# A TWO LEVEL MORPHOLOGICAI ANALYSIS OF KOREAN 

Deok-Bong Kim, Sung-Jin Lee, Key-Sun Choi, and Gil-Chang Kim Center for Artificial Intelligence Rescarch<br>Computer Science Department, KAIST<br>373-1 Kusong-Dong, Yusong-Ku, Tacjon 305-701, Korea<br>E-mail: \{dbkim, kschoi\}@csking.kaist.ac.kr

#### Abstract

ABS'IRAC'I'

The two-lcvel morphology model has reccived a greal deal of attculion and has been implemented for languages like Finnish, Foglish, Japancse, Russian, l'rench, and so on. However, this model has been claimed to be inappropriale for Korcan morphological antalysis, because the complex conjugation (inflection) and agglutination in word formation, and the syllablebascd reptesentation of words may lead to a hage number of two-level morphological rules. In this paper, we show that the lwo-level model can be satceessfully applied to Korean and its rule size is limilcd to only 52. An exicnsion of two-level morphology is described for Korean language.

## INTRODUCTION

The two-level morphology model (Koskennieni, 1983; Antworth, 1990; Barton, 1986; Ritchie, 1991 ; Sproat, 1992) is a well-known computational model of mor phology, which has adaptability as well as simplic ity. In practice, this model has been successfully applied to several languages inchading Finnish, English, Japanese, Russian, and French. However, the twolevel model has been considered to be inappropriate for Korean (Kang, 1992; Kwon, 1991). That is, the two-level morphological analysis of Korean is belicved to be difficult and infeasible because the complex conjugation (inflection) and agglutination in word fornation, and the syllable-based representation of words may lead to a huge number of two-level morphological rules. In this paper, we show that the two-level model can be successfully applied to Korean and its rule size is limited to only 52.

This paper presents a successful two-level system for Korcan morphological analysis. The system was based on a shareware PC-KIMMO (Antworth, 1990);
however, we extended the $\mathrm{I} / \mathrm{O}$ component of $\mathrm{P}^{\mathrm{P}}$ (, KIMMO to landle Korean alphabet IIANGUL; we constructed a Korean dictionary and a Korean morphological grammar (i.c., morphotactics and spelling rules) for the I' - -KIMMO; we also used a shareware KGl'N (Miles, 1991) to translate the linguistic epelling rules into the cxecutable autornata (i.e., finite state transducers (FSTs)). This paper focuses on the dic tionary and the morphological grammar for Korean.

## 'TWO-LEVEL REPRESENTATION OF KOREAN WORDS

The two level model is concerned with directly mapping between two representations of a word: (1) the surface form (Sl') as it appears in the text, and (2) the lexical form (LF) which is represented as a sequence of basic morphs and diacritics (e.g., ' + ' to mark mor-phene boundary and '\#' for word boundary). As a result, an input word in the two-level model is analyzed by mapping the word itself (SF) to a sequence of lexical forms in dictionary without intermediate stages. In this section, we present a two-level representation of Korcan words.

To understand the two level description for Korean morphology, one should be properly faniliar with Kurean alphabet and their transcription system. So we first describe them. For ordinary writing system, the Korean alphabet consists of 40 letters: 10 pure vowels, 11 compound vowels, 14 basic consonants and 5 double consonants. A Korean word is represented with a sequence of syllables; a syllable can be made up of a consonant, a vowel, and a consonant; there are several forms of syllables (c.g., $C V, C V C, V C, V$, and $C$ forms); and initial consonant letter may not be distinguished from final consonant letter. However, the initial consonant and the final consonant must be distinguished from each other for successful two-level

Table 1：The transcription of Korean alphabet（HANGUL）．

system；if not，it might cause a lot of useless work （i．e．，invalid mapping）and incorrect results because i －$t h$ consonant in a word is not clear whether it is an initial consonant or a final consonant．Furthermore，to write two－level spelling rules for PC－KIMMO，each of Korean alphabet must be mapped to ASCII character on the keyboard．Therefore，we devised a transcrip－ tion system for Korean alphabet as shown in Table 1， which has the following features：
－There is no letter corresponding to the initial con－ sonant＇$a$＇．We did not consider the letter be－ cause it is a sort of an orthographic filler for the ordinary writing systern and is not pronounced．
－The initial consonant letters are not the same as the final consonant letters．（To sce this，compare the initial consonants MYCODE（I）with the final consonants MYCODE（F）in Table 1．）
－Each of compound vowels is represented by a pair of two letters：a semi－vowel letter（i．e．，$y$ or $w$ ） and one of pure vowel letters excluding＇i9＇／ul and＇의＇／$\ddot{\sigma} /$ ；here＇위＇and＇와＇are treated as the compound vowels．
－There are two archiphoneme letters：（1）the archiphoneme $A$ for the proper treatment of vowel harmony ${ }^{1}$ ，which can be changed into NULL，

[^0]symbol 0 ，a vowel letter $a$ ，or a vowel letter 9 by context；and（2）the archiphoneme $I$ for the proper treatment of predicative postposition＇ ol ＇ $/ i /$ ，which can be changed into either 0 or a vowel letter $i$ by context．

We believe that our transcription system makes it sim－ ple and clear to describe two－level spelling rules of Ko－ rean，and it cnables the two－lcvel processor to handle efficiently the complex spelling changes．

Here，three special symbols are used properly to treat lexical irregularities of Korean verbal morphol－ ogy：＋for regularity，$X$ for＇$l c$＇－irregularity，and $\$$ for all irregularitics excluding the＇$l c$＇－irregularity；$X$ must be differentiated from $\$$ because of the following rea－ sons．In Korean morphology，most of verbal stems ending in the syllable＇E⿱日一／f／are irregular．The fi－ nal syllable＇豆＇／h／of the stem，when followed by the vowel＇od＇／$\%$／and preceded by any vowel other than the light vowels（＇of＇$/ a /$ and＇$\Omega$＇／／／），is changed into ＇ed＇$/ b /$ and the consonant＇$e$＇$/ / /$ is added to the pre－ ceding syllable．We call it＇$l$＇－irregularity．For exam－ ple，the verb stem＇关르＇／$h \mathrm{i}-\mathrm{f}$／（to flow）plus the suffix ＇어＇／／（INFINITIVE）becomes the verbal word＇茕러＇ ／hit－b／．However，there is＇le＇－irregularity which oc－
harmony where $\partial$ has an alternation $a$ if the final vowel of a verbal stem is a light vowel $a$ or $o$ ．For example，the verb stem＇ㅗ．＇／ $60 /$（to see）plus the suffix＇어＇／$/ \mathrm{/} /$（INFINI－ TIVE）becomes the verbal word＇ $\boldsymbol{y}$ of／bo－a／．However， the verb stem＇주＇／cu／（to give）plus the suffix＇어＇／／／ （INFINITIVE）becomes the verbal word＇zo어＇／cu－z／．As a result，the archiphoneme $A$ is used for the initial vowel $\partial$ of suflixes，which is to distinguish it from $\partial$ elsewhere．
curs in the same context as ' $l$ '-irregularity: it causes only to be changed the following vowel '어'/ / into 'el'/b/; for example, the verb stem 'ole' $\boldsymbol{e}$ i-li/ (to arrive) plus the suflix '어'/o/ (INI'INL'IIVE) becomes the verbal word '이르러'/i-li-b/. Therelore, a mechanism is needed to treat them properly.

One of the special symbols is used to represent a specific lexical form, and is almost placed at the end of the lexical form. For example, the verbal stem gull has two meanings, i.e., "curved" as an adjective and "grill" as a verb. In this case, the problem is on the difference between the variation forms for adjective and those for verb; when it is combined with a suffix $A$, the surface form becomes cither the guBe as adjective, or the guwe as verb. To dislinguish between them, the following lexical forms can be listed in dictionary: gulB+ for regular adjective, and gu $3 \$$ for ' $b$ '-irregular verb.

## WORD STRUCTURE AND LEXICONS

The word structure in general denotes knowledge of the internal morpheme combinations of known words. As a result, it shows how morplemes can combine to form valid words; it is important to a proper word recognition. In the two-level model it is represented with linked lexicons, i.c., with continnation classes of morphemes.

The continuation classes used in our lexicons are as follows: interjection (IJ), prenoun ( PR ), adverb ( AJ ), noun ( NN ), pronoun ( PN ), mumeral ( NU ), verb (VI), adjective ( $A J$ ), verbalizer (VR), postposition (Pl), I-postposition (IP), nonimal-prefix (NF), verbal-prefix (VF), prefinal-ending (YE), final-ending ( FL ), nominal-ending ( NH$)^{2}$, Begin, and Fud. livery class indicates a lexicon. Mowever, the Begin and End are some special lexicons; Begin amounts to the initial state in automata, and $\operatorname{Br} \pi$ d has the same role as the final state; in fact, there is no lexical entry. The following shows our linked lexicons.

```
    Begin -> interjection | prenoun | adverb
    | nown | pronoun | numeral | verb
    | adjoctive | nominal-predix
    | verbal-prefix
```

[^1]```
interjection -> End
prenoun -> End
adverb }->\mathrm{ End | postposition
nominal-prefix >-> noun
verbal-prefix }->\mathrm{ verb | adjective
noun -> End | postposition
    | I-postposition | verbalizer
pronoun -> End | postposition
    | I-postposition
numeral -> End | postposition
            | I-postposition
verb -> prefinal-ending | final-ending
    | nominal-onding
adjective -> prefinal-ending
            | final-onding | nominal-onding
verbalizer >> prefinal-onding
    | final-ording | nominal-onding
I-postposition -> prefinal-ending
    | final-ending | nominal-ending
postposition -> End
prefinal-ending ->> final-ending
    | nominal-manding
final-onding -> End
nominal-onding -> End | postposition
    | I-postposition
```

The right arrow ' $-\gamma$ ' indicates that a class on its left side can continue with one of classes on its right side; a vertical bar ' $\mid$ ' indicates OR.

## TWO-LEVEL RULES AND FINITE STATE AUTOMATA

Based on the work of Korean morphology by Lee (1991), 52 two-level rules has been developed for the Korean morphological alternations. By way of an example, we explain the following Korean morphological alternation in the two-level framework.

In Korean, some verbals ending in the final consonant $B$ are irregular. The final consonant $B$ of the stem, when followed by a vowel, is changed into $w$. But it is not changed when followed by a consonant. For example, when an irregular verb doB (to help) is combined with the suffix $A$, it is changed into dowa. In the two-level system, it is represented as follows:

[^2]This shows a correspondence between lexical representation and surface representation. In PC-KIMMO, such a correspondence is represented with the notation lexical-character:surface-character like $d: d, o: 0, B: w$, $\$: 0,+: 0$, and $A: a$. IIere the lexical character $\$$ is a signal indicating that a basic word or stem followed by it is irregular, and it corresponds to a surface 0 (the NULL symbol) which is not printed in the output form. The lexical + (a morpherne boundary symbol) also corresponds to a surface 0 .

The above alternation may be described as the following two-level rule:

$$
B: w \Leftrightarrow-\$: 0+: 0 \wedge: @(B \text { Variation Rulc) }
$$

This rule states that a lexical $B$ is realized as a surface $w$ if and only if it is followed by the conjugation information $\$$, the morpheme boundary + , and a linking suffix $A$. A surface @in the above rule stands for any alphabetic character that constitutes a feasible pair with a lexical $A$. For example, the surface @may be realized as $a$, $c$, or 0 when all feasible pairs with lexical $A$ are like $A: a, A: c$, and $A: 0$.

The two-level rules can be automatically translated into the state transition tables by using a rule compiler such as TWOL (Karttunen, 1987) and KGEN (Miles, 1991). The tables built by KGEN may be actually used in PC-KIMMO. The above rule is translated by KGEN into the state transition table bclow:

|  | $B$ | $B$ | $\$$ | + | 1 | $@$ | (Icxical charactcrs) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $w$ | $@$ | 0 | 0 | $@$ | $@$ | (surface characters) |
| $1:$ | 2 | 5 | 1 | 1 | 1 | 1 |  |
| 2. | 0 | 0 | 3 | 0 | 0 | 0 |  |
| 3. | 0 | 0 | 0 | 4 | 0 | 0 |  |
| 4. | 0 | 0 | 0 | 0 | 1 | 0 |  |
| $5:$ | 2 | 5 | 6 | 1 | 1 | 1 |  |
| $6:$ | 2 | 5 | 1 | 7 | 1 | 1 |  |
| $7:$ | 2 | 5 | 1 | 1 | 0 | 1 |  |

The rows of the table represent the seven states, in which final states are marked with colons and nonfinal states are marked with periods. The columns represent arcs from one state to another. $\Lambda$ zero transition indicates that there is no valid transition from that state for that input symbol.

## CONCLUSION

We have shown that the two-level morphology model, which has been claimed to be inappropriate for Ko rean, can be successfully applied to Korean. That is, we have implemented a successful two-level morphology system for Korean (see APPENDIX). This systern was based on PC-KIMMO which is a shareware. However, we modified the I/O component of PC-KIMMO to handle Korean alphabet HANGUL; we have constructed a Korean dictionary for the PCKIMMO, which contains about 12,000 entries; we represented a Korean morphotactics for the PC-KIMMO, which indicates the morphological structures of known words; we wrote 52 two-level spelling rules for the PC-KIMMO, which recover almost all spelling alternations in Korean morphology.

Our two-lcvel system has been experimented with 2,172 randomly words selected from Korean textbooks ( 413,975 words) for elementary education. For this test set, the system produces the correct outputs although it includes about $5 \%$ extra incorrect analyses (i.e., overyeneration). Here the overgeneration is ascribed to the fact that it results from the weak cxpressive power of morphotactic information in PCKIMMO.
