proposed an instance-wise multi-exit method via the entropy of the output probability distribution to speed-up BERT inference.

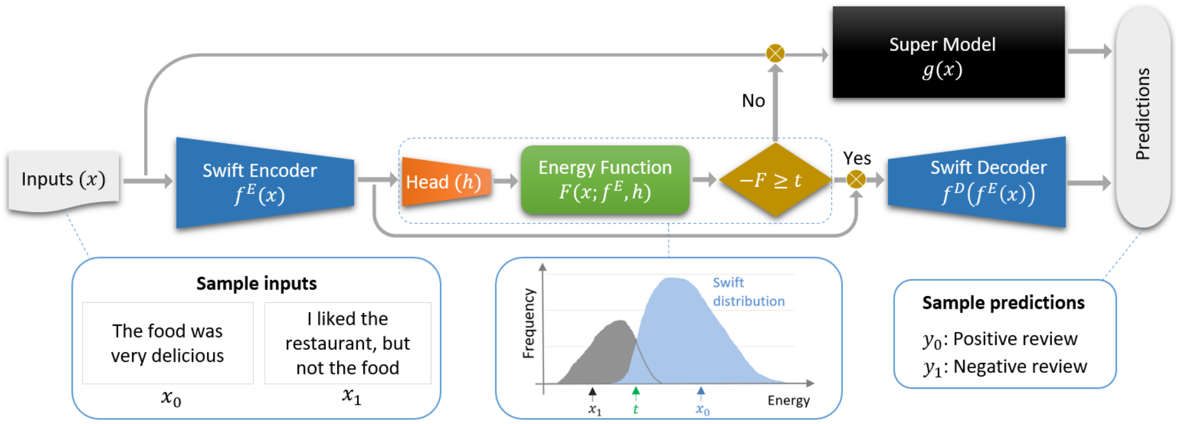

Figure 1: Overall framework of the proposed energy-based joint inference strategy (E-LANG).

As a length-adaptive method, Kim and Cho (2021) introduced a dynamic inference framework with one-shot training of transformers for both sequence- and token-level classification. Also, in (Hou et al., 2020), an architecture named DynaBERT was proposed for adaptively adjusting the computations by choosing sub-networks of different widths and depths. Both Length-Adaptive and DynaBERT utilized knowledge distillation and data augmentation to improve their performance.

Although early-exit and adaptive methods have made significant progress and work well in practice, they often require architectural manipulation and re-training. In addition, they are only applicable to encoder-only backbones and classification tasks. In contrast, our method can work with out-of-the-box pre-trained models without a need for re-training and are also applicable for encoder-decoder structures and sequence-to-sequence tasks.

3 Proposed Method

We propose a new energy-based joint inference method called E-LANG, where a large/accurate language model (**Super**) is jointly employed with a small/fast one (**Swift**) to achieve efficient inference without sacrificing the accuracy. To this end, inspired by the method in (Akbari et al., 2021), a routing mechanism empowered by energy-based models (EBM) is introduced to dynamically distribute the input samples between the Super and Swift models. Similar to the out-of-distribution (OOD) detection problem, our goal is to identify the OOD samples that are hard to handle for the Swift and forward them to the Super model. On the other hand, we have the in-distribution data for which the Swift can make highly reliable and accurate predictions. In other words, the routing mechanism needs to detect whether or not the input data fits in the Swift's distribution (i.e., the one the Swift has been trained with). Inspired by the success of EBMs in dealing with OOD detection problems (Lee et al., 2019), the energy characteristics of data samples for an efficient and effective routing are investigated in our work. The overall framework of E-LANG is shown in Figure 1.

3.1 Energy-Based Models

The goal of EBM is to build an energy function denoted by $E(\mathbf{x}) : \mathbb{R}^D \rightarrow \mathbb{R}$ that maps an input data $\mathbf{x} \in \mathbb{R}^D$ to a non-probabilistic energy value $y \in \mathbb{R}$. To turn a collection of arbitrary energies for all possible outputs (denoted by Y) into a normalized probability distribution, Gibbs distribution can be used as follows (LeCun et al., 2006):

$$p(y|\mathbf{x}) = \frac{e^{-E(\mathbf{x},y)}}{\int_{y' \in Y} e^{-E(\mathbf{x},y')}}, \qquad (1)$$

where the negative log of the denominator expresses the Helmholtz free energy (LeCun et al., 2006) defined as $F(\mathbf{x}) = -log\big(\int_{y' \in Y} e^{-E(\mathbf{x},y')}\big)$.

In machine learning, there is a deep relationship between the EBMs and discriminative models, which can be seen by connecting the Gibbs distribution in Equation (1) and the categorical distribution derived for a discriminative model. A discriminative classifier is defined as a function for mapping the input $\mathbf{x}$ to C real-valued logits (i.e., for C number of class labels): $f(\mathbf{x}) : \mathbb{R}^D \rightarrow \mathbb{R}^C$. In order to derive a categorical distribution over C possible outputs, the softmax function is utilized:

$$p(y|\mathbf{x}) = \frac{e^{f_y(\mathbf{x})}}{\sum_i^C e^{f_i(\mathbf{x})}}, \qquad (2)$$

where $f_y(\mathbf{x})$ denotes the logit (probability) of the yth class label. Based on the inherent connection between the Gibbs and categorical distributions defined in (1) and (2), the energy function for a given input $(\mathbf{x}, y)$ can be defined as $E(\mathbf{x}, y) = -f_y(\mathbf{x})$. The free energy function $F(\mathbf{x}; f)$ can then be obtained by taking the negative log of the categorical distribution denominator as:

$$F(\mathbf{x}; f) = -log \sum_{i}^{C} e^{f_i(\mathbf{x})}. \tag{3}$$

3.2 Energy-Based Joint Inference

Our goal is to detect the easy samples suitable for the Swift, which are indeed the ones with high likelihood in the density function. The energy-based density function for Swift is then defined as:

$$p(\mathbf{x}) = \frac{e^{-F(\mathbf{x};f)}}{\int_{\mathbf{x}} e^{-F(\mathbf{x};f)}}, \tag{4}$$

where the denominator is the normalized densities, which can be intractable to compute or estimate. By taking the logarithm of both sides, we obtain:

$$log\big(p(\mathbf{x})\big) = -F(\mathbf{x}; f) - log(\int_{\mathbf{x}} e^{-F(\mathbf{x};f)}). \tag{5}$$

The $log(\int_{\mathbf{x}} e^{-F(\mathbf{x};f)})$ term has no effect on the distribution of the overall energy values because it is constant for all $\mathbf{x}$. As a result, $-F(\mathbf{x}; f)$, i.e., the negative free energy, has a linear alignment with the log likelihood function, which makes it a well-suited solution to the easy vs. hard detection problem in our framework. To this end, lower energy values indicate higher likelihood and represent easier (more fit) samples for the Swift model.

More precisely, for a threshold δ on the density function such that $p(\mathbf{x}) < \delta$, then a threshold t on the negative free energy can be calculated according to (5) as $-F(\mathbf{x}; f) < t = log(\delta \int_{\mathbf{x}} e^{-F(\mathbf{x};f)})$. In practice, for a given input, an energy function is applied to the outputs of the Swift model during inference time to calculate the energy score. Then, if the negative energy value is smaller than a threshold, the input is identified as a bad sample for the Swift, and is sent to the Super model.

Given the energy threshold t, the Swift classifier $f(\mathbf{x})$, and the Super classifier defined as $g(\mathbf{x}) : \mathbb{R}^D \rightarrow \mathbb{R}^C$, the joint inference function $J(\mathbf{x}; f, g, t) \in [1, C]$ for a classification task with C classes can then be expressed by:

$$J(\mathbf{x}; f, g, t) = \begin{cases} f(\mathbf{x}) & \text{if } -F(\mathbf{x}; f) \geq t \\ g(\mathbf{x}) & \text{otherwise.} \end{cases} \tag{6}$$

3.2.1 Encoder-Decoder Architectures

The proposed energy-based joint inference solution can be directly applied to the encoder-only models such as BERT that are designed for text classification tasks. To this end, the energy scores corresponding to the BERT-based Swift model are obtained using Equation (3) and the joint inference is performed based on Equation 6.

On the other hand, for the encoder-decoder (auto-encoder) architectures such as T5, which are usually considered as generative models, some modifications are required. Encoder-decoder models are basically designed for sequence-to-sequence (e.g., text-to-text) problems such as translation or summarization. Although such models can also be employed for classification tasks, they still consider the task as a text generation (sequence-to-sequence) problem, where the target labels and the output predictions are treated as a sequence or a piece of text.

In Section 3.1, it was discussed that there is an inherent connection between the discriminative classifiers and the EBMs. In order to benefit from this characteristic for encoder-decoder architectures, we consider adding an extra classification head (i.e., a single linear layer) to the Swift model. As encoders are commonly considered as better feature extractors for training a classifier rather than the decoders, we place the extra head after the Swift encoder. While freezing the pre-trained encoder model (denoted by f^E), the extra energy head (denoted by h) is trained as a regular classifier head with C class labels. Note that the decoder is not required for training the head. The corresponding free energy function is then defined as follows:

$$F(\mathbf{x}; f^E, h) = -log \sum_{i}^{C} e^{h_i\left(f^E(x)\right)}, \tag{7}$$

where $f^E(x)$ denotes the outputs of the encoder's last hidden state. These features are then fed to the extra head h to obtain the logits for the ith class required for computing the energy scores.

In this approach, as the decoder part of the Swift model is not required for calculating the energy scores, less computations are involved and the joint inference is performed more efficiently.

For text-to-text (or sequence-to-sequence) problems such as translation, the output is a sequence of M word-pieces from a vocabulary/dictionary of size N. To still utilize the relationship of discriminative models and EBMs in designing and training the extra energy head, we can treat the text-to-text models as M multi-class classifiers. In this case, the number of class labels, i.e., C in (7), is equal to N. The final energy score is then calculated as the average of M energy values as follows:

$$F(\mathbf{x}; f^E, h) = -\frac{1}{M} \sum_m^M \Big(log \sum_i^C e^{h_{m,i}\left(f^E(x)\right)}\Big), \quad (8)$$

where $h_{m,i}(.)$ denotes the logits corresponding to the mth word in the sequence and ith class label.

Denote the Swift's decoder by f^D, the joint inference function, $J(\mathbf{x}; f, g, h, t)$, based on energy scores in either Equation (7) or (8) is expressed as:

$$J = \begin{cases} f^D\big(f^E(x)\big) & \text{if } -F(\mathbf{x}; f^E, h) \geq t \\ g(\mathbf{x}) & \text{otherwise.} \end{cases} \quad (9)$$

3.3 Softmax and Entropy Mechanisms

In addition to energy, softmax and entropy (Xin et al., ACL 2020) scores can also be used for analyzing the Swift model's performance in the routing mechanism. In this sub-section, we study the mathematical connection of them with the energy score and their potential to solve our problem.

3.3.1 Softmax-Based Mechanism

The softmax score for a classifier is expressed by:

$$\max_y p(y|\mathbf{x}) = \max_y \frac{e^{f_y(\mathbf{x})}}{\sum_i^C e^{f_i(\mathbf{x})}} = \frac{e^{f_{max}(\mathbf{x})}}{\sum_i^C e^{f_i(\mathbf{x})}}. \quad (10)$$

By taking the logarithm of both sides, we see the connection between the log of the softmax and the free energy score formulated in Equation (3):

$$\begin{aligned} log \max_y p(y|\mathbf{x}) &= log(e^{f_{max}(\mathbf{x})}) - log \sum_i^C e^{f_i(\mathbf{x})} \\ &= f_{max}(\mathbf{x}) + F(\mathbf{x}; f), \end{aligned} \quad (11)$$

where all logits are shifted by their maximum $f_{max}(x)$. Plugging in the energy term to (5) yields:

$$\begin{aligned} log \max_y p(y|\mathbf{x}) &= -log(p(\mathbf{x})) + f_{max}(\mathbf{x}) \\ &\quad -log\Big(\int_{\mathbf{x}} e^{-F(\mathbf{x};f)}\Big). \end{aligned} \quad (12)$$

It is observed that for the samples with high likelihood of being in the Swift's distribution, the free energy goes lower, but the max logit tends to go higher. Due to this shifting, unlike the energy score, the softmax score is not well-aligned with the probability density $p(\mathbf{x})$. As a result, the softmax score is less reliable for our routing module to analyze the performance of the Swift.

3.3.2 Entropy-Based Mechanism

The entropy score is a measure of randomness in the processed information, and is calculated as:

$$H(\mathbf{x}; f) = -\sum_i^C f_i.log(f_i), \quad (13)$$

where $f_i(\mathbf{x})$ is the probability (logit) corresponding to the ith class label. Let U be the internal energy, i.e., the expectation value of the energy function (Oh et al., 2020), defined by:

$$U(\mathbf{x}; f) = \sum_i^C E(\mathbf{x}, i) f_i. \quad (14)$$

According to Oh et al. (2020), the entropy can be defined in terms of the internal and free energy functions as: $H(\mathbf{x}; f) = U(\mathbf{x}; f) - F(\mathbf{x}; f)$, where all logits are shifted by the internal energy U. Substituting the free energy from (5) yields:

$$H(\mathbf{x}; f) = log(p(\mathbf{x})) + U(\mathbf{x}; f) + log\Big(\int_{\mathbf{x}} e^{-F(\mathbf{x};f)}\Big), \quad (15)$$

which shows, due to the shifting caused by internal energy, the entropy is not reliably aligned with the probability density $p(\mathbf{x})$. Thus, it is a less suitable routing mechanism unlike the energy score.

4 Experimental Results

In this section, the performance of E-LANG on different architectures such as T5 and BERT; and benchmarks such as GLUE (Wang et al., 2019b), SuperGLUE (Wang et al., 2019a), and WMT (Bojar et al., 2016) is evaluated and compared with the Super models and previous works.

4.1 T5-Based Joint Inference

In Table 1, the T5-based results on GLUE, SuperGLUE, and WMT benchmarks are reported. For all the tasks, we use T5-11B (with 87×10^{11} FLOPs) and T5-large (with 4.25×10^{11} FLOPs) as our Super and Swift models, respectively. The average GPU-based running time and accuracy of both models compared with E-LANG are also summarized in the table. Note that the T5 models used in this experiment have been separately fine-tuned on each of the downstream tasks given in Table 1. The extra energy head for each of these tasks was also separately trained and used based on the task-specific number of classes, i.e., C in Equation (7).

Table 1: Joint inference results with T5 architecture on GLUE and SuperGLUE development sets, and WMT's English-to-Romanian translation. The FLOPs for Super and Swift are respectively 87×10^{11} and 4.25×10^{11}.

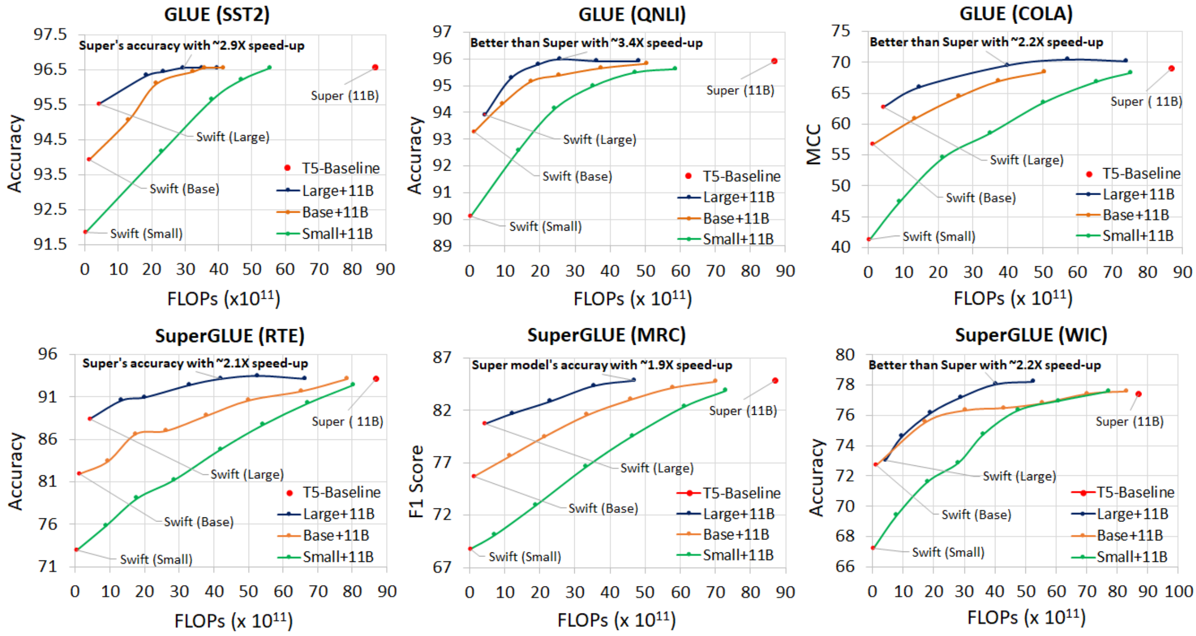

Figure 2: Joint inference trade-off curves with T5 architecture on GLUE and SuperGLUE development sets. Each point is obtained with a different energy threshold.

The total FLOPs for our method is measured as a weighted average of the Super and Swift FLOPs based on their usage frequency as:

$$FLOPs = \frac{1}{N_{sw} + N_{su}} \big(N_{sw}.(F_{sw}^{E} + F_h + F_{sw}^{D}) + N_{su}.(F_{sw}^{E} + F_h + F_{su})\big), \quad (16)$$

where N_{su} and N_{sw} are respectively the number of samples processed by the Super (with F_{su} FLOPs) and Swift (with F_{sw}^{E}, F_{sw}^{D}, and F_h FLOPs for the encoder, decoder, and energy head). Note that F_h is equal to $\approx$0.00001$\times10^{11}$, which has a very insignificant overhead in our framework.

As presented in Table 1, E-LANG can reach the Super model's accuracy on all GLUE tasks with an average 3.3X in FLOPs and 1.8X in running time speed-ups. For some tasks such as QNLI, MRPC, and COLA, we even outperform the Super model, which leads to a higher average accuracy of 89.7% than the Super model with 89.5% on GLUE. For the SuperGLUE benchmark, with an average FLOPs and running time speed-up of 2.9X and 2.0X, our method achieves the same accuracy as the Super model on MRC and CB; and better accuracy on RTE and WIC. On BoolQ and COPA, although 99% and 97% of the Super's accuracy are respectively obtained, it is with 1.7X and 1.4X less FLOPs and latency, on average.

In order to analyze the generality of E-LANG to other NLP problems rather than text classification (Section 3.2.1), we also apply our method to two text-to-text tasks including SuperGLUE's WSC and WMT's English-to-Romanian (EnRo) translation. As given in the table, our method achieves the Super model's accuracy on both WSC and EnRo with 4.2X and 1.4X less FLOPs, respectively.

Figure 2 illustrates the accuracy vs. FLOPs trade-off curves for some tasks in GLUE and Super-

GLUE benchmarks. The curves related to all tasks are given in the supplementary materials. The trade-off points on the curves are dynamically achieved at the inference time by selecting different thresholds, i.e., t in Equations (6) and (9). Larger values for t will result in routing more input data to the Super model, which consequently provides more accurate, but slower inference. As the Swift is able to make accurate predictions for the majority of input data, the dynamic inference with a small enough t can reach the Super model's accuracy but with a much lower computational cost and latency.

Figure 3 illustrates the distribution of the energy scores across the input samples in GLUE tasks. For each task, the distributions of the samples processed by the Super and the Swift models are plotted. As shown, the samples routed to the Super model tend to have lower energy scores that are indeed considered as out-of-distribution samples for the Swift. On the other hand, in overall, higher scores are observed for the Swift distribution, that is for the samples handled by the Swift only. For some tasks such as MRPC and QNLI, the Swift is shown to be highly capable of handling the majority of the input samples. This is also supported by the results in Table 1 and Figure 2, where 91% (for MRPC) and 75% (for QNLI) of the samples are accurately processed by the Swift. In contrast, for other datasets including RTE and MNLI with Swift ratio of less than 50%, most of the samples are hard for the Swift, which are transferred to the Super model. Based on our experiments, the most optimal results for our joint inference framework is achieved when the crossing point of the two distributions (highlighted in green in the figures) is chosen as the threshold t in Equation (9).

4.1.1 Ablation Studies

In Sections 3.3.1 and 3.3.2, the possibility of using softmax and entropy scores instead of energy score was theoretically analyzed. To support that analysis and also experimentally evaluate the performance of different routing mechanisms, an ablation study on GLUE is performed, which is presented in Table 2. In this study, we report the joint inference results based on softmax, entropy, and random scores (i.e., randomly distributing the samples between Super and Swift). Our experiments show that, compared to the random score, softmax and entropy can result in satisfactory performance on routing the samples. However, as also discussed in Sections 3.3.1 and 3.3.2, the energy score is still a better mechanism with about 14% less FLOPs. Another potential mechanism is the perplexity (Chen et al., 1998), but since it provides the same information as entropy, we did not add any extra experiment on it.

The results with the usage of different Swift models including T5-small (with 0.33×10^{11} FLOPs) and T5-base (with 1.24×10^{11} FLOPs) are also given in Table 2. Using these models as Swifts can lead to good performance on some tasks, but not all of them. For example, on SST2, the joint inference with T5-small and T5-base Swifts can respectively reach the Super's accuracy with 1.9X and 2.X less computations. In general, although these models are smaller and require less FLOPs, our results in Table 2 indicate that they perform worse than T5-large in our joint inference structure. In Figure 2, the trade-off curves for different Swift models are shown for GLUE and SuperGLUE.

Moreover, to show the effectiveness of the extra energy head for the Swift encoder, the E-LANG results based on last linear layer of the Swift decoder is also given and compared in Table 2. As reported, the E-LANG empowered by the energy head on the Swift encoder outperforms the case with the decoder's head in both FLOPs (36.8% less) and accuracy (0.7% better). As explained in Section 3.2.1, this shows the deep connection between the encoder's features, discriminative models, and the proposed routing mechanism via the energy head.

We observed that E-LANG can achieve a high performance even when applied to individually pre-trained Super and Swift models. But, more improvement can still be obtained by performing KD from the Super to the Swift model, especially at the fine-tuning process for downstream tasks. To study this, we apply the KD technique in (Sanh et al., 2019) to the Super and Swift models for some GLUE tasks. As summarized in Table 3, the Super model's accuracy for QNLI, SST2, and COLA is respectively attained by the distillation-based E-LANG with 29.2%, 48.5%, and 14.3% less FLOPs than E-LANG (without distillation). The results show the effectiveness of E-LANG along with other compression techniques such as distillation. The trade-off curves for this experiment will be provided in the supplementary materials.

4.2 BERT-Based Joint Inference

In this section, the proposed energy-based joint inference method is applied to the BERT architecture (Devlin et al., 2019) and compared with

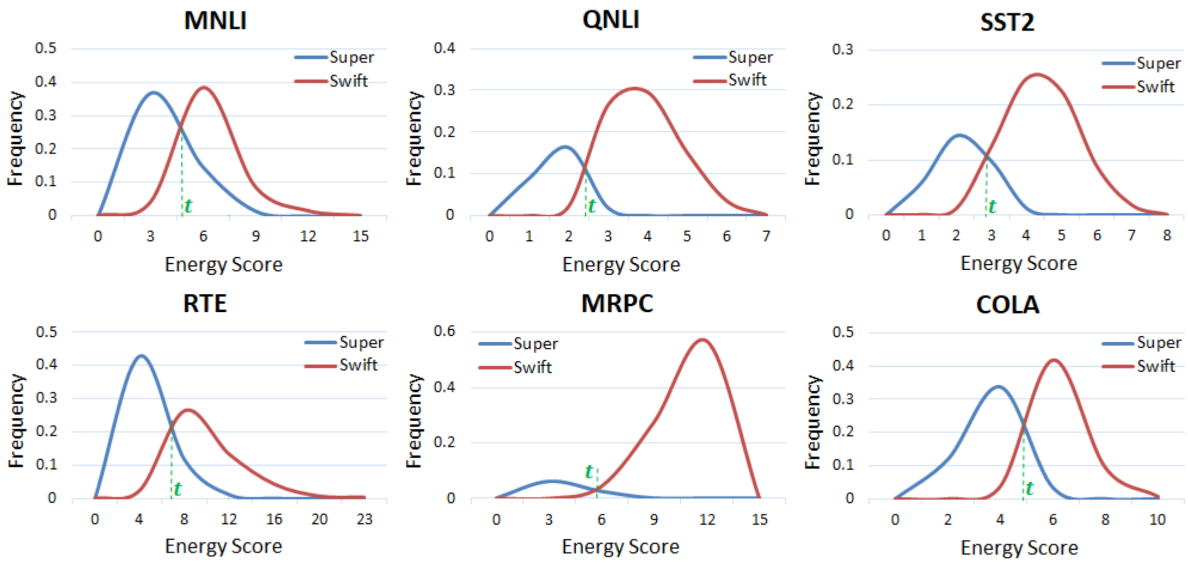

Figure 3: Energy score distribution for GLUE tasks. t shows the optimal threshold.

+ Distillation	**18.2 / 96.0**	**15.2 / 96.6**	**34.2 / 69.5**

Table 3: Distillation-based results with T5 in terms of FLOPs/Accuracy.

BERT-based SOTA in both fixed-size and dynamic inference. The majority of the previous methods employ knowledge distillation and data augmentation techniques for training their student models. For a fair comparison, we follow the same practice and use the transformer distillation and augmentation strategies in TinyBERT (Jiao et al., 2020) to train and prepare our Swift model (i.e., BERT$_{Tiny}$ with 1.2×10^9 FLOPs). Moreover, similar to the other works, we use BERT$_{Base}$ (with 21.8×10^9 FLOPs) as our Super (i.e., teacher) model.

In Table 4, the comparison results with the baseline BERT$_{Base}$ and SOTA on GLUE benchmark are presented in terms of accuracy, FLOPs, and latency. Compared to the Super model, E-LANG delivers better accuracy on SST2 and RTE with 3.5X and 2.0X FLOPs speed-up; and the same accuracy on QNLI, MRPC, and QQP with 2.4X, 2.7X, and 7.0X FLOPs speed-up, respectively. On MNLI and COLA, 99.8% and 97.3% of the Super model's accuracy are achieved, but with an average FLOPs speed-up of 2.3X. On average, E-LANG outperforms the Super model with 0.1% higher accuracy, 3.2X less FLOPs, and 1.6X less latency.

Compared with SOTA, our method achieves the best performance on all GLUE tasks, except MRPC for which SqueezeBERT outperforms all due to having a more accurate teacher (Iandola et al., 2020). There are some works such as ELECTRA (Clark et al., 2020) and MobileBERT (Sun et al., 2020) that require less FLOPs than our method, but they only reach 95% of the baseline's accuracy. Compared to other methods, GhostBERT (Huang et al., 2021) and DynaBERT (Hou et al., 2020) give the closest performance to the baseline and even the same as ours on some tasks such as QNLI. However, on average, they still need about 30% more FLOPs on GLUE compared to E-LANG.

The E-LANG accuracy vs. FLOPs trade-off curves compared to SOTA on some of GLUE tasks are shown in Figure 4. The trade-off curves for all the tasks are reported in the supplementary materials. Among the SOTA methods presented in Table

Table 4: Joint inference results with BERT architecture on GLUE development set compared with SOTA.

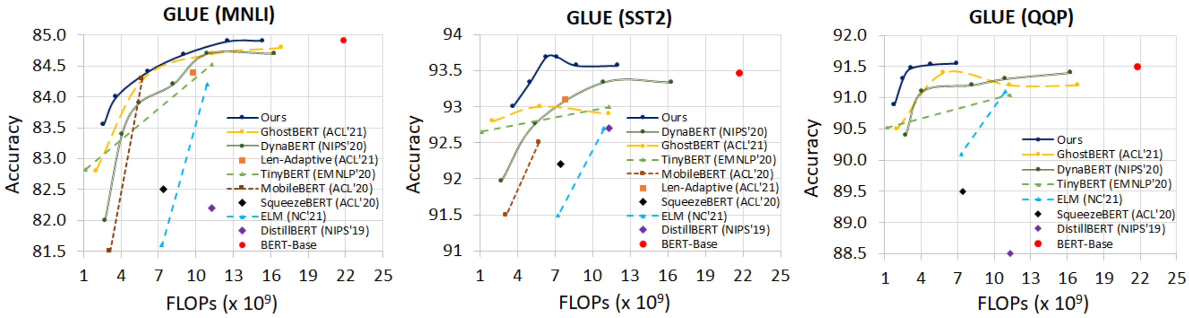

Figure 4: Joint inference trade-off curves with BERT on GLUE development set compared with SOTA.

4 and Figure 4, only DeeBERT (Xin et al., ACL 2020), Length-Adaptive (Kim and Cho, 2021), and DynaBERT (Hou et al., 2020) are in the category of dynamic inference, where a single model can operate at different trade-off points between accuracy and computational cost. The other approaches propose fixed-size smaller versions of BERT$_{Base}$, which require re-training for every trade-off point.

To investigate the orthogonality of E-LANG with others, we integrate our energy-based joint inference strategy with DynaBERT that is SOTA in BERT-based adaptive inference. In other words, we analyze whether E-LANG can be added on top of other efficient methods to benefit both from their designs and our approach. In this experiment, the DynaBERT configurations with the highest accuracy (i.e., width=0.75 & depth=1.0) and the lowest FLOPs (i.e., width=0.5 & depth=0.25) are respectively employed as the Super and Swift models in our framework. The corresponding joint inference results on MNLI, SST2, and QQP are reported in Table 5. As observed, we accomplish the DynaBERT Super's accuracy for MNLI and SST2 with 1.7X and 3.1X less FLOPs. For QQP, our method combined with DynaBERT even outperforms DynaBERT by 0.1% with 2.6X FLOPs speed-up.

	MNLI	SST2	QQP
DynaBERT (Swift) (w=0.5, d=0.25)	2.7 / 82.0	2.7 / 91.9	2.7 / 90.4
DynaBERT (Super) (w=0.75, d=1.0)	16.3 / 84.7	16.3 / 93.3	16.3 / 91.4
Ours+DynaBERT	**9.4 / 84.7**	**5.2 / 93.3**	**6.2 / 91.5**

Table 5: Orthogonality of E-LANG (ours) with DynaBERT in terms of FLOPs/Accuracy.

5 Conclusion

In this paper, we introduced E-LANG, an energy-based joint inference approach, which integrates Super and Swift language models for achieving efficient inference without sacrificing the accuracy. Our method can work with both encoder-only (e.g., BERT) and encoder-decoder (e.g., T5) architectures, and is also applicable for text classification and sequence-to-sequence problems. The proposed joint inference strategy was theoretically and experimentally analyzed with an extensive set of experiments and ablation studies. Our results showed that E-LANG outperforms SOTA in both fixed-size and dynamic inference over different benchmarks such as GLUE and SuperGLUE. One future direction to this work is to apply E-LANG to multiple Super and Swift models with different sizes.

A Supplementary Materials

This section contains the supplementary materials.

A.1 Code and Demo

We shared our code to make it easy to reproduce our BERT-based results. In addition to the code, we included a video demo that contains a demonstration of T5-based E-LANG. The BERT-based E-LANG source-code with the detailed running instructions and the T5-based E-LANG demo are available here[1].

Please note that the demo is based on screen recording of a web application we built to show the use-cases of our method in real-world scenarios. Figure 5 shows a screenshot of the demo application.

The T5-based E-LANG code with detailed instructions is also shared in a 'code' directory in the supplementary materials file.

A.2 Additional Results and Visualizations

The trade-off curves (for the experiments given in Table 1) with T5 architecture on GLUE and SuperGLUE tasks are respectively shown in Figures 6 and 7. The ablation over different Swift models are also given in the figures.

In Figure 8, the accuracy vs. FLOPs trade-off curves for distillation-based experiments (reported in Table 3) are also given. On QNLI, distillation-based E-LANG (denoted by DE-LANG) with 4.8× less computations than the Super model outperforms E-LANG with 3.4× FLOPs speed-up, although both methods performs 0.1% more accurate than the Super model. DE-LANG on SST2 can also achieve the Super model's accuracy with 5.7× less computations, while the original E-LANG achieves the same performance with only 2.9× speed-up. Moreover, DE-LANG can improve the Super model's accuracy by 0.1% with 2.9× speed-up on SST2. For COLA, DE-LANG achieves a better FLOPs speed-up of 2.5× than E-LANG with 2.2× speed-up, where both outperform the Super model's accuracy by 0.4%.

Figure 9 also illustrates the corresponding curves for the BERT-based results of Table 4, which are compared with previous works in fixed-size and adaptive inference.

Abstract

We introduce PRIMERA, a pre-trained model for multi-document representation with a focus on summarization that reduces the need for dataset-specific architectures and large amounts of fine-tuning labeled data. PRIMERA uses our newly proposed pre-training objective designed to teach the model to connect and aggregate information across documents. It also uses efficient encoder-decoder transformers to simplify the processing of concatenated input documents. With extensive experiments on 6 multi-document summarization datasets from 3 different domains on zero-shot, few-shot and full-supervised settings, PRIMERA outperforms current state-of-the-art dataset-specific and pre-trained models on most of these settings with large margins.[1]

1 Introduction

Multi-Document Summarization is the task of generating a summary from a cluster of related documents. State-of-the-art approaches to multi-document summarization are primarily either graph-based (Liao et al., 2018; Li et al., 2020; Pasunuru et al., 2021), leveraging graph neural networks to connect information between the documents, or hierarchical (Liu and Lapata, 2019a; Fabbri et al., 2019; Jin et al., 2020), building intermediate representations of individual documents and then aggregating information across. While effective, these models either require domain-specific additional information e.g. Abstract Meaning Representation (Liao et al., 2018), or discourse graphs (Christensen et al., 2013; Li et al., 2020), or use dataset-specific, customized architectures, making it difficult to leverage pretrained language models. Simultaneously, recent pretrained language models (typically encoder-decoder transformers) have shown the advantages of pretraining and transfer learning for generation and summarization (Raffel et al., 2020; Lewis et al., 2020; Beltagy et al., 2020; Zaheer et al., 2020). Yet, existing pretrained models either use single-document pretraining objectives or use encoder-only models that do not work for generation tasks like summarization (e.g., CDLM, Caciularu et al., 2021).

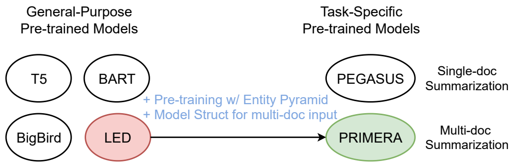

Figure 1: PRIMERA vs existing pretrained models.

Therefore, we argue that these pretrained models are not necessarily the best fit for multi-document summarization. Alternatively, we propose a simple pretraining approach for multi-document summarization, reducing the need for dataset-specific architectures and large fine-tuning labeled data (See Figure 1 to compare with other pretrained models). Our method is designed to teach the model to identify and aggregate salient information across a "cluster" of related documents during pretraining. Specifically, our approach uses the Gap Sentence Generation objective (GSG) (Zhang et al., 2020), i.e. masking out several sentences from the input document, and recovering them in order in the decoder. We propose a novel strategy for GSG sentence masking which we call, Entity Pyramid, inspired by the Pyramid Evaluation method (Nenkova and Passonneau, 2004). With Entity Pyramid, we mask salient sentences in the entire cluster then train the model to generate them, encouraging it to find important information across documents and aggregate it in one summary.

We conduct extensive experiments on **6** multi-document summarization datasets from **3** different domains. We show that despite its simplic-

Documents are separated with <doc-sep> tokens and they are assigned global attention.

Other tokens except for <s> have local attention only.

Selected sentences are replaced with a special [sent mask] token

The model is trained to generate the masked sentences

Figure 2: Model Structure of PRIMERA.

ity, PRIMERA achieves superior performance compared with prior state-of-the-art pretrained models, as well as dataset-specific models in both few-shot and full fine-tuning settings. PRIMERA performs particularly strong in zero- and few-shot settings, significantly outperforming prior state-of-the-art up to **5** Rouge-1 points with as few as 10 examples. Our contributions are summarized below:

1. We release PRIMERA, the first pretrained generation model for multi-document inputs with focus on summarization.
2. We propose Entity Pyramid, a novel pretraining strategy that trains the model to select and aggregate salient information from documents.
3. We extensively evaluate PRIMERA on 6 datasets from 3 different domains for zero-shot, few-shot and fully-supervised settings. We show that PRIMERA outperforms current state-of-the-art on most of these evaluations with large margins.

2 Model

In this section, we discuss our proposed model PRIMERA, a new pretrained general model for multi-document summarization. Unlike prior work, PRIMERA minimizes dataset-specific modeling by simply concatenating a set of documents and processing them with a general efficient encoder-decoder transformer model (§2.1). The underlying transformer model is pretrained on an unlabeled multi-document dataset, with a new entity-based sentence masking objective to capture the salient information within a set of related documents (§2.2).

2.1 Model Architecture and Input Structure

Our goal is to minimize dataset-specific modeling to leverage general pretrained transformer models for the multi-document task and make it easy to use in practice. Therefore, to summarize a set of related documents, we simply concatenate all the documents in a single long sequence, and process them with an encoder-decoder transformer model. Since the concatenated sequence is long, instead of more standard encoder-decoder transformers like BART (Lewis et al., 2020) and T5 (Raffel et al., 2020), we use the Longformer-Encoder-Decoder (LED) Model (Beltagy et al., 2020), an efficient transformer model with linear complexity with respect to the input length.[2] LED uses a sparse local+global attention mechanism in the encoder self-attention side while using the full attention on decoder and cross-attention.

When concatenating, we add special document separator tokens (`<doc-sep>`) between the documents to make the model aware of the document boundaries (Figure 2). We also assign global attention to these tokens which the model can use to share information across documents (Caciularu et al., 2021) (see §5 for ablations of the effectiveness of this input structure and global attention).

2.2 Pretraining objective

In summarization, task-inspired pretraining objectives have been shown to provide gains over general-purpose pretrained transformers (PEGASUS; Zhang et al., 2020). In particular, PEGASUS introduces Gap Sentence Generation (GSG) as a pretraining objective where some sentences are masked in the input and the model is tasked to generate them. Following PEGASUS, we use the GSG objective, but introduce a new masking strategy designed for multi-document summarization. As in GSG, we select and mask out m summary-like sentences from the input documents we want to summarize, i.e. every selected sentence is replaced by a

---

[2] We use LED and not other efficient transformers like Bigbird-PEGASUS (Zaheer et al., 2020) for two reasons, the first is that BigBird's global attention can't be assigned to individual tokens in the middle of the sequence, which is important for the representation of long documents as shown in Caciularu et al. (2021). Second, because pretrained checkpoints are available for LED, while BigBird-PEGASUS released the already fine-tuned checkpoints.

Document #1 Wildfires have burned across tens of thousands of acres of parched terrain in Colorado, spurring thousands of evacuations ...(0.107)..., residents have sought shelter in middle schools, and local officials fear tourists usually drawn to the region for the summer may not come.

Document #2 ... *In Colorado's southwest, authorities have shuttered the San Juan National Forest in southwestern Colorado and residents of more than 2,000 homes were forced to evacuate.(0.187)* No homes had been destroyed ... *"Under current conditions, one abandoned campfire or spark could cause a catastrophic wildfire, ..., with human life and property," said San Juan National Forest Fire Staff Officer Richard Bustamante*...

Document #3 The Buffalo Fire west of Denver is ... Several wildfires in Colorado have prompted thousands of home evacuations ...(0.172)... Nearly 1,400 homes have been evacuated in Summit County, Colorado, ...(0.179)... "Under current conditions, one abandoned campfire or spark could cause a catastrophic wildfire, ... , with human life and property," said Richard Bustamante, SJNF forest fire staff officer ...

Entities with High Frequency

Colorado, 416, Tuesday, Wildfires, San Juan National Forest,...

Figure 3: An example on sentence selection by Principle vs our Entity Pyramid strategy. Italic text in red is the sentence with the highest Principle ROUGE scores, which is thereby chosen by the Principle Strategy. Most frequent entity 'Colorado' is shown with blue, followed by the Pyramid ROUGE scores in parenthesis. The final selected sentence by Entity Pyramid strategy is in *italic*. which is a better pseudo-summary than the ones selected by the Principle strategy.

single token `[sent-mask]` in the input, and train the model to generate the concatenation of those sentences as a "pseudo-summary" (Figure 2). This is close to abstractive summarization because the model needs to reconstruct the masked sentences using the information in the rest of the documents.

The key idea is how to select sentences that best summarize or represent a set of related input documents (which we also call a "cluster"), not just a single document as in standard GSG. Zhang et al. (2020) use three strategies - Random, Lead (first m sentences), and "Principle". The "Principle" method computes sentence salience score based on ROUGE score of each sentence, s_i, w.r.t the rest of the document ($D/\{s_i\}$), i.e. $\text{Score}(s_i) = \textsc{Rouge}(s_i, D/\{s_i\})$. Intuitively, this assigns a high score to the sentences that have a high overlap with the other sentences.

However, we argue that a naive extension of such strategy to multi-document summarization would be sub-optimal since multi-document inputs typically include redundant information, and such strategy would prefer an exact match between sentences, resulting in a selection of less representative information.

For instance, Figure 3 shows an example of sentences picked by the Principle strategy (Zhang et al., 2020) vs our Entity Pyramid approach. The figure shows a cluster containing three news articles discussing a wildfire happened in Corolado, and the pseudo-summary of this cluster should be related to the location, time and consequence of the wildfire, but with the Principle strategy, the non-salient sentences quoting the words from an officer are assigned the highest score, as the exact same sentence appeared in two out of the three articles. In comparison, instead of the quoted words, our strategy selects the most representative sentences in the cluster with high frequency entities.

To address this limitation, we propose a new masking strategy inspired by the Pyramid Evaluation framework (Nenkova and Passonneau, 2004) which was originally developed for evaluating summaries with multiple human written references. Our strategy aims to select sentences that best represent the entire cluster of input documents.

2.2.1 Entity Pyramid Masking

Pyramid Evaluation The Pyramid Evaluation method (Nenkova and Passonneau, 2004) is based on the intuition that relevance of a unit of information can be determined by the number of references (i.e. gold standard) summaries that include it. The unit of information is called Summary Content Unit (SCU); words or phrases that represent single facts. These SCUs are first identified by human annotators in each reference summary, and they receive a score proportional to the number of reference summaries that contain them. A Pyramid Score for a candidate summary is then the normalized mean of the scores of the SCUs that it contains. One advantage of the Pyramid method is that it directly assesses the content quality.

Entity Pyramid Masking Inspired by how content saliency is measured in the Pyramid Evaluation, we hypothesize that a similar idea could be applied in multi-document summarization to identify salient sentences for masking. Specifically, for a cluster with multiple related documents, the more documents an SCU appears in, the more salient that information should be to the cluster. Therefore, it should be considered for inclusion in the pseudo-summary in our masked sentence generation objective. However, SCUs in the original Pyramid Evaluation are human-annotated, which is not feasible for large scale pretraining. As a proxy, we explore leveraging information expressed as named entities, since they are key building blocks in extracting information from text about events/objects and the relationships between their participants/parts (Jurafsky and Martin, 2009). Following the Pyramid

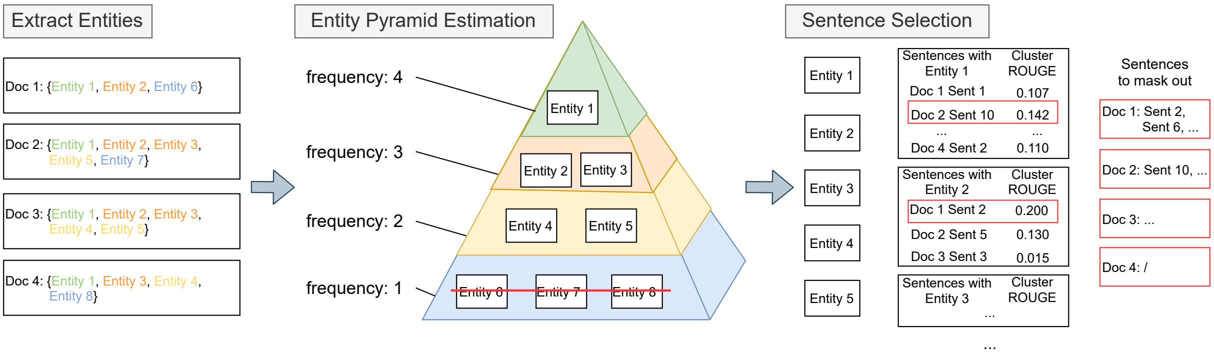

Figure 4: The Entity Pyramid Strategy to select salient sentences for masking. Pyramid entity is based on the frequency of entities in the documents. The most representative sentence are chosen based on Cluster ROUGE for each entity with frequency > 1, e.g. Sentence 10 in Document 2 for Entity 1.

Algorithm 1 Entity Pyramid Sentence Selection

```
Input: Document cluster
Input: List of entities w/ frequency $> 1$. $N$ length of the list
Input: $m$ number of sentences to select
Output: List of sentences to mask
$E \leftarrow$ sort entities by frequency, descending
$selected = []$
for $i \leftarrow 1$ to $|E|$ do
    $SentCand \leftarrow$ all sentences in the cluster containing $E[i]$
    $cur\_sent = \arg\max_{s \in SentCand} Score(s)$
    $selected.append(cur\_sent)$
    if $|selected| == m$ then
        Break
    end if
end for
Return $selected$
```

framework, we use the entity frequency in the cluster as a proxy for saliency. Concretely, as shown in Fig. 4, we have the following three steps to select salient sentences in our masking strategy:

1. *Entity Extraction*. We extract named entities using SpaCy (Honnibal et al., 2020).[3]

2. *Entity Pyramid Estimation*. We then build an Entity Pyramid for estimating the salience of entities based on their document frequency, i.e. the number of documents each entity appears in.

3. *Sentence Selection*. Similar to the Pyramid evaluation framework, we identify salient sentences with respect to the cluster of related documents. Algorithm 1 shows the sentence selection procedure. As we aim to select the entities better representing the whole cluster instead of a single document, we first remove all entities from the Pyramid that appear only in one document. Next, we iteratively select entities from top of the pyramid to bottom (i.e., highest to lowest frequency), and then select sentences in the document that include the entity as the initial candidate set. Finally, within this candidate set, we find the most representative sentences to the cluster by measuring the content overlap of the sentence w.r.t documents other than the one it appears in. This final step supports the goal of our pre-training objective, namely to reconstruct sentences that can be recovered using information from other documents in the cluster, which encourages the model to better connect and aggregate information across multiple documents. Following Zhang et al. (2020) we use ROUGE scores (Lin, 2004) as a proxy for content overlap. For each sentence s_i, we specifically define a Cluster ROUGE score as $Score(s_i) = \sum_{\{doc_j \in C, s_i \notin doc_j\}} \text{ROUGE}(s_i, doc_j)$ Where C is the cluster of related documents.

Note that different from the importance heuristic defined in PEGASUS (Zhang et al., 2020), Entity Pyramid strategy favors sentences that are representative of more documents in the cluster than the exact matching between fewer documents (See Figure 3 for a qualitative example.) . The benefit of our strategy is shown in an ablation study (§5).

3 Experiment Goals

We aim to answer the following questions:

- Q1: How does PRIMERA perform, compared with existing pre-trained generation models in zero- and few-shot settings? See §4.2.
- Q2: How does PRIMERA perform, compared with current state-of-the-art models, in the fully supervised setting? See §4.5.
- Q3: How much is the contribution of each component in PRIMERA, i.e. input structure, pretraining, and masking strategy? See §5.
- Q4: What is the effect of our entity pyramid

---

[3] Note that entity information is only used at pretraining time. This is unlike some prior work (e.g. Pasunuru et al. (2021)) that utilize additional information (like named entities, coref, discourse, or AMR) at fine-tuning and inference time.

Dataset	#Examples	#Doc/C	Len_{src}	Len_{summ}
Newshead (2020)	360K	3.5	1734	-
Multi-News (2019)	56K	2.8	1793	217

Table 1: The statistics of all the datasets we explore in this paper. *We use subsets of Wikisum (10/100, 3200) for few-shot training and testing only.

strategy, compared with the strategy used in PEGASUS? See §5.

- Q5: Is PRIMERA able to capture salient information and generate fluent summaries? See §6.

With these goals, we explore the effectiveness of PRIMERA quantitatively on multi-document summarization benchmarks, verify the improvements by comparing PRIMERA with multiple existing pretrained models and SOTA models, and further validate the contribution of each component with carefully controlled ablations. An additional human evaluation is conducted to show PRIMERA is able to capture salient information and generate more fluent summaries.

4 Experiments

4.1 Experimental Setup

Implementation Details We use the Longformer-Encoder-Decoder (LED) (Beltagy et al., 2020) large as our model initialization, The length limits of input and output are 4096 and 1024, respectively, with sliding window size as $w = 512$ for local attention in the input. (More implementation details of pretraining process can be found in Appx §A)

Pretraining corpus For pretraining, our goal is to use a large resource where each instance is a set of related documents without any ground-truth summaries. The *Newshead* dataset (Gu et al., 2020) (row 1, Table 1) is an ideal choice; it is a relatively large dataset, where every news event is associated with multiple news articles.

Evaluation Datasets We evaluate our approach on wide variety of multi-document summarization datasets plus one single document dataset from various domains (News, Wikipedia, and Scientific literature). See Table 1 for dataset statistics and Appx. §B for details of each dataset.

Evaluation metrics Following previous works (Zhang et al., 2020), we use ROUGE scores (R-1, -2, and -L), which are the standard evaluation metrics, to evaluate the downstream task of multi-document summarization.[4] For better readability, we use AVG ROUGE scores (R-1, -2, and -L) for evaluation in the few-shot setting.

4.2 Zero- and Few-shot Evaluation

Many existing works in adapting pretrained models for summarization require large amounts of fine-tuning data, which is often impractical for new domains. In contrast, since our pretraining strategy is mainly designed for multi-document summarization, we expect that our approach can quickly adapt to new datasets without the need for significant fine-tuning data. To test this hypothesis, we first provide evaluation results in zero and few-shot settings where the model is provided with no, or only a few (10 and 100) training examples. Obtaining such a small number of examples should be viable in practice for new datasets.

Comparison To better show the utility of our pretrained models, we compare with three state-of-the-art pretrained generation models: BART (Lewis et al., 2020)[5], PEGASUS (Zhang et al., 2020) and Longformer-Encoder-Decoder(LED) (Beltagy et al., 2020). These pretrained models have been shown to outperform dataset-specific models in summarization (Lewis et al., 2020; Zhang et al., 2020), and because of pretraining, they are expected to also work well in the few-shot settings. As there is no prior work doing few-shot and zero-shot evaluations on all the datasets we consider, and also the results in the few-shot setting might be influenced by sampling variability (especially with only 10 examples) (Bragg et al., 2021), we run the same experiments for the compared models five times with different random seeds (shared with all the models), with the publicly available checkpoints .[6]

Similar to Pasunuru et al. (2021), the inputs of all the models are the concatenations of the documents within the clusters (in the same order), each document is truncated based on the input length limit divided by the total number of documents so

---

[4] We use https://github.com/google-research/google-research/tree/master/rouge with default stemmer settings.

[5] Pilot experiments comparing BART and T5 showed BART to outperform T5 on the few-shot evaluation of Multi-News (with AVG ROUGE of 23.5/26.4 (T5) v.s. 25.2/26.7 (BART) for 10/100 training examples, respectively). Thus, we are using BART as one of the baselines.

Table 2: Zero-shot results. The models in the first block use the full-length attention ($O(n^2)$) and are pretrained on the single document datasets. The numbers in the parenthesis following each dataset indicate the output length limit set for inference. PEGASUS⋆ means results taken exactly from PEGASUS (Zhang et al., 2020), where available.

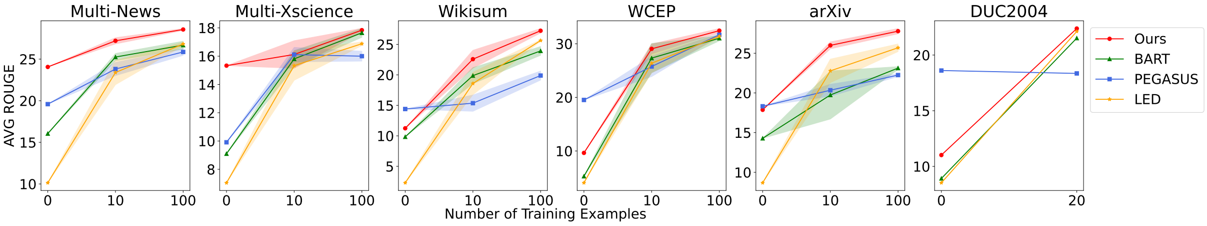

Figure 5: The AVG ROUGE scores (R-1, R-2 and R-L) of the pretrained models with 0, 10 and 100 training data with variance. All the results of few-shot experiments (10 and 100) are obtained by the average of 5 random runs (with std, and the same set of seeds shared by all the models). Note that DUC2004 only has 50 examples, we use 20/10/20 for train/valid/test in the few-shot experiments.

that all documents are represented in the input. [7]

To preserve the same format as the corresponding pretrained models, we set the length limit of output for BART and PEGASUS exactly as their pretrained settings on all of the datasets (except for the zero-shot experiments, the details can be found in Sec.4.3). Regarding length limit of inputs, we tune the baselines by experimenting with 512, 1024, 4096 on Multi-News dataset in few-shot setting (10 data examples), and the model with length limit 512(PEGASUS)/1024(BART) achieves the best performance, thus we use this setting (detailed experiment results for different input lengths can be found in Appx. §C.1). We use the same length limit as our model for the LED model, i.e. 4096/1024 for input and output respectively, for all the datasets.

4.3 Zero-Shot Results

For zero-shot[8] abstractive summarization experiments, since the models have not been trained on the downstream datasets, the lengths of generated summaries mostly depend on the pretrained settings. Thus to better control the length of generated summaries and for a fair comparison between all models, following Zhu et al. (2021), we set the length limit of the output at inference time to the average length of gold summaries.[9] Exploring other approaches to controlling length at inference time (e.g., Wu et al., 2021) is an orthogonal direction, which we leave for future work.

Table 2 shows the performance comparison among all the models. Results indicate that our model achieves substantial improvements compared with all the three baselines on most of the datasets. As our model is pretrained on clusters of documents with longer input and output, the benefit is stronger on the dataset with longer summaries, e.g. Multi-News and arXiv. Comparing PEGASUS and BART models, as the objective of PEGASUS is designed mainly for summarization tasks, not surprisingly it has relatively better performances across different datasets. Interestingly, LED underperforms other models, plausibly since part of the positional embeddings (1k to 4k) are not pretrained. Encouragingly, our model performs the best, demonstrating the benefits of our pretraining strategy for multi-document summarization.

4.4 Few Shot Evaluation

Compared with the strict zero-shot scenario, few-shot experiments are closer to the practical scenarios, as it is arguably affordable to label dozens of examples for almost any application.

---

[7] Pilot experiments show simple truncation results in inferior performance, which is in line with Pasunuru et al. (2021).

[8] For clarity, by zero-shot we mean using the pretrained model directly without any additional supervision.

[9] In practice, it is reasonable to assume knowing the approximate length of the expected summary for a given task/domain.

We fine-tune all of the four models on different subsets with 10 and 100 examples, and the results are shown in Figure 5. (hyperparameter settings in Appx. §D.1) Since R-1, -2, and -L show the same trend, we only present the average of the three metrics in the figure for brevity (full ROUGE scores can be found in Appx. Table 8) To show the generality, all the results of few-shot experiments are the average over 5 runs on different subsets (shared by all the models).

The result of each run is obtained by the 'best' model chosen based on the ROUGE scores on a randomly sampled few-shot validation set with the same number of examples as the training set, which is similar with Zhang et al. (2020). Note that their reported best models have been selected based on the whole validation set which may give PEGASUS some advantage. Nevertheless, we argue that sampling few-shot validation sets as we do here is closer to real few-shot scenarios (Bragg et al., 2021).

Our model outperforms all baselines on all of the datasets with 10 and 100 examples demonstrating the benefits of our pretraining strategy and input structure. Comparing the performances of our model with the different number of training data fed in, our model converges faster than other models with as few as 10 data examples.

4.5 Fully Supervised Evaluation

To show the advantage of our pretrained model when there is abundant training data, we also train the model with the full training set (hyperparameter settings can be found in Appx. §D.2). Table 3 shows the performance comparison with previous state-of-the-art[10], along with the results of previous SOTA. We observe that PRIMERA achieves state-of-the-art results on Multi-News, WCEP, and arXiv, while slightly underperforming the prior work on Multi-XScience (R-1). One possible explanation is that in Multi-XScience clusters have less overlapping information than in the corpus on which PRIMERA was pretrained. In particular, the source documents in this dataset are the abstracts of all the publications cited in the related work paragraphs, which might be less similar to each other and the target related work(i.e., their summary) . PRIMERA outperforms the LED model (State-of-the-art) on the arXiv dataset while using a sequence length 4x shorter (4K in PRIMERA v.s. 16K in LED), further showing that the pretraining and input structure of our model not only works for multi-document summarization, but can be also effective for summarizing single documents having multiple sections.

Datasets	Previous SOTA			PRIMERA		
	R-1	R-2	R-L	R-1	R-2	R-L
Multi-News	49.2	19.6	24.5	**49.9**	**21.1**	**25.9**
Multi-XScience	**33.9**	6.8	**18.2**	31.9	**7.4**	18.0
WCEP	35.4	15.1	25.6	**46.1**	**25.2**	**37.9**
arXiv	46.6	19.6	41.8	**47.6**	**20.8**	**42.6**

Table 3: Fully supervised results. Previous SOTA are from Pasunuru et al. (2021) for Multi-News, Lu et al. (2020) for Multi-XScience[11], Hokamp et al. (2020) for WCEP, and Beltagy et al. (2020) for arXiv.

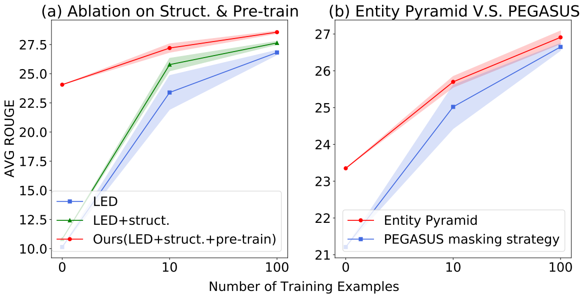

Figure 6: Ablation study with the few-shot setting on the Multi-News dataset regarding to (a) input Structure (`<doc-sep>` tokens between documents and global attention on them) and pretraining, (b) pretraining using PEGASUS vs our approach.

5 Ablation Study

We conduct ablation studies on the Multi-News dataset in few-shot setting, to validate the contribution of each component in our pretrained models.

Input structure: In Figure 6 (a) we observe the effectiveness of both pretraining and the input structure (`<doc-sep>` tokens between documents and global attention on them).

Sentence masking strategy: To isolate the effect of our proposed pretraining approach, we compare with a model with exactly the same architecture when pretrained on the same amount of data but using the PEGASUS (Zhang et al., 2020) masking strategy instead of ours. In other words, we keep all the other settings the same (e.g., data, length limit of input and output, pretraining dataset, input structure, as well as the separators) and only modify the pretraining masking strategy. We run the same experiments under zero-/few-shot scenar-

---

[9] We re-evaluate the generated summaries of the models from Lu et al. (2020) for Multi-XScience, as we use a different version of ROUGE.

[10] Due to the lack of computational resources, we do not train the model on Wikisum.

ios on the Multi-News dataset as in §4.2, and the results are shown in Figure 6 (b). The model pretrained with our Entity Pyramid strategy shows a clear improvement under few-shot scenarios.

6 Human Evaluation

We also conduct human evaluations to validate the effectiveness of PRIMERA on DUC2007 and TAC2008 (Dang and Owczarzak, 2008) datasets in the few-shot setting (10/10/20 examples for train/valid/test). Both datasets consist of clusters of news articles, and DUC2007 contains longer inputs (25 v.s. 10 documents/cluster) and summaries (250 v.s. 100 words). Since the goal of our method is to enable the model to better aggregate information across documents, we evaluate the content quality of the generated summaries following the original Pyramid human evaluation framework (Nenkova and Passonneau, 2004). In addition, we also evaluate the fluency of generated summaries following the DUC guidelines.[12]

Settings Three annotators[13] are hired to do both Pyramid Evaluation and Fluency evaluation, they harmonize the standards on one of the examples. Specifically, for each data example, we provide three anonymized system generated summaries, along with a list of SCUs. The annotators are asked to find all the covered SCUs for each summary, and score the fluency in terms of Grammaticality, Referential clarity and Structure & Coherence, according to DUC human evaluation guidelines, with a scale 1-5 (worst to best). They are also suggested to make comparison between three generated summaries into consideration when scoring the fluency. To control for the ordering effect of the given summaries, we re-order the three summaries for each data example, and ensure the chance of their appearance in different order is the same (e.g. BART appears as summary A for 7 times, B for 7 times and C for 6 times for both datasets). The instruction for human annotation can be found in Figure 7 and Figure 8 in the appendix. Annotators were aware that annotations will be used solely for computing aggregate human evaluation metrics and reporting in the scientific paper.

Compared Models We compare our model with LED and PEGASUS in human evaluations. Because PEGASUS is a task-specific model for abstractive summarization, and LED has the same architecture and length limits as our model with the parameters inherited from BART, which is more comparable with our model than vanilla BART.

Model	DUC2007(20)				TAC2008(20)			
	S_r	R	P	F	S_r	R	P	F
PEGASUS	6.0	2.5	2.4	2.4	**8.7**	**9.1**	9.4	9.1
LED	9.6	3.9	4.0	3.8	6.9	7.1	**10.8**	8.4
PRIMERA	**12.5**	**5.1**	**5.0**	**5.0**	8.5	8.9	10.0	**9.3**

Table 4: Pyramid Evaluation results: Raw scores S_r, (R)ecall, (P)recision and (F)-1 score. For readability, Recall, Precision and F-1 scores are multiplied by 100.

Model	DUC2007(20)			TAC2008(20)		
	Gram.	Ref.	Str.&Coh.	Gram.	Ref.	Str.&Coh.
PEGASUS	4.45	4.35	1.95	**4.40**	4.20	3.20
LED	4.35	4.50	3.20	3.10	3.80	2.55
PRIMERA	**4.70**	**4.65**	**3.70**	**4.40**	**4.45**	**4.10**

Table 5: The results of Fluency Evaluation on two datasets, in terms of the Grammaticality , Referential clarity and Structure & Coherence.

Pyramid Evaluation Both TAC and DUC datasets include SCU (Summary Content Unit) annotations and weights identified by experienced annotators. We then ask 3 annotators to make a binary decision whether each SCU is covered in a candidate summary. Following Nenkova and Passonneau (2004), the raw score of each summary is then computed by the sum of weights of the covered SCUs, i.e. $S_r = \sum_{SCU} w_i I(SCU_i)$, where $I(SCU_i)$ is an indicator function on whether SCU_i is covered by the current summary, and w_i is the weight of SCU_i. In the original pyramid evaluation, the final score is computed by the ratio of S_r to the maximum possible weights with the same number of SCUs as in the generated summaries. However, the total number of SCUs of generated summaries is not available in the simplified annotations in our design. To take consideration of the length of generated summaries and make a fair comparison, instead, we compute Recall, Precision and F-1 score regarding lengths of both gold references and system generated summaries as

$$\text{R}=\frac{S_r}{len(gold)};\quad \text{P}=\frac{S_r}{len(sys)};\quad \text{F1}=\frac{2\cdot R\cdot P}{(R+P)}$$

Fluency Evaluation Fluency results can be found in Table 5, and PRIMERA has the best performance on both datasets in terms of all aspects. Only

[13] We recruited expert annotators with payment above average of the participants' demographics.

for Grammaticality PRIMERA's top performance is matched by PEGASUS.

7 Related Work

Neural Multi-Document Summarization These models can be categorized into two classes, graph-based models (Yasunaga et al., 2017; Liao et al., 2018; Li et al., 2020; Pasunuru et al., 2021) and hierarchical models (Liu and Lapata, 2019a; Fabbri et al., 2019; Jin et al., 2020). Graph-based models often require auxiliary information (e.g., AMR, discourse structure) to build an input graph, making them reliant on auxiliary models and less general. Hierarchical models are another class of models for multi-document summarization, examples of which include multi-head pooling and inter-paragraph attention (Liu and Lapata, 2019a), MMR-based attention (Fabbri et al., 2019; Mao et al., 2020), and attention across representations of different granularity (words, sentences, and documents) (Jin et al., 2020). Prior work has also shown the advantages of customized optimization in multi-document summarization (e.g., RL; Su et al., 2021). Such models are often dataset-specific and difficult to develop and adapt to other datasets or tasks.

Pretrained Models for Summarization Pretrained language models have been successfully applied to summarization, e.g., BERTSUM (Liu and Lapata, 2019b), BART (Lewis et al., 2020), T5 (Raffel et al., 2020). Instead of regular language modeling objectives, PEGASUS (Zhang et al., 2020) introduced a pretraining objective with a focus on summarization, using Gap Sentence Generation, where the model is tasked to generate summary-worthy sentences, and Zou et al. (2020) proposed different pretraining objectives to reinstate the original document, specifically for summarization task as well. Contemporaneous work by Rothe et al. (2021) argued that task-specific pretraining does not always help for summarization, however, their experiments are limited to single-document summarization datasets. Pretraining on the titles of HTMLs has been recently shown to be useful for few-shot short-length single-document summarization as well (Aghajanyan et al., 2021). Goodwin et al. (2020) evaluate three state-of-the-art models (BART, PEGASUS, T5) on several multi-document summarization datasets with low-resource settings, showing that abstractive multi-document summarization remains challenging. Efficient pretrained transformers (e.g., Longformer (Beltagy et al., 2020) and BigBird (Zaheer et al., 2020) that can process long sequences have been also proven successful in summarization, typically by the ability to process long inputs, connecting information across the entire sequence. CDLM (Caciularu et al., 2021) is a follow-up work for pretraining the Longformer model in a cross-document setting using global attention on masked tokens during pretraining. However, this model only addresses encoder-specific tasks and it is not suitable for generation. In this work, we show how efficient transformers can be pretrained using a task-inspired pretraining objective for multi-document summarization. Our proposed method is also related to the PMI-based token masking Levine et al. (2020) which improves over random token masking outside summarization.

8 Conclusion and Future Work

In this paper, we present PRIMERA a pre-trained model for multi-document summarization. Unlike prior work, PRIMERA minimizes dataset-specific modeling by using a Longformer model pretrained with a novel entity-based sentence masking objective. The pretraining objective is designed to help the model connect and aggregate information across input documents. PRIMERA outperforms prior state-of-the-art pre-trained and dataset-specific models on 6 summarization datasets from 3 different domains, on zero, few-shot, and full fine-tuning setting. PRIMERA's top performance is also revealed by human evaluation.

In zero-shot setting, we can only control the output length of generated summaries at inference time by specifying a length limit during decoding. Exploring a controllable generator in which the desired length can be injected as part of the input is a natural future direction. Besides the summarization task, we would like to explore using PRIMERA for other generation tasks with multiple documents as input, like multi-hop question answering.

Ethics Concern

While there is limited risk associated with our work, similar to existing state-of-the-art generation models, there is no guarantee that our model will always generate factual content. Therefore, caution must be exercised when the model is deployed in practical settings. Factuality is an open problem in existing generation models.

A Implementation details of pre-training

As the multi-document summarization task has a higher compression ratio, defined as $len(Summary)/len(Input)$, (e.g. 12% for Multi-News dataset and 15% for Multi-Xscience dataset), we use 15% as the ratio of masked sentences for generation. In addition to this 15% masked sentences, following PEGASUS (Zhang et al., 2020), we also copy an additional 15% of the input sentences to the output without masking them in the input. This allows the model to also learn to copy information from the source directly and found to be useful by Zhang et al. (2020).

We pretrain the model for 100K steps, with early stopping, batch size of 16, Adam optimizer with a learning rate of $3e{-}5$ following Beltagy et al. (2020), with 10K warmup steps and linear decay. The pretraining process takes likely 7 days on 4 A100 GPUs.

As the backbone of PRIMERA is the Longformer Encoder Decoder model (LED), it has the same number of parameters with LED (447M).

B Detailed Description on the Evaluation Datasets

The details of evaluation datasets can be found below.

Multi-News (Fabbri et al., 2019): A multi-document dataset with summaries written by professional editors from the newser.com.

Wikisum (Liu* et al., 2018) Each summary is a Wikipedia article, and the source documents are either citations in the reference section or the Web Search results of section titles.[14] In our experiments, we use the data crawled by Liu and Lapata (2019a).

WCEP (Gholipour Ghalandari et al., 2020) is built based on news events from Wikipedia Current Events Portal and the references are obtained similar to Wikisum. There are at most 100 documents within each cluster in the original dataset, thus we remove all the duplicates and only keep up to 10 documents for each cluster based on the relevance score in the original dataset, which is similar to the WCEP-10 variant in the original paper.

Multi-X-Science (Lu et al., 2020) a multi-document summarization dataset created from scientific articles, the summaries are paragraphs of related work section, while source documents include the abstracts of the query and referred papers.

DUC benchmarks (Dang, 2005) include multi-document summarization datasets in the news domain, with 10-30 documents and 3-4 human-written summaries per cluster. Since these datasets are small, we use them primarily for a few-shot evaluation. We use DUC2003 for training (only one of the reference summaries for each document is used for training) and DUC2004 as test.

ArXiv (Cohan et al., 2018) is a single document summarization dataset in the scientific paper domain. Each document is a scientific paper, and the summary is the corresponding abstract. As each scientific paper consists of multiple sections, we treat each section as a separate document within a cluster in our experiments. This is to evaluate our model's effectiveness on summarizing single documents having multiple sections.

C Details on Compared models

The details of compared models in the zero-/few-shot setting can be found below.

BART (Lewis et al., 2020) an encoder-decoder transformer model pretrained on the objective of reconstructing the corrupted documents in multiple ways, e.g. Token Deletion, Text Infilling, Sentence Rotation and etc.

PEGASUS (Zhang et al., 2020) a pretrained model designed for abstractive summarization as the downstream task, especially for the single document input. It is trained on the objective of Gap Sentence Generation on C4 (Raffel et al., 2020) and Hugenews datasets (Note that the pretraining data size in PEGASUS is magnitudes larger than ours). As it is only evaluated on one multi-document summarization dataset (Multi-news), we rerun the model on all the datasets. To verify the quality of our reproduction, the average ROUGE scores of our re-run model vs. (the ones reported on the paper) with 10 examples and 100 examples fed are 23.81 ± 0.79 vs. (24.13) and 25.86 ± 0.41 vs. (25.48), with minor differences plausibly resulting from different samplings.

---

[14] Due to the large size of the dataset, we evaluate all the models on the first 3200 data in the test set. And in the few-shot experiments, we randomly choose few examples (10 or 100) from the training set and validation set.

Length Limit	BART			PEGASUS		
	R-1	R-2	R-L	R-1	R-2	R-L
512	-	-	-	**39.0**	**12.1**	**20.3**
1024	**42.3**	**13.7**	**19.7**	37.6	10.7	18.8
4096	37.9	11.0	17.5	34.9	8.7	17.6

Table 6: The ROUGE score (R-1/R-2/R-3) for pretrained models (BART and PEGASUS) with different input length limit in few-shot setting (10 data example) on the multi-news dataset. The results are the average over 5 runs on different subsets (the same seeds shared with all the other models in this paper).

Longformer Encoder-Decoder (LED) (Beltagy et al., 2020) is the initial state of our model before pretraining. The parameters of LED are inherited from the BART model, and to enable the model to deal with longer input, the position embeddings are repeatedly copied from BART's 1K position embeddings. It is different from our model with respect to both pretraining and input structure (document separators and global attentions), with global attention on the (<s>) token only and no document separators.

C.1 Detailed Experiment for Input Length Limit

We run an experiment to select the proper length limit for compared pretrained models, i.e. BART and PEGASUS. Specifically, we train both models with different input length limits (512/1024/4096) in the few-shot setting (with 10 data examples) on the multi-news dataset. Similar as the few-shot experiments described in §4.2, we train each model with each specific input length limit for 5 times on different subsets, which are shared by all the models. As shown in Table 6, BART with length limit 1024 performs the best and PEGASUS with length limit 512 performs the best, thus in all our experiments, we use 1024 as the input length limit for BART and 512 for PEGASUS.

D Hyperparameters in Few-shot and Full Supervised Experiments

D.1 Few-shot Experiments

We use Adam as the optimizer with linear scheduled learning rate $3e-5$ for BART, LED and our model, and use the default optimization settings of the few-shot experiments from Zhang et al. (2020), i.e. AdaFactor optimizer with scheduled learning rate $5e-4$. For all the experiments with 10 examples, the batch size is 10, the models are trained for 200 steps, with warm-up as 20 steps. For the experiments with 100 examples, we use the same batch size, with the total step and warm-up step set to be 1000 and 100, respectively.

D.2 Fully Supervised Experiments

We use Adam as the optimizer with linear scheduled learning rate $3e-5$, and batch size as 16 for all the datasets in the full supervised experiments. The number of steps and warm-up steps are set based on the size of the datasets. The details can be found in Table 7

Dataset	Total Steps	Warmup Steps
Multi-News	25k	2.5k
Multi-XScience	20k	2k
WCEP	5k	.5k
arXiv	40k	4k

Table 7: Details of total steps and warm-up steps used in the Full Supervised experiments.

E Detailed Results in Few-shot Setting

The exact ROUGE scores in Figure 5 are shown in Table 8.

Model	0 Examples	10 Examples	100 Examples

Table 8: Detailed ROUGE scores (R-1/R-2/R-L) on all the datasets in the few-shot setting (corresponds to Figure 5)

F Detailed Analysis on Fully Supervised Experiments

To show the advantage of our pre-trained model when there is sufficient data, we also train the model with the full training set, and the results can be found in Table 9-12[15], along with the results from previous works. Differently from the zero-/few-shot experiments, here we report the state-of-the-art results on different datasets, as they were presented in the corresponding original papers. Since we use the same train/valid/test set as in those prior works, we can perform a fair comparison , without re-running all those extremely time-consuming experiments .

Overall, our model achieves state-of-the-art on Multi-News (see Table 9 , WCEP dataset (see Table 11) and arXiv dataset (see Table 12).

Models	ROUGE-1	ROUGE-2	ROUGE-L
PEGASUS (Zhang et al., 2020)	47.52	18.72	24.91
BART-Long-Graph (Pasunuru et al., 2021)	49.03	19.04	24.04
BART-Long-Graph(1000) (Pasunuru et al., 2021)	49.24	18.99	23.97
BART-Long(1000) (Pasunuru et al., 2021)	49.15	19.50	24.47
Ours	**49.94**	**21.05**	**25.85**

Table 9: ROUGE scores of the previous models and our fully supervised model on the Multi-News dataset. The results of PEGASUS is from Zhang et al. (2020), and the other results are from Pasunuru et al. (2021)

Multi-News The experiment results on Multi-News dataset can be found in Table 9. Specifically, the PEGASUS model (Zhang et al., 2020) is pre-trained on a large-scale single-document dataset with the Gap Sentence Generation objective, which is the same as ours, but with a different masking strategy, BART-Long (Pasunuru et al., 2021) uses the same model structure as ours , and BART-Long-Graph (Pasunuru et al., 2021) additionally has discourse graph injected. Comparing the results with the BART-Long model, our model is around 1 ROUGE point higher, which may result from either better model structure or pre-training. Interestingly, in one of the ablation studies in Pasunuru et al. (2021), they find that the BART-Long model achieves its best performance with the length limit of 1000, and no further improvement is found when the length limit is greater than that. Thus we may conclude the gap between the performances is mainly from our design on the model, i.e. the document separators, proper global attention as well as the pre-training on a multi-document dataset.

Models	R1	R2	RL*
LEAD	27.46	4.57	-
BERTABS	31.56	5.02	-
BART	32.83	6.36	-
SCIBERTABS	32.12	5.59	-
SOTA(Pointer Generator)	**34.11**	6.76	18.2
LEAD(ours)	26.49	4.26	14.70
Ours	31.93	**7.37**	18.02

Table 10: ROUGE scores of the previous models and our fully supervised model on the Multi-Xscience dataset. All the results are from Lu et al. (2020). * The ROUGE-L is not comparable as we have different settings on the settings of evaluation, see the gap between LEAD and LEAD(ours).

Models	R1	R2	RL
BERTREG (Gholipour Ghalandari et al., 2020)	35.0	13.5	25.5
SUBMODULAR+ABS(Gholipour Ghalandari et al., 2020)	30.6	10.1	21.4
DynE (Hokamp et al., 2020)	35.4	15.1	25.6
Ours	**46.08**	**25.21**	**37.86**

Table 11: ROUGE scores of the previous models and our fully supervised model on the WCEP dataset.

WCEP As for the WCEP dataset, BERTREG (Gholipour Ghalandari et al., 2020) is a Regression-based sentence ranking system with BERT embedding, which is used as extractive summarization method, while Submodular+Abs is a simple two-step abstractive summarization model with a submodular-based extractive summarizer followed by a bottom-up abstractive summarizer (Gehrmann et al., 2018). DynE is a BART-based abstractive approach, which is to ensemble multiple input, allowing single document summarization models to be directly leveraged on the multi-document summarization task. Our model outperforms all the models by a large margin, including the SOTA model DynE, and it may indicate that the plain structure is more effective than purely ensembling the output of single documents.

arXiv In addition to the experiments on multi-document summarization datasets, we also compare our fully supervised model with previous works on the arXiv dataset, with each section treated as a single document. All the models to be compared with are based on pre-trained models, and Bigbird-PEGASUS and LED utilize the pre-training of PEGASUS (Zaheer et al., 2020) and BART (Lewis et al., 2020), respectively. However, both Bigbird and LED apply more efficient attentions, which make the models able to take longer

---

[15] Due to the lack of computational resources, we do not train the model on Wikisum.

Models	R1	R2	RL
PEGASUS (1K)	44.21	16.95	38.83
Bigbird-PEGASUS (3k)	46.63	19.02	41.77
LED(4K)	44.40	17.94	39.76
LED(16K)	46.63	19.62	41.83
Ours(4k)	**47.58**	**20.75**	**42.57**

Table 12: ROUGE scores of the previous models and our fully supervised model on the arXiv dataset. The result of PEGASUS and BigBird-PEGASUS are from (Zaheer et al., 2020), and the results of LED are from (Beltagy et al., 2020). The number in the parenthesis indicates the length limit of the input.

input (3k for BigBird, 4K and 16k for LED). Our model has a better performance than all the models, including LED(16K), which allows for the input 4 times longer than ours. It is worth mentioning that LED(4K) has the same structure as our model, with the same length limit of the input, and with the pre-training on multi-document datasets, our model is more than 3 ROUGE point better than it, which shows that the strategy not only works for multi-document summarization but can also effectively improve single-document summarization for long documents.

G Examples of Generated Summaries

We show an example (from Multi-News) of generated summaries by PRIMERA and compared models trained with different number of examples in Table 13. And we show an example from DUC2007 (which is one of the examples used for human evaluation) with generated summaries by PRIMERA and two compared models in Table 14, with all the models trained on 10 data examples from DUC2007.

Instruction on Human Annotations

Overview:

1- Content quality

The goal of this evaluation is to assess the content quality of a system generated summary based on human-written reference summaries. We will be using the Pyramid evaluation framework (Nenokva and Passonneau, 2004): https://aclanthology.org/N04-1019.pdf

The evaluation works like this. There are 3 things provided for each evaluation example:
1- The original documents
2- System generated summaries
3- A set of "information nuggets" or "facts" in the human-reference summaries. These are pre-annotated in the dataset and are atomic short phrases that refer to a specific piece of information in the documents. For example *"Britain opted out of Euro system."* is an information nugget.

For annotation, we will simply go through the list of information nuggets and check if they appear in the system generated summary. A summary is considered good if it includes many of the information nuggets.

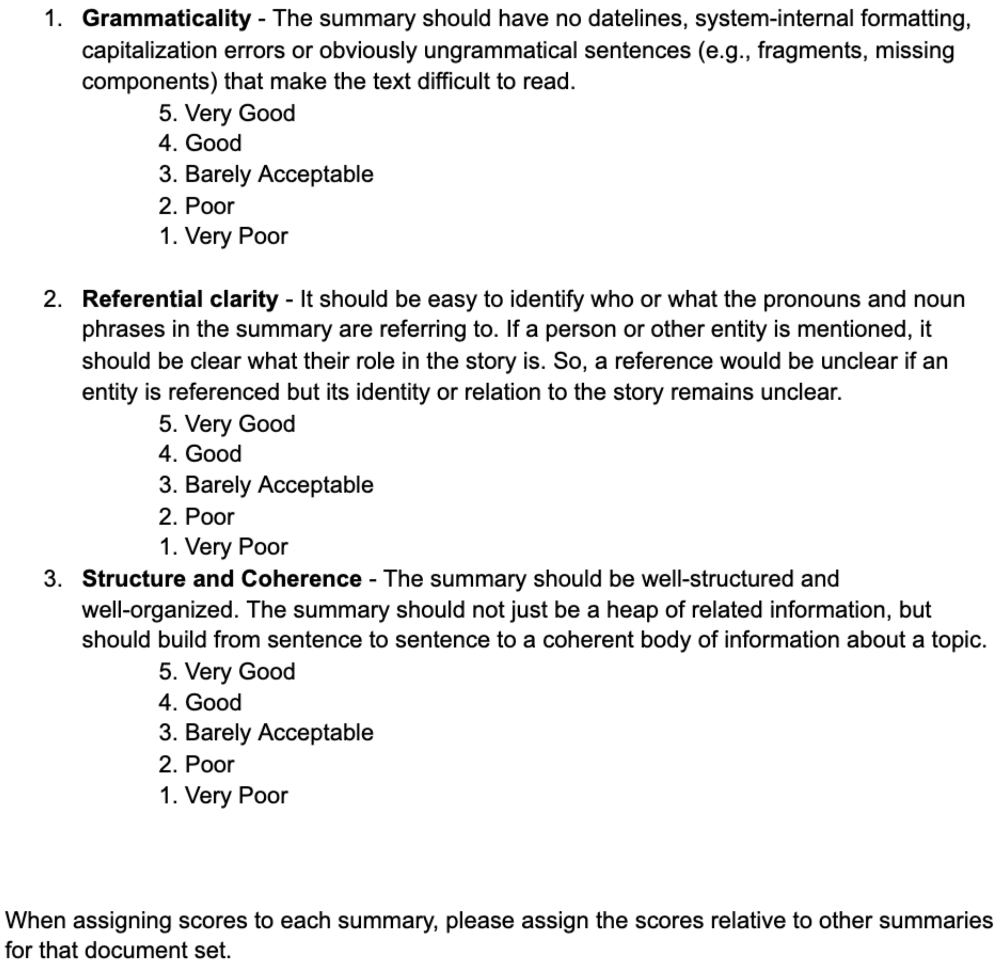
1. Documents (40 examples in total)
    a. Information nuggets: https://docs.google.com/spreadsheets/d/1BRbv-aaVpNDWTKOhQBGYABYzhKWAhk6cGnD5ROIyquY/edit?usp=sharing
    b. Three summaries, A, B and C: See below
2. Annotations:
    a. **For each summary**, check all the information in the information checklist in the following way,
        i. If the information is covered in the summary, check the corresponding checkbox
        ii. Otherwise, leave it blank.

2- Fluency:

There are multiple candidate summaries (3) for each system and we would like to rank the summaries from most most fluent to least.

Specifically, for each summary, answer the following questions:

Figure 7: Annotation instruction for human annotators.



1. **Grammaticality** - The summary should have no datelines, system-internal formatting, capitalization errors or obviously ungrammatical sentences (e.g., fragments, missing components) that make the text difficult to read.
    5. Very Good
    4. Good
    3. Barely Acceptable
    2. Poor
    1. Very Poor

2. **Referential clarity** - It should be easy to identify who or what the pronouns and noun phrases in the summary are referring to. If a person or other entity is mentioned, it should be clear what their role in the story is. So, a reference would be unclear if an entity is referenced but its identity or relation to the story remains unclear.
    5. Very Good
    4. Good
    3. Barely Acceptable
    2. Poor
    1. Very Poor
3. **Structure and Coherence** - The summary should be well-structured and well-organized. The summary should not just be a heap of related information, but should build from sentence to sentence to a coherent body of information about a topic.
    5. Very Good
    4. Good
    3. Barely Acceptable
    2. Poor
    1. Very Poor

When assigning scores to each summary, please assign the scores relative to other summaries for that document set.

Figure 8: Annotation instruction for human annotators.

Model	Summaries
PRIMERA-0	BALTIMORE (AP) — The U.S. Coast Guard says it's looking for a man who has cost the service about $500,000 after responding to nearly 30 of his fake distress calls.. The Coast Guard also said such false distress alerts detract from their ability to respond to actual alerts.Anyone with information about the caller is asked to contact the Coast Guard's regional command center at 410-576-2525 or email investigators at CGIS-Baltimore@uscg.mil..
PRIMERA-10	The U.S. Coast Guard says it's looking for a man who has cost the service about $500,000 after responding to nearly 30 of his fake distress calls. In a press release published Friday, the Coast Guard says the 28 calls have originated from around the area of Annapolis, Maryland. Each call involved the same male voice and used an emergency radio channel. The two most recent calls were made on the night of July 21 and the early morning of July 22. The Coast Guard also says hoax calls distract rescuers from real emergencies, putting both the public and the responding crews at risk. "Calls like these not only put our crews at risk, but they put the lives of the public at risk," said Lt. Cmdr. Sara Wallace, who heads the response sector in Maryland. "Calls like these not only put our crews at risk, but they put the lives of the public at risk." Anyone with information about the caller is asked to contact the Coast Guard's regional command center at 410-576-2525 or email investigators at CGIS-Baltimore@uscg.mil.
PRIMERA-100	The US Coast Guard is looking for a man who has cost the service about $500,000 after making 28 false distress calls from Maryland. The 28 calls have involved the same male voice and used an emergency radio channel, the AP reports. The Coast Guard says it has responded to nearly 30 of the fake calls and that the estimated cost of the responses is $500,000. The caller has been making the calls since July 2014. He could be facing a six-year prison sentence, a $10,000 civil fine, and a $250,000 criminal fine, the AP reports. "A hoax call is a deadly and serious offense," says Lt. Cmdr. Sara Wallace, head of the response sector in Maryland. "Calls like these not only put our crews at risk, but they put the lives of the public at risk."
PEGASUS-100	The US Coast Guard has responded to 28 false distress calls in two years—and it's a man who's been making the calls, not the waves. The unidentified caller has made the calls in Annapolis, Maryland, since July 2014, the Coast Guard reports. Each call involved the same male voice and used an emergency radio channel. The two most recent calls were made on the night of July 21 and early morning of July 22. The Coast Guard says the calls were made in the hope that the public would get into the water. Rather than responding to actual alerts, the calls were made to divert the attention of rescue crews from real emergencies, the AP reports. The Coast Guard says the cost of the responses to these false alarms is about $500,000. The caller made 28 false distress alerts from Annapolis, Maryland, beginning in July 2014, according to the Coast Guard. The estimated cost of the responses to these false alarms is $500,000. The Coast Guard says the calls were made in the hope that the public would get into the water. Rather than responding to actual alerts, the calls were made to divert the attention of rescue crews from real emergencies, the AP reports.
Fully Supervised	The US Coast Guard says it's looking for a man who has cost the service about $500,000 after responding to nearly 30 of his fake distress calls, the AP reports. In a press release published Friday, the Coast Guard says the 28 calls have originated from around the area of Annapolis, Maryland. Each call involved the same male voice and used an emergency radio channel. The two most recent calls were made on the night of July 21 and the early morning of July 22. The Coast Guard also says hoax calls distract rescuers from real emergencies, putting both the public and the responding crews at risk. "A hoax call is a deadly and serious offense," says Lt. Cmdr. Sara Wallace, who heads the response sector in Maryland. "Calls like these not only put our crews at risk, but they put the lives of the public at risk." Making false distress calls is a felony, punishable by a maximum of six years in prison, a $10,000 civil fine, $250,000 criminal fine, and a reimbursement to the Coast Guard for their efforts, the Coast Guard says.
Ground Truth	The US Coast Guard says it's looking for a man who has cost the service about $500,000 after responding to nearly 30 of his fake distress calls, reports the AP. In a press release published Friday, the Coast Guard says the 28 calls have originated from around the area of Annapolis, Maryland. Each call involved the same male voice and used an emergency radio channel. He's been making the calls since July 2014. The two most recent calls were made on the night of July 21 and the early morning of July 22. “A hoax call is a deadly and serious offense,” a Coast Guard rep tells NBC4, which notes that such calls are a felony that carry six years in prison, $10,000 civil fine, $250,000 criminal fine, and reimbursement to the Coast Guard. "Calls like these not only put our crews at risk, but they put the lives of the public at risk.”

Table 13: Generated summaries from PRIMERA and best baseline model (according ROUGE score on this example) trained with different number of training examples. The data used here is the #10 in the test set of Multi-News dataset on Huggingface.

Model	Summaries
PEGASUS	In 1996, Congress passed the Line-Item Veto Act, which gave the president the power to cut individual projects from tax and spending bills without vetoing the entire legislation. The act was followed by the President's line-item veto, which he used to trim 144 million dollars from a 248 billion dollars defense spending bill. He also used the veto power to block a congressional rejection of his line-item veto on 38 military construction projects. The bill was passed by the House and the President signed it into law. The veto was challenged by members of both parties who said it was unconstitutional because it gave the president unchecked power to rewrite legislation. The Supreme Court agreed on Friday to hear argument and decide the constitutionality of the president line-item veto. In 1998 the President used his line-item veto to cut $38 million from a military construction bill. In 1999 the President used his line-item veto to cut $54 million from a military spending bill. In 2000 the President used his line-item veto to cut $54 million from a defense spending bill. In January the President vetoed a tax and spending bill, which gave him the power to cut individual projects from tax and spending bills without vetoing the entire legislation. In February the President vetoed a spending bill, which gave him the power to cut individual projects from tax and spending bills without vetoing the entire legislation. In September the President used his line-item veto to cut $54 million from a defense spending bill. The bill was rejected by the House and the President vetoed it. In November the President used his line-item veto to trim 144 million dollars from a defense spending bill.
LED	In 1996, the Republican-led Congress passed the Line Item Veto Act, giving the president the power to delete individual items of spending and tax bills. Clinton used the power to cut individual projects from tax and spending bills. In February 1999, the President Clinton vetoed a congressional rejection of his line-item veto on 38 military construction projects. In May 1999, the President Clinton used the line-item veto to cut individual items of spending and tax breaks. In 2000, the President Clinton used the line-item veto to cancel individual items of spending and tax breaks. In May 2000, the President Clinton threatened to use the line-item veto to cancel all military spending and tax breaks. In June 2000, the President Clinton used the line-item veto to cut individual items of spending and tax breaks. In August 2000, the President Clinton used the line-item veto to cut individual items of spending and tax breaks. In September 2000, the President Clinton used the line-item veto to cut individual items of spending and tax breaks. In 2000, the President Clinton used the line-item veto to cut individual items of spending and tax breaks. In 2001, the President Clinton used the line-item veto to cut individual items of spending and tax breaks. In June 2000, the President Clinton used the line-item veto to cut individual items of spending and tax breaks. In August 2000, the President Clinton used the line-item veto to cut individual items of spending and tax breaks. In September 2000, the President Clinton used the line-item veto to cut individual items of spending and tax breaks. In 2000, the President Clinton used the line-item veto to cancel individual items of spending and tax breaks. In 2001, the President Clinton used the line-item veto to cut individual items of spending and tax breaks. In June 2000, the President Clinton used the line-item veto to cut individual items of spending and tax breaks.
PRIMERA	In 1996, Congress gave the President the power to veto specific items of tax and spending bills. Before the law's enactment in 1996, the president could veto an entire spending measure but not individual items. The court ruled that such a specialized veto can be authorized only through a constitutional amendment. In January 1997, the line-item veto law was passed. It was passed under the Republican Party's "Contract with Congress". It was passed after President Clinton vetoed thirteen relatively obscure research and spending programs, almost all of the military spending increases approved by Congress. In October 1998, Clinton used his line-item veto authority to have trimmed 144 million U.S. dollars from a 248 billion defense spending bill. In November 1998, Clinton vetoed 38 military construction projects, worth 287 million U.S. dollars. In February 1999, the Justice Department appealed the line-item veto law to the Supreme Court, which agreed to hear argument and decide the constitutionality of the law. Earlier this month, a federal judge struck down the line-item veto law as unconstitutional. The highest court's review will yield a momentous balance of powers ruling. The case is scheduled to be argued before the justices on April 27. The line item veto, strongly supported by President Bill Clinton and a number of his predecessors, was passed in 1996 under the Republican Party's "Contract with Congress". It was passed in January 1997. Before the law's enactment, the only way presidents could reject spending laws was to veto whole budget bills. In 1996, Congress gave the president the power to cancel individual items in tax and spending bills. In January 1997, the line-item veto law was passed. It was passed under the Republican Party's "Contract with Congress". It was passed in January 1997. In 1998, President Clinton threatened to veto some items of the military construction bill because of the increased funding. In November 1998, Clinton used his line-item veto power to delete 38 projects in 24 states worth 287 million U.S. dollars. In February 1999, the Justice Department appealed the line-item veto law to the Supreme Court, which agreed to hear a case about its constitutionality.
Ground Truth	In 1996 a Republican congress overwhelmingly passed a Line Item Veto Act allowing presidents (including the incumbent Democratic president), to strike individual tax or spending items within 5 days after signing a bill into law. Congress could restore those items in a new bill passed by majority vote. If the president vetoed that bill, Congress could override that veto with a two-thirds majority. Proponents argued that the law preserved the integrity of federal spending, saved billions of dollars, and that it did not repeal any portion of a law, but was simply a delegated spending authorization from Congress. In January 1997, the first year of the law, the president vetoed 163 line-items in six bills, and in 1998 82 line-items in 11 bills. In October 1997 Congress overrode the president's line-item veto against 36 of 38 military construction projects. Initial 1997 efforts by congressmen to challenge the law in the Supreme Court were rejected due to lack of standing. On June 25, 1998 after lower courts rejected the Line Item Veto Act as unconstitutional, on appeal by the White House the Supreme Court ruled 6-3 that Congress unconstitutionally violated the principle of separation of powers, because that procedure allows the president to create a law that was not voted on by either house of Congress in violation of the Constitution's Article I "presentment" clause. A constitutional amendment would be required to institute line item vetoes. Justices Breyer and Scalia argued similar dissenting opinions that separation of powers was not violated.

Table 14: Generated summaries from PRIMERA, PEGASUS and LED trained with 10 training examples, along with one (out of four) ground-truth summary. The data used here is D0730 in DUC2007.

Dynamic Global Memory for Document-level Argument Extraction

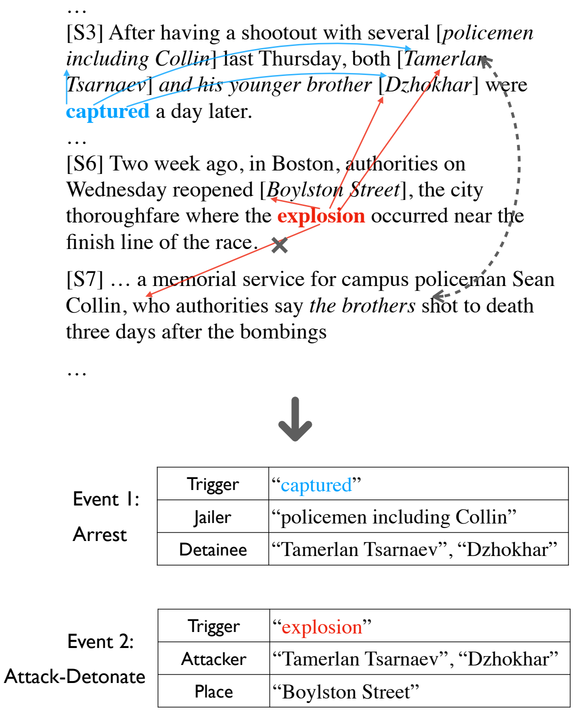
Xinya Du **Sha Li** **Heng Ji**
Department of Computer Science
University of Illinois Urbana-Champaign
`{xinyadu2,shal2,hengji}@illinois.edu`

Abstract

Extracting informative arguments of events from news articles is a challenging problem in information extraction, which requires a global contextual understanding of each document. While recent work on document-level extraction has gone beyond single-sentence and increased the cross-sentence inference capability of end-to-end models, they are still restricted by certain input sequence length constraints and usually ignore the global context between events. To tackle this issue, we introduce a new global neural generation-based framework for document-level event argument extraction by constructing a document memory store to record the contextual event information and leveraging it to implicitly and explicitly help with decoding of arguments for later events. Empirical results show that our framework outperforms prior methods substantially and it is more robust to adversarially annotated examples with our constrained decoding design.[1]

1 Introduction

An event is a specific occurrence involving participants (people, objects, etc.). Understanding events in the text is necessary for building machine reading systems, as well as for downstream tasks such as information retrieval, knowledge base population, and trend analysis of real-life world events (Sundheim, 1992). Event Extraction has long been studied as a local sentence-level task (Grishman and Sundheim, 1996; Ji and Grishman, 2008b; Grishman, 2019; Lin et al., 2020). This has driven researchers to focus on developing approaches for sentence-level predicate-argument extraction. This is problematic when events and their arguments spread across multiple sentences – in real-world cases, events are often written throughout a document.[2]



…

[S3] After having a shootout with several [*policemen including Collin*] last Thursday, both [*Tamerlan Tsarnaev*] *and his younger brother* [*Dzhokhar*] were **captured** a day later.

…

[S6] Two week ago, in Boston, authorities on Wednesday reopened [*Boylston Street*], the city thoroughfare where the **explosion** occurred near the finish line of the race.

[S7] … a memorial service for campus policeman Sean Collin, who authorities say *the brothers* shot to death three days after the bombings

…

Event 1: Arrest

Trigger	"captured"
Jailer	"policemen including Collin"
Detainee	"Tamerlan Tsarnaev", "Dzhokhar"

Event 2: Attack-Detonate

Trigger	"explosion"
Attacker	"Tamerlan Tsarnaev", "Dzhokhar"
Place	"Boylston Street"

Figure 1: Document-level event argument extraction.

In Figure 1, the excerpt of a news article describes two events in the 3rd sentence (an arrest event triggered by "captured") and the 6th sentence (an attack event triggered by "explosion"). S6 on its own contains little information about the arguments/participants of the explosion event, but together with the context of S3 and S7, we can find the informative arguments for the ATTACKER role. In this work, we focus on the *informative argument* extraction problem, which is more practical and requires much a broader view of cross-sentence context (Li et al., 2021). For example, although "the brothers" also refers to "Tamerlan T." and "Dzhokhar" (and closer to the trigger word), it

---

[1] Our code and resources are available at `https://github.com/xinyadu/memory_docie` for research purpose.

[2] In WIKIEVENTS (Li et al., 2021), nearly 40% of events have an argument outside the sentence containing the trigger.

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics
Volume 1: Long Papers, pages 5264 - 5275
May 22-27, 2022

should not be extracted as an informative argument.

In recent years, there have been efforts focusing on event extraction beyond sentence boundaries with end-to-end learning (Ebner et al., 2020; Du, 2021; Li et al., 2021). Most of the work still focuses on modeling each event independently (Li et al., 2021) and ignores the global context partially because of the pretrained models' length limit and their lack of attention for distant context (Khandelwal et al., 2018). Du et al. (2021) propose to model dependency between events directly via the design of generation output format, yet it is not able to handle longer documents with more events – whereas in real-world news articles there are often more than fifteen inter-related events (Table 2).

In addition, previous work often overlooks the consistency between extracted event structures across the long document. For example, if one person has been identified as a JAILER in an event, it's unlikely that the same person is an ATTACKER in another event in the document (Figure 1), according to world event knowledge (Sap et al., 2019; Yao et al., 2020).

In this paper, to tackle these challenges and have more consistent/coherent extraction results, we propose a document-level memory-enhanced training and decoding framework (Figure 2) for the problem. It can leverage relevant and necessary context beyond the length constraint of end-to-end models, by using the idea of a dynamic memory store. It helps the model leverage previously generated/extracted event information during both training (implicitly) and during test/decoding (explicitly). More specifically, during training, it retrieves the most similar event sequence in the memory store as additional input context to mode. Plus, it performs constrained decoding based on the memory store and our harvested global knowledge-based argument pairs from the ontology.

We conduct extensive experiments and analysis on the WIKIEVENTS corpus and show that our framework significantly outperforms previous methods either based on neural sequence labeling or text generation. We also demonstrate that the framework achieves larger gains over baseline non memory-based models as the number of events grows in the document, and it is more robust to manually designed adversarial examples.

2 Task Definition

In this work, we focus on the challenging problem of extracting **informative arguments of events**[3] from the document. Each event consists of (1) a trigger expression which is a continuous span in the document, it is of a type E which is predefined in an ontology; (2) and a set of arguments $\{arg_1, arg_2, ...\}$, each of them has a role predefined in the ontology, for event type E. In the annotation guideline/ontology, the "template" that describes the connections between arguments of the event type is also provided. For example, when E is *Arrest*, its corresponding arguments to be extracted should have roles: JAILER (`<arg1>`), DETAINEE (`<arg2>`), CRIME (`<arg3>`), PLACE (`<arg4>`). Its description template is:

> `<arg1>` arrested or jailed `<arg2>` for `<arg3>` crime at `<arg4>` place

Given a long news document $Doc = \{..., \text{<Trg1>}, ..., x_i, ..., \text{<Trg2>}, ..., x_n\}$ with given event triggers, our goal is to extract all the informative argument spans to fill in the role of $E1$, $E2$, etc. For the example piece in Figure 1, $E1$ is *Arrest* (triggered by <Trg1> "captured") and $E2$ is *Attack-Detonate* (<Trg2> is "explosion").

The ontology is constructed by the DARPA KAIROS project[4] for event annotation. It defines 67 event types in a three-level hierarchy, which is richer than the ACE05 ontology with only 33 event types for sentence-level extraction.

3 Methodology

In this section, we describe our memory-enhanced neural generation-based framework (Figure 2) for extracting informative event arguments from the document. Our base model is based on a sequence-to-sequence pretrained language model for text generation. We first introduce how we leverage previously extracted events as additional context for training the text generation-based event extraction model to help the model automatically capture event dependency knowledge (Section 3.1). To *explicitly* help the model satisfy the global event knowledge-based constraints (e.g., it is improbable that one person would be JAILER in event A and then ATTACKER in event B), we propose a dynamic

---

[3] Name entity mentions are recognized as more informative than nominal mentions.

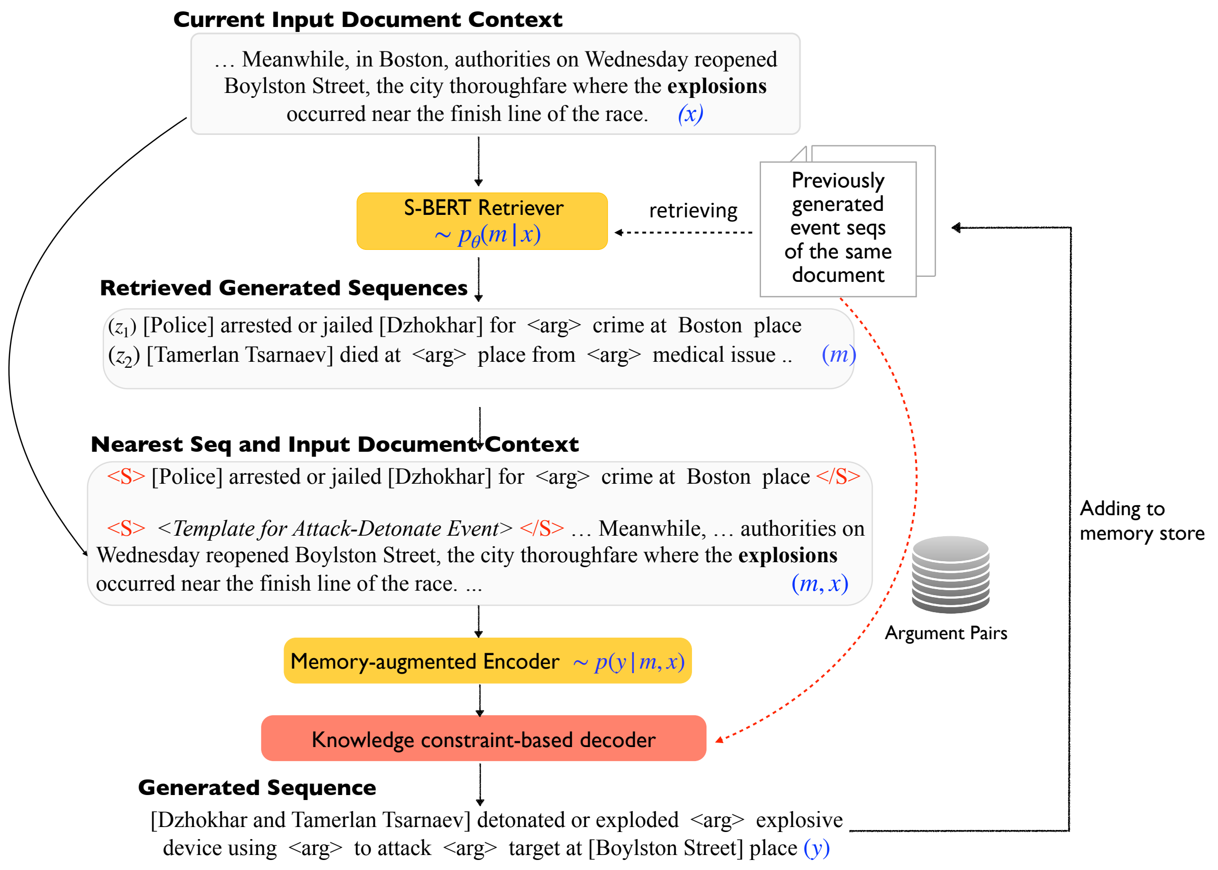

Figure 2: Our Framework for Memory-enhanced Training and Decoding.

decoding process with world knowledge-based argument pair constraints (Section 3.2).

3.1 Memory-enhanced Generation Model for Argument Extraction

Following Li et al. (2021), the main model of our framework is based on the pretrained encoder-decoder model BART (Lewis et al., 2020). The intuition behind using BART for the extraction task is that it is pre-trained as a denoising autoencoder – reconstruct the original input sequence. This fits our objective of extracting argument spans from the input document because the extracted arguments' tokens are from the input sequence. The generation model takes (1) *context:* the concatenation of the piece of text x (of document D) containing the current event trigger[5] and the event type's corresponding template in the ontology; (2) *memory store* m: of previously extracted events of the same document D, as input, and learns a distribution $p(y|x,m)$ over possible outputs y. The ground truth sequence y is a sequence of a template where the placeholder `<arg>`s are filled by the gold-standard argument spans of the current event.[6]

$$p(y|x,m) = \prod_{i}^{N} p(y_i|y_{1:i-1},x,m) \qquad (1)$$

To be more specific on building the dependency between events across the document, we use the most relevant event in the memory store m as additional context, instead of the entire memory store. To retrieve the most relevant "event" (i.e., a generated sequence) from the memory store $m = \{m_1, m_2, ...\}$, we use S-BERT (Reimers and Gurevych, 2019) for dense retrieval (i.e., retrieval with dense representations provided by NN). S-BERT is a modification of the BERT model (Devlin et al., 2019) that uses siamese and triplet network structures to obtain semantically meaningful embeddings for text sequences. We can compare the distance between two input sequences with cosine-similarity in an easier and faster way. Given a current input document piece x, we encode all of

---

[5] Up to the maximum length limit of the pre-trained model.

[6] The gold sequence for the 1st event in Figure 1 would be "[policemen including Collin] arrested or jailed [Tamerlan T. and Dzhokhar] for <arg> crime at <arg> place"

the previously generated event sequences in the memory store and x. Then we calculate the similarity scores with vector space cosine-similarity and normalization:

$$\text{score}(m_i|x) = \frac{\exp f(x, m_i)}{\sum_{m_i \in m} \exp f(x, m_i)}$$
$$f(x, m_i) = Embed(x)^T Embed(m_i)$$

Afterwards, we select the m_i with the highest similarity score: $m^R = \arg\max_i \text{score}(m_i|x)$

To summarize, the input sequence for the memory-enhanced model consists of the retrieved generated event sequence (m^R), the template for the current event type (T) – provided by the ontology/dataset, and the context words from the document (x_1, ..., x_n):

$$\text{<S>}\ m_1^R, m_2^R, ..., \text{</S>}$$
$$\text{<S>}\ T_1, T_2, ...\ \text{</S>} \quad x_1, x_2, ..., x_n\ \text{[EOS]}$$

During training time, the memory store consists of gold-standard event sequences – while at test time, it contains real generated event sequences. The training objective is to minimize the negative log likelihood over all $((x, m^R, T), y)$ instances. Since we fix the parameters from S-BERT, the retrieval module's parameters are not updated during training. Thus the training time cost of our memory-based training is almost the same to the simple generation-based model.

3.2 Constrained Decoding with Global Knowledge-based Argument Pairs

The constrained/dynamic decoding is an important stage in our framework. We first harvest a number of world knowledge-based event argument pairs that are probable/improbable of happening with the same entity being the argument. For example, (<Event Type: Arrest, Argument Role: JAILER> | <Event Type: Attack-Detonate, Argument Role: ATTACKER>) is an improbable pair. In the framework (Figure 2), they are called "argument pairs". Then based on the argument pairs constraints, the dynamic decoding is conducted throughout the document – if one entity is decoded in an event in the earlier part of the document, it should not be decoded later in another event if the results are incompatible with the improbable argument pairs.

Algorithm 1: Automatic Harvesting Argument Pairs from the Event Ontology

```
Input  : Event Ontology $O$, consisting of $|O|$ events'
         information. For each event $E_i \in O$, it has a
         set of argument roles $(A_1^i, A_2^i, ...)$.
Output : A set of (<Event Type, Argument Role> |
         <Event Type, Argument Role>) pairs with
         "probable" or "improbable" denotation.
1  $impro\_arg\_pairs \longleftarrow \{\}$;
2  $pro\_arg\_pairs \longleftarrow \{\}$;
   // Enumerate event type pairs
3  for $i \leftarrow 1$ to $|O|$ do
4      for $j \leftarrow i + 1$ to $|O|$ do
5          $cnt(i, j)$ = count # of $(E_i, E_j)$
             co-occurrence in the training documents;
6          if $cnt(i, j) == 0$ then continue;
           // Enumerate argument pairs
7          for $A_k^i \in E_i$ args $(A_1^i, A_2^i, ...)$ do
8              for $A_h^j \in E_j$ args $(A_1^j, A_2^j, ...)$ do
9                  if $entity\_type(A_k^i) != entity\_type(A_h^j)$ then continue;
10                 $cnt\_args(A_k^i, A_h^j)$ = count # of
                     $(A_k^i, A_h^j)$ being the same entity
                     in the training set documents;
11                 if $\frac{cnt\_args(A_k^i, A_h^j)}{cnt(i,j)} > 0.001$ then
                     $impro\_arg\_pairs$.add((< $E_i, A_k^i$ > | < $E_j, A_h^j$ >));
12                 else
13                     $pro\_arg\_pairs$.add((< $E_i, A_k^i$ > | < $E_j, A_h^j$ >))
14                 end
15             end
16         end
17     end
18 end
```

Harvesting Global Knowledge-based Argument Pairs from the Ontology We first run an algorithm to automatically harvest all candidate argument pairs (Algorithm 1). Basically, we

- First enumerate all possible event type pairs, and count how many times they co-occur in the training set (Line 2–6).
- Then we enumerate all possible argument types pairs that share the same entity type from the ontology (e.g., argument ORGANIZATION (ORG) and argument VICTIM (PER) don't have the same entity type), and count how many times both of the args are of the same entity in training docs (e.g., "Dzhokhar" are both DETAINEE and ATTACKER in two events in Figure 1) (Line 7–11).
- Finally we add into the set of probable argument pairs, whose normalized score is above a threshold (99% of the candidate arguments with non-zero score); and the rest into the set of improba-

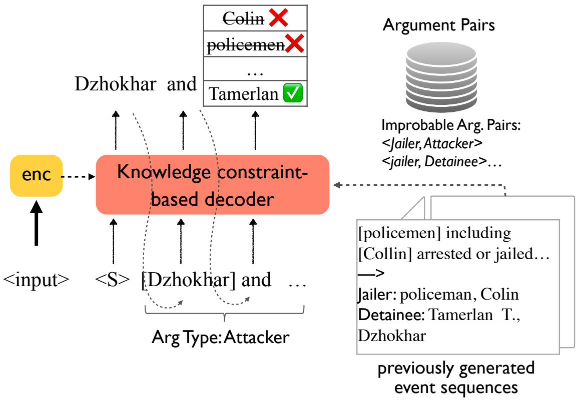

Figure 3: Constrained/Dynamic Decoding.

ble pairs (Line 11–14).

After automatic harvesting, since there is noise in the dataset as well as cases not covered, we conduct a human curation process to mark certain improbable argument pairs as probable, based on world knowledge. Finally, we obtain 1,568 improbable argument pairs and 687 probable pairs.

	# pairs with global co-occurrence stats	# pairs after human curation
improbable	1,855	1,568
probable	400	687

Table 1: Statistics of Harvested Argument Pairs.

Dynamic Decoding Process During the decoding process, we keep an explicit data structure in the memory store, to record what entities have been decoded and what argument roles they are assigned to (Figure 3). During decoding the arguments of later events in the document, assuming we are at a time step t for generating the sequence for event E_i, to generate token y_t, we first determine the argument role (A_k) it corresponds to. Then we search through the memory store if there are extracted entities e that have argument role A_h, where $< A_k, A_h >$ is an improbable argument pair. Then when decoding to token at time step t, we decrease the probability (after softmax) of generating/extracting tokens in entity e according to the improbable argument pair rule. Compared to decreasing the probability of extracting certain conflicting entities, we are more reserved in utilizing the probable argument pairs, only if the same entity has been assigned the argument role for more than 5 times in the document, we are increasing the probability of extracting the same entity (generating the token of the entity) for the corresponding argument role (the most co-occurred).

After the generation process for the current event, we add the newly generated event sequence (extracted arguments) back into the memory store.

4 Experiments

4.1 Dataset and Evaluation Metrics

We conduct evaluations on the newly released WIKIEVENTS dataset (Li et al., 2021). As compared to the ACE05[7] sentence-level extraction benchmark, WIKIEVENTS focuses on annotations for informative arguments and for multiple events in the document-level event extraction setting, and is the only benchmark dataset for this purpose to now. It contains real-world news articles annotated with the DARPA KAIROS ontology. As shown in the dataset paper, the distance between informative arguments and event trigger is 10 times larger than the distance between local/uninformative arguments (including pronouns) and event triggers. This demonstrates more needs for modeling long document context and event dependency and thus it requires a good benchmark for evaluating our proposed models. The statistics of the dataset are shown in Table 2. We use the same data split and preprocessing step as in the previous work.

	Train	Dev	Test
Documents	206	20	20
Sentences	5262	378	492
Avg. number of events	15.73	17.25	18.25
Avg. number of tokens	789.33	643.75	712.00

Table 2: Dataset Statistics

As for evaluation, we use the same criteria as in previous work. We consider an argument span to be correctly identified if its offsets match any of the gold/reference informative arguments of the current event (i.e., argument identification); and it is correctly classified if its semantic role also matches (i.e., argument classification) (Li et al., 2013).

To judge whether the extracted argument and the gold-standard argument span match, since the exact match is too strict that some correct candidates are considered as spurious (e.g., "the 22 policemen" and "22 policemen" do not match under the exact match standard). Following Huang and Riloff (2012); Li et al. (2021), we use head word match

---

F1 (*Head F1*). We also report performance under a more lenient metric "*Coref F1*": the extracted argument span gets full credit if it is coreferential with the gold-standard arguments (Ji and Grishman, 2008a). The coreference links information between informative arguments across the document are given in the gold annotations.

	Arg. Classification	
	Head M.	Coref. M.
BART-Gen	50.00	53.12
Memory-based Training	50.75	53.73
Our Best Model (w/ knowledge constrained decoding)	53.73	56.72

Table 4: Performance (%) on adversarial examples.

4.2 Results

We compare our framework to a number of competitive baselines. (Shi and Lin, 2019) is a popular baseline for semantic role labeling (predicate-argument prediction). It performs sequence labeling based on automatically extracted features from BERT (Devlin et al., 2019) and uses Conditional Random Fields (Lafferty et al., 2001) for structured prediction (**BERT-CRF**). Li et al. (2021) propose to use conditional neural text generation model for the document-level argument extraction problem, it handles each event in isolation (**BART-Gen**).

For our proposed memory-enhanced training with retrieved additional context, we denote it as **Memory-based Training**. We also present the argument pairs constrained decoding results separately to see both components' contributions.[8]

In Table 3, we present the main results for the document-level informative argument extraction. The score for argument identification is strictly higher than argument classification since it only requires span offset match. We observe that:

- The neural generation-based models (BART-Gen and our framework) are superior in this document-level informative argument extraction problem, as compared to the sequence labeling-based approaches. Plus, generation-based methods only require one pass as compared to span enumeration-based methods (Wadden et al., 2019; Du and Cardie, 2020).

- As compared to the raw BART-Gen, with our memory-based training – leveraging previously closest extracted event information substantially helps increase precision (P) and F-1 scores, with smaller but notable improvement in recall especially under Coref Match.

- With additional argument pair constrained decoding, there is an additional significant improvement in precision and F-1 scores. This can be mainly attributed to two factors: (I) during constrained decoding, we relied more on "improbable arg. pairs" as a checklist to make sure that the same entity not generated for conflicting argument roles in the same document, and only utilize very few top "probable arg. pairs" for promoting the decoding for frequently appearing entities; (II) If an entity has been decoded in previous event A by mistake then under the argument pair rule, it will not be decoded in event B even if it correct – which might hurt the recall.

Robustness to Adversarial Examples To test how the models react to specially designed adversarial examples, we select a quarter of documents from the original test set, and add one more adversarial event into each of them by adding a few

---

[8] All significance tests for F-1 are computed using the paired bootstrap procedure of 5k samples of generated sequences (Berg-Kirkpatrick et al., 2012).

new sentences. The additional event is designed to "attract" the model to make mistakes that are against our global knowledge-based argument pair rules.[9] An excerpt for one example:

> Tandy, then 19, **talks** to his close friend, Stephen Silva, about ... Tandy and Silva both **died** as lifeguards together at the Harvard pool. Later a kid was **killed** by a Stephen Silva-lookalike guy.

In this example, we know "Stephen Silva" died in the second event "Life.Die" triggered by **died**. Although it is also mentioned in the last sentence, "Stephen Silva" should not be extracted as the KILLER. In Table 4, we summarize the F-1 scores of argument classification models. Firstly we see on the adversarial examples, the performance scores all drop as compared to the normal setting (Table 3), proving it's harder to maintain robustness in this setting. Our best model with argument pair constrained decoding outperforms substantially both BART-Gen and our memory-based training model. The gap is larger than the general evaluation setting, which shows the advantage of *explicitly* enforcing the reasoning/constraint rules.

5 Further Analysis

In this section, we further provide more insights with quantitative and qualitative analysis, as well as error analysis for the remaining challenges.

Influence of Similarity-based Retrieval In Table 5, we first investigate what happens when our similarity-based retrieval module is removed – we find that the F-1 scores substantially drop. There's also a drop of scores across metrics when we retrieve a random event from the memory store. It is interesting that the model gets slightly better performance with random memory than not using any retrieved/demonstration sequences. This corresponds to the findings in other domains of NLP on how demonstrations lead to performance gain when using pre-trained language models (especially in the few-shot learning setting).

Document Length and # of Events In Figure 4, we examine how performances change as the document length and the number of events per document grow. First we observe that as the document length grows, challenges grow for both the baseline and our framework (F-1 drops from over 70% to around 55%). While our framework maintains a larger advantage when document is longer than 250 words. As the number of events per document grows (from <=8 to around 25), our model's performance is not affected much (F-1 all over 60%). While the baseline system's F-1 score drops to around 50%.

Models	Arg. I.		Arg. C.	
	H. M.	C. M.	H. M.	C. M.
Memory-based Training	58.52	63.45	53.60	57.95
w/o retrieval	56.84	61.82	51.29	55.69
w/ random memory	57.65	62.69	52.22	57.17

Table 5: Ablation (%) for similarity-based retrieval.

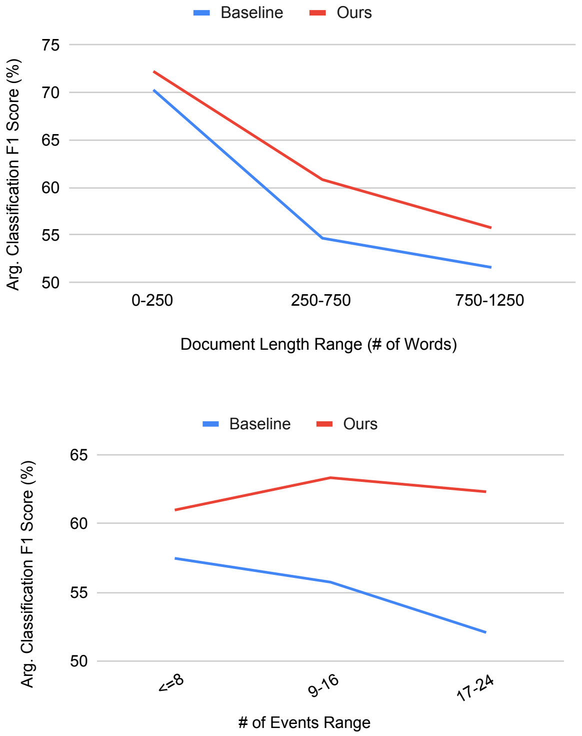

Figure 4: Effect of doc length and events # per doc.

Qualitative Analysis We present a couple of representative examples (Table 6). In the first example, for the event triggered by **wounds**, it's hard to find the VICTIM argument "Ahmad Khan Rahimi" since it's explicitly mentioned far before the current sentence. But with retrieved additional context, both our framework variants are able to extract the full name correctly. In the second example, "Cuba" was mentioned in two sentences with two events (Impede event triggered by **sidesteps** and Arrest triggered by **capture**). But it only participated in the first event. According to our argument pair

	Missing	Spurious	Misclassified
Head M	239 (52.88%)	187 (41.37%)	26 (5.75%)
Coref M	213 (52.85%)	161 (39.95%)	29 (7.20%)

Table 7: Types of Errors Made by Our Framework.

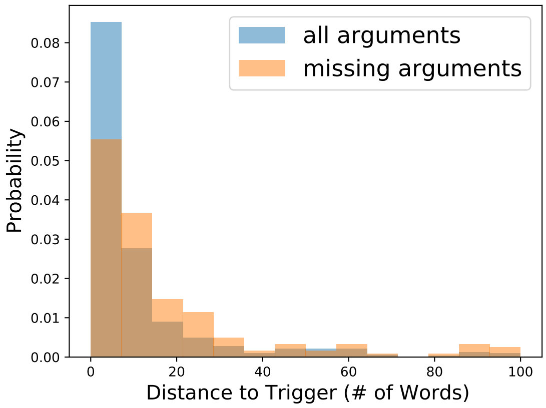

Figure 5: Distribution of Distance between Informative Arguments and the Gold-standard Triggers.

constraints – it's improbable that one entity is both an IMPEDER and a JAILER, our framework with constrained decoding conducts reasoning to avoid the wrong extraction.

Error Analysis and Remaining Challenges Table 7 categorizes types of argument extraction errors made by our best model. The majority of errors is from missing arguments and only around 7% of cases are caused by incorrectly-assigned argument roles (e.g., a PLACE argument is mistakenly labeled as a TARGET argument). Interestingly, from Figure 5's distribution, we see that as compared to the distance of gold-standard informative arguments to the trigger (avg. 80.41 words), the missing arguments are far away (avg. 136.39 words) – showing the hardness of extracting distant arguments as compared to local arguments.

Finally we examine deeper the example predictions and categorize reasons for errors into the following types: (1) *Challenge to obtain an accurate boundary of the argument span.* In the example excerpt "On Sunday, a suicide bombing in the southeastern province of [Logar] left eight ...", our model extracts "southeastern province" as PLACE. Similarly in "... were transported to [Kabul] city..", our model extracts "city" as DESTINATION. In both cases the model gets no credit. To mitigate this problem, models should be able to identify certain noun phrase boundaries with external knowledge. Plus, the improvement of data annotation and evaluation is also needed – the model should get certain credit though the span does not overlap but related to the gold argument. (2) *Long distance dependency and deeper context understanding.* In news, most of the contents are written by the author while certain content is cited from participants. While models usually do not distinguish the difference and consider the big stance difference. In the excerpt "Bill Richard, whose son, Martin, was the youngest person killed in the bombing, said Tsarnaev could have backed out ... Instead, Richard said, he chose hate. he chose destruction. He chose death. ...", the full name of the informative argument ("D. Tsarnaev") was mentioned at the very beginning of the document. Although our model can leverage previously decoded events, it is not able to fully understand the speaker's point of view and misses the full KILLER argument span.

6 Related Work

Event Knowledge There has been work on acquiring event-event knowledge/subevent knowledge with heuristic-based rules or crowdsourcing-based methods. Sap et al. (2019) propose to use crowdsourcing for obtaining *if-then* relations between events. Bosselut et al. (2019) use generative language models to generate new event knowledge based on crowdsourced triples. Yao et al. (2020) propose a weakly-supervised approach to extract sub-event relation tuples from the text. In our work, we focus on harvesting knowledge-based event argument pair constraints from the predefined ontology with training data co-occurrence statistics. Plus, the work above on knowledge acquisition has not investigated explicitly encoding the knowledge/constraints for improving the performance of models of document-level event extraction related tasks.

Document-level Event Extraction Event extraction has been mainly studied under the document-level setting (the template filling tasks from the MUC conferences (Grishman and Sundheim, 1996)) and the sentence-level setting (using the ACE data (Doddington et al., 2004) and BioNLP shared tasks (Kim et al., 2009)). In this paper, we focus on the document-level event argument extraction task which is a less-explored and challenging topic (Du et al., 2021; Li et al., 2021). To support the progress for the problem, Ebner et al. (2020) built RAMS dataset, and it contains annotations for cross-sentence arguments but for each document it contains only one event. Later Li et al. (2021) built the benchmark WIKIEVENTS with complete event annotations for each document. Regarding the methodology, neural text generation-based models have been proved to be superior at this document-level task (Huang et al., 2021; Du et al., 2021; Li et al., 2021). But they are still limited by the maximum length context issue and mainly focus on modeling one event at a time. Yang and Mitchell (2016) proposed a joint extraction approach that models cross-event dependencies – but it's restricted to events co-occurring within a sentence and only does trigger typing. In our framework, utilizing the memory store can help better capture global context and avoid the document length constraint. Apart from event extraction, in the future, it's worth investigating how to leverage the global memory idea for other document-level IE problems like (N-ary) relation extraction (Quirk and Poon, 2017; Yao et al., 2019).

7 Conclusions and Future Work

In this work, we examined the effect of global document-level "memory" on informative event argument extraction. In the new framework, we propose to leverage the previously extracted events as additional context to help the model learn the dependency across events. At test time, we propose to use a dynamic decoding process to help the model satisfy global knowledge-based argument constraints. Experiments demonstrate that our approach achieves substantial improvements over prior methods and has a larger advantage when document length and events number increase. For future work, we plan to investigate how to extend our method to multi-document event extraction cases.

Abstract

There is a growing interest in the combined use of NLP and machine learning methods to predict gaze patterns during naturalistic reading. While promising results have been obtained through the use of transformer-based language models, little work has been undertaken to relate the performance of such models to general text characteristics. In this paper we report on experiments with two eye-tracking corpora of naturalistic reading and two language models (BERT and GPT-2). In all experiments, we test effects of a broad spectrum of features for predicting human reading behavior that fall into five categories (syntactic complexity, lexical richness, register-based multiword combinations, readability and psycholinguistic word properties). Our experiments show that both the features included and the architecture of the transformer-based language models play a role in predicting multiple eye-tracking measures during naturalistic reading. We also report the results of experiments aimed at determining the relative importance of features from different groups using SP-LIME.

1 Introduction

Extensive studies using eye-trackers to observe gaze patterns have shown that humans read sentences efficiently by performing a series of fixations and saccades (for comprehensive overviews, see, e.g. Rayner et al. (2012), Seidenberg (2017), and Brysbaert (2019)). During a fixation, the eyes stay fixed on a word and remain fairly static for 200-250 milliseconds. Saccades are rapid jumps between fixations that typically last 20-40 ms and span 7-9 characters. In addition, when reading, humans do not fixate one word at a time, i.e. some saccades run in the opposite direction, and some words or word combinations are fixed more than once or skipped altogether. Much of the early work in this area was concerned with the careful construction of sentences to model human reading behavior and understand predictive language processing (Staub, 2015; Kuperberg and Jaeger, 2016). The use of isolated, decontextualized sentences in human language processing research has been questioned on ecological validity grounds. With the growing awareness of the importance of capturing naturalistic reading, new corpora of eye movement data over contiguous text segments have emerged. Such corpora serve as a valuable source of data for establishing the basic benchmarks of eye movements in reading and provide an essential testing ground for models of eye movements in reading, such as the E-Z Reader model (Reichle et al., 1998) and the SWIFT model (Engbert et al., 2005). They are also used to evaluate theories of human language processing in psycholinguistics: For example, the predictions of two theories of syntactic processing complexity (dependency locality theory and surprisal) were tested in the Dundee Corpus, which contains the eye-tracking record of 10 participants reading 51,000 words of newspaper text (Demberg and Keller, 2008). Subsequent work has presented accounts where the ability of a language model to predict reading times is a linear function of its perplexity (Goodkind and Bicknell, 2018). More recent work has employed transformer-based language models to directly predict human reading patterns across new datasets of eye-tracking and electroencephalogra-

phy during natural reading (Schrimpf et al., 2021; Hollenstein et al., 2021, for more details see the related work section below). While this work has made significant progress, there is limited work aimed at determining the role of general text properties in predicting eye movement patterns in corpora of naturalistic reading. To date, research has addressed this issue only peripherally (Lowder et al., 2018; Snell and Theeuwes, 2020; Hollenstein et al., 2021), examining the role of text features only on the basis of a small number of linguistic features.

In this paper, we conduct a systematic investigation of the effects of text properties on eye movement prediction: We determine the extent to which these properties affect the prediction accuracy of two transformer-based language models, BERT and GPT-2. The relationship between these properties and model performance is investigated in two ways: (a) building on the approaches in Lowder et al. (2018) and Hollenstein et al. (2021), by investigating the sensitivity of model predictions to a wide range of text features, and (b) by incorporating text features into the transformer-based language models. With respect to the latter, we examine the effects of the preceding sentence on gaze measurement within the sentence of interest. This was motivated by psycholinguistic literature that has demonstrated "spillover" effects, where the fixation duration on a word is affected by linguistic features of the preceding context (Pollatsek et al., 2008; Shvartsman et al., 2014, see also Barrett and Hollenstein (2020) for a reference to the utility of information about preceding input). Computational reading models have not addressed linguistic concepts beyond the level of the fixated word much, with a few exceptions, e.g. spillover effects related to previewing the next word n+1 during the current fixation on word n (Engbert et al., 2005). Here we extend the study of spillover effects to the effects of textual features of the preceding sentence. To our knowledge, this is the first systematic attempt to investigate the effects of textual features on the prediction of eye-tracking measures in a corpus of naturalistic reading by considering a large number of features spanning different levels of linguistic analysis.

2 Related work

In this section, we provide a brief overview of the available literature that has used transformer-based language models to predict human reading patterns, as well as the literature that has investigated the role of text properties on word predictability during naturalistic reading.

Schrimpf et al. (2021) evaluated a broad range of language models on the match of their internal representations to three datasets of human neural activity (fMRI and ECoG) during reading. Their results indicated that transformer-based models perform better than recurrent networks or word-level embedding models. They also found that the models with the best match with human language processing were models with unidirectional attention transformer architectures: specifically the generative pretrained transformer (GPT-2) (Radford et al., 2019), consistently outperformed all other models in both fMRI and ECoG data from sentence-processing tasks. Hollenstein et al. (2021) presented the first study analyzing to what extent transformer language models are able to directly predict human gaze patterns during naturalistic reading. They compare the performance of language-specific and multilingual pretrained and fine-tuned BERT and XLM models to predict reading time measures of eye-tracking datasets in four languages (English, Dutch, German, and Russian). Their results show that both monolingual and multilingual transformer-based models achieve surprisingly high accuracy in predicting a range of eye-tracking features across all four languages. For the English GECO dataset, which is also used in the current study, the BERT and XLM models yielded prediction accuracies (100 - mean absolute error (MAE)) ranging between 91.15% (BERT-EN) and 93.89% (XLM-ENDE).

To our knowledge, the first study to investigate the role of textual characteristics on word predictability during naturalistic reading is an experimental study conducted by Lowder et al. (2018). This study implemented a large-scale cumulative cloze task to collect word-by-word predictability data (surprisal and entropy reduction scores) for 40 text passages which were subsequently read by 32 participants while their eye movements were recorded. Lowder et al. (2018) found that surprisal scores were associated with increased reading times in all eye-tracking measures. They also observed a significant effect of text difficulty, measured by Flesch–Kincaid grade level of each paragraph (Kincaid et al., 1975), such that increases in text difficulty were associated with increased reading times. Crucially, their study yielded evidence of interactions between predictability (surprisal scores) and paragraph difficulty. In the above-mentioned computational study, Hollenstein et al. (2021) also investigated the influence of textual characteristics (word length, text readability) on model performance. Text readability was measured using Flesch Reading Ease scores (Flesch, 1948). Their results indicated that the models learned to reflect characteristics of human reading, such as sensitivity to word length. They also found that model accuracy was higher in more easily readable sentences.

3 Experiments

3.1 Datasets

We analyze eye movement data from two eye-tracking corpora of natural reading, the Ghent Eye-Tracking Corpus (GECO; (Cop et al., 2017)) and the Provo corpus (Luke and Christianson, 2018). In both corpora the participants read full sentences within longer spans of naturally occurring text at their own speed while their eye movements were recorded. The GECO corpus is large dataset of eye movement of a monolingual and bilingual readers who read a complete novel, Agatha Christie's 'The Mysterious Affair at Styles'. It contains eye-tracking data from 14 English native speakers and 19 bilingual speakers of Dutch and English, who read parts of the novel in its original English version and another part of its Dutch translation. In the present work, we focus on the analysis of the data from the monolingual English native speakers. These participants read a total of 5031 sentences amounting to a total of 54364 word tokens. The Provo Corpus is a dataset of eye movements of skilled readers reading connected text. It consists of eye movement data from 84 native English-speaking participants from Brigham Young University, who read 55 short passages from a variety of sources, including online news articles, popular science magazines, and public-domain works of fiction. These passages were an average of 50 words long for a total of 2,689 word tokens.

3.2 Measurement of text properties

The texts from both datasets (GECO and PROVO) were automatically analyzed using CoCoGen (Ströbel et al., 2016), a computational tool that implements a sliding window technique to calculate sentence-level measurements that capture the within-text distributions of scores for a given language feature (for current applications of the tool in the context of text classification, see Kerz et al. (2020, 2021)). We extract a total of 107 features that fall into five categories: (1) measures of syntactic complexity (N=16), (2) measures of lexical richness (N=14), (3) register-based n-gram frequency measures (N=25), (4) readability measures (N=14), and (5) psycholinguistic measures (N=38). A concise overview of the features used in this study is provided in Table 5 in the appendix. Tokenization, sentence splitting, part-of-speech tagging, lemmatization and syntactic PCFG parsing were performed using Stanford CoreNLP (Manning et al., 2014). The syntactic complexity measures comprise (i) surface measures that concern the length of production units, such as the mean length of words, clauses and sentences, (ii) measures of the type and incidence of embeddings, such as dependent clauses per T-Unit or verb phrases per sentence or (iii) the frequency of particular types of particular structures, such as the number of complex nominal per clause. These features are implemented based on descriptions in Lu (2010) and using the Tregex tree pattern matching tool (Levy and Andrew, 2006) with syntactic parse trees for extracting specific patterns. Lexical richness measures fall into three distinct sub-types: (i) lexical density, such as the ratio of the number of lexical (as opposed to grammatical) words to the total number of words in a text,

(iii) lexical variation, i.e. the range of vocabulary as displayed in language use, captured by text-size corrected type-token ratio and (iii) lexical sophistication, i.e. the proportion of relatively unusual or advanced words in the learner's text, such as the number of New General Service List (Browne et al., 2013). The operationalizations of these measures follow those described in Lu (2012) and Ströbel (2014). The register-based n-gram frequency measures are derived from the five register sub-components of the Contemporary Corpus of American English (COCA, (Davies, 2008)): spoken, magazine, fiction, news and academic language[1]. These measures consider both the register-specific frequency rank and count:

$$Norm_{n,s,r} = \frac{|C_{n,s,r}| \cdot \log\left[\prod_{c \in |C_{n,s,r}|} freq_{n,r}(c)\right]}{|U_{n,s}|} \tag{1}$$

Let $A_{n,s}$ be the list of n-grams ($n \in [1, 5]$) appearing within a sentence s, $B_{n,r}$ the list of n-gram appearing in the n-gram frequency list of register r ($r \in \{acad, fic, mag, news, spok\}$) and $C_{n,s,r} = A_{n,s} \cap B_{n,r}$ the list of n-grams appearing both in s and the n-gram frequency list of register r. $U_{n,s}$ is defined as the list of unique n-gram in s, and $freq_{n,r}(a)$ the frequency of n-gram a according to the n-gram frequency list of register r. The total of 25 measures results from the combination of (a) a 'reference list' containing the top 100k most frequent n-grams and their frequencies from one of five registers of the COCA corpus and (b) the size of the n-gram ($n \in [1, 5]$). The readability measures combine a word familiarity variable defined by prespecified vocabulary resource to estimate semantic difficulty together with a syntactic variable, such as average sentence length. Examples of these measures are the Fry index (Fry, 1968) or the SMOG (McLaughlin, 1969). Finally, the psycholinguistic measures capture cognitive aspects of reading not directly addressed by the surface vocabulary and syntax features of traditional formulas. These measures include a word's average age-of-acquisition (Kuperman et al., 2012) or prevalence, which refers to the number of people knowing the word (Brysbaert et al., 2019; Johns et al., 2020).

3.3 Eye-tracking measures

We analyze data from eight word-level reading time measures, which were also investigated in Hollenstein et al. (2021). The measures include general word-level characteristics such as (1) the number of fixations (NFX), i.e. the number of times a subject fixates on a given word w, averaged over all participants, (2) mean fixation duration (MFD), the average fixation duration of all fixations made on w, averaged over all participants and (3) fixation proportion (FXP), the number of subjects that fixated w, divided by the total number of participants. 'Early processing' measures pertain to the early lexical and syntactic processing and are based on the first time a word is fixated. These features include: (4) first fixation duration (FFD), i.e. the duration of the first fixation on w (in milliseconds), averaged over all subjects and (5) first pass duration (FPD), i.e. the sum of all fixations on w from the first time a subject fixates w to the first time the subject fixates another token. 'Late processing' measures capture the late syntactic processing and are based on words which were fixated more than once. These measures comprise (6) total fixation duration (TFD), i.e. the sum of the duration of all fixations made on w, averaged over all subjects, (7) number of re-fixations (NRFX), the number of times w is fixated after the first fixation, i.e., the maximum between 0 and the NFIX-1, averaged over all subjects and (8) re-read proportion (RRDP), the number of subjects that fixated w more than once, divided by the total number of subjects. The means, standard deviations and observed ranges for all eye-tracking features are shown in Tables 1 and 2. Like in Hollenstein et al. (2021), before being entered into the models, all eye-tracking features were scaled between 0 and 100 so that the loss can be calculated uniformly over all features.

---

[1] The Contemporary Corpus of American English is the largest genre-balanced corpus of American English, which at the time the measures were derived comprised of 560 million words.

4 Modeling approach

Deep neural transformer-based language models create contextualized word representations that are sensitive to the context in which the words appear. These models have yielded significant improvements on a diverse array of NLP tasks, ranging from question answering to coreference resolution. We compare two such models in terms of their ability to predict eye-tracking features: ‘Bidirectional Encoder Representations from Transformers’ (BERT) (Devlin et al., 2018) and ‘Generative Pre-trained Transformer 2’ (GPT-2) (Radford et al., 2019). BERT is an autoencoder model trained with a dual objective function of predicting masked words and the next sentence. It consists of stacked transformer encoder blocks and uses self-attention, where each token in an input sentence looks at the bidirectional context, i.e. tokens on left and right of the considered token. In contrast, GPT-2 is an autoregressive model consisting of stacked transformer decoder blocks trained with a language modelling objective, where the given sequence of tokens is used to predict the next token. While GPT-2 uses self-attention as well, it employs masking to prevent words from attending to following tokens, hereby processing language fully unidirectionally. BERT is trained on the BooksCorpus (800M words) and Wikipedia (2,500M words), whereas GPT-2 is trained on WebText, an 8-million documents subset of CommonCrawl amounting to 40 GB of text. We chose the BERT base model (cased) because it is most comparable to GPT-2 with respect to number of layers and dimensionality (BERT base model (cased) has 110M trainable parameters, GPT-2 has 117M).

We evaluate the eye-tracking predictions of the models both on within-domain text, using an 80/10/10 split of the much larger GECO dataset (representing fiction language), as well as on out-of-domain text using the complete, much smaller PROVO dataset (comprising also online news and popular science magazine language). Furthermore, since overly aggressive fine-tuning may cause catastrophic forgetting (Howard and Ruder, 2018), we perform all experiments both with ‘frozen’ language models, where all the layers of the language model are frozen and only the attached neural network layers are trained, and also ‘fully fine-tuned’ language models, where the error is back-propagated through the entire architecture and the pretrained weights of the model are updated based on the GECO training set.

For all models we explored in this paper, we apply a dropout rate of 0.1 and a l2 regularization of 1×10^{-4}. We use AdamW as the optimizer and mean squared error as the loss function. We use a fixed learning rate with warmup. During warmup, the learning rates are linearly increased to the peak learning rates and then fixed. For BERT with a ‘frozen’ language model, the peak learning rate is 5×10^{-4} with 5 warmup steps and for GPT-2 with a ‘frozen’ language model, it is 0.001 also with 5 warmup steps. Models with ’fully fine-tuned’ language models are trained with two phases. In the first phase, the weights of the language models are frozen and only regression layers are trained. During this phase, peak learning rates of 3×10^{-4} for BERT and 0.001 for GPT-2 are used. For both models, the first phase is performed over 12 epochs with 5 warmup steps. In the second phase, we unfreeze the weights of language models and fine-tune the language models together with the regression layers. During this phase, the BERT-based model is trained with a peak learning rate of 5×10^{-5} while GPT-2-based model is trained with a peak learning rate of 5×10^{-4}. The number of warmup steps for training both models in this phase is 3. We adopted a two-phase training procedure since preliminary experiments showed that this procedure yields same results as training the entire models from the first epoch, yet it can speed up model convergence. All hyper-parameters are optimized through grid search.

4.1 Influence of text characteristics on model performance

To investigate the impact of the text properties listed in Section 3.2 on prediction accuracy, we partitioned the GECO testset into deciles according to each textual property, i.e. each of the 107 features. We then calculated the Pearson correlation coefficients between the decile of a given textual feature and the mean absolute error (MAE) of a given model. We expected to observe higher prediction accuracy (lower MAE) for sentences with higher readability, lower syntactic complexity, lower lexical richness, higher n-gram frequency and less demanding psycholinguistic properties, i.e. lower age-of-acquisition scores and higher prevalence scores.

4.2 Integration of text characteristics using a hybrid modeling approach

To determine whether eye movement patterns were affected by textual characteristics of the previous sentences (sentence spillover effects), a bidirectional LSTM (BLSTM) model was integrated into the predictive models (Figure 1). This BLSTM model reads 107 dimensional vectors of textual features $CM_{i-N}, \cdots, CM_{i-1}$ from N previous sentences[2] as its input, transforms them through 4 BLSTM layers of 512 hidden units each, and outputs a 1024 dimensional vector $[\overrightarrow{h}_{4N}|\overleftarrow{h}_{41}]$, that is a concatenation of the last hidden states of the 4th BLSTM layer in the forward and backward directions $\overrightarrow{h}_{4N}$, $\overleftarrow{h}_{41}$. A fully connected (FC) layer is added on top of the BLSTM layers to reduce the dimension of BLSTM model output to 256 (C_i). Meanwhile, another FC layer is added to the pre-trained language model (BERT or GPT-2) in order to reduce its logits to the same dimension ($E_{i1}, \cdots, E_{iM}$). The reduced BLSTM output is then added to each of the reduced language model logits. Finally, the 256-dimensional joint vectors are fed to a final regression layer to predict human reading behavior. The procedures used to train the 'hybrid' models with textual characteristics of the previous sentences was identical to those specified above. Grid search yielded the same optimized values for all hyper-parameters, except for the peak learning rate of 'fully fine-tuned' model with GPT-2 in second training phase, which was 1×10^{-4}.

To assess the relative importance of the feature groups, we employed Submodular Pick Lime (SP-LIME; Ribeiro et al. (2016)), a method to construct a global explanation of a model by aggregating the weights of the linear models. We first construct local explanations using LIME with a linear local explanatory model, exponential kernel function with Hamming distance and a kernel width of $\sigma = 0.75\sqrt{d}$, where d is the number of feature groups. The global importance score of the SP-LIME for a given feature group j can then be derived by: $I_j = \sqrt{\sum_{i=1}^{n} |W_{ij}|}$, where W_{ij} is the jth coefficient of the fitted linear regression model to explain a data sample x_i.

---

[2] Experiments with $N \in [1, 5]$ were performed and $N = 1$ performed best.

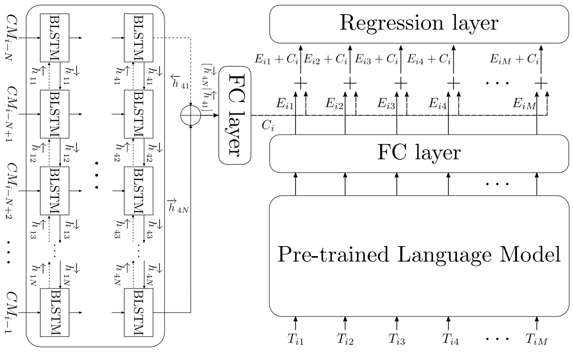

Figure 1: Visualization of approach used to integrate information on complexity of preceding language input for sentence i.

5 Results & Discussion

We use sentence-level accuracy (100-MAE) and coefficients of determination ($R2$) as metrics to evaluate the performance of all models. Table 3 shows the evaluation results for all models averaged over all eye-tracking features. Table 3 shows that both BERT and GPT-2 models predicted the eye-tracking features of both datasets with more than 92% accuracy. The fine-tuned models performed consistently better than the pretrained-only ('frozen') models both on the within-domain text (GECO) and on the out-of-domain text (PROVO). This result indicates that the learned representations are general enough to be successfully applied both in the prediction of reading patterns of fiction texts as well as in the prediction of news and popular science texts. The BERT models consistently outperformed the GPT-2 models with a difference in $R2$ of as much as 10.54% on the within-domain data (GECO). This result stands in sharp contrast with those reported in Schrimpf et al. (2021) summarised in Section 2. In their interpretation of the success of GPT-2 in predicting neural activity during reading, Schrimpf et al. (2021) state that "GPT-2 is also arguably the most cognitively plausible of the transformer models (because it uses unidirectional, forward attention)". Especially in view of the remarkable margin by which the BERT models outperformed the GPT-2 models here, it appears that arguments that infer cognitive plausibility from prediction success should be viewed with caution (see also Merkx and Frank (2020) for further intricacies of the issue). The most accurately predicted individual eye-tracking measures were fixation probability (FXP), mean fixation duration (MFD) and first fixation duration (FFD), indicating that prediction accuracy was generally better for early measures than for late measures. A detailed overview of the results for each eye-tracking measure across all models and datasets is provided in Table 7 in the appendix. This finding suggests that the accurate prediction of late measures – that are assumed to reflect higher order processes such as syntactic and semantic integration, revision, and ambiguity resolution – may benefit from the inclusion of contextual information beyond the current sentence.

	PROVO	43.67	6.08	93.92
GPT-2 ft	GECO	46.29	6.48	93.52
	PROVO	55.73	5.06	94.94
GPT-2 ft + com S-1	GECO	47.53	6.38	93.62
	PROVO	56.77	5.08	94.92

Note: 'fr' = freeze all layers of language model; 'ft' = the entire model is fine-tuned; '+ com S-1' = including textual features of previous sentence

5.1 Relationship of prediction accuracy and text characteristics

The correlation analyses of the textual features and the mean absolute error revealed that prediction accuracy was affected by the text characteristics of the sentence under consideration. Such effects were found across all eye-tracking metrics for both BERT and GPT-2 models in both their frozen and fully fine-tuned variants. For reasons of space, we focus our discussion on the predictions of the BERT frozen model of first pass durations on the GECO dataset (additional results for both frozen and fine-tuned BERT models for both first pass duration and total fixation duration are provided in Figure 3 in the appendix). Figure 2 visualizes the impact of all textual features that reached correlation coefficients $r > |0.2|$ along with the feature group they belong to. As is evident in Figure 2 the prediction accuracy of the BERT frozen model was impacted by features from all five feature groups with individual features affecting prediction accuracy in opposite ways. A strong impact ($r > |0.5|$) was observed for several features of the n-gram feature group: Fixation durations of sentences with higher scores on ngram-frequency features from the news, magazine and spoken registers were predicted more accurately than those with lower scores on these measures. The SMOG readability index, which estimates the years of education a person needs to understand a piece of writing, also has a strong impact: Predicted first pass durations were less accurate in sentences with higher SMOG scores. Several features from the lexical richness, syntactic complexity and readability groups had a moderate impact on prediction accuracy ($|0.3| < r < |0.5|$): For example, predictions of fixation durations were less accurate on sentences of with a more clausal embedding (ClausesPerSentence) and greater lexical sophistication (MeanLengthWord, Sophistication.ANC and Sophistication.BNC). A similar effect was also observed for the psycholinguistic age-of-acquisition features (AoA mean, AoA max), where predictions of fixations times were less accurate for later acquired words. Note that the finding that the correlation coefficients of the readability features have opposite signs is due to the fact that these are either defined to quantify ease of reading (e.g. Flesch Kincaid Reading Ease) or reading difficulty (e.g. SMOG index).

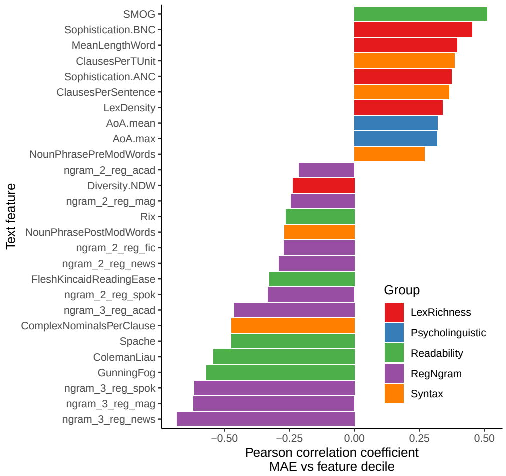

Figure 2: Pearson correlations between model performance (mean absolute error), and the deciles of the respective text characteristics. For measures with negative correlation coefficients, model performance increased with higher values of the text characteristics (Data from 'BERT frozen' predictions of First pass duration (FPD) on GECO testdata).

5.2 Prediction accuracy of hybrid models

Turning to the results of the hybrid models with integrated information on textual characteristics of the preceding sentence, we found that highest accuracy ($R2 = 58.36\%$) was achieved by the fine-tuned BERT model. This amounts to an increase in performance over a model trained without that information of 1.53%. This result demonstrates that future studies should take textual spillover effects into account. Our best-fitting model outperformed not only the best-performing BERT model in Hollenstein et al. (2021), BERT-BASE-MULTILINGUAL-CASED (Wolf et al., 2019) but also the overall best-performing transformer-based model, XLM-MLM-ENDE-1024 (Lample and Conneau, 2019) tested in that study. This result demonstrates that the claim put forth in Hollenstein et al. (2021) that multilingual models show an advantage over language specific ones and that multilingual models might provide cognitively more plausible representations in predicting reading needs to be viewed with caution.

The results of the feature ablation experiments revealed that the main sources of the greater prediction accuracy of the hybrid models was asso-

Table 4: Feature ablation of different models on PROVO dataset. Most important feature groups are bolded.

		Syn. complex	Lex. richness	Psych.	Reg. ngram	Read.
BERT	fr	**5.69**	5.34	3.22	5.44	4.74
	ft	**2.48**	1.64	1.25	1.44	1.30
GPT-2	fr	9.06	9.62	7.91	**10.10**	9.85
	ft	16.07	7.02	12.20	**18.82**	12.68

ciated with information concerning the syntactic complexity, lexical richness and n-gram frequency of the preceding sentence. An overview of the results is presented in Table 4. We focus here on the results on the out-of-domain testset (PROVO) for which improvements over models without the integrated textual information were more pronounced. As is evident in Table 4, the central role of the three feature groups listed above result was observed across models (BERT vs. GPT-2) and across training procedures (frozen vs. fine-tuning). However, Table 4 also demonstrates clear differences between the models: While the BERT models show greater sensitivity to syntactic complexity, the GPT-2 models mostly benefit from information concerning n-gram frequency. A possible interpretation of this finding is that a unidirectional model like GPT-2 relies more strongly on word sequencing than a bidirectional one. Future research is needed to examine this in more detail so that effects associated with differences in model architecture can be disentangled.

6 Conclusion

In this paper we conducted the first systematic investigation of the role of general text features in predicting human reading behavior using transformer-based language models (BERT & GPT-2). We have shown (1) that model accuracy is systematically linked to sentence-level text features spanning five measurement categories (syntax, complexity, lexical richness, register-specific N-gram frequency, readability, and psycholinguistic properties), and (2) that prediction accuracy can be improved by using hybrid models that consider spillover effects from the previous sentence.

Abstract

Recent work in multilingual machine translation (MMT) has focused on the potential of positive transfer between languages, particularly cases where higher-resourced languages can benefit lower-resourced ones. While training an MMT model, the supervision signals learned from one language pair can be *transferred* to the other via the tokens shared by multiple source languages. However, the transfer is inhibited when the token overlap among source languages is small, which manifests naturally when languages use different writing systems. In this paper, we tackle inhibited transfer by augmenting the training data with alternative signals that unify different writing systems, such as phonetic, romanized, and transliterated input. We test these signals on Indic and Turkic languages, two language families where the writing systems differ but languages still share common features. Our results indicate that a straightforward *multi-source self-ensemble* — training a model on a mixture of various signals and ensembling the outputs of the same model fed with different signals during inference — outperforms strong ensemble baselines by 1.3 BLEU on both language families. Further, we find that incorporating alternative inputs via self-ensemble can be particularly effective in low-resource settings, leading to +5 BLEU when only 5% of the total training data is accessible. Finally, our analysis demonstrates that including alternative signals yields more consistency and translates named entities more accurately, which is crucial for increased factuality of automated systems.

1 Introduction

Machine translation has seen great progress, with improvements in quality and successful commercial applications. However, the majority of this improvement benefits languages with large quantities of high-quality training data (high-resource languages). Recently, researchers have focused on the development of multilingual translation models (Aharoni et al., 2019; Fan et al., 2020) capable of translating between many different language pairs rather than specialized models for each translation direction. In particular, such multilingual models hold great promise for improving translation quality for *low-resource* languages, as grouping languages together allows them to benefit from linguistic similarities as well as shared data between related languages. For example, training a translation system with combined Assamese and Bengali data would enable transfer learning between the two languages.

We investigate how to enable multilingual translation models to optimally learn these similarities between languages and leverage this similarity to improve translation quality. The fundamental unit representing lingual similarity is the token — languages that are similar often have similar words or phrases — and during training, translation models can learn strong representations of tokens in low-resource languages if they are also present in high-resource languages. However, a challenge arises when similar languages share only a small amount of tokens, which inhibits the transfer to limited and trivial cases of token sharing, e.g., punctuation marks and digits. This is particularly clear in cases where similar languages are written in different scripts, as the amount of shared tokens is small compared to languages using the same written script. An example would be Hindi and Gujarati, which have phonetic similarity but are written in their own native scripts.

To tackle inhibited transfer due to distinct writing systems, we transform the original input via *transliteration*, the process of converting text from one script to another, to get alternative signal from the original source sentences. Transliteration has

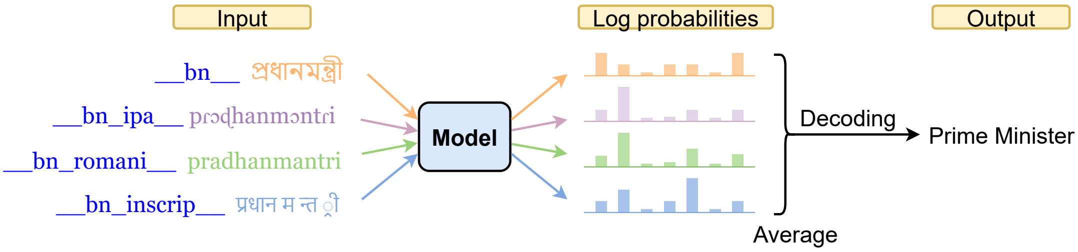

Figure 1: A generic illustration of self-ensemble for a multilingual translation system while translating Bengali to English. The input contains different signals, each preceded by a special language token ('__bn__' indicates input in original Bengali script, '__bn_ipa__' the phonetic version of the same Bengli input, '__bn_romani__' the romanized version and '__bn_inscrip__' the same input but written in the script of Hindi, a language within the same language family). The log probabilities output by the model given each type of input are averaged for subsequent decoding process.

been used in many real world cases, such as converting Cyrillic Serbian to Latin Serbian, as the language is commonly written with both scripts, or typing in romanized Hindi for convenience on a Latin-script keyboard. To unify various writing scripts to increase token overlap, we experiment with three types of transliteration: **(1)** transliterate into phonemes expressed by international phonetic alphabet (IPA), **(2)** transliterate into Latin script (ROMANI), and **(3)** transliterate into a script used by another language within the same language family (INSCRIP). Beyond training on alternative inputs created through transliteration, we also systematically examine approaches to combining different signals. Our experimental results on Indic and Turkic datasets demonstrate that **(i)** a *self-ensemble* (Figure 1) – training a model on the mixture of different signals and using an ensemble of the *same* model given different input signals during inference time, outperforms other methods such as multi-source ensemble and multi-encoder architecture, which require training multiple models or significant architectural changes. **(ii)** Further, without the need for additional bitext, a self-ensemble over the original and transliterated input consistently outperforms baselines, and is particularly effective when the training set is small (e.g. low-resource languages) with improvements of up to +5 BLEU. **(iii)** Finally, the improvements in BLEU originate from clear gain in the accuracy and consistency in the translation of named entities, which has strong implications for increased factuality of automated translation systems.

2 Method

Multilingual translation models enable languages to learn from each other, meaning low-resource languages can benefit from similarities to high-resource languages where data is plentiful. However, surface-level differences between languages, such as writing system, can obscure semantic similarities. We describe an approach to transliterating input sentences to various alternative forms that maximize transfer learning between different languages, and various modeling approaches to incorporating such varied inputs.

2.1 Alternative Inputs Bridge the Gap between Surface Form and Meaning

While training a multilingual translation system, tokens shared by multiple source languages serve as anchors to transfer information obtained from learning one language pair to the other. For example, the translation of 'terisini' in low-resourced Uzbek data can benefit from the word 'derisinin' in relatively high-resourced Turkish data after tokenizing into sub-word units. However, the transfer is hindered when the amount of shared tokens is small — exacerbated by cases where the source and target languages are written in different scripts.[1] To alleviate the issue of various writing systems and encourage languages to transfer, we focus on alternative signals that unify the script of source languages and have larger token overlap. The core concept we explore is how to best leverage *transliteration*, or the process of converting the text from one script to the other. We demonstrate that transliteration can be an effective data augmentation approach that improves the translation performance *without the need of acquiring additional parallel data.* We explore three alternative inputs that allow

---

[1] Muller et al. (2021) show that the discrepancy in scripts causes failure to transfer in multilingual models and further hurts performance in downstream tasks.

models to share information more easily across languages with low token overlap but high semantic similarity. Figure 4 in Appendix C shows example alternative signals of the same Oriya sentence.

Phonetic Input. Related languages in the same language family usually sound similar, such as languages in the Romance language family and those in the Indo-Aryan language family. Although cognates can be captured to some degree for Romance languages on subword-level, it is difficult for the Indo-Aryan family as those languages use different writing systems. Therefore, to fully exploit shared information, we transform the original textual input (BASE) into the phonetic space, where the basic units are phonemes expressed in international phonetic alphabet (IPA). For example, 'প্রধানমন্ত্রী' in Bengali looks like 'pɾɔdhanmɔntɾi' in IPA form.

Romanized Input. Many languages use Latin alphabet (or Roman alphabet) in their default writing system, if not, they more or less have romanization of their default script in order to accommodate conventional keyboards, e.g., Chinese can be typed on U.S. keyboards through Pinyin, the romanization of Chinese. To utilize this existing form of alternative input, the romanized input is another signal we explore in this work. For example, 'প্রধানমন্ত্রী' looks like 'pradhanmantri' in romanized form.

In-family Script Input. The two previous alternative representations introduce tokens not present in the existing vocabulary, which increases the number of input and output representations the translation models must learn. Further, phonetic input is artificial in the sense that it is not used by people to communicate to each other in written form — and only used for pronunciation. Romanization naturally would introduce many additional tokens if the source language does not use Latin script. A third alternative that does not suffer these drawbacks is transliterate source language into the script of any of the other source languages in the multilingual translation model. To take advantage of language relatedness (Dhamecha et al., 2021), we unify the source languages with the script used by a language within the same language family (INSCRIP). This method has the additional advantage of not needing to learn new subword tokenization models or replace the old vocabulary with a new one since all the inputs are expressed in one of the existing multilingual model's source language scripts. For example, 'প্রধানমন্ত্রী' looks like 'प्रधानमन्त्री' when transliterated into Hindi script.

Advantages of Transliterated Inputs. Various different input representations have been inserted into translation models, from parse trees (Li et al., 2017; Currey and Heafield, 2018) to pretrained embeddings (Artetxe et al., 2018; Conneau et al., 2018). Compared to these alternatives, transliteration has several clear advantages. Most importantly, transliteration is fast and accurate. Several existing alternatives often use other models to produce a different input, such as a parse tree, which cascades error from the first model into the translation model. Comparatively, the alphabet alignment between various writing systems is quite well known, even for many low-resource languages, as alphabet is one of the foundational aspects of studying any new language. Similarly, phonetic pronunciation guides are often widely available. These resources are also easily accessible programmatically, making them ideal for converting large quantities of supervised training data, for instance, the `espkea-ng` tool supports phonemization of more than 100 languages and accents. Beyond the ease of creating transliterations, we emphasize that this technique does not require any data annotation or collection of parallel data. Thus, it can be utilized in any existing translation system.

2.2 Adding Transliterated Input Combinations to Translation Models

How can additional transliterated inputs be incorporated into modern machine translation architectures? Since each alternative signal could capture a different view of the original input, in addition to training on each of the individual alternative signal alone, we investigate different approaches to combining them.

Straight Concatenation The simplest combination strategy is to concatenate different input signals and separate them by a special token. For instance, to combine the original and phonetic input, we re-arrange the input to be of the format: "*[original input]* `[SEP]` *[phonetic input]*". During training, the decoder explicitly attends to tokens in both input signals. The advantage of this method is that no architectural change is required as all modification is operated on the input data. However, as the concatenated input becomes longer, this method requires more computation to train compared to the baseline model trained on the original input only.

Multi-Encoder Architectures Prior works have found multi-encoder architecture to be effective for multi-source machine translation (Nishimura et al., 2018). To cope with input from different sources, each encoder in the multi-encoder architecture deals with one type of input. To attend to multiple encoders on the decoder side, four cross-attention mechanisms can be adopted. We direct the reader to Appendix A for a detailed description of these attention variations. Although prior work investigates the efficacy of this approach, it is a complicated model choice requiring non-trivial architectural changes.

Multi-Source Ensemble Ensembles are usually employed to boost the performance of a translation system. In a standard setup, each ensemble component is trained with identical configuration except for the random seed. We generalize this method to multi-source ensemble, i.e., individual ensemble components are trained on different transliterated inputs. During inference time, each component is fed with the type of transliteration it was trained on and produces the predicted log probabilities, which are averaged over all components for the subsequent decoding process. It is important for models trained on different source signals to have the same target vocabulary so that the average of log probabilities can happen. Unlike the previous two methods, this approach requires training multiple full models, thus requiring even more computation.

Multi-Source Self-Ensemble Ensembling models that are trained on different input transliterations has the advantage that each individual model is maximally *simple* — only the input data for training changes. However, it comes with the downside that multiple different models need to be trained. This creates challenges particularly when models grow in size, as a new model would need to be created for each different transliterated input.

Instead, we propose the *Multi-Source Self-Ensemble*, which has all the advantages of traditional ensembling, but only requires *one* model to be trained. Previous works in self-ensembles have focused on model robustness (Liu et al., 2018), which is distinct from varying input representations. Other work creates inputs in different languages (Fan et al., 2020), but have to use a translation model to create those inputs first.

In our case, we train the model with different transliterated inputs mapping to the same translated target sentence. Concretely, the model is trained on the mixture of various input signals, each preceded by a special language token indicating which type of signal this input belongs to. At inference time, the alternative transliterated signals of the same test sentence are fed to the same model and the log probabilities produced by these separate passes are averaged as in multi-source ensemble. This approach is simple to implement as it requires no architectural change, meaning the transliterated inputs we propose can be added seamlessly to any existing translation library. Unlike multi-source ensemble, only one model needs to be trained, stored and loaded for inference, greatly simplifying the ensembling process and increasing the scalability of our approach (particularly as translation models increase in size). To enforce fair comparison between multi-source self-ensemble and multi-source ensemble, we *scale* the former so that it has the same number of parameters as that of all ensemble components of the latter. For the purpose of minimally impacting inference speed, the scaling is done only to the encoder embedding dimension so that the decoder remains the same.

3 Experimental setup

Dataset We train our model on two language families: Indic and Turkic. The Indic dataset is from the WAT MultiIndic MT task[2], including 10 Indic languages and in total around 11 million Indic-English bi-texts. Six of the Indic languages are Indo-Aryan languages and the rest are Dravidian languages. All of these languages use a different writing system. The Turkic dataset is collected from the open parallel corpus (Tiedemann, 2012)[3]. For relatively high-resourced language Turkish, we randomly select 4 million subset from the CCAligned (El-Kishky et al., 2020) corpus. Within this dataset, two languages use Cyrillic alphabet (Kazakh and Kyrgyz) and the rest use Latin alphabet. Detailed dataset statistics are displayed in Table 7 in Appendix B.

Single-input model To test the effectiveness of each input signal, we train models on each *single* type of input: original input (BASE), phonetic input (IPA), romanized input (ROMANI) or input all expressed in the script of a language within the same language family (INSCRIP). On the Indic dataset,

for the Inscrip signal, all Indo-Aryan languages are transliterated into Hindi script, and all Dravidian languages into Tamil script. On the Turkic dataset, all languages in Latin script are transliterated into Cyrillic script.

Multi-Source Ensemble A baseline for ensembling models trained on different signals is the standard ensemble (Base+Base) where two Base models are ensembled, each trained with a different random seed. Although there are multiple combinations of input signals, we only discuss the cases where Base is combined with one of {IPA, Romani, Inscrip}, since in our preliminary experiments, we found dropping the Base model leads to significantly degraded performance.

Multi-Source Self-Ensemble Similar to above, we train a single model on the mixture of original input and one of {IPA, Romani, Inscrip} input for multi-source self-ensemble. To enforce fair comparisons with the ensembled models, which have more parameters in total, we train two sizes of the self-ensemble (SE) model, one having the same size of a single baseline model, the other scaled to have twice the number of parameters of a single Base model.

Data Preprocessing We use `espeak-ng`[4] to convert the original input to phonetic input. For Indic languages, we use `indic-trans`[5] (Bhat et al., 2015) to obtain the romanized as well as the in-family transliterated input. On the Turkic dataset, we manually align the Cyrillic and Latin alphabet and substitute the letter(s) in one script with the corresponding one in another.[6] The Indic languages are tokenized with `indic_nlp_library` and the rest are tokenized with `mosesdecoder`[7]. We use `sentencepiece`[8] to create 32K BPE (Sennrich et al., 2016) subword vocabularies for each type of input signal. Examples longer than 250 tokens are discarded. We merge the source dictionaries of different signals by dropping duplicated tokens, while keeping the decoder dictionaries all the same in order to compute the average log probabilities in ensemble settings.

Training & Evaluation We train many-to-En language directions during training (10 and 5 directions for Indic and Turkic dataset respectively). The architecture is a standard 6-layer encoder 6-layer decoder Transformer model, with 512 embedding dimension and 2048 hidden dimension in the default setting. For the scaled self-ensemble model, we increase the encoder hidden dimension such that the number of parameters in this model approximately matches that of n baseline models ($n = 2$ for results in Table 1). We use 4000 warmup steps and learning rate 0.0003. Both the dropout and attention dropout rate are set to 0.2. Label smoothing is set to 0.1. Data from different language pairs are sampled with 1.5 temperature sampling. We

train all models for 18 epochs and 40 epochs for Indic and Turkic dataset respectively and evaluate the best checkpoint selected by dev loss. We use `spBLEU`[9] (Goyal et al., 2021; Guzmán et al., 2019) to compute the BLEU scores.[10]

4 Results

In this section, we compare the performance of our proposed multi-source self-ensemble model to various alternative ways of input combinations on two low-resource language families: Indic and Turkic languages. Furthermore, we show multi-source self-ensemble learns faster and generates more consistent and accurate translations.

4.1 Performance of Multi-Source Self-Ensemble

Our method is based on the hypothesis that incorporating alternative inputs increases the token overlap of source languages, which benefits the transfer during training. To verify this, we compute average sentence-level uni-gram overlap of all source language pairs (Table 2) and find that alternative signals do have higher token overlap compared to the original input. For instance, the IPA signal, having similar average sentence length as BASE , has much higher token overlap (0.15 vs. 0.03).

Do increased token overlaps result in better translation performance? We train models on each of the alternative inputs alone and report the results in the left column of Table 1. We find that using only one alternative input in the source has either worse or similar performance as the original baseline, indicating higher token overlap among source languages does not guarantee better BLEU scores. The degraded performance is likely due to unfavorable interference introduced by shared tokens in the alternative signals. The interference may create information loss[11] or increased ambiguity[12], which reinforces the importance of combining alternative inputs with the original input.

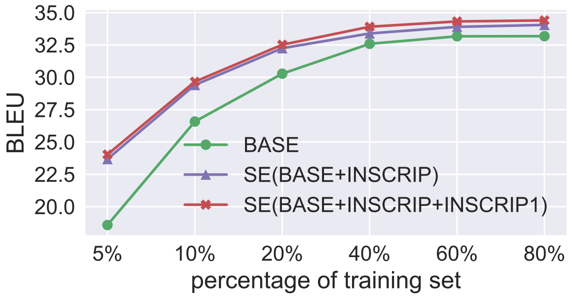

Figure 2: Learning curve of the baseline model BASE and the same-sized self-ensemble model trained on the original input as well as transliterated input. INSCRIP denotes the transliteration where the target script for Indo-Aryan and Dravidian languages are Hindi and Tamil respectively. The target scripts of INSCRIP1 are Oriya and Kannada respectively.

Due to undesired interference exhibited in the alternative input spaces, we therefore adopt the input combination using our proposed *Multi-Source Self-Ensemble* to combine the original input and alternative signals. Results in left lower part of Table 1 demonstrate improvements over the single-input baseline. Our best performing alternative input configuration improves +1.0 BLEU on Turkic languages and +0.6 BLEU on Indic languages for 93M parameter models.

In production, model ensembles are often employed to achieve the best possible performance. This is usually done by training multiple models each initialized with a different random seed (Bawden et al., 2020; Tran et al., 2021b), and averaging the predicted next token probabilities at inference time. We also provide results against these strong ensemble baselines and observe +1.3 BLEU improvements on both Indic and Turkic languages. Note that, to enforce a fair comparison, we compare a scaled version of the multi-source self-ensemble model which has the same number of parameters as multiple ensemble baseline components.

[10] While prior work (Kocmi et al., 2021) has shown better correlation between neural metrics and human ratings, there have not been extensive evaluations for low-resource languages, especially for systems dealing with various writing scripts. Therefore we use spBLEU which is consistent with previous works (Goyal et al., 2021).

[11] For example, the punctuation marks are lost during phonemization process.

[12] For instance, multiple words may have the same pronunciation and thus have the same input in IPA form, which makes the learning harder.

Configuration	BLEU
Single-input Baseline	
BASE	33.6
Straight Concatenation	
BASE+<SEP>+IPA	33.7
BASE+<SEP>+ROMANI	33.7
BASE+<SEP>+INSCRIP	33.6
Multi-Encoder Architectures	
Bi-Encoder

BASE+INSCRIP	34.0
Quad-Encoder	
BASE+BASE+BASE+BASE	34.3
BASE+IPA+ROMANI+INSCRIP	34.1
Multi-source Self-ensemble	
BASE+INSCRIP	34.2

Table 3: Indic test set BLEU of models trained on straight concatenation of input as well as multi-encoder architectures. Training on the concatenated input does not impact the BLEU much. Multi-encoder architectures, although having a lot more number of parameters, for instance, quad-encoder, achieve similar performance of a much smaller multi-source self-ensemble.

4.2 Advantages of Multi-Source Self-Ensemble

Architectural Simplicity. As introduced in §2.2, there are various ways to incorporate multiple inputs, such as concatenation to form a longer input or using multiple encoders networks. In Table 3, we show that using multiple encoders has no improvements over the comparable baseline with raw text input, and straight concatenation only brings marginal gains (+0.1 BLEU). Further, our simple but effective Multi-Source Self-Ensemble technique reaches the same performance as that of a much larger quad-encoder model, which requires non-trivial architectural changes and takes more compute to train. Thus, our technique is suitable to be used out of the box in any seq-to-seq library.

	C-BLEU	NE-F1
Single-input Baseline		
BASE	34.7	55.9
Single-input Alternative Input		
IPA	33.8	54.7
ROMANI	33.0	54.5
INSCRIP	35.3	55.4
Multi-Source Self-Ensemble		
BASE+IPA	**36.2**	56.1
BASE+ROMANI	35.5	56.3
BASE+INSCRIP	**36.2**	**56.4**

Table 4: The consistency BLEU (**C-BLEU**) and exact named entity match F1 (**NE-F1**) of MultiIndic test set. Higher **C-BLEU** scores imply more consistent output in many-to-En setting. Higher **NE-F1** scores indicate better translation of named entities.

Faster Learning in Low-Resource Settings. To understand how self-ensemble performs with different amounts of data, we plot the learning curve of both the baseline and the self-ensemble model on 5%[13] to 80% of the total Indic training set.[14] As shown in Figure 2, the self-ensemble model outperforms the baseline model by a large margin when the amount of training data is small (**+5 BLEU** when only 5% of the total set is used for training). This is the scenario for most low-resource languages, as the gap gradually closes when more data is available. Overall, the multi-source self-ensemble model is consistently better than the baseline model irrespective of training data scale. This suggests that transliteration can be a cheap and effective data augmentation approach when used in conjunction with multi-source self-ensemble.

Improved Output Consistency. We conduct a deeper analysis to understand the performance improvement of Multi-Source Self-Ensembles beyond BLEU scores alone. We find that our proposed technique generates much more consistent output, which could be a benefit of alternative signals transferring information more easily amongst source languages. We propose consistency BLEU (**C-BLEU**) to quantify the consistency of multi-way evaluation output of a many-to-En translation model. We treat the output of L_1-En direction as reference and output of all other L_i-En directions as hypothesis. We compute this for all N source languages in the dataset, accounting for total $N(N-1)$ C-BLEU scores, then take the average of all (Table 4). While training on IPA or ROMANI alone does not outperform the baseline in terms of C-BLEU, model trained on INSCRIP input improves the score by +1.3. Self-ensemble over BASE and IPA increases the C-BLEU to **36.2** (and from **36.3** to **38.1** with scaled model), indicating the alternative signals are best trained together with the original input.

---

[13] When the training set is very small (5% and 10%), we train for 60 epochs and select the model by dev loss.

[14] The transliterated input are those of the same subset of training data, thus no sentences having new semantic meaning are added in the multi-source self-ensemble setup.

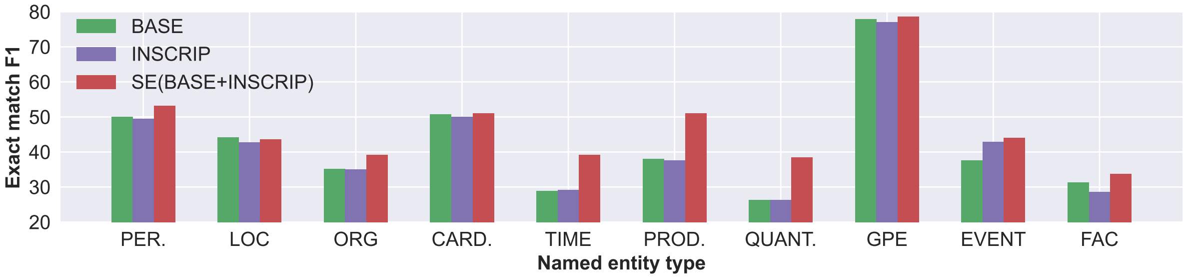

Figure 3: The exact named entity match F1 score of BASE INSCRIP and same-sized self-ensemble model trained on the previous two inputs (SE(BASE+INSCRIP)). Although the results of the self-ensemble model only slightly outperforms the baseline (55.9 vs. 56.4), the gains are more obvious when breaking the results by entity type.

Improved Named Entity Accuracy. The previous analysis implies the self-ensemble model outputs more consistent translation, yet this does not mean the consistent translations are accurate. In this section, we conduct an analysis targeted at named entities. We use spaCy (Honnibal et al., 2020) NER tagger to extract all named entities, and then compute the exact match of the extracted entities. According to the results in Table 4, self-ensemble introduces small gains (+0.5) in terms of named entity F1 (NE-F1), whereas the scaled self-ensemble boosts NE-F1 score by **+1.1**. Although the improvement is small in aggregate, we find significant improvement when breaking down by entity type. As shown in Figure 3, the multi-source self-ensemble model (without scaling) outperforms the baseline model on certain entity types, e.g., person, organization, time and event by a large margin.

5 Related work

5.1 Alternative Input for Multilingual MT

Our work can be viewed as multilingual MT (Firat et al., 2016) combined with multi-source MT (Zoph and Knight, 2016), where the sources are not other languages but rather alternative transliterated signals. The transliterated input has been explored in the past for translation system. Nakov and Ng (2009) use transliteration as a preprocessing step for their phrase-based SMT model to tackle systematic spelling variation. Both Chakravarthi et al. (2019) and Koneru et al. (2021) convert Dravidian languages to Latin script and train multilingual models with *both source and target* in Latin script; the latter identify code-switching to be a challenge during back-transliteration. Besides converting to Latin script, Dabre et al. (2018) use another common script, Devanagari, for Indic languages. In addition to the natural written scripts, previous works also explored artificial script, such as IPA. Liu et al. (2019) incorporate phonetic representations, specifically for Chinese Pinyin, to cope with homophone noise. Unlike our work, Chakravarthi et al. (2019) adopt transliteration to IPA for both the source and target. Apart from transliterated input, other potential alternative signals we did not fully explored include orthographic syllable units (Kunchukuttan and Bhattacharyya, 2016, 2020), morpheme-based units (Ataman et al., 2017; Dhar et al., 2020), and character (Lee et al., 2017) or byte (Wang et al., 2019a) level input in addition to the subword-level units (Sennrich et al., 2016).

5.2 Input signal combination

Multi-encoder architecture is the most common way to combine input from different sources. While previous works mainly use additional encoders to encode syntactic information (Li et al., 2017; Currey and Heafield, 2018) or input in another language (Nishimura et al., 2018), we feed in each encoder with different signals of the same sentence. Prior works also investigated approaches to combining input at different granularity (Ling et al., 2015; Chen et al., 2018; Casas et al., 2020). Wang et al. (2019b) combine the decoupled lexical and semantic representations through an attention mechanism. Another common method of utilizing additional input signal is multi-task learning, force the model to output extra labels (Luong et al., 2016; Grönroos et al., 2017). Apart from combining the sources during training, inference-time ensemble (Garmash and Monz, 2016) is often adopted by recent submissions to shared MT tasks (Ng et al., 2019; Tran et al., 2021a). The ensemble components are usually separate systems trained with different random initialization or language pairs. Fan et al. (2020) ensemble the same model by feeding in source sentences in different languages. The self-ensemble approach was also found to make networks more robust after adding random noises (Liu et al., 2018). Prior work also uses the term "self-ensemble" to refer to an ensemble of models using weights from different time steps during training (Xu et al., 2020).

6 Conclusion

To overcome the low token-overlap issue exhibited in multilingual MT systems due to distinct writing system, we examined three alternative signals (phonetic, romanized and in-family transliterated input) and investigated four approaches (input concatenation, multi-encoder, multi-source ensemble, self-ensemble) to combining them with the original input. Our results show that training a single model with a mixture of diverse signals and performing self-ensemble during inference time can improve BLEU by 1.3 points on Indic and Turkic dataset. The improvements can reach +5 BLEU when training data size is small. Further, we show this approach generate more accurate and consistent translation of named entities which greatly impacts the factuality accuracy of news translation.

A Multi-encoder architecture

As has been systematically explored by Libovický et al. (2018), there are four kinds of multi-encoder cross-attention that can be applied on the decoder side: (1) Serial: cross-attention to each encoder is performed layer by layer. (2) Parallel: cross-attention to each encoder is performed in parallel and then the outputs are added together before feeding to the feed-forward layer. (3) Flat: outputs of all encoders are concatenated along the length dimension as the input to a single cross-attention. (4) Hierarchical: a second attention block is added to attend to the representations output by the parallel cross-attention. While models in Table 3 all use the parallel cross-attention described in § 2.2, Table 5 ablates different multi-source cross-attention mechanisms. Three out of four cross-attention achieve similar performance, whereas the 'flat' attention is considerably worse. This echos the findings by Libovický et al. (2018).

Config.	BLEU	Config.	BLEU
Serial	34.1	Flat	24.9
Parallel	34.0	Hierarchical	34.1

Table 5: Indic test set BLEU scores of multi-encoder architecture trained on BASE+INSCRIP using different multi-source cross-attention. All mechanisms perform similarly except *flat* cross-attention.

B Experiments

B.1 Data statistics

The number of training examples for each language in both Turkic and Indic dataset is shown in Table 7. We evaluate the Turkic dataset on multi-way FloRes101 devtest set, each having 1012 examples. To evaluate the Indic models, we use the provided multi-way test set of WAT21 MultiIndic task, each having 2390 examples.

B.2 Input concatenation analysis

In § 4, results show that models trained on the concatenated input does not bring any discernible improvement, but rather the performance is almost the same. To understand if the model has indeed utilized the concatenated alternative signals, we take the trained model and evaluate BLEU scores on the corrupted input. Specifically, one part of the concatenated input is corrupted while the other is left intact. The corruption is done by shuffling the tokens within the selected part of the input. Overall, we find that the model indeed pays attention to both parts of the input, as corrupting any part of them leads to large regression in BLEU scores (Table 6). Moreover, no matter which type of signal is put in the front of the sentence, the model always pays more attention to the original input rather than the phonetic input, since corrupting the original input causes larger performance degradation than corrupting the phonetic input.

Config.	BLEU	Config.	BLEU
BASE + IPA	23.3	IPA + BASE	23.0
BASE' + IPA	3.3	IPA' + BASE	13.9
BASE + IPA'	20.2	IPA + BASE'	9.5

Table 6: Models trained on concatenated original and phonetic input while evaluated on partially corrupted input. We use IPA' to denote the phonetic part of the input is in corruption. Results are reported on the FloRes101 Indic languages instead of MultiIndic test set.

C Example alternative input signal

We present example alternative signals in Figure 4 and Figure 5. When the input are transformed to scripts other than their native script, there are more shared tokens in the source languages (as highlighted in Figure 5).

D Analysis

D.1 Token overlap details

In § 4 we show the token overlap of various signals aggregated over all source language pairs, in this section we show the token overlap of *each* source language pair in Table 8 for the original input and in Table 9 for the in-family transliterated input[15]. Before performing transliteration, all source languages share only a small amount of token overlap except between Marathi and Hindi. The shared tokens between native scripts are mostly punctuation marks, digits and English tokens. After transliteration, the token overlap becomes more obvious and a clear division between language families can be found.

D.2 Similarity in latent space

Besides examining the consistency of system output as in § 4.2, we also measure the distance of

source representations in the latent space. Concretely, we compute the average of normalized Euclidean distance over all source language pairs:

$$\frac{1}{\binom{N}{2}} \sum_{m,n} dist(l_m, l_n)$$

, where N is the total number of source languages, $dist(l_m, l_n)$ compute the distance between a sentence in language m and language n:

$$\begin{aligned} &dist(l_m, l_n) = \\ &\quad \frac{1}{2}\Big(\frac{1}{|l_m|} \sum_{i} \min_{j} \big(dist(w_{mi}, w_{nj})\big) + \\ &\quad \frac{1}{|l_n|} \sum_{j} \min_{i} \big(dist(w_{mi}, w_{nj})\big)\Big) \end{aligned}$$

, where $|l_m|$ and $|l_n|$ are the number of tokens within sentence in language m and language n respectively. w_{mi} represents the i^{th} encoder output of sentence l_m. $dist$ represents the Euclidean distance between the two vectors. We additionally normalize the distance with $\sqrt{d}$ where d is the dimension of the dense vector. Adding the scaling factor is to make the scaled self-ensemble model comparable with the rest variants.

As shown in Table 10, none of the alternative signals alone can lead to more similar source representations. While training on the original input and one alternative input, only the combination of BASE and INSCRIP lowers the distance of original input representations from 0.60 to 0.58. The distances become even more smaller while training the scaled self-ensemble model. The distances

Config.	BASE	IPA	ROMANI	INSCRIP
Trained separately	0.60	0.62	0.60	0.61

Phone-ing it in: Towards Flexible, Multi-Modal Language Model Training using Phonetic Representations of Data

Colin Leong
University of Dayton
`cleong1@udayton.edu`

Daniel Whitenack
SIL International
`dan_whitenack@sil.org`

Abstract

Multi-modal techniques offer significant untapped potential to unlock improved NLP technology for local languages. However, many advances in language model pre-training are focused on text, a fact that only increases systematic inequalities in the performance of NLP tasks across the world's languages. In this work, we propose a multi-modal approach to train language models using whatever text and/or audio data might be available in a language. Initial experiments using Swahili and Kinyarwanda data suggest the viability of the approach for downstream Named Entity Recognition (NER) tasks, with models pre-trained on phone data showing an improvement of up to 6% F1-score above models that are trained from scratch. Preprocessing and training code will be uploaded to https://github.com/sil-ai/phone-it-in.

1 Introduction

Pre-trained language models are increasingly applied in ways that are agnostic to targeted downstream tasks (Brown et al., 2020). This usage has led to a proliferation of large language models trained on enormous amounts of data. For example, the recent Megatron-Turing NLG 530B model was trained on the Pile, which includes 800GB+ of text (Gao et al., 2021), and other large language models utilize large portions of the 200TB+ common crawl data.[1] These large data sets include impressive amounts of text, but all languages are not represented equally (or at all) in that text. The reality is that only a negligible fraction of the 7000+ currently spoken languages (Eberhard et al., 2021) have sufficient text corpora to train state-of-the-art language models. This data scarcity results in systematic inequalities in the performance of NLP tasks across the world's languages (Blasi et al., 2021).

Local language communities that are working to develop and preserve their languages are producing diverse sets of data beyond pure text. The Bloom Library project,[2] for example, is being used by local language communities to create and translate "shell" or "template" books into many languages (426 languages at the time this paper is being written). However, Bloom allows users to do more than just translate text. Users are also recording audio tracks and sign language videos, which has resulted in 1600+ oral translations. Other examples showing the multi-modal nature of data in local languages include: (i) the creation of ChoCo: a multimodal corpus of the Choctaw language (Brixey and Artstein, 2021); (ii) SIL International's 50+ year effort to document endangered Austronesian languages via text, audio, and video (Quakenbush, 2007); (iii) the grassroots Masakhane effort catalyzing the creation and use of diverse sets of African language data (∀ et al., 2020); and (iv) work with the Me'phaa language of western Mexico that is producing digital recordings (video and audio) along with vocabulary, grammar and texts (Marlett and Weathers, 2018). These diverse data sources are effectively unusable by traditional text-based NLP techniques. In the light of data scarcity on these languages, they offer significant untapped potential to unlock improved NLP technology, if text data can be leveraged along with audio, image and video data. Furthermore, flexible multi-modal technology such as this will make it easier to include diverse people and communities such as those described above within the NLP technology development process - audio-based technology reducing the need for literacy, for example.

In this paper, we propose a multi-modal approach to train both language models and models for downstream NLP tasks using whatever text and/or audio data might be available in a language (or even in a related language). Our method uti-

May 22-27, 2022

lizes recent advances in phone recognition and text/grapheme-to-phone transliteration to convert input audio and text into a common phonetic representation (the IPA phone inventory). We then pre-train character-based language models in this phone-space. Finally, we fine-tune models for downstream tasks by mapping text-based training data into the phonetic representation. Thus, in addition to flexibility in pre-training, our method provides a way to reuse labeled text data for common NLP tasks, like Named Entity Recognition or Sentiment Analysis, in the context of audio inputs.

We demonstrate our phonetic approach by training Named Entity Recognition (NER) models for Swahili [`swh`][3] using various combinations of Swahili text data, Swahili audio data, Kinyarwanda [kin] text data, and Kinyarwanda audio data. These two languages both originate from from the same language family, Bantu, and are spoken by millions of people in Eastern Africa, often within the same country, resulting in some overlap in loan words, etc. [4] However, they are both considered low-resource languages. Kinyarwanda in particular, though spoken by approximately 13-22 million people[5], has very little text data available in that language, with fewer than 3,000 articles on the Kinyarwanda-language Wikipedia, and Swahili comparatively ahead but still poorly resourced at approximately 68,000 articles, far less than many European languages.[6], though some datasets have been created such as KINNEWS (Niyongabo et al., 2020). On the other hand, Kinyarwanda is uniquely placed as a language to leverage speech-based technologies, due to well-organized efforts[7] to collect voice data for that language. It is in fact one of the largest subsets available on the Common Voice Dataset (Ardila et al., 2019), with 1,183 hours of voice clips collected and validated. Choosing these two languages allowed us to test the use of the technique on legitimately low-resourced languages that could benefit from improved NLP technology, and which as part of the same family of languages might be similar enough in vocabulary, grammar, sound systems and so on, to benefit from cross-lingual training.

We find that simple NER models, which just look for the presence or absence of entities, can be trained on small amounts of data (around 2000 samples) in the phonetic representation. Models trained for complicated NER tasks in the phonetic representation, which look for entities and their locations within a sequence, are improved (by up to 6+% in F1 score) through pre-training a phonetic language model using a combination of text and audio data. We see this improvement when fine-tuning either a Swahili or Kinyarwanda language model for downstream Swahili tasks, which implies that one could make use of text and audio data in related languages to boost phonetic language model performance. The utility of the method in data scarce scenarios and importance of pre-training depends on the complexity of the downstream task.

2 Related Work

There have been a series of attempts to utilize phonetic representations of language to improve or extend automatic speech recognition (ASR) models. Some of these jointly model text and audio data using sequences of phonemes combined with sequences of text characters. Sundararaman et al. (2021), for example, uses a joint transformer architecture that encodes sequences of phonemes and sequences of text simultaneously. However, this joint model is utilized to learn representations that are more robust to transcription errors. The architecture still requires text inputs (from ASR transcriptions) and generates outputs in both text and phoneme representations. In contrast, our approach allows for text input, audio input, or text plus audio input to language models.

Similarly, in (Chaudhary et al., 2018) and (Bharadwaj et al., 2016) investigate the potential of phoneme-based or phoneme aware representations and models, showing gains in performance, language transfer, and flexibility across written scripts. These works conduct training on text-based data only, using Epitran to convert to phonemes.

Baevski et al. (2021) transforms unlabeled text (i.e., not aligned with corresponding audio files) into phonemes in a scheme to train speech recognition models without any labeled data. This scheme involves a generator model trained jointly with a discriminator model. The generator model converts

audio, segmented into phonetic units into predicted phonemes, and the discriminator model attempts to discriminate between these predicted phonemes and the phonemes transliterated from unlabeled text. Although both text and audio are utilized in this work, they are not input to the same model and the primary output of the training scheme is a model that creates good phonetic speech representations from input audio.

Outside of speech recognition focused work, Shen et al. (2020) (and other researchers cited therein) attempt to "fuse" audio and text at the word level for emotion recognition. They introduce another architecture that internally represents both audio and text. However, the so-called WISE framework relies on speech recognition to generate the text corresponding to audio frames in real-time. The current work explicitly avoids reliance on speech recognition. The 2021 Multimodal Sentiment Analysis (MuSe) challenge continues this vein of research integrating audio, video, text, and physiology data in an emotion recognition task (Stappen et al., 2021). Contributions to this challenge, such as Vlasenko et al. (2021), introduce a variety of ways to "fuse" audio and text inputs. However, these contributions are squarely focused on emotion/sentiment analysis and do not propose methods for flexible, phonetic language models.

Lakhotia et al. (2021) introduced functionality for "textless" NLP. They explored the possibility of creating a dialogue system from only audio inputs (i.e., without text). As part of this system, language models are directly trained on audio units without any text. This advances the state-of-the-art with regard to self-supervised speech methods, but it does not provide the flexibility in audio and/or text language modeling introduced here.

3 Methodology

Our approach is inspired by the fact that many languages are primarily oral, with writing systems that represent spoken sounds. We convert both text and audio into single common representation of sounds, or "phones," represented using the International Phonetic Alphabet, or IPA. Then, we perform both language model pre-training and the training of models for downstream tasks in this phonetic representation. Well-tested architectures, such as BERT-style transformer models (Vaswani et al., 2017), are thus flexibly extended to either speech or audio data.

Regarding the conversion process of text and audio data, we leverage recent advances to transliterate this data into corresponding sounds represented by IPA phonetic symbols. This transliteration is possible for speech/audio data using tools such as the Allosaurus universal phone recognizer, which can be applied without additional training to any language (Li et al., 2020), though it can benefit from fine-tuning(Siminyu et al., 2021). To convert text data to phonemes we can use tools such as the Epitran grapheme-to-phoneme converter (Mortensen et al., 2018), which is specifically designed to provide precise phonetic transliterations in low-resource scenarios.

Fig. 1 shows how downstream models for certain NLP tasks, like Named Entity Recognition (NER), are performed in the phonetic representation. Labeled data sets for NLP tasks need to be mapped or encoded into the phonetic representation to train downstream models. However, once this mapping is accomplished, models trained in the phonetic representation can perform tasks with audio input that are typically restricted to processing text input.

3.1 Phonetic Language Modeling

One complication arising from direct speech-to-phone transcription is the loss of word boundaries in the transcription. This is expected, as natural speech does not put any pauses between the words in an utterance. This does, however, result in mixing text data sets containing clear word boundaries with speech data sets containing no clear word boundaries.

Borrowing from techniques used on languages that do not indicate word boundaries by the use of whitespace, we address the problem by removing all whitespace from our data sets after phone transliteration. We train *character-based* language models over the resulting data. Character-based models such as CharFormer (Tay et al., 2021) or ByT5 (Xue et al., 2021) have shown promise in recent years for language modeling, even if this approach is known to have some trade offs related to shorter context windows.

3.2 Potential Information Losses

The transliteration of text and audio data into phonetic representations presents several other challenges related to potential loss of information or injection of noise:

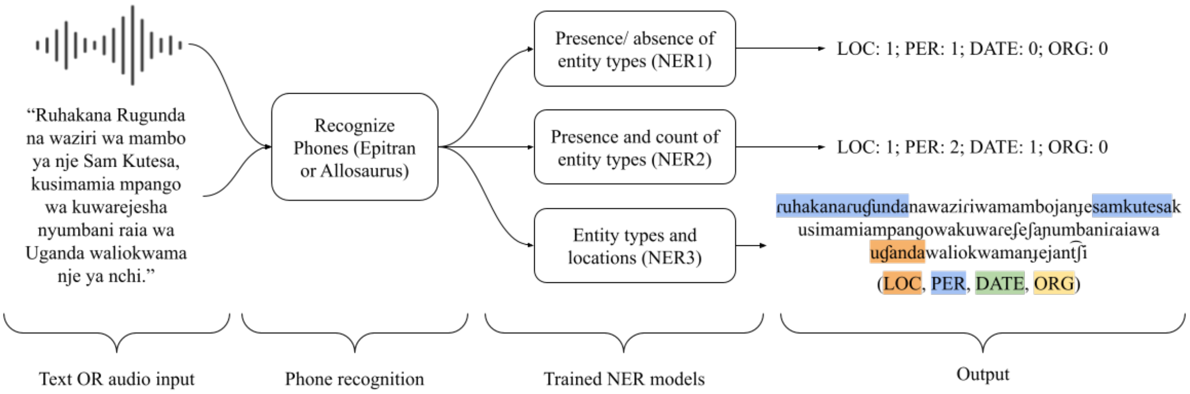

Figure 1: Our approach: input from either modality can be converted by phone recognition, e.g. Epitran for text, Allosaurus for speech. Then we test on several downstream tasks which we designate NER1, NER2, NER3.

1. *Loss of suprasegmental information*: In some languages, meaning may be encoded through tones, or pitch changes *across* sounds (aka across segments, or "suprasegmental"). Particularly for tonal languages such as Mandarin Chinese [`cmn`], this loss can represent a significant informational loss particularly for homophones with different tones, as seen in (Amrhein and Sennrich, 2020). While IPA symbols can represent these intricacies, it adds complexity

2. *Phone/phoneme differences*: As noted in (Li et al., 2020), speech sounds which are physically different (different *phones*), may be *perceived* as the same (one *phoneme*) by speakers of one language, but these same sounds could perhaps be distinguished by speakers of another language. For example, the French words words *bouche*, and *bûche* contain phones (/u/ vs. /y/) which may sound "the same" to English speakers, but are semantically different to French speakers. In other words, in English, both *phones* map to the same *phoneme* perceptually. As the Allosaurus phone recognizer recognizes the actual phones/sounds, not their perceived phonemes, it would transcribe these two phones to different representations even for English speech. This can be mitigated to an extent by customizing the output of Allosaurus on a per-language basis, see Sec. 4.3.

3. *Simple errors in phone recognition*: As noted in (Siminyu et al., 2021), even the best-trained Allosaurus models, fine-tuned on language-specific data, have a non-trivial Phone Error Rate (PER).

An important question, therefore, is whether these added sources of noise/information losses are outweighed by the potential benefits in terms of flexibility. Does working in a phonetic representation cause a prohibitive amount of information loss? We constructed our experiments and data sets in order to answer this question.

4 Experiments

In order to evaluate the quality of learned phonetic representations, we transliterate several text and audio data sets in the Swahili [`swh`] language. We pre-train phonetic language models on various combinations of these data sets and evaluate downstream performance on NER tasks. See Fig. 2 for a detailed overview of these various combinations.

We refer to these combinations as denoted by downstream tasks (SNER for **S**wahili NER), and pre-training language ((**K** for **K**inyarwanda, **S** for **S**wahili) as well as data modality (**T** for text, **A** for audio). By way of example, the SNER+ST2 model results from pre-training using **2** swh **t**ext datasets (ST2) and fine-tuning on the swh **NER** (SNER) task, whereas the SNER+SAT model results from pre-training using **s**wh **a**udio and **t**ext data (SAT).

Kinyarwanda [`kin`] data is used in our experiments as a language related to the target language (`swh`) with existing text and audio resources that, in some ways, surpasses those available in the target language. Thus, we pre-train some models on `kin` data while fine-tuning for the downstream NER task using `swh` data.

Three different formulations of the NER task, from more simple (NER1) to more compli-

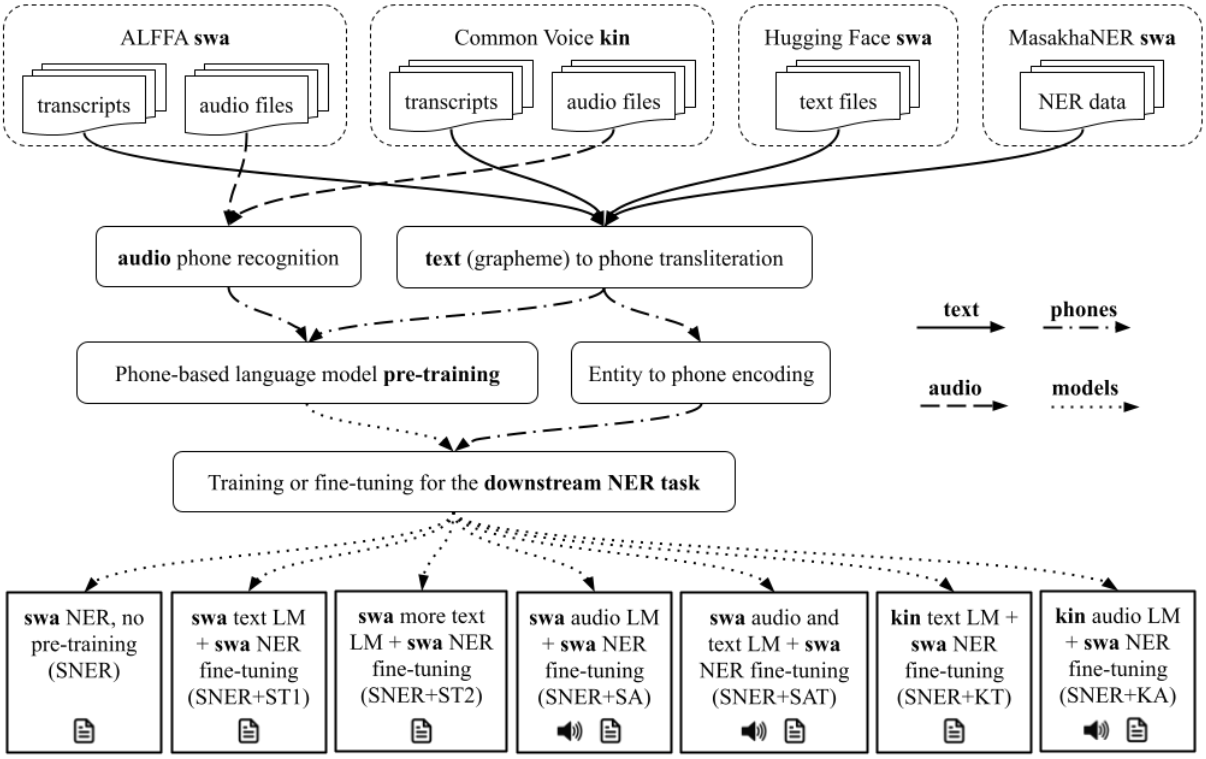

Figure 2: Training scenarios: we pre-train on various combinations of phonemized datasets, evaluating on the downstream NER task. SNER-ST denotes "**S**wahili **T**ext (ST) pre-training, **S**wahili **NER** (SNER) fine-tuning", SNER-SAT denotes Swahili NER with **S**wahili **A**udio and **T**ext (SAT) pre-training, SNER-**KA** uses **K**inyarwanda **A**udio (KA), etc.

cated/granular (NER3), are used (see Fig. 2) to help determine the applicability of our methods to less challenging (NER1) to more challenging (NER3) tasks. The NER1 task tries to determine the presence or absence of certain kinds of entities within an input. For our task we use PER, ORG, DATE, and LOC entities. The NER2 task additionally requires models to predict the correct numbers of these entities within an input. Finally, the NER3 task requires models to determine entities at the correct locations with an input sequence of phones.

For all of these tasks, we first convert text data to phones using Epitran and audio data to phones using Allosaurus. Then, we pre-train on various combinations of data, before fine-tuning on NER.

4.1 Data Sources

For `swh` pre-training data we use: (i) the "Language Modeling Data for Swahili" dataset (Shikali and Refuoe, 2019) hosted on Hugging Face (which we refer to as the "HF Swahili" data set); and (ii) the ALFFA speech dataset (Gelas et al., 2012). For ALFFA data we process both the audio files (using Allosaurus) and the original "gold" text transcriptions (using Epitran).

For Kinyarwanda pre-training data, we use the Common Voice (CV) Kinyarwanda 6.1 subset (Ardila et al., 2019). Again, we utilize both the audio files and transcriptions. Due to the large size of the CV 6.1 Kinyarwanda subset, we processed only about 80% of the audio files.

For fine-tuning the downstream NER task, we use the MasakhaNER data set (Adelani et al., 2021). As with other text-based data sets, we transform the NER sample with Epitran to map the samples into the phonetic representation.

4.2 Entity to Phone Encoding

For the downstream NER tasks we map or encode the NER annotations into the phonetic representation. We thus edited the labels (PER, ORG, DATE, and LOC) to convert them from word-level labels to phone-level labels as shown in Fig. 3. Unlike (Kuru et al., 2016), we leave in the B- and I- prefixes.

Our fork of the MasakhaNER data set, which implements our phonetic representations of the labels, is published on Github.[8].

---

[8] https://github.com/cdleong/masakhane-ner

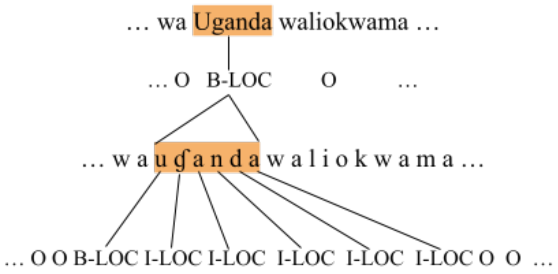

Figure 3: Adaptation of word-level NER annotations to character-level annotations.

4.3 Phone Inventory Considerations

As mentioned already, we use Allosaurus for phone recognition with audio inputs. In order to ensure consistency with Epitran, we took advantage of Allosaurus's inventory customization feature, giving it the phone inventories specified by the same language in Epitran. The inventory used throughout this work (for `swh`) is the swa-Latn inventory from Epitran.[9] When this inventory is supplied as input, Allosaurus will only output symbols from the inventory. We followed similar practice when transliterating Kinyarwanda data.

We compare the output of Epitran and Allosaurus on the ALFFA dataset. Following the practice of (Li et al., 2020), we used the `editdistance`[10] library to calculate the Phone Error Rate (PER). Having no ground truth phone annotations, we instead take Epitran's outputs as "ground truth" for comparison. The mean PER between the outputs is 23.7%. This result is consistent with Siminyu et al. (2021), which finds PERs as high as 72.8% when testing on on the Bukusu (bxk), Saamia (lsm) and East Tusom languages (an endangered subdialect of the Tungkhulic language family). However, by training the phone recognizer on even minimal amounts of data in these languages, PERs were improved significantly.

A spreadsheet with detailed results for 10k samples from ALFFA can be found online.[11]

4.4 Model Architecture and Training

All models use the SHIBA implementation of CANINE (Tanner and Hagiwara, 2021). SHIBA was designed for use on the Japanese [`jpn`] language, which does not include spaces between its characters (similar to our phonetic representations without word boundaries). We used the default hyperparameter settings for SHIBA pre-training and fine-tuning, because we are primarily concerned with the relative impact of various combinations of pre-training data on the downstream NER tasks. We use the Hugging Face transformers library (Wolf et al., 2020) to train all models.

Because of the small size of the NER data set used during fine-tuning, we enabled Hugging Face's early stopping callback for all downstream training runs. We stopped these runs if they did not improve training loss after 20 evaluations. Nonetheless, we found after a number of trials that the models quickly overfit using this setting. We also experimented with modifying this on several trials to stop based on the evaluation loss instead, but this change did not significantly influence the evaluation results.

Following the example of Adelani et al. (2021), we do not run downstream model trainings once, but multiple times. We also pre-trained each phonetic language model multiple times with different random seeds. We report averages of these multiple trials in the following.

Scripts and code for our experiments will be uploaded to Github.[12]

5 Results and Discussion

Table 1 presents the F1 scores for our training scenarios in the downstream NER1 and NER2 tasks. The models that utilize pre-training on the `kin` audio and text data give the best results. However, pre-training does not appear to dramatically influence the level. F1 scores in the range of 74-85% suggests the minimum viability of these phonetic models for simple NLP tasks.

Table 2 presents the F1 scores for our various training scenarios in the downstream NER3 task, which should be the most challenging for our phonetic models. The influence of pre-training is more noticeable for this task. Further, the models pre-trained on the `kin` audio and text data have the best performance. This is likely due to the fact that the `kin` data is both large and higher quality (in terms of sound quality) as compared to the ALFFA Swahili data. This benefit of this data size and quality appears to outweigh any degradation due to the pre-training occurring in a different (although related) language.

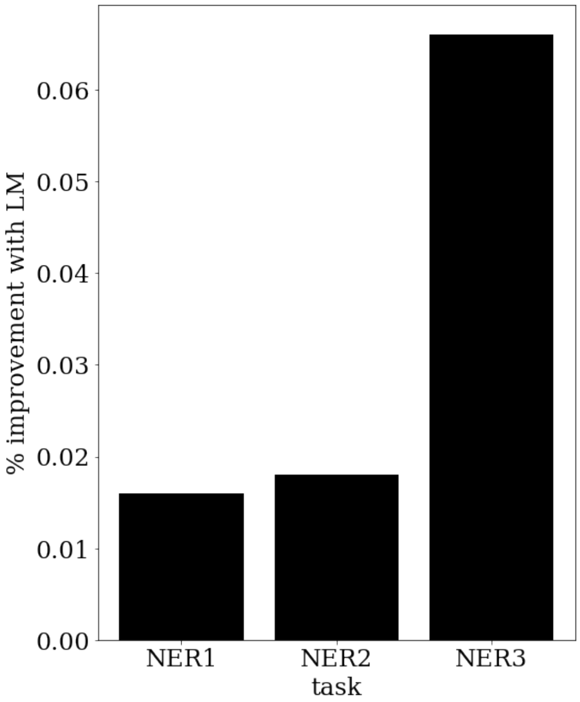

Figure 4: The max percentage improvement with fine-tuning for each kind of NER task that was explored. Presence/absence of entity types (NER1), presence and *count* of entity types (NER2), and prediction of entity types and precise locations (NER3).

The importance (or relative impact) of pre-training phonetic language models increases with the complexity of the NER task. Fig. 4 shows the maximum percentage improvement due to pre-training for each of our NER tasks. This suggests that simple NLP tasks with a small number of output classes are much easier to port to phonetic representations, even without pre-training, while more complicated NLP tasks may require a more significant amount of text and/or audio data for pre-training. We expect this trend to carry through to tasks like sentiment analysis, which could be formulated as a simple classification task with NEG, NEU, and POS sentiment labels or a more complicated aspect based sentiment analysis task.

6 Conclusions and Further Work

The proposed method for multi-modal training using phonetic representations of data has minimum viability for simple NER tasks. For more complicated NER tasks, pre-training phonetic language models boosts downstream model performance by up to 6% in F1 scores. This pre-training can be performed in the target language or in a related language using text and/or audio data. Thus, the method provides flexibility in the data needed to train language models, while also allowing for audio and/or text inputs to models trained on downstream NLP tasks.

We anticipate exploring various extensions to and validations of this method in the future. Specifically, we would like to explore methods that might mitigate performance degradation due to a lack of word boundaries in our method. Subword tokenization techniques, such as Byte-Pair Encodings (BPE) (Sennrich et al., 2016; Gage, 1994), or character-based word segmentation techniques might help in detecting and exploiting repeating patterns within the phonetic representation. Furthermore, the word embedding techniques used by (Chaudhary et al., 2018) or (Bharadwaj et al., 2016) have been shown to work well, and would be worth investigating how the removal of space-delimited word boundaries would affect this.

We would also like to validate our methods on a variety of other data sets and tasks. We selected the MasakhaNER dataset for evaluation because we specifically wished to evaluate results on actual low-resource languages supported by both Allosaurus and Epitran. While there are still, we argue, detectable improvements in downstream results with our method, further work would benefit from additional evaluations on other data sets or tasks. In particular, the Swahili News Classification corpus (David, 2020) corpus may provide a useful evaluation.

We did not investigate going from audio to phones, then phones to words/characters, judging that information losses and errors would likely compound in multiple stages of processing. Instead, we focused on what could be achieved with the Allosaurus "universal phone transcriber" without any language-specific finetuning. A truly universal transcriber would increase flexibility when training for truly low-resource scenarios.

Nevertheless, it has been shown by Siminyu et al. (2021) that it is possible to improve phone recognition with even small amounts (approximately 100 sentences) of annotation. It may be possible to improve phonetic language modeling results by performing this fine-tuning in the target language.

Experiments involving other languages with, e.g. languages that are *not* related would help to isolate the role of relatedness, lexical overlap, or related sound systems/phonology.

While we do not claim that conversion to phones provides better performance generally, we believe that our experiments show that the fundamental idea of converting *either* text *or* audio data to the common phone representation provides a viable path to more flexible approach to certain downstream NLP tasks, worthy of further development.

Acknowledgements

The authors wish to thank Dr. Vijayan Asari, Dr. Steven Rogers, Dr. Julia Kreutzer, Dr. Graham Neubig, Dr. David Mortenson, Andre Niyongabo Rubungo, and Joshua Turner for advice, helpful discussions, assistance in debugging, and time spent in proofreading. In addition, David Adelani and the Masakhane community provided invaluable help, encouragement and assistance with the MasakhaNER dataset.

We used GNU Parallel for much of the dataset processing (Tange, 2011). In combination with Lhoest et al. (2021) from Hugging Face, GNU Parallel significantly accelerated pre-processing and phone transcription.

ClearML (AI, 2019) provided experiment tracking, model and dataset management, and (when needed) prompt and helpful technical support. As our project involved the creation of over 20 distinct dataset variations and training many models on some of them, these management tools significantly eased the entire research process.

Ethics Statement

This research project uses open datasets and models, which are used in accordance with corresponding licenses to the best of our knowledge. For the downstream task in question (NER), we used the MasakhaNER dataset, which is constructed from newspaper data. Where this newspaper data includes mentions of individuals, the individuals are public figures. The domain of this NER data is limited to the newspaper/news domain, which should be kept in mind while considering the applicability of the methods presented.

In terms of compute, the work presented here required approximately 200 pre-training or finetuning jobs tracked via ClearML. Each run lasted no more than 1-2 hoursfor finetuning, but generally much longer for pretraining (on the order of a day), and only consumed one GPU resource at a time (either an A100 or P100). This computation sums up to around 5-6 GPU-weeks on the A100, about one gpu-week on the Titan RTX, and several compute-days each for the other GPUs. Additional exploratory work and debugging consumed another few GPU-days on Google Colab.

Abstract

We introduce a noisy channel approach for language model prompting in few-shot text classification. Instead of computing the likelihood of the label given the input (referred as direct models), channel models compute the conditional probability of the input given the label, and are thereby required to explain every word in the input. We use channel models for recently proposed few-shot learning methods with no or very limited updates to the language model parameters, via either in-context demonstration or prompt tuning. Our experiments show that, for both methods, channel models significantly outperform their direct counterparts, which we attribute to their stability, i.e., lower variance and higher worst-case accuracy. We also present extensive ablations that provide recommendations for when to use channel prompt tuning instead of other competitive methods (e.g., direct head tuning): channel prompt tuning is preferred when the number of training examples is small, labels in the training data are imbalanced, or generalization to unseen labels is required.

1 Introduction

Prompting large language models, by prepending natural language text or continuous vectors (called *prompts*) to the input, has shown to be promising in few-shot learning (Brown et al., 2020). Prior work has proposed methods for finding better prompt (Shin et al., 2020; Li and Liang, 2021; Lester et al., 2021) or better scoring of the output from the model (Zhao et al., 2021; Holtzman et al., 2021). These studies *directly* predict target tokens to determine the prediction for an end task. Despite promising results, they can be unstable with high variance across different verbalizers (text expression for labels) and seeds, and the worst-case performance is often close to random (Perez et al., 2021; Lu et al., 2021).

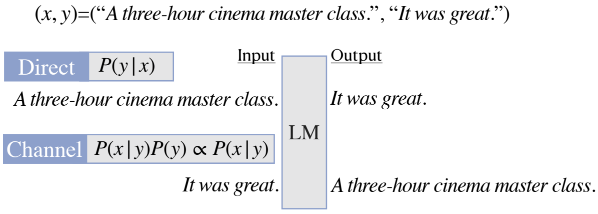

Figure 1: An illustration of the direct model and the channel model for language model prompting in the sentiment analysis task.

In this paper, we introduce alternative *channel* models for prompted few-shot text classification with large language models, inspired by noisy channel models in machine translation (Brown et al., 1993; Koehn et al., 2003; Yu et al., 2017; Yee et al., 2019) and their extensions to other tasks (Yogatama et al., 2017; Lewis and Fan, 2018). Unlike *direct* models that compute the conditional probability of the label token given the input, channel models compute the conditional probability of the input given the output (Figure 1). Intuitively, channel models are required to explain every word in the input, potentially amplifying training signals in the low data regime. We study the impact of channel models for language model prompting where the parameters of the language model are frozen. In particular, we compare channel models with their direct counterparts for (1) demonstration methods, either concatenation-based (Brown et al., 2020) or our proposed, ensemble-based (Section 4.1.3), and (2) prompt tuning (Lester et al., 2021).

Our experiments on eleven text classification datasets show that channel models outperform their direct counterparts by a large margin. We attribute the strong performance of channel models to their stability: they have lower variance and significantly higher worst-case accuracy then their direct counterparts over different verbalizers and seeds. We additionally find a direct model with *head tuning*—tuning the LM head while freezing other parameters—is surprisingly effective, often outperforming direct models with other forms of tuning.

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics
Volume 1: Long Papers, pages 5316 - 5330

While different methods are preferred given different conditions, the channel model with prompt tuning (denoted as channel prompt tuning) significantly outperforms all direct baselines when (1) the training data is imbalanced, or (2) generalization to unseen labels is required.

In summary, our contributions are three-fold:

1. We introduce a noisy channel approach for language model prompting in few-shot text classification, showing that they significantly outperform their direct counterparts for both demonstration methods and prompt tuning.
2. We find particularly strong performance of channel models over direct models when the training data is imbalanced or generalization to unseen labels is required.
3. Based on extensive ablations, we provide recommendations between different models (direct vs. channel and prompt tuning vs. head tuning) based on given conditions such as the target task, the size of training data, the number of classes, the balance between labels in the training data, and whether generalization to unseen labels is required.

2 Related Work

2.1 Channel Model

Let x and y be the input and the output, respectively. The most widely used models, denoted as *direct* models, compute $P(y|x)$. In contrast, *noisy channel* models maximize $P(x|y)P(y)$ (Shannon, 1948; Brown et al., 1993).[1] While the noisy channel approach has been the most successful in machine translation (Yamada and Knight, 2001; Koehn et al., 2003; Yu et al., 2017; Yee et al., 2019), it has also been studied in more general NLP tasks. Prior work provides a theoretical analysis that channel models approach their asymptotic errors more rapidly than their direct counterparts (Ng and Jordan, 2002), and empirically shows that channel models are more robust to distribution shift in text classification (Yogatama et al., 2017) or question answering (Lewis and Fan, 2018), and in a few-shot setup (Ding and Gimpel, 2019).

In this paper, we explore channel models using a large language model on a wide range of text classification tasks, focusing on prompt-based few-shot learning.

2.2 Few-shot Learning

Prior work in few-shot learning has used different approaches, including semi-supervised learning with data augmentation or consistency training (Miyato et al., 2017; Clark et al., 2018; Xie et al., 2020; Chen et al., 2020) and meta learning (Finn et al., 2017; Huang et al., 2018; Bansal et al., 2020). Recent work has introduced *prompting* (or *priming*) of a large language model. For example, Brown et al. (2020) proposes to use a concatenation of training examples as a demonstration, so that when it is prepended to the input and is fed to the model, the model returns the output following the pattern in the training examples. This is especially attractive as it eliminates the need for updating parameters of the language model, which is often expensive and impractical. Subsequent work proposes alternative ways of scoring labels through better model calibration (Zhao et al., 2021; Holtzman et al., 2021), or learning better prompts, either in a discrete space (Shin et al., 2020; Jiang et al., 2020; Gao et al., 2021) or in a continuous space (Li and Liang, 2021; Lester et al., 2021; Liu et al., 2021; Zhong et al., 2021; Qin and Eisner, 2021). Almost all of them are direct models, computing the likelihood of y given x with the prompts.

Our work is closely related to two recent papers. Tam et al. (2021) studies a label-conditioning objective for masked language models; although this is not strictly a generative channel model, conditioning on the output y is similar to our work. However, they are still optimizing a discriminative objective, and inference at test time is the same as with the direct model. Holtzman et al. (2021) explores zero-shot models that compute the probability of x given y based on Pointwise Mutual Information, but with a restriction that the input and the output are interchangeable. To the best of our knowledge, our work is the first that uses a noisy channel model for few-shot language model prompting for classification, and also the first to draw the connection with the noisy channel literature.

3 Formulation

We focus on text classification tasks. The goal is to learn a task function $f : \mathcal{X} \rightarrow \mathcal{C}$, where $\mathcal{X}$ is the

---

[1] We follow Yu et al. (2017); Yee et al. (2019) in using the terms direct models and channel models. They are often referred as discriminative models and generative models in prior work (Yogatama et al., 2017; Lewis and Fan, 2018). In principle, these two distinctions are not always equivalent, e.g., a model that computes $P(x, y) = P(y|x)P(x)$ is generative but not a channel model.

Method	Zero-shot	Concat-based Demonstrations	Ensemble-based Demonstrations
Direct	$P_{\mathrm{LM}}(v(c_i)\|x)$	$P_{\mathrm{LM}}(v(c_i)\|x^1, v(c^1)...x^k, v(c^k), x)$	$\Pi_{j=1}^{K} P_{\mathrm{LM}}(v(c_i)\|x^j, v(c^j), x)$
Direct++	$\frac{P_{\mathrm{LM}}(v(c_i)\|x)}{P_{\mathrm{LM}}(v(c_i)\|\texttt{NULL})}$	$\frac{P_{\mathrm{LM}}(v(c_i)\|x^1,v(c^1)...x^k,v(c^k),x)}{P_{\mathrm{LM}}(v(c_i)\|x^1,v(c^1)...x^k,v(c^k),\texttt{NULL})}$	$\Pi_{j=1}^{K} \frac{P_{\mathrm{LM}}(v(c_i)\|x^j,v(c^j),x)}{P_{\mathrm{LM}}(v(c_i)\|x^j,v(c^j),\texttt{NULL})}$
Channel	$P_{\mathrm{LM}}(x\|v(c_i))$	$P_{\mathrm{LM}}(x\|x^1, v(c^1)...x^k, v(c^k), v(c_i))$	$\Pi_{j=1}^{K} P_{\mathrm{LM}}(x\|v(c^j), x^j, v(c_i))$

Table 1: Comparison of zero-shot, concat-based demonstrations, and ensemble-based demonstrations (Section 4.1). $\{(x^j, c^j)\}_{j=1}^{K}$ is training data and v is the verbalizer.

set of all natural language texts and $\mathcal{C} = \{c_1...c_m\}$ is a set of labels. We consider three formulations.

Direct computes distributions of labels $c_i \in \mathcal{C}$ given the input $x \in \mathcal{X}$: $P(c_i|x)$. This is the most widely used method in modern neural networks.

Direct++ is a stronger direct model that computes $\frac{P(c_i|x)}{P(c_i|\texttt{NULL})}$ instead of $P(c_i|x)$, following the method from Holtzman et al. (2021) and the non-parametric method from Zhao et al. (2021). This approach is motivated by the fact that language models can be poorly calibrated and suffer from competition between different strings with the same meaning. This approach is used for the demonstration methods in Section 4.1.

Channel uses Bayes' rule to reparameterize $P(c_i|x)$ as $\frac{P(x|c_i)P(c_i)}{P(x)}$. As we are generally interested in $\mathrm{argmax}_{c_i \in \mathcal{C}} \frac{P(x|c_i)P(c_i)}{P(x)}$ and $P(x)$ is independent from c_i, it is sufficient to model $P(x|c_i)P(c_i)$. We assume $P(c_i) = \frac{1}{|\mathcal{C}|}$ and only compute $P(x|c_i)$.

4 Method

We explore direct and channel models using a causal language model (LM) P_{LM} that gives the conditional probability of the text y when followed by x. More precisely, given the text $x = x_1...x_{t_x}$ and $y = y_1...y_{t_y}$ ($x_1...x_{t_x}, y_1...y_{t_y} \in \mathcal{V}$, where $\mathcal{V}$ is the vocabulary set), $P_{\mathrm{LM}}(y|x)$ indicates $\Pi_{t'=1}^{t_y} P_{\mathrm{LM}}(y_{t'}|x_1...x_{t_x} y_1...y_{t'-1})$.[2]

When learning a task function $f : \mathcal{X} \to \mathcal{C}$, we also assume a pre-defined *verbalizer* $v : \mathcal{C} \to \mathcal{X}$ which maps each label into a natural language expression. For example, if the task is sentiment analysis with $\mathcal{C} = \{c^+, c^-\}$, an example input text x would be "A three-hour cinema master class" and an example v would have $v(c^+)$ ="It was great" and $v(c^-)$ ="It was terrible". In a few-shot setup, we are also given a set of K training examples $\mathcal{D} = \{(x^1, c^1), \cdots, (x^K, c^K)\}$.

We are interested in methods where there are no trainable parameters (Section 4.1) or the number of trainable parameters is very small, typically less than 0.01% of the total (Section 4.2). This follows prior observations that updating and saving a large number of parameters for every task is expensive and often infeasible (Rebuffi et al., 2017; Houlsby et al., 2019; Lester et al., 2021).

4.1 Demonstration methods

In demonstration methods, there are no trainable parameters. We explore three ways of making a prediction, as summarized in Table 1.

4.1.1 Zero-shot

We follow Brown et al. (2020) in computing $P(c_i|x)$ and $P(x|c_i)$ as $P_{\mathrm{LM}}(v(c_i)|x)$ and $P_{\mathrm{LM}}(x|v(c_i))$, respectively. For example, given x ="A three-hour cinema master class", the direct model compares the probabilities of "It was great" and "It was terrible" when following "A three-hour cinema master class", while the channel model considers the probabilities of "A three-hour cinema master class" when following "It was great" or "It was terrible".

4.1.2 Concat-based demonstrations

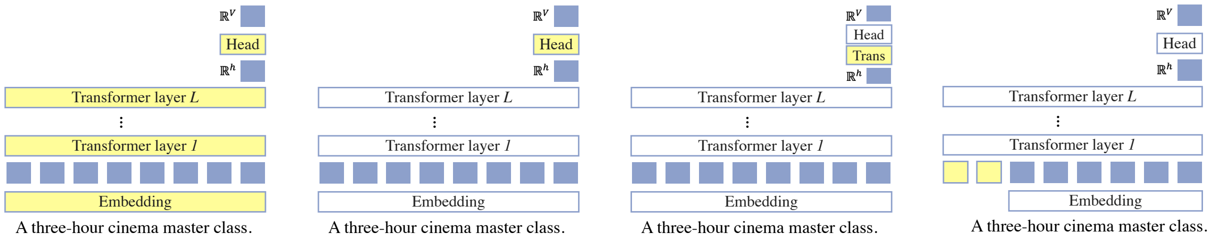
We follow the few-shot learning method in Brown et al. (2020). The key idea is to prepend a concatenation of K training examples to the input so that a language model can learn the task setup from the input. The original method was used for a direct model, but can be naturally extended for a channel model. Concretely, $P(c_i|x)$ in direct models is obtained via $P_{\mathrm{LM}}(v(c_i)|x^1, v(c^1), \cdots, x^K, v(c^K), x)$, and $P(x|c_i)$ in channel models is obtained via $P_{\mathrm{LM}}(x|v(c^1), x^1, \cdots, v(c^K), x^K, v(c_i))$.

4.1.3 Ensemble-based demonstrations

We propose a new method as an alternative to the concat-based method, which we find to be

---

[2] In practice, we use length normalization that was found to be effective by Holtzman et al. (2021).



(a) All finetuning (b) Head tuning (c) Transformation tuning (d) Prompt tuning

Figure 2: Different finetuning methods, which compute the distributions of the next token given “A three-hour cinema master class”. Yellow and white boxes are trainable and frozen parameters, respectively. h and V denote the hidden dimension of the LM and the vocabulary size of $v(c_1)...v(c_m)$, respectively. *All finetuning* is a typical finetuning method that updates all parameters of the LM (illustrated as a reference). *Head tuning*, *Transformation tuning* and *Prompt tuning* are described in Section 4.2; they update a very limited number of parameters.

a stronger direct model. Instead of concatenating K training examples as one sequence and getting output probabilities from an LM once, we obtain output probabilities from an LM K times conditioned on one training example at a time, and multiply the resulting probabilities. Specifically, $P(c_i|x)$ is computed via $\Pi_{j=1}^{K} P_{\text{LM}}(v(c_i)|x^j, v(c^j), x)$ and $P(x|c_i)$ is computed via $\Pi_{j=1}^{K} P_{\text{LM}}(x|v(c^j), x^j, v(c_i))$. This method also reduces the memory consumption—the concat-based method uses $O(K^2)$ while this method uses $O(K)$—and eliminates the dependency on the ordering of training examples, which has been shown to significantly impact the model performance (Zhao et al., 2021; Lu et al., 2021).

4.2 Tuning methods

We also explore methods that tune a very limited number of model parameters, as summarized in Figure 2. We study head tuning (Section 4.2.1) and transformation tuning (Section 4.2.2) for direct models. We also consider prompt tuning (Section 4.2.3) for both direct and channel models, which we refer as direct prompt tuning and channel prompt tuning, respectively. All models share the same input-output interface with the zero-shot setup in Table 1 during training and inference.

4.2.1 Head tuning

Head tuning finetunes the head—the matrix in the LM which transforms the hidden representation from the last transformer layer to the logit values. Let $\mathbf{O} \in \mathbb{R}^{|\mathcal{V}| \times h}$ be the head and $\mathbf{h}_x \in \mathbb{R}^h$ be the hidden representations from the last transformer layer given x, $P_{\text{LM}}(v_i|x)$ for a token $v_i \in \mathcal{V}$ is computed via an i-th element of $\text{Softmax}(\mathbf{O}\mathbf{h}_x)$. We finetune $\mathbf{O}$ while freezing all other parameters of the LM. Although $\mathbf{O}$ is tied with the embedding matrix of the LM during language model pretraining, we separate them during head tuning.[3]

4.2.2 Transformation tuning

As an alternative to head tuning, we transform $\mathbf{O}$ with a new transformation matrix $\mathbf{U} \in \mathbb{R}^{h \times h}$. Specifically, $P_{\text{LM}}(v_i|x)$ for a token $v_i \in \mathcal{V}$ is computed via an i-th element of $\text{Softmax}(\mathbf{O}\mathbf{U}\mathbf{h}_x)$. We train $\mathbf{U}$, initialized from an identity matrix, and freeze other parameters including $\mathbf{O}$.

4.2.3 Prompt tuning

Prompt tuning is the method that has recently gathered much attention (Li and Liang, 2021; Lester et al., 2021; Liu et al., 2021). The key idea is to consider the LM as a black-box model and instead learn continuous prompt embeddings. We follow the method from Lester et al. (2021) where n prompt tokens $u_1...u_n$ are prepended to the input, and the embeddings of $u_1...u_n$ are learned. In other words, direct models compute $P(c_i|x) = P_{\text{LM}}(v(c_i)|u_1...u_n, x)$, and channel models compute $P(x|c_i) = P_{\text{LM}}(x|u_1...u_n, v(c_i))$. The parameters in the LM are frozen except the embeddings of $u_1...u_n$.[4]

5 Experimental Setup

5.1 Datasets

We report results for eleven text classification datasets, following Zhang et al. (2015) and Gao

---

[3] This is different from head tuning from prior work, e.g., Le Scao and Rush (2021), which finetunes $\tilde{P}_{\text{LM}}$ and uses a separate, randomly initialized head instead of the LM head.

[4] This is different from prompt tuning in Gao et al. (2021); Liu et al. (2021) which jointly trains prompt embeddings and the parameters of the LM.

Dataset	Task	$\lvert\mathcal{C}\rvert$
SST-2	Sentiment analysis (movie)	2
SST-5	Sentiment analysis (movie)	5
MR	Sentiment analysis (movie)	2
CR	Sentiment analysis (electronics)	2
Amazon	Sentiment analysis (Amazon)	5
Yelp	Sentiment analysis (Yelp)	5
TREC	Question classification (answer type)	6
AGNews	News classification (topic)	4
Yahoo	Question classification (topic)	10
DBPedia	Ontology classification	14
Subj	Subjectivity classification	2

Table 2: Datasets used for experiments. $\lvert\mathcal{C}\rvert$ denotes the number of classes.See Appendix A for samples.

et al. (2021): SST-2 (Socher et al., 2013), SST-5 (Socher et al., 2013), MR (Pang and Lee, 2005), CR (Hu and Liu, 2004), Amazon (McAuley and Leskovec, 2013), Yelp (Zhang et al., 2015), TREC (Voorhees and Tice, 2000), AGNews (Zhang et al., 2015), Yahoo (Zhang et al., 2015), DBPedia (Lehmann et al., 2015) and Subj (Pang and Lee, 2004). The datasets include a varied number of classes per task, from 2 to 14. See Table 10 in Appendix A for dataset samples.

5.2 Training Data

For few-shot learning, we primarily use training set size $K = 16$, but explore $K = \{4, 16, 64, \text{Full}\}$ in the ablations. We sample the K examples uniformly from the *true* distribution of the training data. We relax the assumption from prior work of an equal number of training examples per label (Gao et al., 2021; Logan IV et al., 2021), for more realistic and challenging evaluation.

We follow all the hyperameters and details from prior work (Appendix B) which eliminates the need for a held-out validation set. The very limited data is better used for training rather than validation, and cross-validation is less helpful when the validation set is extremely small (Perez et al., 2021).

5.3 Language Models

We use GPT-2 (Radford et al., 2019) for the LM. We primarily use GPT-2 Large but also experiment with varying sizes (Small, Medium, Large and X-Large) for the ablations in Appendix C. While we only experiment with GPT-2, our experiments are easily extendable to other causal language models.

5.4 Evaluation

We use accuracy as a metric for all datasets.

We experiment with 4 different verbalizers (taken from Gao et al. (2021); full list provided in Appendix A), 5 different random seeds for sampling training data, and 4 different random seeds for training. We then report *Average accuracy* and *Worst-case accuracy*.[5] We consider the worst-case accuracy to be as important as the average accuracy given significantly high variance of few-shot learning models, as shown in previous work (Zhao et al., 2021; Perez et al., 2021). The worst-case accuracy is likely of more interest in high-risk applications (Asri et al., 2016; Guo et al., 2017).

Other implementation details are in Appendix B. All experiments are reproducible from `github.com/shmsw25/Channel-LM-Prompting`.

6 Experimental Results

This section reports results from demonstration methods (Section 6.1), tuning methods (Section 6.2) and ablations (Section 6.3). Discussion is provided in Section 7.

6.1 Main Results: Demonstration Methods

Table 3 shows the performance of demonstration methods.

Direct vs. Direct++ Direct++ significantly outperforms the naive direct model across all setups, indicating that using $\frac{P(c_i|x)}{P(c_i|\texttt{NULL})}$ instead of $P(c_i|x)$ is highly beneficial as claimed by Holtzman et al. (2021); Zhao et al. (2021).

Concat vs. Ensemble Our proposed, ensemble-based method is better than the concat-based method in direct models, by 7% absolute in the average accuracy and the worst-case accuracy, when macro-averaged across all datasets.

In contrast, the ensemble-based method is not always better in channel models; it is better only on the datasets with long inputs. We conjecture that the ensemble-based method may suffer when labels in the training data are not balanced, which direct++ explicitly takes into account as described in Zhao et al. (2021).

Direct++ vs. Channel In a few-shot setting, channel models outperform direct models in almost all cases. The strongest channel model outperforms the strongest direct model by 3.1% and 7.2% absolute, in terms of the average accuracy and the worst-case accuracy, respectively.

---

[5] We also report standard deviation and best-case accuracy in the Appendix.

Table 3: Results from demonstration methods. All with GPT-2 Large. Two numbers respectively indicate the average and the worst-case accuracy over different verbalizers (zero-shot and few-shot) and data seeds (few-shot). 'Avg.' in the last row indicate the macro-average across all datasets.

Standard deviation and the best-case accuracy are reported in Table 11 and Table 12 in the Appendix. They indicate strong performance of channel models can be attributed to their low variance. The highest best-case accuracy is achieved by direct++ on most datasets, but it has a higher variance, having lower average and the worst-case accuracy than channel models.

Zero-shot vs. Few-shot Performance of direct models sometimes degrades in a few-shot setting, which is also observed by prior work (Zhao et al., 2021). This is likely because demonstrations provided by the training data may cause the model to be miscalibrated and easily biased by the choice of demonstrations. However, channel models achieve few-shot performance that is significantly better than zero-shot methods on all datasets.

6.2 Main Results: Tuning Methods

Table 4 shows the performance of tuning methods.

Comparison when prompt tuning When using prompt tuning, channel models consistently outperform direct models by a large margin on all datasets. Improvements are 13.3% and 23.5% absolute in the average and the worst-case accuracy, respectively.

Standard deviation and the best-case accuracy are reported in Table 13 in the Appendix. Consistent with the findings in Section 6.1, the strong performance of channel prompt tuning can be explained by the low variance of channel prompt tuning. Direct prompt tuning often achieves higher best-case accuracy; however, due to its high variance, its overall accuracy is lower, with significantly lower worst-case accuracy.

Data	Direct			Channel
	Head	Trans	Prompt	Prompt
SST-2	80.2/68.6	77.3/57.5	72.6/50.9	**85.8/81.3**

Table 4: Performance of tuning methods with a limited number of trainable parameters. All methods use GPT-2 Large, and are run 80 times. *Head*, *Trans*, *Prompt* indicate head tuning, transformation tuning and prompt tuning, respectively. We report the average / worst-case accuracies, separated by a slash. 'Avg.' is the macro-average across all datasets.

Head tuning vs. prompt tuning We find that head tuning is a very strong method, despite often being omitted as a baseline in prior work. It significantly outperforms direct prompt tuning in all cases. It also outperforms channel prompt tuning on some datasets, particularly significantly on TREC and Subj. For these datasets, the task—finding the type of the answer to the question or identifying the subjectivity of the statement—is inherently different from language modeling, and likely benefits from directly updating the LM parameters, rather than using the LM as a black box.

Still, channel prompt tuning outperforms direct head tuning on most datasets. The largest gains

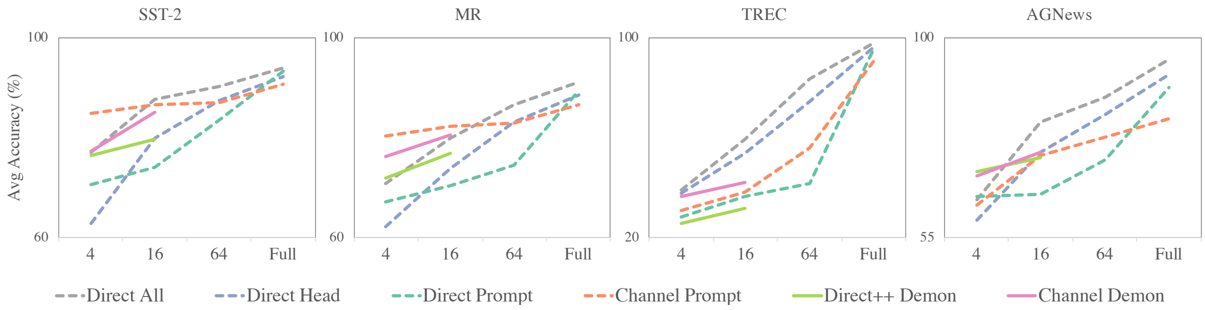

Figure 3: **Varying the number of training examples** (K). All models use GPT-2 Large. *All*, *Head* and *Prompt* indicate finetuning all parameters of the LM, head tuning and prompt tuning, respectively. *Direct++ Demon* and *Channel Demon* indicate demonstration-based methods (the best out of concat-based and ensemble-based is taken). Models are run 4 times for K = full (4 verbalizers) and 20 times for others (4 verbalizers and 5 data seeds). Channel models are more competitive with smaller K; less competitive with larger K.

are achieved on Yahoo and DBPedia. In fact, on these datasets, channel prompt tuning even outperforms *all finetuning*—finetuning all parameters of the LM—which achieves 48.9/43.8 on Yahoo and 66.3/50.4 on DBPedia. We conjecture that using $K = 16$ on these datasets naturally requires generalization to unseen labels due to the large number of classes ($|\mathcal{C}| = 10$ and 14), where channel prompt tuning significantly outperforms direct models, as we show in Section 6.4.

6.3 Ablations

For the ablations, we report experiments on SST-2, MR, TREC and AGNews, using one train seed (instead of four), and four verbalizers and five data seeds (as in main experiments).

Varying the number of training examples We vary the number of training examples (K) and report the average accuracy in Figure 3. All methods achieve higher accuracy as K increases. While we confirm strong performance of channel prompt tuning with $K \leq 16$, head tuning outperforms channel head tuning when $K = 64$. When K = Full, both direct prompt tuning and head tuning outperform channel prompt tuning. We think this is because (1) training signals amplified by channel models (Lewis and Fan, 2018) are more significant when K is small, and (2) channel models are more beneficial when labels on the training data are imbalanced (confirmed in the next ablation), which is more likely to happen with smaller K.

It is also worth noting that our experiment with K = Full confirms the finding from Lester et al. (2021) that direct prompt tuning matches the performance of all finetuning—finetuning all parameters of the LM—while being much more parameter-efficient. This only holds with K = Full; in a few-shot setup, all finetuning significantly outperforms other methods. This contradicts traditional analysis that having less trainable parameters is better when the training data is scarce (Ng and Jordan, 2002). It is likely because such analysis did not take into account language model pretraining, which gives supervision to the model yet is not the training data for an end task.

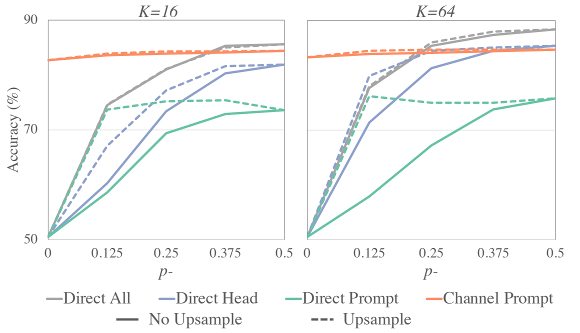

Figure 4: **Impact of imbalance in labels.** The average accuracy on SST-2 and MR of different methods with varying ratios of negative labels on the training data (denoted as p^-), when $K = 16$ (left) or 64 (right). As p^- increases, the data is more balanced. Channel models are more robust to imbalanced training data.

Impact of imbalance in labels On binary datasets (SST-2 and MR), we vary the label imbalance in the training data with $K = \{16, 64\}$. Specifically, let $\mathcal{C} = \{c^+, c^-\}$ and $p^- = |\{(x, c) \in \mathcal{D} | c = c^-\}| / |\mathcal{D}|$, i.e., the ratio of c^- in the training data. We vary p^- to be $\{0, 0.125, 0.250, 0.375, 0.5\}$. $p^- = 0.5$ means the labels are perfectly balanced, and $p^- = 0$ means that labels in the training data only include c^+. We additionally compare with *upsampling* baselines

Data	Zero-shot		Finetuning				
	Direct++	Channel	Direct All	Direct Head	Direct Trans	Direct Prompt	Channel Prompt
SST-2	80.3/76.9	77.1/74.8	50.2/49.1	50.2/49.1	50.2/49.1	50.2/49.1	**85.5/82.5**

MR	77.4/73.2	74.3/69.3	50.0/50.0	50.0/50.0	50.0/50.0	50.0/50.0	**80.9/74.8**
CR	77.9/69.7	65.8/60.2	50.0/50.0	50.0/50.0	50.0/50.0	50.0/50.0	**80.9/74.8**
TREC	27.7/12.6	30.5/19.4	**50.8**/31.0	44.8/29.6	44.6/**32.8**	33.9/17.4	34.3/26.0
Subj	52.0/48.8	57.8/51.5	50.0/50.0	50.0/50.0	50.0/50.0	50.0/50.0	**66.6/57.6**

Table 5: Model performance when there is at least one label at test time that was unseen during training. All models are run 20 times (4 verbalizers and 5 data seeds). *All*, *Head*, *Trans* and *Prompt* indicate finetuning all parameters of the LM, head tuning, transformation tuning and prompt tuning, respectively. We report the average and the worst-case accuracy, separated by a slash.

Figure 5: Model performance when transferred to unseen data, where x-axis indicates training data. *Direct Head* is not applicable when label space is not shared (when test datasets are TREC, AGNews and Subj). Channel models have better generalization capacity than direct models.

where we upsample training examples with infrequent labels so that the model has seen an equal number of examples per label during training.

Results are reported in Figure 4. All direct models are sensitive to the imbalance in training data, even though they benefit from upsampling when p^- is small. Channel prompt tuning is insensitive to the imbalance, and significantly outperforms direct models when p^- is small; it even outperforms all finetuning when $p^- < 0.25$. When p^- is near to 0.5, direct head tuning matches or outperforms channel prompt tuning.

It is also worth noting that direct prompt tuning with upsampling matches or outperforms all finetuning and head tuning when p^- is small.

6.4 Generalization to unseen labels

We experiment with a challenging scenario where the model must generalize to unseen labels. While it may be seen as an extreme scenario, this is often a practical setting, e.g., the problem is defined with a set of labels but later an addition of the new label may be needed.

First, we sample K training examples as in main experiments but excluding one random label, so that at least one label at test time was unseen during training. Table 5 reports the results. All direct models are unable to predict the label that is unseen at training time. However, channel prompt tuning can predict unseen labels and achieves considerably better performance than zero-shot. It outperforms all finetuning on 2-way classification datasets, and outperforms head tuning on five datasets except for TREC on which head tuning achieves very strong performance on seen labels.

Next, we run zero-shot transfer learning, where the model is trained on one dataset and is tested on another dataset. Here, head tuning is not applicable when the labels are not shared between two datasets. Figure 5 shows the results. Channel prompt tuning outperforms all direct models including all finetuning on all datasets except for TREC. It is particularly competitive when the tasks are inherently similar, e.g., transfer between 2-way sentiment analysis and 5-way sentiment analysis in the first three figures. In fact, in such cases, performance is close to the models trained on in-domain data. When tasks are inherently different, e.g., the rest of the figures in Figure 5, gains over zero-shot performance are relatively small; we think more work should be done to make cross-task transfer better and to discover when it is possible.

7 Discussion & Conclusion

In this work, we introduced a noisy channel approach for few-shot text classification through LM prompting, where we either provide demonstrations to the LM or tune the prompt embeddings in the continuous space. Our experiments on eleven datasets show that channel models significantly outperform their direct counterparts, mainly because of their stability, i.e., lower variance and better worst-case accuracy. We also found that direct head tuning is more competitive than previously thought, and different methods are preferred given different conditions. Specifically, channel prompt tuning is preferred in the following scenarios.

K is small Channel prompt tuning is more competitive when there are fewer training examples. We hypothesize two reasons: (1) Channel models are more stable (i.e., achieve low variance and high worst-case accuracy), unlike direct models that are highly unstable with small k (Zhao et al., 2021; Perez et al., 2021; Lu et al., 2021). (2) Channel models provide more signals by requiring the model to explain the input word-by-word (as claimed in Lewis and Fan (2018)) which is beneficial in the low data regime.

Data is imbalanced or $|\mathcal{C}|$ is large When the training data is even slightly imbalanced, no direct models are competitive. We think this is because the LM head relies too much on unconditional distributions of labels. Channel prompt tuning is less sensitive because labels are only a conditioning variable. Label imbalance in the training data is a real-world problem, especially when k is small and $|\mathcal{C}|$ is large. We thus suggest this is an important area for future work.

Generalization to unseen labels is required All direct models are unable to predict labels that are unseen during training, indicating that they overfit in the label space. In contrast, channel models can predict unseen labels, likely because the label space is indirectly modeled. This is in line with prior work that shows channel models are more competitive under a distribution shift (Yogatama et al., 2017; Lewis and Fan, 2018).

Task is closer to language modeling If the task is too different from language modeling even with carefully chosen verbalizers (e.g., TREC and Subj), head tuning outperforms prompt tuning. This is likely because it benefits from directly updating the parameters of the LM. This may mean that causal LMs are not suitable for all tasks, or we need more sophisticated methods to apply causal LMs for such tasks without updating the LM parameters.

Limitations and future work While we show that channel models are competitive in few-shot text classification, there are limitations that provide avenues for future work. First, it is not as easy to use channel models for non classification tasks where modeling prior distributions is non-trivial. We think future work can obtain the prior with a separate model and incorporate it to the conditional LM as done by Lewis and Fan (2018), potentially with beam search decoding as in Yu et al. (2017); Yee et al. (2019).

Second, while this paper focuses on causal LMs, it is an open question how to use a channel model with masked LMs. Although we think channel models are not inherently restricted to causal LMs, the specific way in which existing masked LMs are pretrained makes it hard to use channel models without updating the LM parameters, e.g., masked LMs are not trained to generate long sentences. One recent approach uses a label-conditioning objective (Tam et al., 2021) as a clever way to introduce a channel-like model with existing masked LMs. Extending and further integrating these different approaches would be important for using channel models in a wider range of scenarios.

A Samples & Verbalizers

Table 10 shows samples from each dataset. Table 6 shows a list of verbalizers (four for each dataset), mainly taken from Gao et al. (2021) and label words included in the original data.

B Implementation Details

We use PyTorch (Paszke et al., 2019) and Huggingface Transformers (Wolf et al., 2020). For MR, we use the sentence polarity dataset version 1.0. We use the batch size of 32 and the sequence length of 128 for datasets with short input text (SST-2, SST-5, MR, TREC) and the batch size of 16 and the sequence length of 256 for datasets with long input text (AGNews, Amazon, Yelp, DBPedia, Yahoo, Subj). When the concat-based demonstration method is used, the sequence length is multiplied by the number of training examples, yet is bounded by 1024 which is a strict limit of GPT-2.

For all finetuning experiments, we train the model for 100 global steps. We use the loss divided by the number of all tokens in the batch. We use Adam optimizer (Kingma and Ba, 2015) with no weight decay and no warmup steps. For head tuning, transformation tuning and prompt tuning, we use the learning rate $\{0.1, 0.01, 0.001\}$ and choose the one that gives the lowest training loss on average in order to eliminate the need of the validation data. The chosen learning rate values are reported in Table 7. For all finetuning, we use the learning rate of 10^{-5}. For prompt tuning, we use $n = 20$ prompt tokens which embeddings are initialized from a random subset of the top 5000 vocabularies, following the original paper (Lester et al., 2021).

Table 13: Full results from tuning methods; analogous to Table 4. *Head*, *Trans*, *Prompt* indicate head tuning, transformation tuning and prompt tuning, respectively. *Avg*, *Std*, *Best* and *Worst* indicate the average accuracy, standard deviation, the best-case accuracy and the worst-case accuracy, respectively.

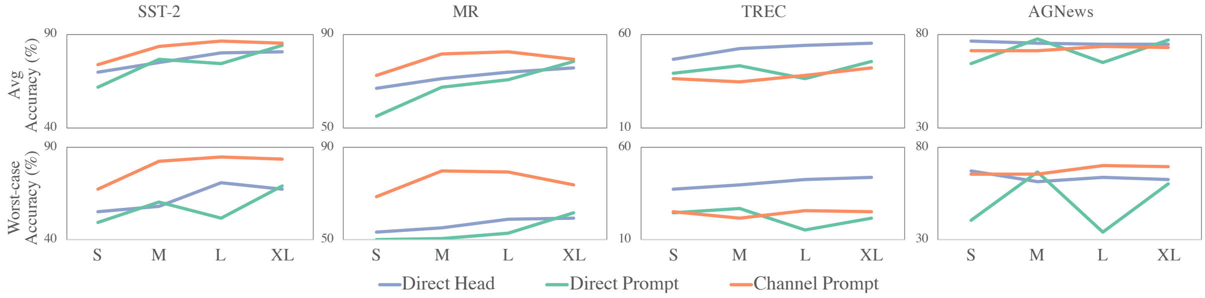

Figure 6: **Varying the size of LMs** from GPT-2 Small to GPT-2 X-Large. The average accuracy (top) and the worst-case accuracy (bottom) are reported. All models are run 20 times (4 verbalizers and 5 data seeds). *Head* and *Prompt* indicate head tuning and prompt tuning, respectively. Trends are consistent across different sizes of LM.

C Additional Results

More metrics Table 11, 12 and 13 report the average accuracy, the variance, the best-case accuracy and the worst-case accuracy using the concat-based demonstration, the ensemble-based demonstration and the tuning methods, respectively. Results consistently indicate that channel models achieve significantly lower variance and higher worst-case accuracy. The best-case accuracy is often achieved by direct models, but channel models outperform direct models on average.

Varying the size of LMs We vary the size of LMs and report the average and the worst-case accuracy in Figure 6. The trends—no matter the best performance is achieved by channel prompt tuning or direct head tuning—are fairly consistent across varying size of LMs.

Multilingual unsupervised sequence segmentation transfers to extremely low-resource languages

Department of Linguistics, University of Washington
`{cmdowney, sdrizin, levonh, shivin7}@uw.edu`

Abstract

We show that unsupervised sequence-segmentation performance can be transferred to extremely low-resource languages by pre-training a Masked Segmental Language Model (Downey et al., 2021) multilingually. Further, we show that this transfer can be achieved by training over a collection of low-resource languages that are typologically similar (but phylogenetically unrelated) to the target language. In our experiments, we transfer from a collection of 10 Indigenous American languages (AmericasNLP, Mager et al., 2021) to K'iche', a Mayan language. We compare our multilingual model to a monolingual (from-scratch) baseline, as well as a model pre-trained on Quechua only. We show that the multilingual pre-trained approach yields consistent segmentation quality across target dataset sizes, exceeding the monolingual baseline in 6/10 experimental settings. Our model yields especially strong results at small target sizes, including a zero-shot performance of 20.6 F1. These results have promising implications for low-resource NLP pipelines involving human-like linguistic units, such as the *sparse transcription* framework proposed by Bird (2020).

1 Introduction

Unsupervised sequence segmentation (at the word, morpheme, and phone level) has long been an area of interest in languages without whitespace-delimited orthography (e.g. Chinese, Uchiumi et al., 2015; Sun and Deng, 2018), morphologically complex languages without rule-based morphological analyzers (Creutz and Lagus, 2002), and automatically phone-transcribed speech data (Goldwater et al., 2009; Lane et al., 2021), respectively. It has been particularly important for lower-resource languages in which there is little or no gold-standard data on which to train supervised models (Joshi et al., 2020).

In modern neural end-to-end systems, unsupervised segmentation is usually performed via information-theoretic algorithms such as BPE (Sennrich et al., 2016) and SentencePiece (Kudo and Richardson, 2018). However, the segmentations they produce are largely non-sensical to humans (Park et al., 2021). The motivating tasks listed above instead require unsupervised approaches that correlate more closely with human judgements of the boundaries of linguistic units. For example, in a human-in-the-loop framework such as the *sparse transcription* proposed by Bird (2020), lexical items are automatically proposed to native speakers for confirmation, and it is important that these candidates be (close to) sensical, recognizable pieces of language.

In this paper, we investigate the utility of recent models that have been developed to conduct unsupervised surface morpheme segmentation as a byproduct of a language modeling objective (e.g. Kawakami et al., 2019; Downey et al., 2021, see Section 2). The key idea is that recent breakthroughs in crosslingual language modeling and transfer learning (Conneau and Lample, 2019; Artetxe et al., 2020, *inter alia*) can be leveraged to facilitate transferring unsupervised segmentation performance to a new target language, using these types of language models.

Specifically, we investigate the effectiveness of multilingual pre-training in a Masked Segmental Language Model (Downey et al., 2021) when applied to a low-resource target. We pre-train our model on the ten Indigenous languages of the 2021 AmericasNLP shared task dataset (Mager et al., 2021), and apply it to another low-resource, Indigenous, and morphologically complex language of Central America: K'iche' (quc), which at least

---

*Equal contribution from starred authors, sorted by last name. Sincere thanks to: Gina-Anne Levow, Shane Steinert Threlkeld, and Sara Ng for helpful comments and discussion; Francis Tyers for access to the K'iche' data; Manuel Mager for access to the morphologically-segmented validation data

Proceedings of the 60th Annual Meeting of the Association for Computational Linguistics
Volume 1: Long Papers, pages 5331 - 5346
May 22-27, 2022

phylogenetically is unrelated to the pre-training languages (Campbell et al., 1986).

We hypothesize that multilingual pre-training on similar, possibly contact-related languages, will outperform both a monolingual baseline trained from scratch and a model pre-trained on a single language (Quechua) with the same amount of pre-training data. We also expect that the pre-trained models will perform increasingly better than the monolingual baseline the smaller the target corpus is.

Indeed, our experiments show that a pre-trained multilingual model provides stable performance across all dataset sizes and far exceeds the monolingual baseline at low-to-medium target sizes. We additionally show that the multilingual model achieves a zero-shot segmentation performance of 20.6 F1 on the K'iche' data, where the monolingual baseline yields a score of zero. These results suggest that transferring from a multilingual model can greatly assist unsupervised segmentation in very low-resource languages, even those that are morphologically rich. The results also provide evidence for the idea that transfer from multilingual models works at a more moderate scale than is typical for recent crosslingual models (3.15 million parameters for our models).

In the following section, we overview work relating to unsupervised segmentation, crosslingual pre-training, and transfer-learning (Section 2). We then introduce the multilingual data used in our experiments, and the additional pre-processing we performed to prepare the data for pre-training (Section 3). Next we provide a brief overview of the type of Segmental Language Model used in our experiments, as well as our multilingual pre-training process (Section 4). After this, we describe our experimental process applying the pre-trained and from-scratch models to varying target data sizes (Section 5). Finally, we discuss the results of our experiments and their significance for low-resource pipelines, both within unsupervised segmentation and for other NLP tasks more generally (Sections 6 and 7).

2 Related Work

Work related to the present study largely falls either into the field of (unsupervised) word segmentation, or the field(s) of crosslingual language modeling and transfer learning. To our knowledge, we are the first to propose a multilingual model for unsupervised word/morpheme-segmentation.

Unsupervised Segmentation Current state-of-the-art unsupervised segmentation has largely been achieved with Bayesian models such as Hierarchical Dirichlet Processes (Teh et al., 2006; Goldwater et al., 2009) and Nested Pitman-Yor (Mochihashi et al., 2009; Uchiumi et al., 2015). Adaptor Grammars (Johnson and Goldwater, 2009) have been successful as well. Models such as *Morfessor* (Creutz and Lagus, 2002), which are based on Minimal Description Length (Rissanen, 1989) are also widely used for unsupervised morphology.

As Kawakami et al. (2019) note, most of these models have weak language modeling ability, being unable to take into account much other than the immediate local context of the sequence. Another line of techniques has focused on models that are both strong language models and good for sequence segmentation. Many are in some way based on Connectionist Temporal Classification (Graves et al., 2006), and include Sleep-WAke Networks (Wang et al., 2017), Segmental RNNs (Kong et al., 2016), and Segmental Language Models (Sun and Deng, 2018; Kawakami et al., 2019; Wang et al., 2021; Downey et al., 2021). In this work, we conduct experiments using the Masked Segmental Language Model of Downey et al. (2021), due to its good performance and scalability, the latter usually regarded as an obligatory feature of multilingual models (Conneau et al., 2020a; Xue et al., 2021, *inter alia*).

Crosslingual and Transfer Learning Crosslingual modeling and training has been an especially active area of research following the introduction of language-general encoder-decoders in Neural Machine Translation, offering the possibility of zero-shot translation (i.e. translation for language pairs not seen during training; Ha et al., 2016; Johnson et al., 2017).

The arrival of crosslingual language model pretraining (XLM, Conneau and Lample, 2019) further demonstrates that large models pre-trained on multiple languages yield state-of-the-art performance across an abundance of multilingual tasks including zero-shot text classification (e.g. XNLI, Conneau et al., 2018), and that pre-trained transformer encoders provide great initializations for MT systems and language models in very low-resource languages.

Since XLM, numerous studies have attempted to single out which components of crosslingual training contribute to transferability from one language to another (e.g. Conneau et al., 2020b). Others have questioned the importance of multilingual training, and have instead proposed that even monolingual pre-training can provide effective transfer to new languages (Artetxe et al., 2020). Though some like Lin et al. (2019) have tried to systematically study which aspects of pre-training languages/corpora enable effective transfer, in practice the choice is often driven by availability of data and other ad-hoc factors.

Currently, large crosslingual successors to XLM such as XLM-R (Conneau et al., 2020a), MASS (Song et al., 2019), mBART (Liu et al., 2020), and mT5 (Xue et al., 2021) have achieved major success, and are the starting point for a large portion of multilingual NLP systems. These models all rely on an enormous amount of parameters and pre-training data, the bulk of which comes from very high-resource languages. In contrast, in this paper we assess whether multilingual pre-training on a suite of very low-resource languages, which combine to yield a moderate amount of unlabeled data, can provide good transfer to similar languages which are also very low-resource.

3 Data and Pre-processing

We draw data from three main datasets. We use the AmericasNLP 2021 open task dataset (Mager et al., 2021) to pre-train our multilingual models. The multilingual dataset from Kann et al. (2018) serves as segmentation validation data for our pre-training process in these languages. Finally, data from Tyers and Henderson (2021) is used as the training set for our experiments transferring to K'iche', and Richardson and Tyers (2021) provides the validation and test data for these experiments.

AmericasNLP 2021 The AmericasNLP data consists of train and validation files for ten low-resource Indigenous languages of Central and South America: Asháninka (cni), Aymara (aym), Bribri (bzd), Guaraní (gug), Hñähñu (oto), Nahuatl (nah), Quechua (quy), Rarámuri (tar), Shipibo Konibo (shp), and Wixarika (hch). For each language, AmericasNLP also includes parallel Spanish sets, which we do not use. The data was originally curated for the AmericasNLP 2021 shared task on low-resource Machine Translation. (Mager et al., 2021).[1]

We augment the Asháninka and Shipibo-Konibo training sets with additional available monolingual data from Bustamante et al. (2020),[2] which is linked in the official AmericasNLP repository. We add both the training and validation data from this corpus to the *training* set of our splits.

To pre-process for a multilingual language modeling setting, we first remove lines that contain urls, copyright boilerplate, or that contain no alphabetic characters. We also split lines that are longer than 2000 characters into sentences/clauses where evident. Because we use the Nahuatl and Wixarika data from Kann et al. (2018) as validation data, we remove any overlapping lines from the AmericasNLP set. We create a combined train file as the concatenation of the training data from each of the ten languages, as well as a combined validation file likewise.

Because the original ratio of Quechua training data is so high compared to all other languages (Figure 1), we downsample it to 2^{15} examples, the closest order of magnitude to the next-largest training set. A plot of the balanced (final) composition of our AmericasNLP train and validation sets is seen in Figure 2.

To compare the effect of multilingual and monolingual pre-training, we also pre-train a model on Quechua alone, since it has by far the most data (Figure 1). However, the full Quechua training set has about 50k fewer lines than our balanced AmericasNLP set (Figure 2). To create a fair comparison between multilingual and monolingual pre-training, we additionally create a downsampled version of the AmericasNLP set of equal size to the Quechua data (120,145 lines). The detailed composition of our data is available in Appendix A.

Kann et al (2018) The data from Kann et al. (2018), originally curated for a segmentation task on polysynthetic low-resource languages, contains morphologically segmented sentences for Nahuatl and Wixarika. We use these examples as validation data for segmentation quality during the pre-training process. We clean this data in the same manner as the AmericasNLP sets.

K'iche' data The K'iche' data used in our study was curated for Tyers and Henderson (2021). The

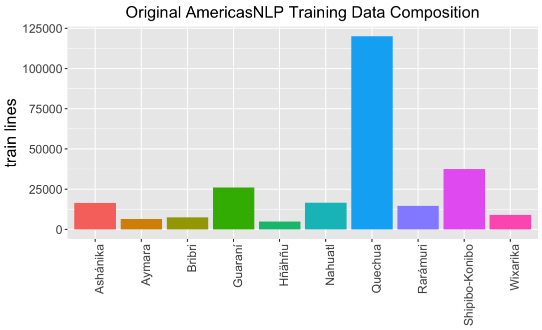

Figure 1: Original (imbalanced) language composition of the AmericasNLP training set

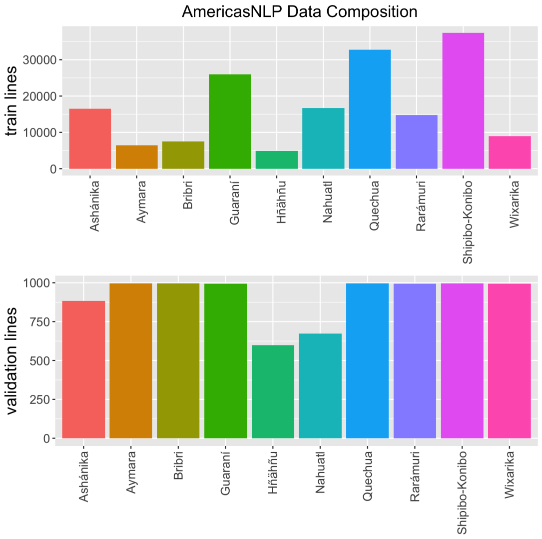

Figure 2: Final language composition of our AmericasNLP splits after downsampling Quechua

raw (non-gold-segmented) data, used as the training set in our transfer experiments, comes from a section of this data web-scraped by the Crúbadán project (Scannell, 2007). This data is relatively noisy, so we clean it by removing lines with urls or lines where more than half of the characters are non-alphabetic. We also remove duplicate lines. The final data consists of 47,729 examples and is used as our full-size training set for K'iche'. Our experiments involve testing transfer at different resource levels, so we also create smaller training sets by downsampling the original to lower orders of magnitude.

For evaluating segmentation performance on K'iche', we use the segmented sentences from Richardson and Tyers (2021),[3] which were created for a shared task on morphological segmentation. These segmentations were created by a hand-crafted FST, then manually disambiguated. Because gold-segmented sentences are so rare, we concatenate the original train/validation/test splits and then split them in half into final validation and test sets.

4 Model and Pre-training

This section gives an overview of the Masked Segmental Language Model (MSLM), introduced in Downey et al. (2021), along with a description of our pre-training procedure.

MSLMs An MSLM is a variant of a Segmental Language Model (SLM) (Sun and Deng, 2018; Kawakami et al., 2019; Wang et al., 2021), which takes as input a sequence of characters $\mathbf{x}$ and outputs a probability distribution for a sequence of segments $\mathbf{y}$ such that the concatenation of $\mathbf{y}$ is equivalent to $\mathbf{x}$: $\pi(\mathbf{y}) = \mathbf{x}$. An MSLM is composed of a Segmental Transformer Encoder and an LSTM-based Segment Decoder (Downey et al., 2021). See Figure 3.

The MSLM training objective is based on the prediction of masked-out spans. During a forward pass, the encoder generates an encoding for every position in $\mathbf{x}$, for a segment up to k symbols long; the encoding at position $i-1$ corresponds to every possible segment that starts at position i. Therefore, the encoding approximates

$$p(\mathbf{x}_{i:i+1}, \mathbf{x}_{i:i+2}, ..., \mathbf{x}_{i:i+k} | \mathbf{x}_{<i}, \mathbf{x}_{\geq i+k})$$

To ensure that the encodings are generated based only on the portions of $\mathbf{x}$ that are outside of the predicted span, the encoder uses a Segmental Attention Mask (Downey et al., 2021) to mask out tokens inside the segment. Figure 3 shows an example of such a mask with $k = 2$.

Finally, the Segment Decoder of an SLM determines the probability of the j^{th} character of the segment of $\mathbf{y}$ that begins at index i, $\mathbf{y}^i_j$, using the encoded context:

$$p(\mathbf{y}^i_j | \mathbf{y}^i_{0:j}, \mathbf{x}_{<i}, \mathbf{x}_{\geq i+k}) = Decoder(h^i_{j-i}, y^i_{j-1})$$

The output of the decoder is not conditional on the determination of other segment boundaries. The probability of $\mathbf{y}$ is modeled as the marginal probability over all possible segmentations of $\mathbf{x}$. Because directly marginalizing is computationally intractable, the marginal is computed using dynamic programming over a forward-pass lattice.

---

The maximum-probability segmentation is determined by Viterbi decoding. The training objective optimizes language-modeling performance, which is measured in Bits Per Character (bpc).

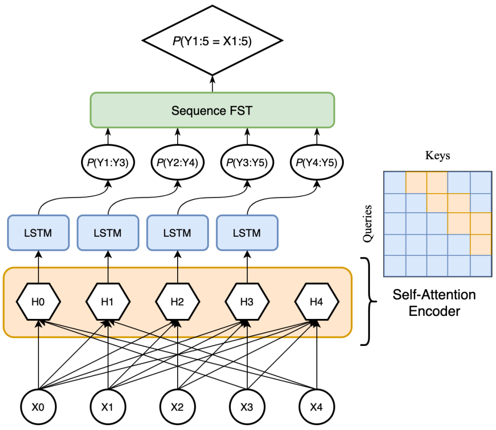

Figure 3: Masked Segmental Language model (left) and Segmental Attention Mask (right). (Figure 3 in Downey et al., 2021)

Pre-training Procedure In our experiments, we test the transferability of multilingual and monolingual pre-trained MSLMs. The multilingual models are trained on the AmericasNLP 2021 data (see Section 3). Since SLMs operate on plain text, we can train the model directly on the multilingual concatenation of this data, and evaluate it by its language modeling performance on the concatenated validation data. As mentioned in Section 3, we create two versions of the multilingual pre-trained model: one trained on the full AmericasNLP set (∼172k lines) and the other trained on the downsampled set, which is the same size as the Quechua training set (∼120k lines). We designate these models MULTI-PT$_{full}$ and MULTI-PT$_{down}$, respectively. Our pre-trained monolingual model is trained on the full Quechua set (QUECHUA-PT).

Each model is an MSLM with four encoder layers, hidden size 256, feedforward size 512, and four attention heads. Character embeddings are initialized using Word2Vec (Mikolov et al., 2013) over the training data. The maximum segment size is set to 10. The best model is chosen as the one that minimizes the Bits Per Character (bpc) loss on the validation set. For further pre-training details, see Appendix B.

To evaluate the effect of pre-training on the segmentation quality for languages within the pre-training set, we also log MCC between the model output and gold-segmented secondary validation sets available in Nahuatl and Wixarika (Kann et al., 2018, see Section 3). Figure 4 shows the unsupervised segmentation quality for Nahuatl and Wixarika almost monotonically increases during pre-training (MULTI-PT$_{full}$).

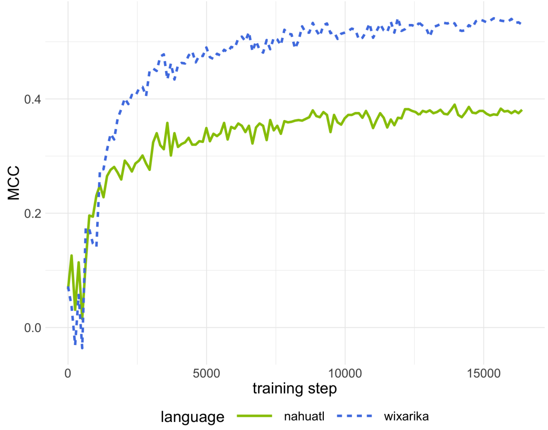

Figure 4: Plot of segmentation quality for Nahuatl and Wixarika during multilingual pre-training (measured by Matthews Correlation Coefficient with gold segmentation)

5 Experiments

We evaluate whether multilingual pre-training facilitates effective low-resource transfer learning for unsupervised segmentation. To do this, we pre-train SLMs on one or all of the AmericasNLP 2021 languages (Mager et al., 2021) and transfer it to a new target language: K'iche' (Tyers and Henderson, 2021). K'iche' is a morphologically rich Mayan language with several classes of inflectional prefixes and suffixes (Txchajchal Batz et al., 1996). An example sentence can be found in Table 1, which also shows our model's input and target output format.

As a baseline, we train a monolingual K'iche' model from scratch. We evaluate performance with respect to the size of the target training set, simulating varying degrees of low-resource setting. To do this, we downsample the K'iche' training set to 8 smaller sizes, for 9 total: {256, 512, ... 2^{15}, 47.7k (full)}. For each size, we both train a monolingual baseline and fine-tune the pre-trained models we describe in Section 4.[4]

---

[4] All of the data and software required to run these experiments can be found at `https://github.com/cmdowney88/XLSLM`

Orthography	kinch'aw ruk' le nunan
Linguistic Segmentation	k-in-ch'aw r-uk' le nu-nan
Translation	"I speak with my mother"
Model Input	`kinch'awruk'lenunan`
Target Output	`k in ch'aw r uk' le nu nan`

Table 1: Example K'iche' sentence from Tyers and Henderson (2021). This sentence consists of multiple words, some of which consist of multiple morphemes. The model receives the sentence as an unsegmented stream of characters and the target output is a sequence of morphemes (word and morpheme boundaries are treated the same, since the former is a subtype of the latter)

Architecture and Modeling All models are Masked Segmental Language Models (MSLMs) with the architecture described in Section 4. The only difference is that the baseline model is initialized with a character vocabulary *only* covering the particular K'iche' training set (size-specific). The character vocabulary of the K'iche' data is a subset of the AmericasNLP vocabulary, so we are able to transfer the multilingual models without changing the embedding and output layers. The Quechua vocabulary is *not* a superset of the K'iche', so we add the missing characters to the Quechua model's embedding block *before* pre-training (these are randomly initialized). The character embeddings for the baseline are initialized using Word2Vec (Mikolov et al., 2013) on the training set (again, size-specific).

Evaluation Metrics SLMs can be trained in either a fully unsupervised or "lightly" supervised manner (Downey et al., 2021). In the former case, only the language modeling loss (Bits Per Character, bpc) is used to pick parameters and checkpoints. In the latter, the segmentation quality on gold-segmented validation data can be considered. Though our validation set is gold-segmented, we pick the best parameters and checkpoints based on bpc only, simulating the unsupervised case. However, to monitor the change in segmentation quality during training, we also use Matthews Correlation Coefficient (MCC). This measure frames segmentation as a character-wise binary classification task (i.e. boundary vs. no boundary), and measures correlation with the gold segmentation.

To make our results comparable with the wider word-segmentation literature, we use the scoring script from the SIGHAN Segmentation Bakeoff (Emerson, 2005) for our final segmentation F1. For each model and target size, we choose the best checkpoint (by bpc), apply the model to the combined validation and test set, and use the SIGHAN script to score the output.

For comparison to the Chinese Word-Segmentation and speech literature, any whitespace segmentation in the validation/test data is discarded before it is fed to the model. However, SLMs can also be trained to treat spaces like any other character, and thus could be able to take advantage of existing segmentation in the input. We leave this for future work.

Parameters and Trials For our training procedure (both training the baseline from scratch and fine-tuning the pre-trained models) we tune hyperparameters on three of the nine dataset sizes (256, 2048, and full) and choose the optimal parameters by bpc. For each of the other sizes, we directly apply the chosen parameters from the tuned dataset of the closest size (on a log scale). We tune over five learning rates and three encoder dropout values. As in pre-training, we set the maximum segment length to 10. For more details on our training procedure, see Appendix B.

6 Results

The results of our K'iche' transfer experiments at various target sizes can be found in Table 2. In general, the (full) pre-trained multilingual model (Multi-PT$_{full}$) demonstrates good performance across dataset sizes, with the lowest segmentation performance (20.6 F1) being in the zero-shot case and the highest (40.7) achieved on 2^{14} examples. The monolingual baseline outperforms Multi-PT$_{full}$ at the two largest target sizes, as well as at size 4096 (achieving the best overall F1 of 44.8), but performs very poorly under 2048 examples, and has no zero-shot ability (unsurprisingly, since it is a random initialization).

Interestingly, other than in the zero-shot case, Quechua-PT and the comparable Multi-PT$_{down}$ perform very similarly to each other. However, the zero-shot transferability of MULTI-PT$_{down}$ is almost twice that of the model trained on Quechua only. MULTI-PT$_{full}$ exceeds both MULTI-PT$_{down}$ and QUECHUA-PT by a wide margin in every setting. Finally, all models show increasing performance until about size 4096, after which more target examples don't provide a large increase in segmentation quality.

Interpretation These results show that MULTI-PT$_{full}$ provides consistent performance across target sizes as small as 512 examples. Even for size 256, there is only a 9% (relative) drop in quality from the next-largest size. Further, the pre-trained model's zero-shot performance is impressive given the baseline is effectively 0 F1.

On the other hand, the performance of the monolingual baseline at larger sizes seems to suggest that given enough target data, it is better to train a model devoted to the target language only. This is consistent with previous results (Wu and Dredze, 2020; Conneau et al., 2020a). However, it should also be noted that MULTI-PT$_{full}$ never trails the baseline by more than 5.2 F1.

One less-intuitive result is the dip in the baseline's performance at sizes 8192 and 2^{14}. We believe this discrepancy may be partly explainable by sensitivity to hyperparameters in the baseline. Though the best baseline trial at size 2048 exceeds MULTI-PT$_{full}$ by a small margin, the baseline shows large variation in performance across the top-four hyperparameter settings at this size, where MULTI-PT$_{full}$ actually performs better on average and much more consistently (Table 3). We thus believe the dip in performance for the baseline at sizes 8192 and 2^{14} may be due to an inability to extrapolate hyperparameters from other experimental settings.

7 Analysis and Discussion

Standing of Hypotheses Within the framework of unsupervised segmentation, these results provide strong evidence that relevant linguistic patterns can be learned over a collection of low-resource languages, and then transferred to a new language without much (or any) target training data. Further, it is shown that the target language need not be (phylogenetically) related to any of the pre-training languages, even though details of morphological structure are ultimately language-specific.

The hypothesis that multilingual pre-training yields increasing advantage over a from-scratch baseline at smaller target sizes is also strongly supported. This result is consistent with related work showing this to be a key advantage of the multilingual approach (Wu and Dredze, 2020).

The hypothesis that multilingual pre-training also yields better performance than monolingual pre-training given the same amount of data seems to receive mixed support from our experiments. On one hand, the comparable multilingual model has a clear advantage over the Quechua model in the zero-shot setting, and outperforms the latter in 5/10 settings more generally. However, because the Quechua data lacks several frequent K'iche' characters (and these embeddings remain randomly initialized), it is unclear how much of this advantage comes from the multilingual training *per-se*. Instead, the advantage may be due to the multilingual model's full coverage of the target vocabulary—an advantage which may disappear at larger target sizes. Further analysis of this hypothesis will require additional investigation.

Significance The above results, especially the strong zero-shot transferability of segmentation performance, suggest that the type of language model used here learns some abstract linguistic pattern(s) that are generalizable across languages, and even to new ones. It is possible that these generalizations could take the form of abstract stem/affix or word-order patterns, corresponding roughly to the lengths and order of morphosyntactic units. Because MSLMs operate on the character level (and in these languages orthographic characters mostly correspond to phones), it is also possible the model could recognize syllable structure in the data (the ordering of consonants and vowels in human languages is relatively constrained), and learn to segment on syllable boundaries.

It is also helpful to remember that we select the training suite and target language to have some characteristics in common that may help facilitate transfer. The AmericasNLP languages are almost all morphologically rich, with many considered polysynthetic (Mager et al., 2021), a feature that K'iche' shares (Suárez, 1983). Further, all of the languages, including K'iche', are spoken in countries where either Spanish or Portuguese is the official language, and have very likely had close contact with these Iberian languages and borrowed lexical items. Finally, the target language family (Mayan) has also been shown to have close historical contact with the families of several of the

AmericasNLP set (Nahuatl, Rarámuri, Wixarika, Hñähñu), forming a Linguistic Area or *Sprachbund* (Campbell et al., 1986).

It is possible that one or several of these shared characteristics facilitates the strong transfer shown here, in both our multilingual and monolingual pre-trained models. However, our current study does not conclusively show this to be the case. Lin et al. (2019) show that factors like linguistic similarity and geographic contact are often not as important for transfer success as non-linguistic features such as the raw size of the source dataset. Indeed, the fact that our Quechua pre-trained model performs similarly to the comparable multilingual model (at least at larger target sizes) suggests that the benefit to using MULTI-PT$_{full}$ could be interpreted as a combined advantage of pre-training data size and target vocabulary coverage.

The nuanced question of whether multilingual pre-training *itself* enables better transfer than monolingual pre-training requires more study. However, taking a more pragmatic point of view, multilingual training can be seen as a methodology to 1) acquire more data than is available from any one language and 2) ensure broader vocabulary overlap with the target language. Our character-based model is of course different from more common word- or subword-based approaches, but with these too, attaining pre-trained embeddings that cover a novel target language is an important step in cross-lingual transfer (Garcia et al., 2021; Conneau et al., 2020a; Artetxe et al., 2020, *inter alia*)

Future Work We believe some future studies would shed light on the nuances of segmentation transfer-learning. First, pre-training either multilingually or monolingually on languages that are *not* linguistically similar to the target language could help isolate the advantage given by pre-training on *any* language data (vs. similar language data).

Second, we have noted that monolingual pre-training on a language that does not have near-full vocabulary coverage of the target language leaves some embeddings randomly initialized, yielding worse performance at small target sizes. Pre-training a model on a single language that happens to have near-complete vocabulary coverage of the target could give a better view of whether multilingual training intrinsically yields advantages, or whether monolingual training is disadvantaged mainly due to this lack of vocabulary coverage.

Finally, because none of the present authors have any training in the K'iche' language, we are unable to perform a linguistically-informed error analysis of our model's output (e.g. examining the types of words and morphemes which are erroneously (un)segmented, rather than calculating an overall precision and recall for the predicted and true morpheme boundaries, as we do in this study). However, we make all of our model outputs available in our public repository, so that future work may provide a more nuanced analysis of the types of errors unsupervised segmentation models are prone to make.

8 Conclusion

This study has shown that unsupervised sequence segmentation ability can be transferred via multilingual pre-training to a novel target language with little or no target data. The target language also need not be from the same family as a pre-training language for successful transfer. While training a monolingual model from scratch on large amounts of target data results in good segmentation quality, our experiments show that pre-trained models, especially multilingual ones, far exceed the baseline at small target sizes ($\leq$1024), and seem to be much more robust to hyperparameter variation at medium sizes (2048, 8192, 2^{14}).

One finding that may have broader implications is that pre-training can be conducted over a set of low-resource languages with some typological or geographic connection to the target, rather than over a crosslingual suite centered around high-resource languages like English and other European languages. Most modern crosslingual models have huge numbers of parameters (XLM has 570 million, mT5 has up to 13 billion, Xue et al., 2021), and are trained on enormous amounts of data, usually bolstered by hundreds of gigabytes in the highest-resource languages (Conneau et al., 2020a).

In contrast, our results suggest that effective transfer may be possible at smaller scales, by combining the data of low-resource languages and training moderately-sized, more targeted pre-trained multilingual models (our model has 3.15 million parameters). Of course, this study can only support this possibility within the unsupervised segmentation task, so future work will be needed to investigate whether transfer to and from low-resource languages can be extended to other tasks.

A AmericasNLP Datasets

Composition The detailed composition of our preparation of the AmericasNLP 2021 training and validation sets can be found in Tables 4 and 5 respectively. `train_1.mono.cni`, `train_2.mono.cni`, `train_1.mono.shp`, and `train_2.mono.shp` are the additional monolingual sources for Asháninka and Shipibo-Konibo obtained from Bustamante et al. (2020). `train_downsampled.quy` is the version of the Quechua training set downsampled to 2^{15} lines to be more balanced with the other languages. `train.anlp` is the concatenation of the training set of every language before Quechua downsampling, and `train_balanced.anlp` is the version after Quechua downsampling. `train_downsampled.anlp` is the version of our multilingual set downsampled to be the same size as `train.quy`. MULTI-PT$_{full}$ is pre-trained on `train_balanced.anlp`, MULTI-PT$_{down}$ is pre-trained on `train_downsampled.anlp`, and QUECHUA-PT is pre-trained on `train.quy`.

Citations A more detailed description of the sources and citations for the AmericasNLP set can be found in the original shared task paper (Mager et al., 2021). Here, we attempt to give a brief listing of the proper citations.

All of the validation data originates from AmericasNLI (Ebrahimi et al., 2021) which is a translation of the Spanish XNLI set (Conneau et al., 2018) into the 10 languages of the AmericasNLP 2021 open task.

The training data for each of the languages comes from a variety of different sources. The **Asháninka** training data is sourced from Ortega et al. (2020); Cushimariano Romano and Sebastián Q. (2008); Mihas (2011) and consists of stories, educational texts, and environmental laws. The **Aymara** training data consists mainly of news text from the GlobalVoices corpus (Prokopidis et al., 2016) as available through OPUS (Tiedemann, 2012). The **Bribri** training data is from six sources (Feldman and Coto-Solano, 2020; Margery, 2005; Jara Murillo, 2018a; Constenla et al., 2004; Jara Murillo and Segura, 2013; Jara Murillo, 2018b; Flores Solórzano, 2017) ranging from dictionaries and textbooks to story books. The **Guaraní** training data consists of blogs and web news sources collected by Chiruzzo et al. (2020). The **Nahuatl** training data comes from the Axolotl parallel corpus (Gutierrez-Vasques et al., 2016). The **Quechua** training data was created from the JW300 Corpus (Agić and Vulić, 2019), including Jehovah's Witnesses text and dictionary entries collected by Huarcaya Taquiri (2020). The **Rarámuri** training data consists of phrases from the Rarámuri dictionary (Brambila, 1976). The **Shipibo-Konibo** training data consists of translations of a subset of the Tatoeba dataset (Montoya et al., 2019), translations from bilingual education books (Galarreta et al., 2017), and dictionary entries (Loriot et al., 1993). The **Wixarika** training data consists of translated Hans Christian Andersen fairy tales from Mager et al. (2018).

No formal citation was given for the source of the **Hñähñu** training data (see Mager et al., 2021).

B Hyperparameter Details

Pre-training The character embeddings for our multilingual model are initialized by training CBOW (Mikolov et al., 2013) on the AmericasNLP training set for 32 epochs, with a window size of 5. Special tokens like `<bos>` that do not appear in the training corpus are randomly initialized. These pre-trained embeddings are not frozen during training.

We pre-train for 16,768 steps, using the Adam optimizer (Kingma and Ba, 2015). We apply a linear warmup for 1024 steps, and a linear decay afterward. We sweep eight learning rates on a grid of the interval $[0.0005, 0.0009]$ and encoder dropout values $\{12.5\%, 25\%\}$. A dropout rate of 6.25% is applied both to the embeddings before being passed to the encoder, and to the hidden-state and start-symbol encodings input to the decoder (see Downey et al., 2021). Checkpoints are taken every 128 steps.

K'iche' Transfer Experiments Similar to the pre-trained model, character embeddings are initialized using CBOW on the given training set for 32 epochs with a window size of 5, and these embeddings are not frozen during training.

All models are trained using the Adam optimizer (Kingma and Ba, 2015) for 8192 steps on all but the two smallest sizes, which are trained for 4096 steps. A linear warmup is used for the first 1024 steps (512 for the smallest sets), followed by linear decay. We set the maximum segment length to 10. A dropout rate of 6.25% is applied to the input embeddings, plus h and the start-symbol for the decoder. Checkpoints are taken every 64 steps for sizes 256 and 512, and every 128 steps for every other size.

For all training set sizes, we sweep 5 learning rates and 3 encoder dropout rates, but the swept set is different for each. For size 256, we sweep learning rates {5e-5, 7.5e-5, 1e-4, 2.5e-4, 5e-4} and (encoder) dropout rates {12.5%, 25%, 50%}. For size 2048, we sweep learning rates {1e-4, 2.5e-4, 5e-4, 7.5e-4, 1e-3} and dropouts {12.5%, 25%, 50%}. For the full training size, we sweep learning rates {1e-4, 2.5e-4, 5e-4, 7.5e-4, 1e-3} and dropouts {6.5%, 12.5%, 25%}.

KinyaBERT: a Morphology-aware Kinyarwanda Language Model

Antoine Nzeyimana
University of Massachusetts Amherst
anthonzeyi@gmail.com

Andre Niyongabo Rubungo
Polytechnic University of Catalonia
niyongabor.andre@gmail.com

Abstract

Pre-trained language models such as BERT have been successful at tackling many natural language processing tasks. However, the unsupervised sub-word tokenization methods commonly used in these models (e.g., byte-pair encoding – BPE) are sub-optimal at handling morphologically rich languages. Even given a morphological analyzer, naive sequencing of morphemes into a standard BERT architecture is inefficient at capturing morphological compositionality and expressing word-relative syntactic regularities. We address these challenges by proposing a simple yet effective two-tier BERT architecture that leverages a morphological analyzer and explicitly represents morphological compositionality. Despite the success of BERT, most of its evaluations have been conducted on high-resource languages, obscuring its applicability on low-resource languages. We evaluate our proposed method on the low-resource morphologically rich Kinyarwanda language, naming the proposed model architecture *KinyaBERT*. A robust set of experimental results reveal that *KinyaBERT* outperforms solid baselines by 2% in F1 score on a named entity recognition task and by 4.3% in average score of a machine-translated GLUE benchmark. *KinyaBERT* fine-tuning has better convergence and achieves more robust results on multiple tasks even in the presence of translation noise.[1]

1 Introduction

Recent advances in natural language processing (NLP) through deep learning have been largely enabled by vector representations (or embeddings) learned through language model pre-training (Bengio et al., 2003; Mikolov et al., 2013; Pennington et al., 2014; Bojanowski et al., 2017; Peters et al., 2018; Devlin et al., 2019). Language models such as BERT (Devlin et al., 2019) are pre-trained on large text corpora and then fine-tuned on downstream tasks, resulting in better performance on many NLP tasks. Despite attempts to make multilingual BERT models (Conneau et al., 2020), research has shown that models pre-trained on high quality monolingual corpora outperform multilingual models pre-trained on large Internet data (Scheible et al., 2020; Virtanen et al., 2019). This has motivated many researchers to pre-train BERT models on individual languages rather than adopting the “language-agnostic” multilingual models. This work is partly motivated by the same findings, but also proposes an adaptation of the BERT architecture to address representational challenges that are specific to morphologically rich languages such as Kinyarwanda.

In order to handle rare words and reduce the vocabulary size, BERT-like models use statistical sub-word tokenization algorithms such as byte pair encoding (BPE) (Sennrich et al., 2016). While these techniques have been widely used in language modeling and machine translation, they are not optimal for morphologically rich languages (Klein and Tsarfaty, 2020). In fact, sub-word tokenization methods that are solely based on surface forms, including BPE and character-based models, cannot capture all morphological details. This is due to morphological alternations (Muhirwe, 2007) and non-concatenative morphology (McCarthy, 1981) that are often exhibited by morphologically rich languages. For example, as shown in Table 1, a BPE model trained on 390 million tokens of Kinyarwanda text cannot extract the true sub-word lexical units (i.e. morphemes) for the given words. This work addresses the above problem by proposing a language model architecture that explicitly represents most of the input words with morphological parses produced by a morphological analyzer. In this architecture BPE is only used to handle words which cannot be directly decomposed by the morphological analyzer such as misspellings,

Table 1: Comparison between morphemes and BPE-produced sub-word tokens. Stems are underlined.

proper names and foreign language words.

Given the output of a morphological analyzer, a second challenge is in how to incorporate the produced morphemes into the model. One naive approach is to feed the produced morphemes to a standard transformer encoder as a single monolithic sequence. This approach is used by Mohseni and Tebbifakhr (2019). One problem with this method is that mixing sub-word information and sentence-level tokens in a single sequence does not encourage the model to learn the actual morphological compositionality and express word-relative syntactic regularities. We address these issues by proposing a simple yet effective two-tier transformer encoder architecture. The first tier encodes morphological information, which is then transferred to the second tier to encode sentence level information. We call this new model architecture KinyaBERT because it uses BERT's masked language model objective for pre-training and is evaluated on the morphologically rich Kinyarwanda language.

This work also represents progress in low resource NLP. Advances in human language technology are most often evaluated on the main languages spoken by major economic powers such as English, Chinese and European languages. This has exacerbated the language technology divide between the highly resourced languages and the underrepresented languages. It also hinders progress in NLP research because new techniques are mostly evaluated on the mainstream languages and some NLP advances become less informed of the diversity of the linguistic phenomena (Bender, 2019). Specifically, this work provides the following research contributions:

- A simple yet effective two-tier BERT architecture for representing morphologically rich languages.
- New evaluation datasets for Kinyarwanda language including a machine-translated subset of the GLUE benchmark (Wang et al., 2019) and a news categorization dataset.
- Experimental results which set a benchmark for future studies on Kinyarwanda language understanding, and on using machine-translated versions of the GLUE benchmark.
- Code and datasets are made publicly available for reproducibility[1].

2 Morphology-aware Language Model

Our modeling objective is to be able to express morphological compositionality in a Transformer-based (Vaswani et al., 2017) language model. For morphologically rich languages such as Kinyarwanda, a set of morphemes (typically a stem and a set of functional affixes) combine to produce a word with a given surface form. This requires an alternative to the ubiquitous BPE tokenization, through which exact sub-word lexical units (i.e. morphemes) are used. For this purpose, we use a morphological analyzer which takes a sentence as input and, for every word, produces a stem, zero or more affixes and assigns a part of speech (POS) tag to each word. This section describes how this morphological information is obtained and then integrated in a two-tier transformer architecture (Figure 1) to learn morphology-aware input representations.

2.1 Morphological Analysis and Part-of-Speech Tagging

Kinyarwanda, the national language of Rwanda, is one of the major Bantu languages (Nurse and Philippson, 2006) spoken in central and eastern Africa. Kinyarwanda has 16 noun classes. Modifiers (demonstratives, possessives, adjectives, numerals) carry a class marking morpheme that agrees with the main noun class. The verbal morphology (Nzeyimana, 2020) also includes subject and object markers that agree with the class of the subject or object. This agreement therefore enables users of the language to approximately disambiguate referred entities based on their classes. We leverage this syntactic agreement property in designing our unsupervised POS tagger.

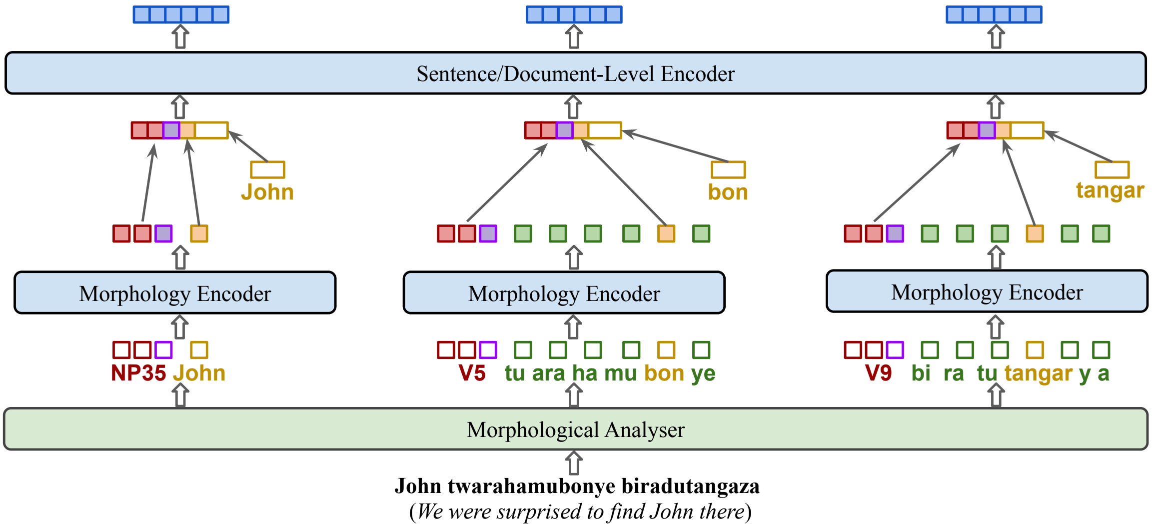

Figure 1: KinyaBERT model architecture: Encoding of the sentence 'John twarahamusanze biradutangaza' (*We were surprised to find John there*). The morphological analyzer produces morphemes for each word and assigns a POS tag to it. The two-tier transformer model then generates contextualized embeddings (**blue** vectors at the top). The **red** colored embeddings correspond to the POS tags, **yellow** is for the stem embeddings, **green** is for the variable length affixes while the **purple** embeddings correspond to the affix set.

Our morphological analyzer for Kinyarwanda was built following finite-state two-level morphology principles (Koskenniemi, 1983; Beesley and Karttunen, 2000, 2003). For every inflectable word type, we maintain a morphotactics model using a directed acyclic graph (DAG) that represents the regular sequencing of morphemes. We effectively model all inflectable word types in Kinyarwanda which include verbals, nouns, adjectives, possessive and demonstrative pronouns, numerals and quantifiers. The morphological analyzer also includes many hand-crafted rules for handling morphographemics and other linguistic regularities of the Kinyarwanda language. The morphological analyzer was independently developed and calibrated by native speakers as a closed source solution before the current work on language modeling. Similar to Nzeyimana (2020), we use a classifier trained on a stemming dataset to disambiguate between competing outputs of the morphological analyzer. Furthermore, we improve the disambiguation quality by leveraging a POS tagger at the phrase level so that the syntactic context can be taken into consideration.

We devise an unsupervised part of speech tagging algorithm which we explain here. Let $x = (x_1, x_2, x_3, ...x_n)$ be a sequence of tokens (e.g. words) to be tagged with a corresponding sequence of tags $y = (y_1, y_2, y_3, ...y_n)$. A sample of actual POS tags used for Kinyarwanda is given in Table 12 the Appendix. Using Bayes' rule, the optimal tag sequence y^* is given by the following equation:

$$\begin{aligned} y^* &= \arg\max_y P(y|x) \\ &= \arg\max_y \frac{P(x|y)P(y)}{P(x)} \\ &= \arg\max_y P(x|y)P(y) \end{aligned} \tag{1}$$

A standard hidden Markov model (HMM) can decompose the result of Equation 1 using first order Markov assumption and independence assumptions into $P(x|y) = \prod_{t=1}^{n} P(x_t|y_t)$ and $P(y) = \prod_{t=1}^{n} P(y_t|y_{t-1})$. The tag sequence y^* can then be efficiently decoded using the Viterbi algorithm (Forney, 1973). A better decoding strategy is presented below.

Inspired by Tsuruoka and Tsujii (2005), we devise a greedy heuristic for decoding y^* using the same first order Markov assumptions but with bidirectional decoding.

First, we estimate the local emission probabilities $P(x_t|y_t)$ using a factored model given in the following equation:

$$\begin{aligned} &P(x_t|y_t) \propto \tilde{P}(x_t|y_t) \\ &\tilde{P}(x_t|y_t) = \tilde{P}_m(x_t|y_t)\tilde{P}_p(x_t|y_t)\tilde{P}_a(x_t|y_t) \end{aligned} \tag{2}$$

In Equation 2, $\tilde{P}_m(x_t|y_t)$ corresponds to the probability/score returned by a morphological disambiguation classifier, representing the uncertainty of the morphology of x_t. $\tilde{P}_p(x_t|y_t)$ corresponds to a local precedence weight between competing POS tags. These precedence weights are manually crafted through qualitative evaluation (See Table 12 in Appendix for examples). $\tilde{P}_a(x_t|y_t)$ quantifies the local neighborhood syntactic agreement between Bantu class markers. When there are two or more agreeing class markers in neighboring words, the tagger should be more confident of the agreeing parts of speech. A basic agreement score can be the number of agreeing class markers within a window of seven words around a given candidate x_t. We manually designed a more elaborate set of agreement rules and their weights for different contexts. Therefore, the actual agreement score $\tilde{P}_a(x_t|y_t)$ is a weighted sum of the matched agreement rules. Each of the unnormalized measures $\tilde{P}$ in Equation 2 is mapped to the $[0, 1]$ range using a sigmoid function $\sigma(z|z_A, z_B)$ given in Equation 3, where z is the score of the measure and $[z_A, z_B]$ is its estimated active range.

$$\sigma(z|z_A, z_B) = [1 + exp(-8\frac{z - z_A}{z_B - z_A})]^{-8} \qquad (3)$$

After estimating the local emission model, we greedily decode $y^*_t = \arg\max y_t\tilde{P}(y_t|x)$ in decreasing order of $\tilde{P}(x_t|y_t)$ using a first order bidirectional inference of $\tilde{P}(y_t|x)$ as given in the following equation:

$$\tilde{P}(y_t|x) =$$
$$\begin{cases} \tilde{P}(x_t|y_t)\tilde{P}(y_t|y^*_{t-1}, y^*_{t+1})\tilde{P}(y^*_{t-1}|x)\tilde{P}(y^*_{t+1}|x) \\ \qquad \text{if both } y^*_{t-1} \text{ and } y^*_{t+1} \text{ have been decoded;} \\ \tilde{P}(x_t|y_t)\tilde{P}(y_t|y^*_{t-1})\tilde{P}(y^*_{t-1}|x) \\ \qquad \text{if only } y^*_{t-1} \text{ has been decoded;} \\ \tilde{P}(x_t|y_t)\tilde{P}(y_t|y^*_{t+1})\tilde{P}(y^*_{t+1}|x) \\ \qquad \text{if only } y^*_{t+1} \text{ has been decoded;} \\ \tilde{P}(x_t|y_t) \text{ otherwise} \end{cases} \qquad (4)$$

The first order transition measures $\tilde{P}(y_t|y_{t-1})$, $\tilde{P}(y_t|y_{t+1})$ and $\tilde{P}(y_t|y_{t-1}, y_{t+1})$ are estimated using count tables computed over the entire corpus by aggregating local emission marginals $\tilde{P}(y_t) = \sum_{x_t} \tilde{P}(x_t, y_t)$ obtained through morphological analysis and disambiguation.

2.2 Morphology Encoding

The overall architecture of our model is depicted in Figure 1. This is a two-tier transformer encoder architecture made of a token-level morphology encoder that feeds into a sentence/document-level encoder. The morphology encoder is made of a small transformer encoder that is applied to each analyzed token separately in order to extract its morphological features. The extracted morphological features are then concatenated with the token's stem embedding to form the input vector fed to the sentence/document encoder. The sentence/document encoder is made of a standard transformer encoder as used in other BERT models. The sentence/document encoder uses untied position encoding with relative bias as proposed in Ke et al. (2020).

The input to the morphology encoder is a set of embedding vectors, three vectors relating to the part of speech, one for the stem and one for each affix when available. The transformer encoder operation is applied to these embedding vectors without any positional information. This is because positional information at the morphology level is inherent since no morpheme repeats and each morpheme always occupies a known (i.e. fixed) slot in the morphotactics model. The extracted morphological features are four encoder output vectors corresponding to the three POS embeddings and one stem embedding. Vectors corresponding to the affixes are left out since they are of variable length and the role of the affixes in this case is to be attended to by the stem and the POS tag so that morphological information can be captured. The four morphological output feature vectors are further concatenated with another stem embedding at the sentence level to form the input vector for the main sentence/document encoder.

The choice of this transformer-based architecture for morphology encoding is motivated by two factors. First, Zaheer et al. (2020) has demonstrated the importance of having "global tokens" such as `[CLS]` token in BERT models. These are tokens that attend to all other tokens in the modeled sequence. These "global tokens" effectively encapsulate some "meaning" of the encoded sequence. Second, the POS tag and stem represent the high level information content of a word. Therefore, having the POS tag and stem embeddings be transformed into morphological features is a viable option. The POS tag and stem embeddings thus serve as the "global tokens" at the morphology encoder level since they attend to all other morphemes that can be associated with them.

In order to capture subtle morphological information, we make one of the three POS embeddings span an affix set vocabulary that is a subset of the all affixes power set. We form an affix set vocabulary $\mathcal{V}_a$ that is made of the N most frequent affix combinations in the corpus. In fact, the morphological model of the language enforces constraints on which affixes can go together for any given part of speech, resulting in an affix set vocabulary that is much smaller than the power set of all affixes. Even with limiting the affix set vocabulary $\mathcal{V}_a$ to a fixed size, we can still map any affix combination to $\mathcal{V}_a$ by dropping zero or very few affixes from the combination. Note that the affix set embedding still has to attend to all morphemes at the morphology encoder level, making it adapt to the whole morphological context. The affix set embedding is depicted by the **purple** units in Figure 1 and a sample of $\mathcal{V}_a$ is given in Table 13 in the Appendix.

2.3 Pre-training Objective

Similar to other BERT models, we use a masked language model objective. Specifically, 15% of all tokens in the training set are considered for prediction, of which 80% are replaced with `[MASK]` tokens, 10% are replaced with random tokens and 10% are left unchanged. When prediction tokens are replaced with `[MASK]` or random tokens, the corresponding affixes are randomly omitted 70% of the time or left in place for 30% of the time, while the units corresponding to POS tags and affix sets are also masked. The pre-training objective is then to predict stems and the associated affixes for all tokens considered for prediction using a two-layer feed-forward module on top of the encoder output.

For the affix prediction task, we face a multi-label classification problem where for each prediction token, we predict a variable number of affixes. In our experiments, we tried two methods. For one, we use the Kullback–Leibler (KL) divergence[2] loss function to solve a regression task of predicting the N-length affix distribution vector. For this case, we use a target affix probability vector $\boldsymbol{a_t} \in \mathbb{R}^N$ in which each target affix index is assigned $\frac{1}{m}$ probability and 0 probability for non-target affixes. Here m is the number of affixes in the word to be predicted and N is the total number of all affixes. We call this method "Affix Distribution Regression" (ADR) and model variant KinyaBERT$_{ADR}$. Alternatively, we use cross entropy loss and just predict the affix set associated with the prediction word; we call this method "Affix Set Classification" (ASC) and the model variant KinyaBERT$_{ASC}$.

3 Experiments

In order to evaluate the proposed architecture, we pre-train KinyaBERT (101M parameters for KinyaBERT$_{ADR}$ and 105M for KinyaBERT$_{ASC}$) on a 2.4 GB of Kinyarwanda text along with 3 baseline BERT models. The first baseline is a BERT model pre-trained on the same Kinyarwanda corpus and with the same position encoding (Ke et al., 2020), same batch size and pre-training steps, but using the standard BPE tokenization. We call this first baseline model BERT$_{BPE}$ (120M parameters). The second baseline is a similar BERT model pre-trained on the same Kinyarwanda corpus but tokenized by a morphological analyzer. For this model, the input is just a sequence of morphemes, in a similar fashion to Mohseni and Tebbifakhr (2019). We call this second baseline model BERT$_{MORPHO}$ (127M parameters). For BERT$_{MORPHO}$, we found that predicting 30% of the tokens achieves better results than using 15% because of the many affixes generated. The third baseline is XLM-R (Conneau et al., 2020) (270M parameters) which is pre-trained on 2.5 TB of multilingual text. We evaluate the above models by comparing their performance on downstream NLP tasks.

Text size	2.4 GB

Table 2: Summary of the pre-training corpus.

3.1 Pre-training details

KinyaBERT model was implemented using Pytorch version 1.9. The morphological analyzer and POS tagger were implemented in a shared library using POSIX C. Morphological parsing of the corpus was performed as a pre-processing step, taking 20 hours to segment the 390M-token corpus on an 12-core desktop machine. Pre-training was performed using RTX 3090 and RTX 2080Ti desktop GPUs. Each KinyaBERT model takes on average 22 hours to train for 1000 steps on one RTX 3090 GPU or 29 hours on one RTX 2080Ti GPU. Baseline models (BERT$_{BPE}$ and BERT$_{MORPHO}$) were pre-trained on cloud tensor processing units (TPU v3-8 devices each with 128 GB memory) us-

[2] `https://en.wikipedia.org/wiki/Kullback%E2%80%93Leibler_divergence`

ing PyTorch/XLA[3] package and a TPU-optimized fairseq toolkit (Ott et al., 2019). Pre-training on TPU took 2.3 hours per 1000 steps. The baselines were trained on TPU because there were no major changes needed to the existing RoBERTA (base) architecture implemented in fairseq and the TPU resources were available and efficient. In all cases, pre-training batch size was set to 2560 sequences, with maximum 512 tokens in each sequence. The maximum learning rates was set to 4×10^{-4} which is achieved after 2000 steps and then linearly decays. Our main results and ablation results were obtained from models pre-trained for 32K steps in all cases. Other pre-training details, model architectural dimensions and other hyper-parameters are given in the Appendix.

3.2 Evaluation tasks

Machine translated GLUE benchmark – The General Language Understanding Evaluation (GLUE) benchmark (Wang et al., 2019) has been widely used to evaluate pre-trained language models. In order to assess KinyaBERT performance on such high level language tasks, we used Google Translate API to translate a subset of the GLUE benchmark (MRPC, QNLI, RTE, SST-2, STS-B and WNLI tasks) into Kinyarwanda. CoLA task was left because it is English-specific. MNLI and QQP tasks were also not translated because they were too expensive to translate with Google's commercial API. While machine translation adds more noise to the data, evaluating on this dataset is still relevant because all models compared have to cope with the same noise. To understand this translation noise, we also run user evaluation experiments, whereby four volunteers proficient in both English and Kinyarwanda evaluated a random sample of 6000 translated GLUE examples, and assigned a score to each example on a scale from 1 to 4 (See Table 11 in Appendix). These scores help us characterize the noise in the data and contextualize our results with regards to other GLUE evaluations. Results on these GLUE tasks are shown in Table 3.

Named entity recognition (NER) – We use the Kinyarwanda subset of the MasakhaNER dataset (Adelani et al., 2021) for NER task. This is a high quality NER dataset annotated by native speakers for major African languages including Kinyarwanda. The task requires predicting four entity types: Persons (PER), Locations (LOC), Organizations (ORG), and date and time (DATE). Results on this NER task are presented in Table 4.

News Categorization Task (NEWS) – For a document classification experiment, we collected a set of categorized news articles from seven major news websites that regularly publish in Kinyarwanda. The articles were already categorized, so no more manual labeling was needed. This dataset is similar to Niyongabo et al. (2020), but in our case, we limited the number collected articles per category to 3000 in order to have a more balanced label distribution (See Table 10 in the Appendix). The final dataset contains a total of 25.7K articles spanning 12 categories and has been split into training, validation and test sets in the ratios of 70%, 5% and 25% respectively. Results on this NEWS task are presented in Table 5.

For each evaluation task, we use a two-layer feed-forward network on top of the sentence encoder as it is typically done in other BERT models. The fine-tuning hyper-parameters are presented in Table 14 in the Appendix.

3.3 Main results

The main results are presented in Table 3, Table 4, and Table 5. Each result is the average of 10 independent fine-tuning runs. Each average result is shown with the standard deviation of the 10 runs. Except for XLM-R, all other models are pre-trained on the same corpus (See Table 2) for 32K steps using the same hyper-parameters.

On the GLUE task, KinyaBERT$_{ASC}$ achieves 4.3% better average score than the strongest baseline. KinyaBERT$_{ASC}$ also leads to more robust results on multiple tasks. It is also shown that having just a morphological analyzer is not enough: BERT$_{MORPHO}$ still under-performs even though it uses morphological tokenization. Multilingual XLM-R achieves least performance in most cases, possibly because it was not pre-trained on Kinyarwanda text and uses inadequate tokenization.

On the NER task, KinyaBERT$_{ADR}$ achieves best performance, about 3.2% better average F1 score than the strongest baseline. One of the architectural differences between KinyaBERT$_{ADR}$ and KinyaBERT$_{ASC}$ is that KinyaBERT$_{ADR}$ uses three POS tag embeddings while KinyaBERT$_{ASC}$ uses two. Assuming that POS tagging facilitates named entity recognition, this empirical result suggests that increasing the amount of POS tag information

in the model, possibly through diversification (i.e. multiple POS tag embedding vectors per word), can lead to better NER performance.

The NEWS categorization task resulted in differing performances between validation and test sets. This may be a result that solving such task does not require high level language modeling but rather depends on spotting few keywords. Previous research on a similar task (Niyongabo et al., 2020) has shown that simple classifiers based on TF-IDF features suffice to achieve best performance.

The morphological analyzer and POS tagger inherently have some level of noise because they do not always perform with perfect accuracy. While we did not have a simple way of assessing the impact of this noise in this work, we can logically expect that the lower the noise the better the results could be. Improving the morphological analyzer and POS tagger and quantitatively evaluating its accuracy is part of future work. Even though our POS tagger uses heuristic methods and was evaluated mainly through qualitative exploration, we can still see its positive impact on the pre-trained language model. We did not use previous work on Kinyarwanda POS tagging because it is largely different from this work in terms of scale, tag dictionary and dataset size and availability.

We plot the learning curves during fine-tuning process of KinyaBERT and the baselines. The results in Figure 2 indicate that KinyaBERT fine-tuning has better convergence across all tasks. Additional results also show that positional attention (Ke et al., 2020) learned by KinyaBERT has more uniform and smoother relative bias while BERT$_{BPE}$ and BERT$_{MORPHO}$ have more noisy

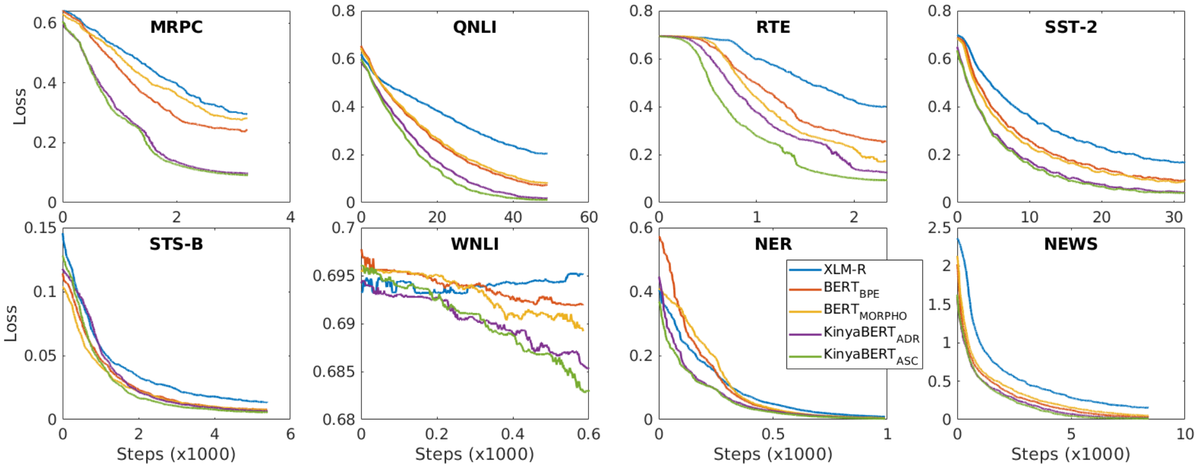

Figure 2: Comparison of fine-tuning loss curves between KinyaBERT and baselines on the evaluation tasks. KinyaBERT$_{ASC}$ achieves the best convergence in most cases, indicating better effectiveness of its model architecture and pre-training objective.

relative positional bias (See Figure 3 in Appendix). This is possibly an indication that KinyaBERT allows learning better word-relative syntactic regularities. However, this aspect needs to be investigated more systematically in future research.

While the main sentence/document encoder of KinyaBERT is equivalent to a standard BERT "BASE" configuration on top of a small morphology encoder, overall, the model actually decreases the number of parameters by more than 12% through embedding layer savings. This is because using morphological representation reduces the vocabulary size. Using smaller embedding vectors at the morphology encoder level also significantly reduces the overall number of parameters. Table 8 in Appendix shows the vocabulary sizes and parameter count of KinyaBERT in comparison to the baselines. While the sizing of the embeddings was done essentially to match BERT "BASE" configuration, future studies can shed more light on how different model sizes affect performance.

3.4 Ablation study

We conducted an ablation study to clarify some of the design choices made for KinyaBERT architecture. We make variations along two axes: (i) morphology input and (ii) pre-training task, which gave us four variants that we pre-trained for 32K steps and evaluated on the same downstream tasks.

- **AFS→STEM+ASC**: Morphological features are captured by two POS tag and one affix set vectors. We predict both the stem and affix set. This corresponds to KinyaBERT$_{ASC}$ presented in the main results.
- **POS→STEM+ADR**: Morphological features are carried by three POS tag vectors and we predict the stem and affix probability vector. This corresponds to KinyaBERT$_{ADR}$.
- **AVG→STEM+ADR**: Morphological features are captured by two POS tag vectors and the pointwise average of affix hidden vectors from the morphology encoder. We predict the stem and affix probability vector.
- **STEM→STEM**: We omit the morphology encoder and train a model with only the stem parts without affixes and only predict the stem.

Ablation results presented in Table 6 indicate that using affix sets for both morphology encoding and prediction gives better results for many GLUE tasks. The under-performance of "STEM→STEM" on high resource tasks (QNLI and SST-2) is an indication that morphological information from affixes is important. However, the utility of this information depends on the task as we see mixed results on other tasks.

Due to a large design space for a morphology-aware language model, there are still a number of other design choices that can be explored in future studies. One may vary the amount of POS tag embeddings used, vary the size affix set vocabulary or the dimension of the morphology encoder embeddings. One may also investigate the potential of other architectures for the morphology encoder, such as convolutional networks. Our early attempt of using recurrent neural networks (RNNs) for the morphology encoder was abandoned because it was too slow to train.

4 Related Work

BERT-variant pre-trained language models (PLMs) were initially pre-trained on monolingual high-resource languages. Multilingual PLMs that include both high-resource and low-resource languages have also been introduced (Devlin et al., 2019; Conneau et al., 2020; Xue et al., 2021; Chung et al., 2020). However, it has been found that these multilingual models are biased towards high-resource languages and use fewer low quality and uncleaned low-resource data (Kreutzer et al., 2022). The included low-resource languages are also very limited because they are mainly sourced from Wikipedia articles, where languages with few articles like Kinyarwanda are often left behind (Joshi et al., 2020; Nekoto et al., 2020).

Joshi et al. (2020) classify the state of NLP for Kinyarwanda as "Scraping-By", meaning it has been mostly excluded from previous NLP research, and require the creation of dedicated resources and models. Kinyarwanda has been studied mostly in descriptive linguistics (Kimenyi, 1976, 1978a,b, 1988; Jerro, 2016). Few recent NLP works on Kinyarwanda include Morphological Analysis (Muhirwe, 2009; Nzeyimana, 2020), Text Classification (Niyongabo et al., 2020), Named Entity Recognition (Rijhwani et al., 2020; Adelani et al., 2021; Sälevä and Lignos, 2021), POS tagging (Garrette and Baldridge, 2013; Garrette et al., 2013; Duong et al., 2014; Fang and Cohn, 2016; Cardenas et al., 2019), and Parsing (Sun et al., 2014; Mielens et al., 2015). There is no prior study on pre-trained language modeling for Kinyarwanda.

There are very few works on monolingual PLMs for African languages. To the best of our knowledge there is currently only AfriBERT (Ralethe, 2020) that has been pre-trained on Afrikaans, a language spoken in South Africa. In this paper, we aim to increase the inclusion of African languages in NLP community by introducing a PLM for Kinyarwanda. Differently to the previous works (see Table 15 in Appendix) which solely pre-trained unmodified BERT models, we propose an improved BERT architecture for morphologically rich languages.

Recently, there has been a research push to improve sub-word tokenization by adopting character-based models (Ma et al., 2020; Clark et al., 2022). While these methods are promising for the "language-agnostic" case, they are still solely based on the surface form of words, and thus have the same limitations as BPE when processing morphologically rich languages. We leave it to future research to empirically explore how these character-based methods compare to morphology-aware models.

5 Conclusion

This work demonstrates the effectiveness of explicitly incorporating morphological information in language model pre-training. The proposed two-tier Transformer architecture allows the model to represent morphological compositionality. Experiments conducted on Kinyarwanda, a low resource morphologically rich language, reveal significant performance improvement on several downstream NLP tasks when using the proposed architecture. These findings should motivate more research into morphology-aware language models.

On the Calibration of Pre-trained Language Models using Mixup Guided by Area Under the Margin and Saliency

Seo Yeon Park and Cornelia Caragea
Computer Science
University of Illinois Chicago
`spark313@uic.edu` `cornelia@uic.edu`

Abstract

A well-calibrated neural model produces confidence (probability outputs) closely approximated by the expected accuracy. While prior studies have shown that mixup training as a data augmentation technique can improve model calibration on image classification tasks, little is known about using mixup for model calibration on natural language understanding (NLU) tasks. In this paper, we explore mixup for model calibration on several NLU tasks and propose a novel mixup strategy for pre-trained language models that improves model calibration further. Our proposed mixup is guided by both the Area Under the Margin (AUM) statistic (Pleiss et al., 2020) and the saliency map of each sample (Simonyan et al., 2013). Moreover, we combine our mixup strategy with model miscalibration correction techniques (i.e., label smoothing and temperature scaling) and provide detailed analyses of their impact on our proposed mixup. We focus on systematically designing experiments on three NLU tasks: natural language inference, paraphrase detection, and commonsense reasoning. Our method achieves the lowest expected calibration error compared to strong baselines on both in-domain and out-of-domain test samples while maintaining competitive accuracy.

1 Introduction

Training a well-calibrated classifier that produces a match between confidence (the probability output that a model assigns to a prediction) and correctness (accuracy), is important in modern neural networks. As an example, if an AI-based application *knows what it does not know*, or in other words, the chance that the current prediction is wrong, a human is more helpful to correct the error. However, many works reveal that current deep neural networks are prone to over-confidence, which implies that the models' confidence is not reliable (Guo et al., 2017). This is a critical issue on the deployment of AI-based user applications such as the healthcare domain (Zhu et al., 2018; Li et al., 2019) or safety-critical domain (Sarabadani, 2019) due to the problem of prediction trustworthiness.

Recently, the study of calibration on neural network models especially on natural language processing tasks has started to receive attention. To overcome the problem of miscalibration, numerous suggestions on how to address it have been proposed. For example, Guo et al. (2017) revealed that using temperature scaling before the final softmax layer reduces calibration errors. Müller et al. (2019), Kumar and Sarawagi (2019), and Wang et al. (2020a) found that label smoothing and its variants yield better calibration for neural machine translation. Desai and Durrett (2020) also reported that the aforementioned miscalibration correction methods can be applied to calibrate pre-trained language models which are often miscalibrated potentially due to over-parameterization.

Mixup (Zhang et al., 2018) is a data augmentation method for deep neural networks in which additional samples are generated during training by combining random pairs of training inputs and their associated labels. While simple to implement, mixup has been shown to improve both predictive performance and model calibration, particularly on image classification tasks due to its regularization effect through data augmentation (Thulasidasan et al., 2019). The recent success of mixup on image classification has led to the development of various mixup strategies for NLU especially those that use hidden state representations (Guo et al., 2019a; Chen et al., 2020; Zhang et al., 2020; Sun et al., 2020; Kong et al., 2020; Yin et al., 2021). However, most prior works on NLU focus on performance improvement using mixup rather than model calibration. Despite its benefits for calibration, a mixup for correcting miscalibrated predictions is still an under-explored topic in NLU. While Kong et al. (2020) explored BERT (Devlin et al., 2019) cali-

bration using mixup for both in-domain and out-of-domain, they only focused on generating mixup samples by utilizing the distance between instances in the feature space. In contrast, we propose a novel mixup method, in which we first leverage the behavior of a model on individual samples during training (training dynamics), which can reveal samples with distinct pronounced characteristics—whether they are easy-to-learn or hard-to-learn/ambiguous for the model, and then we generate mixup samples by mixing easy-to-learn with hard-to-learn/ambiguous samples according to their similarity/dissimilarity provided by saliency maps. Saliency maps capture how much each data portion contributes to the final classification decision of a sample (Simonyan et al., 2013). Intuitively, easy-to-learn samples help with model optimization, whereas hard-to-learn or potentially ambiguous samples are essential for learning since they are the most challenging for the model (Swayamdipta et al., 2020), and mixing them using saliency maps can yield better calibrated models (more realistic model confidence), e.g., mixing easy-to-learn with hard-to-learn/ambiguous samples by similarity in saliency maps can benefit in-domain calibration and by dissimilarity can benefit out-of-domain calibration. To monitor training dynamics, we use the Area Under the Margin (AUM) statistic (Pleiss et al., 2020) which measures how different a true label for a sample is compared to a model's *beliefs* at each epoch and is calculated as the average difference between the logit values for a sample's assigned class and its highest non-assigned class across training epochs.

Moreover, we combine our mixup with well-known miscalibration correction methods such as label smoothing and temperature scaling (Guo et al., 2017) to investigate their impact on our proposed mixup. We conduct a comprehensive set of experiments using BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019) to show the efficacy of our mixup approach by testing on three NLU tasks: natural language inference, paraphrase detection, and commonsense reasoning. We achieve the lowest Expected Calibration Error (ECE) without accuracy drops in comparison with strong baseline methods. Our contributions are as follows:

- We propose a novel mixup method which is guided by AUM and saliency signals and is targeted at improving model calibration. Specifically, we compare logits to categorize samples into two sets (i.e., a set of easy-to-learn samples and another set of hard-to-learn/ambiguous samples), and interpolate samples across these two sets by finding the most similar and most dissimilar samples from the other set while leveraging saliency (to compute sample similarities) for pre-trained language models' calibration on in-domain and out-of-domain data.
- We combine our method with miscalibration correction techniques (i.e., label smoothing, temperature scaling) to investigate their impact on our proposed mixup.
- We conduct comprehensive experiments showing that our method achieves the lowest expected calibration errors (ECEs) on both in-domain and out-of-domain samples compared with strong baselines without accuracy drops on multiple NLU tasks, namely, natural language inferences, paraphrase detection, and commonsense reasoning.

2 Related Work

Model Calibration Calibration on NLU tasks has been widely studied in related literature. Nguyen and O'Connor (2015) provided the method of how to analyze the calibration of non-neural NLP models. Guo et al. (2017) examined the calibration of modern deep neural networks and revealed that techniques such as temperature scaling and dropout affect the calibration on binary/multi-class classification tasks. Wang et al. (2020b) investigated the calibration of neural machine translation models and found that inference suffers from serious miscalibration. Jagannatha and Yu (2020) demonstrated that neural networks show high calibration error on structured predictions such as NER, POS, and QA, and proposed to use a binary class forecaster to calibrate the predictor confidence for a defined output entity of interest. Desai and Durrett (2020) explored pre-trained language models' calibration in combination with temperature scaling and label smoothing both on in-domain and out-of-domain datasets. Jung et al. (2020) jointly optimized two objectives (a cross-entropy loss and a calibration loss) and directly penalized the difference between the predicted and the true posterior probabilities dynamically over the training steps. He et al. (2021) obtained better calibration on natural language understanding tasks by augmenting and training the classifier jointly with an energy-based model using noise-contrastive estimation.

Mixup Mixup (Zhang et al., 2018) is a method for data augmentation in which additional samples are generated during training by convexly combining random pairs and their associated labels, and aims to alleviate overfitting. Verma et al. (2019) showed that manipulating hidden representations rather than manipulating input-level features on mixup results in better regularization effects due to the fact that it encourages the neural network to focus more on representations of the real training examples in a low dimensional subspace. Many works have empirically noticed regularization effects that improve model performance on deep neural networks. For example, Guo et al. (2019a) explored the NLU specific mixup strategy by using sentence and word embeddings on CNNs and LSTMs to add performance gains in supervised text classification. Chen et al. (2020) proposed mixup for semi-supervised learning in which labeled and unlabeled samples are interpolated with their hidden representations to improve the performance of text classification. Zhang et al. (2020) explored mixup for sequence labeling tasks with active learning to improve the performance of supervised sequence labeling tasks. Yin et al. (2021) proposed mixup that interpolates every instance in a mini-batch to boost the performance of NLU tasks on the pre-trained language model RoBERTa (Liu et al., 2019). Similar to us, Yoon et al. (2021) explored mixup by incorporating saliency signals to generate augmented samples. Precisely, they use saliency signals to select a span of text from one sample to be replaced with another text span from another sample. However, in contrast, our method first divides data samples into two categories (easy-to-learn and hard-to-learn/ambiguous categories) according to their AUM (Pleiss et al., 2020) distribution monitored over training epochs and then uses saliency to find the most similar/dissimilar samples across these two data categories.

Recently, several works started to explore mixup for NLU model calibration. For example, Thulasidasan et al. (2019) investigated the impact of mixup for model calibration of NLU but only explored in-domain settings with simple deep learning architecture such as CNNs. Kong et al. (2020) explored BERT calibration using mixup as a regularization component on in-domain and out-of-domain. However, their mixup method only relied on the feature space distance between samples. In contrast, we explore a novel mixup method in which we categorize the training samples into two sets using AUM (Pleiss et al., 2020) and combine samples across these two sets based on saliency signals, for in-domain and out-of-domain model calibration.

3 Approach

3.1 Mixup

Background Let $\mathcal{D}_{train} = \{(x_i, y_i)\}_{i=1,\cdots,n}$ be a training set and f a language model. Mixup training generates vicinity training samples according to the rule introduced in Zhang et al. (2018):

$$\begin{aligned} \tilde{x} &= \lambda x_i + (1-\lambda)x_j \\ \tilde{y} &= \lambda y_i + (1-\lambda)y_j \end{aligned} \tag{1}$$

where x_i and x_j are two randomly sampled input points, y_i and y_j are their associated one-hot encoded labels, and λ is a mixing ratio sampled from a Beta(α, α) distribution with a hyper-parameter α. In mixup, training data is augmented by linearly interpolating training samples in the input space.

3.2 Proposed Approach

We propose a mixup method targeted at improving model calibration that synthesizes samples guided by the Area Under the Margin (AUM) (Pleiss et al., 2020) and saliency (Simonyan et al., 2013).

Data Categorization In our method, we first categorize $\mathcal{D}_{train}$ into two sets (a set of easy-to-learn samples and a set of hard-to-learn/ambiguous samples) according to the AUM of each sample. Given a sample (x_i, y_i), we compute $AUM(x_i, y_i)$ as the area under the margin averaged across all training epochs T. Specifically, at some epoch $t \in T$, the margin is defined as:

$$M^t(x_i, y_i) = z_{y_i} - max_{y_i!=k}(z_k) \tag{2}$$

where $M^t(x_i, y_i)$ is the margin of example x_i with gold label y_i, z_{y_i} is the logit corresponding to the gold label y_i, and $max_{y_i!=k}(z_k)$ is the largest *other* logit corresponding to label k not equal to y_i. Precisely, the margin measures how different a gold label is compared to a model's *beliefs* at each epoch t. The AUM of (x_i, y_i) across all epochs is:

$$AUM(x_i, y_i) = \frac{1}{T}\sum_{t=1}^{T} M^t(x_i, y_i) \tag{3}$$

Intuitively, the samples with high AUM are easy-to-learn (the model's belief matches the gold label), but they are essential for model optimization, while

Algorithm 1 : Identify high/low AUM samples

```
Require: $\mathcal{D}_{train} = \{(x_i, y_i)\}_{i=1,\cdots,n}$; model $f$
function DATA-CATEGORIZATION($\mathcal{D}_{train}$)
    $\mathcal{D}_{high} \leftarrow \emptyset, \mathcal{D}_{low} \leftarrow \emptyset$
    Train $f$ for $T$ epochs and compute $AUM(x_i, y_i)$ for each $i$ as in Eq. (3)
    for each $(x_i, y_i) \in \mathcal{D}_{train}$ do
        if $AUM(x_i, y_i) < median$ then
            $\mathcal{D}_{low} \leftarrow \mathcal{D}_{low} \cup (x_i, y_i)$
        else if $AUM(x_i, y_i) \geq median$ then
            $\mathcal{D}_{high} \leftarrow \mathcal{D}_{high} \cup (x_i, y_i)$
        end if
    end for
    return $\mathcal{D}_{high}, \mathcal{D}_{low}$
end function
```

Algorithm 2 : Proposed Mixup

```
Require: $\mathcal{D}_{train} = \{(x_i, y_i)\}_{i=1,\cdots,n}$; model $f$
$\mathcal{D}_{high}, \mathcal{D}_{low} \leftarrow$ DATA-CATEGORIZATION($\mathcal{D}_{train}$)
for $k$ := 0 to T do
    $Total\_Loss \leftarrow 0$
    for $i$ := 0 to $|\mathcal{D}_{train}|$ do
        $Loss \leftarrow CrossEntropy(f(x_i), y_i)$
        Construct a saliency map $S$ by computing the gradient of $Loss$ with respect to $\mathbf{z}$
        if $(x_i, y_i) \in \mathcal{D}_{high}$ then:
            Find the most similar/dissimilar samples from $\mathcal{D}_{low}$ using Eq. (4)
        else if $(x_i, y_i) \in \mathcal{D}_{low}$ then:
            Find the most similar/dissimilar samples from $\mathcal{D}_{high}$ using Eq. (5)
        end if
        Generate two mixup samples, one for $(x_i, y_i)$ and its most similar sample and another for $(x_i, y_i)$ and its most dissimilar sample, using Eq. 1.
        Compute $CrossEntropy$ loss for each mixup sample
        $Loss \leftarrow \beta Loss + \gamma Loss' + \delta Loss''$
    end for
    $Total\_Loss \leftarrow Total\_Loss + Loss$
    Update the model weights
end for
```

the samples with low AUM are hard-to-learn or ambiguous (and hence they are the most challenging for the model), but they are essential for learning. Our proposed mixup method first splits $\mathcal{D}_{train}$ into two data categories depending on whether the AUM value is high or low, namely, $\mathcal{D}_{high}$ and $\mathcal{D}_{low}$. In experiments, we compute the median AUM over the entire training samples and use it as a threshold to split the dataset. If a sample has a lower AUM than the threshold, we add the sample to $\mathcal{D}_{low}$, otherwise we add it to $\mathcal{D}_{high}$. Accordingly, we balance $\mathcal{D}_{high}$ and $\mathcal{D}_{low}$, but other splits are possible. We then conduct a mixup operation by referring to each other set. Mixing easy-to-learn and hard-to-learn adjusts the difficulty of samples and hence adjusts models' confidence according to samples' difficulties and yields better calibrated models. The data categorization step is summarized in Algorithm 1.

Mixup using Saliency Signals We conduct a mixup operation on the two data categories generated by Algorithm 1 using saliency signals (as detailed below). For the mixup, rather than selecting random samples from $\mathcal{D}_{high}$ and $\mathcal{D}_{low}$ to mix, we utilize saliency signals to select samples. To measure saliency, gradient-based methods are usually used for saliency computation (Li et al., 2016; Rei and Søgaard, 2018; Yoon et al., 2021). Following this idea, we simply compute the gradient of the classification loss L with respect to each logit value $z_i \in \mathbf{z}$ and take the absolute value of the gradient components as the saliency map or signature S for a sample $(x_i, y_i) \in \mathcal{D}_{train}$. For a sample (x_i, y_i), we then leverage its saliency map S to find the most similar and most dissimilar samples from the other data category that (x_i, y_i) does not belong to according to its AUM, in order to calibrate in-domain and out-of-domain data. For example, if $(x_i, y_i) \in \mathcal{D}_{high}$, we find its most similar sample (x'_i, y'_i) and its most dissimilar sample (x''_i, y''_i) from $\mathcal{D}_{low}$, that return the largest and smallest cosine similarity, respectively, with the saliency map S of (x_i, y_i). That is, the most similar and most dissimilar samples to $(x_i, y_i) \in \mathcal{D}_{high}$ are calculated as follows:

$$\begin{aligned}(x'_i, y'_i) &= \underset{(x_j, y_j) \in \mathcal{D}_{low}}{\text{argmax}} \; CosSim(S, S^{(x_j, y_j)}) \\ (x''_i, y''_i) &= \underset{(x_j, y_j) \in \mathcal{D}_{low}}{\text{argmin}} \; CosSim(S, S^{(x_j, y_j)})\end{aligned} \tag{4}$$

Similarly, if (x_i, y_i) belongs to $\mathcal{D}_{low}$, we find the most similar/dissimilar samples from $\mathcal{D}_{high}$ that return the largest/smallest cosine similarity with S

as follows:

$$\begin{aligned}(x'_i, y'_i) &= \underset{(x_j,y_j)\in\mathcal{D}_{high}}{\operatorname{argmax}} \; CosSim(S, S^{(x_j,y_j)}) \\ (x''_i, y''_i) &= \underset{(x_j,y_j)\in\mathcal{D}_{high}}{\operatorname{argmin}} \; CosSim(S, S^{(x_j,y_j)})\end{aligned} \tag{5}$$

We then generate two mixup samples for a given sample (x_i, y_i) by interpolating the selected samples, which are the most similar sample (x'_i, y'_i), and the most dissimilar sample (x''_i, y''_i). For the mixup operation, we follow the original mixing ratio sampling strategy which is shown in Eq. (1). The ratio λ is sampled from a Beta(α, α) distribution with a hyper-parameter α.

Intuitively, by synthesizing the original sample and the most similar sample from the other data category, we calibrate in-domain data. The augmented sample mimics in-domain sample since it aligns the most with the original sample. Furthermore, by selecting the sample from the other category, we allow the generated mixup sample to combine easy-to-learn and hard-to-learn samples properly. By synthesizing the original and the most dissimilar sample from the other data category, we calibrate out-of-domain data. The augmented sample mimics out-of-domain instances since we pick a sample that is the most dissimilar to the original sample. As above, by selecting the sample from the other category, we allow the augmented sample to contain both information of easy-to-learn and hard-to-learn samples, useful for both optimization and learning. Note that our mixup method mixes samples on the level of `[CLS]` hidden state representations generated by task-specific layer on top of the pre-trained language model. We summarize the process in Algorithm 2. We combine each loss by weighted sum (see Alg. 2) where β, γ, δ are hyper-parameters that sum up to 1. In our experiments, we conduct our mixup operation using mini-batch SGD to update the model weights. Note that other saliency measures are possible to compute similarity/dissimilarity between samples and will be an interesting future direction.

3.3 Calibration Metrics

A model is perfectly calibrated when the confidence estimate $\hat{p}$ of the model is equal to true probability (accuracy) $\mathbb{P}(\hat{y} = y|\hat{p}) = \hat{p}$. (Naeini et al., 2015; Guo et al., 2017; Desai and Durrett, 2020). This can be empirically approximated by discretizing the probability interval into a fixed number of bins $M = 10$ where each bin b_m contains predicted probabilities that encompass the interval. The expected calibration error (ECE) is calculated by weighting the average of the difference between each bin's accuracy and confidence as follows:

$$\text{acc}(b_m) = \frac{1}{|b_m|}\sum_{i\in b_m} \mathbb{1}(\hat{y}_i = y_i)$$

$$\text{conf}(b_m) = \frac{1}{|b_m|}\sum_{i\in b_m} \hat{p}_i$$

$$\text{ECE} = \sum_{m=1}^{M} \frac{|b_m|}{N}|\text{acc}(b_m) - \text{conf}(b_m)|$$

where N is the total number of predictions.

3.4 Miscalibration Correction Methods

We explore the combination of miscalibration correction methods (described below) with mixup to investigate their impact on our proposed mixup for model calibration.

Label Smoothing (LS) In supervised learning, one-hot encoded labels fail to provide uncertainty of inputs due to the fact that all the probability mass is given to one class. This results in over-confident models since the largest logit becomes larger than the others which removes the uncertainty of label space. Label smoothing (LS) is a solution to penalize this by preventing the models from becoming over-confident. In this work, we incorporate label smoothing with our proposed mixup. We generate smoothed one-hot target signal while creating mixup instances by distributing $\frac{\sigma}{|y|-1}$ mass over non ground-truth classes, where $\sigma \in (0, 1)$ is a hyper-parameter and $|y|$ is the number of classes.[1]

Temperature Scaling (TS) Temperature scaling (TS) is a post-processing step which re-scales the logit vector $\mathbf{z}$ using a single scale parameter temperature, $T > 0$ for all classes. TS has the effect of softening the outputs to be uniform with $T > 1$, while $T \to 0$ has the effect of collapsing probability mass to one class. We explore the effect of TS when incorporated with our proposed mixup.

4 Experiments

4.1 Tasks and Datasets

We evaluate our calibration-targeted mixup on three natural language understanding tasks: natural lan-

---

[1] For example, the smoothed one-hot target of [1,0,0] is [0.99, 0.0005, 0.0005] when $\sigma = 0.001$ and $|y| = 3$.

guage inference, paraphrase detection, and commonsense reasoning. We evaluate the models in-domain (training and testing on data from the same distribution) and out-of-domain (training and testing on data from different distributions). Mixup reduces the number of undesirable oscillations when predicting especially on out-of-distribution samples (Zhang et al., 2018). Hence, effective mixup should be less prone to over-fitting when handling out-of-distribution data. To test the benefits of our proposed method for pre-trained language model calibration, we use in-domain trained models to predict out-of-distribution test samples. We describe our in-domain and out-of-domain sets as follows.

Natural Language Inference Stanford Natural Language Inference (SNLI) is a natural language inference task to predict if the relation between a hypothesis and a premise is *entailment, contradiction,* or *neutral* (Bowman et al., 2015). Multi-Genre Natural Language Inference (MNLI) captures natural language inference with more diverse domains (Williams et al., 2018) than SNLI.

Paraphrase Detection Quora Question Pairs (QQP) is a paraphrase detection task to test if two questions are semantically equivalent (Iyer et al., 2017). TwitterPPDB (TPPDB) is to determine whether sentence pairs from Twitter convey similar semantics when they share URLs (Lan et al., 2017)

Commonsense Reasoning Situations With Adversarial Generations (SWAG) is a commonsense reasoning task to choose the most plausible continuation of a sentence among four candidates (Zellers et al., 2018). HellaSWAG is a dataset built using adversarial filtering to generate challenging out-of-domain samples. It is distributionally different in that its examples exploit statistical biases in pre-trained models.

4.2 Comparison Methods

In this work, we explore the mixup effects on NLU with the goal of producing better calibrated models, in particular pre-trained language models, which are BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019). We consider the following baselines:

- **Pre-trained Language Models** : Pre-trained language models fine-tuning on each downstream task using BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019).
- **Mixup** (Zhang et al., 2018; Thulasidasan et al., 2019): Mixup augments training data by linearly interpolating randomly selected training samples in the input space. The interpolation of Mixup is performed on the input embeddings obtained from the first layer of the language model.
- **Manifold-mixup (M-mixup)** (Verma et al., 2019) : An extension of Mixup, which interpolates training samples in the hidden feature space. The interpolation of Manifold-mixup is performed on the features obtained from the last layer of the language model.

Each method is compared with two variants where miscalibration correction methods (label smoothing, LS and temperature scaling, TS) are applied.[2]

4.3 Implementation Details

We use the same set of hyper-parameters across all tasks as Desai and Durrett (2020) for a fair comparison. We train models with a maximum of 3 epochs. For BERT, we set batch size of 16, a learning rate of 1e-5, gradient clip of 1.0, and no weight decay. For RoBERTa, we set batch size of 32, a learning rate of 2e-5, gradient clip of 1.0, and weight decay of 0.1. We follow the published train/validation/test split by Desai and Durrett (2020).[3] For mixup, we use a mixing ratio sampling strategy hyper-parameter $\alpha = 0.4$. We use loss weight hyper-parameters, β, γ, δ, values as $0.8/0.1/0.1$ respectively. We did hyper-parameter search for label smoothing $\sigma \in [0.001, 0.003, 0.01, 0.03, 0.1, 0.3]$. We use $\sigma = 0.01/0.03/0.3$ for BERT, $\sigma = 0.003/0.03/0.3$ for RoBERTa on SNLI/QQP/SWAG, respectively. We use threshold values for splitting data into two groups $\mathcal{D}_{high}$ and $\mathcal{D}_{low}$ (the median AUM over full training samples) as $3.5/4.4/2.5$ for BERT, $3.4/4.0/2.7$ for RoBERTa on SNLI/QQP/SWAG, respectively. For all results, we report the mean across five training runs with random restarts. Finally, all experiments are conducted on a single NVIDIA RTX A5000 24G GPU with a total time for fine-tuning all models being under 24 hours. Temperature scaling (TS) searches are performed in the range of [0.01,5.0] with a granularity of 0.01 using development datasets. TS is completed very fast since it uses separate cached logits.

---

[2] For vanila pre-trained language models with/without label smoothing results, we use the reported results from Desai and Durrett (2020).

Table 1: Expected Calibration Error (ECE) in percentage (%) on BERT (top) and RoBERTa (bottom). Bold text shows the best ECE. Lower ECE implies better-calibrated models. We report the mean ECE across five runs with random restarts. The subscript represents the corresponding standard deviation (e.g., $1.29_{0.4}$ indicates 1.29 ± 0.4).

4.4 Results

We show the comparison of experimental results (ECE) on BERT and RoBERTa in Table 1. For each task, we train the model on in-domain training set, and evaluate its expected calibration errors (ECEs) on in-domain and out-of-domain test sets. We make the following observations:

First, for in-domain data, label smoothing (LS) does not exhibit its effectiveness on pre-trained language models' calibration. Specifically, for in-domain data, pre-trained language models with LS (i.e., BERT+LS/RoBERTa+LS) achieve higher expected calibration errors (ECEs) compared with vanilla pre-trained language models (i.e., BERT/RoBERTa) on all tasks. In contrast, out-of-domain gains benefit from LS (except RoBERTa on MNLI). From these results, we conclude that simply incorporating label uncertainty (through label smoothing) is not an effective regularization method since LS does not consistently improve the model calibration (especially for the in-domain setting). While temperature scaling (TS) corrects the miscalibration of vanilla pre-trained language models (see BERT/RoBERTa No TS vs. TS in the table), it fails to correct miscalibrated pre-trained language models with LS (see BERT+LS/RoBERTa+LS No TS vs. TS) in-domain. Interestingly, for some cases of out-of-domain data, pre-trained language models with LS show comparatively low ECEs while TS further reduces ECEs (e.g., BERT(LS) on TwitterPPDB/HellaSWAG, RoBERTa(LS) on TwitterPPDB). However, its impact is not enough as it still results in high ECE. This implies that TS is not a notable strategy either to pre-trained language models' calibration. Accordingly, we conclude that stronger regularization techniques are required to calibrate the pre-trained language models.

Second, we find that mixup on the hidden feature space (i.e., M-Mixup) generally yields lower ECE than mixup on the input embedding space (i.e., Mixup) on most tasks. We infer that Mixup generates augmented samples that are not "good" for model calibration (i.e., semantically or syntactically) and fails to encourage regularization effects that arise from mixup. We observe that mixup training with LS is beneficial to reduce ECEs on some tasks. We find that TS leads to much lower ECEs on Mixup and M-Mixup (with and without LS) on most tasks. However, this implies that baseline mixup methods fail to produce well-calibrated models independently (without LS or TS). This supports our intuition and motivation for the design of a more robust approach of mixup.

Table 2: The comparison of accuracy (%) on BERT (top) and RoBERTa (bottom). We report the mean accuracy across five training runs with the standard deviation shown in subscript (e.g., $90.01_{0.4}$ indicates 90.01 ± 0.4).

Third, we observe that our proposed mixup yields the best calibrated models (lowest ECEs) both on in-domain and out-of-domain data (except on SWAG with RoBERTa). We observe that often LS effectively operates along with our proposed mixup and achieves the lowest ECEs on most tasks on in-domain and out-of-domain settings. In contrast to baseline mixup methods, our proposed mixup performs well on in-domain and out-of-domain even without applying post-calibration correction TS (see ECE values of baselines compared with our ECE values). We also observe that TS improves the model calibration further on our mixup training in most cases. Accordingly, we confirm the robustness of our AUM and saliency guided mixup for pre-trained language models calibration.

Accuracy We explore the accuracy of mixup training and show comparisons in Table 2. We make the following observations: 1) Both BERT+LS/RoBERTa+LS generally lead to substantial accuracy drops especially on in-domain compared with BERT/RoBERTa (i.e., 4.49% accuracy drops on SWAG). This implies that label smoothing (LS) fails to improve model generalization by simply manipulating labels (changing from hard to soft labels). This potentially leads to a loss of information that is correlated to model generalization (Müller et al., 2019). 2) Mixup and M-Mixup fail to achieve an accuracy that is as good as that of vanilla pre-trained language models, potentially due to an increased chance of manifold intrusion resulting from conflicts between the synthetic samples of the mixup and original training data (Guo et al., 2019b). 3) In contrast, our proposed mixup method generally achieves competitive accuracy regardless of applying LS or not. This evidence supports the robustness of our proposed mixup. Note that TS does not affect the model's accuracy because it does not change the maximum of the softmax function.

4.5 Ablation Study

Effect of AUM and Saliency We investigate the effectiveness of each component (i.e., AUM and saliency) in our proposed mixup. As shown in Table 3, our proposed mixup without the AUM (i.e., -AUM) and without saliency (i.e., -Saliency) generally increase the expected calibration errors. In our method without using AUM, we randomly divide training data into two categories and conduct mixup operation based on saliency map. In our method without using saliency, we randomly pick two samples from the opposite low and high AUM set and conduct mixup operation. The results demonstrate that both metrics (AUM and saliency) are required to improve model calibration.

	- Saliency	2.91	2.63	0.98	1.02	1.41	1.27	4.80	4.54	6.92	4.78	6.82	3.37
	- dissimilar	2.01	0.93	2.98	1.58	2.52	0.73	6.69	4.77	5.17	4.54	11.39	6.43
	- similar	2.69	2.33	5.14	3.40	3.10	2.62	2.01	1.84	10.43	8.94	7.87	6.11

Table 3: Ablation study to investigate the effect of each component in our proposed mixup. We report results (% ECE) of our mixup without using AUM (i.e., -AUM), without using saliency (i.e., -Saliency), without utilizing the most dissimilar sample selected from the other data category obtained by AUM (i.e., -dissimilar), and without utilizing the most similar sample selected from the other data category obtained by AUM (i.e., -similar).

Effect of selecting the most similar and dissimilar samples We explore the effectiveness of selecting the most similar and dissimilar samples, which are used for mixing purposes for in-domain and out-of-domain calibration, respectively. Specifically, in our proposed mixup, we synthesize additional samples that mimic in-domain data by selecting the most similar sample from the other category (e.g., an easy-to-learn sample is mixed with a hard-to-learn/ambiguous sample that is most similar to the easy-to-learn sample, by saliency maps). This is because the selected sample aligns the most with the given sample. This intuitively results in better model generalization due to the effect arising from data augmentation (i.e., augmenting samples that are particularly similar to in-domain data) and allows better in-domain calibration. Similarly, we calibrate out-of-domain by augmenting a sample that mimics out-of-domain distribution. This is because we select the sample that is the most different from a given sample by selecting the most dissimilar sample from the other category. To verify this intuition, we conduct our proposed mixup when excluding the most similar instance (i.e., -similar) and the most dissimilar instance (i.e., -dissimilar), respectively.

Table 3 shows the results of this ablation. We observe that our proposed mixup without using the most dissimilar sample (i.e., -dissimilar) results in higher ECEs compared with our mixup that uses dissimilar samples on all tasks in the out-of-domain setting for both BERT and RoBERTa. Interestingly, we observe that our proposed mixup without using the most similar sample (i.e., -similar) results in higher ECEs compared with our mixup that uses the most similar samples on in-domain and out-of-domain data for both BERT and RoBERTa. These results support that selecting the most similar/dissimilar samples effectively calibrates pre-trained models for in-domain/out-of-domain data.

5 Conclusion

We proposed a novel mixup guided by the Area Under the Margins (AUM) and saliency maps to mitigate the miscalibration of pre-trained language models BERT and RoBERTa. We showed that our proposed mixup method achieves the lowest Expected Calibration Errors (ECEs) for both pre-trained language models on various types of natural language understanding tasks, for both in-domain and out-of-domain data. For future work, we will enhance our proposed mixup further, focusing not only on model calibration but also on performance gains. Exploring different saliency maps for computing sample similarity/disimilarity (and its degree) is another interesting future direction.

Abstract

Natural language inference (NLI) has been widely used as a task to train and evaluate models for language understanding. However, the ability of NLI models to perform inferences requiring understanding of figurative language such as idioms and metaphors remains understudied. We introduce the **IMPLI** (**I**diomatic and **M**etaphoric **P**aired **L**anguage **I**nference) dataset, an English dataset consisting of paired sentences spanning idioms and metaphors. We develop novel methods to generate 24k semi-automatic pairs as well as manually creating 1.8k gold pairs. We use **IMPLI** to evaluate NLI models based on RoBERTa fine-tuned on the widely used MNLI dataset. We then show that while they can reliably detect entailment relationship between figurative phrases with their literal counterparts, they perform poorly on similarly structured examples where pairs are designed to be non-entailing. This suggests the limits of current NLI models with regard to understanding figurative language and this dataset serves as a benchmark for future improvements in this direction.[1]

1 Introduction

Understanding figurative language (i.e., that in which the intended meaning of the utterance differs from the literal compositional meaning) is a particularly difficult area in NLP (Shutova, 2011; Veale et al., 2016), but is essential for proper natural language understanding. We consider here two types of figurative language: idioms and metaphors. Idioms can be viewed as non-compositional multiword expressions (Jochim et al., 2018), and have been historically difficult for NLP systems. For instance, sentiment systems struggle with multiword expressions in which individual words do not directly contribute to the sentiment (Sag et al., 2002). Metaphors involve linking conceptual properties of two or more domains, and are known to be pervasive in everyday language (Lakoff and Johnson, 1980; Stefanowitsch and Gries, 2008; Steen et al., 2010). Recent work has shown that these types of figurative language are impactful across a broad array of NLP tasks (see §2.1).

Idioms	Jamie was *pissed off* this afternoon. → Jamie was *irritated* this afternoon
	There's a marina down *in the docks*. ↛ There's a marina down *under scrutiny*.
Metaphors	The *hearts of men were softened*. → The *men were made kindler and gentler*.
	The gun *kicked* into my shoulder. ↛ The *mule* kicked into my shoulder.

Table 1: Examples of entailment (→) and non-entailment pairs (↛) from the **IMPLI** dataset.

Large-scale pre-training and transformer-based architectures have yielded increasingly powerful language models (Vaswani et al., 2017; Devlin et al., 2019; Liu et al., 2019). However, relatively little work has explored these models' representations of figurative and creative language. NLI datasets have widely been used for evaluating the performance of language models (Dagan et al., 2006; Bowman et al., 2015a; Williams et al., 2018), but there are insufficient figurative language datasets in which a literal sentence is linked to a corresponding figurative counterpart that are large enough to be suitable for evaluating NLI. Due to the creative nature of human language, creating a dataset of diverse, high-quality literal/figurative pairs is time-consuming and difficult.

To address this gap, we build a new English dataset of paired expressions designed to be leveraged to explore model performance via NLI. Our dataset, **IMPLI** (**I**diomatic/**M**etaphoric **P**aired **L**anguage **I**nference), is comprised of both silver pairs, which are built using semi-automated

methods (§3.1), as well as hand-written gold pairs (§3.4), crafted to reflect both entailment and non-entailment scenarios. Each pair consists of a sentence containing a figurative expression (idioms/metaphors) and a literal counterpart, designed to be either entailed or non-entailed by the figurative expression (Table 1 shows some examples).

Our contribution thus consists of three key parts:

- We create a new **`IMPLI`** dataset consisting of 24,029 silver and 1,831 gold sentence pairs consisting of idiomatic and metaphoric phrases that result in both entailment and non-entailment relationship (see Table 2).
- We evaluate language models in an NLI setup, showing that metaphoric language is surprisingly easy, while non-entailing idiomatic relationships remain extremely difficult.
- We evaluate model performance in a number of experiments, showing that incorporating idiomatic expressions into the training data is less helpful than expected, and that idioms that can occur more in more flexible syntactic contexts tend to be easier to classify.

2 Background

2.1 Figurative Language and NLP

Figurative language includes idioms, metaphors, metonymy, hyperbole, and more. Critically, figurative language is that in which speaker meaning (what the speaker intends to accomplish through an utterance) differs from the literal meaning of that utterance. This leads to problems in NLP systems if they are trained mostly on literal data, as their representations for particular words and/or phrases will not reflect their figurative intended meanings.

Figurative language has a significant impact on many NLP tasks. Metaphoric understanding has been shown to be necessary for proper machine translation (Mao et al., 2018; Mohammad et al., 2016). Sentiment analysis also relies critically on figurative language: irony and sarcasm can reverse the polarity of a sentence, while metaphors and idioms may make more subtle changes in the speaker meaning (Ghosh et al., 2015). Political discourse tasks including bias, misinformation, and political framing detection benefit from joint learning with metaphoricity (Huguet Cabot et al., 2020). Figurative language engendered by creativity on social media also poses difficulty for many NLP tasks including identifying depression symptoms (Yadav et al., 2020; Iyer et al., 2019) and hate speech detection (Lemmens et al., 2021).

We are here focused on idioms and metaphors. There is currently a gap in diagnostic datasets for idioms, and our work fills this gap. There exist some relevant metaphoric resources (see §2.2); metaphors are known to be extremely common and important to understanding figurative language, our resource serves to build upon this work.

2.2 NLI and related challenges

Natural language inference is the task of predicting, given two fragments of text, whether the meaning of one (*premise*) entails the other (*hypothesis*) (Dagan et al., 2006). The task is formulated as a 3-way classification problem, in which the premise and hypothesis pairs are labeled as *entailment*, *contradiction*, or *neutral*, if their relationship could not be directly inferred (Bowman et al., 2015b). NLI has been widely used as an evaluation task for language understanding, and there have been a large number of challenging datasets, which have been used to further our understanding of the capabilities of language models (Wang et al., 2018, 2019).

Paired data for figurative language is relatively sparse, and there is a gap in the diagnostic datasets used for NLI in this area. Previous work includes the literal/metaphoric paraphrases of Mohammad et al. (2016) and Bizzoni and Lappin (2018), although both contain only hundreds of samples, insufficient for proper model training and evaluation. With regard to NLI, early work proposed the task of textual entailment as a way of understanding metaphor processing capabilities (Agerri et al., 2008; Agerri, 2008). Poliak et al. (2018) build a dataset for diverse NLI, which includes some creative language such as puns, albeit making no claims with regard to figurativeness.

Zhou et al. (2021) build a dataset consisting of paired idiomatic and literal expressions. They begin with a set of 823 idiomatic expressions yielding 5,170 sentences, and had annotators manually rewrite sentences containing these idioms as literal expressions. We expand on this methodology by having annotators only correct definitions for the idioms themselves and use these definitions to automatically generate the literal interpretations of the idioms by replacing them into appropriate contexts: this allows us to scale up to over 24k silver sentences. We also expand beyond paraphrasing by incorporating both entailment and non-entailment

Fig. Type	Ent.	Gold/silver	Description	Count
Idioms	→	Silver	Replace idiom used in figurative context with definition	16652
	↛	Silver	Replace idiom used in literal context with definition	886
	↛	Silver	Replace idiom used in figurative context with adversarial definition	6116
	→	Gold	Hand written literal definition of idiom	532
	↛	Gold	Manual replacement of key words in definition w/ antonyms	375
	↛	Gold	Hand written non-entailed sentence	254
Metaphors	→	Silver	Replace metaphoric construction with literal construction	375
	→	Gold	Hand written literal paraphrase of metaphor	388
	↛	Gold	Hand written non-entailed sentence	282

Table 2: **Dataset Summary**: Overview of entailments/non-entailment types in `IMPLI`. (→) denotes entailments, (↛) non-entailments. Note that the descriptions are simplified: some intermediate steps are omitted (see §3.1).

pairs to enable NLI-based evaluation.

Similar to this work, Chakrabarty et al. (2021a) build a dataset for NLI based on figurative language. Their dataset consists of figurative/literal pairs recast from previously developed simile and metaphor datasets, along with a parallel dataset between ironic and non-ironic rephrasing. This sets the groundwork for figurative NLI, but the dataset is relatively small outside of the irony domain, and the non-entailments are generated purely by replacing words with their antonyms, restricting the novelty of the hypotheses. Their dataset is relatively easy for NLI models; here we show that figurative language can be challenging, particularly with regard to non-entailments.

Zhou et al. (2021) and Chakrabarty et al. (2021a) provide invaluable resources for figurative NLI; our works aims to covers gaps in a number of areas. First, we generate a large number of both entailment and non-entailment pairs, allowing for better evaluation of adversarial non-entailing examples. Second, our silver methods allow for rapid development of larger scale data, allowing for model training and evaluation. We show that while entailment pairs are relatively easy (accuracy scores ranging from .86 to .89), the non-entailment pairs are exceedingly challenging, with the `roberta-large` model achieving accuracy scores ranging from .311 to .539.

3 Building a Dataset

Our `IMPLI` dataset is built from idiomatic and metaphoric sentences paired with entailing and non-entailing counterparts, from both silver pairs (§3.1) and manually written sentences (§3.4). For our purposes, we follow McCoy et al. (2019) in conflating the neutral and contradiction categories into a non-entailment label. We then label every pair as either entailment (→) or non-entailment (↛).

Due to the difficult nature of the task and to avoid issues with crowdsourcing (Bowman et al., 2020), we employed expert annotators. We used two fluent English speakers, both graduate students in linguistics with strong knowledge in figurative language, paid at a rate of $20/hr. For each method below, we ran pilot studies, incorporated annotator feedback and iteratively assessed the viability of identifying and generating appropriate expressions. As the annotators were working on generating new expressions, agreement was not calculated: we instead assessed the quality of the resulting expressions (see Section 3.3). Table 2 contains an overview of the different entailment and non-entailment types collected (Detail examples are also provided in Appendix D).

3.1 Silver pairs

First, we explore a method for generating silver pairs using annotators to create phrase definitions which can be inserted automatically into relevant contexts, yielding a large number of possible entailment and non-entailment pairs that differ only with regard to the relevant phrase. Our procedure hinges on a key assumption: for any given figurative phrase, we can generate a contextually independent literal paraphrase. We then replace the original expression with the literal paraphrase, following the assumption that the figurative expression necessarily entails its literal paraphrase:

> He's stuck in bed, which is his *hard cheese*. → He's stuck in bed, which is his *bad luck*.

Conversely, in contexts where the original phrase is used literally, replacing it with the literal paraphrase should yield a non-entailment relation.

> Switzerland is famous for six cheeses, sometimes referred to as *hard cheeses*.

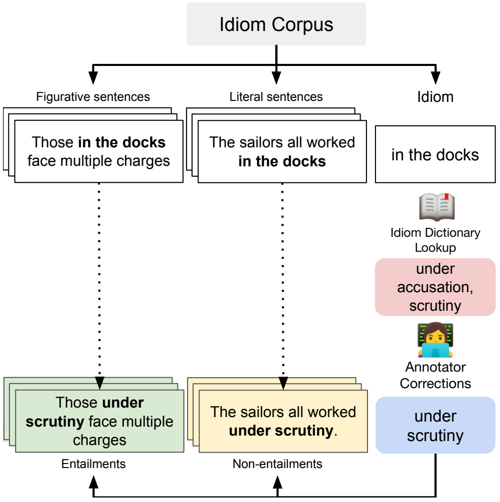

Figure 1: **Idiomatic definition replacement**. Pairs are generated using corrected dictionary definitions, substituted into figurative (left) and literal (center) sentences.

↛ Switzerland is famous for six cheeses, sometimes referred to as *bad luck*.

3.1.1 Idioms

To build idiomatic pairs, we use three corpora that contain sentences with idiomatic expressions (IEs) labelled as either figurative or literal.[2] These are the MAGPIE Corpus (Haagsma et al., 2020), the PIE Corpus (Adewumi et al., 2021), and the SemEval 2013 Task 5 (Korkontzelos et al., 2013). We collect the total set of IEs that are present in these corpora. We then extract definitions for these using freely available online idiom dictionaries.[3]

These definitions are often faulty, incomplete, or improperly formatted. We employed annotators to make manual corrections. The annotators were given the original IE as well as the definition extracted from the dictionary. The annotators were asked to ensure that the dictionary definition given was (1) a correct literal interpretation and (2) fit syntactically in the same environments as the original IE. If the definition met both of these criteria, the IE can be replaced by its definition to yield an entailment pair. If either criterion was not met, annotators were asked to minimally update the definition so that it satisfied the requirements.

In total this process yielded 697 IE definitions. We then used the above corpora, replacing these definitions into the original sentences (see Figure 1). We use the figurative/literal labels from the original corpora: replacing them into figurative contexts yields entailment relations, while replacing them into contexts where the phrase is meant literally then yields non-entailments.

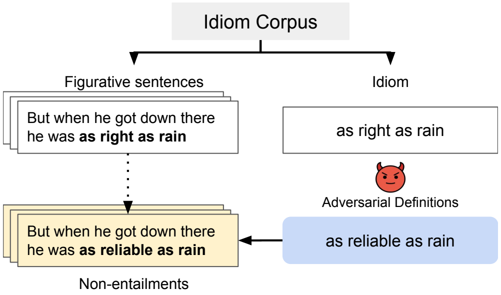

Figure 2: **Adversarial Pair Generation**. Non-entailing pairs are generated by replacing adversarial definitions into figurative contexts.

Original IE	Adversarial Definition
man of the cloth	tailor
heart of gold	cold, mean heart
come clean	bathe
turn a trick	do a magic trick

Table 3: Sampled hand-written adversarial definitions.

3.1.2 Adversarial Definitions

As a second method for generating non-entailment pairs, we asked annotators to write novel, adversarial definitions for IEs. Given a particular phrase, they were instructed to invent a new meaning for the IE that was not entailed by the true meaning, but which seemed reasonable presuming they had never heard the original IE. Some examples of this process are shown in Table 3.

We then replace these adversarial definitions into figurative sentences from the corpora. This yields pairs where the premise is an idiom used figuratively, and the hypothesis is a sentence that attempts to rephrase the idiom literally, but does so incorrectly, thus yielding non-entailments (Figure 2).

3.1.3 Metaphors

Metaphors are handled in a similar way: we start with a collection of minimal metaphoric expressions (MEs). These are subject-verb-object and adjective-noun constructions from Tsvetkov et al. (2014). Each is annotated as being either literal or metaphoric, along with an example sentence. We passed these MEs directly to annotators, who were then instructed to replace a word in the ME so that it would be considered literal in a neutral context.

1. *drop* prices → *reduce* prices

---

[2] We here use "idiomatic expression" or "IE" to refer to the specific idiom in question (ie. "kick the bucket", "spill the beans"), as opposed to the sentence/context containing it.

[3] `www.theidioms.com`, `www.wiktionary.org`

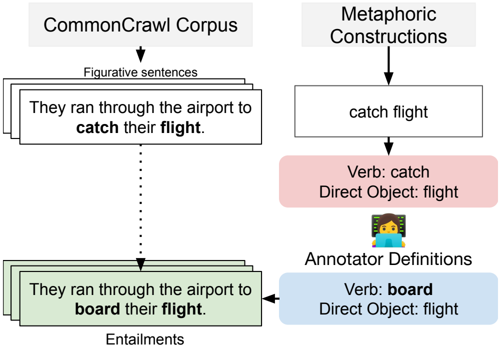

Figure 3: **Metaphor entailment generation**. Pairs are generated using annotator-defined literal translations substituted into metaphoric contexts.

2. **hard** truth → **unpleasant** truth
3. *hairy* problem → *difficult* problem

These can then be replaced in a similar fashion: we start with the original figurative sentence, replace the ME with the literal replacements, and the result is an entailing pair with the metaphoric sentence entailing the literal.

We apply this procedure to the dataset of Tsvetkov et al. (2014), yielding 100 metaphoric/literal NLI entailment pairs. We then take a portion of the Common Crawl dataset[4], and identify sentences that contain these original MEs. We identify sentences that contain the words from the metaphoric phrase, and replace the metaphoric word itself with its literal counterpart. This yields 645 additional silver pairs.

3.2 Postprocessing

For all silver methods, we also employ syntactic postprocessing to overcome a number of hurdles. First, phrases used idiomatically often follow different syntactic patterns than when used literally.

> **Original:** These point *out of this world*, but where to is not made clear.
> **Replaced:** *These point *wonderful*, but where to is not made clear.

This phrase in literal contexts functions syntactically as a prepositional phrase, while idiomatically it is used as an adjective. When replaced with the definition "wonderful" in a literal context, we get a grammatically incoherent sentence. Second, phrases in their literal usage often do not form full constituents, due to the string-matching approach of the original datasets. Many literal usages of these phrases are thus incompatible with the defined replacement.

- I think [this one has *to die*] *for* the other one to live.
- Turn *in* [*the raw* edges] of both seam allowances towards each other and match the folded edges.
