#### Abstract

We present two systems for the task of morphological inflection, i.e., finding a target morphological form, given a lemma and a set of target tags. Both are trained on datasets of three sizes: low, medium and high. The first uses a simple Long Short-Term Memory (LSTM) for lowsized dataset, while it uses an LSTMbased encoder-decoder based model for the medium and high sized datasets. The second uses a simple Gated Recurrent Unit (GRU) for low-sized data, while it uses a combination of simple LSTMs, simple GRUs, stacked GRUs and encoderdecoder models, depending on the language, for medium-sized data. Though the systems are not very complex, they give accuracies above baseline accuracies on high-sized datasets, around baseline accuracies for medium-sized datasets but mostly accuracies lower than baseline for low-sized datasets.

## 1 Introduction

The CoNLL-SIGMOPRHON 2017 shared task Cotterell et al. (2017) consists of two subtasks out of which we participate only in the first subtask, which involves generating a target inflected form from a given lemma with its part-of-speech. For instance, the word writing is the present continuous inflected form of the lemma write. The models were trained on three differently-sized datasets. The low-sized datasets had around 100 training samples, the medium-sized datasets had around 1000 training samples and the high-sized datasets had around 10000 samples for most languages. Datasets were provided for a total of 52 languages.

## 2 Background

Prior to neural network based approaches to morphological reinflection, most systems used a 3step approach to solve the problem: 1) String alignment between the lemma and the target (morphologically transformed form), 2) Rule extraction from spans of the aligned strings and 3) Rule application to previously unseen lemmas to transform them. Durrett and DeNero (2013) and Ahlberg et al. $(2014 ; 2015)$ used the above approaches, with each of them using different string alignment algorithms and different models to extract rules from these alignment tables. However, in these kinds of systems, the types of rules to be generated must be specified, which should also be engineered to take into account language-specific transformational behaviour.

Faruqui et al. (2016) proposed a neural network based system which abstracts away the above steps by modeling the problem as one of generating a character sequence, character-by-character. Akin to machine translation systems, this system uses an encoder-decoder LSTM model as proposed by Hochreiter and Schmidhuber (1997). The encoder is a bidirectional LSTM, while the decoder LSTM feeds into a softmax layer for every character position in the target string. A beam search is used to create many output sequences and the best one is chosen based on predicted scores from the softmax layer. This model takes into account the fact that the target and the root word are similar, except for the parts that have been changed due to inflection, by feeding the root word directly to the decoder as well. A separate neural net is trained for every language.

## 3 System Description

We have modeled our system based on the system proposed by Faruqui et al. (2016), as described
in the previous section. However we have made some modifications to the above system, to account for the three different sizes of datasets and to account for the behaviour of morphological transformations of independent languages. We submitted two submissions for the shared task, each of which we describe in the following sections.

In all the models, some structural and hyperparametrical features remain the same. The characters in the root word are represented using character indices, while the morphological features of the target word are represented using binary vectors. Each character of the root word is then embedded as a character embedding of dimension 64 , to form the root word embedding. If an encoder is used, it is bidirectional and the the input word embeddings feed into it. The output of the encoder (if any), concatenated with the root word embedding, feeds into the decoder. All recurrent units have hidden layer dimensions of 256 , meaning that they transform the input to a vector of dimension 256. Over the decoder layer is a softmax layer that is used to predict the character that must occur at each character position of the target word. In order to maintain a constant word length, we use paddings of ' 0 ' characters. All models use categorical cross-entropy as the loss function and the Adam optimizer as reported by Kingma and Ba (2014) for optimization.

### 3.1 First Submission

### 3.1.1 Low-sized Dataset

For training the model on the low-sized dataset, we did not use any encoder and we used a simple LSTM with a single layer as the recurrent unit (Figure 1).

### 3.1.2 Medium-sized Dataset

For training the model on the medium-sized dataset, we used a bidirectional LSTM as the encoder and a simple LSTM with a single layer as the decoder (Figure 2).

### 3.1.3 High-sized Dataset

For training the model on the high-sized dataset, we used a bidirectional LSTM as the encoder and a simple LSTM with a single layer as the decoder (Figure 2).

Figure 1: $\quad C_{1}, . ., C_{n}$ represent characters of the root word while $O_{1}, . ., O_{n}$ represent characters of the output word

### 3.2 Second Submission

### 3.2.1 Low-sized Dataset

For training the model on the low-sized dataset, we did not use any encoder and we used a simple GRU, as reported by Cho et al. (2014), with a single layer as the recurrent unit (Figure 3).

### 3.2.2 Medium-sized Dataset

For medium-sized dataset, we used different model configurations for different languages. Four different kinds of configurations were used:

1) Bidirectional LSTM as the encoder and a simple LSTM with a single layer as the decoder (Figure 2) 2) Bidirectional GRU as the encoder and a simple GRU with a single layer as the decoder (Figure 4) 3) No encoder and a simple GRU with a single layer as the recurrent unit (Figure 3) 4) Bidirectional GRU as the encoder and a deep GRU (two GRUs stacked one above the other) as the decoder (Figure 5)

The specific configuration used for each language has been listed in Table 1. The configuration numbers indicated in the table are according to those mentioned above.

### 3.2.3 High-sized Dataset

For high-sized data, we were unable to complete experiments for the second submission due to lack of time. However, we have been able to perform
$\left.\left.\left.\begin{array}{|c|c|}\hline \text { Configuration } & \text { Language List } \\ \hline 1 & \text { Arabic, Basque, Bengali, Catalan, Georgian, Latin, Quechua, Urdu } \\ 2 & \text { Kurmanji }\end{array}\right\} \begin{array}{c}\text { Bulgarian, Czech, Estonian, Faroese, German, Icelandic, Irish, Latvian, Lithuanian, } \\ 3\end{array} \quad \begin{array}{c}\text { Norwegian-Bokmal, Persian, Polish, Swedish }\end{array}\right] \begin{array}{c}\text { Albanian, Armenian, Danish, Dutch, English, Finnish, French, Haida, Hebrew, Hindi, } \\ \text { Hungarian, Italian, Khaling, Lower-Sorbian, Macedonian, Navajo, Northern-Sami, } \\ \text { Norwegian-Nynorsk, Portuguese, Romanian, Russian, Scottish-Gaelic, Serbo-Croatian, } \\ \text { Slovak, Slovene, Sorani, Spanish, Turkish, Ukrainian, Welsh }\end{array}\right]$

Table 1: Configurations for different languages for medium-sized data for submission-2.

| Language | B | S-1(T) | S-2(T) |
| :--- | :---: | :---: | :---: |
| Norwegian-Bokmal | 69.0 | 52.6 | 62.7 |
| Danish | 59.8 | 46.1 | 49.8 |
| Urdu | 30.3 | 31.2 | 43.7 |
| Hindi | 31.0 | 33.4 | 40.8 |
| Swedish | 54.3 | 40.6 | 39.4 |

Table 2: Accuracies for top-5 languages for low data.

| Language | BL | S-1 | S-2 |
| :--- | :---: | :---: | :---: |
| Quechua | 68.1 | 93.0 | 93.0 |
| Bengali | 75.0 | 91.0 | 91.0 |
| Portuguese | 92.9 | 86.0 | 89.6 |
| Urdu | 86.1 | 88.0 | 88.0 |
| Georgian | 90.0 | 87.7 | 87.7 |

Table 3: Accuracies for top-5 languages for medium data.

| Language | BL | S-1 |
| :--- | :---: | :---: |
| Basque | 6.0 | 100.0 |
| Welsh | 67.0 | 99.4 |
| Hindi | 94.0 | 99.3 |
| Persian | 77.6 | 98.9 |
| Portuguese | 97.4 | 98.5 |

Table 4: Accuracies for top- 5 languages for high data.

| Language | BL | S-1 | S-2 |
| :--- | :---: | :---: | :---: |
| Norwegian-Bokmal | 0.489 | 0.71 | 0.55 |
| Danish | 0.669 | 0.95 | 0.87 |
| Swedish | 0.884 | 1.08 | 1.09 |
| Norwegian-Nynorsk | 0.928 | 1.41 | 1.23 |
| Dutch | 0.69 | 1.42 | 1.24 |

Table 5: Levenshtein distances for top-5 languages for low data.

some ablation studies on high-size datasets, which have been discussed in the analysis section.

## 4 Evaluation

### 4.1 Results on Test Set

The evaluation results were obtained using the evaluation script and the test set provided by the shared task organizers. Baseline accuracies were also obtained from the baseline model provided. The best five baseline accuracies, accuracies for the first submission and accuracies for the second submission can be found in Table 2, Table 3 and Table 4 for each of the three dataset sizes: low, medium and high respectively. Similar results for Levenshtein distances can be found in Table 5, Table 6 and Table 7. In these tables, BL stands for Baseline, S-1 stands for Submission-1 and S-2 stands for Submission-2.

Figure 3: $\quad C_{1}, . ., C_{n}$ represent characters of the root word while $O_{1}, . ., O_{n}$ represent characters of the output word

| Language | BL | S-1 | S-2 |
| :--- | :---: | :---: | :---: |
| Portuguese | 0.103 | 0.21 | 0.16 |
| Bengali | 0.44 | 0.19 | 0.19 |
| Quechua | 1.706 | 0.28 | 0.28 |
| Welsh | 1.02 | 0.4 | 0.29 |
| Georgian | 0.225 | 0.32 | 0.32 |

Table 6: Levenshtein distances for top-5 languages for medium data.

The complete set of accuracies and Levenshtein distances for all languages have been included in Appendix-1 (tables 8 to 10), sorted by accuracies. The main observation from these tables is that languages belonging to the same language family tend to get similar similar results by our system, which is intuitively valid (although there are many exceptions). For example, Romance and Slavic languages tend to occur together in these tables.

However, it is not evident from these tables that morphologically more complex languages should be harder to learn, which seems to be counter-

| Language | BL | $\mathrm{S}-1$ |
| :--- | :---: | :---: |
| Basque | 3.32 | 0.0 |
| Serbo-Croatian | 0.36 | 0.0 |
| Welsh | 0.45 | 0.01 |
| Hindi | 0.075 | 0.02 |
| Persian | 0.567 | 0.02 |

Table 7: Levenshtein distances for top-5 languages for high data.

Figure 4: $\quad C_{1}, . ., C_{n}$ represent characters of the root word while $O_{1}, \ldots, O_{n}$ represent characters of the output word
intuitive. For example, Turkish is above French. This may be because of hyperparameters or configurations selected for different languages (which were different, in an attempt to maximize accuracy on the development data).

Figures 6 to 10 show the correlation between accuracy and Levenshtein distance for all three sizes of datasets for submission-1 and for low and medium sizes of datasets for submission-2.

### 4.2 Ablation Studies

While we were unable to run an exhaustive hyperparameter search due to lack of time, we performed some experiments, where the choice of hyperparameters was guided by intuitions developed from analysis of the dataset and results obtained on smaller subsets of the data. We have presented some key observations from our analysis in the ensuing sub-sections.

### 4.2.1 Early Stop Patience

We observed that for low-sized datasets, both the models (LSTM as well as GRU based) required that at least 10 epochs be run before early stop, every time no progress is detected on the validation set. Setting this patience to less than 5 , resulted in near 0 accuracies for most languages and printing of nonsensical target words. For medium-sized datasets, this patience value can be set to around

Figure 5: $\quad C_{1}, . ., C_{n}$ represent characters of the root word while $O_{1}, . ., O_{n}$ represent characters of the output word

Figure 6: Accuracy vs. Levenshtein Distance for high data (submission-1)

6-8 while for high-sized datasets, it can be set to around 3-4. However, in order to ensure best results, we set our patience value to 10 across all models, training sizes and languages in the final system.

### 4.2.2 External Feature Categories

In last year's version of the shared task, the morphological features in the dataset were annotated along with the category of each feature. For instance, a sample training feature set from last year is: 'pos=N,def=DEF,case=NOM/ACC/GEN,num=SG'. This year, however, the category of each feature was not provided, i.e., the same example above would appear in this year's format as:

Figure 7: Accuracy vs. Levenshtein Distance for medium data (submission-1)

Figure 8: Accuracy vs. Levenshtein Distance for low data (submission-1)
'N,DEF,NOM/ACC/GEN,SG'. Our studies show that while it is conceptually true that the presence of feature categories means exploring a shorter search space, the absence of them does not make a difference to the accuracies obtained for high and medium sized datasets. In the case of low-sized datasets, marginally better accuracies (around $0.5-1 \%$ ) were obtained when the categories were incorporated into the dataset (this was done manually). However, this might also be the effect of random initialization of parameters.

Figure 9: Accuracy vs. Levenshtein Distance for medium data (submission-2)

Figure 10: Accuracy vs. Levenshtein Distance for low data (submission-2)

### 4.2.3 Choice of Recurrent Unit

Simple Recurrent Neural Networks (RNNs) performed the poorest on all sizes of datasets. For low-sized datasets, in almost all cases, using a GRU gave better results than using an LSTM. On an average, the accuracy increased by $2.33 \%$ when shifting from LSTM to GRU as the choice of recurrent unit.

In the case of medium-sized datasets, 8 out of 52 languages performed better with an LSTM than a GRU, while the rest showed better performance with a GRU.

### 4.2.4 Convolutional Layers

We also ran experiments using convolutional layers, in which the root word was convolved and the convolution was concatenated along with the root word and passed to the encoder layer (if any). The rest of the network structure remained the same. For low-sized and medium-sized datasets, adding convolutional layers resulted in the accuracy dropping to near 0 . For high-sized datasets, we were unable to finish running the experiments on all languages due to lack of time. However for the few languages on which we performed convolutional ablation studies, it did seem to improve accuracy by around $1.5 \%$ on an average.

### 4.2.5 Stacking Recurrent Units

Deeper models (more than one layer of LSTM/GRU) resulted in drastic accuracy drops for low-sized datasets. For medium-sized datasets, 30 out of 52 languages showed an accuracy improvement upon stacking two GRU layers, while the accuracy drop in the rest 22 was not drastic but appreciable.

## 5 Conclusions

There are two main conclusions. One is that different configurations of deep neural networks work well for different languages. The second is that deep learning may not be the right approach for low-sized data.

Results for low-size were poor for almost all languages. It is to be noted that we used purely deep learning. If deep learning is augmented with other transduction, rule-based or knowledge-based methods, the results for low-size could perhaps be improved.

For high-sized data, for one language (Basque), we even got an accuracy of $100 \%$. For medium, the highest was $93 \%$ and for low, the highest was $69 \%$.

## Appendix-1

In Tables 8 to 10 (on this page and the next), BA stands for baseline accuracy, BLD for baseline Levenshtein Distance, S1A for submission-1 accuracy, S1LD for submission-1 Levenshtein Distance, S2A for submission-2 accuracy and S2LD for submission-2 Levenshtein Distance. All three tables are sorted by submission-1 accuracy, since we have results for all dataset sizes for this submission.
