Preface by the General Chair

Welcome to EMNLP-IJCNLP 2019 in Hong Kong! I hope that this will be a successful conference in the 25-year tradition of EMNLP and IJCNLP, as well as an enjoyable and enriching experience for all. Continuing recent trends, this year has seen overwhelming interest from researchers from all over the world. We received a total of 2,914 submissions, which is a 37% increase over EMNLP 2018 (2,117 submissions).

The three Program Co-Chairs, Jing Jiang, Vincent Ng, and Xiaojun Wan, oversaw the entire submission process, a truly Herculean feat. I am deeply grateful for your support. Managing such a large number of submissions would not have been possible without the hard work of a whopping 152 Area Chairs headed by 18 Senior Area Chairs as well, each responsible for overseeing a broad area. Under them, the combined effort of over 1,700 reviewers, each carefully examining submissions through the lens of their expertise, resulted in 465 long and 218 short papers to be presented at the main conference. Your efforts have been indispensable for making this conference happen.

I would like to express special thanks to Priscilla Rasmussen, the ACL Business Manager, who has been indispensable through many years of not only EMNLP but many other key NLP conferences. All of this would not have been possible without you. My deepest gratitude to David Yarowsky, Jian Su, and Noah Smith, and many others from the SIGDAT and AFNLP boards for their invaluable guidance in navigating difficult issues surrounding the daunting task I was faced with.

The hard work of our hosts, the Local Organizing Committee Chair Kam-Fai Wong and members Samuel Tam, Emmanuele Chersoni, Churen Huang, Wenjie Li, Derek F. Wong, and Ruifeng Xu, have especially been vital in bringing together EMNLP-IJCNLP 2019.

As many as 17 workshops and a co-located conference, CoNLL, have been coordinated by the Workshop Chairs Vera Demberg and Naoaki Okazaki. EMNLP-IJNLP 2019 will also be hosting a full-day tutorial and six half-day tutorials organized by the Tutorial Chairs Timothy Baldwin and Marine Carpuat. The combined efforts of the Demonstration Chairs Ruihong Huang and Sebastian Padó have culminated in a total of 44 accepted demo papers (out of 110 submissions) in addition to the overwhelming main conference papers. I am deeply grateful for your endless labor that brought to fruition an exciting program I am proud to be a part of.

We sought to make EMNLP 2019 a venue that is as welcoming and inclusive as possible to all. In this effort, we worked on continuing and expanding the diversity and inclusion (D&I) efforts initiated in recent NLP conferences as well as the Widening NLP workshop. The D&I committee, co-chaired by Chi-Kiu (Jackie) Lo and Vivek Srikumar, joined their forces with the Childcare Policy and Grant Coordinators Olivia Kwong and Sujian Li to help remove any obstacles to participating in a key event in the NLP community. Student Volunteer Coordinator and Student Scholarship Chair Wenjie Li and Marzieh Saeidi coordinated providing scholarships to students and non-students wanting to join us, who otherwise might not have had the means to. The D&I committee focused on several initiatives involving mentoring, both for first-time conference attendees and otherwise, providing accommodations and improving accessibility for participants if necessary, and generally making the conference experience a broadly comfortable one. For those unable to travel, we hope that the efforts of our Remote Presentation Chair, Derek F. Wong, enabled you to still feel included in the conference. We hope that these efforts to make EMNLP inclusive and welcoming will help enrich the conference.

A warm thank you to Micha Elsner, the General Publication Chair, Publication Chairs Fei Liu and Pontus Stenetorp, and also to Serena Villata, the Conference Handbook Chair, Kai-Wei Chang, the Conference Handbook Advisor, Natalie Schluter, the Conference Handbook Proofreader, for their strong sense of duty resulting in excellent supporting materials, arguably the most important contribution to many! I

must also thank Publicity Chairs Sebastian Ruder and Wei Xu, and Website and Conference App Chairs Kevin Duh and Henning Wachsmuth for your excellent promotion. We owe our success to reaching all those that could be interested, which cultivated a strong interest within the NLP community.

Last but not least, I would like to express my deepest gratitude to our sponsors, whose generous support has been invaluable in building up EMNLP and IJCNLP to what it is now, and to our Local Sponsorship Chair, Dongyan Zhao, for his assistance. A special thank you to Google, Facebook, Apple, ASAPP, and Salesforce, our Diamond sponsors. Many thanks to our Platinum sponsors Huawei, Baidu, DeepMind, and Amazon. We are also profoundly grateful to our Gold level sponsors PolyAI, Naver, ByteDance, Megagon Labs, Zhuiyi Technology, Verisk Analytics, and Xiaomi, Silver level sponsors Duolingo, SAP, Babelscape, eBay, and Cisco, Bronze level sponsor Shannon.AI, and finally, our supporting organization MEHK. Thank you for your monumental support towards hosting another (hopefully!) successful year of EMNLP-IJCNLP.

Finally, I would like to once again welcome you to EMNLP-IJCNLP 2019! We hope that this will be an exciting and memorable experience for you, especially if you are joining us for the first time. The NLP community is as thriving as ever, and I am honored to have had a part in hosting one of the leading conferences in the area of Natural Language Processing.

EMNLP-IJCNLP 2019 General Chair

Kentaro Inui, Tohoku University, Japan

Preface by the Program Committee Co-Chairs

Welcome to EMNLP-IJCNLP 2019, the first joint EMNLP and IJCNLP conference! While this is the first time IJCNLP is held in Hong Kong, EMNLP left its footprints here in 2000 when it was still a tiny conference. There is nothing more exciting than seeing it return to Hong Kong after 19 years as one of the largest NLP conferences.

Owing to a significant increase in the number of submissions to recent NLP conferences, we, for the first time in the history of EMNLP and IJCNLP, attempted to reduce workload for reviewers by implementing a dual submission policy, where we disallowed authors to submit papers that are under review by a journal or another conference at the time of submission. Despite this policy, EMNLP-IJCNLP received 2914 submissions (excluding those withdrawn by the authors after initial submissions). This is an increase of over 30% compared with EMNLP 2018, making EMNLP-IJCNLP 2019 the largest NLP conference ever! Out of the 2914 submissions, 38 were desk-rejected for various reasons including formatting problems, length problems and violation of the dual submission policy. In spite of the record number of submissions, we managed to maintain a similar acceptance rate as past NLP conferences given the vast amount of space available to us at the AsiaWorld-Expo. In the end, we accepted 683 submissions. Some statistics of the accepted papers can be found below.

	Long	Short	Total
Reviewed	1,813	1,063	2,876
Accepted as talk	164 (9.0%)	48 (4.5%)	212 (7.3%)
Accepted as poster	301 (16.6%)	170 (16.0%)	471 (16.4%)
Accepted (total)	465 (25.6%)	218 (20.5%)	683 (23.7%)

In addition, EMNLP-IJCNLP 2019 will feature 11 papers accepted by the Transactions of the Association for Computational Linguistics (TACL), out of which 8 will be presented orally and 3 as posters.

Handling close to 3000 submissions was a daunting task, but we were fortunate that a large team of volunteers from our community offered to help. Unlike last year's EMNLP, where a submission was reviewed in one of eight mega-areas, we organized this year's submissions into 18 areas, hoping that smaller areas would make things more manageable for our program committee. While traditionally large areas such as Information Extraction, Machine Learning for NLP, and Machine Translation and Multilinguality continued to receive a large number of submissions, areas such as Dialog and Interactive Systems and Summarization and Generation have grown significantly owing to the recent surge of interest in automated response generation.

We adopted a program committee structure similar to that of ACL 2019. For each area, we invited one Senior Area Chair, who worked with a team of Area Chairs (ranging from 4 to 18 per area) and an army of reviewers (1721 in total across all areas). Having a large number of ACs (152 in total) allowed us to assign each of them a reasonable number of papers, which in turn enabled them to better focus on evaluating each paper. Each submission was assigned to three reviewers and one AC. We allowed both the reviewers and the ACs to bid for papers, but used a combination of their bids and the TPMS (Toronto Paper Matching System) scores to assign papers. Although this lengthened the paper assignment process, we believe it allowed us to better match the submissions with reviewers. We also adopted a review form similar to what was used in ACL 2019 as we heard generally good feedback about less structured review forms. While NAACL HLT 2019 and ACL 2019 eliminated author response, we decided that it would be beneficial to keep it even though it put time pressure on our already tight reviewing schedule and resulted in additional work for our program committee members.

This year we received some submissions that raised ethical concerns from the reviewers, and we found that no existing guidelines could be applied. We decided to err on the side of acceptance, encouraging authors of otherwise acceptance-worthy papers to more deeply explore these issues in final drafts, and

encouraging the community to carry out further work.

We are extremely grateful to all the Senior Area Chairs, especially those who had a large number of submissions in their areas. The Senior Area Chairs did a fantastic job in nominating Area Chairs, recruiting reviewers and making final recommendations. We would also like to thank all the Area Chairs and reviewers for their hard work in writing meta-reviews and reviews, as well as leading and participating in the discussions. Special thanks to those emergency reviewers who offered help with short notice. Without the dedication of our program committee members, we would not be able to put together this conference program.

Award papers are an integral part of every NLP conference. Based on recommendations made by the ACs and the reviewers, we identified five candidates for the Best Paper award and another five for the Best Resource Paper award. We would like to thank Tim Baldwin, Claire Cardie, Dan Gildea, Qun Liu, Ellen Riloff, and Luke Zettlemoyer for serving in the Best Paper award committee, and Katrin Erk, Graeme Hirst, Gina-Anne Levow, Percy Liang, and Nianwen Xue for serving in the Best Resource Paper award committee. The award winners will be announced at the closing ceremony.

We are excited to have the following three keynote speakers: Noam Slonim (IBM Haifa), on automated debating technologies; Meeyoung Cha (KAIST), on research challenges in computational social science; and Kyunghyun Cho (NYU), on neural sequence modeling. We would like to thank them for traveling to Hong Kong to give the keynote speeches.

There are also many other people who contributed tremendously to the conference program, and we are very grateful for their help:

- Kentaro Inui, the General Conference Chair, who is always there to offer his help and advice;
- All the members of the Conference Coordinating Committee, who provided valuable advice on various issues that came up during the review process;
- David Chang and Julia Hockenmaier, Program Chairs of EMNLP 2018, who shared very helpful tips from their past experience;
- Rich Gerber from SoftConf, who helped us set up the conference submission site and always responded to our queries promptly;
- Other recent *ACL chairs who offered their help when we contacted them despite their busy schedule;
- TACL editors-in-chief Mark Johnson, Lillian Lee and Brian Roark, as well as TACL editorial assistant Cindy Robinson, for coordinating the TACL presentations with us;
- Micha Elsner, Fei Liu and Pontus Stenetorp, the Publication Chairs, who worked hard to compile the conference proceedings and kindly accommodated many last minute requests from authors;
- Kevin Duh, Henning Wachsmuth, Wei Xu and Sebastian Ruder, the Website Chairs and Publicity Chairs, who helped us make numerous announcements in a timely manner;
- Serena Villata, Natalie Schluter and Kai-Wei Chang for preparing and proofreading the conference handbook;
- Members of the Local Organizing Committee for making the local arrangements;
- Derek Wong, the Remote Presentation Chair, for taking care of remote presentations;
- Priscilla Rasmussen, whom we directed many inquiries to.

Again, welcome to EMNLP-IJCNLP 2019! We hope you will have a memorable conference experience!

EMNLP-IJCNLP 2019 Program Co-Chairs

Jing Jiang, Singapore Management University, Singapore
Vincent Ng, University of Texas at Dallas, USA
Xiaojun Wan, Peking University, China

Organizing Committee

General Chair
Kentaro Inui, Tohoku University, Japan

Program Committee Co-chairs
Jing Jiang, Singapore Management University, Singapore
Vincent Ng, University of Texas at Dallas, USA
Xiaojun Wan, Peking University, China

Local Arrangements Committee
Kam-Fai Wong, Chinese University of Hong Kong, China (chair)
Samuel Tam, Chinese University of Hong Kong, China
Emmanuele Chersoni, Hong Kong Polytechnic University, China
Churen Huang, Hong Kong Polytechnic University, China
Wenjie Li, Hong Kong Polytechnic University, China
Derek F. Wong, University of Macau, China
Ruifeng Xu, Harbin Institute of Technology, Shenzhen, China

Local Sponsorship Chair
Dongyan Zhao, Peking University, China

Workshop Co-chairs
Vera Demberg, Saarland University, Germany
Naoaki Okazaki, Tokyo Institute of Technology, Japan

Tutorial Co-chairs
Timothy Baldwin, University of Melbourne, Australia
Marine Carpuat, University of Maryland, College Park, USA

Demonstration Co-chairs
Ruihong Huang, Texas A&M University, USA
Sebastian Padó, University of Stuttgart, Germany

General Publication Chair
Micha Elsner, Ohio State University, USA

Publication Chairs
Fei Liu, University of Central Florida, USA
Pontus Stenetorp, University College London, UK

Conference Handbook Chair
Serena Villata, CNRS, France

Conference Handbook Advisor
Kai-Wei Chang, University of California at Los Angeles, USA

Conference Handbook Proofreader

Natalie Schluter, IT University of Copenhagen, Denmark

Publicity Chairs
Sebastian Ruder, National University of Ireland, Ireland
Wei Xu, Ohio State University, USA

Website and Conference App Chairs
Kevin Duh, John Hopkins University, USA
Henning Wachsmuth, Paderborn University, Germany

Remote Presentation Chair
Derek F. Wong, University of Macau, China

Student Volunteer Coordinator and Student Scholarship Chairs
Wenjie Li, Hong Kong Polytechnic University, China
Marzieh Saeidi, Facebook AI Research, UK

Childcare Policy and Grant Coordinators
Olivia Kwong, Chinese University of Hong Kong, China
Sujian Li, Peking University, China

Diversity and Inclusion Chairs
Chi-Kiu (Jackie) Lo, National Research Council Canada, Canada
Vivek Srikumar, University of Utah, USA

Program Committee

Program Committee Co-chairs
Jing Jiang, Singapore Management University, Singapore
Vincent Ng, University of Texas at Dallas, USA
Xiaojun Wan, Peking University, China

Senior Area Chairs
Dialog and Interactive Systems
Amanda Stent, Bloomberg, USA

Discourse and Pragmatics
Bonnie Webber, University of Edinburgh, UK

Information Extraction
Dan Roth, University of Pennsylvania, USA

Information Retrieval and Document Analysis
Hang Li, Bytedance Technology, China

Lexical Semantics
Mona Diab, George Washington University, USA

Linguistic Theories, Cognitive Modeling and Psycholinguistics
Andrew Kehler, University of California, San Diego, USA

Machine Learning for NLP
Kevin Duh, Johns Hopkins University, USA

Machine Translation and Multilinguality
Chris Quirk, Microsoft Research, USA

Phonology, Morphology and Word Segmentation
Yuji Matsumoto, Nara Institute of Science and Technology, Japan

Question Answering
Scott Wen-tau Yih, Facebook AI Research, USA

Sentence-level Semantics
Mirella Lapata, University of Edinburgh, UK

Sentiment Analysis and Argument Mining
Yulan He, University of Warwick, UK

Social Media and Computational Social Science
Dirk Hovy, Bocconi University, Italy

Speech, Vision, Robotics, Multimodal and Grounding
Haizhou Li, National University of Singapore, Singapore

Summarization and Generation
Michael White, Ohio State University, USA

Tagging, Chunking, Syntax and Parsing
Yue Zhang, Westlake University, China

Text Mining and NLP Applications
Jimmy Lin, University of Waterloo, Canada

Textual Inference and Other Areas of Semantics
Alessandro Moschitti, Amazon, USA

Area Chairs

Dialog and Interactive Systems
Luciana Benotti, Asli Celikyilmaz, Yun-Nung Chen, Milica Gasic, Ryuichiro Higashinaka, Casey Kennington, Kazunori Komatani, Sungjin Lee, Stefan Ultes

Discourse and Pragmatics

jhieva, Yue Dong, Yufang Hou, Yuhao Zhang, Yujiu Yang, Yulia Grishina, Yuxuan Lai, Yves Scherrer, Zhaochun Ren

Invited Speaker: Meeyoung Cha, KAIST
Current Challenges in Computational Social Science

Abstract: Artificial intelligence (AI) is reshaping business and science. Computational social science is an interdisciplinary field that solves complex societal problems by adopting AI-driven methods, processes, algorithms, and systems on data of various forms. This talk will review some of the latest advances in the research that focuses on fake news and legal liability. I will first discuss the structural, temporal, and linguistic traits of fake news propagation. One emerging challenge here is the increasing use of automated bots to generate and propagate false information. I will also discuss the current issues on the legal liability of AI and robots, particularly on how to regulate them (e.g., moral machine, punishment gap). This talk will suggest new opportunities to tackle these problems.

Bio: Meeyoung Cha is an associate professor at the School of Computing in KAIST. Dr. Cha's research interests are in analyzing complex network systems, including web and social media. Her research in the field of data science, artificial intelligence, and computational social science has gained more than 12,000 citations based on Google Scholar and has received the best paper awards at ACM IMC and ICWSM. Dr. Cha is currently in the editorial board member of PeerJ and ACM Transactions on Social Computing, and she has served as a program co-chair for ICWSM 2015. Dr. Cha has worked at Facebook's Data Science Team as a Visiting Professor in 2015−2016. Since 2019, she is jointly affiliated with the Institute for Basic Science (IBS) in Korea as a Chief Investigator.

Invited Speaker: Kyunghyun Cho, New York University
Curiosity-driven Journey into Neural Sequence Models

Abstract: In this talk, I take the audience on a tour of my earlier and recent experiences in building neural sequence models. I start from the earlier experience of using a recurrent net for sequence-to-sequence learning and talk about the attention mechanism. I discuss factors behind the success of these earlier approaches, and how these were embraced by the community even before they sota'd. I then move on to a more recent research direction in unconventional neural sequence models that automatically learn to decide on the order of generation.

Bio: Kyunghyun Cho is an associate professor of computer science and data science at New York University and a research scientist at Facebook AI Research. He was a postdoctoral fellow at University of Montreal until summer 2015 under the supervision of Prof. Yoshua Bengio, and received PhD and MSc degrees from Aalto University early 2014 under the supervision of Prof. Juha Karhunen, Dr. Tapani Raiko and Dr. Alexander Ilin. He tries his best to find a balance among machine learning, natural language processing, and life, but almost always fails to do so.

Invited Speaker: Noam Slonim, IBM Haifa Research Lab

Project Debater - How Persuasive can a Computer be?

Abstract: Project Debater is the first AI system that can meaningfully debate a human opponent. The system, an IBM Grand Challenge, is designed to build coherent, convincing speeches on its own, as well as provide rebuttals to the opponent's main arguments. In February 2019, Project Debater competed against Harish Natarajan, who holds the world record for most debate victories, in an event held in San Francisco that was broadcasted live world-wide. In this talk I will tell the story of Project Debater, from conception to a climatic final event, describe its underlying technology, and discuss how it can be leveraged for advancing decision making and critical thinking.

Bio: Noam Slonim is a Distinguished Engineer at IBM Research AI. He received his doctorate from the Interdisciplinary Center for Neural Computation at the Hebrew University and held a post-doc position at the Genomics Institute at Princeton University. During his PhD, Noam received the best paper award in UAI and ECIR, and the best presentation award at SIGIR. Noam joined the IBM Haifa Research Lab in 2007, and in 2011 he proposed to develop Project Debater. He has been serving as the Principal Investigator of the project since then. Noam published around 60 peer reviewed articles, focusing on the last few years on advancing the emerging field of Computational Argumentation. Finally, Noam used to have a secondary career as a TV script writer. Coincidentally, or not, in a sitcom he co-created back in 1998, the last episode was focused on competitive debates.

Table of Contents

Attending to Future Tokens for Bidirectional Sequence Generation
Carolin Lawrence, Bhushan Kotnis and Mathias Niepert 1

Attention is not not Explanation
Sarah Wiegreffe and Yuval Pinter 11

Practical Obstacles to Deploying Active Learning
David Lowell, Zachary C. Lipton and Byron C. Wallace 21

Transfer Learning Between Related Tasks Using Expected Label Proportions
Matan Ben Noach and Yoav Goldberg 31

Knowledge Enhanced Contextual Word Representations
Matthew E. Peters, Mark Neumann, Robert Logan, Roy Schwartz, Vidur Joshi, Sameer Singh and Noah A. Smith 43

How Contextual are Contextualized Word Representations? Comparing the Geometry of BERT, ELMo, and GPT-2 Embeddings
Kawin Ethayarajh 55

Room to Glo: A Systematic Comparison of Semantic Change Detection Approaches with Word Embeddings
Philippa Shoemark, Farhana Ferdousi Liza, Dong Nguyen, Scott Hale and Barbara McGillivray 66

Correlations between Word Vector Sets
Vitalii Zhelezniak, April Shen, Daniel Busbridge, Aleksandar Savkov and Nils Hammerla 77

Game Theory Meets Embeddings: a Unified Framework for Word Sense Disambiguation
Rocco Tripodi and Roberto Navigli 88

Guided Dialog Policy Learning: Reward Estimation for Multi-Domain Task-Oriented Dialog
Ryuichi Takanobu, Hanlin Zhu and Minlie Huang 100

Multi-hop Selector Network for Multi-turn Response Selection in Retrieval-based Chatbots
Chunyuan Yuan, Wei Zhou, Mingming Li, Shangwen Lv, Fuqing Zhu, Jizhong Han and Songlin Hu 111

MoEL: Mixture of Empathetic Listeners
Zhaojiang Lin, Andrea Madotto, Jamin Shin, Peng Xu and Pascale Fung 121

Entity-Consistent End-to-end Task-Oriented Dialogue System with KB Retriever
Libo Qin, Yijia Liu, Wanxiang Che, Haoyang Wen, Yangming Li and Ting Liu 133

Building Task-Oriented Visual Dialog Systems Through Alternative Optimization Between Dialog Policy and Language Generation
Mingyang Zhou, Josh Arnold and Zhou Yu 143

DialogueGCN: A Graph Convolutional Neural Network for Emotion Recognition in Conversation
Deepanway Ghosal, Navonil Majumder, Soujanya Poria, Niyati Chhaya and Alexander Gelbukh 154

Knowledge-Enriched Transformer for Emotion Detection in Textual Conversations
Peixiang Zhong, Di Wang and Chunyan Miao 165

Interpretable Relevant Emotion Ranking with Event-Driven Attention
Yang Yang, Deyu ZHOU, Yulan He and Meng Zhang 177

Justifying Recommendations using Distantly-Labeled Reviews and Fine-Grained Aspects
Jianmo Ni, Jiacheng Li and Julian McAuley 188

Using Customer Service Dialogues for Satisfaction Analysis with Context-Assisted Multiple Instance Learning
Kaisong Song, Lidong Bing, Wei Gao, Jun Lin, Lujun Zhao, Jiancheng Wang, Changlong Sun, Xiaozhong Liu and Qiong Zhang 198

Leveraging Dependency Forest for Neural Medical Relation Extraction
Linfeng Song, Yue Zhang, Daniel Gildea, Mo Yu, Zhiguo Wang and jinsong su 208

Open Relation Extraction: Relational Knowledge Transfer from Supervised Data to Unsupervised Data
Ruidong Wu, Yuan Yao, Xu Han, Ruobing Xie, Zhiyuan Liu, Fen Lin, Leyu Lin and Maosong Sun 219

Improving Relation Extraction with Knowledge-attention
Pengfei Li, Kezhi Mao, Xuefeng Yang and Qi Li 229

Jointly Learning Entity and Relation Representations for Entity Alignment
Yuting Wu, Xiao Liu, Yansong Feng, Zheng Wang and Dongyan Zhao 240

Tackling Long-Tailed Relations and Uncommon Entities in Knowledge Graph Completion
Zihao Wang, Kwunping Lai, Piji Li, Lidong Bing and Wai Lam 250

Low-Resource Name Tagging Learned with Weakly Labeled Data
Yixin Cao, Zikun Hu, Tat-seng Chua, Zhiyuan Liu and Heng Ji 261

Learning Dynamic Context Augmentation for Global Entity Linking
Xiyuan Yang, Xiaotao Gu, Sheng Lin, Siliang Tang, Yueting Zhuang, Fei Wu, Zhigang Chen, Guoping Hu and Xiang Ren 271

Open Event Extraction from Online Text using a Generative Adversarial Network
Rui Wang, Deyu ZHOU and Yulan He 282

Learning to Bootstrap for Entity Set Expansion
Lingyong Yan, Xianpei Han, Le Sun and Ben He 292

Multi-Input Multi-Output Sequence Labeling for Joint Extraction of Fact and Condition Tuples from Scientific Text
Tianwen Jiang, Tong Zhao, Bing Qin, Ting Liu, Nitesh Chawla and Meng Jiang 302

Cross-lingual Structure Transfer for Relation and Event Extraction
Ananya Subburathinam, Di Lu, Heng Ji, Jonathan May, Shih-Fu Chang, Avirup Sil and Clare Voss 313

Uncover the Ground-Truth Relations in Distant Supervision: A Neural Expectation-Maximization Framework
Junfan Chen, Richong Zhang, Yongyi Mao, Hongyu Guo and Jie Xu 326

Doc2EDAG: An End-to-End Document-level Framework for Chinese Financial Event Extraction
Shun Zheng, Wei Cao, Wei Xu and Jiang Bian 337

Event Detection with Trigger-Aware Lattice Neural Network
Ning Ding, Ziran Li, Zhiyuan Liu, Haitao Zheng and Zibo Lin 347

A Boundary-aware Neural Model for Nested Named Entity Recognition
Changmeng Zheng, Yi Cai, Jingyun Xu, Ho-fung Leung and Guandong Xu 357

Learning the Extraction Order of Multiple Relational Facts in a Sentence with Reinforcement Learning
Xiangrong Zeng, Shizhu He, Daojian Zeng, Kang Liu, Shengping Liu and Jun Zhao 367

CaRe: Open Knowledge Graph Embeddings
Swapnil Gupta, Sreyash Kenkre and Partha Talukdar 378

Self-Attention Enhanced CNNs and Collaborative Curriculum Learning for Distantly Supervised Relation Extraction
Yuyun Huang and Jinhua Du 389

Neural Cross-Lingual Relation Extraction Based on Bilingual Word Embedding Mapping
Jian Ni and Radu Florian 399

Leveraging 2-hop Distant Supervision from Table Entity Pairs for Relation Extraction
xiang deng and Huan Sun 410

EntEval: A Holistic Evaluation Benchmark for Entity Representations
Mingda Chen, Zewei Chu, Yang Chen, Karl Stratos and Kevin Gimpel 421

Joint Event and Temporal Relation Extraction with Shared Representations and Structured Prediction
Rujun Han, Qiang Ning and Nanyun Peng 434

Hierarchical Text Classification with Reinforced Label Assignment
Yuning Mao, Jingjing Tian, Jiawei Han and Xiang Ren 445

Investigating Capsule Network and Semantic Feature on Hyperplanes for Text Classification
Chunning Du, Haifeng Sun, Jingyu Wang, Qi Qi, Jianxin Liao, Chun Wang and Bing Ma 456

Label-Specific Document Representation for Multi-Label Text Classification
Lin Xiao, Xin Huang, Boli Chen and Liping Jing 466

Hierarchical Attention Prototypical Networks for Few-Shot Text Classification
Shengli Sun, Qingfeng Sun, Kevin Zhou and Tengchao Lv 476

Many Faces of Feature Importance: Comparing Built-in and Post-hoc Feature Importance in Text Classification
Vivian Lai, Zheng Cai and Chenhao Tan 486

Enhancing Local Feature Extraction with Global Representation for Neural Text Classification
Guocheng Niu, Hengru Xu, Bolei He, Xinyan Xiao, Hua Wu and Sheng GAO 496

Latent-Variable Generative Models for Data-Efficient Text Classification
Xiaoan Ding and Kevin Gimpel 507

PaRe: A Paper-Reviewer Matching Approach Using a Common Topic Space
Omer Anjum, Hongyu Gong, Suma Bhat, Wen-Mei Hwu and JinJun Xiong 518

Linking artificial and human neural representations of language
Jon Gauthier and Roger Levy 529

Neural Text Summarization: A Critical Evaluation
Wojciech Kryscinski, Nitish Shirish Keskar, Bryan McCann, Caiming Xiong and Richard Socher 540

Neural data-to-text generation: A comparison between pipeline and end-to-end architectures
Thiago Castro Ferreira, Chris van der Lee, Emiel van Miltenburg and Emiel Krahmer 552

MoverScore: Text Generation Evaluating with Contextualized Embeddings and Earth Mover Distance
Wei Zhao, Maxime Peyrard, Fei Liu, Yang Gao, Christian M. Meyer and Steffen Eger 563

Select and Attend: Towards Controllable Content Selection in Text Generation
Xiaoyu Shen, Jun Suzuki, Kentaro Inui, Hui Su, Dietrich Klakow and Satoshi Sekine 579

Sentence-Level Content Planning and Style Specification for Neural Text Generation
Xinyu Hua and Lu Wang 591

Translate and Label! An Encoder-Decoder Approach for Cross-lingual Semantic Role Labeling
Angel Daza and Anette Frank 603

Syntax-Enhanced Self-Attention-Based Semantic Role Labeling
Yue Zhang, Rui Wang and Luo Si 616

VerbAtlas: a Novel Large-Scale Verbal Semantic Resource and Its Application to Semantic Role Labeling
Andrea Di Fabio, Simone Conia and Roberto Navigli 627

Parameter-free Sentence Embedding via Orthogonal Basis
Ziyi Yang, Chenguang Zhu and Weizhu Chen 638

Evaluation Benchmarks and Learning Criteria for Discourse-Aware Sentence Representations
Mingda Chen, Zewei Chu and Kevin Gimpel 649

Extracting Possessions from Social Media: Images Complement Language
Dhivya Chinnappa, Srikala Murugan and Eduardo Blanco 663

Learning to Speak and Act in a Fantasy Text Adventure Game
Jack Urbanek, Angela Fan, Siddharth Karamcheti, Saachi Jain, Samuel Humeau, Emily Dinan, Tim Rocktäschel, Douwe Kiela, Arthur Szlam and Jason Weston 673

Help, Anna! Visual Navigation with Natural Multimodal Assistance via Retrospective Curiosity-Encouraging Imitation Learning
Khanh Nguyen and Hal Daumé III 684

Incorporating Visual Semantics into Sentence Representations within a Grounded Space
Patrick Bordes, Eloi Zablocki, Laure Soulier, Benjamin Piwowarski and patrick Gallinari 696

Neural Naturalist: Generating Fine-Grained Image Comparisons
Maxwell Forbes, Christine Kaeser-Chen, Piyush Sharma and Serge Belongie 708

Fine-Grained Evaluation for Entity Linking
Henry Rosales-Méndez, Aidan Hogan and Barbara Poblete 718

Supervising Unsupervised Open Information Extraction Models
Arpita Roy, Youngja Park, Taesung Lee and Shimei Pan 728

Neural Cross-Lingual Event Detection with Minimal Parallel Resources
Jian Liu, Yubo Chen, Kang Liu and Jun Zhao 738

KnowledgeNet: A Benchmark Dataset for Knowledge Base Population
Filipe Mesquita, Matteo Cannaviccio, Jordan Schmidek, Paramita Mirza and Denilson Barbosa 749

Effective Use of Transformer Networks for Entity Tracking
Aditya Gupta and Greg Durrett 759

Explicit Cross-lingual Pre-training for Unsupervised Machine Translation
Shuo Ren, Yu Wu, Shujie Liu, Ming Zhou and Shuai Ma 770

Latent Part-of-Speech Sequences for Neural Machine Translation
Xuewen Yang, Yingru Liu, Dongliang Xie, Xin Wang and Niranjan Balasubramanian 780

Improving Back-Translation with Uncertainty-based Confidence Estimation
Shuo Wang, Yang Liu, Chao Wang, Huanbo Luan and Maosong Sun 791

Towards Linear Time Neural Machine Translation with Capsule Networks
Mingxuan Wang 803

Modeling Multi-mapping Relations for Precise Cross-lingual Entity Alignment
Xiaofei Shi and Yanghua Xiao 813

Supervised and Nonlinear Alignment of Two Embedding Spaces for Dictionary Induction in Low Resourced Languages
Masud Moshtaghi 823

Beto, Bentz, Becas: The Surprising Cross-Lingual Effectiveness of BERT
Shijie Wu and Mark Dredze 833

Iterative Dual Domain Adaptation for Neural Machine Translation
Jiali Zeng, Yang Liu, Jinsong SU, yubing Ge, Yaojie Lu, Yongjing Yin and jiebo luo 845

Multi-agent Learning for Neural Machine Translation
tianchi bi, hao xiong, Zhongjun He, Hua Wu and Haifeng Wang 856

Pivot-based Transfer Learning for Neural Machine Translation between Non-English Languages
Yunsu Kim, Petre Petrov, Pavel Petrushkov, Shahram Khadivi and Hermann Ney 866

Context-Aware Monolingual Repair for Neural Machine Translation
Elena Voita, Rico Sennrich and Ivan Titov 877

Multi-Granularity Self-Attention for Neural Machine Translation
Jie Hao, Xing Wang, Shuming Shi, Jinfeng Zhang and Zhaopeng Tu 887

Improving Deep Transformer with Depth-Scaled Initialization and Merged Attention
Biao Zhang, Ivan Titov and Rico Sennrich 898

A Discriminative Neural Model for Cross-Lingual Word Alignment
Elias Stengel-Eskin, Tzu-ray Su, Matt Post and Benjamin Van Durme 910

One Model to Learn Both: Zero Pronoun Prediction and Translation
Longyue Wang, Zhaopeng Tu, Xing Wang and Shuming Shi 921

Dynamic Past and Future for Neural Machine Translation
Zaixiang Zheng, Shujian Huang, Zhaopeng Tu, XIN-YU DAI and Jiajun CHEN 931

Revisit Automatic Error Detection for Wrong and Missing Translation – A Supervised Approach
Wenqiang Lei, Weiwen Xu, Ai Ti Aw, Yuanxin Xiang and Tat Seng Chua 942

Towards Understanding Neural Machine Translation with Word Importance
Shilin He, Zhaopeng Tu, Xing Wang, Longyue Wang, Michael Lyu and Shuming Shi 953

Multilingual Neural Machine Translation with Language Clustering
Xu Tan, Jiale Chen, Di He, Yingce Xia, Tao QIN and Tie-Yan Liu 963

Don't Forget the Long Tail! A Comprehensive Analysis of Morphological Generalization in Bilingual Lexicon Induction
Paula Czarnowska, Sebastian Ruder, Edouard Grave, Ryan Cotterell and Ann Copestake 974

Pushing the Limits of Low-Resource Morphological Inflection
Antonios Anastasopoulos and Graham Neubig 984

Cross-Lingual Dependency Parsing Using Code-Mixed TreeBank
Meishan Zhang, Yue Zhang and Guohong Fu 997

Hierarchical Pointer Net Parsing
Linlin Liu, Xiang Lin, Shafiq Joty, Simeng Han and Lidong Bing 1007

Semi-Supervised Semantic Role Labeling with Cross-View Training
Rui Cai and Mirella Lapata 1018

Low-Resource Sequence Labeling via Unsupervised Multilingual Contextualized Representations
Zuyi Bao, Rui Huang, Chen Li and Kenny Zhu 1028

A Lexicon-Based Graph Neural Network for Chinese NER
Tao Gui, Yicheng Zou, Qi Zhang, Minlong Peng, Jinlan Fu, Zhongyu Wei and Xuanjing Huang 1040

CM-Net: A Novel Collaborative Memory Network for Spoken Language Understanding
Yijin Liu, Fandong Meng, Jinchao Zhang, Jie Zhou, Yufeng Chen and Jinan Xu 1051

Tree Transformer: Integrating Tree Structures into Self-Attention
Yaushian Wang, Hung-Yi Lee and Yun-Nung Chen 1061

Semantic Role Labeling with Iterative Structure Refinement
Chunchuan Lyu, Shay B. Cohen and Ivan Titov 1071

Entity Projection via Machine Translation for Cross-Lingual NER
Alankar Jain, Bhargavi Paranjape and Zachary C. Lipton 1083

A Bayesian Approach for Sequence Tagging with Crowds
Edwin D. Simpson and Iryna Gurevych 1093

A systematic comparison of methods for low-resource dependency parsing on genuinely low-resource languages
Clara Vania, Yova Kementchedjhieva, Anders Søgaard and Adam Lopez 1105

Target Language-Aware Constrained Inference for Cross-lingual Dependency Parsing
Tao Meng, Nanyun Peng and Kai-Wei Chang 1117

Look-up and Adapt: A One-shot Semantic Parser
Zhichu Lu, Forough Arabshahi, Igor Labutov and Tom Mitchell 1129

Similarity Based Auxiliary Classifier for Named Entity Recognition
Shiyuan Xiao, Yuanxin Ouyang, Wenge Rong, Jianxin Yang and Zhang Xiong 1140

Variable beam search for generative neural parsing and its relevance for the analysis of neuro-imaging signal
Benoit Crabbé, Murielle Fabre and Christophe Pallier 1150

Are We Modeling the Task or the Annotator? An Investigation of Annotator Bias in Natural Language Understanding Datasets
Mor Geva, Yoav Goldberg and Jonathan Berant 1161

Robust Text Classifier on Test-Time Budgets
Md Rizwan Parvez, Tolga Bolukbasi, Kai-Wei Chang and Venkatesh Saligrama 1167

Commonsense Knowledge Mining from Pretrained Models
Joe Davison, Joshua Feldman and Alexander Rush 1173

RNN Architecture Learning with Sparse Regularization
Jesse Dodge, Roy Schwartz, Hao Peng and Noah A. Smith 1179

Analytical Methods for Interpretable Ultradense Word Embeddings
Philipp Dufter and Hinrich Schütze 1185

Investigating Meta-Learning Algorithms for Low-Resource Natural Language Understanding Tasks
Zi-Yi Dou, Keyi Yu and Antonios Anastasopoulos 1192

Retrofitting Contextualized Word Embeddings with Paraphrases
Weijia Shi, Muhao Chen, Pei Zhou and Kai-Wei Chang 1198

Incorporating Contextual and Syntactic Structures Improves Semantic Similarity Modeling
Linqing Liu, Wei Yang, Jinfeng Rao, Raphael Tang and Jimmy Lin 1204

Neural Linguistic Steganography
Zachary Ziegler, Yuntian Deng and Alexander Rush 1210

The Feasibility of Embedding Based Automatic Evaluation for Single Document Summarization
Simeng Sun and Ani Nenkova 1216

Attention Optimization for Abstractive Document Summarization
Min Gui, Junfeng Tian, Rui Wang and Zhenglu Yang 1222

Rewarding Coreference Resolvers for Being Consistent with World Knowledge
Rahul Aralikatte, Heather Lent, Ana Valeria Gonzalez, Daniel Herschcovich, Chen Qiu, Anders Sandholm, Michael Ringaard and Anders Søgaard 1229

An Empirical Study of Incorporating Pseudo Data into Grammatical Error Correction
Shun Kiyono, Jun Suzuki, Masato Mita, Tomoya Mizumoto and Kentaro Inui 1236

A Multilingual Topic Model for Learning Weighted Topic Links Across Corpora with Low Comparability
Weiwei Yang, Jordan Boyd-Graber and Philip Resnik 1243

Measure Country-Level Socio-Economic Indicators with Streaming News: An Empirical Study
Bonan Min and Xiaoxi Zhao 1249

Towards Extracting Medical Family History from Natural Language Interactions: A New Dataset and Baselines
Mahmoud Azab, Stephane Dadian, Vivi Nastase, Larry An and Rada Mihalcea 1255

Multi-task Learning for Natural Language Generation in Task-Oriented Dialogue
Chenguang Zhu, Michael Zeng and Xuedong Huang 1261

Dirichlet Latent Variable Hierarchical Recurrent Encoder-Decoder in Dialogue Generation
Min Zeng, Yisen Wang and Yuan Luo 1267

Semi-Supervised Bootstrapping of Dialogue State Trackers for Task-Oriented Modelling
Bo-Hsiang Tseng, Marek Rei, Paweł Budzianowski, Richard Turner, Bill Byrne and Anna Korhonen 1273

A Progressive Model to Enable Continual Learning for Semantic Slot Filling
Yilin Shen, Xiangyu Zeng and Hongxia Jin 1279

CASA-NLU: Context-Aware Self-Attentive Natural Language Understanding for Task-Oriented Chatbots
Arshit Gupta, Peng Zhang, Garima Lalwani and Mona Diab 1285

Sampling Matters! An Empirical Study of Negative Sampling Strategies for Learning of Matching Models in Retrieval-based Dialogue Systems
Jia Li, Chongyang Tao, wei wu, Yansong Feng, Dongyan Zhao and Rui Yan 1291

Zero-shot Cross-lingual Dialogue Systems with Transferable Latent Variables
Zihan Liu, Jamin Shin, Yan Xu, Genta Indra Winata, Peng Xu, Andrea Madotto and Pascale Fung 1297

Modeling Multi-Action Policy for Task-Oriented Dialogues
Lei Shu, Hu Xu, Bing Liu and Piero Molino 1304

An Evaluation Dataset for Intent Classification and Out-of-Scope Prediction
Stefan Larson, Anish Mahendran, Joseph J. Peper, Christopher Clarke, Andrew Lee, Parker Hill, Jonathan K. Kummerfeld, Kevin Leach, Michael A. Laurenzano, Lingjia Tang and Jason mars 1311

Automatically Learning Data Augmentation Policies for Dialogue Tasks
Tong Niu and Mohit Bansal 1317

uniblock: Scoring and Filtering Corpus with Unicode Block Information
Yingbo Gao, Weiyue Wang and Hermann Ney 1324

Multilingual word translation using auxiliary languages
Hagai Taitelbaum, Gal Chechik and Jacob Goldberger 1330

Towards Better Modeling Hierarchical Structure for Self-Attention with Ordered Neurons
Jie Hao, Xing Wang, Shuming Shi, Jinfeng Zhang and Zhaopeng Tu 1336

Vecalign: Improved Sentence Alignment in Linear Time and Space
Brian Thompson and Philipp Koehn 1342

Simpler and Faster Learning of Adaptive Policies for Simultaneous Translation
Baigong Zheng, Renjie Zheng, Mingbo Ma and Liang Huang 1349

Adversarial Learning with Contextual Embeddings for Zero-resource Cross-lingual Classification and NER
Phillip Keung, yichao lu and Vikas Bhardwaj 1355

Recurrent Positional Embedding for Neural Machine Translation
Kehai Chen, Rui Wang, Masao Utiyama and Eiichiro Sumita 1361

Machine Translation for Machines: the Sentiment Classification Use Case
amirhossein tebbifakhr, Luisa Bentivogli, Matteo Negri and Marco Turchi 1368

Investigating the Effectiveness of BPE: The Power of Shorter Sequences
Matthias Gallé 1375

HABLex: Human Annotated Bilingual Lexicons for Experiments in Machine Translation
Brian Thompson, Rebecca Knowles, Xuan Zhang, Huda Khayrallah, Kevin Duh and Philipp Koehn 1382

Handling Syntactic Divergence in Low-resource Machine Translation
Chunting Zhou, Xuezhe Ma, Junjie Hu and Graham Neubig 1388

Speculative Beam Search for Simultaneous Translation
Renjie Zheng, Mingbo Ma, Baigong Zheng and Liang Huang 1395

Self-Attention with Structural Position Representations
Xing Wang, Zhaopeng Tu, Longyue Wang and Shuming Shi 1403

Exploiting Multilingualism through Multistage Fine-Tuning for Low-Resource Neural Machine Translation
Raj Dabre, Atsushi Fujita and Chenhui Chu 1410

Unsupervised Domain Adaptation for Neural Machine Translation with Domain-Aware Feature Embeddings
Zi-Yi Dou, Junjie Hu, Antonios Anastasopoulos and Graham Neubig 1417

A Regularization-based Framework for Bilingual Grammar Induction
Yong Jiang, Wenjuan Han and Kewei Tu 1423

Encoders Help You Disambiguate Word Senses in Neural Machine Translation
Gongbo Tang, Rico Sennrich and Joakim Nivre 1429

Korean Morphological Analysis with Tied Sequence-to-Sequence Multi-Task Model
Hyun-Je Song and Seong-Bae Park 1436

Efficient Convolutional Neural Networks for Diacritic Restoration
Sawsan Alqahtani, Ajay Mishra and Mona Diab 1442

Improving Generative Visual Dialog by Answering Diverse Questions
Vishvak Murahari, Prithvijit Chattopadhyay, Dhruv Batra, Devi Parikh and Abhishek Das . . . 1449

Cross-lingual Transfer Learning with Data Selection for Large-Scale Spoken Language Understanding
Quynh Do and Judith Gaspers 1455

Multi-Head Attention with Diversity for Learning Grounded Multilingual Multimodal Representations
Po-Yao Huang, Xiaojun Chang and Alexander Hauptmann 1461

Decoupled Box Proposal and Featurization with Ultrafine-Grained Semantic Labels Improve Image Captioning and Visual Question Answering
Soravit Changpinyo, Bo Pang, Piyush Sharma and Radu Soricut 1468

REO-Relevance, Extraness, Omission: A Fine-grained Evaluation for Image Captioning
Ming Jiang, Junjie Hu, Qiuyuan Huang, Lei Zhang, Jana Diesner and Jianfeng Gao 1475

WSLLN:Weakly Supervised Natural Language Localization Networks
Mingfei Gao, Larry Davis, Richard Socher and Caiming Xiong 1481

Grounding learning of modifier dynamics: An application to color naming
Xudong Han, Philip Schulz and Trevor Cohn 1488

Robust Navigation with Language Pretraining and Stochastic Sampling
Xiujun Li, Chunyuan Li, Qiaolin Xia, Yonatan Bisk, Asli Celikyilmaz, Jianfeng Gao, Noah A. Smith and Yejin Choi 1494

Towards Making a Dependency Parser See
Michalina Strzyz, David Vilares and Carlos Gómez-Rodríguez 1500

Unsupervised Labeled Parsing with Deep Inside-Outside Recursive Autoencoders
Andrew Drozdov, Patrick Verga, Yi-Pei Chen, Mohit Iyyer and Andrew McCallum 1507

Dependency Parsing for Spoken Dialog Systems
Sam Davidson, Dian Yu and Zhou Yu 1513

Span-based Hierarchical Semantic Parsing for Task-Oriented Dialog
Panupong Pasupat, Sonal Gupta, Karishma Mandyam, Rushin Shah, Mike Lewis and Luke Zettlemoyer 1520

Enhancing Context Modeling with a Query-Guided Capsule Network for Document-level Translation
Zhengxin Yang, Jinchao Zhang, Fandong Meng, Shuhao Gu, Yang Feng and Jie Zhou 1527

Simple, Scalable Adaptation for Neural Machine Translation
Ankur Bapna and Orhan Firat 1538

Controlling Text Complexity in Neural Machine Translation
Sweta Agrawal and Marine Carpuat 1549

Investigating Multilingual NMT Representations at Scale
Sneha Kudugunta, Ankur Bapna, Isaac Caswell and Orhan Firat 1565

Hierarchical Modeling of Global Context for Document-Level Neural Machine Translation
Xin Tan, Longyin Zhang, Deyi Xiong and Guodong Zhou 1576

Cross-Lingual Machine Reading Comprehension
Yiming Cui, Wanxiang Che, Ting Liu, Bing Qin, Shijin Wang and Guoping Hu 1586

A Multi-Type Multi-Span Network for Reading Comprehension that Requires Discrete Reasoning
Minghao Hu, Yuxing Peng, Zhen Huang and Dongsheng Li 1596

Neural Duplicate Question Detection without Labeled Training Data
Andreas Rücklé, Nafise Sadat Moosavi and Iryna Gurevych 1607

Asking Clarification Questions in Knowledge-Based Question Answering
Jingjing Xu, Yuechen Wang, Duyu Tang, Nan Duan, Pengcheng Yang, Qi Zeng, Ming Zhou and Xu SUN 1618

Multi-View Domain Adapted Sentence Embeddings for Low-Resource Unsupervised Duplicate Question Detection
Nina Poerner and Hinrich Schütze 1630

Multi-label Categorization of Accounts of Sexism using a Neural Framework
Pulkit Parikh, Harika Abburi, Pinkesh Badjatiya, Radhika Krishnan, Niyati Chhaya, Manish Gupta and Vasudeva Varma 1642

The Trumpiest Trump? Identifying a Subject's Most Characteristic Tweets
Charuta Pethe and Steve Skiena 1653

Finding Microaggressions in the Wild: A Case for Locating Elusive Phenomena in Social Media Posts
Luke Breitfeller, Emily Ahn, David Jurgens and Yulia Tsvetkov 1664

Reinforced Product Metadata Selection for Helpfulness Assessment of Customer Reviews
Miao Fan, Chao Feng, Mingming Sun and Ping Li 1675

Learning Invariant Representations of Social Media Users
Nicholas Andrews and Marcus Bishop 1684

(Male, Bachelor) and (Female, Ph.D) have different connotations: Parallelly Annotated Stylistic Language Dataset with Multiple Personas
Dongyeop Kang, Varun Gangal and Eduard Hovy 1696

Movie Plot Analysis via Turning Point Identification
Pinelopi Papalampidi, Frank Keller and Mirella Lapata 1707

Latent Suicide Risk Detection on Microblog via Suicide-Oriented Word Embeddings and Layered Attention
Lei Cao, Huijun Zhang, Ling Feng, Zihan Wei, Xin Wang, Ningyun Li and Xiaohao He 1718

Deep Ordinal Regression for Pledge Specificity Prediction
Shivashankar Subramanian, Trevor Cohn and Timothy Baldwin 1729

Data-Efficient Goal-Oriented Conversation with Dialogue Knowledge Transfer Networks
Igor Shalyminov, Sungjin Lee, Arash Eshghi and Oliver Lemon 1741

Multi-Granularity Representations of Dialog
Shikib Mehri and Maxine Eskenazi 1752

Are You for Real? Detecting Identity Fraud via Dialogue Interactions
Weikang Wang, Jiajun Zhang, Qian Li, Chengqing Zong and Zhifei Li 1762

Hierarchy Response Learning for Neural Conversation Generation
Bo Zhang and Xiaoming Zhang 1772

Knowledge Aware Conversation Generation with Explainable Reasoning over Augmented Graphs
zhibin liu, Zheng-Yu Niu, Hua Wu and Haifeng Wang 1782

Adaptive Parameterization for Neural Dialogue Generation
Hengyi Cai, Hongshen Chen, Cheng Zhang, Yonghao Song, Xiaofang Zhao and Dawei Yin . . 1793

Towards Knowledge-Based Recommender Dialog System
Qibin Chen, Junyang Lin, Yichang Zhang, Ming Ding, Yukuo Cen, Hongxia Yang and Jie Tang 1803

Structuring Latent Spaces for Stylized Response Generation
Xiang Gao, Yizhe Zhang, Sungjin Lee, Michel Galley, Chris Brockett, Jianfeng Gao and Bill Dolan 1814

Improving Open-Domain Dialogue Systems via Multi-Turn Incomplete Utterance Restoration
Zhufeng Pan, Kun Bai, Yan Wang, Lianqiang Zhou and Xiaojiang Liu 1824

Unsupervised Context Rewriting for Open Domain Conversation
Kun Zhou, Kai Zhang, Yu Wu, Shujie Liu and Jingsong Yu 1834

Dually Interactive Matching Network for Personalized Response Selection in Retrieval-Based Chatbots
Jia-Chen Gu, Zhen-Hua Ling, Xiaodan Zhu and Quan Liu 1845

DyKgChat: Benchmarking Dialogue Generation Grounding on Dynamic Knowledge Graphs
Yi-Lin Tuan, Yun-Nung Chen and Hung-yi Lee 1855

Retrieval-guided Dialogue Response Generation via a Matching-to-Generation Framework
Deng Cai, Yan Wang, Wei Bi, Zhaopeng Tu, Xiaojiang Liu and Shuming Shi 1866

Scalable and Accurate Dialogue State Tracking via Hierarchical Sequence Generation
Liliang Ren, Jianmo Ni and Julian McAuley 1876

Low-Resource Response Generation with Template Prior
Ze Yang, wei wu, Jian Yang, Can Xu and zhoujun li 1886

A Discrete CVAE for Response Generation on Short-Text Conversation
Jun Gao, Wei Bi, Xiaojiang Liu, Junhui Li, Guodong Zhou and Shuming Shi 1898

Who Is Speaking to Whom? Learning to Identify Utterance Addressee in Multi-Party Conversations
Ran Le, Wenpeng Hu, Mingyue Shang, Zhenjun You, Lidong Bing, Dongyan Zhao and Rui Yan 1909

A Semi-Supervised Stable Variational Network for Promoting Replier-Consistency in Dialogue Generation
Jinxin Chang, Ruifang He, Longbiao Wang, Xiangyu Zhao, Ting Yang and Ruifang Wang . . . 1920

Modeling Personalization in Continuous Space for Response Generation via Augmented Wasserstein Autoencoders
Zhangming Chan, Juntao Li, Xiaopeng Yang, Xiuying Chen, Wenpeng Hu, Dongyan Zhao and Rui Yan 1931

Variational Hierarchical User-based Conversation Model
JinYeong Bak and Alice Oh 1941

Recommendation as a Communication Game: Self-Supervised Bot-Play for Goal-oriented Dialogue
Dongyeop Kang, Anusha Balakrishnan, Pararth Shah, Paul Crook, Y-Lan Boureau and Jason Weston 1951

CoSQL: A Conversational Text-to-SQL Challenge Towards Cross-Domain Natural Language Interfaces to Databases
Tao Yu, Rui Zhang, Heyang Er, Suyi Li, Eric Xue, Bo Pang, Xi Victoria Lin, Yi Chern Tan, Tianze Shi, Zihan Li, Youxuan Jiang, Michihiro Yasunaga, Sungrok Shim, Tao Chen, Alexander Fabbri, Zifan Li, Luyao Chen, Yuwen Zhang, Shreya Dixit, Vincent Zhang, Caiming Xiong, Richard Socher, Walter Lasecki and Dragomir Radev 1962

A Practical Dialogue-Act-Driven Conversation Model for Multi-Turn Response Selection
Harshit Kumar, Arvind Agarwal and Sachindra Joshi 1980

How to Build User Simulators to Train RL-based Dialog Systems
Weiyan Shi, Kun Qian, Xuewei Wang and Zhou Yu 1990

Low-Rank HOCA: Efficient High-Order Cross-Modal Attention for Video Captioning
Tao Jin, Siyu Huang, Yingming Li and Zhongfei Zhang 2001

Image Captioning with Very Scarce Supervised Data: Adversarial Semi-Supervised Learning Approach
Dong-Jin Kim, Jinsoo Choi, Tae-Hyun Oh and In So Kweon 2012

Dual Attention Networks for Visual Reference Resolution in Visual Dialog
Gi-Cheon Kang, Jaeseo Lim and Byoung-Tak Zhang 2024

Unsupervised Discovery of Multimodal Links in Multi-image, Multi-sentence Documents
Jack Hessel, Lillian Lee and David Mimno 2034

UR-FUNNY: A Multimodal Language Dataset for Understanding Humor
Md Kamrul Hasan, Wasifur Rahman, AmirAli Bagher Zadeh, Jianyuan Zhong, Md Iftekhar Tanveer, Louis-Philippe Morency and Mohammed (Ehsan) Hoque 2046

Partners in Crime: Multi-view Sequential Inference for Movie Understanding
Nikos Papasarantopoulos, Lea Frermann, Mirella Lapata and Shay B. Cohen 2057

Guiding the Flowing of Semantics: Interpretable Video Captioning via POS Tag
Xinyu Xiao, Lingfeng Wang, Bin Fan, Shinming Xiang and Chunhong Pan 2068

A Stack-Propagation Framework with Token-Level Intent Detection for Spoken Language Understanding
Libo Qin, Wanxiang Che, Yangming Li, Haoyang Wen and Ting Liu 2078

Talk2Car: Taking Control of Your Self-Driving Car
Thierry Deruyttere, Simon Vandenhende, Dusan Grujicic, Luc Van Gool and Marie-Francine Moens 2088

Fact-Checking Meets Fauxtography: Verifying Claims About Images
Dimitrina Zlatkova, Preslav Nakov and Ivan Koychev 2099

Video Dialog via Progressive Inference and Cross-Transformer
Weike Jin, Zhou Zhao, Mao Gu, Jun Xiao, Furu Wei and Yueting Zhuang 2109

Executing Instructions in Situated Collaborative Interactions
Alane Suhr, Claudia Yan, Jack Schluger, Stanley Yu, Hadi Khader, Marwa Mouallem, Iris Zhang and Yoav Artzi 2119

Fusion of Detected Objects in Text for Visual Question Answering
Chris Alberti, Jeffrey Ling, Michael Collins and David Reitter 2131

TIGEr: Text-to-Image Grounding for Image Caption Evaluation
Ming Jiang, Qiuyuan Huang, Lei Zhang, Xin Wang, Pengchuan Zhang, Zhe Gan, Jana Diesner and Jianfeng Gao 2141

Universal Adversarial Triggers for Attacking and Analyzing NLP
Eric Wallace, Shi Feng, Nikhil Kandpal, Matt Gardner and Sameer Singh 2153

To Annotate or Not? Predicting Performance Drop under Domain Shift
Hady Elsahar and Matthias Gallé 2163

Adaptively Sparse Transformers
Gonçalo M. Correia, Vlad Niculae and André F. T. Martins 2174

Show Your Work: Improved Reporting of Experimental Results
Jesse Dodge, Suchin Gururangan, Dallas Card, Roy Schwartz and Noah A. Smith 2185

A Deep Factorization of Style and Structure in Fonts
Akshay Srivatsan, Jonathan Barron, Dan Klein and Taylor Berg-Kirkpatrick 2195

Cross-lingual Semantic Specialization via Lexical Relation Induction
Edoardo Maria Ponti, Ivan Vulić, Goran Glavaš, Roi Reichart and Anna Korhonen 2206

Modelling the interplay of metaphor and emotion through multitask learning
Verna Dankers, Marek Rei, Martha Lewis and Ekaterina Shutova 2218

How well do NLI models capture verb veridicality?
Alexis Ross and Ellie Pavlick 2230

Modeling Color Terminology Across Thousands of Languages
Arya D. McCarthy, Winston Wu, Aaron Mueller, William Watson and David Yarowsky 2241

Negative Focus Detection via Contextual Attention Mechanism
Longxiang Shen, Bowei Zou, Yu Hong, Guodong Zhou, Qiaoming Zhu and AiTi Aw 2251

A Unified Neural Coherence Model
Han Cheol Moon, Tasnim Mohiuddin, Shafiq Joty and Chi Xu 2262

Topic-Guided Coherence Modeling for Sentence Ordering by Preserving Global and Local Information
Byungkook Oh, Seungmin Seo, Cheolheon Shin, Eunju Jo and Kyong-Ho Lee 2273

Neural Generative Rhetorical Structure Parsing
Amandla Mabona, Laura Rimell, Stephen Clark and Andreas Vlachos 2284

Weak Supervision for Learning Discourse Structure
Sonia Badene, Kate Thompson, Jean-Pierre Lorré and Nicholas Asher 2296

Predicting Discourse Structure using Distant Supervision from Sentiment
Patrick Huber and Giuseppe Carenini 2306

The Myth of Double-Blind Review Revisited: ACL vs. EMNLP
Cornelia Caragea, Ana Uban and Liviu P. Dinu 2317

Uncover Sexual Harassment Patterns from Personal Stories by Joint Key Element Extraction and Categorization
Yingchi Liu, Quanzhi Li, Marika Cifor, Xiaozhong Liu, Qiong Zhang and Luo Si 2328

Identifying Predictive Causal Factors from News Streams
Ananth Balashankar, Sunandan Chakraborty, Samuel Fraiberger and Lakshminarayanan Subramanian 2338

Training Data Augmentation for Detecting Adverse Drug Reactions in User-Generated Content
Sepideh Mesbah, Jie Yang, Robert-Jan Sips, Manuel Valle Torre, Christoph Lofi, Alessandro Bozzon and Geert-Jan Houben 2349

Deep Reinforcement Learning-based Text Anonymization against Private-Attribute Inference
Ahmadreza Mosallanezhad, Ghazaleh Beigi and Huan Liu 2360

Tree-structured Decoding for Solving Math Word Problems
Qianying Liu, Wenyv Guan, Sujian Li and Daisuke Kawahara 2370

PullNet: Open Domain Question Answering with Iterative Retrieval on Knowledge Bases and Text
Haitian Sun, Tania Bedrax-Weiss and William Cohen 2380

Cosmos QA: Machine Reading Comprehension with Contextual Commonsense Reasoning
Lifu Huang, Ronan Le Bras, Chandra Bhagavatula and Yejin Choi 2391

Finding Generalizable Evidence by Learning to Convince Q&A Models
Ethan Perez, Siddharth Karamcheti, Rob Fergus, Jason Weston, Douwe Kiela and Kyunghyun Cho 2402

Ranking and Sampling in Open-Domain Question Answering
Yanfu Xu, Zheng Lin, Yuanxin Liu, Rui Liu, Weiping Wang and Dan Meng 2412

A Non-commutative Bilinear Model for Answering Path Queries in Knowledge Graphs
Katsuhiko Hayashi and Masashi Shimbo 2422

Generating Questions for Knowledge Bases via Incorporating Diversified Contexts and Answer-Aware Loss
Cao Liu, Kang Liu, Shizhu He, Zaiqing Nie and Jun Zhao 2431

Multi-Task Learning for Conversational Question Answering over a Large-Scale Knowledge Base
Tao Shen, Xiubo Geng, Tao QIN, Daya Guo, Duyu Tang, Nan Duan, Guodong Long and Daxin Jiang 2442

BiPaR: A Bilingual Parallel Dataset for Multilingual and Cross-lingual Reading Comprehension on Novels
Yimin Jing, Deyi Xiong and Zhen Yan 2452

Language Models as Knowledge Bases?
Fabio Petroni, Tim Rocktäschel, Sebastian Riedel, Patrick Lewis, Anton Bakhtin, Yuxiang Wu and Alexander Miller 2463

NumNet: Machine Reading Comprehension with Numerical Reasoning
Qiu Ran, Yankai Lin, Peng Li, Jie Zhou and Zhiyuan Liu 2474

Unicoder: A Universal Language Encoder by Pre-training with Multiple Cross-lingual Tasks
Haoyang Huang, Yaobo Liang, Nan Duan, Ming Gong, Linjun Shou, Daxin Jiang and Ming Zhou 2485

Addressing Semantic Drift in Question Generation for Semi-Supervised Question Answering
Shiyue Zhang and Mohit Bansal 2495

Adversarial Domain Adaptation for Machine Reading Comprehension
Huazheng Wang, Zhe Gan, Xiaodong Liu, Jingjing Liu, Jianfeng Gao and Hongning Wang . . 2510

Incorporating External Knowledge into Machine Reading for Generative Question Answering
Bin Bi, Chen Wu, Ming Yan, Wei Wang, Jiangnan Xia and Chenliang Li 2521

Answering questions by learning to rank - Learning to rank by answering questions
George Sebastian Pirtoaca, Traian Rebedea and Stefan Ruseti 2531

Discourse-Aware Semantic Self-Attention for Narrative Reading Comprehension
Todor Mihaylov and Anette Frank 2541

Revealing the Importance of Semantic Retrieval for Machine Reading at Scale
Yixin Nie, Songhe Wang and Mohit Bansal 2553

PubMedQA: A Dataset for Biomedical Research Question Answering
Qiao Jin, Bhuwan Dhingra, Zhengping Liu, William Cohen and Xinghua Lu 2567

Quick and (not so) Dirty: Unsupervised Selection of Justification Sentences for Multi-hop Question Answering
Vikas Yadav, Steven Bethard and Mihai Surdeanu 2578

Answering Complex Open-domain Questions Through Iterative Query Generation
Peng Qi, Xiaowen Lin, Leo Mehr, Zijian Wang and Christopher D. Manning 2590

NL2pSQL: Generating Pseudo-SQL Queries from Under-Specified Natural Language Questions
Fuxiang Chen, Seung-won Hwang, Jaegul Choo, Jung-Woo Ha and Sunghun Kim 2603

Leveraging Frequent Query Substructures to Generate Formal Queries for Complex Question Answering
Jiwei Ding, Wei Hu, Qixin Xu and Yuzhong Qu 2614

Incorporating Graph Attention Mechanism into Knowledge Graph Reasoning Based on Deep Reinforcement Learning
Heng Wang, Shuangyin Li, Rong Pan and Mingzhi Mao 2623

Learning to Update Knowledge Graphs by Reading News
Jizhi Tang, Yansong Feng and Dongyan Zhao 2632

DIVINE: A Generative Adversarial Imitation Learning Framework for Knowledge Graph Reasoning
Ruiping Li and Xiang Cheng 2642

Original Semantics-Oriented Attention and Deep Fusion Network for Sentence Matching
Mingtong Liu, Yujie Zhang, Jinan Xu and Yufeng Chen 2652

Representation Learning with Ordered Relation Paths for Knowledge Graph Completion
Yao Zhu, Hongzhi Liu, Zhonghai Wu, Yang Song and Tao Zhang 2662

Collaborative Policy Learning for Open Knowledge Graph Reasoning
Cong Fu, Tong Chen, Meng Qu, Woojeong Jin and Xiang Ren 2672

Modeling Event Background for If-Then Commonsense Reasoning Using Context-aware Variational Autoencoder
Li Du, Xiao Ding, Ting Liu and Zhongyang Li 2682

Asynchronous Deep Interaction Network for Natural Language Inference
Di Liang, Fubao Zhang, Qi Zhang and Xuanjing Huang 2692

Keep Calm and Switch On! Preserving Sentiment and Fluency in Semantic Text Exchange
Steven Y. Feng, Aaron W. Li and Jesse Hoey 2701

Query-focused Scenario Construction
Su Wang, Greg Durrett and Katrin Erk 2712

Semi-supervised Entity Alignment via Joint Knowledge Embedding Model and Cross-graph Model
Chengjiang Li, Yixin Cao, Lei Hou, Jiaxin Shi, Juanzi Li and Tat-Seng Chua 2723

Designing and Interpreting Probes with Control Tasks
John Hewitt and Percy Liang 2733

Specializing Word Embeddings (for Parsing) by Information Bottleneck
Xiang Lisa Li and Jason Eisner 2744

Deep Contextualized Word Embeddings in Transition-Based and Graph-Based Dependency Parsing - A Tale of Two Parsers Revisited
Artur Kulmizev, Miryam de Lhoneux, Johannes Gontrum, Elena Fano and Joakim Nivre 2755

Semantic graph parsing with recurrent neural network DAG grammars
Federico Fancellu, Sorcha Gilroy, Adam Lopez and Mirella Lapata 2769

75 Languages, 1 Model: Parsing Universal Dependencies Universally
Dan Kondratyuk and Milan Straka 2779

Interactive Language Learning by Question Answering
Xingdi Yuan, Marc-Alexandre Côté, Jie Fu, Zhouhan Lin, Chris Pal, Yoshua Bengio and Adam Trischler 2796

What's Missing: A Knowledge Gap Guided Approach for Multi-hop Question Answering
Tushar Khot, Ashish Sabharwal and Peter Clark 2814

KagNet: Knowledge-Aware Graph Networks for Commonsense Reasoning
Bill Yuchen Lin, Xinyue Chen, Jamin Chen and Xiang Ren 2829

Learning with Limited Data for Multilingual Reading Comprehension
Kyungjae Lee, Sunghyun Park, Hojae Han, Jinyoung Yeo, Seung-won Hwang and Juho Lee . 2840

A Discrete Hard EM Approach for Weakly Supervised Question Answering
Sewon Min, Danqi Chen, Hannaneh Hajishirzi and Luke Zettlemoyer 2851

Is the Red Square Big? MALeViC: Modeling Adjectives Leveraging Visual Contexts
Sandro Pezzelle and Raquel Fernández 2865

Investigating BERT's Knowledge of Language: Five Analysis Methods with NPIs
Alex Warstadt, Yu Cao, Ioana Grosu, Wei Peng, Hagen Blix, Yining Nie, Anna Alsop, Shikha Bordia, Haokun Liu, Alicia Parrish, Sheng-Fu Wang, Jason Phang, Anhad Mohananey, Phu Mon Htut, Paloma Jeretic and Samuel R. Bowman 2877

Representation of Constituents in Neural Language Models: Coordination Phrase as a Case Study
Aixiu AN, Peng Qian, Ethan Wilcox and Roger Levy 2888

Towards Zero-shot Language Modeling
Edoardo Maria Ponti, Ivan Vulić, Ryan Cotterell, Roi Reichart and Anna Korhonen 2900

What Gets Echoed? Understanding the "Pointers" in Explanations of Persuasive Arguments
David Atkinson, Kumar Bhargav Srinivasan and Chenhao Tan 2911

Modeling Frames in Argumentation
Yamen Ajjour, Milad Alshomary, Henning Wachsmuth and Benno Stein 2922

AMPERSAND: Argument Mining for PERSuAsive oNline Discussions
Tuhin Chakrabarty, Christopher Hidey, Smaranda Muresan, Kathy McKeown and Alyssa Hwang 2933

Evaluating adversarial attacks against multiple fact verification systems
James Thorne, Andreas Vlachos, Christos Christodoulopoulos and Arpit Mittal 2944

Nonsense!: Quality Control via Two-Step Reason Selection for Annotating Local Acceptability and Related Attributes in News Editorials
Wonsuk Yang, seungwon yoon, Ada Carpenter and Jong Park 2954

Evaluating Pronominal Anaphora in Machine Translation: An Evaluation Measure and a Test Suite
Prathyusha Jwalapuram, Shafiq Joty, Irina Temnikova and Preslav Nakov 2964

A Regularization Approach for Incorporating Event Knowledge and Coreference Relations into Neural Discourse Parsing
Zeyu Dai and Ruihong Huang 2976

Weakly Supervised Multilingual Causality Extraction from Wikipedia
Chikara Hashimoto 2988

Attribute-aware Sequence Network for Review Summarization
Junjie Li, Xuepeng Wang, Dawei Yin and Chengqing Zong 3000

Extractive Summarization of Long Documents by Combining Global and Local Context
Wen Xiao and Giuseppe Carenini 3011

Enhancing Neural Data-To-Text Generation Models with External Background Knowledge
Shuang Chen, Jinpeng Wang, Xiaocheng Feng, Feng Jiang, Bing Qin and Chin-Yew Lin 3022

Reading Like HER: Human Reading Inspired Extractive Summarization
Ling Luo, Xiang Ao, Yan Song, Feiyang Pan, Min Yang and Qing He 3033

Contrastive Attention Mechanism for Abstractive Sentence Summarization
Xiangyu Duan, Hongfei Yu, Mingming Yin, Min Zhang, Weihua Luo and Yue Zhang 3044

NCLS: Neural Cross-Lingual Summarization
Junnan Zhu, Qian Wang, Yining Wang, Yu Zhou, Jiajun Zhang, Shaonan Wang and Chengqing Zong 3054

Clickbait? Sensational Headline Generation with Auto-tuned Reinforcement Learning
Peng Xu, Chien-Sheng Wu, Andrea Madotto and Pascale Fung 3065

Concept Pointer Network for Abstractive Summarization
Wenbo Wang, Yang Gao, Heyan Huang and Yuxiang Zhou 3076

Surface Realisation Using Full Delexicalisation
Anastasia Shimorina and Claire Gardent 3086

IMaT: Unsupervised Text Attribute Transfer via Iterative Matching and Translation
Zhijing Jin, Di Jin, Jonas Mueller, Nicholas Matthews and Enrico Santus 3097

Better Rewards Yield Better Summaries: Learning to Summarise Without References
Florian Böhm, Yang Gao, Christian M. Meyer, Ori Shapira, Ido Dagan and Iryna Gurevych . . 3110

Mixture Content Selection for Diverse Sequence Generation
Jaemin Cho, Minjoon Seo and Hannaneh Hajishirzi 3121

An End-to-End Generative Architecture for Paraphrase Generation
Qian Yang, Zhouyuan Huo, Dinghan Shen, Yong Cheng, Wenlin Wang, Guoyin Wang and Lawrence Carin 3132

Table-to-Text Generation with Effective Hierarchical Encoder on Three Dimensions (Row, Column and Time)
Heng Gong, Xiaocheng Feng, Bing Qin and Ting Liu 3143

Subtopic-driven Multi-Document Summarization
Xin Zheng, Aixin Sun, Jing Li and Karthik Muthuswamy 3153

Referring Expression Generation Using Entity Profiles
Meng Cao and Jackie Chi Kit Cheung 3163

Exploring Diverse Expressions for Paraphrase Generation
Lihua Qian, Lin Qiu, Weinan Zhang, Xin Jiang and Yong Yu 3173

Enhancing AMR-to-Text Generation with Dual Graph Representations
Leonardo F. R. Ribeiro, Claire Gardent and Iryna Gurevych 3183

Keeping Consistency of Sentence Generation and Document Classification with Multi-Task Learning
Toru Nishino, Shotaro Misawa, Ryuji Kano, Tomoki Taniguchi, Yasuhide Miura and Tomoko Ohkuma 3195

Toward a Task of Feedback Comment Generation for Writing Learning
Ryo Nagata 3206

Improving Question Generation With to the Point Context
Jingjing Li, Yifan Gao, Lidong Bing, Irwin King and Michael R. Lyu 3216

Deep Copycat Networks for Text-to-Text Generation
Julia Ive, Pranava Madhyastha and Lucia Specia 3227

Towards Controllable and Personalized Review Generation
Pan Li and Alexander Tuzhilin 3237

Answers Unite! Unsupervised Metrics for Reinforced Summarization Models
Thomas Scialom, Sylvain Lamprier, Benjamin Piwowarski and Jacopo Staiano 3246

Long and Diverse Text Generation with Planning-based Hierarchical Variational Model
Zhihong Shao, Minlie Huang, Jiangtao Wen, Wenfei Xu and xiaoyan zhu 3257

"Transforming" Delete, Retrieve, Generate Approach for Controlled Text Style Transfer
Akhilesh Sudhakar, Bhargav Upadhyay and Arjun Maheswaran 3269

An Entity-Driven Framework for Abstractive Summarization
Eva Sharma, Luyang Huang, Zhe Hu and Lu Wang 3280

Neural Extractive Text Summarization with Syntactic Compression
Jiacheng Xu and Greg Durrett 3292

Domain Adaptive Text Style Transfer
Dianqi Li, Yizhe Zhang, Zhe Gan, Yu Cheng, Chris Brockett, Bill Dolan and Ming-Ting Sun 3304

Let's Ask Again: Refine Network for Automatic Question Generation
Preksha Nema, Akash Kumar Mohankumar, Mitesh M. Khapra, Balaji Vasan Srinivasan and Balaraman Ravindran 3314

Earlier Isn't Always Better: Sub-aspect Analysis on Corpus and System Biases in Summarization

Do We Really Need Fully Unsupervised Cross-Lingual Embeddings?
Ivan Vulić, Goran Glavaš, Roi Reichart and Anna Korhonen 4407

Weakly-Supervised Concept-based Adversarial Learning for Cross-lingual Word Embeddings
Haozhou Wang, James Henderson and Paola Merlo 4419

Aligning Cross-Lingual Entities with Multi-Aspect Information
Hsiu-Wei Yang, Yanyan Zou, Peng Shi, Wei Lu, Jimmy Lin and Xu SUN 4431

Contrastive Language Adaptation for Cross-Lingual Stance Detection
Mitra Mohtarami, James Glass and Preslav Nakov 4442

Jointly Learning to Align and Translate with Transformer Models
Sarthak Garg, Stephan Peitz, Udhyakumar Nallasamy and Matthias Paulik 4453

Social IQa: Commonsense Reasoning about Social Interactions
Maarten Sap, Hannah Rashkin, Derek Chen, Ronan Le Bras and Yejin Choi 4463

Self-Assembling Modular Networks for Interpretable Multi-Hop Reasoning
Yichen Jiang and Mohit Bansal 4474

Posing Fair Generalization Tasks for Natural Language Inference
Atticus Geiger, Ignacio Cases, Lauri Karttunen and Christopher Potts 4485

Everything Happens for a Reason: Discovering the Purpose of Actions in Procedural Text
Bhavana Dalvi, Niket Tandon, Antoine Bosselut, Wen-tau Yih and Peter Clark 4496

CLUTRR: A Diagnostic Benchmark for Inductive Reasoning from Text
Koustuv Sinha, Shagun Sodhani, Jin Dong, Joelle Pineau and William L. Hamilton 4506

Taskmaster-1: Toward a Realistic and Diverse Dialog Dataset
Bill Byrne, Karthik Krishnamoorthi, Chinnadhurai Sankar, Arvind Neelakantan, Ben Goodrich, Daniel Duckworth, Semih Yavuz, Amit Dubey, Kyu-Young Kim and Andy Cedilnik 4516

Multi-Domain Goal-Oriented Dialogues (MultiDoGO): Strategies toward Curating and Annotating Large Scale Dialogue Data
Denis Peskov, Nancy Clarke, Jason Krone, Brigi Fodor, Yi Zhang, Adel Youssef and Mona Diab 4526

Build it Break it Fix it for Dialogue Safety: Robustness from Adversarial Human Attack
Emily Dinan, Samuel Humeau, Bharath Chintagunta and Jason Weston 4537

GECOR: An End-to-End Generative Ellipsis and Co-reference Resolution Model for Task-Oriented Dialogue
Jun Quan, Deyi Xiong, Bonnie Webber and Changjian Hu 4547

Task-Oriented Conversation Generation Using Heterogeneous Memory Networks
Zehao Lin, Xinjing Huang, Feng Ji, Haiqing Chen and Yin Zhang 4558

Aspect-based Sentiment Classification with Aspect-specific Graph Convolutional Networks
Chen Zhang, Qiuchi Li and Dawei Song 4568

Coupling Global and Local Context for Unsupervised Aspect Extraction
Ming Liao, Jing Li, Haisong Zhang, Lingzhi Wang, Xixin Wu and Kam-Fai Wong 4579

Transferable End-to-End Aspect-based Sentiment Analysis with Selective Adversarial Learning
Zheng Li, Xin Li, Ying Wei, Lidong Bing, Yu Zhang and Qiang Yang 4590

CAN: Constrained Attention Networks for Multi-Aspect Sentiment Analysis
Mengting Hu, Shiwan Zhao, Li Zhang, Keke Cai, Zhong Su, Renhong Cheng and Xiaowei Shen 4601

Leveraging Just a Few Keywords for Fine-Grained Aspect Detection Through Weakly Supervised Co-Training
Giannis Karamanolakis, Daniel Hsu and Luis Gravano 4611

Integrating Text and Image: Determining Multimodal Document Intent in Instagram Posts
Julia Kruk, Jonah Lubin, Karan Sikka, Xiao Lin, Dan Jurafsky and Ajay Divakaran 4622

Neural Conversation Recommendation with Online Interaction Modeling
Xingshan Zeng, Jing Li, Lu Wang and Kam-Fai Wong 4633

Different Absorption from the Same Sharing: Sifted Multi-task Learning for Fake News Detection
Lianwei Wu, Yuan Rao, Haolin Jin, Ambreen Nazir and Ling Sun 4644

Text-based inference of moral sentiment change
Jing Yi Xie, Renato Ferreira Pinto Junior, Graeme Hirst and Yang Xu 4654

Detecting Causal Language Use in Science Findings
Bei Yu, Yingya Li and Jun Wang 4664

Multilingual and Multi-Aspect Hate Speech Analysis
Nedjma Ousidhoum, Zizheng Lin, Hongming Zhang, Yangqiu Song and Dit-Yan Yeung 4675

MultiFC: A Real-World Multi-Domain Dataset for Evidence-Based Fact Checking of Claims
Isabelle Augenstein, Christina Lioma, Dongsheng Wang, Lucas Chaves Lima, Casper Hansen, Christian Hansen and Jakob Grue Simonsen 4685

A Deep Neural Information Fusion Architecture for Textual Network Embeddings
Zenan Xu, Qinliang Su, Xiaojun Quan and Weijia Zhang 4698

You Shall Know a User by the Company It Keeps: Dynamic Representations for Social Media Users in NLP
Marco Del Tredici, Diego Marcheggiani, Sabine Schulte im Walde and Raquel Fernández . . . 4707

Adaptive Ensembling: Unsupervised Domain Adaptation for Political Document Analysis
Shrey Desai, Barea Sinno, Alex Rosenfeld and Junyi Jessy Li 4718

Macrocosm: Social Media Persona Linking for Open Source Intelligence Applications
Graham Horwood, Ning Yu, Thomas Boggs, Changjiang Yang and Chad Holvenstot 4731

A Hierarchical Location Prediction Neural Network for Twitter User Geolocation
Binxuan Huang and Kathleen Carley 4732

Trouble on the Horizon: Forecasting the Derailment of Online Conversations as they Develop
Jonathan P. Chang and Cristian Danescu-Niculescu-Mizil 4743

A Benchmark Dataset for Learning to Intervene in Online Hate Speech
Jing Qian, Anna Bethke, Yinyin Liu, Elizabeth Belding and William Yang Wang 4755

Detecting and Reducing Bias in a High Stakes Domain
Ruiqi Zhong, Yanda Chen, Desmond Patton, Charlotte Selous and Kathy McKeown 4765

CodeSwitch-Reddit: Exploration of Written Multilingual Discourse in Online Discussion Forums
Ella Rabinovich, Masih Sultani and Suzanne Stevenson 4776

Modeling Conversation Structure and Temporal Dynamics for Jointly Predicting Rumor Stance and Veracity
Penghui Wei, Nan Xu and Wenji Mao 4787

Reconstructing Capsule Networks for Zero-shot Intent Classification
Han Liu, Xiaotong Zhang, Lu Fan, Xuandi Fu, Qimai Li, Xiao-Ming Wu and Albert Y.S. Lam 4799

Domain Adaptation for Person-Job Fit with Transferable Deep Global Match Network
Shuqing Bian, Wayne Xin Zhao, Yang Song, Tao Zhang and Ji-Rong Wen 4810

Heterogeneous Graph Attention Networks for Semi-supervised Short Text Classification
Hu Linmei, Tianchi Yang, Chuan Shi, Houye Ji and Xiaoli Li 4821

Comparing and Developing Tools to Measure the Readability of Domain-Specific Texts
Elissa Redmiles, Lisa Maszkiewicz, Emily Hwang, Dhruv Kuchhal, Everest Liu, Miraida Morales, Denis Peskov, Sudha Rao, Rock Stevens, Kristina Gligorić, Sean Kross, Michelle Mazurek and Hal Daumé III 4831

News2vec: News Network Embedding with Subnode Information
Ye Ma, Lu Zong, Yikang Yang and Jionglong Su 4843

Recursive Context-Aware Lexical Simplification
Sian Gooding and Ekaterina Kochmar 4853

Leveraging Medical Literature for Section Prediction in Electronic Health Records
Sara Rosenthal, Ken Barker and Zhicheng Liang 4864

Neural News Recommendation with Heterogeneous User Behavior
Chuhan Wu, Fangzhao Wu, Mingxiao An, Tao Qi, Jianqiang Huang, Yongfeng Huang and Xing Xie 4874

Reviews Meet Graphs: Enhancing User and Item Representations for Recommendation with Hierarchical Attentive Graph Neural Network
Chuhan Wu, Fangzhao Wu, Tao Qi, Suyu Ge, Yongfeng Huang and Xing Xie 4884

Event Representation Learning Enhanced with External Commonsense Knowledge
Xiao Ding, Kuo Liao, Ting Liu, Zhongyang Li and Junwen Duan 4894

Learning to Discriminate Perturbations for Blocking Adversarial Attacks in Text Classification
Yichao Zhou, Jyun-Yu Jiang, Kai-Wei Chang and Wei Wang 4904

A Neural Citation Count Prediction Model based on Peer Review Text
Siqing Li, Wayne Xin Zhao, Eddy Jing Yin and Ji-Rong Wen 4914

Connecting the Dots: Document-level Neural Relation Extraction with Edge-oriented Graphs
Fenia Christopoulou, Makoto Miwa and Sophia Ananiadou 4925

Semi-supervised Text Style Transfer: Cross Projection in Latent Space
Mingyue Shang, Piji Li, Zhenxin Fu, Lidong Bing, Dongyan Zhao, Shuming Shi and Rui Yan 4937

Question Answering for Privacy Policies: Combining Computational and Legal Perspectives
Abhilasha Ravichander, Alan W Black, Shomir Wilson, Thomas Norton and Norman Sadeh . 4947

Stick to the Facts: Learning towards a Fidelity-oriented E-Commerce Product Description Generation
Zhangming Chan, Xiuying Chen, Yongliang Wang, Juntao Li, Zhiqiang Zhang, Kun Gai, Dongyan Zhao and Rui Yan 4959

Fine-Grained Entity Typing via Hierarchical Multi Graph Convolutional Networks
Hailong Jin, Lei Hou, Juanzi Li and Tiansi Dong 4969

Learning to Infer Entities, Properties and their Relations from Clinical Conversations
Nan Du, Mingqiu Wang, Linh Tran, Gang Lee and Izhak Shafran 4979

Practical Correlated Topic Modeling and Analysis via the Rectified Anchor Word Algorithm
Moontae Lee, Sungjun Cho, David Bindel and David Mimno 4991

Modeling the Relationship between User Comments and Edits in Document Revision
Xuchao Zhang, Dheeraj Rajagopal, Michael Gamon, Sujay Kumar Jauhar and ChangTien Lu 5002

PRADO: Projection Attention Networks for Document Classification On-Device
Karthik Krishnamoorthi, Sujith Ravi and Zornitsa Kozareva 5012

Subword Language Model for Query Auto-Completion
Gyuwan Kim 5022

Enhancing Dialogue Symptom Diagnosis with Global Attention and Symptom Graph
Xinzhu Lin, Xiahui He, Qin Chen, Huaixiao Tou, Zhongyu Wei and Ting Chen 5033

Counterfactual Story Reasoning and Generation
Lianhui Qin, Antoine Bosselut, Ari Holtzman, Chandra Bhagavatula, Elizabeth Clark and Yejin Choi 5043

Encode, Tag, Realize: High-Precision Text Editing
Eric Malmi, Sebastian Krause, Sascha Rothe, Daniil Mirylenka and Aliaksei Severyn 5054

Answer-guided and Semantic Coherent Question Generation in Open-domain Conversation
Weichao Wang, Shi Feng, Daling Wang and Yifei Zhang 5066

Read, Attend and Comment: A Deep Architecture for Automatic News Comment Generation
Ze Yang, Can Xu, wei wu and zhoujun li 5077

A Topic Augmented Text Generation Model: Joint Learning of Semantics and Structural Features
hongyin tang, Miao Li and Beihong Jin 5090

LXMERT: Learning Cross-Modality Encoder Representations from Transformers
Hao Tan and Mohit Bansal 5100

Phrase Grounding by Soft-Label Chain Conditional Random Field
Jiacheng Liu and Julia Hockenmaier 5112

What You See is What You Get: Visual Pronoun Coreference Resolution in Dialogues
Xintong Yu, Hongming Zhang, Yangqiu Song, Yan Song and Changshui Zhang 5123

YouMakeup: A Large-Scale Domain-Specific Multimodal Dataset for Fine-Grained Semantic Comprehension
Weiying Wang, Yongcheng Wang, Shizhe Chen and Qin Jin 5133

DEBUG: A Dense Bottom-Up Grounding Approach for Natural Language Video Localization
Chujie Lu, Long Chen, Chilie Tan, Xiaolin Li and Jun Xiao 5144

CrossWeigh: Training Named Entity Tagger from Imperfect Annotations
Zihan Wang, Jingbo Shang, Liyuan Liu, Lihao Lu, Jiacheng Liu and Jiawei Han 5154

A Little Annotation does a Lot of Good: A Study in Bootstrapping Low-resource Named Entity Recognizers
Aditi Chaudhary, Jiateng Xie, Zaid Sheikh, Graham Neubig and Jaime Carbonell 5164

Open Domain Web Keyphrase Extraction Beyond Language Modeling
Lee Xiong, Chuan Hu, Chenyan Xiong, Daniel Campos and Arnold Overwijk 5175

TuckER: Tensor Factorization for Knowledge Graph Completion
Ivana Balazevic, Carl Allen and Timothy Hospedales 5185

Human-grounded Evaluations of Explanation Methods for Text Classification
Piyawat Lertvittayakumjorn and Francesca Toni 5195

A Context-based Framework for Modeling the Role and Function of On-line Resource Citations in Scientific Literature
He Zhao, Zhunchen Luo, Chong Feng, Anqing Zheng and Xiaopeng Liu 5206

Adversarial Reprogramming of Text Classification Neural Networks
Paarth Neekhara, Shehzeen Hussain, Shlomo Dubnov and Farinaz Koushanfar 5216

Document Hashing with Mixture-Prior Generative Models
Wei Dong, Qinliang Su, Dinghan Shen and Changyou Chen 5226

On Efficient Retrieval of Top Similarity Vectors
Shulong Tan, Zhixin Zhou, Zhaozhuo Xu and Ping Li 5236

Multiplex Word Embeddings for Selectional Preference Acquisition
Hongming Zhang, Jiaxin Bai, Yan Song, Kun Xu, Changlong Yu, Yangqiu Song, Wilfred Ng and Dong Yu 5247

MulCode: A Multiplicative Multi-way Model for Compressing Neural Language Model
Yukun Ma, Patrick H. Chen and Cho-Jui Hsieh 5257

It's All in the Name: Mitigating Gender Bias with Name-Based Counterfactual Data Substitution
Rowan Hall Maudslay, Hila Gonen, Ryan Cotterell and Simone Teufel 5267

Examining Gender Bias in Languages with Grammatical Gender
Pei Zhou, Weijia Shi, Jieyu Zhao, Kuan-Hao Huang, Muhao Chen, Ryan Cotterell and Kai-Wei Chang 5276

Weakly Supervised Cross-lingual Semantic Relation Classification via Knowledge Distillation
Yogarshi Vyas and Marine Carpuat 5285

Improved Word Sense Disambiguation Using Pre-Trained Contextualized Word Representations
Christian Hadiwinoto, Hwee Tou Ng and Wee Chung Gan 5297

Do NLP Models Know Numbers? Probing Numeracy in Embeddings
Eric Wallace, Yizhong Wang, Sujian Li, Sameer Singh and Matt Gardner 5307

A Split-and-Recombine Approach for Follow-up Query Analysis
Qian Liu, Bei Chen, Haoyan Liu, Jian-Guang LOU, Lei Fang, Bin Zhou and Dongmei Zhang 5316

Text2Math: End-to-end Parsing Text into Math Expressions
Yanyan Zou and Wei Lu 5327

Editing-Based SQL Query Generation for Cross-Domain Context-Dependent Questions
Rui Zhang, Tao Yu, Heyang Er, Sungrok Shim, Eric Xue, Xi Victoria Lin, Tianze Shi, Caiming Xiong, Richard Socher and Dragomir Radev 5338

Syntax-aware Multilingual Semantic Role Labeling
Shexia He, Zuchao Li and Hai Zhao 5350

Cloze-driven Pretraining of Self-attention Networks
Alexei Baevski, Sergey Edunov, Yinhan Liu, Luke Zettlemoyer and Michael Auli 5360

Bridging the Gap between Relevance Matching and Semantic Matching for Short Text Similarity Modeling
Jinfeng Rao, Linqing Liu, Yi Tay, Wei Yang, Peng Shi and Jimmy Lin 5370

A Syntax-aware Multi-task Learning Framework for Chinese Semantic Role Labeling
Qingrong Xia, Zhenghua Li and Min Zhang 5382

Transfer Fine-Tuning: A BERT Case Study
Yuki Arase and Jun'ichi Tsujii 5393

Data-Anonymous Encoding for Text-to-SQL Generation
Zhen Dong, Shizhao Sun, Hongzhi Liu, Jian-Guang Lou and Dongmei Zhang 5405

Capturing Argument Interaction in Semantic Role Labeling with Capsule Networks
Xinchi Chen, Chunchuan Lyu and Ivan Titov 5415

Learning Programmatic Idioms for Scalable Semantic Parsing
Srinivasan Iyer, Alvin Cheung and Luke Zettlemoyer 5426

JuICe: A Large Scale Distantly Supervised Dataset for Open Domain Context-based Code Generation
Rajas Agashe, Srinivasan Iyer and Luke Zettlemoyer 5436

Model-based Interactive Semantic Parsing: A Unified Framework and A Text-to-SQL Case Study
Ziyu Yao, Yu Su, Huan Sun and Wen-tau Yih 5447

Modeling Graph Structure in Transformer for Better AMR-to-Text Generation
Jie Zhu, Junhui Li, Muhua Zhu, Longhua Qian, Min Zhang and Guodong Zhou 5459

Syntax-Aware Aspect Level Sentiment Classification with Graph Attention Networks
Binxuan Huang and Kathleen Carley 5469

Learning Explicit and Implicit Structures for Targeted Sentiment Analysis
Hao Li and Wei Lu 5478

Capsule Network with Interactive Attention for Aspect-Level Sentiment Classification
Chunning Du, Haifeng Sun, Jingyu Wang, Qi Qi, Jianxin Liao, Tong Xu and Ming Liu 5489

Emotion Detection with Neural Personal Discrimination
Xiabing Zhou, Zhongqing Wang, Shoushan Li, Guodong Zhou and Min Zhang 5499

Specificity-Driven Cascading Approach for Unsupervised Sentiment Modification
Pengcheng Yang, Junyang Lin, Jingjing Xu, Jun Xie, Qi Su and Xu SUN 5508

LexicalAT: Lexical-Based Adversarial Reinforcement Training for Robust Sentiment Classification
Jingjing Xu, Liang Zhao, Hanqi Yan, Qi Zeng, Yun Liang and Xu SUN 5518

Leveraging Structural and Semantic Correspondence for Attribute-Oriented Aspect Sentiment Discovery
Zhe Zhang and Munindar Singh 5528

From the Token to the Review: A Hierarchical Multimodal approach to Opinion Mining
Alexandre Garcia, Pierre Colombo, Florence d'Alché-Buc, Slim Essid and Chloé Clavel 5539

Shallow Domain Adaptive Embeddings for Sentiment Analysis
Prathusha K Sarma, Yingyu Liang and William Sethares 5549

Domain-Invariant Feature Distillation for Cross-Domain Sentiment Classification
Mengting Hu, Yike Wu, Shiwan Zhao, Honglei Guo, Renhong Cheng and Zhong Su 5559

A Novel Aspect-Guided Deep Transition Model for Aspect Based Sentiment Analysis
Yunlong Liang, Fandong Meng, Jinchao Zhang, Jinan Xu, Yufeng Chen and Jie Zhou 5569

Human-Like Decision Making: Document-level Aspect Sentiment Classification via Hierarchical Reinforcement Learning
Jingjing Wang, Changlong Sun, Shoushan Li, Jiancheng Wang, Luo Si, Min Zhang, Xiaozhong Liu and Guodong Zhou 5581

A Dataset of General-Purpose Rebuttal
Matan Orbach, Yonatan Bilu, Ariel Gera, Yoav Kantor, Lena Dankin, Tamar Lavee, Lili Kotlerman, Shachar Mirkin, Michal Jacovi, Ranit Aharonov and Noam Slonim 5591

Rethinking Attribute Representation and Injection for Sentiment Classification
Reinald Kim Amplayo 5602

A Knowledge Regularized Hierarchical Approach for Emotion Cause Analysis
Chuang Fan, Hongyu Yan, Jiachen Du, Lin Gui, Lidong Bing, Min Yang, Ruifeng Xu and Ruibin Mao 5614

Automatic Argument Quality Assessment - New Datasets and Methods
Assaf Toledo, Shai Gretz, Edo Cohen-Karlik, Roni Friedman, Elad Venezian, Dan Lahav, Michal Jacovi, Ranit Aharonov and Noam Slonim 5625

Fine-Grained Analysis of Propaganda in News Article
Giovanni Da San Martino, Seunghak Yu, Alberto Barrón-Cedeño, Rostislav Petrov and Preslav Nakov 5636

Context-aware Interactive Attention for Multi-modal Sentiment and Emotion Analysis
Dushyant Singh Chauhan, Md Shad Akhtar, Asif Ekbal and Pushpak Bhattacharyya 5647

Sequential Learning of Convolutional Features for Effective Text Classification
Avinash Madasu and Vijjini Anvesh Rao 5658

The Role of Pragmatic and Discourse Context in Determining Argument Impact
Esin Durmus, Faisal Ladhak and Claire Cardie 5668

Aspect-Level Sentiment Analysis Via Convolution over Dependency Tree
Kai Sun, Richong Zhang, Samuel Mensah, Yongyi Mao and Xudong Liu 5679

Understanding Data Augmentation in Neural Machine Translation: Two Perspectives towards Generalization
Guanlin Li, Lemao Liu, Guoping Huang, Conghui Zhu and Tiejun Zhao 5689

Simple and Effective Noisy Channel Modeling for Neural Machine Translation
Kyra Yee, Yann Dauphin and Michael Auli 5696

MultiFiT: Efficient Multi-lingual Language Model Fine-tuning
Julian Eisenschlos, Sebastian Ruder, Piotr Czapla, Marcin Kadras, Sylvain Gugger and Jeremy Howard 5702

Hint-Based Training for Non-Autoregressive Machine Translation
Zhuohan Li, Zi Lin, Di He, Fei Tian, Tao QIN, Liwei WANG and Tie-Yan Liu 5708

Working Hard or Hardly Working: Challenges of Integrating Typology into Neural Dependency Parsers
Adam Fisch, Jiang Guo and Regina Barzilay 5714

Cross-Lingual BERT Transformation for Zero-Shot Dependency Parsing
Yuxuan Wang, Wanxiang Che, Jiang Guo, Yijia Liu and Ting Liu 5721

Multilingual Grammar Induction with Continuous Language Identification
Wenjuan Han, Ge Wang, Yong Jiang and Kewei Tu 5728

Quantifying the Semantic Core of Gender Systems
Adina Williams, Damian Blasi, Lawrence Wolf-Sonkin, Hanna Wallach and Ryan Cotterell . . 5734

Perturbation Sensitivity Analysis to Detect Unintended Model Biases
Vinodkumar Prabhakaran, Ben Hutchinson and Margaret Mitchell 5740

Automatically Inferring Gender Associations from Language
Serina Chang and Kathy McKeown 5746

Reporting the Unreported: Event Extraction for Analyzing the Local Representation of Hate Crimes
Aida Mostafazadeh Davani, Leigh Yeh, Mohammad Atari, Brendan Kennedy, Gwenyth Portillo Wightman, Elaine Gonzalez, Natalie Delong, Rhea Bhatia, Arineh Mirinjian, Xiang Ren and Morteza Dehghani 5753

Minimally Supervised Learning of Affective Events Using Discourse Relations
Jun Saito, Yugo Murawaki and Sadao Kurohashi 5758

Event Detection with Multi-Order Graph Convolution and Aggregated Attention
Haoran Yan, Xiaolong Jin, Xiangbin Meng, Jiafeng Guo and Xueqi Cheng 5766

Coverage of Information Extraction from Sentences and Paragraphs
Simon Razniewski, Nitisha Jain, Paramita Mirza and Gerhard Weikum 5771

HMEAE: Hierarchical Modular Event Argument Extraction
Xiaozhi Wang, Ziqi Wang, Xu Han, Zhiyuan Liu, Juanzi Li, Peng Li, Maosong Sun, Jie Zhou and Xiang Ren 5777

Entity, Relation, and Event Extraction with Contextualized Span Representations
David Wadden, Ulme Wennberg, Yi Luan and Hannaneh Hajishirzi 5784

Next Sentence Prediction helps Implicit Discourse Relation Classification within and across Domains
Wei Shi and Vera Demberg 5790

Split or Merge: Which is Better for Unsupervised RST Parsing?
Naoki Kobayashi, Tsutomu Hirao, Kengo Nakamura, Hidetaka Kamigaito, Manabu Okumura and Masaaki Nagata 5797

BERT for Coreference Resolution: Baselines and Analysis
Mandar Joshi, Omer Levy, Luke Zettlemoyer and Daniel Weld 5803

Linguistic Versus Latent Relations for Modeling Coherent Flow in Paragraphs
Dongyeop Kang and Eduard Hovy 5809

Event Causality Recognition Exploiting Multiple Annotators' Judgments and Background Knowledge
Kazuma Kadowaki, Ryu Iida, Kentaro Torisawa, Jong-Hoon Oh and Julien Kloetzer 5816

What Part of the Neural Network Does This? Understanding LSTMs by Measuring and Dissecting Neurons
Ji Xin, Jimmy Lin and Yaoliang Yu 5823

Quantity doesn't buy quality syntax with neural language models
Marten van Schijndel, Aaron Mueller and Tal Linzen 5831

Higher-order Comparisons of Sentence Encoder Representations
Mostafa Abdou, Artur Kulmizev, Felix Hill, Daniel M. Low and Anders Søgaard 5838

Text Genre and Training Data Size in Human-like Parsing
John Hale, Adhiguna Kuncoro, Keith Hall, Chris Dyer and Jonathan Brennan 5846

Feature2Vec: Distributional semantic modelling of human property knowledge
Steven Derby, Paul Miller and Barry Devereux 5853

Sunny and Dark Outside?! Improving Answer Consistency in VQA through Entailed Question Generation
Arijit Ray, Karan Sikka, Ajay Divakaran, Stefan Lee and Giedrius Burachas 5860

GeoSQA: A Benchmark for Scenario-based Question Answering in the Geography Domain at High School Level
Zixian Huang, Yulin Shen, Xiao Li, Yu'ang Wei, Gong Cheng, Lin Zhou, Xinyu Dai and Yuzhong Qu 5866

Revisiting the Evaluation of Theory of Mind through Question Answering
Matthew Le, Y-Lan Boureau and Maximilian Nickel 5872

Multi-passage BERT: A Globally Normalized BERT Model for Open-domain Question Answering
Zhiguo Wang, Patrick Ng, Xiaofei Ma, Ramesh Nallapati and Bing Xiang 5878

A Span-Extraction Dataset for Chinese Machine Reading Comprehension
Yiming Cui, Ting Liu, Wanxiang Che, Li Xiao, Zhipeng Chen, Wentao Ma, Shijin Wang and Guoping Hu 5883

MICRON: Multigranular Interaction for Contextualizing RepresentatiON in Non-factoid Question Answering
Hojae Han, Seungtaek Choi, Haeju Park and Seung-won Hwang 5890

Machine Reading Comprehension Using Structural Knowledge Graph-aware Network
Delai Qiu, Yuanzhe Zhang, Xinwei Feng, Xiangwen Liao, Wenbin Jiang, Yajuan Lyu, Kang Liu and Jun Zhao 5896

Answering Conversational Questions on Structured Data without Logical Forms
Thomas Mueller, Francesco Piccinno, Peter Shaw, Massimo Nicosia and Yasemin Altun 5902

Improving Answer Selection and Answer Triggering using Hard Negatives
Sawan Kumar, shweta garg, Kartik Mehta and Nikhil Rasiwasia 5911

Can You Unpack That? Learning to Rewrite Questions-in-Context
Ahmed Elgohary, Denis Peskov and Jordan Boyd-Graber 5918

Quoref: A Reading Comprehension Dataset with Questions Requiring Coreferential Reasoning
Pradeep Dasigi, Nelson F. Liu, Ana Marasovic, Noah A. Smith and Matt Gardner 5925

Zero-shot Reading Comprehension by Cross-lingual Transfer Learning with Multi-lingual Language Representation Model
Tsung-Yuan Hsu, Chi-Liang Liu and Hung-yi Lee 5933

QuaRTz: An Open-Domain Dataset of Qualitative Relationship Questions
Oyvind Tafjord, Matt Gardner, Kevin Lin and Peter Clark 5941

Giving BERT a Calculator: Finding Operations and Arguments with Reading Comprehension
Daniel Andor, Luheng He, Kenton Lee and Emily Pitler 5947

A Gated Self-attention Memory Network for Answer Selection
Tuan Lai, Quan Hung Tran, Trung Bui and Daisuke Kihara 5953

Polly Want a Cracker: Analyzing Performance of Parroting on Paraphrase Generation Datasets
Hong-Ren Mao and Hung-Yi Lee 5960

Query-focused Sentence Compression in Linear Time
Abram Handler and Brendan O'Connor 5969

Generating Personalized Recipes from Historical User Preferences
Bodhisattwa Prasad Majumder, Shuyang Li, Jianmo Ni and Julian McAuley 5976

Generating Highly Relevant Questions
Jiazuo Qiu and Deyi Xiong 5983

Improving Neural Story Generation by Targeted Common Sense Grounding
Huanru Henry Mao, Bodhisattwa Prasad Majumder, Julian McAuley and Garrison Cottrell . . 5988

Abstract Text Summarization: A Low Resource Challenge
Shantipriya Parida and Petr Motlicek 5994

Generating Modern Poetry Automatically in Finnish
Mika Hämäläinen and Khalid Alnajjar 5999

SUM-QE: a BERT-based Summary Quality Estimation Model
Stratos Xenouleas, Prodromos Malakasiotis, Marianna Apidianaki and Ion Androutsopoulos . 6005

An Empirical Comparison on Imitation Learning and Reinforcement Learning for Paraphrase Generation
Wanyu Du and Yangfeng Ji 6012

Countering the Effects of Lead Bias in News Summarization via Multi-Stage Training and Auxiliary Losses
Matt Grenander, Yue Dong, Jackie Chi Kit Cheung and Annie Louis 6019

Learning Rhyming Constraints using Structured Adversaries
Harsh Jhamtani, Sanket Vaibhav Mehta, Jaime Carbonell and Taylor Berg-Kirkpatrick 6025

Question-type Driven Question Generation
Wenjie Zhou, Minghua Zhang and Yunfang Wu 6032

Deep Reinforcement Learning with Distributional Semantic Rewards for Abstractive Summarization
Siyao Li, Deren Lei, Pengda Qin and William Yang Wang 6038

Clause-Wise and Recursive Decoding for Complex and Cross-Domain Text-to-SQL Generation
Dongjun Lee 6045

Do Nuclear Submarines Have Nuclear Captains? A Challenge Dataset for Commonsense Reasoning over Adjectives and Objects
James Mullenbach, Jonathan Gordon, Nanyun Peng and Jonathan May 6052

Aggregating Bidirectional Encoder Representations Using MatchLSTM for Sequence Matching
Bo Shao, Yeyun Gong, Weizhen Qi, Nan Duan and Xiaola Lin 6059

What Does This Word Mean? Explaining Contextualized Embeddings with Natural Language Definition
Ting-Yun Chang and Yun-Nung Chen 6064

Pre-Training BERT on Domain Resources for Short Answer Grading
Chul Sung, Tejas Dhamecha, Swarnadeep Saha, Tengfei Ma, Vinay Reddy and Rishi Arora . . 6071

WIQA: A dataset for "What if..." reasoning over procedural text
Niket Tandon, Bhavana Dalvi, Keisuke Sakaguchi, Peter Clark and Antoine Bosselut 6076

Evaluating BERT for natural language inference: A case study on the CommitmentBank
Nanjiang Jiang and Marie-Catherine de Marneffe 6086

Incorporating Domain Knowledge into Medical NLI using Knowledge Graphs
Soumya Sharma, Bishal Santra, Abhik Jana, Santosh Tokala, Niloy Ganguly and Pawan Goyal6092

The FLORES Evaluation Datasets for Low-Resource Machine Translation: Nepali–English and Sinhala–English
Francisco Guzmán, Peng-Jen Chen, Myle Ott, Juan Pino, Guillaume Lample, Philipp Koehn, Vishrav Chaudhary and Marc'Aurelio Ranzato 6098

Mask-Predict: Parallel Decoding of Conditional Masked Language Models
Marjan Ghazvininejad, Omer Levy, Yinhan Liu and Luke Zettlemoyer 6112

Learning to Copy for Automatic Post-Editing
Xuancheng Huang, Yang Liu, Huanbo Luan, Jingfang Xu and Maosong Sun 6122

Exploring Human Gender Stereotypes with Word Association Test
Yupei Du, Yuanbin Wu and Man Lan 6133

A Modular Architecture for Unsupervised Sarcasm Generation
Abhijit Mishra, Tarun Tater and Karthik Sankaranarayanan 6144

Generating Classical Chinese Poems from Vernacular Chinese
Zhichao Yang, Pengshan Cai, Yansong Feng, Fei Li, Weijiang Feng, Elena Suet-Ying Chiu and hong yu 6155

Set to Ordered Text: Generating Discharge Instructions from Medical Billing Codes
Litton J Kurisinkel and Nancy Chen 6165

Constraint-based Learning of Phonological Processes
Shraddha Barke, Rose Kunkel, Nadia Polikarpova, Eric Meinhardt, Eric Bakovic and Leon Bergen 6176

Detect Camouflaged Spam Content via StoneSkipping: Graph and Text Joint Embedding for Chinese Character Variation Representation
Zhuoren Jiang, Zhe Gao, Guoxiu He, Yangyang Kang, Changlong Sun, Qiong Zhang, Luo Si and Xiaozhong Liu 6187

An Attentive Fine-Grained Entity Typing Model with Latent Type Representation
Ying Lin and Heng Ji 6197

An Improved Neural Baseline for Temporal Relation Extraction
Qiang Ning, Sanjay Subramanian and Dan Roth 6203

Improving Fine-grained Entity Typing with Entity Linking
Hongliang Dai, Donghong Du, Xin Li and Yangqiu Song 6210

Combining Spans into Entities: A Neural Two-Stage Approach for Recognizing Discontiguous Entities
Bailin Wang and Wei Lu 6216

Cross-Sentence N-ary Relation Extraction using Lower-Arity Universal Schemas
Kosuke Akimoto, Takuya Hiraoka, Kunihiko Sadamasa and Mathias Niepert 6225

Gazetteer-Enhanced Attentive Neural Networks for Named Entity Recognition
Hongyu Lin, Yaojie Lu, Xianpei Han, Le Sun, Bin Dong and Shanshan Jiang 6232

"A Buster Keaton of Linguistics": First Automated Approaches for the Extraction of Vossian Antonomasia
Michel Schwab, Robert Jäschke, Frank Fischer and Jannik Strötgen 6238

Multi-Task Learning for Chemical Named Entity Recognition with Chemical Compound Paraphrasing
Taiki Watanabe, Akihiro Tamura, Takashi Ninomiya, Takuya Makino and Tomoya Iwakura . . 6244

FewRel 2.0: Towards More Challenging Few-Shot Relation Classification
Tianyu Gao, Xu Han, Hao Zhu, Zhiyuan Liu, Peng Li, Maosong Sun and Jie Zhou 6250

ner and pos when nothing is capitalized
Stephen Mayhew, Tatiana Tsygankova and Dan Roth 6256

CaRB: A Crowdsourced Benchmark for Open IE
Sangnie Bhardwaj, Samarth Aggarwal and Mausam Mausam 6262

Weakly Supervised Attention Networks for Entity Recognition
Barun Patra and Joel Ruben Antony Moniz 6268

Revealing and Predicting Online Persuasion Strategy with Elementary Units
Gaku Morio, Ryo Egawa and Katsuhide Fujita 6274

A Challenge Dataset and Effective Models for Aspect-Based Sentiment Analysis
Qingnan Jiang, Lei Chen, Ruifeng Xu, Xiang Ao and Min Yang 6280

Learning with Noisy Labels for Sentence-level Sentiment Classification
Hao Wang, Bing Liu, Chaozhuo Li, Yan Yang and Tianrui Li 6286

DENS: A Dataset for Multi-class Emotion Analysis
Chen Liu, Muhammad Osama and Anderson De Andrade 6293

Multi-Task Stance Detection with Sentiment and Stance Lexicons
Yingjie Li and Cornelia Caragea 6299

A Robust Self-Learning Framework for Cross-Lingual Text Classification
Xin Dong and Gerard de Melo 6306

Learning to Flip the Sentiment of Reviews from Non-Parallel Corpora
Canasai Kruengkrai 6311

Label Embedding using Hierarchical Structure of Labels for Twitter Classification
Taro Miyazaki, Kiminobu Makino, Yuka Takei, Hiroki Okamoto and Jun Goto 6317

Interpretable Word Embeddings via Informative Priors
Miriam Hurtado Bodell, Martin Arvidsson and Måns Magnusson 6323

Adversarial Removal of Demographic Attributes Revisited
Maria Barrett, Yova Kementchedjhieva, Yanai Elazar, Desmond Elliott and Anders Søgaard . . 6330

A deep-learning framework to detect sarcasm targets
Jasabanta Patro, Srijan Bansal and Animesh Mukherjee 6336

In Plain Sight: Media Bias Through the Lens of Factual Reporting
Lisa Fan, Marshall White, Eva Sharma, Ruisi Su, Prafulla Kumar Choubey, Ruihong Huang and Lu Wang 6343

Incorporating Label Dependencies in Multilabel Stance Detection
William Ferreira and Andreas Vlachos 6350

Investigating Sports Commentator Bias within a Large Corpus of American Football Broadcasts
Jack Merullo, Luke Yeh, Abram Handler, Alvin Grissom II, Brendan O'Connor and Mohit Iyyer 6355

Charge-Based Prison Term Prediction with Deep Gating Network
Huajie Chen, Deng Cai, Wei Dai, Zehui Dai and Yadong Ding 6362

Restoring ancient text using deep learning: a case study on Greek epigraphy
Yannis Assael, Thea Sommerschield and Jonathan Prag 6368

Embedding Lexical Features via Tensor Decomposition for Small Sample Humor Recognition
Zhenjie Zhao, Andrew Cattle, Evangelos Papalexakis and Xiaojuan Ma 6376

EDA: Easy Data Augmentation Techniques for Boosting Performance on Text Classification Tasks
Jason Wei and Kai Zou 6382

Neural News Recommendation with Multi-Head Self-Attention
Chuhan Wu, Fangzhao Wu, Suyu Ge, Tao Qi, Yongfeng Huang and Xing Xie 6389

What Matters for Neural Cross-Lingual Named Entity Recognition: An Empirical Analysis
Xiaolei Huang, Jonathan May and Nanyun Peng 6395

Telling the Whole Story: A Manually Annotated Chinese Dataset for the Analysis of Humor in Jokes
Dongyu Zhang, Heting Zhang, Xikai Liu, Hongfei LIN and Feng Xia 6402

Generating Natural Anagrams: Towards Language Generation Under Hard Combinatorial Constraints
Masaaki Nishino, Sho Takase, Tsutomu Hirao and Masaaki Nagata 6408

STANCY: Stance Classification Based on Consistency Cues
Kashyap Popat, Subhabrata Mukherjee, Andrew Yates and Gerhard Weikum 6413

Cross-lingual intent classification in a low resource industrial setting
Talaat Khalil, Kornel Kiełczewski, Georgios Christos Chouliaras, Amina Keldibek and Maarten Versteegh 6419

SoftRegex: Generating Regex from Natural Language Descriptions using Softened Regex Equivalence
Jun-U Park, Sang-Ki Ko, Marco Cognetta and Yo-Sub Han 6425

Using Clinical Notes with Time Series Data for ICU Management
Swaraj Khadanga, Karan Aggarwal, Shafiq Joty and Jaideep Srivastava 6432

Spelling-Aware Construction of Macaronic Texts for Teaching Foreign-Language Vocabulary
Adithya Renduchintala, Philipp Koehn and Jason Eisner 6438

Towards Machine Reading for Interventions from Humanitarian-Assistance Program Literature
Bonan Min, Yee Seng Chan, Haoling Qiu and Joshua Fasching 6444

RUN through the Streets: A New Dataset and Baseline Models for Realistic Urban Navigation
Tzuf Paz-Argaman and Reut Tsarfaty 6449

Context-Aware Conversation Thread Detection in Multi-Party Chat
Ming Tan, Dakuo Wang, Yupeng Gao, Haoyu Wang, Saloni Potdar, Xiaoxiao Guo, Shiyu Chang and Mo Yu 6456

Conference Program

Tuesday, November 5, 2019

08:45–09:00 *Opening Remarks*

09:00–10:00 *Keynote I: Noam Slonim*

10:00–10:30 *Coffee Break*

10:30–12:00 *Session 1*

Session 1A: Machine Learning I

10:30–10:48 *Attending to Future Tokens for Bidirectional Sequence Generation*
Carolin Lawrence, Bhushan Kotnis and Mathias Niepert

10:48–11:06 *Attention is not not Explanation*
Sarah Wiegreffe and Yuval Pinter

11:06–11:24 *Practical Obstacles to Deploying Active Learning*
David Lowell, Zachary C. Lipton and Byron C. Wallace

11:24–11:42 *Transfer Learning Between Related Tasks Using Expected Label Proportions*
Matan Ben Noach and Yoav Goldberg

11:42–12:00 [TACL] *Insertion-based Decoding with automatically Inferred Generation Order*
Jiatao Gu, Qi Liu and Kyunghyun Cho

Session 1B: Lexical Semantics I

10:30–10:48 *Knowledge Enhanced Contextual Word Representations*
Matthew E. Peters, Mark Neumann, Robert Logan, Roy Schwartz, Vidur Joshi, Sameer Singh and Noah A. Smith

10:48–11:06 *How Contextual are Contextualized Word Representations? Comparing the Geometry of BERT, ELMo, and GPT-2 Embeddings*
Kawin Ethayarajh

11:06–11:24 *Room to Glo: A Systematic Comparison of Semantic Change Detection Approaches with Word Embeddings*
Philippa Shoemark, Farhana Ferdousi Liza, Dong Nguyen, Scott Hale and Barbara McGillivray

11:24–11:42 *Correlations between Word Vector Sets*
Vitalii Zhelezniak, April Shen, Daniel Busbridge, Aleksandar Savkov and Nils Hammerla

11:42–12:00 *Game Theory Meets Embeddings: a Unified Framework for Word Sense Disambiguation*
Rocco Tripodi and Roberto Navigli

Session 1C: Dialog and Interactive Systems I

10:30–10:48 *Guided Dialog Policy Learning: Reward Estimation for Multi-Domain Task-Oriented Dialog*
Ryuichi Takanobu, Hanlin Zhu and Minlie Huang

10:48–11:06 *Multi-hop Selector Network for Multi-turn Response Selection in Retrieval-based Chatbots*
Chunyuan Yuan, Wei Zhou, Mingming Li, Shangwen Lv, Fuqing Zhu, Jizhong Han and Songlin Hu

11:06–11:24 *MoEL: Mixture of Empathetic Listeners*
Zhaojiang Lin, Andrea Madotto, Jamin Shin, Peng Xu and Pascale Fung

11:24–11:42 *Entity-Consistent End-to-end Task-Oriented Dialogue System with KB Retriever*
Libo Qin, Yijia Liu, Wanxiang Che, Haoyang Wen, Yangming Li and Ting Liu

11:42–12:00 *Building Task-Oriented Visual Dialog Systems Through Alternative Optimization Between Dialog Policy and Language Generation*
Mingyang Zhou, Josh Arnold and Zhou Yu

Session 1D: Sentiment Analysis and Argument Mining I

10:30–10:48 *DialogueGCN: A Graph Convolutional Neural Network for Emotion Recognition in Conversation*
Deepanway Ghosal, Navonil Majumder, Soujanya Poria, Niyati Chhaya and Alexander Gelbukh

10:48–11:06 *Knowledge-Enriched Transformer for Emotion Detection in Textual Conversations*
Peixiang Zhong, Di Wang and Chunyan Miao

11:06–11:24 *Interpretable Relevant Emotion Ranking with Event-Driven Attention*
Yang Yang, Deyu ZHOU, Yulan He and Meng Zhang

11:24–11:42 *Justifying Recommendations using Distantly-Labeled Reviews and Fine-Grained Aspects*
Jianmo Ni, Jiacheng Li and Julian McAuley

11:42–12:00 *Using Customer Service Dialogues for Satisfaction Analysis with Context-Assisted Multiple Instance Learning*
Kaisong Song, Lidong Bing, Wei Gao, Jun Lin, Lujun Zhao, Jiancheng Wang, Changlong Sun, Xiaozhong Liu and Qiong Zhang

Poster and Demo Session 1: Information Extraction, Information Retrieval and Document Analysis, Linguistic Theories

Leveraging Dependency Forest for Neural Medical Relation Extraction
Linfeng Song, Yue Zhang, Daniel Gildea, Mo Yu, Zhiguo Wang and jinsong su

Open Relation Extraction: Relational Knowledge Transfer from Supervised Data to Unsupervised Data
Ruidong Wu, Yuan Yao, Xu Han, Ruobing Xie, Zhiyuan Liu, Fen Lin, Leyu Lin and Maosong Sun

Improving Relation Extraction with Knowledge-attention
Pengfei Li, Kezhi Mao, Xuefeng Yang and Qi Li

Jointly Learning Entity and Relation Representations for Entity Alignment
Yuting Wu, Xiao Liu, Yansong Feng, Zheng Wang and Dongyan Zhao

Tackling Long-Tailed Relations and Uncommon Entities in Knowledge Graph Completion
Zihao Wang, Kwunping Lai, Piji Li, Lidong Bing and Wai Lam

Low-Resource Name Tagging Learned with Weakly Labeled Data
Yixin Cao, Zikun Hu, Tat-seng Chua, Zhiyuan Liu and Heng Ji

Learning Dynamic Context Augmentation for Global Entity Linking
Xiyuan Yang, Xiaotao Gu, Sheng Lin, Siliang Tang, Yueting Zhuang, Fei Wu, Zhigang Chen, Guoping Hu and Xiang Ren

Open Event Extraction from Online Text using a Generative Adversarial Network
Rui Wang, Deyu ZHOU and Yulan He

Learning to Bootstrap for Entity Set Expansion
Lingyong Yan, Xianpei Han, Le Sun and Ben He

Multi-Input Multi-Output Sequence Labeling for Joint Extraction of Fact and Condition Tuples from Scientific Text
Tianwen Jiang, Tong Zhao, Bing Qin, Ting Liu, Nitesh Chawla and Meng Jiang

Cross-lingual Structure Transfer for Relation and Event Extraction
Ananya Subburathinam, Di Lu, Heng Ji, Jonathan May, Shih-Fu Chang, Avirup Sil and Clare Voss

Uncover the Ground-Truth Relations in Distant Supervision: A Neural Expectation-Maximization Framework
Junfan Chen, Richong Zhang, Yongyi Mao, Hongyu Guo and Jie Xu

Doc2EDAG: An End-to-End Document-level Framework for Chinese Financial Event Extraction
Shun Zheng, Wei Cao, Wei Xu and Jiang Bian

Event Detection with Trigger-Aware Lattice Neural Network
Ning Ding, Ziran Li, Zhiyuan Liu, Haitao Zheng and Zibo Lin

A Boundary-aware Neural Model for Nested Named Entity Recognition
Changmeng Zheng, Yi Cai, Jingyun Xu, Ho-fung Leung and Guandong Xu

Learning the Extraction Order of Multiple Relational Facts in a Sentence with Reinforcement Learning
Xiangrong Zeng, Shizhu He, Daojian Zeng, Kang Liu, Shengping Liu and Jun Zhao

CaRe: Open Knowledge Graph Embeddings
Swapnil Gupta, Sreyash Kenkre and Partha Talukdar

Self-Attention Enhanced CNNs and Collaborative Curriculum Learning for Distantly Supervised Relation Extraction
Yuyun Huang and Jinhua Du

Neural Cross-Lingual Relation Extraction Based on Bilingual Word Embedding Mapping
Jian Ni and Radu Florian

Leveraging 2-hop Distant Supervision from Table Entity Pairs for Relation Extraction
xiang deng and Huan Sun

EntEval: A Holistic Evaluation Benchmark for Entity Representations
Mingda Chen, Zewei Chu, Yang Chen, Karl Stratos and Kevin Gimpel

Joint Event and Temporal Relation Extraction with Shared Representations and Structured Prediction
Rujun Han, Qiang Ning and Nanyun Peng

Hierarchical Text Classification with Reinforced Label Assignment
Yuning Mao, Jingjing Tian, Jiawei Han and Xiang Ren

Investigating Capsule Network and Semantic Feature on Hyperplanes for Text Classification
Chunning Du, Haifeng Sun, Jingyu Wang, Qi Qi, Jianxin Liao, Chun Wang and Bing Ma

Label-Specific Document Representation for Multi-Label Text Classification
Lin Xiao, Xin Huang, Boli Chen and Liping Jing

Hierarchical Attention Prototypical Networks for Few-Shot Text Classification
Shengli Sun, Qingfeng Sun, Kevin Zhou and Tengchao Lv

Many Faces of Feature Importance: Comparing Built-in and Post-hoc Feature Importance in Text Classification
Vivian Lai, Zheng Cai and Chenhao Tan

Enhancing Local Feature Extraction with Global Representation for Neural Text Classification
Guocheng Niu, Hengru Xu, Bolei He, Xinyan Xiao, Hua Wu and Sheng GAO

Latent-Variable Generative Models for Data-Efficient Text Classification
Xiaoan Ding and Kevin Gimpel

PaRe: A Paper-Reviewer Matching Approach Using a Common Topic Space
Omer Anjum, Hongyu Gong, Suma Bhat, Wen-Mei Hwu and JinJun Xiong

Linking artificial and human neural representations of language
Jon Gauthier and Roger Levy

[DEMO] *IFlyLegal: A Chinese Legal System for Consultation, Law Searching, and Document Analysis*
Ziyue Wang, Baoxin Wang, Xingyi Duan, Dayong Wu, Shijin Wang, Guoping Hu and Ting Liu

[DEMO] *TellMeWhy: Learning to Explain Corrective Feedback for Second Language Learners*
Yi-Huei Lai and Jason Chang

[DEMO] *Honkling: In-Browser Personalization for Ubiquitous Keyword Spotting*
Jaejun Lee, Raphael Tang and Jimmy Lin

[DEMO] *Redcoat: A Collaborative Annotation Tool for Hierarchical Entity Typing*
Michael Stewart, Wei Liu and Rachel Cardell-Oliver

[DEMO] *SEAGLE: A Platform for Comparative Evaluation of Semantic Encoders for Information Retrieval*
Fabian David Schmidt, Markus Dietsche, Simone Paolo Ponzetto and Goran Glavaš

[DEMO] *OpenNRE: An Open and Extensible Toolkit for Neural Relation Extraction*
Xu Han, Tianyu Gao, Yuan Yao, Deming Ye, Zhiyuan Liu and Maosong Sun

[DEMO] *Automatic Taxonomy Induction and Expansion*
Nicolas Rodolfo Fauceglia, Alfio Gliozzo, Sarthak Dash, Md. Faisal Mahbub Chowdhury and Nandana Mihindukulasooriya

[DEMO] *Applying BERT to Document Retrieval with Birch*
Zeynep Akkalyoncu Yilmaz, Shengjin Wang, Wei Yang, Haotian Zhang and Jimmy Lin

12:00–13:30 *Lunch*

13:30–15:00 *Session 2*

Session 2A: Summarization and Generation

13:30–13:48 *Neural Text Summarization: A Critical Evaluation*
Wojciech Kryscinski, Nitish Shirish Keskar, Bryan McCann, Caiming Xiong and Richard Socher

13:48–14:06 *Neural data-to-text generation: A comparison between pipeline and end-to-end architectures*
Thiago Castro Ferreira, Chris van der Lee, Emiel van Miltenburg and Emiel Krahmer

14:06–14:24 *MoverScore: Text Generation Evaluating with Contextualized Embeddings and Earth Mover Distance*
Wei Zhao, Maxime Peyrard, Fei Liu, Yang Gao, Christian M. Meyer and Steffen Eger

14:24–14:42 *Select and Attend: Towards Controllable Content Selection in Text Generation*
Xiaoyu Shen, Jun Suzuki, Kentaro Inui, Hui Su, Dietrich Klakow and Satoshi Sekine

14:42–15:00 *Sentence-Level Content Planning and Style Specification for Neural Text Generation*
Xinyu Hua and Lu Wang

Session 2B: Sentence-level Semantics I

13:30–13:48 *Translate and Label! An Encoder-Decoder Approach for Cross-lingual Semantic Role Labeling*
Angel Daza and Anette Frank

13:48–14:06 *Syntax-Enhanced Self-Attention-Based Semantic Role Labeling*
Yue Zhang, Rui Wang and Luo Si

14:06–14:24 *VerbAtlas: a Novel Large-Scale Verbal Semantic Resource and Its Application to Semantic Role Labeling*
Andrea Di Fabio, Simone Conia and Roberto Navigli

14:24–14:42 *Parameter-free Sentence Embedding via Orthogonal Basis*
Ziyi Yang, Chenguang Zhu and Weizhu Chen

14:42–15:00 *Evaluation Benchmarks and Learning Criteria for Discourse-Aware Sentence Representations*
Mingda Chen, Zewei Chu and Kevin Gimpel

Session 2C: Speech, Vision, Robotics, Multimodal and Grounding I

13:30–13:48 *Extracting Possessions from Social Media: Images Complement Language*
Dhivya Chinnappa, Srikala Murugan and Eduardo Blanco

13:48–14:06 *Learning to Speak and Act in a Fantasy Text Adventure Game*
Jack Urbanek, Angela Fan, Siddharth Karamcheti, Saachi Jain, Samuel Humeau, Emily Dinan, Tim Rocktäschel, Douwe Kiela, Arthur Szlam and Jason Weston

14:06–14:24 *Help, Anna! Visual Navigation with Natural Multimodal Assistance via Retrospective Curiosity-Encouraging Imitation Learning*
Khanh Nguyen and Hal Daumé III

14:24–14:42 *Incorporating Visual Semantics into Sentence Representations within a Grounded Space*
Patrick Bordes, Eloi Zablocki, Laure Soulier, Benjamin Piwowarski and patrick Gallinari

14:42–15:00 *Neural Naturalist: Generating Fine-Grained Image Comparisons*
Maxwell Forbes, Christine Kaeser-Chen, Piyush Sharma and Serge Belongie

Session 2D: Information Extraction I

13:30–13:48 *Fine-Grained Evaluation for Entity Linking*
Henry Rosales-Méndez, Aidan Hogan and Barbara Poblete

13:48–14:06 *Supervising Unsupervised Open Information Extraction Models*
Arpita Roy, Youngja Park, Taesung Lee and Shimei Pan

14:06–14:24 *Neural Cross-Lingual Event Detection with Minimal Parallel Resources*
Jian Liu, Yubo Chen, Kang Liu and Jun Zhao

14:24–14:42 *KnowledgeNet: A Benchmark Dataset for Knowledge Base Population*
Filipe Mesquita, Matteo Cannaviccio, Jordan Schmidek, Paramita Mirza and Denilson Barbosa

14:42–15:00 *Effective Use of Transformer Networks for Entity Tracking*
Aditya Gupta and Greg Durrett

Poster and Demo Session 2: Machine Translation and Mulitilinguality, Phonology, Morphology and Word Segmentation, Tagging, Chunking, Syntax and Parsing

Explicit Cross-lingual Pre-training for Unsupervised Machine Translation
Shuo Ren, Yu Wu, Shujie Liu, Ming Zhou and Shuai Ma

Latent Part-of-Speech Sequences for Neural Machine Translation
Xuewen Yang, Yingru Liu, Dongliang Xie, Xin Wang and Niranjan Balasubramanian

Improving Back-Translation with Uncertainty-based Confidence Estimation
Shuo Wang, Yang Liu, Chao Wang, Huanbo Luan and Maosong Sun

Towards Linear Time Neural Machine Translation with Capsule Networks
Mingxuan Wang

Modeling Multi-mapping Relations for Precise Cross-lingual Entity Alignment
Xiaofei Shi and Yanghua Xiao

Supervised and Nonlinear Alignment of Two Embedding Spaces for Dictionary Induction in Low Resourced Languages
Masud Moshtaghi

Beto, Bentz, Becas: The Surprising Cross-Lingual Effectiveness of BERT
Shijie Wu and Mark Dredze

Iterative Dual Domain Adaptation for Neural Machine Translation
Jiali Zeng, Yang Liu, jinsong su, yubing Ge, Yaojie Lu, Yongjing Yin and jiebo luo

Multi-agent Learning for Neural Machine Translation
tianchi bi, hao xiong, Zhongjun He, Hua Wu and Haifeng Wang

Pivot-based Transfer Learning for Neural Machine Translation between Non-English Languages
Yunsu Kim, Petre Petrov, Pavel Petrushkov, Shahram Khadivi and Hermann Ney

Context-Aware Monolingual Repair for Neural Machine Translation
Elena Voita, Rico Sennrich and Ivan Titov

Multi-Granularity Self-Attention for Neural Machine Translation
Jie Hao, Xing Wang, Shuming Shi, Jinfeng Zhang and Zhaopeng Tu

Improving Deep Transformer with Depth-Scaled Initialization and Merged Attention
Biao Zhang, Ivan Titov and Rico Sennrich

A Discriminative Neural Model for Cross-Lingual Word Alignment
Elias Stengel-Eskin, Tzu-ray Su, Matt Post and Benjamin Van Durme

One Model to Learn Both: Zero Pronoun Prediction and Translation
Longyue Wang, Zhaopeng Tu, Xing Wang and Shuming Shi

Dynamic Past and Future for Neural Machine Translation
Zaixiang Zheng, Shujian Huang, Zhaopeng Tu, XIN-YU DAI and Jiajun CHEN

Revisit Automatic Error Detection for Wrong and Missing Translation – A Supervised Approach
Wenqiang Lei, Weiwen Xu, Ai Ti Aw, Yuanxin Xiang and Tat Seng Chua

Towards Understanding Neural Machine Translation with Word Importance
Shilin He, Zhaopeng Tu, Xing Wang, Longyue Wang, Michael Lyu and Shuming Shi

Multilingual Neural Machine Translation with Language Clustering
Xu Tan, Jiale Chen, Di He, Yingce Xia, Tao QIN and Tie-Yan Liu

Don't Forget the Long Tail! A Comprehensive Analysis of Morphological Generalization in Bilingual Lexicon Induction
Paula Czarnowska, Sebastian Ruder, Edouard Grave, Ryan Cotterell and Ann Copestake

Pushing the Limits of Low-Resource Morphological Inflection
Antonios Anastasopoulos and Graham Neubig

[TACL] *Morphological Analysis Using a Sequence Decoder*
Ekin Akyürek, Erenay Dayanık and Deniz Yuret

Cross-Lingual Dependency Parsing Using Code-Mixed TreeBank
Meishan Zhang, Yue Zhang and Guohong Fu

Hierarchical Pointer Net Parsing
Linlin Liu, Xiang Lin, Shafiq Joty, Simeng Han and Lidong Bing

Semi-Supervised Semantic Role Labeling with Cross-View Training
Rui Cai and Mirella Lapata

Low-Resource Sequence Labeling via Unsupervised Multilingual Contextualized Representations
Zuyi Bao, Rui Huang, Chen Li and Kenny Zhu

A Lexicon-Based Graph Neural Network for Chinese NER
Tao Gui, Yicheng Zou, Qi Zhang, Minlong Peng, Jinlan Fu, Zhongyu Wei and Xuanjing Huang

CM-Net: A Novel Collaborative Memory Network for Spoken Language Understanding
Yijin Liu, Fandong Meng, Jinchao Zhang, Jie Zhou, Yufeng Chen and Jinan Xu

Tree Transformer: Integrating Tree Structures into Self-Attention
Yaushian Wang, Hung-Yi Lee and Yun-Nung Chen

Semantic Role Labeling with Iterative Structure Refinement
Chunchuan Lyu, Shay B. Cohen and Ivan Titov

Entity Projection via Machine Translation for Cross-Lingual NER
Alankar Jain, Bhargavi Paranjape and Zachary C. Lipton

A Bayesian Approach for Sequence Tagging with Crowds
Edwin D. Simpson and Iryna Gurevych

A systematic comparison of methods for low-resource dependency parsing on genuinely low-resource languages
Clara Vania, Yova Kementchedjhieva, Anders Søgaard and Adam Lopez

Target Language-Aware Constrained Inference for Cross-lingual Dependency Parsing
Tao Meng, Nanyun Peng and Kai-Wei Chang

Look-up and Adapt: A One-shot Semantic Parser
Zhichu Lu, Forough Arabshahi, Igor Labutov and Tom Mitchell

Similarity Based Auxiliary Classifier for Named Entity Recognition
Shiyuan Xiao, Yuanxin Ouyang, Wenge Rong, Jianxin Yang and Zhang Xiong

Variable beam search for generative neural parsing and its relevance for the analysis of neuro-imaging signal
Benoit Crabbé, Murielle Fabre and Christophe Pallier

[DEMO] *MY-AKKHARA: A Romanization-based Burmese (Myanmar) Input Method*
Chenchen Ding, Masao Utiyama and Eiichiro Sumita

[DEMO] *LINSPECTOR WEB: A Multilingual Probing Suite for Word Representations*
Max Eichler, Gözde Gül Şahin and Iryna Gurevych

[DEMO] *Joey NMT: A Minimalist NMT Toolkit for Novices*
Julia Kreutzer, Joost Bastings and Stefan Riezler

[DEMO] *Multilingual, Multi-scale and Multi-layer Visualization of Intermediate Representations*
Carlos Escolano, Marta R. Costa-jussà, Elora Lacroux and Pere-Pau Vázquez

[DEMO] *A System for Diacritizing Four Varieties of Arabic*
Hamdy Mubarak, Ahmed Abdelali, Kareem Darwish, Mohamed Eldesouki, Younes Samih and Hassan Sajjad

[DEMO] *What's Wrong with Hebrew NLP? And How to Make it Right*
Reut Tsarfaty, Shoval Sadde, Stav Klein and Amit Seker

[DEMO] *INMT: Interactive Neural Machine Translation Prediction*
Sebastin Santy, Sandipan Dandapat, Monojit Choudhury and Kalika Bali

15:00–15:30 *Coffee Break*

15:30–16:18 *Session 3*

Session 3A: Machine Learning II

15:30–15:42 *Are We Modeling the Task or the Annotator? An Investigation of Annotator Bias in Natural Language Understanding Datasets*
Mor Geva, Yoav Goldberg and Jonathan Berant

15:42–15:54 *Robust Text Classifier on Test-Time Budgets*
Md Rizwan Parvez, Tolga Bolukbasi, Kai-Wei Chang and Venkatesh Saligrama

15:54–16:06 *Commonsense Knowledge Mining from Pretrained Models*
Joe Davison, Joshua Feldman and Alexander Rush

16:06–16:18 *RNN Architecture Learning with Sparse Regularization*
Jesse Dodge, Roy Schwartz, Hao Peng and Noah A. Smith

Session 3B: Semantics

15:30–15:42 *Analytical Methods for Interpretable Ultradense Word Embeddings*
Philipp Dufter and Hinrich Schütze

15:42–15:54 *Investigating Meta-Learning Algorithms for Low-Resource Natural Language Understanding Tasks*
Zi-Yi Dou, Keyi Yu and Antonios Anastasopoulos

15:54–16:06 *Retrofitting Contextualized Word Embeddings with Paraphrases*
Weijia Shi, Muhao Chen, Pei Zhou and Kai-Wei Chang

16:06–16:18 *Incorporating Contextual and Syntactic Structures Improves Semantic Similarity Modeling*
Linqing Liu, Wei Yang, Jinfeng Rao, Raphael Tang and Jimmy Lin

Session 3C: Discourse, Summarization, and Generation

15:30–15:42 *Neural Linguistic Steganography*
Zachary Ziegler, Yuntian Deng and Alexander Rush

15:42–15:54 *The Feasibility of Embedding Based Automatic Evaluation for Single Document Summarization*
Simeng Sun and Ani Nenkova

15:54–16:06 *Attention Optimization for Abstractive Document Summarization*
Min Gui, Junfeng Tian, Rui Wang and Zhenglu Yang

16:06–16:18 *Rewarding Coreference Resolvers for Being Consistent with World Knowledge*
Rahul Aralikatte, Heather Lent, Ana Valeria Gonzalez, Daniel Herschcovich, Chen Qiu, Anders Sandholm, Michael Ringaard and Anders Søgaard

Session 3D: Text Mining and NLP Applications I

15:30–15:42 *An Empirical Study of Incorporating Pseudo Data into Grammatical Error Correction*
Shun Kiyono, Jun Suzuki, Masato Mita, Tomoya Mizumoto and Kentaro Inui

15:42–15:54 *A Multilingual Topic Model for Learning Weighted Topic Links Across Corpora with Low Comparability*
Weiwei Yang, Jordan Boyd-Graber and Philip Resnik

15:54–16:06 *Measure Country-Level Socio-Economic Indicators with Streaming News: An Empirical Study*
Bonan Min and Xiaoxi Zhao

16:06–16:18 *Towards Extracting Medical Family History from Natural Language Interactions: A New Dataset and Baselines*
Mahmoud Azab, Stephane Dadian, Vivi Nastase, Larry An and Rada Mihalcea

Poster and Demo Session 3: Dialog and Interactive Systems, Machine Translation and Multilinuality, Phonology, Morphology, and Word Segmentation, Speech, Vision, Robotics, Multimodal and Grounding, Tagging, Chunking, Syntax and Parsing

Multi-task Learning for Natural Language Generation in Task-Oriented Dialogue
Chenguang Zhu, Michael Zeng and Xuedong Huang

Dirichlet Latent Variable Hierarchical Recurrent Encoder-Decoder in Dialogue Generation
Min Zeng, Yisen Wang and Yuan Luo

Semi-Supervised Bootstrapping of Dialogue State Trackers for Task-Oriented Modelling
Bo-Hsiang Tseng, Marek Rei, Paweł Budzianowski, Richard Turner, Bill Byrne and Anna Korhonen

A Progressive Model to Enable Continual Learning for Semantic Slot Filling
Yilin Shen, Xiangyu Zeng and Hongxia Jin

CASA-NLU: Context-Aware Self-Attentive Natural Language Understanding for Task-Oriented Chatbots
Arshit Gupta, Peng Zhang, Garima Lalwani and Mona Diab

Sampling Matters! An Empirical Study of Negative Sampling Strategies for Learning of Matching Models in Retrieval-based Dialogue Systems
Jia Li, Chongyang Tao, wei wu, Yansong Feng, Dongyan Zhao and Rui Yan

Zero-shot Cross-lingual Dialogue Systems with Transferable Latent Variables
Zihan Liu, Jamin Shin, Yan Xu, Genta Indra Winata, Peng Xu, Andrea Madotto and Pascale Fung

Modeling Multi-Action Policy for Task-Oriented Dialogues
Lei Shu, Hu Xu, Bing Liu and Piero Molino

An Evaluation Dataset for Intent Classification and Out-of-Scope Prediction
Stefan Larson, Anish Mahendran, Joseph J. Peper, Christopher Clarke, Andrew Lee, Parker Hill, Jonathan K. Kummerfeld, Kevin Leach, Michael A. Laurenzano, Lingjia Tang and Jason mars

Automatically Learning Data Augmentation Policies for Dialogue Tasks
Tong Niu and Mohit Bansal

uniblock: Scoring and Filtering Corpus with Unicode Block Information
Yingbo Gao, Weiyue Wang and Hermann Ney

Multilingual word translation using auxiliary languages
Hagai Taitelbaum, Gal Chechik and Jacob Goldberger

Towards Better Modeling Hierarchical Structure for Self-Attention with Ordered Neurons
Jie Hao, Xing Wang, Shuming Shi, Jinfeng Zhang and Zhaopeng Tu

Vecalign: Improved Sentence Alignment in Linear Time and Space
Brian Thompson and Philipp Koehn

Simpler and Faster Learning of Adaptive Policies for Simultaneous Translation
Baigong Zheng, Renjie Zheng, Mingbo Ma and Liang Huang

Adversarial Learning with Contextual Embeddings for Zero-resource Cross-lingual Classification and NER
Phillip Keung, yichao lu and Vikas Bhardwaj

Recurrent Positional Embedding for Neural Machine Translation
Kehai Chen, Rui Wang, Masao Utiyama and Eiichiro Sumita

Machine Translation for Machines: the Sentiment Classification Use Case
amirhossein tebbifakhr, Luisa Bentivogli, Matteo Negri and Marco Turchi

Investigating the Effectiveness of BPE: The Power of Shorter Sequences
Matthias Gallé

HABLex: Human Annotated Bilingual Lexicons for Experiments in Machine Translation
Brian Thompson, Rebecca Knowles, Xuan Zhang, Huda Khayrallah, Kevin Duh and Philipp Koehn

Handling Syntactic Divergence in Low-resource Machine Translation
Chunting Zhou, Xuezhe Ma, Junjie Hu and Graham Neubig

Speculative Beam Search for Simultaneous Translation
Renjie Zheng, Mingbo Ma, Baigong Zheng and Liang Huang

Self-Attention with Structural Position Representations
Xing Wang, Zhaopeng Tu, Longyue Wang and Shuming Shi

Exploiting Multilingualism through Multistage Fine-Tuning for Low-Resource Neural Machine Translation
Raj Dabre, Atsushi Fujita and Chenhui Chu

Unsupervised Domain Adaptation for Neural Machine Translation with Domain-Aware Feature Embeddings
Zi-Yi Dou, Junjie Hu, Antonios Anastasopoulos and Graham Neubig

A Regularization-based Framework for Bilingual Grammar Induction
Yong Jiang, Wenjuan Han and Kewei Tu

Encoders Help You Disambiguate Word Senses in Neural Machine Translation
Gongbo Tang, Rico Sennrich and Joakim Nivre

Korean Morphological Analysis with Tied Sequence-to-Sequence Multi-Task Model
Hyun-Je Song and Seong-Bae Park

Efficient Convolutional Neural Networks for Diacritic Restoration
Sawsan Alqahtani, Ajay Mishra and Mona Diab

Improving Generative Visual Dialog by Answering Diverse Questions
Vishvak Murahari, Prithvijit Chattopadhyay, Dhruv Batra, Devi Parikh and Abhishek Das

Cross-lingual Transfer Learning with Data Selection for Large-Scale Spoken Language Understanding
Quynh Do and Judith Gaspers

Multi-Head Attention with Diversity for Learning Grounded Multilingual Multimodal Representations
Po-Yao Huang, Xiaojun Chang and Alexander Hauptmann

Decoupled Box Proposal and Featurization with Ultrafine-Grained Semantic Labels Improve Image Captioning and Visual Question Answering
Soravit Changpinyo, Bo Pang, Piyush Sharma and Radu Soricut

REO-Relevance, Extraness, Omission: A Fine-grained Evaluation for Image Captioning
Ming Jiang, Junjie Hu, Qiuyuan Huang, Lei Zhang, Jana Diesner and Jianfeng Gao

WSLLN:Weakly Supervised Natural Language Localization Networks
Mingfei Gao, Larry Davis, Richard Socher and Caiming Xiong

Grounding learning of modifier dynamics: An application to color naming
Xudong Han, Philip Schulz and Trevor Cohn

Robust Navigation with Language Pretraining and Stochastic Sampling
Xiujun Li, Chunyuan Li, Qiaolin Xia, Yonatan Bisk, Asli Celikyilmaz, Jianfeng Gao, Noah A. Smith and Yejin Choi

Towards Making a Dependency Parser See
Michalina Strzyz, David Vilares and Carlos Gómez-Rodríguez

Unsupervised Labeled Parsing with Deep Inside-Outside Recursive Autoencoders
Andrew Drozdov, Patrick Verga, Yi-Pei Chen, Mohit Iyyer and Andrew McCallum

Dependency Parsing for Spoken Dialog Systems
Sam Davidson, Dian Yu and Zhou Yu

Span-based Hierarchical Semantic Parsing for Task-Oriented Dialog
Panupong Pasupat, Sonal Gupta, Karishma Mandyam, Rushin Shah, Mike Lewis and Luke Zettlemoyer

16:18–16:30 *Mini-Break*

16:30–18:00 *Session 4*

Session 4A: Neural Machine Translation

16:30–16:48 *Enhancing Context Modeling with a Query-Guided Capsule Network for Document-level Translation*
Zhengxin Yang, Jinchao Zhang, Fandong Meng, Shuhao Gu, Yang Feng and Jie Zhou

16:48–17:06 *Simple, Scalable Adaptation for Neural Machine Translation*
Ankur Bapna and Orhan Firat

17:06–17:24 *Controlling Text Complexity in Neural Machine Translation*
Sweta Agrawal and Marine Carpuat

17:24–17:42 *Investigating Multilingual NMT Representations at Scale*
Sneha Kudugunta, Ankur Bapna, Isaac Caswell and Orhan Firat

17:42–18:00 *Hierarchical Modeling of Global Context for Document-Level Neural Machine Translation*
Xin Tan, Longyin Zhang, Deyi Xiong and Guodong Zhou

Session 4B: Question Answering I

16:30–16:48 *Cross-Lingual Machine Reading Comprehension*
Yiming Cui, Wanxiang Che, Ting Liu, Bing Qin, Shijin Wang and Guoping Hu

16:48–17:06 *A Multi-Type Multi-Span Network for Reading Comprehension that Requires Discrete Reasoning*
Minghao Hu, Yuxing Peng, Zhen Huang and Dongsheng Li

17:06–17:24 *Neural Duplicate Question Detection without Labeled Training Data*
Andreas Rücklé, Nafise Sadat Moosavi and Iryna Gurevych

17:24–17:42 *Asking Clarification Questions in Knowledge-Based Question Answering*
Jingjing Xu, Yuechen Wang, Duyu Tang, Nan Duan, Pengcheng Yang, Qi Zeng, Ming Zhou and Xu SUN

17:42–18:00 *Multi-View Domain Adapted Sentence Embeddings for Low-Resource Unsupervised Duplicate Question Detection*
Nina Poerner and Hinrich Schütze

Session 4C: Social Media and Computational Social Science

16:30–16:48 *Multi-label Categorization of Accounts of Sexism using a Neural Framework*
Pulkit Parikh, Harika Abburi, Pinkesh Badjatiya, Radhika Krishnan, Niyati Chhaya, Manish Gupta and Vasudeva Varma

16:48–17:06 *The Trumpiest Trump? Identifying a Subject's Most Characteristic Tweets*
Charuta Pethe and Steve Skiena

17:06–17:24 *Finding Microaggressions in the Wild: A Case for Locating Elusive Phenomena in Social Media Posts*
Luke Breitfeller, Emily Ahn, David Jurgens and Yulia Tsvetkov

17:24–17:42 *Reinforced Product Metadata Selection for Helpfulness Assessment of Customer Reviews*
Miao Fan, Chao Feng, Mingming Sun and Ping Li

17:42–18:00 *Learning Invariant Representations of Social Media Users*
Nicholas Andrews and Marcus Bishop

Session 4D: Text Mining and NLP Applications II

16:30–16:48 *(Male, Bachelor) and (Female, Ph.D) have different connotations: Parallelly Annotated Stylistic Language Dataset with Multiple Personas*
Dongyeop Kang, Varun Gangal and Eduard Hovy

16:48–17:06 *Movie Plot Analysis via Turning Point Identification*
Pinelopi Papalampidi, Frank Keller and Mirella Lapata

17:06–17:24 *Latent Suicide Risk Detection on Microblog via Suicide-Oriented Word Embeddings and Layered Attention*
Lei Cao, Huijun Zhang, Ling Feng, Zihan Wei, Xin Wang, Ningyun Li and Xiaohao He

17:24–17:42 *Deep Ordinal Regression for Pledge Specificity Prediction*
Shivashankar Subramanian, Trevor Cohn and Timothy Baldwin

17:42–18:00 [TACL] *Enabling Robust Grammatical Error Correction in New Domains: Datasets, Metrics, and Analyses*
Courtney Napoles, Maria Nadejde and Joel Tetreault

Poster and Demo Session 4: Dialog and Interactive Systems, Speech, Vision, Robotics, Multimodal and Grounding

Data-Efficient Goal-Oriented Conversation with Dialogue Knowledge Transfer Networks
Igor Shalyminov, Sungjin Lee, Arash Eshghi and Oliver Lemon

Multi-Granularity Representations of Dialog
Shikib Mehri and Maxine Eskenazi

Are You for Real? Detecting Identity Fraud via Dialogue Interactions
Weikang Wang, Jiajun Zhang, Qian Li, Chengqing Zong and Zhifei Li

Hierarchy Response Learning for Neural Conversation Generation
Bo Zhang and Xiaoming Zhang

Knowledge Aware Conversation Generation with Explainable Reasoning over Augmented Graphs
zhibin liu, Zheng-Yu Niu, Hua Wu and Haifeng Wang

Adaptive Parameterization for Neural Dialogue Generation
Hengyi Cai, Hongshen Chen, Cheng Zhang, Yonghao Song, Xiaofang Zhao and Dawei Yin

Towards Knowledge-Based Recommender Dialog System
Qibin Chen, Junyang Lin, Yichang Zhang, Ming Ding, Yukuo Cen, Hongxia Yang and Jie Tang

Structuring Latent Spaces for Stylized Response Generation
Xiang Gao, Yizhe Zhang, Sungjin Lee, Michel Galley, Chris Brockett, Jianfeng Gao and Bill Dolan

Improving Open-Domain Dialogue Systems via Multi-Turn Incomplete Utterance Restoration
Zhufeng Pan, Kun Bai, Yan Wang, Lianqiang Zhou and Xiaojiang Liu

Unsupervised Context Rewriting for Open Domain Conversation
Kun Zhou, Kai Zhang, Yu Wu, Shujie Liu and Jingsong Yu

Dually Interactive Matching Network for Personalized Response Selection in Retrieval-Based Chatbots
Jia-Chen Gu, Zhen-Hua Ling, Xiaodan Zhu and Quan Liu

DyKgChat: Benchmarking Dialogue Generation Grounding on Dynamic Knowledge Graphs
Yi-Lin Tuan, Yun-Nung Chen and Hung-yi Lee

Retrieval-guided Dialogue Response Generation via a Matching-to-Generation Framework
Deng Cai, Yan Wang, Wei Bi, Zhaopeng Tu, Xiaojiang Liu and Shuming Shi

Scalable and Accurate Dialogue State Tracking via Hierarchical Sequence Generation
Liliang Ren, Jianmo Ni and Julian McAuley

Low-Resource Response Generation with Template Prior
Ze Yang, wei wu, Jian Yang, Can Xu and zhoujun li

A Discrete CVAE for Response Generation on Short-Text Conversation
Jun Gao, Wei Bi, Xiaojiang Liu, Junhui Li, Guodong Zhou and Shuming Shi

Who Is Speaking to Whom? Learning to Identify Utterance Addressee in Multi-Party Conversations
Ran Le, Wenpeng Hu, Mingyue Shang, Zhenjun You, Lidong Bing, Dongyan Zhao and Rui Yan

A Semi-Supervised Stable Variational Network for Promoting Replier-Consistency in Dialogue Generation
Jinxin Chang, Ruifang He, Longbiao Wang, Xiangyu Zhao, Ting Yang and Ruifang Wang

Modeling Personalization in Continuous Space for Response Generation via Augmented Wasserstein Autoencoders
Zhangming Chan, Juntao Li, Xiaopeng Yang, Xiuying Chen, Wenpeng Hu, Dongyan Zhao and Rui Yan

Variational Hierarchical User-based Conversation Model
JinYeong Bak and Alice Oh

Recommendation as a Communication Game: Self-Supervised Bot-Play for Goal-oriented Dialogue
Dongyeop Kang, Anusha Balakrishnan, Pararth Shah, Paul Crook, Y-Lan Boureau and Jason Weston

CoSQL: A Conversational Text-to-SQL Challenge Towards Cross-Domain Natural Language Interfaces to Databases
Tao Yu, Rui Zhang, Heyang Er, Suyi Li, Eric Xue, Bo Pang, Xi Victoria Lin, Yi Chern Tan, Tianze Shi, Zihan Li, Youxuan Jiang, Michihiro Yasunaga, Sungrok Shim, Tao Chen, Alexander Fabbri, Zifan Li, Luyao Chen, Yuwen Zhang, Shreya Dixit, Vincent Zhang, Caiming Xiong, Richard Socher, Walter Lasecki and Dragomir Radev

A Practical Dialogue-Act-Driven Conversation Model for Multi-Turn Response Selection
Harshit Kumar, Arvind Agarwal and Sachindra Joshi

How to Build User Simulators to Train RL-based Dialog Systems
Weiyan Shi, Kun Qian, Xuewei Wang and Zhou Yu

[TACL] *Graph Convolutional Network with Sequential Attention for Goal-Oriented Dialogue Systems*
Suman Banerjee and Mitesh M Khapra

Low-Rank HOCA: Efficient High-Order Cross-Modal Attention for Video Captioning
Tao Jin, Siyu Huang, Yingming Li and Zhongfei Zhang

Image Captioning with Very Scarce Supervised Data: Adversarial Semi-Supervised Learning Approach
Dong-Jin Kim, Jinsoo Choi, Tae-Hyun Oh and In So Kweon

Dual Attention Networks for Visual Reference Resolution in Visual Dialog
Gi-Cheon Kang, Jaeseo Lim and Byoung-Tak Zhang

Unsupervised Discovery of Multimodal Links in Multi-image, Multi-sentence Documents
Jack Hessel, Lillian Lee and David Mimno

UR-FUNNY: A Multimodal Language Dataset for Understanding Humor
Md Kamrul Hasan, Wasifur Rahman, AmirAli Bagher Zadeh, Jianyuan Zhong, Md Iftekhar Tanveer, Louis-Philippe Morency and Mohammed (Ehsan) Hoque

Partners in Crime: Multi-view Sequential Inference for Movie Understanding
Nikos Papasarantopoulos, Lea Frermann, Mirella Lapata and Shay B. Cohen

Guiding the Flowing of Semantics: Interpretable Video Captioning via POS Tag
Xinyu Xiao, Lingfeng Wang, Bin Fan, Shinming Xiang and Chunhong Pan

A Stack-Propagation Framework with Token-Level Intent Detection for Spoken Language Understanding
Libo Qin, Wanxiang Che, Yangming Li, Haoyang Wen and Ting Liu

Talk2Car: Taking Control of Your Self-Driving Car
Thierry Deruyttere, Simon Vandenhende, Dusan Grujicic, Luc Van Gool and Marie-Francine Moens

Fact-Checking Meets Fauxtography: Verifying Claims About Images
Dimitrina Zlatkova, Preslav Nakov and Ivan Koychev

Video Dialog via Progressive Inference and Cross-Transformer
Weike Jin, Zhou Zhao, Mao Gu, Jun Xiao, Furu Wei and Yueting Zhuang

Executing Instructions in Situated Collaborative Interactions
Alane Suhr, Claudia Yan, Jack Schluger, Stanley Yu, Hadi Khader, Marwa Mouallem, Iris Zhang and Yoav Artzi

Fusion of Detected Objects in Text for Visual Question Answering
Chris Alberti, Jeffrey Ling, Michael Collins and David Reitter

TIGEr: Text-to-Image Grounding for Image Caption Evaluation
Ming Jiang, Qiuyuan Huang, Lei Zhang, Xin Wang, Pengchuan Zhang, Zhe Gan, Jana Diesner and Jianfeng Gao

[DEMO] *Chameleon: A Language Model Adaptation Toolkit for Automatic Speech Recognition of Conversational Speech*
Yuanfeng Song, Di Jiang, Weiwei Zhao, Qian Xu, Raymond Chi-Wing Wong and Qiang Yang

[DEMO] *PyOpenDial: A Python-based Domain-Independent Toolkit for Developing Spoken Dialogue Systems with Probabilistic Rules*
Youngsoo Jang, Jongmin Lee, Jaeyoung Park, Kyeng-Hun Lee, Pierre Lison and Kee-Eung Kim

[DEMO] *PolyResponse: A Rank-based Approach to Task-Oriented Dialogue with Application in Restaurant Search and Booking*
Matthew Henderson, Ivan Vulić, Iñigo Casanueva, Paweł Budzianowski, Daniela Gerz, Sam Coope, Georgios Spithourakis, Tsung-Hsien Wen, Nikola Mrkšić and Pei-Hao Su

Tuesday, November 5, 2019 (continued)

[DEMO] *LIDA: Lightweight Interactive Dialogue Annotator*
Edward Collins, Nikolai Rozanov and Bingbing Zhang

[DEMO] *EGG: a toolkit for research on Emergence of lanGuage in Games*
Eugene Kharitonov, Rahma Chaabouni, Diane Bouchacourt and Marco Baroni

[DEMO] *Entity resolution for noisy ASR transcripts*
Arushi Raghuvanshi, Vijay Ramakrishnan, Varsha Embar, Lucien Carroll and Karthik Raghunathan

[DEMO] *Gunrock: A Social Bot for Complex and Engaging Long Conversations*
Dian Yu, Michelle Cohn, Yi Mang Yang, Chun Yen Chen, Weiming Wen, Jiaping Zhang, Mingyang Zhou, Kevin Jesse, Austin Chau, Antara Bhowmick, Shreenath Iyer, Giritheja Sreenivasulu, Sam Davidson, Ashwin Bhandare and Zhou Yu

[DEMO] *HARE: a Flexible Highlighting Annotator for Ranking and Exploration*
Denis Newman-Griffis and Eric Fosler-Lussier

Wednesday, November 6, 2019

09:00–10:00 *Keynote II: Meeyoung Cha*

10:00–10:30 *Coffee Break*

10:30–12:00 *Session 5*

Session 5A: Machine Learning III

10:30–10:48 *Universal Adversarial Triggers for Attacking and Analyzing NLP*
Eric Wallace, Shi Feng, Nikhil Kandpal, Matt Gardner and Sameer Singh

10:48–11:06 *To Annotate or Not? Predicting Performance Drop under Domain Shift*
Hady Elsahar and Matthias Gallé

11:06–11:24 *Adaptively Sparse Transformers*
Gonçalo M. Correia, Vlad Niculae and André F. T. Martins

11:24–11:42 *Show Your Work: Improved Reporting of Experimental Results*
Jesse Dodge, Suchin Gururangan, Dallas Card, Roy Schwartz and Noah A. Smith

11:42–12:00 *A Deep Factorization of Style and Structure in Fonts*
Akshay Srivatsan, Jonathan Barron, Dan Klein and Taylor Berg-Kirkpatrick

Session 5B: Lexical Semantics II

10:30–10:48 *Cross-lingual Semantic Specialization via Lexical Relation Induction*
Edoardo Maria Ponti, Ivan Vulić, Goran Glavaš, Roi Reichart and Anna Korhonen

10:48–11:06 *Modelling the interplay of metaphor and emotion through multitask learning*
Verna Dankers, Marek Rei, Martha Lewis and Ekaterina Shutova

11:06–11:24 *How well do NLI models capture verb veridicality?*
Alexis Ross and Ellie Pavlick

11:24–11:42 *Modeling Color Terminology Across Thousands of Languages*
Arya D. McCarthy, Winston Wu, Aaron Mueller, William Watson and David Yarowsky

11:42–12:00 *Negative Focus Detection via Contextual Attention Mechanism*
Longxiang Shen, Bowei Zou, Yu Hong, Guodong Zhou, Qiaoming Zhu and AiTi Aw

Session 5C: Discourse and Pragmatics

10:30–10:48 *A Unified Neural Coherence Model*
Han Cheol Moon, Tasnim Mohiuddin, Shafiq Joty and Chi Xu

10:48–11:06 *Topic-Guided Coherence Modeling for Sentence Ordering by Preserving Global and Local Information*
Byungkook Oh, Seungmin Seo, Cheolheon Shin, Eunju Jo and Kyong-Ho Lee

11:06–11:24 *Neural Generative Rhetorical Structure Parsing*
Amandla Mabona, Laura Rimell, Stephen Clark and Andreas Vlachos

11:24–11:42 *Weak Supervision for Learning Discourse Structure*
Sonia Badene, Kate Thompson, Jean-Pierre Lorré and Nicholas Asher

11:42–12:00 *Predicting Discourse Structure using Distant Supervision from Sentiment*
Patrick Huber and Giuseppe Carenini

Session 5D: Text Mining and NLP Applications III

10:30–10:48 *The Myth of Double-Blind Review Revisited: ACL vs. EMNLP*
Cornelia Caragea, Ana Uban and Liviu P. Dinu

10:48–11:06 *Uncover Sexual Harassment Patterns from Personal Stories by Joint Key Element Extraction and Categorization*
Yingchi Liu, Quanzhi Li, Marika Cifor, Xiaozhong Liu, Qiong Zhang and Luo Si

11:06–11:24 *Identifying Predictive Causal Factors from News Streams*
Ananth Balashankar, Sunandan Chakraborty, Samuel Fraiberger and Lakshminarayanan Subramanian

11:24–11:42 *Training Data Augmentation for Detecting Adverse Drug Reactions in User-Generated Content*
Sepideh Mesbah, Jie Yang, Robert-Jan Sips, Manuel Valle Torre, Christoph Lofi, Alessandro Bozzon and Geert-Jan Houben

11:42–12:00 *Deep Reinforcement Learning-based Text Anonymization against Private-Attribute Inference*
Ahmadreza Mosallanezhad, Ghazaleh Beigi and Huan Liu

Poster and Demo Session 5: Question Answering, Textual Inference and Other Areas of Semantics

Tree-structured Decoding for Solving Math Word Problems
Qianying Liu, Wenyv Guan, Sujian Li and Daisuke Kawahara

PullNet: Open Domain Question Answering with Iterative Retrieval on Knowledge Bases and Text
Haitian Sun, Tania Bedrax-Weiss and William Cohen

Cosmos QA: Machine Reading Comprehension with Contextual Commonsense Reasoning
Lifu Huang, Ronan Le Bras, Chandra Bhagavatula and Yejin Choi

Finding Generalizable Evidence by Learning to Convince Q&A Models
Ethan Perez, Siddharth Karamcheti, Rob Fergus, Jason Weston, Douwe Kiela and Kyunghyun Cho

Ranking and Sampling in Open-Domain Question Answering
Yanfu Xu, Zheng Lin, Yuanxin Liu, Rui Liu, Weiping Wang and Dan Meng

A Non-commutative Bilinear Model for Answering Path Queries in Knowledge Graphs
Katsuhiko Hayashi and Masashi Shimbo

Generating Questions for Knowledge Bases via Incorporating Diversified Contexts and Answer-Aware Loss
Cao Liu, Kang Liu, Shizhu He, Zaiqing Nie and Jun Zhao

Multi-Task Learning for Conversational Question Answering over a Large-Scale Knowledge Base
Tao Shen, Xiubo Geng, Tao QIN, Daya Guo, Duyu Tang, Nan Duan, Guodong Long and Daxin Jiang

BiPaR: A Bilingual Parallel Dataset for Multilingual and Cross-lingual Reading Comprehension on Novels
Yimin Jing, Deyi Xiong and Zhen Yan

Language Models as Knowledge Bases?
Fabio Petroni, Tim Rocktäschel, Sebastian Riedel, Patrick Lewis, Anton Bakhtin, Yuxiang Wu and Alexander Miller

NumNet: Machine Reading Comprehension with Numerical Reasoning
Qiu Ran, Yankai Lin, Peng Li, Jie Zhou and Zhiyuan Liu

Unicoder: A Universal Language Encoder by Pre-training with Multiple Cross-lingual Tasks
Haoyang Huang, Yaobo Liang, Nan Duan, Ming Gong, Linjun Shou, Daxin Jiang and Ming Zhou

Addressing Semantic Drift in Question Generation for Semi-Supervised Question Answering
Shiyue Zhang and Mohit Bansal

Adversarial Domain Adaptation for Machine Reading Comprehension
Huazheng Wang, Zhe Gan, Xiaodong Liu, Jingjing Liu, Jianfeng Gao and Hongning Wang

Incorporating External Knowledge into Machine Reading for Generative Question Answering
Bin Bi, Chen Wu, Ming Yan, Wei Wang, Jiangnan Xia and Chenliang Li

Answering questions by learning to rank - Learning to rank by answering questions
George Sebastian Pirtoaca, Traian Rebedea and Stefan Ruseti

Discourse-Aware Semantic Self-Attention for Narrative Reading Comprehension
Todor Mihaylov and Anette Frank

Revealing the Importance of Semantic Retrieval for Machine Reading at Scale
Yixin Nie, Songhe Wang and Mohit Bansal

PubMedQA: A Dataset for Biomedical Research Question Answering
Qiao Jin, Bhuwan Dhingra, Zhengping Liu, William Cohen and Xinghua Lu

Quick and (not so) Dirty: Unsupervised Selection of Justification Sentences for Multi-hop Question Answering
Vikas Yadav, Steven Bethard and Mihai Surdeanu

Answering Complex Open-domain Questions Through Iterative Query Generation
Peng Qi, Xiaowen Lin, Leo Mehr, Zijian Wang and Christopher D. Manning

NL2pSQL: Generating Pseudo-SQL Queries from Under-Specified Natural Language Questions
Fuxiang Chen, Seung-won Hwang, Jaegul Choo, Jung-Woo Ha and Sunghun Kim

Leveraging Frequent Query Substructures to Generate Formal Queries for Complex Question Answering
Jiwei Ding, Wei Hu, Qixin Xu and Yuzhong Qu

Incorporating Graph Attention Mechanism into Knowledge Graph Reasoning Based on Deep Reinforcement Learning
Heng Wang, Shuangyin Li, Rong Pan and Mingzhi Mao

Learning to Update Knowledge Graphs by Reading News
Jizhi Tang, Yansong Feng and Dongyan Zhao

DIVINE: A Generative Adversarial Imitation Learning Framework for Knowledge Graph Reasoning
Ruiping Li and Xiang Cheng

Original Semantics-Oriented Attention and Deep Fusion Network for Sentence Matching
Mingtong Liu, Yujie Zhang, Jinan Xu and Yufeng Chen

Representation Learning with Ordered Relation Paths for Knowledge Graph Completion
Yao Zhu, Hongzhi Liu, Zhonghai Wu, Yang Song and Tao Zhang

Collaborative Policy Learning for Open Knowledge Graph Reasoning
Cong Fu, Tong Chen, Meng Qu, Woojeong Jin and Xiang Ren

Modeling Event Background for If-Then Commonsense Reasoning Using Context-aware Variational Autoencoder
Li Du, Xiao Ding, Ting Liu and Zhongyang Li

Asynchronous Deep Interaction Network for Natural Language Inference
Di Liang, Fubao Zhang, Qi Zhang and Xuanjing Huang

Keep Calm and Switch On! Preserving Sentiment and Fluency in Semantic Text Exchange
Steven Y. Feng, Aaron W. Li and Jesse Hoey

Query-focused Scenario Construction
Su Wang, Greg Durrett and Katrin Erk

Semi-supervised Entity Alignment via Joint Knowledge Embedding Model and Cross-graph Model
Chengjiang Li, Yixin Cao, Lei Hou, Jiaxin Shi, Juanzi Li and Tat-Seng Chua

[DEMO] *EUSP: An Easy-to-Use Semantic Parsing PlatForm*
Bo An, Chen Bo, Xianpei Han and Le Sun

[DEMO] *ParaQG: A System for Generating Questions and Answers from Paragraphs*
vishwajeet kumar, Sivaanandh Muneeswaran, Ganesh Ramakrishnan and Yuan-Fang Li

[DEMO] *CFO: A Framework for Building Production NLP Systems*
Rishav Chakravarti, Cezar Pendus, Andrzej Sakrajda, Anthony Ferritto, Lin Pan, Michael Glass, Vittorio Castelli, J William Murdock, Radu Florian, Salim Roukos and Avi Sil

[DEMO] *ABSApp: A Portable Weakly-Supervised Aspect-Based Sentiment Extraction System*
Oren Pereg, Daniel Korat, Moshe Wasserblat, Jonathan Mamou and Ido Dagan

[DEMO] *Memory Grounded Conversational Reasoning*
Seungwhan Moon, Pararth Shah, Rajen Subba and Anuj Kumar

12:00–13:30 *Lunch*

13:30–15:00 *Session 6*

Session 6A: Tagging, Chunking, Syntax and Parsing

13:30–13:48 *Designing and Interpreting Probes with Control Tasks*
John Hewitt and Percy Liang

13:48–14:06 *Specializing Word Embeddings (for Parsing) by Information Bottleneck*
Xiang Lisa Li and Jason Eisner

14:06–14:24 *Deep Contextualized Word Embeddings in Transition-Based and Graph-Based Dependency Parsing - A Tale of Two Parsers Revisited*
Artur Kulmizev, Miryam de Lhoneux, Johannes Gontrum, Elena Fano and Joakim Nivre

14:24–14:42 *Semantic graph parsing with recurrent neural network DAG grammars*
Federico Fancellu, Sorcha Gilroy, Adam Lopez and Mirella Lapata

14:42–15:00 *75 Languages, 1 Model: Parsing Universal Dependencies Universally*
Dan Kondratyuk and Milan Straka

Session 6B: Question Answering II

13:30–13:48 *Interactive Language Learning by Question Answering*
Xingdi Yuan, Marc-Alexandre Côté, Jie Fu, Zhouhan Lin, Chris Pal, Yoshua Bengio and Adam Trischler

13:48–14:06 *What's Missing: A Knowledge Gap Guided Approach for Multi-hop Question Answering*
Tushar Khot, Ashish Sabharwal and Peter Clark

14:06–14:24 *KagNet: Knowledge-Aware Graph Networks for Commonsense Reasoning*
Bill Yuchen Lin, Xinyue Chen, Jamin Chen and Xiang Ren

14:24–14:42 *Learning with Limited Data for Multilingual Reading Comprehension*
Kyungjae Lee, Sunghyun Park, Hojae Han, Jinyoung Yeo, Seung-won Hwang and Juho Lee

14:42–15:00 *A Discrete Hard EM Approach for Weakly Supervised Question Answering*
Sewon Min, Danqi Chen, Hannaneh Hajishirzi and Luke Zettlemoyer

Session 6C: Linguistic Theories, Cognitive Modeling and Psycholinguistics

13:30–13:48 *Is the Red Square Big? MALeViC: Modeling Adjectives Leveraging Visual Contexts*
Sandro Pezzelle and Raquel Fernández

13:48–14:06 *Investigating BERT's Knowledge of Language: Five Analysis Methods with NPIs*
Alex Warstadt, Yu Cao, Ioana Grosu, Wei Peng, Hagen Blix, Yining Nie, Anna Alsop, Shikha Bordia, Haokun Liu, Alicia Parrish, Sheng-Fu Wang, Jason Phang, Anhad Mohananey, Phu Mon Htut, Paloma Jeretic and Samuel R. Bowman

14:06–14:24 *Representation of Constituents in Neural Language Models: Coordination Phrase as a Case Study*
Aixiu AN, Peng Qian, Ethan Wilcox and Roger Levy

14:24–14:42 *Towards Zero-shot Language Modeling*
Edoardo Maria Ponti, Ivan Vulić, Ryan Cotterell, Roi Reichart and Anna Korhonen

14:42–15:00 [TACL] *Neural Network Acceptability Judgments*
Alex Warstadt, Amanpreet Singh and Samuel R. Bowman

Session 6D: Sentiment Analysis and Argument Mining II

13:30–13:48 *What Gets Echoed? Understanding the "Pointers" in Explanations of Persuasive Arguments*
David Atkinson, Kumar Bhargav Srinivasan and Chenhao Tan

13:48–14:06 *Modeling Frames in Argumentation*
Yamen Ajjour, Milad Alshomary, Henning Wachsmuth and Benno Stein

14:06–14:24 *AMPERSAND: Argument Mining for PERSuAsive oNline Discussions*
Tuhin Chakrabarty, Christopher Hidey, Smaranda Muresan, Kathy McKeown and Alyssa Hwang

14:24–14:42 *Evaluating adversarial attacks against multiple fact verification systems*
James Thorne, Andreas Vlachos, Christos Christodoulopoulos and Arpit Mittal

14:42–15:00 *Nonsense!: Quality Control via Two-Step Reason Selection for Annotating Local Acceptability and Related Attributes in News Editorials*
Wonsuk Yang, seungwon yoon, Ada Carpenter and Jong Park

Poster and Demo Session 6: Discourse and Pragmatics, Summarization and Generation

Evaluating Pronominal Anaphora in Machine Translation: An Evaluation Measure and a Test Suite
Prathyusha Jwalapuram, Shafiq Joty, Irina Temnikova and Preslav Nakov

A Regularization Approach for Incorporating Event Knowledge and Coreference Relations into Neural Discourse Parsing
Zeyu Dai and Ruihong Huang

Weakly Supervised Multilingual Causality Extraction from Wikipedia
Chikara Hashimoto

Attribute-aware Sequence Network for Review Summarization
Junjie Li, Xuepeng Wang, Dawei Yin and Chengqing Zong

Extractive Summarization of Long Documents by Combining Global and Local Context
Wen Xiao and Giuseppe Carenini

Enhancing Neural Data-To-Text Generation Models with External Background Knowledge
Shuang Chen, Jinpeng Wang, Xiaocheng Feng, Feng Jiang, Bing Qin and Chin-Yew Lin

Reading Like HER: Human Reading Inspired Extractive Summarization
Ling Luo, Xiang Ao, Yan Song, Feiyang Pan, Min Yang and Qing He

Contrastive Attention Mechanism for Abstractive Sentence Summarization
Xiangyu Duan, Hongfei Yu, Mingming Yin, Min Zhang, Weihua Luo and Yue Zhang

NCLS: Neural Cross-Lingual Summarization
Junnan Zhu, Qian Wang, Yining Wang, Yu Zhou, Jiajun Zhang, Shaonan Wang and Chengqing Zong

Clickbait? Sensational Headline Generation with Auto-tuned Reinforcement Learning
Peng Xu, Chien-Sheng Wu, Andrea Madotto and Pascale Fung

Concept Pointer Network for Abstractive Summarization
Wenbo Wang, Yang Gao, Heyan Huang and Yuxiang Zhou

Surface Realisation Using Full Delexicalisation
Anastasia Shimorina and Claire Gardent

IMaT: Unsupervised Text Attribute Transfer via Iterative Matching and Translation
Zhijing Jin, Di Jin, Jonas Mueller, Nicholas Matthews and Enrico Santus

Better Rewards Yield Better Summaries: Learning to Summarise Without References
Florian Böhm, Yang Gao, Christian M. Meyer, Ori Shapira, Ido Dagan and Iryna Gurevych

Mixture Content Selection for Diverse Sequence Generation
Jaemin Cho, Minjoon Seo and Hannaneh Hajishirzi

An End-to-End Generative Architecture for Paraphrase Generation
Qian Yang, zhouyuan huo, Dinghan Shen, Yong Cheng, Wenlin Wang, Guoyin Wang and Lawrence Carin

Table-to-Text Generation with Effective Hierarchical Encoder on Three Dimensions (Row, Column and Time)
Heng Gong, Xiaocheng Feng, Bing Qin and Ting Liu

Subtopic-driven Multi-Document Summarization
Xin Zheng, Aixin Sun, Jing Li and Karthik Muthuswamy

Referring Expression Generation Using Entity Profiles
Meng Cao and Jackie Chi Kit Cheung

Exploring Diverse Expressions for Paraphrase Generation
Lihua Qian, Lin Qiu, Weinan Zhang, Xin Jiang and Yong Yu

Enhancing AMR-to-Text Generation with Dual Graph Representations
Leonardo F. R. Ribeiro, Claire Gardent and Iryna Gurevych

Keeping Consistency of Sentence Generation and Document Classification with Multi-Task Learning
Toru Nishino, Shotaro Misawa, Ryuji Kano, Tomoki Taniguchi, Yasuhide Miura and Tomoko Ohkuma

Toward a Task of Feedback Comment Generation for Writing Learning
Ryo Nagata

Improving Question Generation With to the Point Context
Jingjing Li, Yifan Gao, Lidong Bing, Irwin King and Michael R. Lyu

Deep Copycat Networks for Text-to-Text Generation
Julia Ive, Pranava Madhyastha and Lucia Specia

Towards Controllable and Personalized Review Generation
Pan Li and Alexander Tuzhilin

Answers Unite! Unsupervised Metrics for Reinforced Summarization Models
Thomas Scialom, Sylvain Lamprier, Benjamin Piwowarski and Jacopo Staiano

Long and Diverse Text Generation with Planning-based Hierarchical Variational Model
Zhihong Shao, Minlie Huang, Jiangtao Wen, Wenfei Xu and xiaoyan zhu

"Transforming" Delete, Retrieve, Generate Approach for Controlled Text Style Transfer
Akhilesh Sudhakar, Bhargav Upadhyay and Arjun Maheswaran

An Entity-Driven Framework for Abstractive Summarization
Eva Sharma, Luyang Huang, Zhe Hu and Lu Wang

Neural Extractive Text Summarization with Syntactic Compression
Jiacheng Xu and Greg Durrett

Domain Adaptive Text Style Transfer
Dianqi Li, Yizhe Zhang, Zhe Gan, Yu Cheng, Chris Brockett, Bill Dolan and Ming-Ting Sun

Let's Ask Again: Refine Network for Automatic Question Generation
Preksha Nema, Akash Kumar Mohankumar, Mitesh M. Khapra, Balaji Vasan Srinivasan and Balaraman Ravindran

Earlier Isn't Always Better: Sub-aspect Analysis on Corpus and System Biases in Summarization
Taehee Jung, Dongyeop Kang, Lucas Mentch and Eduard Hovy

[DEMO] *VizSeq: a visual analysis toolkit for text generation tasks*
Changhan Wang, Anirudh Jain, Danlu Chen and Jiatao Gu

[DEMO] *FAMULUS: Interactive Annotation and Feedback Generation for Teaching Diagnostic Reasoning*
Jonas Pfeiffer, Christian M. Meyer, Claudia Schulz, Jan Kiesewetter, Jan Zottmann, Michael Sailer, Elisabeth Bauer, Frank Fischer, Martin R. Fischer and Iryna Gurevych

[DEMO] *A Summarization System for Scientific Documents*
Shai Erera, Michal Shmueli-Scheuer, Guy Feigenblat, Ora Peled Nakash, Odellia Boni, Haggai Roitman, Doron Cohen, Bar Weiner, Yosi Mass, Or Rivlin, Guy Lev, Achiya Jerbi, Jonathan Herzig, Yufang Hou, Charles Jochim, Martin Gleize, Francesca Bonin, Francesca Bonin and David Konopnicki

[DEMO] *EASSE: Easier Automatic Sentence Simplification Evaluation*
Fernando Alva-Manchego, Louis Martin, Carolina Scarton and Lucia Specia

[DEMO] *ALTER: Auxiliary Text Rewriting Tool for Natural Language Generation*
Qiongkai Xu, Chenchen Xu and Lizhen Qu

15:00–15:30 *Coffee Break*

15:30–16:18 *Session 7*

Session 7A: Machine Translation and Multilinguality I

15:30–15:42 *Lost in Evaluation: Misleading Benchmarks for Bilingual Dictionary Induction*
Yova Kementchedjhieva, Mareike Hartmann and Anders Søgaard

15:42–15:54 *Towards Realistic Practices In Low-Resource Natural Language Processing: The Development Set*
Katharina Kann, Kyunghyun Cho and Samuel R. Bowman

15:54–16:06 *Synchronously Generating Two Languages with Interactive Decoding*
Yining Wang, Jiajun Zhang, Long Zhou, Yuchen Liu and Chengqing Zong

16:06–16:18 *On NMT Search Errors and Model Errors: Cat Got Your Tongue?*
Felix Stahlberg and Bill Byrne

Session 7B: Reasoning and Question Answering

15:30–15:42 *"Going on a vacation" takes longer than "Going for a walk": A Study of Temporal Commonsense Understanding*
Ben Zhou, Daniel Khashabi, Qiang Ning and Dan Roth

15:42–15:54 *QAInfomax: Learning Robust Question Answering System by Mutual Information Maximization*
Yi-Ting Yeh and Yun-Nung Chen

15:54–16:06 *Adapting Meta Knowledge Graph Information for Multi-Hop Reasoning over Few-Shot Relations*
Xin Lv, Yuxian Gu, Xu Han, Lei Hou, Juanzi Li and Zhiyuan Liu

16:06–16:18 *How Reasonable are Common-Sense Reasoning Tasks: A Case-Study on the Winograd Schema Challenge and SWAG*
Paul Trichelair, Ali Emami, Adam Trischler, Kaheer Suleman and Jackie Chi Kit Cheung

Session 7C: Generation I

15:30–15:42 *Pun-GAN: Generative Adversarial Network for Pun Generation*
Fuli Luo, Shunyao Li, Pengcheng Yang, Lei Li, Baobao Chang, Zhifang Sui and Xu SUN

15:42–15:54 *Multi-Task Learning with Language Modeling for Question Generation*
Wenjie Zhou, Minghua Zhang and Yunfang Wu

15:54–16:06 *Autoregressive Text Generation Beyond Feedback Loops*
Florian Schmidt, Stephan Mandt and Thomas Hofmann

16:06–16:18 *The Woman Worked as a Babysitter: On Biases in Language Generation*
Emily Sheng, Kai-Wei Chang, Premkumar Natarajan and Nanyun Peng

Session 7D: Sentiment Analysis and Argument Mining III

15:30–15:42 *On the Importance of Delexicalization for Fact Verification*
Sandeep Suntwal, Mithun Paul, Rebecca Sharp and Mihai Surdeanu

15:42–15:54 *Towards Debiasing Fact Verification Models*
Tal Schuster, Darsh Shah, Yun Jie Serene Yeo, Daniel Roberto Filizzola Ortiz, Enrico Santus and Regina Barzilay

15:54–16:06 *Recognizing Conflict Opinions in Aspect-level Sentiment Classification with Dual Attention Networks*
Xingwei Tan, Yi Cai and Changxi Zhu

16:06–16:18 *Investigating Dynamic Routing in Tree-Structured LSTM for Sentiment Analysis*
Jin Wang, Liang-Chih Yu, K. Robert Lai and Xuejie Zhang

Poster and Demo Session 7: Information Retrieval and Document Analysis, Lexical Semantics, Sentence-level Semantics, Machine Learning

A Label Informative Wide & Deep Classifier for Patents and Papers
Muyao Niu and Jie Cai

Text Level Graph Neural Network for Text Classification
Lianzhe Huang, Dehong Ma, Sujian Li, Xiaodong Zhang and Houfeng WANG

Semantic Relatedness Based Re-ranker for Text Spotting
Ahmed Sabir, Francesc Moreno and Lluís Padró

Delta-training: Simple Semi-Supervised Text Classification using Pretrained Word Embeddings
Hwiyeol Jo and Ceyda Cinarel

Visual Detection with Context for Document Layout Analysis
Carlos Soto and Shinjae Yoo

Evaluating Topic Quality with Posterior Variability
Linzi Xing, Michael J. Paul and Giuseppe Carenini

Neural Topic Model with Reinforcement Learning
Lin Gui, Jia Leng, Gabriele Pergola, yu zhou, Ruifeng Xu and Yulan He

Modelling Stopping Criteria for Search Results using Poisson Processes
Alison Sneyd and Mark Stevenson

Cross-Domain Modeling of Sentence-Level Evidence for Document Retrieval
Zeynep Akkalyoncu Yilmaz, Wei Yang, Haotian Zhang and Jimmy Lin

The Challenges of Optimizing Machine Translation for Low Resource Cross-Language Information Retrieval
Constantine Lignos, Daniel Cohen, Yen-Chieh Lien, Pratik Mehta, W. Bruce Croft and Scott Miller

Rotate King to get Queen: Word Relationships as Orthogonal Transformations in Embedding Space
Kawin Ethayarajh

GlossBERT: BERT for Word Sense Disambiguation with Gloss Knowledge
Luyao Huang, Chi Sun, Xipeng Qiu and Xuanjing Huang

Leveraging Adjective-Noun Phrasing Knowledge for Comparison Relation Prediction in Text-to-SQL
Haoyan Liu, Lei Fang, Qian Liu, Bei Chen, Jian-Guang LOU and Zhoujun Li

Bridging the Defined and the Defining: Exploiting Implicit Lexical Semantic Relations in Definition Modeling
Koki Washio, Satoshi Sekine and Tsuneaki Kato

Don't Just Scratch the Surface: Enhancing Word Representations for Korean with Hanja
Kang Min Yoo, Taeuk Kim and Sang-goo Lee

SyntagNet: Challenging Supervised Word Sense Disambiguation with Lexical-Semantic Combinations
Marco Maru, Federico Scozzafava, Federico Martelli and Roberto Navigli

Hierarchical Meta-Embeddings for Code-Switching Named Entity Recognition
Genta Indra Winata, Zhaojiang Lin, Jamin Shin, Zihan Liu and Pascale Fung

Fine-tune BERT with Sparse Self-Attention Mechanism
Baiyun Cui, Yingming Li, Ming Chen and Zhongfei Zhang

Feature-Dependent Confusion Matrices for Low-Resource NER Labeling with Noisy Labels
Lukas Lange, Michael A. Hedderich and Dietrich Klakow

A Multi-Pairwise Extension of Procrustes Analysis for Multilingual Word Translation
Hagai Taitelbaum, Gal Chechik and Jacob Goldberger

Out-of-Domain Detection for Low-Resource Text Classification Tasks
Ming Tan, Yang Yu, Haoyu Wang, Dakuo Wang, Saloni Potdar, Shiyu Chang and Mo Yu

Harnessing Pre-Trained Neural Networks with Rules for Formality Style Transfer
Yunli Wang, Yu Wu, Lili Mou, Zhoujun Li and Wenhan Chao

Multiple Text Style Transfer by using Word-level Conditional Generative Adversarial Network with Two-Phase Training
Chih-Te Lai, Yi-Te Hong, Hong-You Chen, Chi-Jen Lu and Shou-De Lin

Improved Differentiable Architecture Search for Language Modeling and Named Entity Recognition
Yufan Jiang, Chi Hu, Tong Xiao, Chunliang Zhang and Jingbo Zhu

Using Pairwise Occurrence Information to Improve Knowledge Graph Completion on Large-Scale Datasets
Esma Balkir, Masha Naslidnyk, Dave Palfrey and Arpit Mittal

Single Training Dimension Selection for Word Embedding with PCA
Yu Wang

A Surprisingly Effective Fix for Deep Latent Variable Modeling of Text
Bohan Li, Junxian He, Graham Neubig, Taylor Berg-Kirkpatrick and Yiming Yang

SciBERT: A Pretrained Language Model for Scientific Text
Iz Beltagy, Kyle Lo and Arman Cohan

Humor Detection: A Transformer Gets the Last Laugh
Orion Weller and Kevin Seppi

Combining Global Sparse Gradients with Local Gradients in Distributed Neural Network Training
Alham Fikri Aji, Kenneth Heafield and Nikolay Bogoychev

Small and Practical BERT Models for Sequence Labeling
Henry Tsai, Jason Riesa, Melvin Johnson, Naveen Arivazhagan, Xin Li and Amelia Archer

Data Augmentation with Atomic Templates for Spoken Language Understanding
Zijian Zhao, Su Zhu and Kai Yu

PaLM: A Hybrid Parser and Language Model
Hao Peng, Roy Schwartz and Noah A. Smith

A Pilot Study for Chinese SQL Semantic Parsing
Qingkai Min, Yuefeng Shi and Yue Zhang

Global Reasoning over Database Structures for Text-to-SQL Parsing
Ben Bogin, Matt Gardner and Jonathan Berant

Transductive Learning of Neural Language Models for Syntactic and Semantic Analysis
Hiroki Ouchi, Jun Suzuki and Kentaro Inui

Efficient Sentence Embedding using Discrete Cosine Transform
Nada Almarwani, Hanan Aldarmaki and Mona Diab

A Search-based Neural Model for Biomedical Nested and Overlapping Event Detection
Kurt Junshean Espinosa, Makoto Miwa and Sophia Ananiadou

PAWS-X: A Cross-lingual Adversarial Dataset for Paraphrase Identification
Yinfei Yang, Yuan Zhang, Chris Tar and Jason Baldridge

Pretrained Language Models for Sequential Sentence Classification
Arman Cohan, Iz Beltagy, Daniel King, Bhavana Dalvi and Dan Weld

Emergent Linguistic Phenomena in Multi-Agent Communication Games
Laura Harding Graesser, Kyunghyun Cho and Douwe Kiela

TalkDown: A Corpus for Condescension Detection in Context
Zijian Wang and Christopher Potts

Wednesday, November 6, 2019 (continued)

16:18–16:30 *Mini-Break*

16:30–18:00 *Session 8*

Session 8A: Summarization

16:30–16:48 *Summary Cloze: A New Task for Content Selection in Topic-Focused Summarization*
Daniel Deutsch and Dan Roth

16:48–17:06 *Text Summarization with Pretrained Encoders*
Yang Liu and Mirella Lapata

17:06–17:24 *How to Write Summaries with Patterns? Learning towards Abstractive Summarization through Prototype Editing*
Shen Gao, Xiuying Chen, Piji Li, Zhangming Chan, Dongyan Zhao and Rui Yan

17:24–17:42 *BottleSum: Unsupervised and Self-supervised Sentence Summarization using the Information Bottleneck Principle*
Peter West, Ari Holtzman, Jan Buys and Yejin Choi

17:42–18:00 *Improving Latent Alignment in Text Summarization by Generalizing the Pointer Generator*
Xiaoyu Shen, Yang Zhao, Hui Su and Dietrich Klakow

Session 8B: Sentence-level Semantics II

16:30–16:48 *Learning Semantic Parsers from Denotations with Latent Structured Alignments and Abstract Programs*
Bailin Wang, Ivan Titov and Mirella Lapata

16:48–17:06 *Broad-Coverage Semantic Parsing as Transduction*
Sheng Zhang, Xutai Ma, Kevin Duh and Benjamin Van Durme

17:06–17:24 *Core Semantic First: A Top-down Approach for AMR Parsing*
Deng Cai and Wai Lam

17:24–17:42 *Don't paraphrase, detect! Rapid and Effective Data Collection for Semantic Parsing*
Jonathan Herzig and Jonathan Berant

17:42–18:00 [TACL] *Massively Multilingual Sentence Embeddings for Zero-Shot Cross-Lingual Transfer and Beyond*
Mikel Artetxe and Holger Schwenk

Session 8C: Information Extraction II

16:30–16:48 *Improving Distantly-Supervised Relation Extraction with Joint Label Embedding*
Linmei Hu, Luhao Zhang, Chuan Shi, Liqiang Nie, Weili Guan and Cheng Yang

16:48–17:06 *Leverage Lexical Knowledge for Chinese Named Entity Recognition via Collaborative Graph Network*
Dianbo Sui, Yubo Chen, Kang Liu, Jun Zhao and Shengping Liu

17:06–17:24 *Looking Beyond Label Noise: Shifted Label Distribution Matters in Distantly Supervised Relation Extraction*
Qinyuan Ye, Liyuan Liu, Maosen Zhang and Xiang Ren

17:24–17:42 *Easy First Relation Extraction with Information Redundancy*
Shuai Ma, Gang Wang, Yansong Feng and Jinpeng Huai

17:42–18:00 *Dependency-Guided LSTM-CRF for Named Entity Recognition*
Zhanming Jie and Wei Lu

Session 8D: Information Retrieval and Document Analysis I

16:30–16:48 *Cross-Cultural Transfer Learning for Text Classification*
Dor Ringel, Gal Lavee, Ido Guy and Kira Radinsky

16:48–17:06 *Combining Unsupervised Pre-training and Annotator Rationales to Improve Low-shot Text Classification*
Oren Melamud, Mihaela Bornea and Ken Barker

17:06–17:24 *ProSeqo: Projection Sequence Networks for On-Device Text Classification*
Zornitsa Kozareva and Sujith Ravi

17:24–17:42 *Induction Networks for Few-Shot Text Classification*
Ruiying Geng, Binhua Li, Yongbin Li, Xiaodan Zhu, Ping Jian and Jian Sun

17:42–18:00 *Benchmarking Zero-shot Text Classification: Datasets, Evaluation and Entailment Approach*
Wenpeng Yin, Jamaal Hay and Dan Roth

Poster and Demo Session 8: Machine Learning

A Logic-Driven Framework for Consistency of Neural Models
Tao Li, Vivek Gupta, Maitrey Mehta and Vivek Srikumar

Style Transfer for Texts: Retrain, Report Errors, Compare with Rewrites
Alexey Tikhonov, Viacheslav Shibaev, Aleksander Nagaev, Aigul Nugmanova and Ivan P. Yamshchikov

Implicit Deep Latent Variable Models for Text Generation
Le Fang, Chunyuan Li, Jianfeng Gao, Wen Dong and Changyou Chen

Text Emotion Distribution Learning from Small Sample: A Meta-Learning Approach
Zhenjie Zhao and Xiaojuan Ma

Judge the Judges: A Large-Scale Evaluation Study of Neural Language Models for Online Review Generation
Cristina Garbacea, Samuel Carton, Shiyan Yan and Qiaozhu Mei

Sentence-BERT: Sentence Embeddings using Siamese BERT-Networks
Nils Reimers and Iryna Gurevych

Learning Only from Relevant Keywords and Unlabeled Documents
Nontawat Charoenphakdee, Jongyeong Lee, Yiping Jin, Dittaya Wanvarie and Masashi Sugiyama

Denoising based Sequence-to-Sequence Pre-training for Text Generation
Liang Wang, Wei Zhao, Ruoyu Jia, Sujian Li and Jingming Liu

Dialog Intent Induction with Deep Multi-View Clustering
Hugh Perkins and Yi Yang

Nearly-Unsupervised Hashcode Representations for Biomedical Relation Extraction
Sahil Garg, Aram Galstyan, Greg Ver Steeg and Guillermo Cecchi

Auditing Deep Learning processes through Kernel-based Explanatory Models
Danilo Croce, Daniele Rossini and Roberto Basili

Enhancing Variational Autoencoders with Mutual Information Neural Estimation for Text Generation
Dong Qian and William K. Cheung

Sampling Bias in Deep Active Classification: An Empirical Study
Ameya Prabhu, Charles Dognin and Maneesh Singh

Don't Take the Easy Way Out: Ensemble Based Methods for Avoiding Known Dataset Biases
Christopher Clark, Mark Yatskar and Luke Zettlemoyer

Achieving Verified Robustness to Symbol Substitutions via Interval Bound Propagation
Po-Sen Huang, Robert Stanforth, Johannes Welbl, Chris Dyer, Dani Yogatama, Sven Gowal, Krishnamurthy Dvijotham and Pushmeet Kohli

Rethinking Cooperative Rationalization: Introspective Extraction and Complement Control
Mo Yu, Shiyu Chang, Yang Zhang and Tommi Jaakkola

Experimenting with Power Divergences for Language Modeling
Matthieu Labeau and Shay B. Cohen

Hierarchically-Refined Label Attention Network for Sequence Labeling
Leyang Cui and Yue Zhang

Certified Robustness to Adversarial Word Substitutions
Robin Jia, Aditi Raghunathan, Kerem Göksel and Percy Liang

Visualizing and Understanding the Effectiveness of BERT
Yaru Hao, Li Dong, Furu Wei and Ke Xu

Topics to Avoid: Demoting Latent Confounds in Text Classification
Sachin Kumar, Shuly Wintner, Noah A. Smith and Yulia Tsvetkov

Learning to Ask for Conversational Machine Learning
Shashank Srivastava, Igor Labutov and Tom Mitchell

Language Modeling for Code-Switching: Evaluation, Integration of Monolingual Data, and Discriminative Training
Hila Gonen and Yoav Goldberg

Using Local Knowledge Graph Construction to Scale Seq2Seq Models to Multi-Document Inputs
Angela Fan, Claire Gardent, Chloé Braud and Antoine Bordes

Fine-grained Knowledge Fusion for Sequence Labeling Domain Adaptation
Huiyun Yang, Shujian Huang, XIN-YU DAI and Jiajun CHEN

Exploiting Monolingual Data at Scale for Neural Machine Translation
Lijun Wu, Yiren Wang, Yingce Xia, Tao QIN, Jianhuang Lai and Tie-Yan Liu

Meta Relational Learning for Few-Shot Link Prediction in Knowledge Graphs
Mingyang Chen, Wen Zhang, Wei Zhang, Qiang Chen and Huajun Chen

Distributionally Robust Language Modeling
Yonatan Oren, Shiori Sagawa, Tatsunori Hashimoto and Percy Liang

Unsupervised Domain Adaptation of Contextualized Embeddings for Sequence Labeling
Xiaochuang Han and Jacob Eisenstein

Learning Latent Parameters without Human Response Patterns: Item Response Theory with Artificial Crowds
John P. Lalor, Hao Wu and Hong Yu

Parallel Iterative Edit Models for Local Sequence Transduction
Abhijeet Awasthi, Sunita Sarawagi, Rasna Goyal, Sabyasachi Ghosh and Vihari Piratla

ARAML: A Stable Adversarial Training Framework for Text Generation
Pei Ke, Fei Huang, Minlie Huang and xiaoyan zhu

FlowSeq: Non-Autoregressive Conditional Sequence Generation with Generative Flow
Xuezhe Ma, Chunting Zhou, Xian Li, Graham Neubig and Eduard Hovy

Compositional Generalization for Primitive Substitutions
Yuanpeng Li, Liang Zhao, Jianyu Wang and Joel Hestness

WikiCREM: A Large Unsupervised Corpus for Coreference Resolution
Vid Kocijan, Oana-Maria Camburu, Ana-Maria Cretu, Yordan Yordanov, Phil Blunsom and Thomas Lukasiewicz

Identifying and Explaining Discriminative Attributes
Armins Stepanjans and André Freitas

Patient Knowledge Distillation for BERT Model Compression
Siqi Sun, Yu Cheng, Zhe Gan and Jingjing Liu

Neural Gaussian Copula for Variational Autoencoder
Prince Zizhuang Wang and William Yang Wang

Transformer Dissection: An Unified Understanding for Transformer's Attention via the Lens of Kernel
Yao-Hung Hubert Tsai, Shaojie Bai, Makoto Yamada, Louis-Philippe Morency and Ruslan Salakhutdinov

Learning to Learn and Predict: A Meta-Learning Approach for Multi-Label Classification
Jiawei Wu, Wenhan Xiong and William Yang Wang

Revealing the Dark Secrets of BERT
Olga Kovaleva, Alexey Romanov, Anna Rogers and Anna Rumshisky

Machine Translation With Weakly Paired Documents
Lijun Wu, Jinhua Zhu, Di He, Fei Gao, Tao QIN, Jianhuang Lai and Tie-Yan Liu

Countering Language Drift via Visual Grounding
Jason Lee, Kyunghyun Cho and Douwe Kiela

The Bottom-up Evolution of Representations in the Transformer: A Study with Machine Translation and Language Modeling Objectives
Elena Voita, Rico Sennrich and Ivan Titov

[DEMO] *NeuronBlocks: Building Your NLP DNN Models Like Playing Lego*
Ming Gong, Linjun Shou, Wutao Lin, Zhijie Sang, Quanjia Yan, Ze Yang, Feixiang Cheng and Daxin Jiang

Wednesday, November 6, 2019 (continued)

[DEMO] *Controlling Sequence-to-Sequence Models - A Demonstration on Neural-based Acrostic Generator*
Liang-Hsin Shen, Pei-Lun Tai, Chao-Chung Wu and Shou-De Lin

[DEMO] *AllenNLP Interpret: A Framework for Explaining Predictions of NLP Models*
Eric Wallace, Jens Tuyls, Junlin Wang, Sanjay Subramanian, Matt Gardner and Sameer Singh

[DEMO] *UER: An Open-Source Toolkit for Pre-training Models*
Zhe Zhao, Hui Chen, Jinbin Zhang, Xin Zhao, Tao Liu, Wei Lu, Xi Chen, Haotang Deng, Qi Ju and Xiaoyong Du

[DEMO] *MedCATTrainer: A Biomedical Free Text Annotation Interface with Active Learning and Research Use Case Specific Customisation*
Thomas Searle, Zeljko Kraljevic, Rebecca Bendayan, Daniel Bean and Richard Dobson

Thursday, November 7, 2019

09:00–10:00 *Keynote III: Kyunghyun Cho*

10:00–10:30 *Coffee Break*

10:30–12:00 *Session 9*

Session 9A: Machine Translation and Multilinguality II

10:30–10:48 *Do We Really Need Fully Unsupervised Cross-Lingual Embeddings?*
Ivan Vulić, Goran Glavaš, Roi Reichart and Anna Korhonen

10:48–11:06 *Weakly-Supervised Concept-based Adversarial Learning for Cross-lingual Word Embeddings*
Haozhou Wang, James Henderson and Paola Merlo

11:06–11:24 *Aligning Cross-Lingual Entities with Multi-Aspect Information*
Hsiu-Wei Yang, Yanyan Zou, Peng Shi, Wei Lu, Jimmy Lin and Xu SUN

11:24–11:42 *Contrastive Language Adaptation for Cross-Lingual Stance Detection*
Mitra Mohtarami, James Glass and Preslav Nakov

11:42–12:00 *Jointly Learning to Align and Translate with Transformer Models*
Sarthak Garg, Stephan Peitz, Udhyakumar Nallasamy and Matthias Paulik

Session 9B: Reasoning

10:30–10:48 *Social IQa: Commonsense Reasoning about Social Interactions*
Maarten Sap, Hannah Rashkin, Derek Chen, Ronan Le Bras and Yejin Choi

10:48–11:06 *Self-Assembling Modular Networks for Interpretable Multi-Hop Reasoning*
Yichen Jiang and Mohit Bansal

11:06–11:24 *Posing Fair Generalization Tasks for Natural Language Inference*
Atticus Geiger, Ignacio Cases, Lauri Karttunen and Christopher Potts

11:24–11:42 *Everything Happens for a Reason: Discovering the Purpose of Actions in Procedural Text*
Bhavana Dalvi, Niket Tandon, Antoine Bosselut, Wen-tau Yih and Peter Clark

11:42–12:00 *CLUTRR: A Diagnostic Benchmark for Inductive Reasoning from Text*
Koustuv Sinha, Shagun Sodhani, Jin Dong, Joelle Pineau and William L. Hamilton

Session 9C: Dialog and Interactive Systems II

10:30–10:48 *Taskmaster-1: Toward a Realistic and Diverse Dialog Dataset*
Bill Byrne, Karthik Krishnamoorthi, Chinnadhurai Sankar, Arvind Neelakantan, Ben Goodrich, Daniel Duckworth, Semih Yavuz, Amit Dubey, Kyu-Young Kim and Andy Cedilnik

10:48–11:06 *Multi-Domain Goal-Oriented Dialogues (MultiDoGO): Strategies toward Curating and Annotating Large Scale Dialogue Data*
Denis Peskov, Nancy Clarke, Jason Krone, Brigi Fodor, Yi Zhang, Adel Youssef and Mona Diab

11:06–11:24 *Build it Break it Fix it for Dialogue Safety: Robustness from Adversarial Human Attack*
Emily Dinan, Samuel Humeau, Bharath Chintagunta and Jason Weston

11:24–11:42 *GECOR: An End-to-End Generative Ellipsis and Co-reference Resolution Model for Task-Oriented Dialogue*
Jun Quan, Deyi Xiong, Bonnie Webber and Changjian Hu

11:42–12:00 *Task-Oriented Conversation Generation Using Heterogeneous Memory Networks*
Zehao Lin, Xinjing Huang, Feng Ji, Haiqing Chen and Yin Zhang

Session 9D: Sentiment Analysis and Argument Mining IV

10:30–10:48 *Aspect-based Sentiment Classification with Aspect-specific Graph Convolutional Networks*
Chen Zhang, Qiuchi Li and Dawei Song

10:48–11:06 *Coupling Global and Local Context for Unsupervised Aspect Extraction*
Ming Liao, Jing Li, Haisong Zhang, Lingzhi Wang, Xixin Wu and Kam-Fai Wong

11:06–11:24 *Transferable End-to-End Aspect-based Sentiment Analysis with Selective Adversarial Learning*
Zheng Li, Xin Li, Ying Wei, Lidong Bing, Yu Zhang and Qiang Yang

11:24–11:42 *CAN: Constrained Attention Networks for Multi-Aspect Sentiment Analysis*
Mengting Hu, Shiwan Zhao, Li Zhang, Keke Cai, Zhong Su, Renhong Cheng and Xiaowei Shen

11:42–12:00 *Leveraging Just a Few Keywords for Fine-Grained Aspect Detection Through Weakly Supervised Co-Training*
Giannis Karamanolakis, Daniel Hsu and Luis Gravano

Poster and Demo Session 9: Social Media and Computational Social Science, Text Mining and NLP Applications

Integrating Text and Image: Determining Multimodal Document Intent in Instagram Posts
Julia Kruk, Jonah Lubin, Karan Sikka, Xiao Lin, Dan Jurafsky and Ajay Divakaran

Neural Conversation Recommendation with Online Interaction Modeling
Xingshan Zeng, Jing Li, Lu Wang and Kam-Fai Wong

Different Absorption from the Same Sharing: Sifted Multi-task Learning for Fake News Detection
Lianwei Wu, Yuan Rao, Haolin Jin, Ambreen Nazir and Ling Sun

Text-based inference of moral sentiment change
Jing Yi Xie, Renato Ferreira Pinto Junior, Graeme Hirst and Yang Xu

Detecting Causal Language Use in Science Findings
Bei Yu, Yingya Li and Jun Wang

Multilingual and Multi-Aspect Hate Speech Analysis
Nedjma Ousidhoum, Zizheng Lin, Hongming Zhang, Yangqiu Song and Dit-Yan Yeung

MultiFC: A Real-World Multi-Domain Dataset for Evidence-Based Fact Checking of Claims
Isabelle Augenstein, Christina Lioma, Dongsheng Wang, Lucas Chaves Lima, Casper Hansen, Christian Hansen and Jakob Grue Simonsen

A Deep Neural Information Fusion Architecture for Textual Network Embeddings
Zenan Xu, Qinliang Su, Xiaojun Quan and Weijia Zhang

You Shall Know a User by the Company It Keeps: Dynamic Representations for Social Media Users in NLP
Marco Del Tredici, Diego Marcheggiani, Sabine Schulte im Walde and Raquel Fernández

Adaptive Ensembling: Unsupervised Domain Adaptation for Political Document Analysis
Shrey Desai, Barea Sinno, Alex Rosenfeld and Junyi Jessy Li

Macrocosm: Social Media Persona Linking for Open Source Intelligence Applications
Graham Horwood, Ning Yu, Thomas Boggs, Changjiang Yang and Chad Holvenstot

A Hierarchical Location Prediction Neural Network for Twitter User Geolocation
Binxuan Huang and Kathleen Carley

Trouble on the Horizon: Forecasting the Derailment of Online Conversations as they Develop
Jonathan P. Chang and Cristian Danescu-Niculescu-Mizil

A Benchmark Dataset for Learning to Intervene in Online Hate Speech
Jing Qian, Anna Bethke, Yinyin Liu, Elizabeth Belding and William Yang Wang

Detecting and Reducing Bias in a High Stakes Domain
Ruiqi Zhong, Yanda Chen, Desmond Patton, Charlotte Selous and Kathy McKeown

CodeSwitch-Reddit: Exploration of Written Multilingual Discourse in Online Discussion Forums
Ella Rabinovich, Masih Sultani and Suzanne Stevenson

Modeling Conversation Structure and Temporal Dynamics for Jointly Predicting Rumor Stance and Veracity
Penghui Wei, Nan Xu and Wenji Mao

[TACL] *Measuring Online Debaters' Persuasive Skill from Text over Time*
Kelvin Luu, Chenhao Tan and Noah Smith

Reconstructing Capsule Networks for Zero-shot Intent Classification
Han Liu, Xiaotong Zhang, Lu Fan, Xuandi Fu, Qimai Li, Xiao-Ming Wu and Albert Y.S. Lam

Domain Adaptation for Person-Job Fit with Transferable Deep Global Match Network
Shuqing Bian, Wayne Xin Zhao, Yang Song, Tao Zhang and Ji-Rong Wen

Heterogeneous Graph Attention Networks for Semi-supervised Short Text Classification
Hu Linmei, Tianchi Yang, Chuan Shi, Houye Ji and Xiaoli Li

Comparing and Developing Tools to Measure the Readability of Domain-Specific Texts
Elissa Redmiles, Lisa Maszkiewicz, Emily Hwang, Dhruv Kuchhal, Everest Liu, Miraida Morales, Denis Peskov, Sudha Rao, Rock Stevens, Kristina Gligorić, Sean Kross, Michelle Mazurek and Hal Daumé III

News2vec: News Network Embedding with Subnode Information
Ye Ma, Lu Zong, Yikang Yang and Jionglong Su

Recursive Context-Aware Lexical Simplification
Sian Gooding and Ekaterina Kochmar

Leveraging Medical Literature for Section Prediction in Electronic Health Records
Sara Rosenthal, Ken Barker and Zhicheng Liang

Neural News Recommendation with Heterogeneous User Behavior
Chuhan Wu, Fangzhao Wu, Mingxiao An, Tao Qi, Jianqiang Huang, Yongfeng Huang and Xing Xie

Reviews Meet Graphs: Enhancing User and Item Representations for Recommendation with Hierarchical Attentive Graph Neural Network
Chuhan Wu, Fangzhao Wu, Tao Qi, Suyu Ge, Yongfeng Huang and Xing Xie

Event Representation Learning Enhanced with External Commonsense Knowledge
Xiao Ding, Kuo Liao, Ting Liu, Zhongyang Li and Junwen Duan

Learning to Discriminate Perturbations for Blocking Adversarial Attacks in Text Classification
Yichao Zhou, Jyun-Yu Jiang, Kai-Wei Chang and Wei Wang

A Neural Citation Count Prediction Model based on Peer Review Text
Siqing Li, Wayne Xin Zhao, Eddy Jing Yin and Ji-Rong Wen

Connecting the Dots: Document-level Neural Relation Extraction with Edge-oriented Graphs
Fenia Christopoulou, Makoto Miwa and Sophia Ananiadou

Semi-supervised Text Style Transfer: Cross Projection in Latent Space
Mingyue Shang, Piji Li, Zhenxin Fu, Lidong Bing, Dongyan Zhao, Shuming Shi and Rui Yan

Question Answering for Privacy Policies: Combining Computational and Legal Perspectives
Abhilasha Ravichander, Alan W Black, Shomir Wilson, Thomas Norton and Norman Sadeh

Stick to the Facts: Learning towards a Fidelity-oriented E-Commerce Product Description Generation
Zhangming Chan, Xiuying Chen, Yongliang Wang, Juntao Li, Zhiqiang Zhang, Kun Gai, Dongyan Zhao and Rui Yan

Fine-Grained Entity Typing via Hierarchical Multi Graph Convolutional Networks
Hailong Jin, Lei Hou, Juanzi Li and Tiansi Dong

Learning to Infer Entities, Properties and their Relations from Clinical Conversations
Nan Du, Mingqiu Wang, Linh Tran, Gang Lee and Izhak Shafran

Practical Correlated Topic Modeling and Analysis via the Rectified Anchor Word Algorithm
Moontae Lee, Sungjun Cho, David Bindel and David Mimno

Modeling the Relationship between User Comments and Edits in Document Revision
Xuchao Zhang, Dheeraj Rajagopal, Michael Gamon, Sujay Kumar Jauhar and ChangTien Lu

PRADO: Projection Attention Networks for Document Classification On-Device
Karthik Krishnamoorthi, Sujith Ravi and Zornitsa Kozareva

Subword Language Model for Query Auto-Completion
Gyuwan Kim

Enhancing Dialogue Symptom Diagnosis with Global Attention and Symptom Graph
Xinzhu Lin, Xiahui He, Qin Chen, Huaixiao Tou, Zhongyu Wei and Ting Chen

Thursday, November 7, 2019 (continued)

[DEMO] *TEASPN: Framework and Protocol for Integrated Writing Assistance Environments*
Masato Hagiwara, Takumi Ito, Tatsuki Kuribayashi, Jun Suzuki and Kentaro Inui

[DEMO] *Journalist-in-the-Loop: Continuous Learning as a Service for Rumour Analysis*
Twin Karmakharm, Nikolaos Aletras and Kalina Bontcheva

[DEMO] *MAssistant: A Personal Knowledge Assistant for MOOC Learners*
Lan Jiang, Shuhan Hu, Mingyu Huang, Zhichun Wang, Jinjian Yang, Xiaoju Ye and Wei Zheng

[DEMO] *A Stylometry Toolkit for Latin Literature*
Thomas J. Bolt, Jeffrey H. Flynt, Pramit Chaudhuri and Joseph P. Dexter

[DEMO] *Tanbih: Get To Know What You Are Reading*
Yifan Zhang, Giovanni Da San Martino, Alberto Barrón-Cedeño, Salvatore Romeo, Jisun An, Haewoon Kwak, Todor Staykovski, Israa Jaradat, Georgi Karadzhov, Ramy Baly, Kareem Darwish, James Glass and Preslav Nakov

[DEMO] *Visualizing Trends of Key Roles in News Articles*
Chen Xia, Haoxiang Zhang, Jacob Moghtader, Allen Wu and Kai-Wei Chang

12:00–12:30 *Lunch*

12:30–13:30 *SIGDAT Business Meeting*

13:30–15:00 *Session 10*

Session 10A: Generation II

13:30–13:48 *Counterfactual Story Reasoning and Generation*
Lianhui Qin, Antoine Bosselut, Ari Holtzman, Chandra Bhagavatula, Elizabeth Clark and Yejin Choi

13:48–14:06 *Encode, Tag, Realize: High-Precision Text Editing*
Eric Malmi, Sebastian Krause, Sascha Rothe, Daniil Mirylenka and Aliaksei Severyn

14:06–14:24 *Answer-guided and Semantic Coherent Question Generation in Open-domain Conversation*
Weichao Wang, Shi Feng, Daling Wang and Yifei Zhang

14:24–14:42 *Read, Attend and Comment: A Deep Architecture for Automatic News Comment Generation*
Ze Yang, Can Xu, wei wu and zhoujun li

14:42–15:00 *A Topic Augmented Text Generation Model: Joint Learning of Semantics and Structural Features*
hongyin tang, Miao Li and Beihong Jin

Session 10B: Speech, Vision, Robotics, Multimodal and Grounding II

13:30–13:48 *LXMERT: Learning Cross-Modality Encoder Representations from Transformers*
Hao Tan and Mohit Bansal

13:48–14:06 *Phrase Grounding by Soft-Label Chain Conditional Random Field*
Jiacheng Liu and Julia Hockenmaier

14:06–14:24 *What You See is What You Get: Visual Pronoun Coreference Resolution in Dialogues*
Xintong Yu, Hongming Zhang, Yangqiu Song, Yan Song and Changshui Zhang

14:24–14:42 *YouMakeup: A Large-Scale Domain-Specific Multimodal Dataset for Fine-Grained Semantic Comprehension*
Weiying Wang, Yongcheng Wang, Shizhe Chen and Qin Jin

14:42–15:00 *DEBUG: A Dense Bottom-Up Grounding Approach for Natural Language Video Localization*
Chujie Lu, Long Chen, Chilie Tan, Xiaolin Li and Jun Xiao

Session 10C: Information Extraction III

13:30–13:48 *CrossWeigh: Training Named Entity Tagger from Imperfect Annotations*
Zihan Wang, Jingbo Shang, Liyuan Liu, Lihao Lu, Jiacheng Liu and Jiawei Han

13:48–14:06 *A Little Annotation does a Lot of Good: A Study in Bootstrapping Low-resource Named Entity Recognizers*
Aditi Chaudhary, Jiateng Xie, Zaid Sheikh, Graham Neubig and Jaime Carbonell

14:06–14:24 *Open Domain Web Keyphrase Extraction Beyond Language Modeling*
Lee Xiong, Chuan Hu, Chenyan Xiong, Daniel Campos and Arnold Overwijk

14:24–14:42 *TuckER: Tensor Factorization for Knowledge Graph Completion*

Attending to Future Tokens for Bidirectional Sequence Generation

Carolin Lawrence and **Bhushan Kotnis** and **Mathias Niepert**
NEC Laboratories Europe
{carolin.lawrence, bhushan.kotnis, mathias.niepert}@neclab.eu

Abstract

Neural sequence generation is typically performed token-by-token and left-to-right. Whenever a token is generated only previously produced tokens are taken into consideration. In contrast, for problems such as sequence classification, *bidirectional* attention, which takes both past *and* future tokens into consideration, has been shown to perform much better. We propose to make the sequence generation process bidirectional by employing special placeholder tokens. Treated as a node in a fully connected graph, a placeholder token can take past and future tokens into consideration when generating the actual output token. We verify the effectiveness of our approach experimentally on two conversational tasks where the proposed bidirectional model outperforms competitive baselines by a large margin.

1 Introduction

When generating an output sequence, neural network models typically produce one token at a time. At each generation step, only the already produced sequence is taken into account. However, future and not-yet-produced tokens can also be highly relevant when choosing the current token. The importance of attending to both past and future tokens is apparent in self-attention architectures such as the Transformer (Vaswani et al., 2017). The self-attention module of a Transformer network treats a sequence *bidirectionally* as a fully connected graph of tokens – when a token is produced all other tokens are taken into consideration. However, this requires the entire sequence to be known a priori and when a Transformer is used for sequence generation, the self-attention process only includes previously produced tokens (Vaswani et al. (2017); Radford et al. (2019); *inter alia*). But the *bidirectional* self-attention is a crucial property of the highly successful language model BERT (Devlin et al., 2018). During the pre-training procedure of BERT, a fraction of input tokens is randomly masked out and the training objective is to predict these masked tokens correctly. BERT can then be fine-tuned for various classification tasks. Unfortunately, BERT cannot be directly used for sequence generation because the bidirectional nature of the approach requires the entire sequence to be known beforehand.

Inspired by BERT's masking-based objective, we propose to start out with a sequence of placeholder tokens which are iteratively replaced by tokens from the output vocabulary to eventually generate the full output sequence. For an example see Figure 1. With this novel model component, the self-attention of a Transformer can take both past and future tokens into consideration, leading to *Bi*directional *S*equence generati*on* (BISON). Furthermore, it allows us to directly incorporate the pre-trained language model BERT and, to the best of our knowledge, for the first time directly fine-tune it for sequence generation.

BISON makes two major contributions which we investigate in turn. First, we explore different stochastic placeholder replacement strategies to determine, at training time, where to position the placeholder tokens. This is crucial as we need the BISON models to be exposed to a large number of heterogeneous placeholder configurations. Second, we explore several strategies for iteratively generating, at inference time, a complete output sequence from an initial sequence of placeholders.

We evaluate our bidirectional sequence generation approach on two conversational tasks. BISON outperforms both competitive baselines and state of the art neural network approaches on both datasets by a significant margin.

3	Have	you	been	accepted	or	enrolled	in	an	accredited	degree	or	program	?

Figure 1: Example generation, going from a sequence of the placeholder token $\bar{p}$ (1), to an intermediate representation (2) and to the final output (3).

2 Sequence Generation with Transformers

For sequence-to-sequence tasks, an input sequence $x = x_1, x_2, \ldots, x_{|x|}$ is to be mapped to an output sequence $y = y_1, y_2, \ldots, y_{|y|}$ by some model π_θ with learnable parameters θ. For neural models, this is typically done by first encoding the input sequence x and then calling a decoder t times to produce a sequence y token-by-token, from left-to-right.

A popular choice for both encoder and decoder is the transformer (Vaswani et al., 2017). It takes a sequence of embedded tokens $s = s_1, s_2, \ldots, s_{|s|}$ and treats it as a fully connected graph over which a self-attention module is applied: for each token s_t in the sequence it assigns a probabilistic attention score a_t to every other token in the sentence. For the full mathematical details we refer the reader to (Vaswani et al., 2017).

Typically a transformer *encoder* is employed to encode x, whereas a transformer *decoder* is used to produce y. In contrast to the encoder, the decoder at time step t only has access to previously produced tokens $s_{<t} = s_1, s_2, \ldots, s_{t-1}$. Consequently, the attention module cannot take possible future tokens into account when making its decision at time t. Additionally, in this encoder-decoder framework, there is a disconnect between input x and output y because the self-attention modules are applied to x and y in isolation before they are combined.

The latter weakness has been overcome in recent work (Radford et al., 2018; Wolf et al., 2019; Radford et al., 2019) by feeding the concatenation $s = x \oplus y$ to a transformer decoder. At training time, given the current token s_t, the transformer is trained to predict the next word s_{t+1} via maximum likelihood estimation. At test time, the transformer is conditioned on x and then produces the output y token-by-token. But because the model is a transformer decoder, it is unable to take possible future tokens into account.

3 Bidirectional Sequence Generation

During sequence generation, we want to take both past and future tokens into account. More formally, at time t, we want to attend to both $s_1, \ldots, s_{t-1}$ as well as $s_{t+1}, \ldots, s_{|s|}$. To do this, we give the sequence $s = x \oplus y$, the concatenation of the sequences x and y, to a Transformer encoder, rather than a decoder. Of course, at inference time y is unknown. Thus, we propose to replace each token y_j with a *placeholder token* $\bar{p}$. Since the model needs to be exposed to heterogeneous placeholder token configurations during training time, we introduce a *placeholder strategy* that replaces some tokens y_j with placeholder tokens $\bar{p}$ at training time. Hence, during training, a sequence y is replaced by a sequence $p = p_1, p_2, \ldots, p_{|y|}$, where a token p_j is either the original token y_j or the placeholder token $\bar{p}$. We introduce two placeholder strategies in the following section. At inference time, p contains only placeholder tokens up to some pre-determined maximum sequence length.

With the placeholder strategy in place, a Transformer encoder is given the sequence $s = x \oplus p$ as input. The self-attention module then computes hidden representations r_t of each token s_t by attending to every other token in the sequence s. Because the output sequence is already present in the form of placeholder tokens both past tokens as well as future, not-yet-produced, tokens can be taken into consideration for every token s_t. Following the self-attention step, placeholder tokens are converted into a token from the output vocabulary with a language model (LM) classification layer, where for each placeholder p_t, its hidden representation r_t is mapped to a distribution d_t over the output vocabulary.

At training time, each output sequence token is fed the gold label and updates to the model π_θ are performed using stochastic gradient descent with a cross-entropy loss, i.e.

$$\mathcal{L}_{\pi_\theta} = -\frac{1}{M}\sum_{m=1}^{M}\sum_{j=1}^{|y|}\log \pi_\theta(p_j = y_j|s),$$

where M is the size of a minibatch.

At inference time, the placeholder tokens can be replaced iteratively based on the probability distribution d_t over the output vocabulary for each placeholder p_t. Different sequence generation strategies are outlined in Section 3.2.

3.1 Placeholder Replacement Strategy

At inference time, the output sequence starts out with a sequence of placeholder tokens. To introduce this notion at training time, we require a strategy that replaces some output sequence tokens y_j with the placeholder token $\bar{p}$. The simplest approach would be to replace all output sequence tokens y_j with the placeholder token $\bar{p}$. However, with this approach the model is never confronted with a sequence containing a mix of output sequence tokens and placeholder tokens.

Due to the exponential number of possible replacement configurations per given token sequence, we introduce probabilistic generative models that we can use to draw diverse sequence replacements. To this end, we model the decision whether to use placeholder or input tokens with probabilistic models, two of which we propose in the following.

Bernoulli Random Variables (RV). We model each position of the input sequence with a binary random variable with a fixed mean. For every input sequence and every position i in the sequence, we draw from a Bernoulli variable with mean μ to decide whether to use y_i or $\bar{p}$. The expected number of placeholder tokens in a sequence of length $|y|$ is $|y|\mu$ and the variance is $\sigma^2 = |y|\mu(1-\mu)$. The variance of this strategy is determined by the mean and, therefore, the probabilistic model has one tunable parameter μ.

Gaussian Random Variables. The *number of placeholder tokens* of the input sequence p can be seen as drawn from an unknown optimal Binomial distribution. We can approximate this Binomial with a normal distribution $\mathcal{N}(\mu, \sigma^2)$, where μ is the mean and σ the standard deviation and they are considered hyperparameters. More formally, for every input sequence, we draw a value $P \sim \mathcal{N}(\mu, \sigma^2)$. Multiplied with the sequence length $|y|$, the nearest integer value $\lfloor(|y| \cdot P)\rceil$ is used as the number of placeholder tokens for the given sequence. The positions of the placeholder tokens in the sequence are then determined at random. The resulting probabilistic model's two parameters (mean μ and standard deviation σ) are treated as hyperparameters and are not updated during training. Being able to tune the variance parameter independently from the mean parameter might provide an advantage over the parameterization with Bernoulli RVs.

3.2 Sequence Generation Strategies

Starting with a sequence of placeholder tokens at inference time, it is possible to generate output token sequences in arbitrary order. We experiment with the following strategies. The distribution in all of these strategies are the distributions d_t ($t = 1, ..., n$) for the placeholders over the output vocabulary. We use the term *uncover* to mean that an output token is generated for a placeholder token.

One-step greedy. In a single time step, all placeholder tokens are uncovered simultaneously by picking the most probable token from the output vocabulary for each placeholder.

Highest probability. Placeholders are replaced iteratively and the placeholder to be uncovered is the placeholder that assigns the highest probability to a token from the output vocabulary, indicating the model is the most sure about this token.

Lowest entropy. Placeholders are replaced iteratively and the placeholder to be uncovered is the placeholder that exhibits the lowest entropy over its output vocabulary distribution and the most likely token at this position is chosen. Intuitively, the lowest entropy indicates the position where the uncertainty of the model to decide between tokens of the output vocabulary is the lowest.

Left-to-right. Placeholders are replaced iteratively, moving from left-to-right and thus mimicking the typical writing style for English. Note that this approach still differs from the Transformer decoders because future tokens are considered via the placeholder representations.

No look ahead. To test whether future placeholders hold useful information, we consider an adversarial sequence generation strategy: Again we iteratively uncover placeholders from left-to-right, but we suppress all attention flows from future placeholders. This imitates the behaviour of

a transformer decoder but follows the idea of predicting a token on a placeholder, rather than predicting the next word as is typically done in transformer decoders. If this performs worse than left-to-right, there is indeed valuable information in future placeholder tokens.

4 Experiments

We conduct a series of experiments to explore BISON's behavior. First, we want to compare two token replacement strategies for training as well as the four generation strategies for inference. Second, we want to compare BISON to state of the art methods and investigate the impact of its ability to attend to future tokens.

4.1 Datasets

We run experiments on the two following conversational datasets.

Goal-oriented SHARC (Saeidi et al., 2018). SHARC is a dialogue, text-based question-answering dataset. Unlike many popular QA datasets, answers cannot simply be extracted from the text. Given a regulatory text, such as a text from the UK government's website, and a user scenario with corresponding question, it is necessary to interpret the text in the context of the specific user's needs. Before generating its final answer, a system may generate clarification questions. Finally, the system decides if the answer to the user's original question is "*Yes*", "*No*" or "*Irrelevant*" where the latter means the question cannot be answered with the given text.

We perform the evaluation with the official SHARC script. For a set of generated clarification questions, it computes BLEU n-gram scores for $n = 1, 2, 3, 4$ using a set of clarification question in the set of gold responses. In each step of the conversation, the model under evaluation generates an output token sequence. This output is automatically assigned to the category "*More*" if it is a clarification question, and to "*Yes*", "*No*", and "*Irrelevant*" otherwise. Since this is a classification task we can compute micro and macro accuracy for it. The final model is chosen using the highest BLEU-4 score on the development set.

The SHARC dataset has a hidden test set and, therefore, it is not feasible to evaluate our various model variants. Hence, we take 30 unique rule texts and their corresponding training examples from the training set. This leads to a new development set of 2,465 instances and leaves the official development set to be used as a test set here. Finally we submitted our best model to be evaluated on the hidden test set.

Free-form DAILY DIALOG (Li et al., 2017). DAILY DIALOG is a dataset of written conversations occurring in daily life. Following the authors of the corpus, we report BLEU n-gram scores for $n = 1, 2, 3, 4$ for the generated output sequences with respect to the given gold responses. We tokenize these responses equally to ensure a fair comparison.

4.2 BISON Settings

We implement BISON based on the BERT Pytorch code[1] and initialize with the pre-trained BERT model BERT-BASE-UNCASED (Devlin et al., 2018). Consequently we employ the same model architecture and tokenisation as (Devlin et al., 2018) resulting in a model with about 110M parameters. To remain compatible with the BERT model, we prepend each sequence with a [CLS] token and place a [SEP] token after the input context. Similarly, producing a second [SEP] token indicates the end of sequence generation. For input context of SHARC, we follow Saeidi et al. (2018) and use the concatenation of question, rule text, scenario and history. The input context for DAILY DIALOG is the concatenation of all previous utterances.

On the SHARC and DAILY DIALOG training sets we train for 20 and 40 epochs, respectively, which equates in each case to about $200k$ seen examples. As optimizer we used ADAM (Kingma and Ba, 2015) with $\beta_1 = 0.9$, $\beta_2 = 0.999$, a L2 weight decay of 0.01 and a learning rate warm-up over the first 10% of training steps. As learning rates we consider both the pre-training learning rate of BERT $1e$-4 and the fine-tuning learning rate $3e$-5. On preliminary experiments $3e$-5 proved to be best for SHARC, whereas it is $1e$-4 for DAILY DIALOG. We set the batch size to 15. Finally, the maximum sequence generation length, is set to 50 for SHARC and to 100 for DAILY DIALOG, which was chosen based on values observed in the training data. As the maximum sequence length of the BERT model is 512, longer input sequences are truncated accordingly. For the main results, we employ the sequence generation strategy left-

[1] https://github.com/huggingface/pytorch-pretrained-BERT

to-right, which we found to work best. Later on we also report results for the other strategies.

For the Bernoulli RV approach, we test $\mu \in [0.2, 0.8]$ with increments of 0.1. For the Gaussian RV approach, we test all possible combinations for the following hyperparmeters $\mu = \{0.4, 0.5, 0.6\}$ and $\sigma = \{0.3, 0.6, 0.9\}$. The best combination on the SHARC dev set is $\mu = 0.5, \sigma = 0.6$. It outperforms the best Bernoulli approach ($\mu = 0.7$) by 3.4 point in BLEU-4 score. Some Bernoulli experiments in fact only produced a very small number of clarification question, e.g. $\mu = 0.5$ only generated 9 clarification questions on the development set, whereas in the ground truth responses 846 clarification questions occur. This suggests that a high variance is important, as the Bernoulli setups all have a variance of 0.25 or lower and our best Gaussian approach has a variance of 0.6. We directly employ the Gaussian distribution with $\mu = 0.5, \sigma = 0.6$ on the DAILY DIALOG task.

4.3 Baselines

To measure the success of our proposed approach, we consider the following three baselines.

Encoder-Decoder Transformer (E&D). First, we compare our bidirectional encoder to a standard encoder-decoder Transformer where the decoder only has access to tokens produced so far to compute its self-attention. We use the implementation of OpenNMT (Klein et al., 2017) and employ the parameters suggested by them, but adjust the learning rate to 0.1, which we found to work better for both datasets. Additionally, we increased the word and hidden dimension size to 768 and the number of attention heads to 12 to match the capacity of our model. Training ran for 50 epochs. Needing both an encoder and a decoder, this leads to a total of about 270M parameters.

Encoder-Decoder Transformer with BERT (E&D+B). The power of our bidirectional decoder stems from two advantages. First, we can initialize our model with the pre-trained BERT-BASE-UNCASED model. Second, the decoding process is bidirectional. It would be possible to transfer the first advantage to an encoder-decoder framework by using BERT embeddings. This is however only possible for the input sequence, because the bidirectionality of BERT requires the entire sequence to be available beforehand. Thus, we modify implementation of OpenNMT to use the BERT model as the encoder. The weights are frozen when training the decoder, which produced better results than allowing the gradients to also flow through the BERT model. Again, with both an encoder and decoder, this leads to a total of about 270M parameters.

	Model	Micro Acc.	Macro Acc.	B-1	B-4
SHARC	E&D	31.9	38.9	17.1	1.9
	E&D+B	54.7	60.4	24.3	4.3
	GPT2	60.4	65.1	53.7	33.9
	BISON	**64.9**	**68.8**	**61.8**	**46.2**

Table 1: Results on the SHARC test set, averaged over 3 independent runs for GPT2 and BISON, reporting micro accuracy and macro accuracy in terms of the classification task and BLEU-1 and BLEU-4 on instances for which a clarification question was generated. E&D uses no language model pre-training.

	Model	Micro Acc.	Macro Acc.	B-1	B-4
SHARC	E3	**67.6**	**73.3**	54.1	38.7
	BISON	66.9	71.6	**58.8**	**44.3**

Table 2: Results on the official hidden SHARC test set of our model compared to the best model on the leaderboard, E3 (Zhong and Zettlemoyer, 2019).

GPT2. Radford et al. (2019) present a transformer decoder, GPT2, trained as a language model on large amounts of monolingual text. Radford et al. (2019) showed that it is possible to perform various tasks in a zero-shot setting by priming the language model with an input and letting it generate further words greedily. This setup can be transferred to a supervised setting, where the model is fine-tuned to a dataset by using maximum likelihood estimation to increase the probability of the gold output sequence (Wolf et al., 2019). As the starting point for the supervised learning, we initialize the model with the pre-trained model GPT-2-117M released by Radford et al. (2019)[2] and then fine-tune. With 117M parameters, this model is comparable to our model. Unlike baseline 2, this setup can directly employ a pre-trained model as our approach can, but it is not bidirectional.

4.4 Results

We report the results of our approach, the various baselines, as well as the previous state-of-the-art (SOTA) scores where applicable in Table 1 and 2 for SHARC and in Table 3 for DAILY DIALOG.

On the SHARC dataset, we observe very poor BLEU-4 performance for the encoder-decoder Transformer (E&D), which is consistent with results from Saeidi et al. (2018), who could not get a LSTM-based network to work without an additional classification head. Adding BERT (E&D+B) slightly improves performance. By directly leveraging a pre-trained model, GPT2 outperforms the previous models by a large margin, reaching 33.9% on BLEU-4 and a micro accuracy of 60.4%. BISON is able to take future tokens into consideration and outperforms GPT2 by 12.3 percentage points in BLEU-4 and by 4.5 points in micro accuracy.

We submitted the best BISON model out of the random three of Table 1 to be evaluated on the hidden test set and report results in comparison to the best model on the leaderboard,[3] E3 (Zhong and Zettlemoyer, 2019) in Table 2. BISON outperforms E3 by 5.6 BLEU-4 points, while it is only slightly worse than E3 in terms of accuracy.

On the DAILY DIALOG dataset the information retrieval-based method (IR in Table 3) introduced by Li et al. (2017) is very strong and outperforms the best end-to-end model (E2E) (Luo et al., 2018) by over 16 percentage points in BLEU-4. The best end-to-end model is based on LSTMs and Luo et al. (2018) report performance increases when adding an attention module to their setup. The encoder-decoder transformer (E&D) outperforms this setup by over 2 percentage points in BLEU-4 and we conjecture that this is due to the transformer making more effective use of the attention principle. Adding BERT (E&D+B) does not help much for this dataset. But again we observe a large increase of performance when directly employing pre-trained models. GPT2 performs on par with the IR SOTA, achieving a BLEU-4 score of 19.4%. Again, BISON can outperform GPT2, here with a difference of 6.2 points in BLEU-4 and even larger increases in the other scores.

Effect of bidirectionality. To investigate that our model benefits from bidirectionality, we consider a setup where BISON isn't allowed to attend to future tokens during prediction (see Table 4). It causes a drop in BLEU-4 performance of about 25 points on the SHARC dataset and a drop of 10 points on the DAILY DIALOG dataset. This showcases that BISON during training has learnt to rely on the ability to attend to future tokens.

	past only	48.0	24.6	18.5	14.8

Table 4: Comparison of BISON to a setup where BISON isn't allowed to attend to future tokens, i.e. past only, for SHARC and DAILY DIALOG (DD).

Effect of pre-trained model. We are curious how big the effect of the pre-trained model is. Thus, instead of starting with the BERT-BASE-UNCASED weights, we initialize BISON with random weights drawn from a normal distribution with mean 0.0 and standard deviation of 0.02. Results are presented in Table 5 for SHARC and DAILY DIALOG. Even without a pre-trained language model, our approach can outperform the standard encoder-decoder transformer framework (E&D) on both datasets, although we had to increase the number of epochs for the SHARC dataset to 40. On the DAILY DIALOG task, we are even able to outperform GPT2. This demonstrates

	Model	Micro Acc.	Macro Acc.	B-1	B-4
SHARC	E&D	31.9	38.9	17.1	1.9
	BISON	**52.9**	**57.4**	**21.9**	**2.3**

	BISON	**46.3**	**27.0**	**23.6**	**22.4**

Table 5: Best end-to-end models that do not use a pre-trained language model in comparison with BISON that uses randomly initialized weights for SHARC and DAILY DIALOG (DD), averaged over 3 runs.

Strategy	SHARC	DAILY DIALOG
one step greedy	22.9	9.3
lowest entropy	40.3	16.8
highest probability	**50.9**	16.4
left-to-right	46.2	**23.8**

Table 6: BLEU-4 using various sequence generation strategies for BISON on SHARC and DAILY DIALOG.

Dataset	α^1	α^2	α^3
SHARC	92.6±3.1	5.2±2.4	2.2±1.8
DD	97.0±2.5	2.3±2.3	0.7±0.4
		$\bar{\alpha}^2$	$\bar{\alpha}^3$
SHARC	-	71.7±13.7	28.3±13.7
DD	-	70.2±14.5	29.8±14.5

Table 7: Average attention weights and standard deviation when predicting from left-to-right on both SHARC and DAILY DIALOG (DD) for different parts of the sequence, where α^1 is for the input sequence x, $\alpha^2/\bar{\alpha}^2$ is for the already produced sequence y and $\alpha^3/\bar{\alpha}^3$ is for the sequence of remaining placeholder tokens p. α^k are the normalized attention weights across all three parts, whereas $\bar{\alpha}^k$ normalizes over the second and third part.

the effectiveness of our approach in itself, free of any pre-trained language model.

Effect of sequence generation strategies. We present the different sequence generation strategies in Table 6. The best overall sequence generation strategy is to predict from left to right which achieves good results on both datasets. On the SHARC dataset the highest probability approach performs better than left-to-right. However, on DAILY DIALOG this approach is not as successful. This suggests that it might be worth selecting the best sequence generation strategy for each dataset individually. However, we hypothesize that left-to-right works consistently well due to the left-to-right nature of the English language. A brief experiment with a right-to-left strategy gave poor results.

5 Analysis

We believe that the placeholders capture sequential information present in the language model learned during pre-training. After running a transformer encoder where each position can attend to every other position, a placeholder token will have a probability distribution over the output vocabulary and this distribution is informed by all other tokens in input and output. Thus, a placeholder could be seen as a mixture of tokens with varying probabilities. As placeholders are subsequently uncovered, the other placeholders can update their distribution by taking the newly revealed token into consideration.

For example, in Figure 2, for the sentence"is the animal an endangered animal ?", while generating "endangered", the self-attention head pays attention to the next placeholder token, which in the next step is revealed to be "animal". While producing "endangered", the distribution for the next position already placed a high probability on "animal", thus the current token can take this into consideration and produces "endangered". Further heat maps demonstrating this can be found in the appendix.

The quantify this intuition, we measure the average attention score on various parts of the sequence. For this, we use the left-to-right prediction strategy. Thus, at time t, we can decompose our sequence into three parts: $s = x \oplus y \oplus p$, where x is the input, y the already produced sequence and p the remaining sequence of placeholder tokens. For each attention head, we can decompose the attention probabilities into the three parts,

1. attention on the input text,
2. attention on the current word and already generated words (left of the current word),
3. attention on words that are yet to be generated (right of the current word).

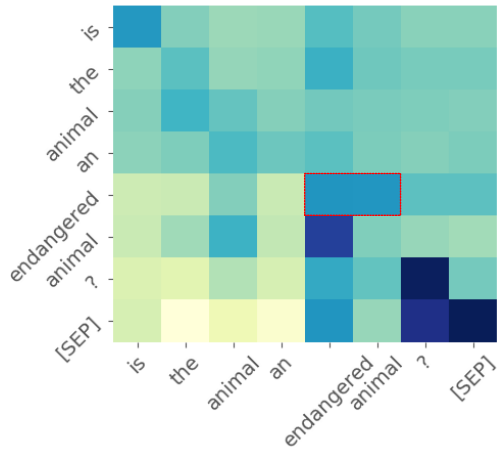

Figure 2: Heat map (darker hues indicate higher attention) that shows an example of where an attention head looks into the future while generating from left to right. Each row shows the attention over the output sequence for this row's placeholder token at that point in time. Word in previous rows have been produced already, whereas words of later rows still hold placeholder tokens. Thus the upper triangle of the matrix shows the attention that is paid to future tokens. The red square shows that while generating the token "endangered", the attention head already takes the next placeholder into account, which is revealed to be "animal" in the next step. Best viewed in color.

This is mathematically expressed as

$$a_t = a_{0:|x|} \oplus a_{|x|+1:|x|+t} \oplus a_{|x|+t+1,|s|},$$

where $|s|$ is the maximum possible sequence length. For each part we can calculate an average leading to three values, a_t^1, a_t^2 and a_t^3.

Averaged over all T generation time steps and all D data points, we can derive a score for each part k, $k = 1, 2, 3$ and each attention head h:

$$\alpha_h^k = \frac{1}{D}\frac{1}{T}\sum_{d=1}^{D}\sum_{t=1}^{T} a_{d,t}^k$$

Note that we use the attention heads in the final BERT self-attention layer. Averaging over all H attention heads, $\alpha^k = \frac{1}{H}\sum_{h=1}^{H}\alpha_h^k$, leads to the results reported in Table 7 for both datasets. Unsurprisingly, we find that with scores of over 90% for both datasets the majority of the attention is focused on the first part, i.e. the conditioning input x (see α^1 in Table 7). The remaining attention is split between the already produced sequence (α^2) and the future tokens (α^3).

To directly compare the relationship within the sequence generation, we re-normalize over α^2 and α^3, leading to new values $\bar{\alpha}^2$ and $\bar{\alpha}^3$ (see Table 7). Here we can see that the past, already produced tokens are about twice as important as the future, not-yet-produced tokens. But with scores of just under 30% on both datasets, we see that a substantial amount of attention is also focused on the future, not-yet-produced tokens.

Interestingly, with a standard deviation of about 14%, the values of $\bar{\alpha}^2$ and $\bar{\alpha}^3$ vary strongly across the different attention heads. For example on the SHARC dataset, we find one attention head where only about 9% is focused on the future and another where it is about 64% and thus this attention head pays more attention to the future than the past. A graphical overview can be found in the appendix for both datasets.

6 Related Work

Transformers (Vaswani et al., 2017) model sequences as fully connected graphs and apply a bidirectional self-attention module where every token can attend to every other token. Because of this a Transformer is not restricted to sequential orderings. However, Vaswani et al. (2017); *inter alia* still restrict themselves to producing tokens from left-to-right and only allow a Transformer decoder to attend to previously produced tokens. Recently, several attempts have been made to lift the left-to-right restriction in Transformer or LSTM-based models (Gu et al., 2019; Stern et al., 2019; Welleck et al., 2019; Zhou et al., 2019), but in those approaches it is not possible to attend to future, not-yet-produced tokens.

Concurrently to our work, (Ghazvininejad et al., 2019) proposed a similar placeholder strategy approach for generating in the context of machine translation. However, they employ an encoder-decoder framework, whereas we only require an encoder, which more closely links input and output via a single shared attention module. Furthermore, they only consider uniform sampling of placeholders whereas we found that the higher variance, which we can control with the Gaussian random variable approach, leads to better results.

Bidirectionality is one of the crucial ingredients in the success of the recently proposed unsupervised language model BERT (Devlin et al., 2018). For this, Devlin et al. (2018) propose a Transformer *encoder* to take full advantage of the bidi-

rectional nature of the Transformer. Their resulting model, BERT, can directly be applied to various classification tasks but not to sequence generation tasks. Our approach shows how a Transformer encoder can be used for sequence generation and this allows us to directly incorporate BERT into our experiments.

GPT (Radford et al., 2018) and GPT2 (Radford et al., 2019) are both pre-trained language models that use a Transformer *decoder* instead, which can only attend to already produced tokens. For dialogue, the GPT model has been fine-tuned for the chit-chat dataset PersonaChat (Zhang et al., 2018) by Wolf et al. (2019). While GPT and GPT2 can immediately be used as a sequence generators, these models do not offer bidirectionality and they cannot attend to not-yet-produced tokens. Our bidirectional encoder for sequence generation can combine the best of both worlds.

7 Conclusion

We introduced bidirectional sequence generation by employing placeholders in the output sequence. These placeholder tokens are subsequently replaced by tokens of the output vocabulary. Crucially, this allows a transformer encoder to attend to both past and future, not-yet-produced token. Simply masking all placeholder tokens is not feasible. Instead we investigated two placeholder strategies, based on Bernoulli and Gaussian random variables. At prediction time, our approach is not restricted to produce the output sequence from left to right. However, this strategy proved to produce most consistent results in our experiments.

Our approach outperforms previous end-to-end approaches that do not make use of any pre-trained language models. In conjunction with the pre-trained language model BERT, our bidirectional sequence generation approach allows us to achieve new state-of-art results on both conversational tasks. In the future, we would like to apply our approach to other sequence generation tasks. Additionally, we wonder if a further performance increase could be achieved if the pre-training of BERT would employ our placeholder strategy.

Abstract

Attention mechanisms play a central role in NLP systems, especially within recurrent neural network (RNN) models. Recently, there has been increasing interest in whether or not the intermediate representations offered by these modules may be used to explain the reasoning for a model's prediction, and consequently reach insights regarding the model's decision-making process. A recent paper claims that 'Attention is not Explanation' (Jain and Wallace, 2019). We challenge many of the assumptions underlying this work, arguing that such a claim depends on one's definition of explanation, and that testing it needs to take into account all elements of the model. We propose four alternative tests to determine when/whether attention can be used as explanation: a simple uniform-weights baseline; a variance calibration based on multiple random seed runs; a diagnostic framework using frozen weights from pretrained models; and an end-to-end adversarial attention training protocol. Each allows for meaningful interpretation of attention mechanisms in RNN models. We show that even when reliable adversarial distributions can be found, they don't perform well on the simple diagnostic, indicating that prior work does not disprove the usefulness of attention mechanisms for explainability.

1 Introduction

Attention mechanisms (Bahdanau et al., 2014) are nowadays ubiquitous in NLP, and their suitability for providing explanations for model predictions is a topic of high interest (Xu et al., 2015; Rocktäschel et al., 2015; Mullenbach et al., 2018; Thorne et al., 2019; Serrano and Smith, 2019). If they indeed offer such insights, many application areas would benefit by better understanding the internals of neural models that use attention as a means for, e.g., model debugging or architecture selection. A recent paper (Jain and Wallace, 2019) points to possible pitfalls that may cause researchers to misapply attention scores as explanations of model behavior, based on a premise that explainable attention distributions should be *consistent* with other feature-importance measures as well as *exclusive* given a prediction.[1] Its core argument, which we elaborate in §2, is that if alternative attention distributions exist that produce similar results to those obtained by the original model, then the original model's attention scores cannot be reliably used to "faithfully" explain the model's prediction. Empirically, the authors show that achieving such alternative distributions is easy for a large sample of English-language datasets.

We contend (§2.1) that while Jain and Wallace ask an important question, and raise a genuine concern regarding potential misuse of attention weights in explaining model decisions on English-language datasets, some key assumptions used in their experimental design leave an implausibly large amount of freedom in the setup, ultimately leaving practitioners without an applicable way for measuring the utility of attention distributions in specific settings.

We apply a more model-driven approach to this question, beginning (§3.2) with testing attention modules' **contribution** to a model by applying a simple baseline where attention weights are frozen to a uniform distribution. We demonstrate that for some datasets, a frozen attention distribution performs just as well as learned attention weights, concluding that randomly- or adversarially-perturbed distributions are not ev-

*Equal contributions.

[1] A preliminary version of our theoretical argumentation was published as a blog post on Medium at http://bit.ly/2OTzU4r. Following the ensuing online discussion, the authors uploaded a post-conference version of the paper to arXiv (v3) which addresses some of the issues in the post. We henceforth refer to this later version.

idence against attention as explanation in these cases. We next (§3.3) examine the **expected variance** in attention-produced weights by initializing multiple training sequences with different random seeds, allowing a better quantification of how much variance can be expected in trained models. We show that considering this background stochastic variation when comparing adversarial results with a traditional model allows us to better interpret adversarial results. In §3.4, we present a simple yet effective **diagnostic tool** which tests attention distributions for their usefulness by using them as frozen weights in a non-contextual multi-layered perceptron (MLP) architecture. The favorable performance of LSTM-trained weights provides additional support for the coherence of trained attention scores. This demonstrates a sense in which attention components indeed provide a meaningful model-agnostic interpretation of tokens in an instance.

In §4, we introduce a **model-consistent** training protocol for finding adversarial attention weights, correcting some flaws we found in the previous approach. We train a model using a modified loss function which takes into account the distance from an ordinarily-trained base model's attention scores in order to learn parameters for adversarial attention distributions. We believe these experiments are now able to support or refute a claim of faithful explainability, by providing a way for convincingly saying by construction that a plausible alternative 'explanation' can (or cannot) be constructed for a given dataset and model architecture. We find that while plausibly adversarial distributions of the consistent kind can indeed be found for the binary classification datasets in question, they are not as extreme as those found in the inconsistent manner, as illustrated by an example from the IMDB task in Figure 2. Furthermore, these outputs do not fare well in the diagnostic MLP, calling into question the extent to which we can treat them as equally powerful for explainability.

Finally, we provide a theoretical discussion (§5) on the definitions of interpretability and explainability, grounding our findings within the accepted definitions of these concepts.

Our four quantitative experiments are illustrated in Figure 1, where each bracket on the left covers the components in a standard RNN-with-attention architecture which we manipulate in each experiment. We urge NLP researchers to consider applying the techniques presented here on their models containing attention in order to evaluate its effectiveness at providing explanation. We offer our code for this purpose at `https://github.com/sarahwie/attention`.

2 Attention Might be Explanation

In this section, we briefly describe the experimental design of Jain and Wallace (2019) and look at the results they provide to support their claim that 'Attention is not explanation'. The authors select eight classification datasets, mostly binary, and two question answering tasks for their experiments (detailed in §3.1).

They first present a correlation analysis of attention scores and other interpretability measures.

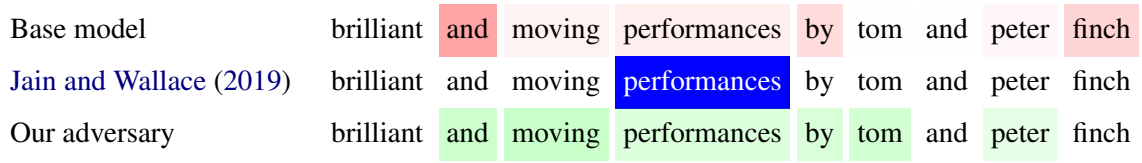

Figure 2: Attention maps for an IMDb instance (all predicted as positive with score > 0.998), showing that in practice it is difficult to learn a distant adversary which is consistent on all instances in the training set.

They find that attention is not strongly correlated with other, well-grounded feature importance metrics, specifically gradient-based and leave-one-out methods (which in turn correlate well with each other). This experiment evaluates the authors' claim of *consistency* – that attention-based methods of explainability cannot be valid if they do not correlate well with other metrics. We find the experiments in this part of the paper convincing and do not focus our analysis here. We offer our simple MLP diagnostic network (§3.4) as an additional way for determining validity of attention distributions, in a more *in vivo* setting.

Next, the authors present an adversarial search for alternative attention distributions which minimally change model predictions. To this end, they manipulate the attention distributions of trained models (which we will call **base** from now on) to discern whether alternative distributions exist for which the model outputs near-identical prediction scores. They are able to find such distributions, first by randomly permuting the base attention distributions on the test data during model inference, and later by adversarially searching for maximally different distributions that still produce a prediction score within ϵ of the base distribution. They use these experimental results as supporting evidence for the claim that attention distributions cannot be explainable because they are not *exclusive*. As stated, the lack of comparable change in prediction with a change in attention scores is taken as evidence for a lack of "faithful" explainability of the attention mechanism from inputs to output.

Notably, Jain and Wallace detach the attention distribution and output layer of their pretrained network from the parameters that compute them (see Figure 1), treating each attention score as a standalone unit independent of the model. In addition, they compute an independent adversarial distribution for each instance.

2.1 Main Claim

We argue that Jain and Wallace's counterfactual attention weight experiments do not advance their thesis, for the following reasons:

Attention Distribution is not a Primitive. From a modeling perspective, detaching the attention scores obtained by parts of the model (i.e. the attention mechanism) degrades the model itself. The base attention weights are not assigned arbitrarily by the model, but rather computed by an integral component whose parameters were trained alongside the rest of the layers; the way they work depends on each other. Jain and Wallace provide alternative distributions which may result in similar predictions, but in the process they remove the very linkage which motivates the original claim of attention distribution explainability, namely the fact that the model was *trained* to attend to the tokens it chose. A reliable adversary must take this consideration into account, as our setup in §4 does.

Existence does not Entail Exclusivity. On a more theoretical level, we hold that attention scores are used as providing *an* explanation; not *the* explanation. The final layer of an LSTM model may easily produce outputs capable of being aggregated into the same prediction in various ways, however the model still makes the choice of a specific weighting distribution using its trained attention component. This mathematically flexible production capacity is particularly evident in binary classifiers, where prediction is reduced to a single scalar, and an average instance (of e.g. the IMDB dataset) might contain 179 tokens, i.e. 179 scalars to be aggregated. This effect is greatly exacerbated when performed independently on each instance.[2] Thus, it is no surprise that Jain and Wal-

[2]Indeed, the most open-ended task, question answering over CNN data, produces considerable difficulty to manipulate its scores by random permutation (Figure 6e in Jain and Wallace (2019)). Similarly, the adversarial examples presented in Appendix C of the paper for the QA datasets select a different token of the correct word's type, which should not surprise us even under an LSTM assumption (encoder hidden

lace find what they are looking for given this degree of freedom.

In summary, due to the per-instance nature of the demonstration and the fact that model parameters have not been learned or manipulated directly, Jain and Wallace have **not shown the existence of an adversarial model** that produces the claimed adversarial distributions. Thus, we cannot treat these adversarial attentions as equally plausible or faithful explanations for model prediction. Additionally, they haven't provided a baseline of how much variation is to be expected in learned attention distributions, leaving the reader to question just how adversarial the found adversarial distributions are.

3 Examining Attention Distributions

In this section, we apply a careful methodological approach for examining the properties of attention distributions and propose alternatives. We begin by identifying the appropriate scope of the models' performance and variance, followed by implementing an empirical diagnostic technique which measures the model-agnostic usefulness of attention weights in capturing the relationship between inputs and output.

3.1 Experimental Setup

In order to make our many points in a succinct fashion as well as follow the conclusions drawn by Jain and Wallace, we focus on experimenting with the binary classification subset of their tasks, and on models with an LSTM architecture (Hochreiter and Schmidhuber, 1997), the only one the authors make firm conclusions on. Future work may extend our experiments to extractive tasks like question answering, as well as other attention-prone tasks, like seq2seq models.

We experiment on the following datasets: Stanford Sentiment Treebank (SST) (Socher et al., 2013), IMDB Large Movie Reviews Corpus (Maas et al., 2011), 20 NEWSGROUPS (hockey vs. baseball),[3] the AG NEWS Corpus,[4] and two prediction tasks from MIMIC-III ICD9 (Johnson et al., 2016): DIABETES and ANEMIA. The tasks are as follows: to predict positive or negative sentiment from sentences (SST) and movie reviews (IMDB), to predict the topic of news articles as either baseball (neg.) or hockey (pos.) in 20 NEWSGROUPS and either world (neg.) or business (pos.) in AG NEWS, to predict whether a patient is diagnosed with diabetes from their ICU discharge summary, and to predict whether the patient is diagnosed with acute (neg.) or chronic (pos.) anemia (both MIMIC-III ICD9). We use the dataset versions, including train-test split, provided by Jain and Wallace.[5] All datasets are in English.[6] Data statistics are provided in Table 1.

We use a single-layer bidirectional LSTM with $\tanh$ activation, followed by an additive attention layer (Bahdanau et al., 2014) and softmax prediction, which is equivalent to the LSTM setup of Jain and Wallace. We use the same hyperparameters found in that work to be effective in training, which we corroborated by reproducing its results to a satisfactory degree (see middle columns of Table 2). We refer to this architecture as the **main setup**, where training results in a **base model**.

Following Jain and Wallace, all analysis is performed on the test set. We report F1 scores on the positive class, and apply the same metrics they use for model comparison, namely Total Variation

states are typically affected by the input word to a noticeable degree).

Distance (TVD) for comparing prediction scores $\hat{y}$ and Jensen-Shannon Divergence (JSD) for comparing weighting distributions α:

$$\text{TVD}(\hat{y}_1, \hat{y}_2) = \frac{1}{2} \sum_{i=1}^{|\mathcal{Y}|} |\hat{y}_{1i} - \hat{y}_{2i}| \,;$$

$$\text{JSD}(\alpha_1, \alpha_2) = \frac{1}{2} \text{KL}[\alpha_1 \parallel \bar{\alpha}] + \frac{1}{2} \text{KL}[\alpha_2 \parallel \bar{\alpha}],$$

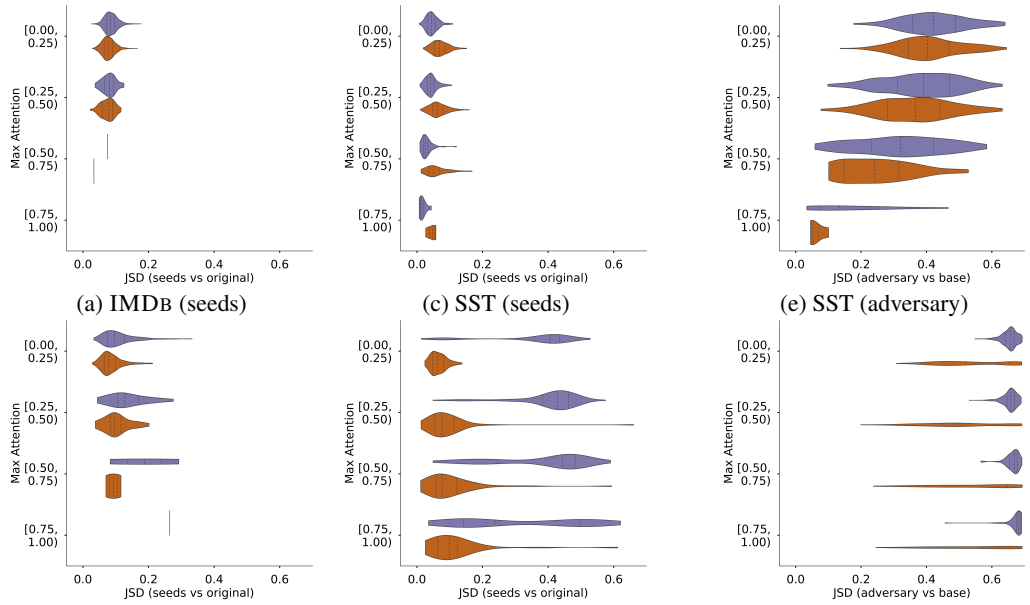
where $\bar{\alpha} = \frac{\alpha_1 + \alpha_2}{2}$.

3.2 Uniform as the Adversary

First, we test the validity of the classification tasks and datasets by examining whether attention is necessary in the first place. We argue that if attention models are not useful compared to very simple baselines, i.e. their parameter capacity is not being used, there is no point in using their outcomes for any type of explanation to begin with. We thus introduce a **uniform** model variant, identical to the main setup except that the attention distribution is frozen to uniform weights over the hidden states.

The results comparing this baseline with the base model are presented in Table 2. If attention was a necessary component for good performance, we would expect a large drop between the two rightmost columns. Somewhat surprisingly, for three of the classification tasks the attention layer appears to offer little to no improvement whatsoever. We conclude that these datasets, notably AG NEWS and 20 NEWSGROUPS, are not useful test cases for the debated question: attention is not explanation if you don't need it. We subsequently ignore the two News datasets, but keep SST, which we deem borderline.

3.3 Variance within a Model



We now test whether the variances observed by Jain and Wallace between trained attention scores and adversarially-obtained ones are unusual. We do this by repeating their analysis on eight models trained from the main setup using different initialization random seeds. The variance introduced in the attention distributions represents a baseline amount of variance that would be considered normal.

The results are plotted in Figure 3 using the same plane as Jain and Wallace's Figure 8 (with two of these reproduced as (e-f)). Left-heavy violins are interpreted as data classes for which the compared model produces attention distributions similar to the base model, and so having an adversary that manages to 'pull right' supports the argument that distributions are easy to manipulate. We see that SST distributions (c, e) are surprisingly robust to random seed change, validating our choice to continue examining this dataset despite its borderline F1 score. On the Diabetes dataset, the negative class is already subject to relatively arbitrary distributions from the different random seed settings (d), making the highly divergent results from the overly-flexible adversarial setup (f) seem less impressive. Our consistently-adversarial setup in §4 will further explore the difficulty of surpassing seed-induced variance between attention distributions.

3.4 Diagnosing Attention Distributions by Guiding Simpler Models

As a more direct examination of models, and as a complementary approach to Jain and Wallace (2019)'s measurement of backward-pass gradient flows through the model for gauging token importance, we introduce a post-hoc training protocol of a non-contextual model **guided** by pre-set weight distributions. The idea is to examine the prediction power of attention distributions in a 'clean' setting, where the trained parts of the model have no access to neighboring tokens of the instance. If pre-trained scores from an attention model perform well, we take this to mean they are helpful and consistent, fulfilling a certain sense of explainability. In addition, this setup serves as an effective diagnostic tool for assessing the utility of adversarial attention distributions: if such distributions are truly alternative, they should be equally useful as guides as their base equivalent, and thus perform comparably.

Our diagnostic model is created by replacing the main setup's LSTM and attention parameters with a token-level affine hidden layer with $\tanh$ activation (forming an MLP), and forcing its output scores to be weighted by a pre-set, per-instance distribution, during both training and testing. This setup is illustrated in Figure 4. The guide weights we impose are the following: **Uniform**, where we force the MLP outputs to be considered equally across each instance, effectively forming an unweighted baseline; **Trained MLP**, where we do not freeze the weights layer, instead allowing the

Guide weights	Diab.	Anemia	SST	IMDb
UNIFORM	0.404	0.873	0.812	0.863
TRAINED MLP	0.699	0.920	0.817	0.888
BASE LSTM	**0.753**	0.931	**0.824**	**0.905**
ADVERSARY (4)	0.503	**0.932**	0.592	0.700

Table 3: F1 scores on the positive class for an MLP model trained on various weighting guides. For ADVERSARY, we set $\lambda \leftarrow 0.001$.

MLP to learn its own attention parameters;[7] **Base LSTM**, where we take the weights learned by the base LSTM model's attention layer; and **Adversary**, based on distributions found adversarially using the consistent training algorithm from §4 below (where their results will be discussed).

The results are presented in Table 3. The first important result, consistent across datasets, is that using pre-trained LSTM attention weights is better than letting the MLP learn them on its own, which is in turn better than the unweighted baseline. Comparing with results from §3.2, we see that this setup also outperforms the LSTM trained with uniform attention weights, suggesting that the attention module is more important than the word-level architecture for these datasets. These findings strengthen the case counter to the claim that attention weights are arbitrary: independent token-level models that have no access to contextual information find them useful, indicating that they encode some measure of token importance which is not model-dependent.

4 Training an Adversary

Having demonstrated three methods which test the meaningfulness of attention distributions as instruments of explainability with adequate control, we now propose a model-consistent training protocol for finding adversarial attention distributions through a coherent parameterization, which holds across all training instances. We believe this setup is able to advance the search for faithful explainability (see §5). Indeed, our results

[7] This is the same as Jain and Wallace's *average* setup.

will demonstrate that the extent to which a model-consistent adversary can be found varies across datasets, and that the dramatic reduction in degree of freedom compared to previous work allows for better-informed analysis.

Model. Given the base model $\mathcal{M}_\text{b}$, we train a model $\mathcal{M}_\text{a}$ whose explicit goal is to provide similar prediction scores for each instance, while distancing its attention distributions from those of $\mathcal{M}_\text{b}$. Formally, we train the adversarial model using stochastic gradient updates based on the following loss formula (summed over instances in the minibatch):

$$\mathcal{L}(\mathcal{M}_a, \mathcal{M}_b)^{(i)} = \text{TVD}(\hat{y}_a^{(i)}, \hat{y}_b^{(i)}) - \lambda \ \text{KL}(\boldsymbol{\alpha}_a^{(i)} \parallel \boldsymbol{\alpha}_b^{(i)}),$$

where $\hat{y}^{(i)}$ and $\boldsymbol{\alpha}^{(i)}$ denote predictions and attention distributions for an instance i, respectively.

λ is a hyperparameter which we use to control the tradeoff between relaxing the prediction distance requirement (low TVD) in favor of more divergent attention distributions (high JSD), and vice versa. When this interaction is plotted on a two-dimensional axis, the shape of the plot can be interpreted to either support the 'attention is not explanation' hypothesis if it is convex (JSD is easily manipulable), or oppose it if it is concave (early increase in JSD comes at a high cost in prediction precision).

Prediction performance. By definition, our loss objective does not directly consider actual prediction performance. The TVD component pushes it towards the same score as the base model, but our setup does not ensure generalization from train to test. It would thus be interesting to inspect the extent of the implicit F1/TVD relationship. We report the highest F1 scores of models whose attention distributions diverge from the base, on average, by at least 0.4 in JSD, as well as their λ setting and corresponding comparison metrics, in Table 4 (full results available in Appendix B). All F1 scores are on par with the original model results reported in Table 2, indicating the effectiveness of our adversarial models at imitating base model scores on the test sets.

Adversarial weights as guides. We next apply the diagnostic setup introduced in §3.4 by training a guided MLP model on the adversarially-trained attention distributions. The results, reported in the bottom line of Table 3, show that despite their local decision-imitation abilities, they are usually completely incapable of providing a non-contextual framework with useful guides.[8] We offer these results as evidence that adversarial distributions, even those obtained consistently for a dataset, deprive the underlying model from some form of understanding it gained over the data, one that it was able to leverage by tuning the attention mechanism towards preferring 'useful' tokens.

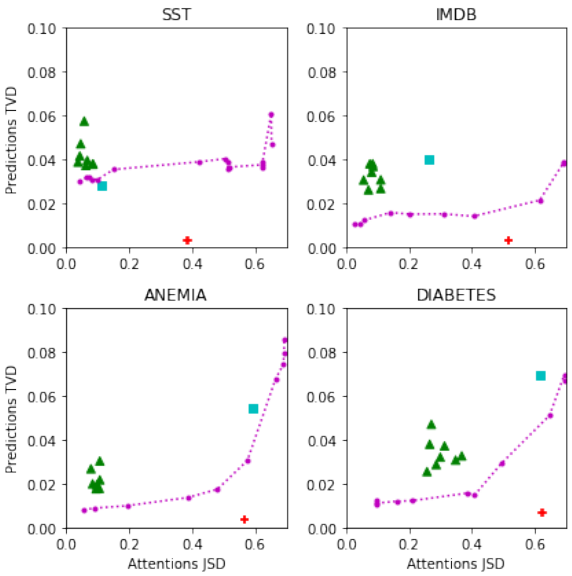

Figure 5: Averaged per-instance test set JSD and TVD from base model for each model variant. JSD is bounded at $\sim$ 0.693. ▲: random seed; ■: uniform weights; dotted line: our adversarial setup as λ is varied; +: adversarial setup from Jain and Wallace (2019).

Dataset	λ	F1 (↑)	TVD (↓)	JSD (↑)
Diabetes	2e-4	0.775	0.015	0.409
Anemia	5e-4	0.942	0.017	0.481
SST	5.25e-4	0.823	0.036	0.514
IMDb	8e-4	0.906	0.014	0.405

Table 4: Best-performing adversarial models with instance-average JSD > 0.4.

TVD/JSD tradeoff. In Figure 5 we present the levels of prediction variance (TVD) allowed

[8] We note the outlying result achieved on the Anemia dataset. This can be explained via the data distribution, which is heavily skewed towards positive examples (see Table 1 in the Appendix), together with the fact (conceded in Jain and Wallace (2019)'s section 4.2.1) that positive instances in detection datasets such as MIMIC tend to contain a handful of indicative tokens, making the particularly helpful distributions reached by a trained model hard to replace by an adversary. Together, this leads to the selected setting of $\lambda = 0.001$ producing average distributions substantially more similar to the base than in the other datasets (JSD $\sim$ 0.58 vs. $>$ 0.61) and thus more useful to the MLP setup.

by models achieving increased attention distance (JSD) on all four datasets. The convex shape of most curves does lend support to the claim that attention scores are easily manipulable; however the extent of this effect emerging from Jain and Wallace's per-instance setup is a considerable exaggeration, as seen by its position (+) well below the curve of our parameterized model set. Again, the SST dataset emerges as an outlier: not only can JSD be increased practically arbitrarily without incurring prediction variance cost, the uniform baseline (■) comes up under the curve, i.e. with a better adversarial score. We again include random seed initializations (▲) in order to quantify a baseline amount of variance.

TVD/JSD plots broken down by prediction class are available in Appendix C. In future work, we intend to inspect the potential of multiple adversarial attention models existing side-by-side, all distant enough from each other.

Concrete Example. Table 2 illustrates the difference between inconsistently-achieved adversarial heatmaps and consistently trained ones. Despite both adversaries approximating the desired prediction score to very high degree, the heatmaps show that Jain and Wallace's model has distributed all of the attention weight to an ad-hoc token, whereas our trained model could only distance itself from the base model distribution by so much, keeping multiple tokens in the > 0.1 score range.

5 Defining Explanation

The umbrella term of "Explainable AI" encompasses at least three distinct notions: *transparency*, *explainability*, and *interpretability*. Lipton (2016) categorizes transparency, or overall human understanding of a model, and post-hoc explainability as two competing notions under the umbrella of interpretability. The relevant sense of transparency, as defined by Lipton (2016) (§3.1.2), pertains to the way in which a specific portion of a model corresponds to a human-understandable construct (which Doshi-Velez and Kim (2017) refer to as a "cognitive chunk"). Under this definition, it should appear sensible of the NLP community to treat attention scores as a vehicle of (partial) transparency. Attention mechanisms do provide a look into the inner workings of a model, as they produce an easily-understandable weighting of hidden states.

Rudin (2018) defines explainability as simply a plausible (but not necessarily faithful) reconstruction of the decision-making process, and Riedl (2019) classifies explainable rationales as valuable in that they mimic what we as humans do when we rationalize past actions: we invent a story that plausibly justifies our actions, even if it is not an entirely accurate reconstruction of the neural processes that produced our behavior at the time. Distinguishing between interpretability and explainability as two separate notions, Rudin (2018) argues that interpretability is more desirable but more difficult to achieve than explainability, because it requires presenting humans with a big-picture understanding of the correlative relationship between inputs and outputs (citing the example of linear regression coefficients). Doshi-Velez and Kim (2017) break down interpretability into further subcategories, depending on the amount of human involvement and the difficulty of the task.

In prior work, Lei et al. (2016) train a model to simultaneously generate rationales and predictions from input text, using gold-label rationales to evaluate their model. Generally, many accept the notion of extractive methods such as Lei et al. (2016), in which explanations come directly from the input itself (as in attention), as plausible. Works such as Mullenbach et al. (2018) and Ehsan et al. (2019) use human evaluation to evaluate explanations; the former based on attention scores over the input, and the latter based on systems with additional rationale-generation capability. The authors show that rationales generated in a post-hoc manner increase user trust in a system.

Citing Ross et al. (2017), Jain and Wallace's requisite for attention distributions to be used as explanation is that there must only exist one or a few closely-related correct explanations for a model prediction. However, Doshi-Velez and Kim (2017) caution against applying evaluations and terminology broadly without clarifying task-specific explanation needs. If we accept the Rudin and Riedl definitions of explainability as providing a *plausible*, but not necessarily *faithful* rationale for model prediction, then the argument against attention mechanisms because they are not exclusive as claimed by Jain and Wallace is invalid, and human evaluation (which they do not consult) is necessary to evaluate the plausibility of generated rationales. Just because there exists another explanation does not mean that the one provided is false

or meaningless, and under this definition the existence of multiple different explanations is not necessarily indicative of the quality of a single one.

Jain and Wallace define attention and explanation as measuring the "responsibility" each input token has on a prediction. This aligns more closely with the more rigorous (Lipton, 2016, §3.1.1) definition of transparency, or Rudin (2018)'s definition of interpretability: human understanding of the model as a whole rather than of its respective parts. The ultimate question posed so far as 'is attention explanation?' seems to be: do high attention weights on certain elements in the input lead the model to make its prediction? This question is ultimately left largely unanswered by prior work, as we address in previous sections. However, under the given definition of transparency, the authors' exclusivity requisite is well-defined and we find value in their counterfactual framework as a concept – if a model is capable of producing multiple sets of diverse attention weights for the same prediction, then the relationship between inputs and outputs used to make predictions is not understood by attention analysis. This provides us with the motivation to implement the adversarial setup coherently and to derive and present conclusions from it. To this end, we additionally provide our §3.4 model to test the relationship between input tokens and output.

In the terminology of Doshi-Velez and Kim (2017), our proposed methods provide a *functionally-grounded* evaluation of attention as explanation, i.e. an analysis conducted on proxy tasks without human evaluation. We believe the proxies we have provided can be used to test the validity of attention as a form of explanation from the ground-up, based on the type of explanation one is looking for.

6 Attention is All you Need it to Be

Whether or not attention is explanation depends on the definition of explainability one is looking for: *plausible* or *faithful* explanations (or both). We believe that prior work focused on providing plausible rationales is not invalidated by Jain and Wallace's or our results. However, we have confirmed that adversarial distributions can be found for LSTM models in some classification tasks, as originally hypothesized by Jain and Wallace. This should provide pause to researchers who are looking to attention distributions for one true, faithful interpretation of the link their model has established between inputs and outputs. At the same time, we have provided a suite of experiments that researchers can make use of in order to make informed decisions about the quality of their models' attention mechanisms when used as explanation for model predictions.

We've shown that alternative attention distributions found via adversarial training methods perform poorly relative to traditional attention mechanisms when used in our diagnostic MLP model. These results indicate that trained attention mechanisms in RNNs on our datasets do in fact learn something meaningful about the relationship between tokens and prediction which cannot be easily 'hacked' adversarially.

We view the conditions under which adversarial distributions can actually be found in practice to be an important direction for future work. Additional future directions for this line of work include application on other tasks such as sequence modeling and multi-document analysis (NLI, QA); extension to languages other than English; and adding a human evaluation for examining the level of agreement with our measures. We also believe our work can provide value to theoretical analysis of attention models, motivating development of analytical methods to estimate the usefulness of attention as an explanation based on dataset and model properties.

Acknowledgments

We thank Yoav Goldberg for preliminary comments on the idea behind the original Medium post. We thank the online community who participated in the discussion following the post, and particularly Sarthak Jain and Byron Wallace for their active engagement, as well as for the high-quality code they released which allowed fast reproduction and modification of their experiments. Abstract

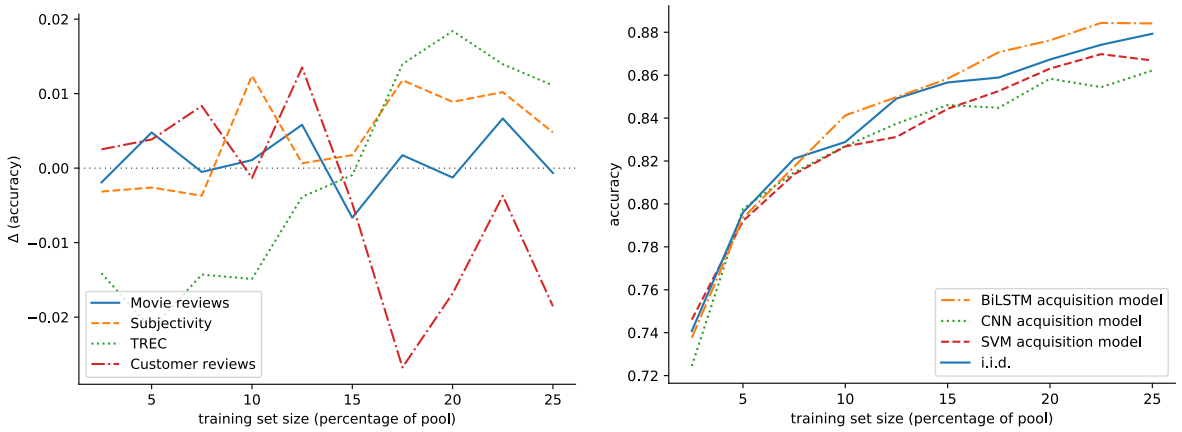
Active learning (AL) is a widely-used training strategy for maximizing predictive performance subject to a fixed annotation budget. In AL one iteratively selects training examples for annotation, often those for which the current model is most uncertain (by some measure). The hope is that active sampling leads to better performance than would be achieved under independent and identically distributed (i.i.d.) random samples. While AL has shown promise in retrospective evaluations, these studies often ignore practical obstacles to its use. In this paper we show that while AL may provide benefits when used with specific models and for particular domains, the benefits of current approaches do not generalize reliably across models and tasks. This is problematic because in practice one does not have the opportunity to explore and compare alternative AL strategies. Moreover, AL couples the training dataset with the model used to guide its acquisition. We find that subsequently training a *successor model* with an actively-acquired dataset does not consistently outperform training on i.i.d. sampled data. Our findings raise the question of whether the downsides inherent to AL are worth the modest and inconsistent performance gains it tends to afford.

1 Introduction



Although deep learning now achieves state-of-the-art results on a number of supervised learning tasks (Johnson and Zhang, 2016; Ghaddar and Langlais, 2018), realizing these gains requires large annotated datasets (Shen et al., 2018). This data dependence is problematic because labels are expensive. Several lines of research seek to reduce the amount of supervision required to achieve acceptable predictive performance, including semi-supervised (Chapelle et al., 2009), transfer (Pan and Yang, 2010), and *active learning* (AL) (Cohn et al., 1996; Settles, 2012).

In AL, rather than training on a set of labeled data sampled at i.i.d. random from some larger population, the learner engages the annotator in a cycle of learning, iteratively selecting training data for annotation and updating its model. *Pool-based* AL (the variant we consider) proceeds in rounds. In each, the learner applies a heuristic to score unlabeled instances, selecting the highest scoring instances for annotation.[1] Intuitively, by selecting training data cleverly, an active learner might achieve greater predictive performance than it would by choosing examples at random.

The more informative samples come at the cost of violating the standard i.i.d. assumption upon which supervised machine learning typically relies. In other words, the training and test data no longer reflect the same underlying data distribution. Empirically, AL has been found to work well with a variety of tasks and models (Settles, 2012; Ramirez-Loaiza et al., 2017; Gal et al., 2017a; Zhang et al., 2017; Shen et al., 2018). However, academic investigations of AL typically omit key real-world considerations that might overestimate its utility. For example, once a dataset is actively acquired with one model, it is seldom investigated whether this training sample will confer benefits if used to train a second model (vs i.i.d. data). Given that datasets often outlive learning algorithms, this is an important practical consideration.

[1] This may be done either deterministically, by selecting the top-k instances, or stochastically, selecting instances with probabilities proportional to heuristic scores.

(a) Performance of AL relative to i.i.d. across corpora.

(b) Transferring actively acquired training sets.

Figure 1: We highlight practical issues in the use of AL. (a) AL yields inconsistent gains, relative to a baseline of i.i.d. sampling, across corpora. (b) Training a BiLSTM with training sets actively acquired based on the uncertainty of other models tends to result in worse performance than training on i.i.d. samples.

In contrast to experimental (retrospective) studies, in a real-world setting, an AL practitioner is not afforded the opportunity to retrospectively analyze or alter their scoring function. One would instead need to expend significant resources to validate that a given scoring function performs as intended for a particular model and task. This would require i.i.d. sampled data to evaluate the comparative effectiveness of different AL strategies. However, collection of such additional data would defeat the purpose of AL, i.e., obviating the need for a large amount of supervision. To confidently use AL in practice, one must have a reasonable belief that a given AL scoring (or *acquisition*) function will produce the desired results *before they deploy it* (Attenberg and Provost, 2011).

Most AL research does not explicitly characterize the circumstances under which AL may be expected to perform well. Practitioners must therefore make the implicit assumption that a given active acquisition strategy is likely to perform well under *any* circumstances. Our empirical findings suggest that this assumption is not well founded and, in fact, common AL algorithms behave inconsistently across model types and datasets, often performing no better than random (i.i.d.) sampling (1a). Further, while there is typically *some* AL strategy which outperforms i.i.d. random samples for a given dataset, *which* heuristic varies.

Contributions. We highlight important but often overlooked issues in the use of AL in practice. We report an extensive set of experimental results on classification and sequence tagging tasks that suggest AL typically affords only marginal performance gains at the somewhat high cost of non-i.i.d. training samples, which do not consistently transfer well to subsequent models.

2 The (Potential) Trouble with AL

We illustrate inconsistent comparative performance using AL. Consider Figure 1a, in which we plot the relative gains (Δ) achieved by a BiLSTM model using a maximum-entropy active sampling strategy, as compared to the same model trained with randomly sampled data. Positive values on the y-axis correspond to cases in which AL achieves better performance than random sampling, 0 (dotted line) indicates no difference between the two, and negative values correspond to cases in which random sampling performs better than AL. Across the four datasets shown, results are decidedly mixed.

And yet realizing these equivocal gains using AL brings inherent drawbacks. For example, acquisition functions generally depend on the underlying model being trained (Settles, 2009, 2012), which we will refer to as the *acquisition model*. Consequently, the collected training data and the acquisition model are *coupled*. This coupling is problematic because manually labeled data tends to have a longer shelf life than models, largely because it is expensive to acquire. However, progress in machine learning is fast. Consequently, in many settings, an actively acquired dataset may remain in use (much) longer than the source model used to acquire it. In these cases, a few natural ques-

tions arise: How does a *successor* model S fare, when trained on data collected via an acquisition model A? How does this compare to training S on natively acquired data? How does it compare to training S on i.i.d. data?

For example, if we use uncertainty sampling under a support vector machine (SVM) to acquire a training set $\mathcal{D}$, and subsequently train a Convolutional Neural Network (CNN) using $\mathcal{D}$, will the CNN perform better than it would have if trained on a dataset acquired via i.i.d. random sampling? And how does it perform compared to using a training corpus actively acquired using the CNN?

Figure 1b shows results for a text classification example using the Subjectivity corpus (Pang and Lee, 2004). We consider three models: a Bidirectional Long Short-Term Memory Network (BiLSTM) (Hochreiter and Schmidhuber, 1997), a Convolutional Neural Network (CNN) (Kim, 2014; Zhang and Wallace, 2015), and a Support Vector Machine (SVM) (Joachims, 1998). Training the LSTM with a dataset actively acquired using either of the other models yields predictive performance that is *worse* than that achieved under i.i.d. sampling. Given that datasets tend to outlast models, these results raise questions regarding the benefits of using AL in practice.

We note that in prior work, Tomanek and Morik (2011) also explored the transferability of actively acquired datasets, although their work did not consider modern deep learning models or share our broader focus on practical issues in AL.

3 Experimental Questions and Setup

We seek to answer two questions empirically: (1) How reliably does AL yield gains over sampling i.i.d.? And, (2) What happens when we use a dataset actively acquired using one model to train a different (successor) model? To answer these questions, we consider two tasks for which AL has previously been shown to confer considerable benefits: text classification and sequence tagging (specifically NER).[2]

To build intuition, our experiments address both linear models and deep networks more representative of the current state-of-the-art for these tasks. We investigate the standard strategy of acquiring data and training using a single model, and also the case of acquiring data using one model and subsequently using it to train a second model. Our experiments consider all possible (acquisition, successor) pairs among the considered models, such that the standard AL scheme corresponds to the setting in which the acquisition and successor models are same. For each pair (A, S), we first simulate iterative active data acquisition with model A to label a training dataset $\mathcal{D}_A$. We then train the successor model S using $\mathcal{D}_A$.

In our evaluation, we compare the relative performance (accuracy or F1, as appropriate for the task) of the successor model trained with corpus $\mathcal{D}_A$ to the scores achieved by training on comparable amounts of native and i.i.d. sampled data. We simulate pool-based AL using labeled benchmark datasets by withholding document labels from the models. This induces a pool of unlabeled data $\mathcal{U}$. In AL, it is common to *warm-start* the acquisition model, training on some modest amount of i.i.d. labeled data $\mathcal{D}_w$ before using the model to score candidates in $\mathcal{U}$ (Settles, 2009) and commencing the AL process. We follow this convention throughout.

Once we have trained the acquisition model on the warm-start data, we begin the simulated AL loop, iteratively selecting instances for labeling and adding them to the dataset. We denote the dataset acquired by model A at iteration t by $\mathcal{D}_A^t$; $\mathcal{D}_A^0$ is initialized to $\mathcal{D}_w$ for all models (i.e., all values of A). At each iteration, the acquisition model is trained with $\mathcal{D}_A^t$. It then scores the remaining unlabeled documents in $\mathcal{U} \setminus \mathcal{D}_A^t$ according to a standard uncertainty AL heuristic. The top n candidates $\mathcal{C}_A^t$ are selected for (simulated) annotation. Their labels are revealed and they are added to the training set: $\mathcal{D}_A^{t+1} \leftarrow \mathcal{D}_A^t \cup \mathcal{C}_A^t$. At the experiment's conclusion (time step T), each acquisition model A will have selected a (typically distinct) subset of $\mathcal{U}$ for training.

Once we have acquired datasets from each acquisition model $\mathcal{D}_A$, we evaluate the performance of each possible successor model when trained on $\mathcal{D}_A$. Specifically, we train each successor model S on the acquired data $\mathcal{D}_A^t$ for all t in the range $[0, T]$, evaluating its performance on a held-out test set (distinct from $\mathcal{U}$). We compare the performance achieved in this case to that obtained using an i.i.d. training set of the same size.

We run this experiment ten times, averaging results to create summary learning curves, as shown

[2] Recent works have shown that AL is effective for these tasks even when using modern, neural architectures (Zhang et al., 2017; Shen et al., 2018), but do not address our primary concerns regarding replicability and transferability.

in Figure 1. All reported results, including i.i.d. baselines, are averages of ten experiments, each conducted with a distinct $\mathcal{D}_w$. These learning curves quantify the comparative performance of a particular model achieved using the same amount of supervision, but elicited under different acquisition models. For each model, we compare the learning curves of each acquisition strategy, including active acquisition using a *foreign* model and subsequent transfer, active acquisition without changing models (i.e., typical AL), and the baseline strategy of i.i.d. sampling.

4 Tasks

We now briefly describe the models, datasets, acquisition functions, and implementation details for the experiments we conduct with active learners for text classification (4.1) and NER (4.2).

4.1 Text Classification

Models We consider three standard models for text classification: Support Vector Machines (SVMs), Convolutional Neural Networks (CNNs) (Kim, 2014; Zhang and Wallace, 2015), and Bidirectional Long Short-Term Memory (BiLSTM) networks (Hochreiter and Schmidhuber, 1997). For SVM, we represent texts via sparse, TF-IDF bag-of-words (BoW) vectors. For neural models (CNN and BiLSTM), we represent each document as a sequence of word embeddings, stacked into an $l \times d$ matrix where l is the length of the sentence and d is the dimensionality of the word embeddings. We initialize all word embeddings with pre-trained GloVe vectors (Pennington et al., 2014).

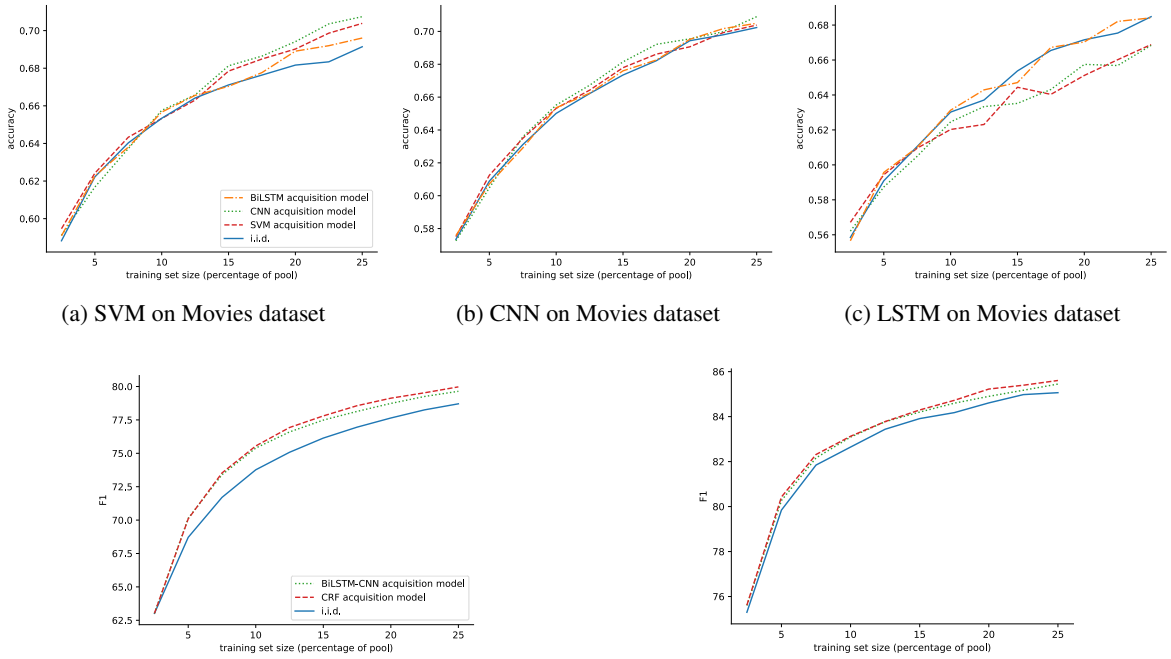
We initialize vector representations for all words for which we do not have pre-trained embeddings uniformly at random. For the CNN, we impose a maximum sentence length of 120 words, truncating sentences exceeding this length and padding shorter sentences. We used filter sizes of 3, 4, and 5, with 128 filters per size. For BiLSTMs, we selected the maximum sentence length such that 90% of sentences in $\mathcal{D}^t$ would be of equal or lesser length.[3] We trained all neural models using the Adam optimizer (Kingma and Ba, 2014), with a learning rate of 0.001, $\beta_1 = 0.9$, $\beta_1 = 0.999$, and $\epsilon = 10^{-8}$.

Datasets We perform text classification experiments using four benchmark datasets. We reserve 20% of each dataset (sampled at i.i.d. random) as test data, and use the remaining 80% as the pool of unlabeled data $\mathcal{U}$. We sample 2.5% of the remaining documents randomly from $\mathcal{U}$ for each $\mathcal{D}_w$. All models receive the same $\mathcal{D}_w$ for any given experiment.

- **Movie Reviews**: This corpus consists of sentences drawn from movie reviews. The task is to classify sentences as expressing positive or negative sentiment (Pang and Lee, 2005).
- **Subjectivity**: This dataset consists of statements labeled as either objective or subjective (Pang and Lee, 2004).
- **TREC**: This task entails categorizing questions into 1 of 6 categories based on the subject of the question (e.g., questions about people, locations, and so on) (Li and Roth, 2002). The TREC dataset defines standard train/test splits, but we generate our own for consistency in train/validation/test proportions across corpora.
- **Customer Reviews**: This dataset is composed of product reviews. The task is to categorize them as positive or negative (Hu and Liu, 2004).

4.2 Named Entity Recognition

Models We consider transfer between two NER models: Conditional Random Fields (CRF) (Lafferty et al., 2001) and Bidirectional LSTM-CNNs (BiLSTM-CNNs) (Chiu and Nichols, 2015).



For the CRF model we use a set of features including word-level and character-based embeddings, word suffix, capitalization, digit contents, and part-of-speech tags. The BiLSTM-CNN model[4] initializes word vectors to pre-trained GloVe vector embeddings (Pennington et al., 2014). We learn all word and character level features from scratch, initializing with random embeddings.

Datasets We perform NER experiments on the CoNLL-2003 and OntoNotes-5.0 English datasets. We used the standard test sets for both corpora, but merged training and validation sets to form $\mathcal{U}$. We initialize each $\mathcal{D}_w$ to 2.5% of $\mathcal{U}$.

- **CoNLL-2003**: Sentences from Reuters news with words tagged as person, location, organization, or miscellaneous entities using an IOB

[3] Passing longer sentences to the BiLSTM degraded performance in preliminary experiments.

[4] Implementation of BiLSTM-CNN is based on https://github.com/asiddhant/Active-NLP.

Individual plots correspond to successor models. Each line corresponds to an acquisition model, with the blue line representing an i.i.d. baseline.

scheme (Tjong Kim Sang and De Meulder, 2003). The corpus contains 301,418 words.

- **OntoNotes-5.0**: A corpus of sentences drawn from a variety of sources including newswire, broadcast news, broadcast conversation, and web data. Words are categorized using eighteen entity categories annotated using the IOB scheme (Weischedel et al., 2013). The corpus contains 2,053,446 words.

4.3 Acquisition Functions

We evaluate these models using three common active learning acquisition functions: classical uncertainty sampling, query by committee (QBC), and Bayesian active learning by disagreement (BALD).

Uncertainty Sampling For text classification we use the entropy variant of uncertainty sampling, which is perhaps the most widely used AL heuristic (Settles, 2009). Documents are selected for annotation according to the function

$$\underset{\mathbf{x}\in\mathcal{U}}{\operatorname{argmax}} -\sum_{j} P(y_j|\mathbf{x}) \log P(y_j|\mathbf{x}),$$

where $\mathbf{x}$ are instances in the pool $\mathcal{U}$, j indexes potential labels of these (we have elided the instance index here) and $P(y_j|\mathbf{x})$ is the predicted probability that $\mathbf{x}$ belongs to class y_j (this estimate is implicitly conditioned on a model that can provide such estimates). For SVM, the equivalent form of this is to choose documents closest to the decision boundary.

For the NER task we use maximized normalized log-probability (MNLP) (Shen et al., 2018) as our AL heuristic, which adapts the least confidence heuristics to sequences by normalizing the log probabilities of predicted tag sequence by the sequence length. This avoids favoring selecting longer sentences (owing to the lower probability of getting the entire tag sequence right).

Documents are sorted in ascending order according to the function

$$\max_{y_1,\ldots,y_n} \frac{1}{n}\sum_{i=1}^{n} \log P(y_i|y_1,\ldots,y_{n-1},\mathbf{x})$$

Where the max over y assignments denotes the most likely set of tags for instance $\mathbf{x}$ and n is the sequence length. Because explicitly calculating the most likely tag sequence is computationally expensive, we follow (Shen et al., 2018) in using a greedy decoding (i.e., beam search with width 1) to determine the model's prediction.

Table 2: F1 measurements for the NER task, with training sets comprising 10% and 20% of the training pool.

Query by Committee For our QBC experiments, we use the bagging variant of QBC (Mamitsuka et al., 1998), in which a committee of n models is assembled by sampling with replacement n sets of m documents from the training data ($\mathcal{D}^t$ at each t). Each model is then trained using a distinct resulting set, and the pool documents that maximize their disagreement are selected. We use 10 as our committee size, and set m as equal to the number of documents in $\mathcal{D}^t$.

For the text classification task, we compute disagreement using Kullback-Leibler divergence (McCallum and Nigamy, 1998), selecting docu-

ments for annotation according to the function

$$\underset{\mathbf{x}\in\mathcal{U}}{\text{argmax}} \frac{1}{C}\sum_{c=1}^{C}\sum_{j} P_c(y_j|\mathbf{x}) \log \frac{P_c(y_j|\mathbf{x})}{P_C(y_j|\mathbf{x})}$$

where $\mathbf{x}$ are instances in the pool $\mathcal{U}$, j indexes potential labels of these instances, and C is the committee size. $P_c(y_j|\mathbf{x})$ is the probability that $\mathbf{x}$ belongs to class y_j as predicted by committee member c. $P_C(y_j|\mathbf{x})$ represents the consensus probability that $\mathbf{x}$ belongs to class y_j, $\frac{1}{C}\sum_{c=1}^{C} P_c(y_j|\mathbf{x})$.

For NER, we compute disagreement using the average per word vote-entropy (Dagan and Engelson, 1995), selecting sequences for annotation which maximize the function

$$-\frac{1}{n}\sum_{i=1}^{n}\sum_{m}\frac{V(y_i,m)}{C}\log\frac{V(y_i,m)}{C}$$

where n is the sequence length, C is the committee size, and $V(y_i, m)$ is the number of committee members who assign tag m to word i in their most likely tag sequence. We do not apply the QBC acquisition function to the OntoNotes dataset, as training the committee for this larger dataset becomes impractical.

Bayesian AL by Disagreement We use the Monte Carlo variant of BALD, which exploits an interpretation of dropout regularization as a Bayesian approximation to a Gaussian process (Gal et al., 2017b; Siddhant and Lipton, 2018). This technique entails applying dropout at test time, and then estimating uncertainty as the disagreement between outputs realized via multiple passes through the model. We use the acquisition function proposed in (Siddhant and Lipton, 2018), which selects for annotation those instances that maximize the number of passes through the model that disagree with the most popular choice:

$$\underset{\mathbf{x}\in\mathcal{U}}{\text{argmax}}(1 - \frac{\text{count}(\text{mode}(y_{\mathbf{x}}^1, ..., y_{\mathbf{x}}^T))}{T})$$

where $\mathbf{x}$ are instances in the pool $\mathcal{U}$, $y_{\mathbf{x}}^i$ is the class prediction of the ith model pass on instance x, and T is the number of passes taken through the model. Any ties are resolved using uncertainty sampling over the mean predicted probabilities of all T passes.

In the NER task, agreement is measured across the entire sequence. Because this acquisition function relies on dropout, we do not consider it for non-neural models (SVM and CRF).

5 Results

We compare transfer between all possible (acquisition, successor) model pairs for each task. We report the performance of each model under all acquisition functions both in tables compiling results (Table 1 and Table 2 for classification and NER, respectively) and graphically via learning curves that plot predictive performance as a function of train set size (Figure 2).

We report additional results, including all learning curves (for all model pairs and for all tasks), and tabular results (for all acquisition functions) in the Appendix. We also provide in the Appendix plots resembling 1a for all (model, acquisition function) pairs that report the difference between performance under standard AL (in which acquisition and successor model are the same) and that under commensurate i.i.d. data, which affords further analysis of the gains offered by standard AL. For text classification tasks, we report accuracies; for NER tasks, we report F1.

To compare the learning curves, we select incremental points along the x-axis and report the performance at these points. Specifically, we report results with training sets containing 10% and 20% of the training pool.

6 Discussion

Results in Tables 1 and 2 demonstrate that standard AL — where the acquisition and successor models are one and the same — performs incon-

	Successor

Acquisition Model	CNN	LSTM	CNN	LSTM	CNN	LSTM	CNN	LSTM
CNN	–	0.961	–	0.968	–	0.988	–	0.973
LSTM	0.989	–	0.996	–	0.992	–	0.980	–
SVM	0.991	0.961	0.997	0.970	0.990	0.987	0.991	0.974

Table 4: Average Spearman's rank correlation coefficients (over five runs) of cosine distances between test set representations learned with native active learning and distances between those learned with transferred actively acquired datasets, at the end of the AL process. Uncertainty is used as the acquisition function in all cases.

sistently across text classification datasets. In 75% of all combinations of model, dataset, and training set size, there exists some acquisition function that outperforms i.i.d. data. This is consistent with the prior literature indicating the effectiveness of AL. However, when implementing AL in a real, live setting, a practitioner would choose a *single* acquisition function ahead of time. To accurately reflect this scenario, we must consider the performance of individual acquisition functions across multiple datasets. Results for individual AL strategies are more equivocal. In our reported classification datapoints, standard AL outperforms i.i.d. sampling in only a slight majority (60.9%) of cases.

AL thus seems to yield modest (though inconsistent) improvements over i.i.d. random sampling, but our results further suggest that this comes at an additional cost: the acquired dataset may not generalize well to new learners. Specifically, models trained on *foreign* actively acquired datasets tend to underperform those trained on i.i.d. datasets. We observe this most clearly in the classification task, where only a handful of (acquisition, successor, acquisition function) combinations lead to performance greater than that achieved using i.i.d. data. Specifically, only 37.5% of the tabulated data points representing dataset transfer (in which acquisition and successor models differ) outperform the i.i.d. baseline.

Results for NER are more favorable for AL. For this task we observe consistent improved performance versus the i.i.d. baseline in both standard AL data points and transfer data points. These results are consistent with previous findings on transferring actively acquired datasets for NER (Tomanek and Morik, 2011).

In standard AL for text classification, the only (model, acquisition function) pairs that we observe to produce better than i.i.d. results with any regularity are uncertainty with SVM or CNN, and BALD with CNN. When transferring actively acquired datasets, we do not observe consistently better than i.i.d. results with *any* combination of acquisition model, successor model, and acquisition function. The success of AL appears to depend very much on the dataset. For example, AL methods – both in the standard and acquisition/successor settings – perform much more reliably on the Subjectivity dataset than any other. In contrast, AL performs consistently poorly on the TREC dataset.

Our findings suggest that AL is brittle. During experimentation, we also found that performance often depends on factors that one may think are minor design decisions. For example, our setup largely resembles that of Siddhant and Lipton (2018), yet initially we observed large discrepancies in results. Digging into this revealed that much of the difference was due to our use of word2vec (Mikolov et al., 2013) rather than GloVe (Pennington et al., 2014) for word embedding initializations. That small decisions like this can result in relatively pronounced performance differences for AL strategies is disconcerting.

A key advantage afforded by neural models is representation learning. A natural question here is therefore whether the representations induced by the neural models differs as a function of the acquisition strategy. To investigate this, we measure pairwise distances between instances in the learned feature space after training. Specifically, for each test instance we calculate its cosine similarity to all other test instances, inducing a ranking. We do this in the three different feature spaces learned by the CNN and LSTM models, respectively, after sampling under the three acquisition models.

We quantify dissimilarities between the rankings induced under different representations via Spearman's rank correlation coefficients. We re-

peat this for all instances in the test set, and average over these coefficients to derive an overall similarity measure, which may be viewed as quantifying the similarity between learned feature spaces via average pairwise similarities within them. As reported in Table 4, despite the aforementioned differences in predictive performance, the learned representations seem to be similar. In other words, sampling under foreign acquisition models does not lead to notably different representations.

7 Conclusions

We extensively evaluated standard AL methods under varying model, domain, and acquisition function combinations for two standard NLP tasks (text classification and sequence tagging). We also assessed performance achieved when transferring an actively sampled training dataset from an acquisition model to a distinct successor model. Given the longevity and value of training sets and the frequency at which new ML models advance the state-of-the-art, this should be an anticipated scenario: Annotated data often outlives models.

Our findings indicate that AL performs unreliably. While a specific acquisition function and model applied to a particular task and domain may be quite effective, it is not clear that this can be predicted ahead of time. Indeed, there is no way to retrospectively determine the relative success of AL without collecting a relatively large quantity of i.i.d. sampled data, and this would undermine the purpose of AL in the first place. Further, even if such an i.i.d. sample were taken as a diagnostic tool early in the active learning cycle, relative success early in the AL cycle is not necessarily indicative of relative success later in the cycle, as illustrated by Figure 1a.

Problematically, even in successful cases, an actively sampled training set is linked to the model used to acquire it. We have found that training successor models with this set will often result in performance worse than that attained using an equivalently sized i.i.d. sample. Results are more favorable to AL for NER, as compared to text classification, which is consistent with prior work (Tomanek and Morik, 2011).

In short, the relative performance of individual active acquisition functions varies considerably over datasets and domains. While AL often does yield gains over i.i.d. sampling, these tend to be marginal and inconsistent. Moreover, this comes at a relatively steep cost: The acquired dataset may be disadvantageous for training subsequent models. Together these findings raise serious concerns regarding the efficacy of active learning in practice.

Abstract

Deep learning systems thrive on abundance of labeled training data but such data is not always available, calling for alternative methods of supervision. One such method is expectation regularization (XR) (Mann and McCallum, 2007), where models are trained based on expected label proportions. We propose a novel application of the XR framework for transfer learning between related tasks, where knowing the labels of task A provides an estimation of the label proportion of task B. We then use a model trained for A to label a large corpus, and use this corpus with an XR loss to train a model for task B. To make the XR framework applicable to large-scale deep-learning setups, we propose a stochastic batched approximation procedure. We demonstrate the approach on the task of Aspect-based Sentiment classification, where we effectively use a sentence-level sentiment predictor to train accurate aspect-based predictor. The method improves upon fully supervised neural system trained on aspect-level data, and is also cumulative with LM-based pretraining, as we demonstrate by improving a BERT-based Aspect-based Sentiment model.

1 Introduction

Data annotation is a key bottleneck in many data driven algorithms. Specifically, deep learning models, which became a prominent tool in many data driven tasks in recent years, require large datasets to work well. However, many tasks require manual annotations which are relatively hard to obtain at scale. An attractive alternative is lightly supervised learning (Schapire et al., 2002; Jin and Liu, 2005; Chang et al., 2007; Graça et al., 2007; Quadrianto et al., 2009a; Mann and McCallum, 2010a; Ganchev et al., 2010; Hope and Shahaf, 2016), in which the objective function is supplemented by a set of domain-specific soft-constraints over the model's predictions on unlabeled data. For example, in *label regularization* (Mann and McCallum, 2007) the model is trained to fit the *true label proportions* of an unlabeled dataset. Label regularization is special case of *expectation regularization* (XR) (Mann and McCallum, 2007), in which the model is trained to fit the conditional probabilities of labels given features.

In this work we consider the case of correlated tasks, in the sense that knowing the labels for task A provides information on the expected label composition of task B. We demonstrate the approach using sentence-level and aspect-level sentiment analysis, which we use as a running example: knowing that a *sentence* has positive sentiment label (task A), we can expect that *most* aspects within this sentence (task B) will also have positive label. While this expectation may be noisy on the individual example level, it holds well in aggregate: given a *set* of positively-labeled sentences, we can robustly estimate the *proportion* of positively-labeled aspects within this set. For example, in a random set of positive sentences, we expect to find 90% positive aspects, while in a set of negative sentences, we expect to find 70% negative aspects. These proportions can be easily either guessed or estimated from a small set.

We propose a novel application of the XR framework for transfer learning in this setup. We present an algorithm (Sec 3.1) that, given a corpus labeled for task A (sentence-level sentiment), learns a classifier for performing task B (aspect-level sentiment) instead, *without* a direct supervision signal for task B. We note that the label information for task A is only used at training time. Furthermore, due to the stochastic nature of the estimation, the task A labels need not be fully accurate, allowing us to make use of *noisy* predictions which are assigned by an automatic classifier (Sections 3.1 and 4). In other words, given

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 31–42,
Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

a medium-sized sentiment corpus with sentence-level labels, and a large collection of *un-annotated* text from the same distribution, we can train an accurate aspect-level sentiment classifier.

The XR loss allows us to use task A labels for training task B predictors. This ability seamlessly integrates into other semi-supervised schemes: we can use the XR loss on top of a pre-trained model to fine-tune the pre-trained representation to the target task, and we can also take the model trained using XR loss and plentiful data and fine-tune it to the target task using the available small-scale annotated data. In Section 5.3 we explore these options and show that our XR framework improves the results also when applied on top of a pre-trained BERT-based model (Devlin et al., 2018).

Finally, to make the XR framework applicable to large-scale deep-learning setups, we propose a stochastic batched approximation procedure (Section 3.2). Source code is available at `https://github.com/MatanBN/XRTransfer`.

2 Background and Related Work

2.1 Lightly Supervised Learning

An effective way to supplement small annotated datasets is to use lightly supervised learning, in which the objective function is supplemented by a set of domain-specific soft-constraints over the model's predictions on unlabeled data. Previous work in lightly-supervised learning focused on training classifiers by using prior knowledge of label proportions (Jin and Liu, 2005; Chang et al., 2007; Musicant et al., 2007; Mann and McCallum, 2007; Quadrianto et al., 2009b; Liang et al., 2009; Ganchev et al., 2010; Mann and McCallum, 2010b; Chang et al., 2012; Wang et al., 2012; Zhu et al., 2014; Hope and Shahaf, 2016) or prior knowledge of features label associations (Schapire et al., 2002; Haghighi and Klein, 2006; Druck et al., 2008; Melville et al., 2009; Mohammady and Culotta, 2015). In the context of NLP, Haghighi and Klein (2006) suggested to use distributional similarities of words to train sequence models for part-of-speech tagging and a classified ads information extraction task. Melville et al. (2009) used background lexical information in terms of word-class associations to train a sentiment classifier. Ganchev and Das (2013); Wang and Manning (2014) suggested to exploit the bilingual correlations between a resource rich language and a resource poor language to train a classifier for the resource poor language in a lightly supervised manner.

2.2 Expectation Regularization (XR)

Expectation Regularization (XR) (Mann and McCallum, 2007) is a lightly supervised learning method, in which the model is trained to fit the conditional probabilities of labels given features. In the context of NLP, XR was used by Mohammady and Culotta (2015) to train twitter-user attribute prediction using hundreds of noisy distributional expectations based on census demographics. Here, we suggest using XR to train a target task (aspect-level sentiment) based on the output of a related source-task classifier (sentence-level sentiment).

Learning Setup The main idea of XR is moving from a fully supervised situation in which each data-point x_i has an associated label y_i, to a setup in which sets of data points U_j are associated with corresponding label proportions $\tilde{\mathbf{p}}_\mathbf{j}$ over that set.

Formally, let $X = \{x_1, x_2, \ldots, x_n\} \subseteq \mathcal{X}$ be a set of data points, $\mathcal{Y}$ be a set of $|\mathcal{Y}|$ class labels, $U = \{U_1, U_2, \ldots, U_m\}$ be a set of sets where $U_j \subseteq X$ for every $j \in \{1, 2, \ldots, m\}$, and let $\tilde{\mathbf{p}}_\mathbf{j} \in R^{|\mathcal{Y}|}$ be the label distribution of set U_j. For example, $\tilde{\mathbf{p}}_\mathbf{j} = \{.7, .2, .1\}$ would indicate that 70% of data points in U_j are expected to have class 0, 20% are expected to have class 1 and 10% are expected to have class 2. Let $p_\theta(x)$ be a parameterized function with parameters θ from $\mathcal{X}$ to a vector of conditional probabilities over labels in $\mathcal{Y}$. We write $p_\theta(y|x)$ to denote the probability assigned to the yth event (the conditional probability of y given x).

A typically objective when training on fully labeled data of (x_i, y_i) pairs is to maximize likelihood of labeled data using the cross entropy loss,

$$L_{cross}(\theta) = -\sum_{i}^{n} \log p_\theta(y_i|x_i)$$

Instead, in XR our data comes in the form of pairs $(U_j, \tilde{\mathbf{p}}_\mathbf{j})$ of sets and their corresponding expected label proportions, and we aim to optimize θ to fit the label distribution $\tilde{\mathbf{p}}_\mathbf{j}$ over U_j, for all j.

XR Loss As counting the number of predicted class labels over a set U leads to a non-differentiable objective, Mann and McCallum (2007) suggest to relax it and use instead the

model's posterior distribution $\hat{\mathbf{p}}_\mathbf{j}$ over the set:

$$\hat{\mathbf{q}}_\mathbf{j}(y) = \sum_{x \in U_j} p_\theta(y|x) \quad (1)$$

$$\hat{\mathbf{p}}_\mathbf{j}(y) = \frac{\hat{\mathbf{q}}_\mathbf{j}(y)}{\sum_{y'} \hat{\mathbf{q}}_\mathbf{j}(y')} \quad (2)$$

where $\mathbf{q}(y)$ indicates the yth entry in $\mathbf{q}$. Then, we would like to set θ such that $\hat{\mathbf{p}}_\mathbf{j}$ and $\tilde{\mathbf{p}}_\mathbf{j}$ are close. Mann and McCallum (2007) suggest to use KL-divergence for this. KL-divergence is composed of two parts:

$$D_{KL}(\tilde{\mathbf{p}}_\mathbf{j} || \hat{\mathbf{p}}_\mathbf{j}) = -\tilde{\mathbf{p}}_\mathbf{j} \cdot \log \hat{\mathbf{p}}_\mathbf{j} + \tilde{\mathbf{p}}_\mathbf{j} \cdot \log \tilde{\mathbf{p}}_\mathbf{j}$$

$$= H(\tilde{\mathbf{p}}_\mathbf{j}, \hat{\mathbf{p}}_\mathbf{j}) - H(\tilde{\mathbf{p}}_\mathbf{j})$$

Since $H(\tilde{\mathbf{p}}_\mathbf{j})$ is constant, we only need to minimize $H(\tilde{\mathbf{p}}_\mathbf{j}, \hat{\mathbf{p}}_\mathbf{j})$, therefore the loss function becomes:[1]

$$L_{XR}(\theta) = -\sum_{j=1}^{m} \tilde{\mathbf{p}}_\mathbf{j} \cdot \log \hat{\mathbf{p}}_\mathbf{j} \quad (3)$$

Notice that computing $\hat{\mathbf{q}}_\mathbf{j}$ requires summation over $p_\theta(x)$ for the entire set U_j, which can be prohibitive. We present batched approximation (Section 3.2) to overcome this.

Temperature Parameter Mann and McCallum (2007) find that XR might find a degenerate solution. For example, in a three class classification task, where $\tilde{p}_j = \{.5, .35, .15\}$, it might find a solution such that $\hat{p}_\theta(y) = \{.5, .35, .15\}$ for every instance, as a result, every instance will be classified the same. To avoid this, Mann and McCallum (2007) suggest to penalize flat distributions by using a temperature coefficient T likewise:

$$p_\theta(y|x) = \left(\frac{e^{\mathbf{z}W + \mathbf{b}}}{\sum_k e^{(\mathbf{z}W + \mathbf{b})_k}} \right)^{\frac{1}{T}} \quad (4)$$

Where $\mathbf{z}$ is a feature vector and W and $\mathbf{b}$ are the linear classifier parameters.

2.3 Aspect-based Sentiment Classification

In the aspect-based sentiment classification (ABSC) task, we are given a sentence and an aspect, and need to determine the sentiment that is expressed towards the aspect. For example the sentence *"Excellent food, although the interior could use some help."* has two aspects: *food* and *interior*, a positive sentiment is expressed about the food, but a negative sentiment is expressed about the interior. A sentence $\alpha = (w_1, w_2, \ldots, w_n)$, may contain 0 or more aspects a_i, where each aspect corresponds to a sub-sequence of the original sentence, and has an associated sentiment label (NEG, POS, or NEU). Concretely, we follow the task definition in the SemEval-2015 and SemEval-2016 shared tasks (Pontiki et al., 2015, 2016), in which the relevant aspects are given and the task focuses on finding the sentiment label of the aspects.

While sentence-level sentiment labels are relatively easy to obtain, aspect-level annotation are much more scarce, as demonstrated in the small datasets of the SemEval shared tasks.

[1] Note also that $\forall_j |U_j| = 1 \iff L_{XR}(\theta) = L_{cross}(\theta)$

3 Technical Contributions

3.1 Transfer-training between related tasks with XR

Consider two classification tasks over a shared input space, a source task s from $\mathcal{X}$ to $\mathcal{Y}^s$ and a target task t from $\mathcal{X}$ to $\mathcal{Y}^t$, which are related through a conditional distribution $P(y^t = i | y^s = j)$. In other words, a labeling decision for task s induces an expected label distribution over the task t. For a set of datapoints $x_1, ..., x_n$ that share a source label y^s, we expect to see a target label distribution of $P(y^t|y^s) = \tilde{\mathbf{p}}_{\mathbf{y^s}}$.

Given a large unlabeled dataset $D^u = (x^u_1, ..., x^u_{|D^u|})$, a small labeled dataset for the target task $D^t = ((x^t_1, y^t_1), ..., (x^t_{|D^t|}, y^t_{|D^t|}))$, classifier $C^s : \mathcal{X} \mapsto \mathcal{Y}^s$ (or sufficient training data to train one) for the source task,[2] we wish to use C^s

[2] Note that the classifier does not need to be trainable or differentiable. It can be a human, a rule based system, a non-parametric model, a probabilistic model, a deep learning net-

and D^u to train a good classifier $C^t : \mathcal{X} \mapsto \mathcal{Y}^t$ for the target task. This can be achieved using the following procedure.

- Apply C^s to D^t, resulting in a noisy source-side labels $\tilde{y}^s_i = C^s(x^t_i)$ for the target task.
- Estimate the conditional probability $P(y^t|\tilde{y}^s)$ table using MLE estimates over D^t

$$\tilde{p}_j(y^t = i|\tilde{y}^s = j) = \frac{\#(y^t = i, \tilde{y}^s = j)}{\#(\tilde{y}^s = j)}$$

  where $\#$ is a counting function over D^t.[3]
- Apply C^s to the unlabeled data D^u resulting in labels $C^s(x^u_i)$. Split D^u into $|\mathcal{Y}^s|$ sets U_j according to the labeling induced by C^s:

$$U_j = \{x^u_i \mid x^u_i \in D^u \wedge C^s(x^u_i) = j\}$$

- Use Algorithm 1 to train a classifier for the target task using input pairs $(U_j, \tilde{\mathbf{p}}_\mathbf{j})$ and the XR loss.

In words, by using XR training, we use the expected label proportions over the target task given predicted labels of the source task, to train a target-class classifier.

3.2 Stochastic Batched Training for Deep XR

Mann and McCallum (2007) and following work take the base classifier $p_\theta(y|x)$ to be a logistic regression classifier, for which they manually derive gradients for the XR loss and train with LBFGs (Byrd et al., 1995). However, nothing precludes us from using an arbitrary neural network instead, as long as it culminates in a softmax layer.

One complicating factor is that the computation of $\hat{\mathbf{q}}_\mathbf{j}$ in equation (1) requires a summation over $p_\theta(x)$ for the entire set U_j, which in our setup may contain hundreds of thousands of examples, making gradient computation and optimization impractical. We instead proposed a *stochastic batched approximation* in which, instead of requiring that the full constraint set U_j will match the expected label posterior distribution, we require that sufficiently large random subsets of it will match the distribution. At each training step we compute the loss and update the gradient with respect to a different random subset. Specifically, in each training step we sample a random pair $(U_j, \tilde{\mathbf{p}}_\mathbf{j})$, sample a random subset U' of U_j of size k, and compute the local XR loss of set U':

$$L_{XR}(\theta; j, U') = -\tilde{\mathbf{p}}_\mathbf{j} \cdot \log \hat{\mathbf{p}}_{\mathbf{u}'} \quad (5)$$

where $\hat{\mathbf{p}}_{\mathbf{u}'}$ is computed by summing over the elements of U' rather than of U_j in equations (1–2). The stochastic batched XR training algorithm is given in Algorithm 1. For large enough k, the expected label distribution of the subset is the same as that of the complete set.

4 Application to Aspect-based Sentiment

We demonstrate the procedure given above by training Aspect-based Sentiment Classifier (ABSC) using sentence-level[4] sentiment signals.

4.1 Relating the classification tasks

We observe that while the sentence-level sentiment does not *determine* the sentiment of individual aspects (a positive sentence may contain negative remarks about some aspects), it is very predictive of the *proportion* of sentiment labels of the fragments within a sentence. Positively labeled sentences are likely to have more positive aspects and fewer negative ones, and vice-versa for negatively-labeled sentences. While these proportions may vary on the individual sentence level, we expect them to be stable when aggregating fragments from several sentences: when considering a large enough sample of fragments that all come from positively labeled sentences, we expect the different samples to have roughly similar label proportions to each other. This situation is idealy suited for performing XR training, as described in section 3.1.

The application to ABSC is almost straightforward, but is complicated a bit by the decomposition of sentences into fragments: each sentence level decision now corresponds to multiple fragment-level decisions. Thus, we apply the sentence-level (task A) classifier C^s on the aspect-level corpus D^t by applying it on the sentence level and then associating the predicted sentence labels with each of the fragments, resulting in

work, etc. In this work, we use a neural classification model.

[3] In theory, we could estimate—or even "guess"—these $|\mathcal{Y}^s| \times |\mathcal{Y}^t|$ values without using D^t at all. In practice, and in particular because we care about the target label proportions given *noisy* source labels $\tilde{y}^s$ assigned by C^s, we use MLE estimates over the tagged D^t.

[4] In practice, our "sentences" are in fact short documents, some of which are composed of two or more sentences.

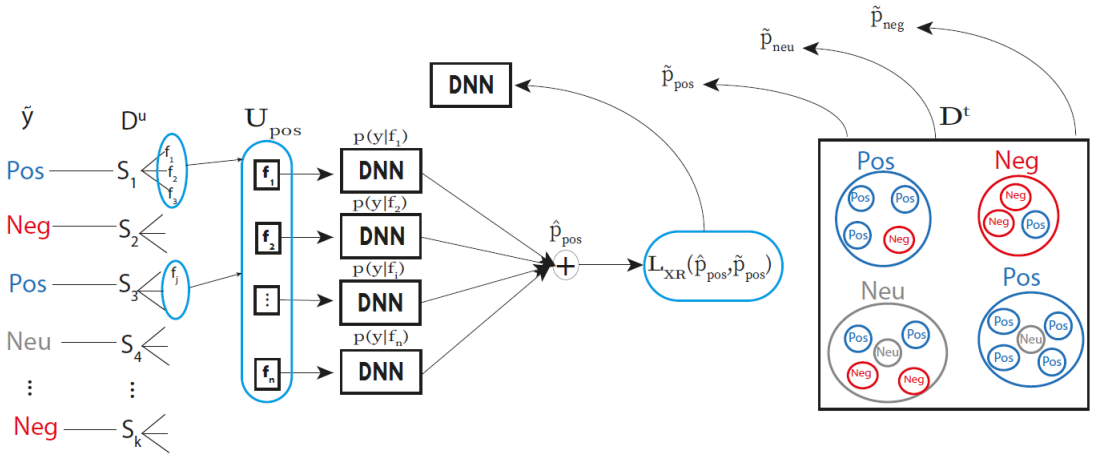

Figure 1: Illustration of the algorithm. C^s is applied to D^u resulting in $\tilde{y}$ for each sentence, U_j is built according with the fragments of the same labelled sentences, the probabilities for each fragment in U_j are summed and normalized, the XR loss in equation (4) is calculated and the network is updated.

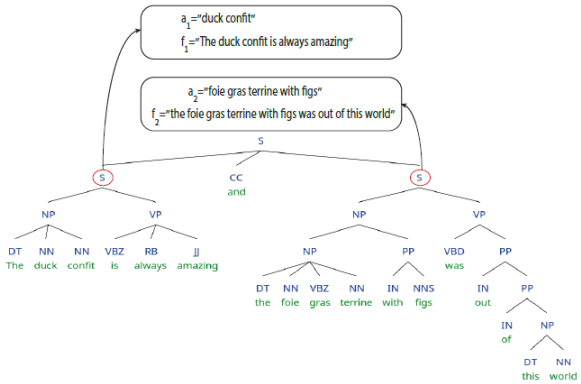

Figure 2: Illustration of the decomposition procedure, when given a_1="duck confit" and a_2= "foie gras terrine with figs" as the pivot phrases.

fragment-level labeling. Similarly, when we apply C^s to the unlabeled data D^u we again do it at the sentence level, but the sets U_j are composed of fragments, not sentences:

$$U_j = \{f_i^\alpha \mid \alpha \in D^u \wedge f_i^\alpha \in \text{frags}(\alpha) \wedge C^s(\alpha) = j\}$$

We then apply algorithm 1 as is: at each step of training we sample a source label $j \in \{\text{POS},\text{NEG},\text{NEU}\}$, sample k fragments from U_j, and use the XR loss to fit the expected fragment-label proportions over these k fragments to $\tilde{\mathbf{p}}_\mathbf{j}$. Figure 1 illustrates the procedure.

4.2 Classification Architecture

We model the ABSC problem by associating each (sentence,aspect) pair with a *sentence-fragment*, and constructing a neural classifier from fragments to sentiment labels. We heuristically decompose a sentence into fragments. We use the same BiLSTM based neural architecture for both sentence classification and fragment classification.

Fragment-decomposition We now describe the procedure we use to associate a sentence fragment with each (sentence,aspect) pairs. The shared tasks data associates each aspect with a pivot-phrase a, where pivot phrase $(w_1, w_2, ...w_l)$ is defined as a pre-determined sequence of words that is contained within the sentence. For a sentence α, a set of pivot phrases $A = (a_1, ..., a_m)$ and a specific pivot phrase a_i, we consult the constituency parse tree of α and look for tree nodes that satisfy the following conditions:[5]

1. The node governs the desired pivot phrase a_i.
2. The node governs either a verb (VB, VBD, VBN, VBG, VBP, VBZ) or an adjective (JJ, JJR, JJS), which is different than any $a_j \in A$.
3. The node governs a minimal number of pivot phrases from $(a_1, ..., a_m)$, ideally only a_i.

We then select the highest node in the tree that satisfies all conditions. The span governed by this node is taken as the fragment associated with as-

[5]Condition (2) coupled with selecting the highest node pushes towards complete phrases that contain opinions (which are usually expressed with adjectives or verbs), while the other conditions focus the attention on the desired pivot phrase.

pect a_i.[6] The decomposition procedure is demonstrated in Figure 2.

When aspect-level information is given, we take the pivot-phrases to be the requested aspects. When aspect-level information is *not available*, we take each noun in the sentence to be a pivot-phrase.

Neural Classifier Our classification model is a simple 1-layer BiLSTM encoder (a concatenation of the last states of a forward and a backward running LSTMs) followed by a linear-predictor. The encoder is fed either a complete sentence or a sentence fragment.

5 Experiments

Data Our *target* task is aspect-based fragment-classification, with small labeled datasets from the SemEval 2015 and 2016 shared tasks, each dataset containing aspect-level predictions for about 2000 sentences in the restaurants reviews domain. Our *source* classifier is based on training on up to 10,000 sentences from the same domain and 2000 sentences for validation, labeled for only for sentence-level sentiment. We additionally have an unlabeled dataset of up to 670,000 sentences from the same domain[7]. We tokenized all datasets using the Tweet Tokenizer from NLTK package[8] and parsed the tokenized sentences with AllenNLP parser.[9]

Training Details Both the sentence level classification models and the models trained with XR have a hidden state vector dimension of size 300, they use dropout (Hinton et al., 2012) on the sentence representation or fragment representation vector (rate=0.5) and optimized using Adam (Kingma and Ba, 2014). The sentence classification is trained with a batch size of 30 and XR models are trained with batch sizes k that each contain 450 fragments[10]. We used a temperature parameter of 1[11]. We use pre-trained 300-dimensional GloVe embeddings[12] (Pennington et al., 2014), and fine-tune them during training. The XR training was validated with a validation set of 20% of SemEval-2015 training set, the sentence level BiLSTM classifiers were validated with a validation of 2000 sentences.[13] When fine-tuning to the aspect based task we used 20% of train in each dataset as validation and evaluated on this set. On each training method the models were evaluated on the validation set, after each epoch and the best model was chosen. The data is highly imbalanced, with only very few sentences receiving a NEU label. We do not deal with this imbalance directly and train both the sentence level and the XR aspect-based training on the imbalanced data. However, when training C^s, we trained five models and chose the best model that predicts correctly at least 20% of the neutral sentences. The models are implemented using DyNet[14] (Neubig et al., 2017).

Baseline models In recent years many neural network architectures with increasing sophistication were applied to the ABSC task (Nguyen and Shirai, 2015; Vo and Zhang, 2015; Tang et al., 2016a,b; Wang et al., 2016; Zhang et al., 2016; Ruder et al., 2016; Ma et al., 2017; Liu and Zhang, 2017; Chen et al., 2017; Liu et al., 2018; Yang et al., 2018; Wang et al., 2018b,a; Fan et al., 2018a,b; Li et al., 2018; Ouyang and Su, 2018). We compare to a series of state-of-the-art ABSC neural classifiers that participated in the shared tasks. TDLSTM-ATT (Tang et al., 2016a) encodes the information around an aspect using forward and backward LSTMs, followed by an attention mechanism. ATAE-LSTM (Wang et al., 2016) is an attention based LSTM variant. MM (Tang et al., 2016b) is a deep memory network with multiple-hops of attention layers. RAM (Chen et al., 2017) uses multiple attention mechanisms combined with a recurrent neural networks and a weighted memory mechanism. LSTM+SynATT+TarRep (He et al., 2018a) is an attention based LSTM which incorporates syn-

[6] On the rare occasions where we cannot find such a node, we take the root node of the tree (the entire sentence) as the fragment for the given aspect.

[7] All of the sentence-level sentiment data is obtained from the Yelp dataset challenge: https://www.yelp.com/dataset/challenge

[8] https://www.nltk.org/

[9] https://allennlp.org/

[10] We also increased the batch sizes of the baselines to match those of the XR setups. This decreased the performance of the baselines, which is consistent with the folk knowledge in the community according to which smaller batch sizes are more effective overall.

[11] Despite (Mann and McCallum, 2007) claim regarding the temperature parameter, we observed lower performance when using it in our setup. However, in other setups this parameter might be found to be beneficial.

[12] https://nlp.stanford.edu/projects/glove/

[13] We also tested the sentence BiLSTM baselines with a SemEval validation set, and received slightly lower results without a significant statistical difference.

Table 1: Average accuracies and Macro-F1 scores over five runs with random initialization along with their standard deviations. Bold: best results or within std of them. * indicates that the method's result is significantly better than all baseline methods, † indicates that the method's result is significantly better than all baselines methods that use the aspect-based data only, with $p < 0.05$ according to a one-tailed unpaired t-test. The data annotations **S**, **N** and **A** indicate training with Sentence-level, Noisy sentence-level and Aspect-level data respectively. Numbers for TDLSTM+Att,ATAE-LSTM,MM,RAM and LSTM+SynATT+TarRep are from (He et al., 2018a). Numbers for Semisupervised are from (He et al., 2018b).

tactic information into the attention mechanism and uses an auto-encoder structure to produce an aspect representations. All of these models are trained only on the small, fully-supervised ABSC datasets.

"Semisupervised" is the semi-supervised setup of (He et al., 2018b), it train an attention-based LSTM model on 30,000 documents additional to an aspect-based train set, 10,000 documents to each class. We consider additional two simple but strong semi-supervised baselines. Sentence-BiLSTM is our BiLSTM model trained on the 10^4 sentence-level annotations, and applied as-is to the individual fragments. Sentence-BiLSTM+Finetuning is the same model, but finetuned on the aspect-based data as explained above. Finetuning is performed using our own implementation of the attention-based model of He et al. (2018b).[15] Both these models are on par with the fully-supervised ABSC models.

Empirical Proportions The proportion constraint sets $\tilde{\mathbf{p}}_\mathbf{j}$ based on the SemEval-2015 aspect-based train data are:
$\tilde{\mathbf{p}}_{\text{POS}} = \{\text{POS} : 0.93, \text{NEG} : 0.06, \text{NEU} : 0.01\}$
$\tilde{\mathbf{p}}_{\text{NEG}} = \{\text{POS} : 0.27, \text{NEG} : 0.7, \text{NEU} : 0.03\}$
$\tilde{\mathbf{p}}_{\text{NEU}} = \{\text{POS} : 0.45, \text{NEG} : 0.41, \text{NEU} : 0.14\}$

5.1 Main Results

Table 1 compares these baselines to three XR conditions.[16]

The first condition, BiLSTM-XR-Dev, performs XR training on the automatically-labeled sentence-level dataset. The only access it has to aspect-level annotation is for estimating the proportions of labels for each sentence-level label, which is done based on the validation set of SemEval-2015 (i.e., 20% of the train set). The XR setting is very effective: without using any in-task data, this model already surpasses all other models, both supervised and semi-supervised, except for the (He et al., 2018b,a) models which achieve higher F1 scores. We note that in contrast to XR, the competing models have complete access to the supervised aspect-based labels. The second condition, BiLSTM-XR, is similar but now the model is allowed to estimate the conditional label proportions based on the entire aspect-based training set (the classifier still does not have direct access to the labels beyond the aggregate proportion information). This improves results further, showing the importance of accurately estimating the proportions. Finally, in BiLSTM-XR+Finetuning, we follow the XR training with fully supervised fine-tuning on the small labeled dataset, using the attention-based model of He et al. (2018b). This achieves the best results, and surpasses also the semi-supervised He et al. (2018b) baseline on accuracy, and matching it on F1.[17]

We report significance tests for the robustness

[15] We changed the LSTM component to a BiLSTM.

[16] To be consistent with existing research (He et al., 2018b), aspects with conflicted polarity are removed.

[17] We note that their setup uses clean and more balanced annotations, i.e. they use 10,000 samples for each label, which helps predicting the infrequent neutral sentiment. We however, use noisy sentence sentiment labels which are automatically obtained from a trained classifier, which trains on 10,000 samples in their natural imbalanced distribution.

of the method under random parameter initialization. Our reported numbers are averaged over five random initialization. Since the datasets are unbalanced w.r.t the label distribution, we report both accuracy and macro-F1.

The XR training is also more stable than the other semi-supervised baselines, achieving substantially lower standard deviations across different runs.

5.2 Further experiments

In each experiment in this section we estimate the proportions using the SemEval-2015 train set.

Effect of unlabeled data size How does the XR training scale with the amount of unlabeled data? Figure 3a shows the macro-F1 scores on the entire SemEval-2016 dataset, with different unlabeled corpus sizes (measured in number of sentences). An unannotated corpus of 5×10^4 sentences is sufficient to surpass the results of the 10^4 sentence-level trained classifier, and more unannotated data further improves the results.

Effect of Base-classifier Quality Our method requires a sentence level classifier C^s to label both the target-task corpus and the unlabeled corpus. How does the quality of this classifier affect the overall XR training? We vary the amount of supervision used to train C^s from 0 sentences (assigning the same label to all sentences), to 100, 1000, 5000 and 10000 sentences. We again measure macro-F1 on the entire SemEval 2016 corpus. The results in Figure 3b show that when using the prior distributions of aspects (0), the model struggles to learn from this signal, it learns mostly to predict the majority class, and hence reaches very low F1 scores of 35.28. The more data given to the sentence level classifier, the better the potential results will be when training with our method using the classifier labels, with a classifiers trained on 100,1000,5000 and 10000 labeled sentences, we get a F1 scores of 53.81, 58.84, 61.81, 65.58 respectively. Improvements in the source task classifier's quality clearly contribute to the target task accuracy.

Effect of k The Stochastic Batched XR algorithm (Algorithm 1) samples a batch of k examples at each step to estimate the posterior label distribution used in the loss computation. How does the size of k affect the results? We use $k = 450$ fragments in our main experiments, but smaller values of k reduce GPU memory load and may train better in practice. We tested our method with varying values of k on a sample of 5×10^4, using batches that are composed of fragments of 5, 25, 100, 450, 1000 and 4500 sentences. The results are shown in Figure 3c. Setting $k = 5$ result in low scores. Setting $k = 25$ yields better F1 score but with high variance across runs. For $k = 100$ fragments the results begin to stabilize, we also see a slight decrease in F1-scores with larger batch sizes. We attribute this drop despite having better estimation of the gradients to the general trend of larger batch sizes being harder to train with stochastic gradient methods.

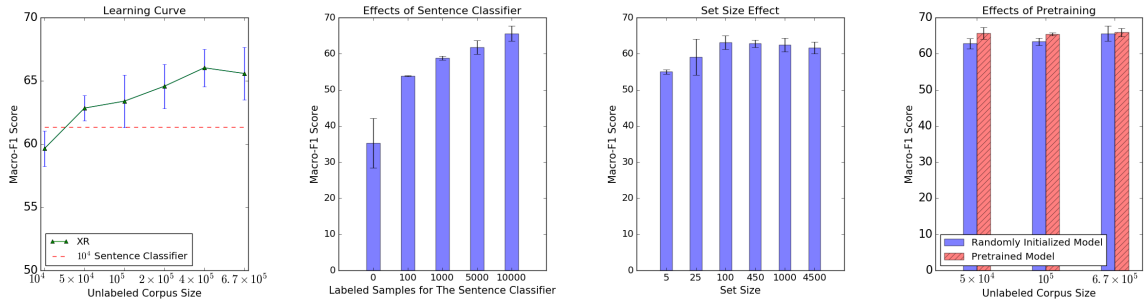
5.3 Pre-training, BERT

The XR training can be performed also over pre-trained representations. We experiment with two pre-training methods: (1) pre-training by training the BiLSTM model to predict the noisy sentence-level predictions. (2) Using the pre-trained BERT representation (Devlin et al., 2018). For (1), we compare the effect of pre-train on unlabeled corpora of sizes of 5×10^4, 10^5 and 6.7×10^5 sentences. Results in Figure 3d show that this form of pre-training is effective for smaller unlabeled corpora but evens out for larger ones.

BERT For the BERT experiments, we experiment with the BERT-base model[18] with $k = 450$ sets, 30 epochs for XR training or sentence level fine-tuning[19] and 15 epochs for aspect based fine-tuning, on each training method we evaluated the model on the dev set after each epoch and the best model was chosen[20]. We compare the following setups:

-BERT→Aspect Based Finetuning: pretrained BERT model finetuned to the aspect based task.

-BERT→ 10^4: A pretrained BERT model finetuned to the sentence level task on the 10^4 sentences, and tested by predicting fragment-level sentiment.



-BERT→10^4→Aspect Based Finetuning: pretrained BERT model finetuned to the sentence level task, and finetuned again to the aspect based one.

-BERT→XR: pretrained BERT model followed by

[18] We could not fit $k = 450$ sets of BERT-large on our GPU.

[19] When fine-tuning to the sentence level task, we provide the sentence as input. When fine-tuning to the aspect-level task, we provide the sentence, a seperator and then the aspect.

[20] The other configuration parameters were the default ones in https://github.com/huggingface/pytorch-pretrained-BERT

Table 2: BERT pre-training: average accuracies and Macro-F1 scores from five runs and their stdev. * indicates that the method's result is significantly better than all baseline methods, † indicates that the method's result is significantly better than all non XR baseline methods, with $p < 0.05$ according to a one-tailed unpaired t-test. The data annotations **S**, **N** and **A** indicate training with Sentence-level, Noisy sentence-level and Aspect-level data respectively.

XR training using our method.

-BERT→ XR → Aspect Based Finetuning: pre-trained BERT followed by XR training and then fine-tuned to the aspect level task.

The results are presented in Table 2. As before, aspect-based fine-tuning is beneficial for both SemEval-16 and SemEval-15. Training a BiLSTM with XR surpasses pre-trained BERT models and using XR training on top of the pre-trained BERT models substantially increases the results even further.

6 Discussion

We presented a transfer learning method based on expectation regularization (XR), and demonstrated its effectiveness for training aspect-based sentiment classifiers using sentence-level supervision. The method achieves state-of-the-art results for the task, and is also effective for improving on top of a strong pre-trained BERT model. The proposed method provides an additional data-efficient tool in the modeling arsenal, which can be applied on its own or together with another training method, in situations where there is a conditional relations between the labels of a source task for which we have supervision, and a target task for which we don't.

While we demonstrated the approach on the sentiment domain, the required conditional dependence between task labels is present in many situations. Other possible application of the method includes training language identification of tweets given geo-location supervision (knowing the geographical region gives a prior on languages spoken), training predictors for renal failure from textual medical records given classifier for diabetes (there is a strong correlation between the two conditions), training a political affiliation classifier from social media tweets based on age-group classifiers, zip-code information, or social-status classifiers (there are known correlations between all of these to political affiliation), training hate-speech detection based on emotion detection, and so on.

Abstract

Contextual word representations, typically trained on unstructured, unlabeled text, do not contain any explicit grounding to real world entities and are often unable to remember facts about those entities. We propose a general method to embed multiple knowledge bases (KBs) into large scale models, and thereby enhance their representations with structured, human-curated knowledge. For each KB, we first use an integrated entity linker to retrieve relevant entity embeddings, then update contextual word representations via a form of word-to-entity attention. In contrast to previous approaches, the entity linkers and self-supervised language modeling objective are jointly trained end-to-end in a multitask setting that combines a small amount of entity linking supervision with a large amount of raw text. After integrating WordNet and a subset of Wikipedia into BERT, the knowledge enhanced BERT (KnowBert) demonstrates improved perplexity, ability to recall facts as measured in a probing task and downstream performance on relationship extraction, entity typing, and word sense disambiguation. KnowBert's runtime is comparable to BERT's and it scales to large KBs.

1 Introduction

Large pretrained models such as ELMo (Peters et al., 2018), GPT (Radford et al., 2018), and BERT (Devlin et al., 2019) have significantly improved the state of the art for a wide range of NLP tasks. These models are trained on large amounts of raw text using self-supervised objectives. However, they do not contain any explicit grounding to real world entities and as a result have difficulty recovering factual knowledge (Logan et al., 2019).

Knowledge bases (KBs) provide a rich source of high quality, human-curated knowledge that can be used to ground these models. In addition, they often include complementary information to that found in raw text, and can encode factual knowledge that is difficult to learn from selectional preferences either due to infrequent mentions of commonsense knowledge or long range dependencies.

We present a general method to insert multiple KBs into a large pretrained model with a Knowledge Attention and Recontextualization (KAR) mechanism. The key idea is to explicitly model *entity spans* in the input text and use an entity linker to retrieve relevant entity embeddings from a KB to form knowledge enhanced entity-span representations. Then, the model recontextualizes the entity-span representations with word-to-entity attention to allow long range interactions between contextual word representations and all entity spans in the context. The entire KAR is inserted between two layers in the middle of a pretrained model such as BERT.

In contrast to previous approaches that integrate external knowledge into task-specific models with task supervision (e.g., Yang and Mitchell, 2017; Chen et al., 2018), our approach learns the entity linkers with self-supervision on unlabeled data. This results in general purpose knowledge enhanced representations that can be applied to a wide range of downstream tasks.

Our approach has several other benefits. First, it leaves the top layers of the original model unchanged so we may retain the output loss layers and fine-tune on unlabeled corpora while training the KAR. This also allows us to simply swap out BERT for KnowBert in any downstream application. Second, by taking advantage of the existing high capacity layers in the original model, the KAR is lightweight, adding minimal additional parameters and runtime. Finally, it is easy to incorporate additional KBs by simply inserting them at other locations.

KnowBert is agnostic to the form of the

KB, subject to a small set of requirements (see Sec. 3.2). We experiment with integrating both WordNet (Miller, 1995) and Wikipedia, thus explicitly adding word sense knowledge and facts about named entities (including those unseen at training time). However, the method could be extended to commonsense KBs such as ConceptNet (Speer et al., 2017) or domain specific ones (e.g., UMLS; Bodenreider, 2004).

We evaluate KnowBert with a mix of intrinsic and extrinsic tasks. Despite being based on the smaller $\text{BERT}_{\text{BASE}}$ model, the experiments demonstrate improved masked language model perplexity and ability to recall facts over $\text{BERT}_{\text{LARGE}}$. The extrinsic evaluations demonstrate improvements for challenging relationship extraction, entity typing and word sense disambiguation datasets, and often outperform other contemporaneous attempts to incorporate external knowledge into BERT.

2 Related Work

Pretrained word representations Initial work learning word vectors focused on static word embeddings using multi-task learning objectives (Collobert and Weston, 2008) or corpus level co-occurence statistics (Mikolov et al., 2013a; Pennington et al., 2014). Recently the field has shifted toward learning context-sensitive embeddings (Dai and Le, 2015; Peters et al., 2018; Devlin et al., 2019). We build upon these by incorporating structured knowledge into these models.

Entity embeddings Entity embedding methods produce continuous vector representations from external knowledge sources. Knowledge graph-based methods optimize the score of observed triples in a knowledge graph. These methods broadly fall into two categories: translational distance models (Bordes et al., 2013; Wang et al., 2014b; Lin et al., 2015; Xiao et al., 2016) which use a distance-based scoring function, and linear models (Nickel et al., 2011; Yang et al., 2014; Trouillon et al., 2016; Dettmers et al., 2018) which use a similarity-based scoring function. We experiment with TuckER (Balazevic et al., 2019) embeddings, a recent linear model which generalizes many of the aforecited models. Other methods combine entity metadata with the graph (Xie et al., 2016), use entity contexts (Chen et al., 2014; Ganea and Hofmann, 2017), or a combination of contexts and the KB (Wang et al., 2014a; Gupta et al., 2017). Our approach is agnostic to the details of the entity embedding method and as a result is able to use any of these methods.

Entity-aware language models Some previous work has focused on adding KBs to generative language models (LMs) (Ahn et al., 2017; Yang et al., 2017; Logan et al., 2019) or building entity-centric LMs (Ji et al., 2017). However, these methods introduce latent variables that require full annotation for training, or marginalization. In contrast, we adopt a method that allows training with large amounts of unannotated text.

Task-specific KB architectures Other work has focused on integrating KBs into neural architectures for specific downstream tasks (Yang and Mitchell, 2017; Sun et al., 2018; Chen et al., 2018; Bauer et al., 2018; Mihaylov and Frank, 2018; Wang and Jiang, 2019; Yang et al., 2019). Our approach instead uses KBs to learn more generally transferable representations that can be used to improve a variety of downstream tasks.

3 KnowBert

KnowBert incorporates knowledge bases into BERT using the Knowledge Attention and Recontextualization component (KAR). We start by describing the BERT and KB components. We then move to introducing KAR. Finally, we describe the training procedure, including the multi-task training regime for jointly training KnowBert and an entity linker.

3.1 Pretrained BERT

We describe KnowBert as an extension to (and candidate replacement for) BERT, although the method is general and can be applied to any deep pretrained model including left-to-right and right-to-left LMs such as ELMo and GPT. Formally, BERT accepts as input a sequence of N Word-Piece tokens (Sennrich et al., 2016; Wu et al., 2016), $(x_1, \ldots, x_N)$, and computes L layers of D-dimensional contextual representations $\mathbf{H}_i \in \mathbb{R}^{N \times D}$ by successively applying non-linear functions $\mathbf{H}_i = \text{F}_i(\mathbf{H}_{i-1})$. The non-linear function is a multi-headed self-attention layer followed by a position-wise multilayer perceptron (MLP)

(Vaswani et al., 2017):

$$\begin{aligned}&\mathrm{F}_i(\mathbf{H}_{i-1}) = \\ &\quad \mathrm{TransformerBlock}(\mathbf{H}_{i-1}) = \\ &\quad \mathrm{MLP}(\mathrm{MultiHeadAttn}(\mathbf{H}_{i-1}, \mathbf{H}_{i-1}, \mathbf{H}_{i-1})).\end{aligned}$$

The multi-headed self-attention uses $\mathbf{H}_{i-1}$ as the query, key, and value to allow each vector to attend to every other vector.

BERT is trained to minimize an objective function that combines both next-sentence prediction (NSP) and masked LM log-likelihood (MLM):

$$\mathcal{L}_{\text{BERT}} = \mathcal{L}_{\text{NSP}} + \mathcal{L}_{\text{MLM}}.$$

Given two inputs $\mathbf{x}_A$ and $\mathbf{x}_B$, the next-sentence prediction task is binary classification to predict whether $\mathbf{x}_B$ is the next sentence following $\mathbf{x}_A$. The masked LM objective randomly replaces a percentage of input word pieces with a special `[MASK]` token and computes the negative log-likelihood of the missing token with a linear layer and softmax over all possible word pieces.

3.2 Knowledge Bases

The key contribution of this paper is a method to incorporate knowledge bases (KB) into a pretrained BERT model. To encompass as wide a selection of prior knowledge as possible, we adopt a broad definition for a KB in the most general sense as fixed collection of K entity nodes, e_k, from which it is possible to compute entity embeddings, $\mathbf{e}_k \in \mathbb{R}^E$. This includes KBs with a typical `(subj, rel, obj)` graph structure, KBs that contain only entity metadata without a graph, and those that combine both a graph and entity metadata, as long as there is some method for embedding the entities in a low dimensional vector space. We also do not make any assumption that the entities are typed. As we show in Sec. 4.1 this flexibility is beneficial, where we compute entity embeddings from WordNet using both the graph and synset definitions, but link directly to Wikipedia pages without a graph by using embeddings computed from the entity description.

We also assume that the KB is accompanied by an entity candidate selector that takes as input some text and returns a list of C potential entity links, each consisting of the start and end indices of the potential mention span and M_m candidate entities in the KG:

$$\begin{aligned}\mathcal{C} = \{\langle(\text{start}_m, \text{end}_m), (e_{m,1}, \ldots, e_{m,M_m})\rangle \mid \\ m \in 1 \ldots C, e_k \in 1 \ldots K\}.\end{aligned}$$

In practice, these are often implemented using precomputed dictionaries (e.g., CrossWikis; Spitkovsky and Chang, 2012), KB specific rules (e.g., a WordNet lemmatizer), or other heuristics (e.g., string match; Mihaylov and Frank, 2018). Ling et al. (2015) showed that incorporating candidate priors into entity linkers can be a powerful signal, so we optionally allow for the candidate selector to return an associated prior probability for each entity candidate. In some cases, it is beneficial to over-generate potential candidates and add a special `NULL` entity to each candidate list, thereby allowing the linker to discriminate between actual links and false positive candidates. In this work, the entity candidate selectors are fixed but their output is passed to a learned context dependent entity linker to disambiguate the candidate mentions.

Finally, by restricting the number of candidate entities to a fixed small number (we use 30), KnowBert's runtime is independent of the size the KB, as it only considers a small subset of all possible entities for any given text. As the candidate selection is rule-based and fixed, it is fast and in our implementation is performed asynchronously on CPU. The only overhead for scaling up the size of the KB is the memory footprint to store the entity embeddings.

3.3 KAR

The Knowledge Attention and Recontextualization component (KAR) is the heart of KnowBert. The KAR accepts as input the contextual representations at a particular layer, $\mathbf{H}_i$, and computes knowledge enhanced representations $\mathbf{H}'_i = \mathrm{KAR}(\mathbf{H}_i, \mathcal{C})$. This is fed into the next pretrained layer, $\mathbf{H}_{i+1} = \mathrm{TransformerBlock}(\mathbf{H}'_i)$, and the remainder of BERT is run as usual.

In this section, we describe the KAR's key components: mention-span representations, retrieval of relevant entity embeddings using an entity linker, update of mention-span embeddings with retrieved information, and recontextualization of entity-span embeddings with word-to-entity-span attention. We describe the KAR for a single KB, but extension to multiple KBs at different layers is straightforward. See Fig. 1 for an overview.

Mention-span representations The KAR starts with the KB entity candidate selector that provides a list of candidate mentions which it uses to compute mention-span representations. $\mathbf{H}_i$ is first pro-

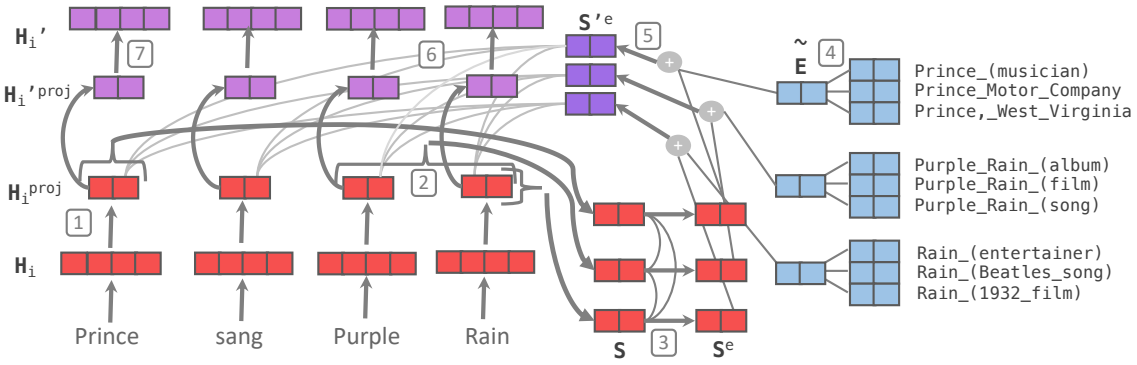

Figure 1: The Knowledge Attention and Recontextualization (KAR) component. BERT word piece representations ($\mathbf{H}_i$) are first projected to $\mathbf{H}_i^{\text{proj}}$ (1), then pooled over candidate mentions spans (2) to compute $\mathbf{S}$, and contextualized into $\mathbf{S}^e$ using mention-span self-attention (3). An integrated entity linker computes weighted average entity embeddings $\tilde{\mathbf{E}}$ (4), which are used to enhance the span representations with knowledge from the KB (5), computing $\mathbf{S}'^e$. Finally, the BERT word piece representations are recontextualized with word-to-entity-span attention (6) and projected back to the BERT dimension (7) resulting in $\mathbf{H}'_i$.

jected to the entity dimension (E, typically 200 or 300, see Sec. 4.1) with a linear projection,

$$\mathbf{H}_i^{\text{proj}} = \mathbf{H}_i \mathbf{W}_1^{\text{proj}} + \mathbf{b}_1^{\text{proj}}. \quad (1)$$

Then, the KAR computes C mention-span representations $\mathbf{s}_m \in \mathbb{R}^E$, one for each candidate mention, by pooling over all word pieces in a mention-span using the self-attentive span pooling from Lee et al. (2017). The mention-spans are stacked into a matrix $\mathbf{S} \in \mathbb{R}^{C \times E}$.

Entity linker The entity linker is responsible for performing entity disambiguation for each potential mention from among the available candidates. It first runs mention-span self-attention to compute

$$\mathbf{S}^e = \text{TransformerBlock}(\mathbf{S}). \quad (2)$$

The span self-attention is identical to the typical transformer layer, exception that the self-attention is between mention-span vectors instead of word piece vectors. This allows KnowBert to incorporate global information into each linking decision so that it can take advantage of entity-entity co-occurrence and resolve which of several overlapping candidate mentions should be linked.[1]

Following Kolitsas et al. (2018), $\mathbf{S}^e$ is used to score each of the candidate entities while incorporating the candidate entity prior from the KB. Each candidate span m has an associated mention-span vector $\mathbf{s}_m^e$ (computed via Eq. 2), M_m candidate entities with embeddings $\mathbf{e}_{mk}$ (from the KB), and prior probabilities p_{mk}. We compute M_m scores using the prior and dot product between the entity-span vectors and entity embeddings,

$$\psi_{mk} = \text{MLP}(p_{mk}, \mathbf{s}_m^e \cdot \mathbf{e}_{mk}), \quad (3)$$

with a two-layer MLP (100 hidden dimensions).

If entity linking (EL) supervision is available, we can compute a loss with the gold entity e_{mg}. The exact form of the loss depends on the KB, and we use both log-likelihood,

$$\mathcal{L}_{\text{EL}} = -\sum_m \log \left(\frac{\exp(\psi_{mg})}{\sum_k \exp(\psi_{mk})} \right), \quad (4)$$

and max-margin,

$$\mathcal{L}_{\text{EL}} = \max(0, \gamma - \psi_{mg}) + \sum_{e_{mk} \neq e_{mg}} \max(0, \gamma + \psi_{mk}), \quad (5)$$

formulations (see Sec. 4.1 for details).

Knowledge enhanced entity-span representations KnowBert next injects the KB entity information into the mention-span representations computed from BERT vectors ($\mathbf{s}_m^e$) to form entity-span representations. For a given span m, we first disregard all candidate entities with score ψ below a fixed threshold, and softmax normalize the remaining scores:

$$\tilde{\psi}_{mk} = \begin{cases} \dfrac{\exp(\psi_{mk})}{\sum_{\psi_{mk} \geq \delta} \exp(\psi_{mk})}, & \psi_{mk} \geq \delta \\ 0, & \psi_{mk} < \delta. \end{cases}$$

[1] We found a small transformer layer with four attention heads and a 1024 feed-forward hidden dimension was sufficient, significantly smaller than each of the layers in BERT. Early experiments demonstrated the effectiveness of this layer with improved entity linking performance.

Then the weighted entity embedding is

$$\tilde{\mathbf{e}}_m = \sum_k \tilde{\psi}_{mk} \mathbf{e}_{mk}.$$

If all entity linking scores are below the threshold δ, we substitute a special `NULL` embedding for $\tilde{\mathbf{e}}_m$. Finally, the entity-span representations are updated with the weighted entity embeddings

$$\mathbf{s}'^e_m = \mathbf{s}^e_m + \tilde{\mathbf{e}}_m, \tag{6}$$

which are packed into a matrix $\mathbf{S}'^e \in \mathbb{R}^{C \times E}$.

Recontextualization After updating the entity-span representations with the weighted entity vectors, KnowBert uses them to recontextualize the word piece representations. This is accomplished using a modified transformer layer that substitutes the multi-headed self-attention with a multi-headed attention between the projected word piece representations and knowledge enhanced entity-span vectors. As introduced by Vaswani et al. (2017), the contextual embeddings $\mathbf{H}_i$ are used for the query, key, and value in multi-headed self-attention. The word-to-entity-span attention in KnowBert substitutes $\mathbf{H}_i^{\text{proj}}$ for the query, and $\mathbf{S}'^e$ for both the key and value:

$$\mathbf{H}_i^{'\text{proj}} = \text{MLP}(\text{MultiHeadAttn}(\mathbf{H}_i^{\text{proj}}, \mathbf{S}'^e, \mathbf{S}'^e)).$$

This allows each word piece to attend to all entity-spans in the context, so that it can propagate entity information over long contexts. After the multi-headed word-to-entity-span attention, we run a position-wise MLP analogous to the standard transformer layer.[2]

Finally, $\mathbf{H}'^{\text{proj}}_i$ is projected back to the BERT dimension with a linear transformation and a residual connection added:

$$\mathbf{H}'_i = \mathbf{H}'^{\text{proj}}_i \mathbf{W}_2^{\text{proj}} + \mathbf{b}_2^{\text{proj}} + \mathbf{H}_i \tag{7}$$

Alignment of BERT and entity vectors As KnowBert does not place any restrictions on the entity embeddings, it is essential to align them with the pretrained BERT contextual representations. To encourage this alignment we initialize $\mathbf{W}_2^{\text{proj}}$ as the matrix inverse of $\mathbf{W}_1^{\text{proj}}$ (Eq. 1). The use of dot product similarity (Eq. 3) and residual connection (Eq. 7) further aligns the entity-span representations with entity embeddings.

[2] As for the multi-headed entity-span self-attention, we found a small transformer layer to be sufficient, with four attention heads and 1024 hidden units in the MLP.

  end
  Initialize $\mathbf{W}_2^{\text{proj}}$ as $(\mathbf{W}_1^{\text{proj}})^{-1}$
  Unfreeze all parameters except entity embeddings
  Minimize $\mathcal{L}_{\text{KnowBert}} = \mathcal{L}_{\text{BERT}} + \sum_{i=1}^{j} \mathcal{L}_{\text{EL}_i}$
end

3.4 Training Procedure

Our training regime incrementally pretrains increasingly larger portions of KnowBert before fine-tuning all trainable parameters in a multitask setting with any available EL supervision. It is similar in spirit to the "chain-thaw" approach in Felbo et al. (2017), and is summarized in Alg. 1.

We assume access to a pretrained BERT model and one or more KBs with their entity candidate selectors. To add the first KB, we begin by pretraining entity embeddings (if not already provided from another source), then freeze them in all subsequent training, including task-specific fine-tuning. If EL supervision is available, it is used to pretrain the KB specific EL parameters, while freezing the remainder of the network. Finally, the entire network is fine-tuned to convergence by minimizing

$$\mathcal{L}_{\text{KnowBert}} = \mathcal{L}_{\text{BERT}} + \mathcal{L}_{\text{EL}}.$$

We apply gradient updates to homogeneous batches randomly sampled from either the unlabeled corpus or EL supervision.

To add a second KB, we repeat the process, inserting it in any layer above the first one. When adding a KB, the BERT layers above it will experience large gradients early in training, as they are subject to the randomly initialized parameters associated with the new KB. They are thus expected to move further from their pretrained values before convergence compared to parameters below the KB. By adding KBs from bottom to top, we

System	PPL	Wikidata MRR	# params. masked LM	# params. KAR	# params. entity embed.	Fwd. / Bwd. time

KnowBert-W+W	**3.5**	**0.31**	110	7.3	406	0.33

Table 1: Comparison of masked LM perplexity, Wikidata probing MRR, and number of parameters (in millions) in the masked LM (word piece embeddings, transformer layers, and output layers), KAR, and entity embeddings for BERT and KnowBert. The table also includes the total time to run one forward and backward pass (in seconds) on a TITAN Xp GPU (12 GB RAM) for a batch of 32 sentence pairs with total length 80 word pieces. Due to memory constraints, the $\text{BERT}_{\text{LARGE}}$ batch is accumulated over two smaller batches.

minimize disruption of the network and decrease the likelihood that training will fail. See Sec. 4.1 for details of where each KB was added.

The entity embeddings and selected candidates contain lexical information (especially in the case of WordNet), that will make the masked LM predictions significantly easier. To prevent leaking into the masked word pieces, we adopt the BERT strategy and replace all entity candidates from the selectors with a special `[MASK]` entity if the candidate mention span overlaps with a masked word piece.[3] This prevents KnowBert from relying on the selected candidates to predict masked word pieces.

4 Experiments

4.1 Experimental Setup

We used the English uncased $\text{BERT}_{\text{BASE}}$ model (Devlin et al., 2019) to train three versions of KnowBert: KnowBert-Wiki, KnowBert-WordNet, and KnowBert-W+W that includes both Wikipedia and WordNet.

KnowBert-Wiki The entity linker in KnowBert-Wiki borrows both the entity candidate selectors and embeddings from Ganea and Hofmann (2017). The candidate selectors and priors are a combination of CrossWikis, a large, precomputed dictionary that combines statistics from Wikipedia and a web corpus (Spitkovsky and Chang, 2012), and the YAGO dictionary (Hoffart et al., 2011). The entity embeddings use a skip-gram like objective (Mikolov et al., 2013b) to learn 300-dimensional embeddings of Wikipedia page titles directly from Wikipedia descriptions without using any explicit graph structure between nodes. As such, nodes in the KB are Wikipedia page titles, e.g., `Prince_(musician)`. Ganea and Hofmann (2017) provide pretrained embeddings for a subset of approximately 470K entities. Early experiments with embeddings derived from Wikidata relations[4] did not improve results.

We used the AIDA-CoNLL dataset (Hoffart et al., 2011) for supervision, adopting the standard splits. This dataset exhaustively annotates entity links for named entities of person, organization and location types, as well as a miscellaneous type. It does not annotate links to common nouns or other Wikipedia pages. At both train and test time, we consider all selected candidate spans and the top 30 entities, to which we add the special `NULL` entity to allow KnowBert to discriminate between actual links and false positive links from the selector. As such, KnowBert models both entity mention detection and disambiguation in an end-to-end manner. Eq. 5 was used as the objective.

KnowBert-WordNet Our WordNet KB combines synset metadata, lemma metadata and the relational graph. To construct the graph, we first extracted all synsets, lemmas, and their relationships from WordNet 3.0 using the `nltk` interface. After disregarding certain symmetric relationships (e.g., we kept the `hypernym` relationship, but removed the inverse `hyponym` relationship) we were left with 28 synset-synset and lemma-lemma relationships. From these, we constructed a graph where each node is either a synset or lemma, and intro-

[3] Following BERT, for 80% of masked word pieces all candidates are replaced with `[MASK]`, 10% are replaced with random candidates and 10% left unmasked.

duced the special `lemma_in_synset` relationship to link synsets and lemmas. The candidate selector uses a rule-based lemmatizer without part-of-speech (POS) information.[5]

Our embeddings combine both the graph and synset glosses (definitions), as early experiments indicated improved perplexity when using both vs. just graph-based embeddings. We used TuckER (Balazevic et al., 2019) to compute 200-dimensional vectors for each synset and lemma using the relationship graph. Then, we extracted the gloss for each synset and used an off-the-shelf state-of-the-art sentence embedding method (Subramanian et al., 2018) to produce 2048-dimensional vectors. These are concatenated to the TuckER embeddings. To reduce the dimensionality for use in KnowBert, the frozen 2248-dimensional embeddings are projected to 200-dimensions with a learned linear transformation.

For supervision, we combined the SemCor word sense disambiguation (WSD) dataset (Miller et al., 1994) with all lemma example usages from WordNet[6] and link directly to synsets. The loss function is Eq. 4. At train time, we did not provide gold lemmas or POS tags, so KnowBert must learn to implicitly model coarse grained POS tags to disambiguate each word. At test time when evaluating we restricted candidate entities to just those matching the gold lemma and POS tag, consistent with the standard WSD evaluation.

Training details To control for the unlabeled corpus, we concatenated Wikipedia and the Books Corpus (Zhu et al., 2015) and followed the data preparation process in BERT with the exception of heavily biasing our dataset to shorter sequences of 128 word pieces for efficiency. Both KnowBert-Wiki and KnowBert-WordNet insert the KB between layers 10 and 11 of the 12-layer $\text{BERT}_{\text{BASE}}$ model. KnowBert-W+W adds the Wikipedia KB between layers 10 and 11, with WordNet between layers 11 and 12. Earlier experiments with KnowBert-WordNet in a lower layer had worse perplexity. We generally followed the fine-tuning procedure in Devlin et al. (2019); see supplemental materials for details.

4.2 Intrinsic Evaluation

Perplexity Table 1 compares masked LM perplexity for KnowBert with $\text{BERT}_{\text{BASE}}$ and $\text{BERT}_{\text{LARGE}}$. To rule out minor differences due to our data preparation, the BERT models are fine-tuned on our training data before being evaluated. Overall, KnowBert improves the masked LM perplexity, with all KnowBert models outperforming $\text{BERT}_{\text{LARGE}}$, despite being derived from $\text{BERT}_{\text{BASE}}$.

Factual recall To test KnowBert's ability to recall facts from the KBs, we extracted 90K tuples from Wikidata (Vrandečić and Krötzsch, 2014) for 17 different relationships such as `companyFoundedBy`. Each tuple was written into natural language such as "Adidas was founded by Adolf Dassler" and used to construct two test instances, one that masks out the subject and one that masks the object. Then, we evaluated whether a model could recover the masked entity by computing the mean reciprocal rank (MRR) of the masked word pieces. Table 1 displays a summary of the results (see supplementary material for results across all relationship types). Overall, KnowBert-Wiki is significantly better at recalling facts than both $\text{BERT}_{\text{BASE}}$ and $\text{BERT}_{\text{LARGE}}$, with KnowBert-W+W better still.

Speed KnowBert is almost as fast as $\text{BERT}_{\text{BASE}}$ (8% slower for KnowBert-Wiki, 32% for KnowBert-W+W) despite adding a large number

[5] https://spacy.io/

[6] To provide a fair evaluation on the WiC dataset which is partially based on the same source, we excluded all WiC train, development and test instances.

KnowBert-W+W	$\text{BERT}_{\text{BASE}}$	89.1

Table 5: Test set F_1 for SemEval 2010 Task 8 relationship extraction. † with MTB pretraining.

of (frozen) parameters in the entity embeddings (Table 1). KnowBert is much faster than $\text{BERT}_{\text{LARGE}}$. By taking advantage of the already high capacity model, the number of trainable parameters added by KnowBert is a fraction of the total parameters in BERT. The faster speed is partially due to the entity parameter efficiency in KnowBert as only as small fraction of parameters in the entity embeddings are used for any given input due to the sparse linker. Our candidate generators consider the top 30 candidates and produce approximately $O(\text{number tokens})$ candidate spans. For a typical 25 token sentence, approximately 2M entity embedding parameters are actually used. In contrast, $\text{BERT}_{\text{LARGE}}$ uses the majority of its 336M parameters for each input.

Integrated EL It is also possible to evaluate the performance of the integrated entity linkers inside KnowBert using diagnostic probes without any further fine-tuning. As these were trained in a multitask setting primarily with raw text, we do not *a priori* expect high performance as they must balance specializing for the entity linking task and learning general purpose representations suitable for language modeling.

Table 2 displays fine-grained WSD F_1 using the evaluation framework from Navigli et al. (2017) and the ALL dataset (combing SemEval 2007, 2013, 2015 and Senseval 2 and 3). By linking to nodes in our WordNet graph and restricting to gold lemmas at test time we can recast the WSD task under our general entity linking framework. The ELMo and BERT baselines use a nearest neighbor approach trained on the SemCor dataset, similar to the evaluation in Melamud et al. (2016), which has previously been shown to be competitive with task-specific architectures (Raganato et al., 2017). As can be seen, KnowBert provides competitive performance, and KnowBert-W+W is able to match the performance of KnowBert-WordNet despite incorporating both Wikipedia and WordNet.

Table 3 reports end-to-end entity linking performance for the AIDA-A and AIDA-B datasets. Here, KnowBert's performance lags behind the current state-of-the-art model from Kolitsas et al. (2018), but still provides strong performance compared to other established systems such as AIDA (Hoffart et al., 2011) and DBpedia Spotlight (Daiber et al., 2013). We believe this is due to the selective annotation in the AIDA data that only annotates named entities. The CrossWikis-based candidate selector used in KnowBert generates candidate mentions for all entities including common nouns from which KnowBert may be learning to extract information, at the detriment of specializing to maximize linking performance for AIDA.

4.3 Downstream Tasks

This section evaluates KnowBert on downstream tasks to validate that the addition of knowledge improves performance on tasks expected to benefit from it. Given the overall superior performance of KnowBert-W+W on the intrinsic evaluations, we focus on it exclusively for evaluation in this section. The main results are included in this section; see the supplementary material for full details.

The baselines we compare against are $\text{BERT}_{\text{BASE}}$, $\text{BERT}_{\text{LARGE}}$, the pre-BERT state of the art, and two contemporaneous papers that add similar types of knowledge to BERT. ERNIE (Zhang et al., 2019) uses TAGME (Ferragina and Scaiella, 2010) to link entities to Wikidata, retrieves the associated entity embeddings, and fuses them into $\text{BERT}_{\text{BASE}}$ by fine-tuning. Soares et al. (2019) learns relationship representations by fine-tuning $\text{BERT}_{\text{LARGE}}$ with large scale "matching the blanks" (MTB) pretraining using entity linked text.

System	Accuracy
ELMo†	57.7
$\text{BERT}_{\text{BASE}}$†	65.4
$\text{BERT}_{\text{LARGE}}$†	65.5
$\text{BERT}_{\text{LARGE}}$††	69.5
KnowBert-W+W	**70.9**

Table 6: Test set results for the WiC dataset (v1.0).
†Pilehvar and Camacho-Collados (2019)
††Wang et al. (2019a)

Relation extraction Our first task is relation extraction using the TACRED (Zhang et al., 2017) and SemEval 2010 Task 8 (Hendrickx et al., 2009) datasets. Systems are given a sentence with marked a subject and object, and asked to predict which of several different relations (or no relation) holds. Following Soares et al. (2019), our KnowBert model uses special entity tokens `[E1]`, `[/E1]`, `[E2]`, `[/E2]` to mark the location of the subject and object in the input sentence, then concatenates the contextual word representations for `[E1]` and `[E2]` to predict the relationship. For TACRED, we also encode the subject and object types with special tokens and concatenate them to the end of the sentence.

For TACRED (Table 4), KnowBert-W+W significantly outperforms the comparable $\text{BERT}_{\text{BASE}}$ systems including ERNIE by 3.5%, improves over $\text{BERT}_{\text{LARGE}}$ by 1.4%, and is able to match the performance of the relationship specific MTB pretraining in Soares et al. (2019). For SemEval 2010 Task 8 (Table 5), KnowBert-W+W F_1 falls between the entity aware $\text{BERT}_{\text{BASE}}$ model from Wang et al. (2019b), and the $\text{BERT}_{\text{LARGE}}$ model from Soares et al. (2019).

Words in Context (WiC) WiC (Pilehvar and Camacho-Collados, 2019) is a challenging task that presents systems with two sentences both containing a word with the same lemma and asks them to determine if they are from the same sense or not. It is designed to test the quality of contextual word representations. We follow standard practice and concatenate both sentences with a `[SEP]` token and fine-tune the `[CLS]` embedding. As shown in Table 6, KnowBert-W+W sets a new state of the art for this task, improving over $\text{BERT}_{\text{LARGE}}$ by 1.4% and reducing the relative gap to 80% human performance by 13.3%.

System	P	R	F_1
UFET	68.8	53.3	60.1
$\text{BERT}_{\text{BASE}}$	76.4	71.0	73.6
ERNIE	78.4	72.9	75.6
KnowBert-W+W	78.6	73.7	**76.1**

Table 7: Test set results for entity typing using the nine general types from (Choi et al., 2018).

Entity typing We also evaluated KnowBert-W+W using the entity typing dataset from Choi et al. (2018). To directly compare to ERNIE, we adopted the evaluation protocol in Zhang et al. (2019) which considers the nine general entity types.[7] Our model marks the location of a target span with the special `[E]` and `[/E]` tokens and uses the representation of the `[E]` token to predict the type. As shown in Table 7, KnowBert-W+W shows an improvement of 0.6% F_1 over ERNIE and 2.5% over $\text{BERT}_{\text{BASE}}$.

5 Conclusion

We have presented an efficient and general method to insert prior knowledge into a deep neural model. Intrinsic evaluations demonstrate that the addition of WordNet and Wikipedia to BERT improves the quality of the masked LM and significantly improves its ability to recall facts. Downstream evaluations demonstrate improvements for relationship extraction, entity typing and word sense disambiguation datasets. Future work will involve incorporating a diverse set of domain specific KBs for specialized NLP applications.

How Contextual are Contextualized Word Representations? Comparing the Geometry of BERT, ELMo, and GPT-2 Embeddings

Kawin Ethayarajh[*]
Stanford University
kawin@stanford.edu

Abstract

Replacing static word embeddings with contextualized word representations has yielded significant improvements on many NLP tasks. However, just how contextual are the contextualized representations produced by models such as ELMo and BERT? Are there infinitely many context-specific representations for each word, or are words essentially assigned one of a finite number of word-sense representations? For one, we find that the contextualized representations of all words are not isotropic in any layer of the contextualizing model. While representations of the same word in different contexts still have a greater cosine similarity than those of two different words, this self-similarity is much lower in upper layers. This suggests that upper layers of contextualizing models produce more context-specific representations, much like how upper layers of LSTMs produce more task-specific representations. In all layers of ELMo, BERT, and GPT-2, on average, less than 5% of the variance in a word's contextualized representations can be explained by a static embedding for that word, providing some justification for the success of contextualized representations.

1 Introduction

The application of deep learning methods to NLP is made possible by representing words as vectors in a low-dimensional continuous space. Traditionally, these word embeddings were *static*: each word had a single vector, regardless of context (Mikolov et al., 2013a; Pennington et al., 2014). This posed several problems, most notably that all senses of a polysemous word had to share the same representation. More recent work, namely deep neural language models such as ELMo (Peters et al., 2018) and BERT (Devlin et al., 2018), have successfully created *contextualized word representations*, word vectors that are sensitive to the context in which they appear. Replacing static embeddings with contextualized representations has yielded significant improvements on a diverse array of NLP tasks, ranging from question-answering to coreference resolution.

The success of contextualized word representations suggests that despite being trained with only a language modelling task, they learn highly transferable and task-agnostic properties of language. In fact, linear probing models trained on frozen contextualized representations can predict linguistic properties of words (e.g., part-of-speech tags) almost as well as state-of-the-art models (Liu et al., 2019a; Hewitt and Manning, 2019). Still, these representations remain poorly understood. For one, just how contextual are these contextualized word representations? Are there infinitely many context-specific representations that BERT and ELMo can assign to each word, or are words essentially assigned one of a finite number of word-sense representations?

We answer this question by studying the geometry of the representation space for each layer of ELMo, BERT, and GPT-2. Our analysis yields some surprising findings:

1. In all layers of all three models, the contextualized word representations of all words are not isotropic: they are not uniformly distributed with respect to direction. Instead, they are *anisotropic*, occupying a narrow cone in the vector space. The anisotropy in GPT-2's last layer is so extreme that two random words will on average have almost perfect cosine similarity! Given that isotropy has both theoretical and empirical benefits for static embeddings (Mu et al., 2018), the extent of anisotropy in contextualized represen-

tations is surprising.

2. Occurrences of the same word in different contexts have non-identical vector representations. Where vector similarity is defined as cosine similarity, these representations are more dissimilar to each other in upper layers. This suggests that, much like how upper layers of LSTMs produce more task-specific representations (Liu et al., 2019a), upper layers of contextualizing models produce more context-specific representations.

3. Context-specificity manifests very differently in ELMo, BERT, and GPT-2. In ELMo, representations of words in the same sentence grow more similar to each other as context-specificity increases in upper layers; in BERT, they become more dissimilar to each other in upper layers but are still more similar than randomly sampled words are on average; in GPT-2, however, words in the same sentence are no more similar to each other than two randomly chosen words.

4. After adjusting for the effect of anisotropy, on average, less than 5% of the variance in a word's contextualized representations can be explained by their first principal component. This holds across all layers of all models. This suggests that contextualized representations do not correspond to a finite number of word-sense representations, and even in the best possible scenario, static embeddings would be a poor replacement for contextualized ones. Still, static embeddings created by taking the first principal component of a word's contextualized representations outperform GloVe and FastText embeddings on many word vector benchmarks.

These insights help justify why the use of contextualized representations has led to such significant improvements on many NLP tasks.

2 Related Work

Static Word Embeddings Skip-gram with negative sampling (SGNS) (Mikolov et al., 2013a) and GloVe (Pennington et al., 2014) are among the best known models for generating static word embeddings. Though they learn embeddings iteratively in practice, it has been proven that in theory, they both implicitly factorize a word-context matrix containing a co-occurrence statistic (Levy and Goldberg, 2014a,b). Because they create a single representation for each word, a notable problem with static word embeddings is that all senses of a polysemous word must share a single vector.

Contextualized Word Representations Given the limitations of static word embeddings, recent work has tried to create context-sensitive word representations. ELMo (Peters et al., 2018), BERT (Devlin et al., 2018), and GPT-2 (Radford et al., 2019) are deep neural language models that are fine-tuned to create models for a wide range of downstream NLP tasks. Their internal representations of words are called *contextualized word representations* because they are a function of the entire input sentence. The success of this approach suggests that these representations capture highly transferable and task-agnostic properties of language (Liu et al., 2019a).

ELMo creates contextualized representations of each token by concatenating the internal states of a 2-layer biLSTM trained on a bidirectional language modelling task (Peters et al., 2018). In contrast, BERT and GPT-2 are bi-directional and uni-directional transformer-based language models respectively. Each transformer layer of 12-layer BERT (base, cased) and 12-layer GPT-2 creates a contextualized representation of each token by attending to different parts of the input sentence (Devlin et al., 2018; Radford et al., 2019). BERT – and subsequent iterations on BERT (Liu et al., 2019b; Yang et al., 2019) – have achieved state-of-the-art performance on various downstream NLP tasks, ranging from question-answering to sentiment analysis.

Probing Tasks Prior analysis of contextualized word representations has largely been restricted to probing tasks (Tenney et al., 2019; Hewitt and Manning, 2019). This involves training linear models to predict syntactic (e.g., part-of-speech tag) and semantic (e.g., word relation) properties of words. Probing models are based on the premise that if a simple linear model can be trained to accurately predict a linguistic property, then the representations implicitly encode this information to begin with. While these analyses have found that contextualized representations encode semantic and syntactic information, they cannot answer *how contextual* these representations are, and to

what extent they can be replaced with static word embeddings, if at all. Our work in this paper is thus markedly different from most dissections of contextualized representations. It is more similar to Mimno and Thompson (2017), which studied the geometry of static word embedding spaces.

3 Approach

3.1 Contextualizing Models

The contextualizing models we study in this paper are ELMo, BERT, and GPT-2[1]. We choose the base cased version of BERT because it is most comparable to GPT-2 with respect to number of layers and dimensionality. The models we work with are all pre-trained on their respective language modelling tasks. Although ELMo, BERT, and GPT-2 have 2, 12, and 12 hidden layers respectively, we also include the input layer of each contextualizing model as its 0^{th} layer. This is because the 0^{th} layer is not contextualized, making it a useful baseline against which to compare the contextualization done by subsequent layers.

3.2 Data

To analyze contextualized word representations, we need input sentences to feed into our pre-trained models. Our input data come from the SemEval Semantic Textual Similarity tasks from years 2012 - 2016 (Agirre et al., 2012, 2013, 2014, 2015). We use these datasets because they contain sentences in which the same words appear in different contexts. For example, the word 'dog' appears in *"A panda dog is running on the road."* and *"A dog is trying to get bacon off his back."* If a model generated the same representation for 'dog' in both these sentences, we could infer that there was no contextualization; conversely, if the two representations were different, we could infer that they were contextualized to some extent. Using these datasets, we map words to the list of sentences they appear in and their index within these sentences. We do not consider words that appear in less than 5 unique contexts in our analysis.

3.3 Measures of Contextuality

We measure how contextual a word representation is using three different metrics: *self-similarity*, *intra-sentence similarity*, and *maximum explainable variance*.

[1]We use the pretrained models provided in an earlier version of the PyTorch-Transformers library.

Definition 1 Let w be a word that appears in sentences $\{s_1,...,s_n\}$ at indices $\{i_1,...,i_n\}$ respectively, such that $w = s_1[i_1] = ... = s_n[i_n]$. Let $f_\ell(s,i)$ be a function that maps $s[i]$ to its representation in layer ℓ of model f. The *self similarity* of w in layer ℓ is

$$SelfSim_\ell(w) = \frac{1}{n^2-n}\sum_j\sum_{k\neq j}\cos(f_\ell(s_j,i_j),f_\ell(s_k,i_k)) \tag{1}$$

where cos denotes the cosine similarity. In other words, the *self-similarity* of a word w in layer ℓ is the average cosine similarity between its contextualized representations across its n unique contexts. If layer ℓ does not contextualize the representations at all, then $SelfSim_\ell(w) = 1$ (i.e., the representations are identical across all contexts). The more contextualized the representations are for w, the lower we would expect its self-similarity to be.

Definition 2 Let s be a sentence that is a sequence $\langle w_1,...,w_n\rangle$ of n words. Let $f_\ell(s,i)$ be a function that maps $s[i]$ to its representation in layer ℓ of model f. The *intra-sentence similarity* of s in layer ℓ is

$$\begin{aligned} IntraSim_\ell(s) &= \frac{1}{n}\sum_i\cos(\vec{s}_\ell, f_\ell(s,i)) \\ \text{where } \vec{s}_\ell &= \frac{1}{n}\sum_i f_\ell(s,i) \end{aligned} \tag{2}$$

Put more simply, the *intra-sentence similarity* of a sentence is the average cosine similarity between its word representations and the sentence vector, which is just the mean of those word vectors. This measure captures how context-specificity manifests in the vector space. For example, if both $IntraSim_\ell(s)$ and $SelfSim_\ell(w)$ are low $\forall\, w \in s$, then the model contextualizes words in that layer by giving each one a context-specific representation that is still distinct from all other word representations in the sentence. If $IntraSim_\ell(s)$ is high but $SelfSim_\ell(w)$ is low, this suggests a less nuanced contextualization, where words in a sentence are contextualized simply by making their representations converge in vector space.

Definition 3 Let w be a word that appears in sentences $\{s_1,...,s_n\}$ at indices $\{i_1,...,i_n\}$ respectively, such that $w = s_1[i_1] = ... = s_n[i_n]$. Let $f_\ell(s,i)$ be a function that maps $s[i]$ to its representation in layer ℓ of model f. Where $[f_\ell(s_1,i_1)...f_\ell(s_n,i_n)]$ is the *occurrence matrix* of w and $\sigma_1...\sigma_m$ are the

first m singular values of this matrix, the *maximum explainable variance* is

$$MEV_\ell(w) = \frac{\sigma_1^2}{\sum_i \sigma_i^2} \tag{3}$$

$MEV_\ell(w)$ is the proportion of variance in w's contextualized representations for a given layer that can be explained by their first principal component. It gives us an upper bound on how well a static embedding could replace a word's contextualized representations. The closer $MEV_\ell(w)$ is to 0, the poorer a replacement a static embedding would be; if $MEV_\ell(w) = 1$, then a static embedding would be a perfect replacement for the contextualized representations.

3.4 Adjusting for Anisotropy

It is important to consider isotropy (or the lack thereof) when discussing contextuality. For example, if word vectors were perfectly isotropic (i.e., directionally uniform), then $SelfSim_\ell(w) = 0.95$ would suggest that w's representations were poorly contextualized. However, consider the scenario where word vectors are so anisotropic that any two words have on average a cosine similarity of 0.99. Then $SelfSim_\ell(w) = 0.95$ would actually suggest the opposite – that w's representations were well contextualized. This is because representations of w in different contexts would on average be more dissimilar to each other than two randomly chosen words.

To adjust for the effect of anisotropy, we use three *anisotropic baselines*, one for each of our contextuality measures. For self-similarity and intra-sentence similarity, the baseline is the average cosine similarity between the representations of uniformly randomly sampled words from different contexts. The more anisotropic the word representations are in a given layer, the closer this baseline is to 1. For maximum explainable variance (MEV), the baseline is the proportion of variance in uniformly randomly sampled word representations that is explained by their first principal component. The more anisotropic the representations in a given layer, the closer this baseline is to 1: even for a random assortment of words, the principal component would be able to explain a large proportion of the variance.

Since contextuality measures are calculated for each layer of a contextualizing model, we calculate separate baselines for each layer as well. We then subtract from each measure its respective baseline to get the *anisotropy-adjusted contexuality measure*. For example, the anisotropy-adjusted self-similarity is

$$\begin{aligned} Baseline(f_\ell) &= \mathbb{E}_{x,y\sim U(\mathcal{O})}\left[\cos(f_\ell(x), f_\ell(y))\right] \\ SelfSim^*_\ell(w) &= SelfSim_\ell(w) - Baseline(f_\ell) \end{aligned} \tag{4}$$

where $\mathcal{O}$ is the set of all word occurrences and $f_\ell(\cdot)$ maps a word occurrence to its representation in layer ℓ of model f. Unless otherwise stated, references to contextuality measures in the rest of the paper refer to the anisotropy-adjusted measures, where both the raw measure and baseline are estimated with 1K uniformly randomly sampled word representations.

4 Findings

4.1 (An)Isotropy

Contextualized representations are anisotropic in all non-input layers. If word representations from a particular layer were isotropic (i.e., directionally uniform), then the average cosine similarity between uniformly randomly sampled words would be 0 (Arora et al., 2017). The closer this average is to 1, the more anisotropic the representations. The geometric interpretation of anisotropy is that the word representations all occupy a narrow cone in the vector space rather than being uniform in all directions; the greater the anisotropy, the narrower this cone (Mimno and Thompson, 2017). As seen in Figure 1, this implies that in almost all layers of BERT, ELMo and GPT-2, the representations of all words occupy a narrow cone in the vector space. The only exception is ELMo's input layer, which produces static character-level embeddings without using contextual or even positional information (Peters et al., 2018). It should be noted that not all static embeddings are necessarily isotropic, however; Mimno and Thompson (2017) found that skipgram embeddings, which are also static, are not isotropic.

Contextualized representations are generally more anisotropic in higher layers. As seen in Figure 1, for GPT-2, the average cosine similarity between uniformly randomly words is roughly 0.6 in layers 2 through 8 but increases exponentially from layers 8 through 12. In fact, word representations in GPT-2's last layer are so anisotropic that any two words have on average an almost perfect cosine similarity! This pattern holds for BERT and

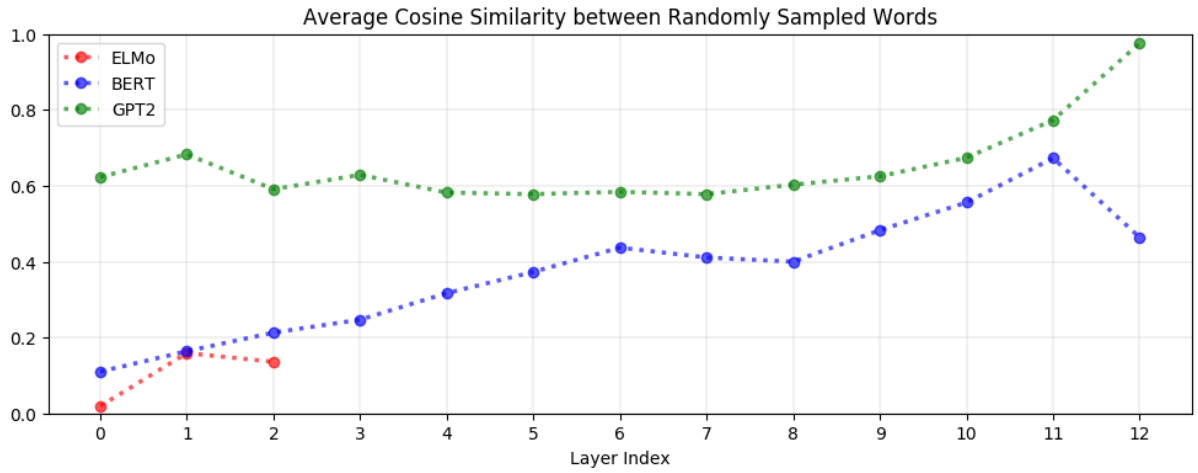

Figure 1: In almost all layers of BERT, ELMo, and GPT-2, the word representations are anisotropic (i.e., not directionally uniform): the average cosine similarity between uniformly randomly sampled words is non-zero. The one exception is ELMo's input layer; this is not surprising given that it generates character-level embeddings without using context. Representations in higher layers are generally more anisotropic than those in lower ones.

ELMo as well, though there are exceptions: for example, the anisotropy in BERT's penultimate layer is much higher than in its final layer.

Isotropy has both theoretical and empirical benefits for static word embeddings. In theory, it allows for stronger "self-normalization" during training (Arora et al., 2017), and in practice, subtracting the mean vector from static embeddings leads to improvements on several downstream NLP tasks (Mu et al., 2018). Thus the extreme degree of anisotropy seen in contextualized word representations – particularly in higher layers – is surprising. As seen in Figure 1, for all three models, the contextualized hidden layer representations are almost all more anisotropic than the input layer representations, which do not incorporate context. This suggests that high anisotropy is inherent to, or least a by-product of, the process of contextualization.

4.2 Context-Specificity

Contextualized word representations are more context-specific in higher layers. Recall from Definition 1 that the self-similarity of a word, in a given layer of a given model, is the average cosine similarity between its representations in different contexts, adjusted for anisotropy. If the self-similarity is 1, then the representations are not context-specific at all; if the self-similarity is 0, that the representations are maximally context-specific. In Figure 2, we plot the average self-similarity of uniformly randomly sampled words in each layer of BERT, ELMo, and GPT-2. For example, the self-similarity is 1.0 in ELMo's input layer because representations in that layer are static character-level embeddings.

In all three models, the higher the layer, the lower the self-similarity is on average. In other words, the higher the layer, the more context-specific the contextualized representations. This finding makes intuitive sense. In image classification models, lower layers recognize more generic features such as edges while upper layers recognize more class-specific features (Yosinski et al., 2014). Similarly, upper layers of LSTMs trained on NLP tasks learn more task-specific representations (Liu et al., 2019a). Therefore, it follows that upper layers of neural language models learn more context-specific representations, so as to predict the next word for a given context more accurately. Of all three models, representations in GPT-2 are the most context-specific, with those in GPT-2's last layer being almost maximally context-specific.

Stopwords (e.g., *'the', 'of', 'to'*) have among the most context-specific representations. Across all layers, stopwords have among the lowest self-similarity of all words, implying that their contextualized representations are among the most context-specific. For example, the words with the lowest average self-similarity across ELMo's layers are *'and', 'of', ''s', 'the'*, and *'to'*. This is relatively surprising, given that these words are not polysemous. This finding suggests that the variety

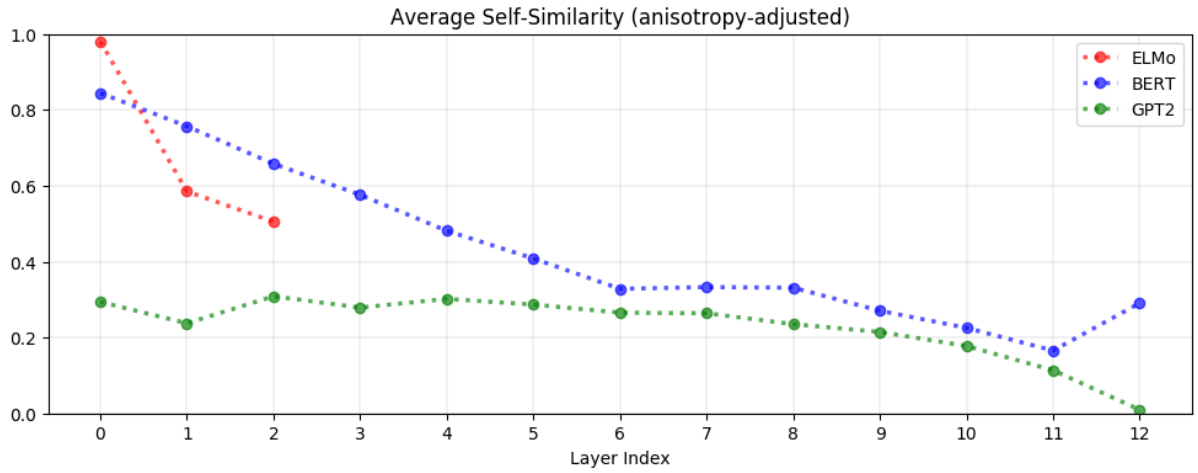

Figure 2: The average cosine similarity between representations of the same word in different contexts is called the word's *self-similarity* (see Definition 1). Above, we plot the average self-similarity of uniformly randomly sampled words after adjusting for anisotropy (see section 3.4). In all three models, the higher the layer, the lower the self-similarity, suggesting that contextualized word representations are more context-specific in higher layers.

of contexts a word appears in, rather than its inherent polysemy, is what drives variation in its contextualized representations. This answers one of the questions we posed in the introduction: ELMo, BERT, and GPT-2 are not simply assigning one of a finite number of word-sense representations to each word; otherwise, there would not be so much variation in the representations of words with so few word senses.

Context-specificity manifests very differently in ELMo, BERT, and GPT-2. As noted earlier, contextualized representations are more context-specific in upper layers of ELMo, BERT, and GPT-2. However, how does this increased context-specificity manifest in the vector space? Do word representations in the same sentence converge to a single point, or do they remain distinct from one another while still being distinct from their representations in other contexts? To answer this question, we can measure a sentence's intra-sentence similarity. Recall from Definition 2 that the intra-sentence similarity of a sentence, in a given layer of a given model, is the average cosine similarity between each of its word representations and their mean, adjusted for anisotropy. In Figure 3, we plot the average intra-sentence similarity of 500 uniformly randomly sampled sentences.

In ELMo, words in the same sentence are more similar to one another in upper layers. As word representations in a sentence become more context-specific in upper layers, the intra-sentence similarity also rises. This suggests that, in practice, ELMo ends up extending the intuition behind Firth's (1957) distributional hypothesis to the sentence level: that because words in the same sentence share the same context, their contextualized representations should also be similar.

In BERT, words in the same sentence are more dissimilar to one another in upper layers. As word representations in a sentence become more context-specific in upper layers, they drift away from one another, although there are exceptions (see layer 12 in Figure 3). However, in all layers, the average similarity between words in the same sentence is still greater than the average similarity between randomly chosen words (i.e., the anisotropy baseline). This suggests a more nuanced contextualization than in ELMo, with BERT recognizing that although the surrounding sentence informs a word's meaning, two words in the same sentence do not necessarily have a similar meaning because they share the same context.

In GPT-2, word representations in the same sentence are no more similar to each other than randomly sampled words. On average, the unadjusted intra-sentence similarity is roughly the same as the anisotropic baseline, so as seen in Figure 3, the anisotropy-adjusted intra-sentence similarity is close to 0 in most layers of GPT-2. In fact, the intra-sentence similarity is highest in the input layer, which does not contextualize words at all. This is in contrast to ELMo and BERT, where the

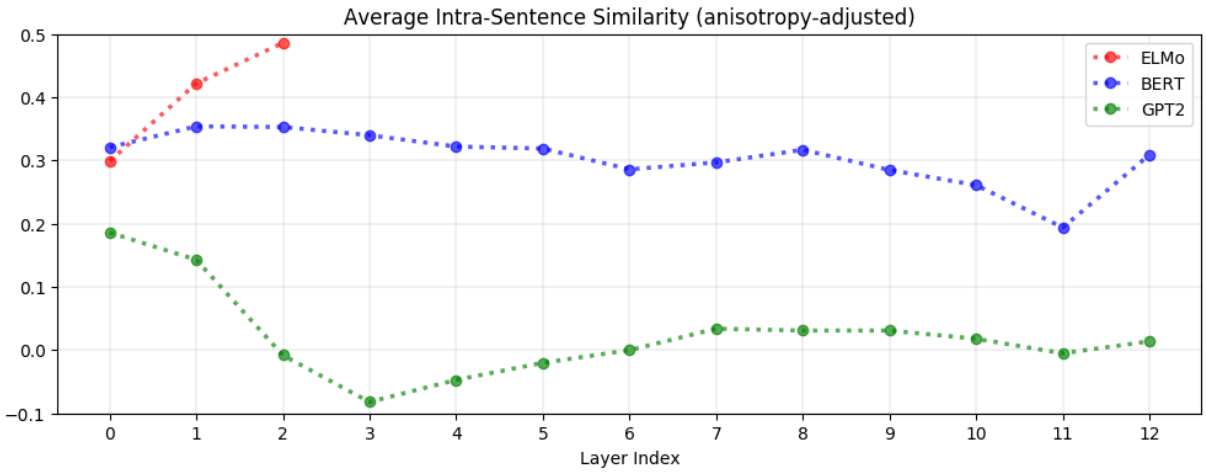

Figure 3: The *intra-sentence similarity* is the average cosine similarity between each word representation in a sentence and their mean (see Definition 2). Above, we plot the average intra-sentence similarity of uniformly randomly sampled sentences, adjusted for anisotropy. This statistic reflects how context-specificity manifests in the representation space, and as seen above, it manifests very differently for ELMo, BERT, and GPT-2.

average intra-sentence similarity is above 0.20 for all but one layer.

As noted earlier when discussing BERT, this behavior still makes intuitive sense: two words in the same sentence do not necessarily have a similar meaning simply because they share the same context. The success of GPT-2 suggests that unlike anisotropy, which accompanies context-specificity in all three models, a high intra-sentence similarity is not inherent to contextualization. Words in the same sentence can have highly contextualized representations without those representations being any more similar to each other than two random word representations. It is unclear, however, whether these differences in intra-sentence similarity can be traced back to differences in model architecture; we leave this question as future work.

4.3 Static vs. Contextualized

On average, less than 5% of the variance in a word's contextualized representations can be explained by a static embedding. Recall from Definition 3 that the *maximum explainable variance* (MEV) of a word, for a given layer of a given model, is the proportion of variance in its contextualized representations that can be explained by their first principal component. This gives us an upper bound on how well a static embedding could replace a word's contextualized representations. Because contextualized representations are anisotropic (see section 4.1), much of the variation *across all words* can be explained by a single vector. We adjust for anisotropy by calculating the proportion of variance explained by the first principal component of uniformly randomly sampled word representations and subtracting this proportion from the raw MEV. In Figure 4, we plot the average anisotropy-adjusted MEV across uniformly randomly sampled words.

In no layer of ELMo, BERT, or GPT-2 can more than 5% of the variance in a word's contextualized representations be explained by a static embedding, on average. Though not visible in Figure 4, the raw MEV of many words is actually below the anisotropy baseline: i.e., a greater proportion of the variance across all words can be explained by a single vector than can the variance across all representations of a single word. Note that the 5% threshold represents the best-case scenario, and there is no theoretical guarantee that a word vector obtained using GloVe, for example, would be similar to the static embedding that maximizes MEV. This suggests that contextualizing models are not simply assigning one of a finite number of word-sense representations to each word – otherwise, the proportion of variance explained would be much higher. Even the average raw MEV is below 5% for all layers of ELMo and BERT; only for GPT-2 is the raw MEV non-negligible, being around 30% on average for layers 2 to 11 due to extremely high anisotropy.

Principal components of contextualized representations in lower layers outperform GloVe and FastText on many benchmarks. As noted

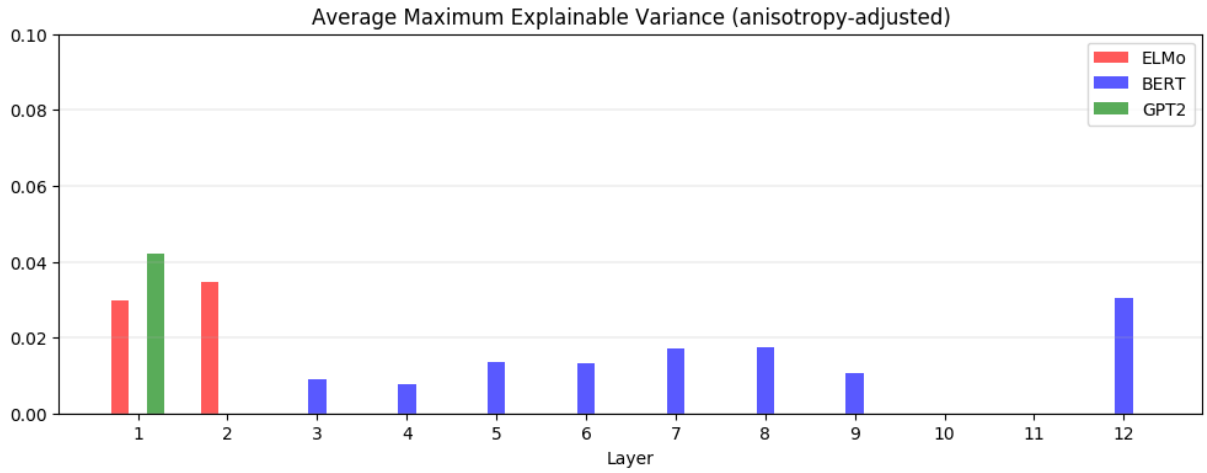

Figure 4: The *maximum explainable variance* (MEV) of a word is the proportion of variance in its contextualized representations that can be explained by their first principal component (see Definition 3). Above, we plot the average MEV of uniformly randomly sampled words after adjusting for anisotropy. In no layer of any model can more than 5% of the variance in a word's contextualized representations be explained by a static embedding.

Table 1: The performance of various static embeddings on word embedding benchmark tasks. The best result for each task is in bold. For the contextualizing models (ELMo, BERT, GPT-2), we use the first principal component of a word's contextualized representations in a given layer as its static embedding. The static embeddings created using ELMo and BERT's contextualized representations often outperform GloVe and FastText vectors.

earlier, we can create static embeddings for each word by taking the first principal component (PC) of its contextualized representations in a given layer. In Table 1, we plot the performance of these *PC static embeddings* on several benchmark tasks[2]. These tasks cover semantic similarity, analogy solving, and concept categorization: SimLex999 (Hill et al., 2015), MEN (Bruni et al., 2014), WS353 (Finkelstein et al., 2002), RW (Luong et al., 2013), SemEval-2012 (Jurgens et al., 2012), Google analogy solving (Mikolov et al., 2013a) MSR analogy solving (Mikolov et al., 2013b), BLESS (Baroni and Lenci, 2011) and AP (Almuhareb and Poesio, 2004). We leave out layers 3 - 10 in Table 1 because their performance is between those of Layers 2 and 11.

The best-performing PC static embeddings belong to the first layer of BERT, although those from the other layers of BERT and ELMo also outperform GloVe and FastText on most benchmarks. For all three contextualizing models, PC static embeddings created from lower layers are more effective those created from upper layers. Those created using GPT-2 also perform markedly worse than their counterparts from ELMo and BERT. Given that upper layers are much more context-specific than lower layers, and given that GPT-2's representations are more context-specific than ELMo and BERT's (see Figure 2), this suggests that the PCs of highly context-specific representations are less effective on traditional benchmarks. Those derived from less context-specific represen-

[2]The Word Embeddings Benchmarks package was used for evaluation.

tations, such as those from Layer 1 of BERT, are much more effective.

5 Future Work

Our findings offer some new directions for future work. For one, as noted earlier in the paper, Mu et al. (2018) found that making static embeddings more isotropic – by subtracting their mean from each embedding – leads to surprisingly large improvements in performance on downstream tasks. Given that isotropy has benefits for static embeddings, it may also have benefits for contextualized word representations, although the latter have already yielded significant improvements despite being highly anisotropic. Therefore, adding an anisotropy penalty to the language modelling objective – to encourage the contextualized representations to be more isotropic – may yield even better results.

Another direction for future work is generating static word representations from contextualized ones. While the latter offer superior performance, there are often challenges to deploying large models such as BERT in production, both with respect to memory and run-time. In contrast, static representations are much easier to deploy. Our work in section 4.3 suggests that not only it is possible to extract static representations from contextualizing models, but that these extracted vectors often perform much better on a diverse array of tasks compared to traditional static embeddings such as GloVe and FastText. This may be a means of extracting some use from contextualizing models without incurring the full cost of using them in production.

6 Conclusion

In this paper, we investigated how contextual contextualized word representations truly are. For one, we found that upper layers of ELMo, BERT, and GPT-2 produce more context-specific representations than lower layers. This increased context-specificity is always accompanied by increased anisotropy. However, context-specificity also manifests differently across the three models; the anisotropy-adjusted similarity between words in the same sentence is highest in ELMo but almost non-existent in GPT-2. We ultimately found that after adjusting for anisotropy, on average, less than 5% of the variance in a word's contextualized representations could be explained by a static embedding. This means that even in the best-case scenario, in all layers of all models, static word embeddings would be a poor replacement for contextualized ones. These insights help explain some of the remarkable success that contextualized representations have had on a diverse array of NLP tasks.

Abstract

Word embeddings are increasingly used for the automatic detection of semantic change; yet, a robust evaluation and systematic comparison of the choices involved has been lacking. We propose a new evaluation framework for semantic change detection and find that (i) using the whole time series is preferable over only comparing between the first and last time points; (ii) independently trained and aligned embeddings perform better than continuously trained embeddings for long time periods; and (iii) that the reference point for comparison matters. We also present an analysis of the changes detected on a large Twitter dataset spanning 5.5 years.

1 Introduction

Semantic change, i.e., the change in the meanings of words, is inherent in language. A new meaning for a word can be added to the original one, become more or less prevalent, or even replace a former meaning (see Koch, 2016). An example is *lit*, which has gained a new sense of 'exciting' or 'awesome', via the extension of its long-established use as slang for 'intoxicated' to describe the vibrant environment in which acts of becoming intoxicated often occur.[1]

Automatically measuring semantic change can discover changes that would not be apparent from manual inspection. It can also facilitate the investigation of mechanisms driving semantic changes, e.g., how these changes are affected by language-internal and social factors. Moreover, there are direct benefits to applications, such as the detection of meaning shifts in polarized words to update sentiment lexicons and the detection of emerging word meanings to update dictionaries.

Word embeddings are increasingly used for automatic semantic change detection (Kutuzov et al., 2018). Words are mapped to low-dimensional vectors, and the semantic change of a word is then measured by comparing its vectors across time periods. Although word embeddings have emerged as one of the most popular approaches to measuring semantic change, researchers are faced with various decisions, including whether to train embeddings independently or continuously, which metric to use to measure change between two time periods, and which ranking approach to use for comparing semantic change candidates.

A major challenge in developing semantic change detection systems is obtaining ground truth data (Kutuzov et al., 2018), which has so far prevented a systematic evaluation of different approaches. Many studies rely on hand-picked examples (e.g., Wijaya and Yeniterzi, 2011; Rodda et al., 2017) or human judgements (e.g., Tredici et al., 2018). Some studies have performed evaluations based on dictionary data (e.g., Cook et al., 2014; Basile and McGillivray, 2018), manual annotation of dictionary senses in corpora (McGillivray et al., 2019), and manual annotation of word types (Kenter et al., 2015), but this approach is not well-suited for recent, yet-to-be-recorded changes.

In this paper, we present a new framework to evaluate semantic change detection systems (Section 5.1). We model multiple semantic change scenarios and compare the impact of different choices that are typical when using word embeddings to analyse semantic change (Section 5.2). Our framework is not specific to the use of word embeddings and can also support the evaluation of other approaches not considered in this paper.[2] We

then apply the approaches to 5.5 years of Twitter data and provide an in-depth analysis of the top-ranked semantic change candidates (Section 6).

2 Related Work

There has been increasing interest in automatic semantic change detection (Tang, 2018; Kutuzov et al., 2018), using methods ranging from neural models to Bayesian learning (e.g., Frermann and Lapata, 2016), Temporal Random Indexing (e.g., Basile and McGillivray, 2018) and dynamic topic modelling (e.g., Blei and Lafferty, 2006). Word embeddings have been especially popular (e.g., Dubossarsky et al., 2017; Hamilton et al., 2016b), and recently Bamler and Mandt (2017) and Rudolph and Blei (2018) explored dynamic embeddings for semantic change detection by training a joint model over all time periods.

Most previous work analysed corpora spanning long time periods (e.g., a few centuries), such as the Google Books Ngrams corpus and the Corpus of Historical American English (e.g., Hamilton et al., 2016b). Recently short-term semantic changes have been studied, for example in Amazon Reviews (Kulkarni et al., 2015), scientific papers (Rudolph and Blei, 2018), news articles (Tang et al., 2016; Yao et al., 2018), and the UK Web Archive (Basile and McGillivray, 2018).

In this paper, we focus on social media: in particular, on Twitter. Semantic change in social media has only been lightly explored, with studies on Twitter (Kulkarni et al., 2015), the VKontake social network (Stewart et al., 2017), and Reddit (Tredici et al., 2018). In comparison to these studies, our data covers a longer time period and our evaluation more deeply explores the various choices involved in semantic change detection.

Much of the previous work on semantic change discovery has relied on qualitative evaluations of small samples from the output, case studies of a few well-known historical changes (e.g., Kim et al., 2014; Hamilton et al., 2016a,b; Stewart et al., 2017), or attested changes extracted from dictionaries (e.g., Rohrdantz et al., 2011; Cook et al., 2014; Basile and McGillivray, 2018). Some evaluations have been based on related tasks for which performance is expected to correlate, such as classifying the time period a text snippet belongs to (Mihalcea and Nastase, 2012) or predicting real-world events (Kutuzov et al., 2017).

Here we look for meaning changes over a short, recent time period. There is little existing literature on words that have undergone meaning change within the relevant time-frame, and language on social media is not always fully reflected in general language dictionaries. Moreover, even if we were able to obtain a substantial list of attested meaning changes, a system might still discover other valid meaning change candidates. Unfortunately, determining the validity of semantic change candidates is time-consuming, labour-intensive, and subjective; so, building on prior approaches (e.g., Kulkarni et al., 2015; Rosenfeld and Erk, 2018; Nguyen and Eisenstein, 2017), we introduce a new synthetic evaluation framework for semantic change detection.

Synthetic evaluation is especially important for short, recent time periods given the lack of other resources for evaluation, but it is also valuable for longer periods to detect hitherto unknown changes. Moreover, phenomena like seasonal trends are more likely to interfere with semantic change detection for short time periods, making this a challenging use case for semantic change detection. At the same time, it is an important use case in order to advance semantic change detection for contemporary data to be used to update lexicons, sentiment/polarity ratings, and other language resources.

3 Data

We collected tweets from Twitter's 'statuses/sample' streaming API endpoint from January 1, 2012, to June 30, 2017. There are a few minor gaps in our data due to occasional data collection issues. Most are a few minutes or at most a day, but one gap spans January and February 2015. Overall, our dataset consists of over 7 billion tweets sent during 1,889 days.

We use the Compact Language Detector version 2 (CLDv2),[3] following guidance from Graham et al. (2014), and we discard any tweets for which CLD detects less than 90% of the text to be in English, resulting in roughly 2.5 billion tweets. The remaining tweets are then lowercased, and usernames, urls, and non-alphanumeric characters (except emoji and hashtags) are removed. The text is then tokenized on whitespace. Digit-only tokens are replaced with '<NUM>'. Finally, we discard tweets that are duplicated within a given month, as tweets which are re-tweeted or copied verba-

[3] https://github.com/CLD2Owners/cld2

tim many times are not independent language samples and may exert undue influence on embeddings (Mikolov et al., 2018). Our final dataset consists of 1,696,142,020 tweets and 20,273,497,107 tokens.

4 Methods

Following the approach introduced by Kim et al. (2014) and adopted by Hamilton et al. (2016b) and others, we divide our dataset into discrete time periods, and for each time period t we compute word embeddings, representing each word w by a d-dimensional vector. We then compare the embeddings between different time periods to measure the semantic change of words. We use monthly bins, but the approach is applicable to time periods of any length, provided there is sufficient data in each bin to train quality embeddings.

4.1 Training Word Embeddings

We train word embeddings using gensim's (Řehůřek and Sojka, 2010) implementation of the continuous bag of words (CBOW; Mikolov et al., 2013) model.[4] Two evaluation tasks (word similarity using the dataset Wordsim353[5] and word analogy using the word test dataset[6]) were used to tune four hyperparameters, resulting in 200 dimensions, a window size of 10, 15 iterations, and a minimum frequency of 500 (per time-step). For all other hyperparameters we use gensim's default values.

4.2 Comparable Embeddings

To compare embeddings for a word between two time-points, the embeddings need to be in the same coordinate axes. We experiment with three approaches: (1) Training continuously by initializing the embeddings for a given time-step t with the embeddings trained at the previous time-step $t-1$ (e.g., Kim et al., 2014); (2) Training embeddings for each time-step independently and post-hoc aligning them (e.g., Hamilton et al., 2016b; Kulkarni et al., 2015) using orthogonal Procrustes (as used by Hamilton et al., 2016b); and (3) combining continuous training and post-hoc alignment (as in Stewart et al., 2017).

4.3 Measuring Semantic Change

We compare two measures for quantifying a word's semantic change between two time points. The first is the cosine distance, a common approach in previous work (Hamilton et al., 2016b; Stewart et al., 2017; Dubossarsky et al., 2017; Kim et al., 2014). The second measure, introduced by Hamilton et al. (2016a), is based on comparing the neighbourhoods of the embeddings. For each time-step t, we first find the ordered set of word w's k nearest neighbours, based on cosine similarity. Following Hamilton et al. (2016a), we set $k = 25$. For any two time-steps, we then take the union S of the two nearest neighbour sets and create a second-order vector v_t where each entry $v_t^{(i)}$ contains the cosine similarity of target word w to neighbouring word $S^{(i)}$ at time t. We then measure the cosine distance between these two second-order vectors.

4.4 Ranking Semantic Change Candidates

Our goal is not only to measure semantic changes for pre-selected words, but to identify which words out of the entire vocabulary have undergone the greatest or most significant semantic change. We compare several approaches to generating ranked lists of the 'most changed' words. The first only measures the change between two time-steps. The remaining approaches consider the whole time series. For the approaches that use the whole time-series, we limit the semantic change candidates to words that occur at least 500 times in at least 75% of the time-steps, simply condensing a word's time-series if there are gaps.

Two-step approach We first measure each word's semantic change between just two pre-selected time-steps (in this study, the first and final time-steps). This simple approach has been used in previous work, such as Kim et al. (2014).

Change-point detection Following Kulkarni et al. (2015), we choose one time-step t_0 as a reference and compute semantic change scores for each word with respect to t_0 at every other time-step t_i. Then, for each word w and each time-step t_i, we compute a *mean-shift* score by partitioning w's time series of semantic change scores at t_i, and

[4] We only report results using CBOW in this paper. We found similar trends when using the skip-gram model, which has been used in previous works on semantic change (e.g., Kim et al., 2014; Kulkarni et al., 2015; Hamilton et al., 2016b; Stewart et al., 2017; Tredici et al., 2018).

[5] http://www.cs.technion.ac.il/~gabr/resources/data/wordsim353/

[6] http://www.fit.vutbr.cz/~imikolov/rnnlm/word-test.v1.txt

calculating the difference between the means of the scores in the two partitions. Following Kulkarni et al. (2015), we use Monte Carlo permutation tests to estimate the statistical significance of mean-shift scores, and take the time-step with the lowest estimated p-value as the change point. Words are first sorted in descending order of the mean-shift scores of their estimated change points and then in ascending order of their p-values.

Kulkarni et al. standardized each word's cosine score for a given time-step relative to the mean score across all words at that time-step. This is meant to help control for corpus artefacts, e.g., shifting sampling biases over time, but its impact has not been demonstrated yet. We compare the results of ranking words without standardization (*raw* scores) and with standardization (z scores).

Global trend detection We also compare three approaches to detect global trends in the same time series of semantic change scores as the change point detection methods. The first approach is fitting a linear regression model $d_i = \alpha + \beta t_i + \epsilon_i$, where d_i is semantic change distance scores, t_i is time periods $\{1, ..., n\}$, and ϵ_i is error. We rank the words based on their absolute β values (slopes), which gives the semantic change per time period under the assumption of a linear relationship.

We also experiment with two correlation measures: Pearson's (r) and Kendall's rank (τ) correlation coefficients. In contrast to linear regression and Pearson's correlation coefficient, Kendall's tau is non-parametric and resistant to outliers (Kendall, 1948). It is therefore often used for measuring trends in time series and change point detection (Quessy et al., 2013). We rank the words based on the absolute values of τ and r.

5 Synthetic Evaluation

To systematically compare the different methodological choices we introduce a new synthetic evaluation framework. We create seven schemas for how a word's distributional statistics may change. Three of these model scenarios in which a semantic change occurs, but crucially the remaining four model scenarios that we would *not* wish to classify as semantic change. Our framework builds on previous approaches that have modelled one type of semantic change—either a word gaining an additional sense (Kulkarni et al., 2015) or a word's original sense being completely replaced (Rosenfeld and Erk, 2018). Furthermore, although most work has focused on *recall*, our framework can also test *precision*, i.e., the ability to distinguish the injected changes from noise.

5.1 Dataset Construction

We first randomly sample 10% of the tweets from a single month from the middle of our empirical dataset (Dec. 2014). We then draw 66 random 70% samples with replacement from this sample. These 66 samples represent a dataset of 66 months (5.5 years) in which no semantic changes occur, but words' distributional statistics still vary from month to month due to sampling noise. This differs from, e.g., Kulkarni et al. (2015), who used a series of exact duplicates of an initial set of documents. Finally, we inject controlled changes by inserting made-up 'pseudowords', carefully changing their frequencies and co-occurrence distributions throughout the time series.

Our procedure for inserting pseudowords is as follows: we split the real words that occur in our empirical data for December 2014 into five equally sized frequency bins. For each pseudoword ρ that we insert, we choose a frequency bin. To represent one of the senses of ρ, we sample a real word w from the relevant frequency bin. For each synthetic month m, we insert ρ replacing each token of w with success probability $p_{(\rho,w,m)}$.

For example, we might insert one pseudoword replacing the instances of the word 'pudding' with a fixed probability throughout the whole time series, and then insert this same pseudoword replacing the instances of the word 'neon' with increasing probability over time. This would model a word that initially has a meaning related to 'pudding', but which then acquires a new sense related to 'neon'. We use seven different schemas: three model different kinds of semantic change (C1–C3), and four model ephemeral changes that we aim to avoid (D1–D4): see Figure 1.

C1: **Description:** This schema models a word that gradually acquires a new sense over time while retaining its original sense (e.g., *snowflake*, *lit*). This corresponds to what Koch (2016, 24) calls 'innovative meaning change' and Tahmasebi et al. (2018, 35) calls 'novel word sense'.

Procedure: Sample one real word w_1 to represent the original pseudosense[7] of the pseudoword ρ and another real word w_2 to rep-

[7] A single pseudosense may in practice correspond to mul-

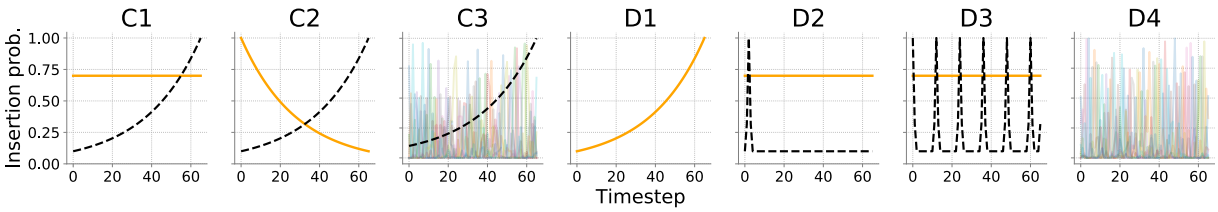

Figure 1: Illustration of our seven schemas for inserting pseudowords into the synthetic dataset. Each line represents a different pseudosense. Lines chart the probability of inserting a pseudoword token replacing a token representing the relevant pseudosense, as a function of 'time'. We vary whether the success probabilities change linearly or logarithmically and the time-steps at which the changes begin and end.

resent its new pseudosense. For each token of w_1 that occurs in the synthetic dataset for month m, insert a token of ρ replacing it with success probability $p_{(\rho,w_1,m)}$, which remains constant throughout the time series. Insert ρ replacing each token of w_2 with success probability $p_{(\rho,w_2,m)}$, which starts low and gradually increases over time.

C2: **Description:** This schema models a word that gradually acquires a new sense over time while its original sense gradually falls out of use (cf., *silly*, which originally meant 'happy' or 'lucky' and now means 'foolish'). This corresponds to the full cycle of genesis and disappearance of lexical polysemy as described by Koch (2016, 25), i.e., an 'innovative meaning change' and a 'reductive meaning change'.

Procedure: Sample one real word w_1 to represent the original sense of the pseudoword ρ, and another real word w_2 to represent its new sense. For each token of w_1 that occurs in the synthetic dataset for month m, insert a token of ρ replacing it with success probability $p_{(\rho,w_1,m)}$, which starts relatively high and gradually decreases over time. Insert ρ replacing each token of w_2 with success probability $p_{(\rho,w_2,m)} = 1 - p_{(\rho,w_1,m)}$.

C3: **Description:** This schema models a word with many senses, different random subsets of which are relatively frequent each month (e.g., an acronym that can refer to many different entities, which may trend at different times). Over time, the word acquires an additional, more stable sense whose frequency does not fluctuate so much from month to month. An example is *BLM*, which has been used to refer to a baseball magazine, a marketing company, a music label, the US Bureau of Land Management, etc., but since 2013 has been consistently associated with the Black Lives Matter movement. This could be considered a 'reductive' meaning change-in-progress, as we start out with multiple competing senses, and one sense gradually comes to dominate without the others having yet died out (see Koch, 2016, Fig. 2).

Procedure: Sample eight real words $\{w_1, w_2, ..., w_8\}$ to represent eight different pseudosenses for the pseudoword ρ. For each month m, draw a multinomial distribution D^m over the first seven sampled words, using a Dirichlet prior with uniform, sparsity-inducing alpha. Replacing each token of a word $w_i, i \in [1, 7]$, insert a token of ρ with success probability $D^m_{w_i}$. Let w_8 represent the new, more stable pseudosense, and for each month m, insert a token of ρ replacing each token of w_8 with success probability $p_{(\rho,w_8,m)}$, which starts low and gradually increases over time.

D1: **Description:** This schema models a word that becomes more frequent over time, but *does not* change its co-occurrence distribution.

Procedure: Sample one real word w to represent the meaning of the pseudoword ρ. For each token of w that occurs in the synthetic dataset for month m, insert a token of ρ replacing the token of w with success probability $p_{(\rho,w,m)}$. $p_{(\rho,w,m)}$ starts relatively low and gradually increases over time.

D2: **Description:** This schema models a word with two senses. One sense is relatively infrequent, but suddenly spikes in frequency (e.g.,

tiple real senses, since the real word we use to represent this pseudosense may itself have multiple senses. There are few words in our dataset with only one sense according to WordNet; so, we restrict our choice to words for which WordNet lists no more than 10 senses. We also require that none of the real words chosen to represent different pseudosenses of a given pseudoword have any senses in common.

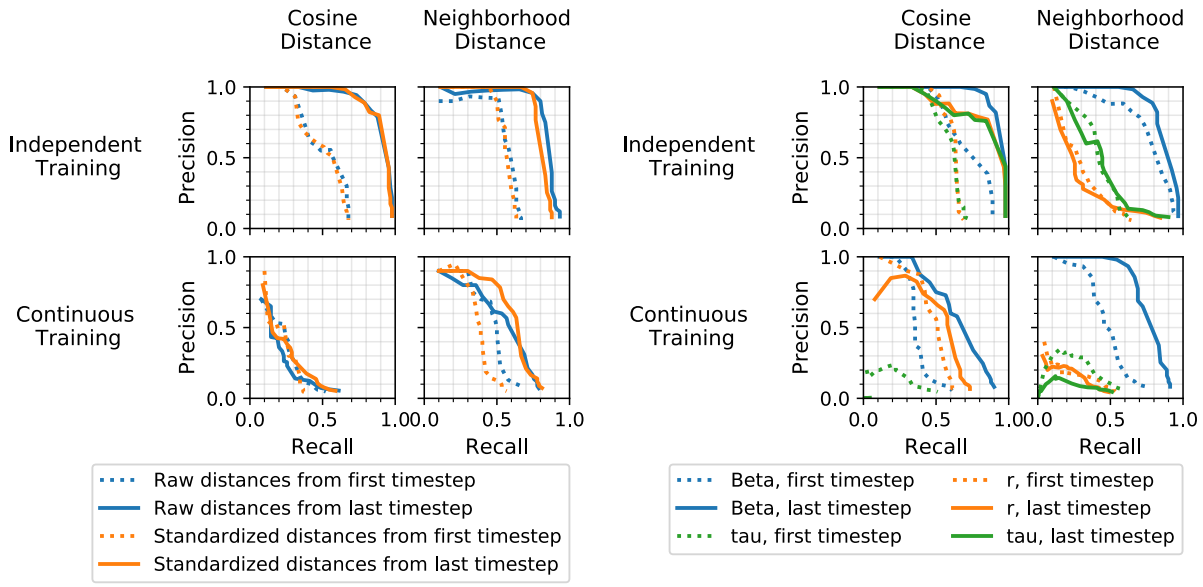

Figure 2: Precision–recall plots for times series approaches for k in range $[0, 1000]$. Left: Change point methods with *Raw* and *Standardized* (z) scores. Right: global trend methods including linear regression (*Beta*), Pearson correlation coefficient (*r*), and Kendall rank correlation coefficient (*tau*). Dashed lines use the first timestep as the reference point for comparison while solid lines use the last timestep.

due to a trending topic), before becoming infrequent again.

Procedure: Sample two real words w_1 and w_2 to represent the two pseudosenses. Insert ρ replacing each token of w_1 with probability $p_{(\rho,w_1,m)}$, which remains constant throughout the time series, and replacing each token of w_2 with probability $p_{(\rho,w_2,m)}$, which starts relatively low, rapidly increases and then rapidly decreases again.

D3: **Description:** This schema models a word with two senses: one is usually relatively infrequent, but spikes in frequency at periodic intervals (i.e., during the same month every year). An example is *turkey*, whose 'poultry' sense tends to be much more frequent around American Thanksgiving and Christmas.

Procedure: Sample two real words w_1 and w_2 to represent the two pseudosenses. Insert ρ replacing each token of w_1 with probability $p_{(\rho,w_1,m)}$, which remains constant throughout the time series, and replace each token of w_2 with probability $p_{(\rho,w_2,m)}$, which is relatively low for most time-steps but rapidly spikes around the same month each year.

D4: **Description:** Like C3, this schema models words that can refer to many different entities, but in this case, an additional, more stable sense does not emerge.

Procedure: Sample seven real words $\{w_1, w_2, ..., w_7\}$ to represent different pseudosenses for ρ. For each month m, draw a multinomial distribution D^m over these seven words, using a Dirichlet prior with uniform, sparsity-inducing alpha. Replacing each token of a word $w_i, i \in [1, 7]$, insert a token of ρ with success probability $D^m_{w_i}$.

For each of these seven schemas, we create thirty pseudowords (six for each of our five frequency bins), and we vary whether the success probabilities change linearly or logarithmically and the time-steps at which the changes begin and end. In total, we insert 90 pseudowords using Schemas C1–C3, which model genuine semantic changes that we would like to be able to detect, and 120 pseudowords using Schemas D1–D4, which model real changes in words' use statistics but do *not* reflect semantic change. The synthetic dataset also contains 887,926 real words.

5.2 Evaluation Results

We evaluate systems by how highly they rank pseudowords from schemas C1–C3 using the Average Precision @ K, which approximates the area under a precision–recall curve over the interval from 0 to K. It is defined as the sum, over every rank r in the top-K list of semantic change

candidates, of the precision at rank r multiplied by the change in recall between ranks $r-1$ and r: $AP@K = \sum_{r=1}^{K} P(r)\Delta R(r)$, where $P(r)$ is the percentage of top-r candidates which are pseudowords belonging to Schemas C1–C3, and $R(r)$ is the percentage of all C1–C3 pseudowords that appear in the top-r. The results are shown in Table 1 (two-step approach, comparing the first and last time steps) and Table 2 (whole time series). Precision–recall curves for the time series approaches are shown in Figure 2.

Continuous training does not ensure that embeddings are comparable. We experiment with three configurations for training the embeddings for the two-step approach: 1) training the embeddings for each time-step independently (ind.); 2) initializing the embeddings for the final time-step with those trained on the first time-step (cont.); and 3) continuous training throughout the whole series, so that the final time-step's embeddings are initialized with the data from all preceding time-steps (cont. whole series).

Continuous training has been used without separate alignment (e.g., Kim et al., 2014) as each time period is a continuation of the embeddings from the previous period. Table 1 shows, however, that alignment is necessary for continuously trained embeddings using the whole series as well as for independent ones when using the cosine distance measure. It is likely that the huge number of training updates in the entire time series causes the embeddings to drift considerably. For the time series approaches, we therefore did not apply the cosine measure without first aligning embeddings.

Using the whole time series is more effective than comparing the first and the last time steps. Overall, the approaches using the whole time series (Table 2) are more effective than the two-step approaches; particularly with regard to finding C1 pseudowords and avoiding D4 pseudowords.

Continuous training provides no benefit for time series approaches. For the time series approaches, independent training tends to perform better than continuous training (Table 2). The lack of improvement with continuous training is particularly noteworthy as independent training is more computationally efficient than continuous training, since different time periods can be trained in parallel. We did not explore the impact of different hyperparameter choices on continuous training, but note this would introduce another level of complexity in tuning model parameters.

	ind.	cont.	cont. (whole series)
cosine (unaligned)	0.00	0.32	0.00
cosine (aligned)	0.25	0.32	0.27
neighbourhood	0.28	0.34	0.30

Table 1: Average Precision @ 50 on the synthetic dataset of the two-step approach with CBOW

Different time series approaches are best paired with different similarity measures. Hamilton et al. (2016a) found that the neighbourhood-based measure tends to assign higher rates of semantic change to nouns, while the cosine measure tends to assign higher rates to verbs. However, they did not compare the overall effectiveness of these methods for semantic change detection.

We find that the neighbourhood-based measure[8] tends to outperform the cosine measure for the change point detection approaches; however, cosine tends to outperform the neighbourhood measure for correlation approaches (see Table 2). For change point detection, standardization of the time series does not have a consistent effect.

The reference point for comparison matters. For almost all configurations in Table 2, the AP @ 50 is better when the reference point is the last time-step. Figure 3 shows Recall@K broken down by pseudoword type. For types C1–C3, higher recall is better. Conversely, lower recall is better for types D1–D4, since these model changes that we do *not* consider to be lasting semantic changes. Recall is consistently low for types D1–D4, but strikingly, recall is also low for type C3 when we compare to the first-step. Schema C3 models words whose distributions change drastically from time-step to time-step, but which gradually become more stable as a new, consistently occurring sense emerges. The representation for the first time-step will thus be very different from subsequent representations, such that comparing to the first step is not effective. In contrast, comparing to the first time-step is expected to be more effective in finding words that become less stable over time.

Correlation-based approaches perform worse than regression or change point detection approaches. Pearson's correlation coefficient is

[8] We apply this to unaligned embeddings; alignment with orthogonal Procrustes has no effect on this measure.

Measure	Training	Comparing to the first time-step					Comparing to the last time-step				
		raw	z	β	r	τ	*raw*	z	β	r	τ
cosine	independent	0.37	0.36	0.51	0.52	0.47	0.54	0.56	0.56	0.48	0.49
cosine	continuous	0.17	0.18	0.34	0.40	0.02	0.13	0.15	0.45	0.34	0.00
neighbourhood	independent	0.47	0.50	0.48	0.23	0.35	0.53	0.56	0.56	0.20	0.30
neighbourhood	continuous	0.35	0.32	0.37	0.05	0.05	0.34	0.42	0.54	0.05	0.00

Table 2: Average Precision @ 50 on the synthetic dataset using time series approaches with CBOW. Change point methods are raw scores (*raw*) and standardized scores (z). Global trend methods are linear regression (β), Pearson correlation coefficient (r), and Kendall rank correlation coefficient (τ).

maximized when the *magnitude* of the change between consecutive time periods is consistent over all time periods whereas maximizing Kendall's τ simply requires the change between consecutive time periods to be of a consistent *sign*. Both correlation measures therefore have particularly poor recall of words that have time periods without a consistent meaning as in the early time periods for pseudowords of type C3.

The β value of the linear regression assumes a linear relationship, but is unfortunately sensitive to outliers (Chatterjee and Hadi, 1986), which likely explains why the regression approach has higher recall than change point approaches for schema D4 (Figure 3), in which a stable sense does not emerge. In general, however, the β values produced for D4 pseudowords appear to be smaller in magnitude than genuine semantic changes (C1–C3) resulting in average precision measures that generally match or exceed change point approaches (Table 2). Regression is also more straightforward and computationally efficient to calculate than change point measures.

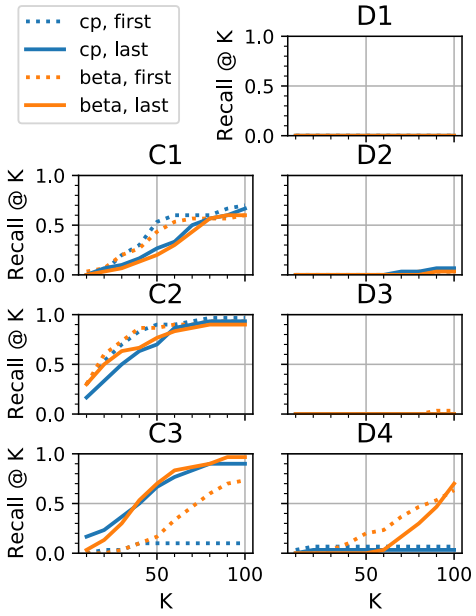

Figure 3: Recall@K of each schema, using independently trained embeddings and the neighbourhood-based measure. 'first'/ 'last' denotes the reference time-step, 'cp' the unstandardized change-point approach, and 'beta' the linear regression approach. C1–C3: higher recall is better, D1–D4: lower is better.

6 Results on Empirical Twitter Data

We now apply the approaches on our full empirical Twitter dataset. Table 3 shows the top 10 semantic change candidates using independent, aligned CBOW embeddings. When using continuously trained embeddings, the top-10 lists are similar.

In line with our synthetic results, we find different candidates when comparing to the first time-step or the last, but they appear to represent similar kinds of semantic change. Most have shifted due to associations with named entities. For example, *vine* (Figure 4a) acquired a new sense in January 2013 when the popular short-form video hosting service Vine was launched. Similarly, *ig*, initially shorthand for 'i guess', became shorthand for the social network Instagram as it gained popularity. The embedding for *shawn* shifted significantly around the beginning of 2014, when the singer Shawn Mendes signed a record deal.

There are also words whose embeddings have shifted due to waning associations with prominent named entities, e.g., *vow* was initially associated with The Vow, a high grossing movie released in Feb. 2012, but by the end of the time series it had shifted back towards synonyms like 'pledge' and 'urge'. Likewise the embedding for *temple* initially reflected the popularity of the video game Temple Run but gradually shifted to the word's canonical meaning, and the embedding for *bcs* initially reflected its usage as an acronym for Bowl Championship Series (a selection system in American college football), but then shifted towards

Comparing to first time-step	vine, temple, unfollowers, favorited, mcm, glo, #ipadgames, shawn, retweeted, vow
Comparing to last time-step	isis, yasss, bcs, temple, 🐶, mcm, 😐, ig, mila, glo

Table 3: Top 10 semantic change candidates of the change-point detection approach without standardization, using independently trained and aligned CBOW embeddings and the cosine distance measure.

'bcoz', 'bec', and other forms of 'because' after the selection system was ended in 2013.

There are also examples of neologisms: *mcm* is a lexicalized acronym for 'Man Crush Monday'. This initially referred to the meme of posting about a man one finds attractive each Monday, but then by metonymic extension came to be used to refer to the subject of the post himself. Another example is *glo*, which in the beginning of our data (Figure 4b) occurs mainly in reference to a Nigerian telecommunication company. A shift in its embedding is driven by the sudden emergence of the expression 'glo up', which was coined in August 2013 by rapper Chief Keef in the song "Gotta Glo Up One Day", and later gained traction as an expression to describe an impressive personal transformation.

Finally, there are words whose detected change-points reflect changes in automated activity. For example, the embedding for *yasss* shifts in early 2017 due to a sudden proliferation of tweets automatically posted to users' Twitter accounts by the live video streaming app LiveMe, which all begin with the text 'YASSS It's time for a great show' followed by the title and link to the video stream. Conversely, the detected change for *favorited* (Figure 4c) coincides with a sudden disappearance of automatically generated tweets about favorited YouTube videos.

7 Conclusion

In this paper, we presented a new evaluation framework and systematically compared the various choices involved in using word embeddings for semantic change detection. We then applied the approaches to a Twitter dataset spanning 5.5 years. Qualitative analysis found that the top ranked words have undergone genuine semantic change although some of the changes are restricted to social media or to Twitter specifically.

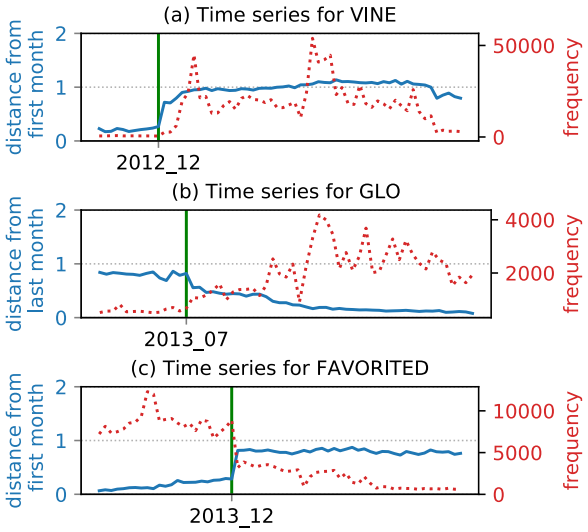

Figure 4: Neighbourhood-based distance (solid blue lines) and frequency (dotted red lines) over time, for three semantic change candidates. Vertical green lines indicate the automatically estimated change-points.

Our framework and dataset can also be used to evaluate approaches not considered in this paper. Moreover, our framework models different semantic change scenarios, and future work could focus on approaches that are able to distinguish between these different scenarios.

Correlations between Word Vector Sets

Vitalii Zhelezniak, April Shen, Daniel Busbridge,
Aleksandar Savkov, Nils Hammerla
{firstname.lastname}@babylonhealth.com

Abstract

Similarity measures based purely on word embeddings are comfortably competing with much more sophisticated deep learning and expert-engineered systems on unsupervised semantic textual similarity (STS) tasks. In contrast to commonly used geometric approaches, we treat a single word embedding as e.g. 300 observations from a scalar random variable. Using this paradigm, we first illustrate that similarities derived from elementary pooling operations and classic correlation coefficients yield excellent results on standard STS benchmarks, outperforming many recently proposed methods while being much faster and trivial to implement. Next, we demonstrate how to avoid pooling operations altogether and compare sets of word embeddings directly via correlation operators between reproducing kernel Hilbert spaces. Just like cosine similarity is used to compare individual word vectors, we introduce a novel application of the centered kernel alignment (CKA) as a natural generalisation of squared cosine similarity for sets of word vectors. Likewise, CKA is very easy to implement and enjoys very strong empirical results.

1 Introduction

Distributed representations of text have had a massive impact on the natural language processing (NLP), information retrieval (IR), and machine learning (ML) communities, thanks in part to their ability to capture rich notions of semantic similarity. While this work originally began with word embeddings (Bengio et al., 2003; Mikolov et al., 2013a; Pennington et al., 2014; Bojanowski et al., 2017; Joulin et al., 2017), there is now an ever-increasing number of representations for longer units of text based on simple aggregations of word vectors (Mitchell and Lapata, 2008; De Boom et al., 2016; Arora et al., 2017; Wieting et al., 2016; Wieting and Gimpel, 2018; Zhelezniak et al., 2019b) as well as complex neural architectures (Le and Mikolov, 2014; Kiros et al., 2015; Hill et al., 2016; Conneau et al., 2017; Gan et al., 2017; Tang et al., 2017; Pagliardini et al., 2018; Zhelezniak et al., 2018; Subramanian et al., 2018; Cer et al., 2018; Devlin et al., 2018).

By contrast, relatively little effort has been directed towards understanding the similarity measures used to compare these textual embeddings, for which cosine similarity remains a convenient and widespread, yet somewhat arbitrary default, despite some emerging research into the alternatives (Camacho-Collados et al., 2015; De Boom et al., 2015; Santus et al., 2018; Zhelezniak et al., 2019b,a). Part of the appeal of cosine similarity perhaps lies in the simple geometric interpretation behind it. However, as embeddings are ultimately just arrays of numbers, we are free to take alternative viewpoints other than the geometric ones, if they lead to illuminating insights or strong-performing methods.

Following Zhelezniak et al. (2019a), we treat a word embedding not as a geometric vector but as a statistical sample (of e.g. 300 observations) from a scalar random variable, and indeed find insights that are both intriguing and noteworthy. We first illustrate that similarities derived from elementary pooling operations and classic univariate correlation coefficients yield excellent results on standard semantic textual similarity (STS) benchmarks, outperforming many recently proposed methods while being much faster and simpler to implement. This empirically validates the advantages of the statistical perspective on word embeddings over the geometric interpretations. In the process, we provide more evidence that departures from normality, and in particular the presence of outliers, can have severe negative effects on the performance of some correlation coeffi-

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 77–87,
Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

cients. We show how to overcome these complications, by selecting an outlier-removing pooling operation such as max-pooling, applying a more robust correlation coefficient such as Spearman's ρ, or simply clipping (winsorizing) the word vectors.

Next, we demonstrate how to avoid pooling operations completely and compare sets of word embeddings directly via correlation operators between reproducing kernel Hilbert spaces (RKHS). We introduce a novel application of the kernel alignment (KA) and the centered kernel alignment (CKA) as a natural generalisation of the squared cosine similarity and Pearson correlation for the sets of word embeddings. These multivariate correlation coefficients are very easy to implement and also enjoy very strong empirical results.

2 Related Work

Several lines of research seek to combine the strength of pretrained word embeddings and the elegance of set- or bag-of-words (BoW) representations. Any method that determines semantic similarity between sentences by comparing the corresponding sets of word embeddings is directly related to our work.

Perhaps the most obvious such approaches are based on elementary pooling operations such as average-, max- and min-pooling (Mitchell and Lapata, 2008; De Boom et al., 2015, 2016). While seemingly over-simplistic, numerous studies have confirmed their impressive performance on the downstream tasks (Arora et al., 2017; Wieting et al., 2016; Wieting and Gimpel, 2018; Zhelezniak et al., 2019b)

One step further, Zhao and Mao (2017); Zhelezniak et al. (2019b) introduce fuzzy bags-of-words (FBoW) where degrees of membership in a fuzzy set are given by the similarities between word embeddings. Zhelezniak et al. (2019b) show a close connection between FBoW and max-pooled word vectors.

Some approaches do not seek to build an explicit representation and instead focus directly on designing a similarity function between sets. Word Mover's Distance (WMD) (Kusner et al., 2015) is an instance of the Earth Mover's Distance (EMD) computed between normalised BoW, with the cost matrix given by Euclidean distances between word embeddings. In the soft cardinality framework of (Jimenez et al., 2010, 2015), the contribution of a word to the cardinality of a set depends on its similarities to other words in the same set. Such sets are then compared using an appropriately defined Jaccard index or related measures. DynaMax (Zhelezniak et al., 2019b) uses universe-constrained fuzzy sets designed explicitly for similarity computations.

Approaches that see word embeddings as statistical objects are very closely related to our work. Virtually all of them treat word embeddings as observations from some D-variate parametric family, where D is the embedding dimension. Arora et al. (2016, 2017) introduce a latent discourse model and show the maximum likelihood estimate (MLE) for the discourse vector to be the weighted average of word embeddings in a sentence, where the weights are given by smooth inverse frequencies (SIF). Nikolentzos et al. (2017); Torki (2018) treat sets of word embeddings as observations from D-variate Gaussians, and compare such sets with cosine similarity between the parameters (means and covariances) estimated by maximum likelihood. Vargas et al. (2019) measure semantic similarity through penalised likelihood ratio between the joint and factorised models and explore Gaussian and von Mises–Fisher likelihoods.

Cosine similarity between covariances is an instance of the RV coefficient and its uncentered version was applied in the context of word embeddings before (Botev et al., 2017). We arrive at a similar coefficient (but with different centering) as a special case of CKA, which in the general case makes no parametric assumptions about disbtributions whatsoever. In particular our version is suitable for comparing sets containing just one word vector, whereas the method of Nikolentzos et al. (2017); Torki (2018) requires at least two vectors in each set. Very recently, Kornblith et al. (2019) used CKA to compare representations between layers of the same or different neural networks. This is again an instance of treating such representations as observations from a D-variate distribution, where D is the dimension of the hidden layer in question. Our use of CKA is completely different from theirs.

Unlike all of the above approaches, (Zhelezniak et al., 2019a) see each word embedding itself as D (e.g. 300) observations from some scalar random variable. They cast semantic similarity as correlations between these random variables and study

their properties using simple tools from univariate statistics. While they consider correlations between individual word vectors and averaged word vectors, they do not formally explore correlations between word vector sets. We review their framework in Section 3 and then proceed to formalise and generalise it to the case of sets of word embeddings.

3 Background: Correlation Coefficients and Semantic Similarity

Suppose we have a word embeddings matrix $\mathbf{W} \in \mathbb{R}^{N \times D}$, where N is the number of words in the vocabulary and D is the embedding dimension (usually 300). In other words, each row $\mathbf{w}^{(i)}$ of $\mathbf{W}$ is a D-dimensional word vector. When applying statistical analysis to these vectors, one might choose to treat each $\mathbf{w}^{(i)}$ as an observation from some D-variate distribution $P_D(E_1, \dots E_D)$ and model it with a Gaussian or a Gaussian Mixture. While such analysis helps in studying the overall geometry of the embedding space (how dimensions correlate and how embeddings cluster), P_D is not directly useful for semantic similarity between individual words.

For the latter, Zhelezniak et al. (2019a) proposed to look at the transpose $\mathbf{W}^T$ and the corresponding distribution $P(W_1, W_2, \dots, W_N)$. Under this perspective, each word vector $\mathbf{w}_{(i)}$ is now a sample of D (e.g. 300) observations from a scalar random variable W_i. Luckily, in applications we are usually not interested in the full joint distribution but only in the similarity between two words, i.e. the bivariate marginal $P(W_i, W_j)$. In practice, we make inferences about this marginal from the paired sample $(\mathbf{w}_{(i)}, \mathbf{w}_{(j)})$ through visualisations (histograms, Q-Q plots, scatter plots, etc.) as well as various statistics.

Zhelezniak et al. (2019a) found that for all common models (GloVe, fastText, word2vec) the means across word embeddings are tightly concentrated around zero (relative to their dimensions), thus making the widely used cosine similarity practically equivalent to Pearson correlation. However, while word2vec vectors seem mostly normal, GloVe and fastText vectors are highly non-normal, likely due to the presence of heavy univariate and bivariate outliers (as suggested by visualisations mentioned earlier). Quantitatively, the majority of GloVe and fastText vectors fail the Shapiro-Wilk normality test at significance level 0.05. Therefore, while Pearson's r (and thus cosine similarity) may be acceptable for word2vec, it is preferable to resort to more robust non-parametic correlation coefficients such as Spearman's ρ or Kendall's τ as a similarity measure between GloVe and fastText vectors.

Finally, very similar conclusions were shown to hold for sentence representations obtained by word vector averaging, also referred to as mean-pooling. In particular, averaged fastText vectors compared with rank correlation coefficients already show impressive results on standard STS tasks, rivaling much more sophisticated systems.

4 Correlations between Word Vector Sets

We are interested in applying the statistical framework from Section 3 to measure the semantic similarity between two sentences s_1 and s_2 given by the sets (or bags) S_1 and S_2 of word embeddings respectively. To formalise this new setup, we may see each set of word embeddings $S = \{\mathbf{w}_{(1)}, \mathbf{w}_{(2)}, \dots, \mathbf{w}_{(k)}\}$ as a sample (of e.g. 300 observations) from some theoretical set of scalar random variables $R = \{W_1, W_2, \dots, W_k\}$. In light of the above, our task then lies in finding correlation coefficients $\text{corr}(R_1, R_2)$ between R_1 and R_2 and their empirical estimates $\widehat{\text{corr}}(S_1, S_2)$ obtained from the paired sample S_1, S_2, hoping that such coefficients will serve as a good proxy for semantic similarity. Recall that for single-word sets $R_1 = \{W_i\}, R_2 = \{W_j\}$ the task simply reduces to computing a univariate correlation between word vectors $\mathbf{w}_{(i)}$ and $\mathbf{w}_{(j)}$, where the choice of the coefficient (Pearson's r, Spearman's ρ, etc.) is made based on the statistics exhibited by the word embeddings matrix. While generalising this to sets of more than one variable is not particularly hard, there are several ways to do so, each with its own advantages and downsides. In the present work, we group these approaches into two broad families: pooling-based and pooling-free correlation coefficients.

4.1 Correlations between Pooled Variables

Pooling-based approaches first reduce a set of random variables to a single scalar random variable $W_{\text{pool}} = f_{\text{pool}}(W_1, W_2, \dots, W_k)$ and then apply univariate correlation coefficients between the pooled variables. In practice this would correspond to pooling word embeddings $\mathbf{w}_{(1)}, \mathbf{w}_{(2)}, \dots, \mathbf{w}_{(k)}$ (along $i = 1{:}k$) into one

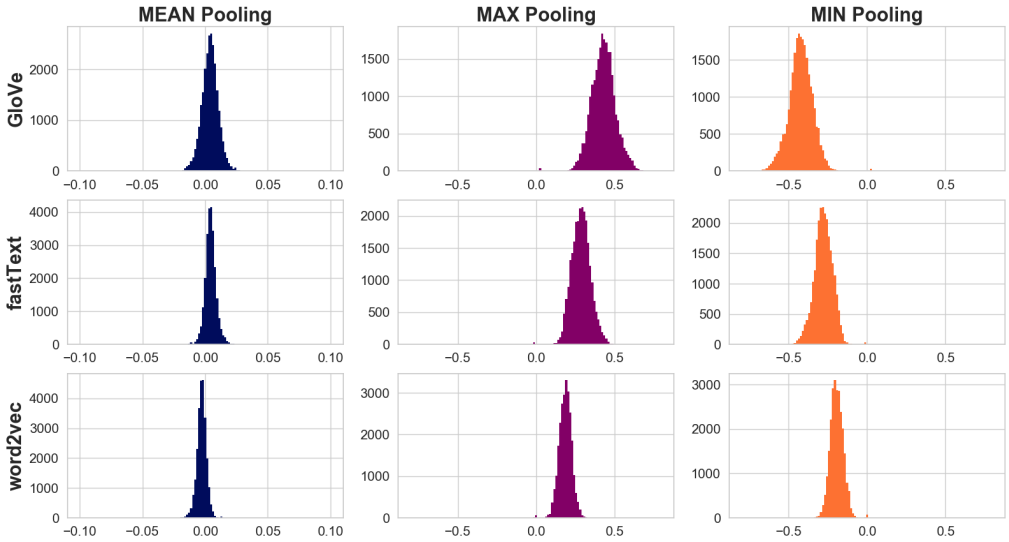

Figure 1: Normalised histograms of the mean distribution for sentence vectors generated by mean-, max- and min-pooling. Sentences were taken from the entire STS dataset (Agirre et al., 2012, 2013, 2014, 2015, 2016; Cer et al., 2017), and we utilise three commonly-used word embedding models: GloVe (Pennington et al., 2014), fastText (Bojanowski et al., 2017), and word2vec (Mikolov et al., 2013b,c).

Algorithm 1 MaxPool-Spearman

Require: Word embeddings for the first sentence $\mathbf{x}^{(1)}, \mathbf{x}^{(2)} \ldots, \mathbf{x}^{(k)} \in \mathbb{R}^{1\times d}$

Require: Word embeddings for the second sentence $\mathbf{y}^{(1)}, \mathbf{y}^{(2)} \ldots, \mathbf{y}^{(l)} \in \mathbb{R}^{1\times d}$

Ensure: Similarity score MS

 # Max-pooling performed element-wise

$\mathbf{x} \leftarrow \text{MAX_POOL}(\mathbf{x}^{(1)}, \mathbf{x}^{(2)} \ldots, \mathbf{x}^{(k)})$

$\mathbf{y} \leftarrow \text{MAX_POOL}(\mathbf{y}^{(1)}, \mathbf{y}^{(2)} \ldots, \mathbf{y}^{(l)})$

$\text{MS} \leftarrow \text{SPEARMANCORRELATION}(\mathbf{x}, \mathbf{y})$

fixed vector $\mathbf{w}_{\text{pool}}$, followed by computing univariate sample correlations. Certainly, these approaches are empirically attractive: not only are they very simple computationally (e.g. see Algorithm 1) but they also keep us in the realm of univariate statisics, where we have an entire arsenal of effective tools for making inferences about W_{pool}.

Unfortunately, it is not always clear *a priori* what should dictate our choice of the pooling function (though, as we will see shortly, for certain functions some statistical justifications do exist). By far the most common pooling operations for word embedding found in the literature are mean-, max- and min-pooling. It is also very common, with some exceptions, to treat these various pooled representation in a completely identical fashion, e.g. by comparing them all with cosine similarity. Intuitively, however, we suggest that the statistics of W_{pool} must heavily depend on the pooling function f_{pool} and thus each such pooled random variable should be studied in its own right. To illustrate this point, we would like to reveal the very different nature of mean- and max- and min-pooled sentence vectors though a practical example.

4.2 Statistics of the Pooled Representations: A Practical Analysis

Let us begin by examining sentence vectors obtained through mean-pooling. Recall that for common word embedding models, the mean across 300 dimensions of a single word embedding $\mathbf{w}_{(i)}$ happens to be close to zero (relative to the dimensions). By the linearity of expectation, we have that $\mathbb{E}[W_{\text{mean}}] = \mathbb{E}\left[\sum_{i=1}^{k} W_i\right] = \sum_{i=1}^{k} \mathbb{E}[W_i]$, and so the mean across $\mathbf{w}_{\text{mean}}$ will also be close to zero at least for small k. In practice, this seems to hold even for moderate k in naturally occurring sentences, as seen in Figure 1. Based on this, we expect Pearson correlation and cosine similarity to have almost identical performance on the downstream tasks, which is confirmed in Figure 2.

On the other hand, intuition tells us that the means of the max-pooled vectors will be shifted

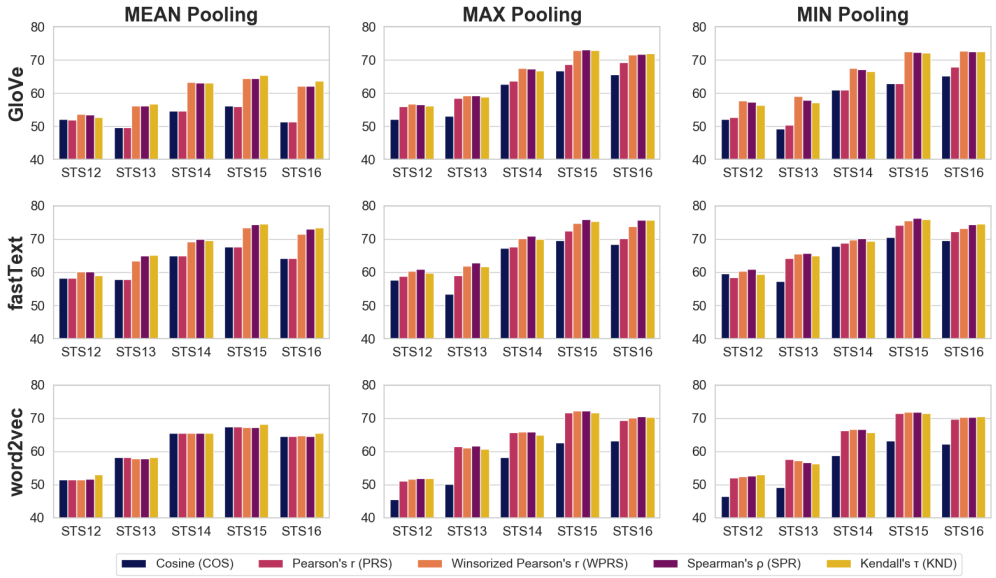

Figure 2: Bar plots of Pearson correlation on STS tasks between human scores and the following set-based similarity metrics: Cosine similarity (COS), Pearson's r (PRS), Winsorized Pearson's r (WPRS), Spearman's ρ (SPR), and Kendall's τ (KND). Plots generated for three pooling methods and the following word embedding models: GloVe (Pennington et al., 2014), fastText (Bojanowski et al., 2017), and word2vec (Mikolov et al., 2013b,c).

to the right because of the max operation, which we see in Figure 1. In this case, cosine similarity and Pearson correlation will yield different results and, in fact, Pearson's r considerably outperforms cosine on the downstream tasks (Figure 2). This in turn empirically adds weight to the statistical interpretation (correlation) over its geometrical counterpart (angle between vectors).

Recall also that unlike word2vec, GloVe and fastText vectors feature heavy univariate outliers, and the same can be expected to hold for the pooled representations; an example is shown in Figure 3. In case of mean-pooled vectors, this particular departure from normality can be successfully detected by the Shapiro-Wilk normality test, informing the appropriate choice of the correlation coefficient (Pearson's r or robust rank correlation). By contrast, such procedure cannot be readily applied to max-pooled and min-pooled vectors as by construction they exhibit additional departures from normality, such as positive and negative skew respectively. It is always a good idea to consult visualisations for such vectors, such as the ones in Figure 3. Interestingly though, we do observe the some noteworthy regularities, which we describe further in Section 5.

The above example is meant to illustrate that even the simplest pooled random variables show strikingly different statistics depending on the aggregation. While the abundance of various pooling operations may be intimidating, the resulting vectors are always subject to the many tools of univariate statistics. As we hope to have shown, even crude analysis can shed light on the nature of these textual representations, which in turn has notable practical implications, as we will see in Section 5.

4.3 Correlations between Random Vectors

Exactly as before, suppose we have two sentences $S_1 = \{\mathbf{x}_{(1)}, \mathbf{x}_{(2)}, \ldots, \mathbf{x}_{(k)}\}$ and $S_2 = \{\mathbf{y}_{(1)}, \mathbf{y}_{(2)}, \ldots, \mathbf{y}_{(l)}\}$ and the corresponding random vectors $\mathbf{X} = (X_1, X_2, \ldots, X_k)$ and $\mathbf{Y} = (Y_1, Y_2, \ldots, Y_l)$. At this point it is important to emphasise again that we relate each word vector $\mathbf{x}_i$ to a random variable X_i and treat the dimensions of $\mathbf{x}_i$ as D observations from that variable, and similarly for $\mathbf{y}_i$ and Y_i. In contrast with the pooling-based approaches, our task here is to find a suitable correlation coefficient directly between the random vectors $\mathbf{X}$ and $\mathbf{Y}$. We begin by recalling the expression for the basic univariate Pearson's r:

$$r_{XY} = \frac{\mathbb{E}_{X,Y}\left[(X - \mu_X)(Y - \mu_Y)\right]}{\sigma_X \sigma_Y}, \quad (1)$$

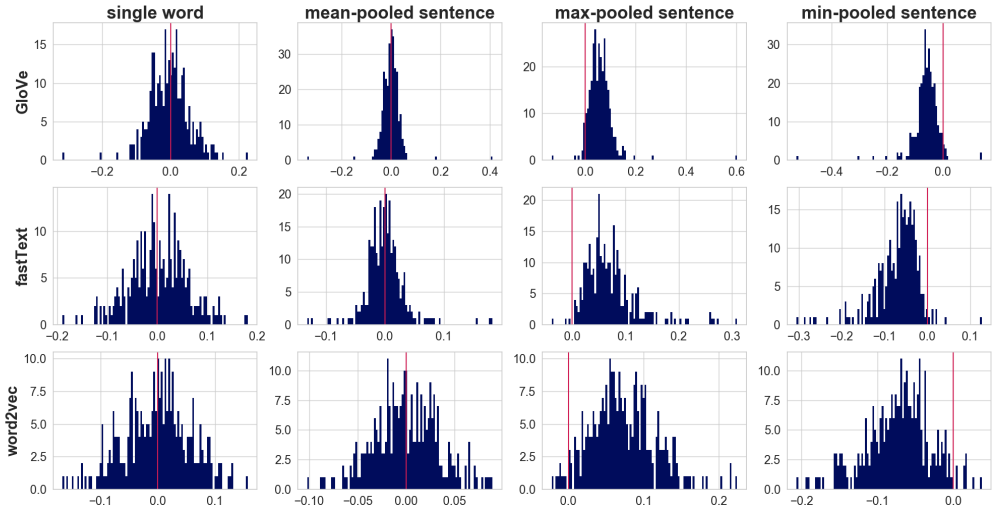

Figure 3: Histograms for word embeddings of the word "cats" and pooled representations of the embeddings for the words in the sentence "I like cats because they are very cute animals".

where

$$\mu_X = \mathbb{E}[X], \quad \sigma_X = \sqrt{\mathbb{E}\left[X^2\right] - \mu_X^2},$$

and similarly for μ_Y and σ_Y. The covariance term $\mathrm{cov}(X, Y)$ in the numerator is readily generalised to random vectors by the following cross-covariance operator between reproducing kernel Hilbert spaces (RKHS) $\mathcal{F}$ and $\mathcal{G}$

$$\mathcal{C}_{\mathbf{XY}} = \mathbb{E}_{\mathbf{X},\mathbf{Y}}\left[(\phi(\mathbf{X}) - \mu_{\mathbf{X}}) \otimes (\psi(\mathbf{Y}) - \mu_{\mathbf{Y}})\right], \tag{2}$$

where $\otimes$ denotes the tensor product and $\mu_{\mathbf{X}} = \mathbb{E}_{\mathbf{X}}\left[\phi(\mathbf{X})\right]$, $\mu_{\mathbf{Y}} = \mathbb{E}_{\mathbf{Y}}\left[\psi(\mathbf{Y})\right]$. Here ϕ and ψ are the feature maps such that $\langle \phi(\mathbf{x}), \phi(\mathbf{x}')\rangle_{\mathcal{F}} = K(\mathbf{x}, \mathbf{x}')$ and $\langle \psi(\mathbf{y}), \psi(\mathbf{y}')\rangle_{\mathcal{G}} = L(\mathbf{y}, \mathbf{y}')$, where K and L are the kernels associated with RKHS $\mathcal{F}$ and $\mathcal{G}$ respectively. Note that if ϕ and ψ are the identity maps, the cross-covariance operator (2) simply becomes the cross-covariance matrix

$$\mathbf{C}_{\mathbf{XY}} = \mathbb{E}_{\mathbf{X},\mathbf{Y}}\left[(\mathbf{X} - \mu_{\mathbf{X}})\left(\mathbf{Y} - \mu_{\mathbf{Y}}\right)^T\right].$$

Gretton et al. (2005a) define the Hilbert-Schmidt independence criterion (HSIC) to be the squared Hilbert-Schmidt norm $||\mathcal{C}_{\mathbf{XY}}||^2_{\mathrm{HS}}$ of (2) and derive an expression for it in terms of kernels K and L

$$\begin{aligned}\mathrm{HSIC}(\mathbf{X}, \mathbf{Y}, K, L) = \\ \mathbb{E}_{\mathbf{X},\mathbf{X}',\mathbf{Y},\mathbf{Y}'}\left[K(\mathbf{X}, \mathbf{X}')L(\mathbf{Y}, \mathbf{Y}')\right] \\ +\mathbb{E}_{\mathbf{X},\mathbf{X}'}\left[K(\mathbf{X}, \mathbf{X}')\right]\mathbb{E}_{\mathbf{Y},\mathbf{Y}'}\left[L(\mathbf{Y}, \mathbf{Y}')\right] \\ -2\mathbb{E}_{\mathbf{X},\mathbf{Y}}\left[\mathbb{E}_{\mathbf{X}'}\left[K(\mathbf{X}, \mathbf{X}')\right]\mathbb{E}_{\mathbf{Y}'}\left[L(\mathbf{Y}, \mathbf{Y}')\right]\right].\end{aligned}$$

They also show the empirical estimate of it to be

$$\mathrm{HSIC}(\mathbf{K}, \mathbf{L}) = (D-1)^{-2}\,\mathrm{Tr}(\mathbf{KHLH}), \tag{3}$$

where $\mathbf{H} = \mathbf{I} - \frac{1}{D}\mathbf{1}\mathbf{1}^T$ is the centering matrix and $\mathbf{K} = K(\mathbf{X}^{(i)}, \mathbf{X}^{(j)}), \mathbf{L} = L(\mathbf{Y}^{(i)}, \mathbf{Y}^{(j)}), i, j = 1{:}D$ are the kernel (Gram) matrices of observations. Crucially, the kernel evaluations for $\mathbf{K}$ take place between $\mathbf{X}^{(i)} = (\mathbf{x}^i_{(1)}, \mathbf{x}^i_{(2)}, \ldots, \mathbf{x}^i_{(k)})$ and $\mathbf{X}^{(j)} = (\mathbf{x}^j_{(1)}, \mathbf{x}^j_{(2)}, \ldots, \mathbf{x}^j_{(k)})$ and not between the individual word embeddings $\mathbf{x}_{(i)}$ and $\mathbf{x}_{(j)}$, and similarly for $\mathbf{L}$. Thus, both $\mathbf{K}$ and $\mathbf{L}$ are square matrices of dimension $D \times D$. Indeed, for (3) to make sense, the dimensions of $\mathbf{K}$ and $\mathbf{L}$ must match. The matching dimension in our case is the word embedding dimension D, while the number of words k and l in the sentences may vary. This is in line with our formalism, which models word vectors as random variables and their dimensions as observations.

Finally, the Centered Kernel Alignment (CKA) (Cortes et al., 2012) is simply defined as

$$\mathrm{CKA}(\mathbf{K}, \mathbf{L}) = \frac{\mathrm{HSIC}(\mathbf{K}, \mathbf{L})}{\sqrt{\mathrm{HSIC}(\mathbf{K}, \mathbf{K})}\sqrt{\mathrm{HSIC}(\mathbf{L}, \mathbf{L})}}. \tag{4}$$

We see now that CKA not only generalises the squared Pearson correlation to the multivariate case, it also allows it to operate in high-dimensional feature spaces, as commonly done in the kernel literature. The reason this is useful is that under certain conditions (when K and L are

Table 1: Mean Pearson correlation on STS tasks for Deep Learning and Set-based methods using fastText. Methods proposed in this work are denoted with ⚒. Values in bold indicate best results per task. Previous results are taken from Perone et al. (2018), Subramanian et al. (2018) and Zhelezniak et al. (2019b,a). † indicates the only STS13 result (to our knowledge) that includes the SMT subtask.

characteristic kernels), HSIC can detect any existing dependence with high probability, as the sample size increases (Gretton et al., 2005b). One can also consider the Uncentered Kernel Alignment (or simply KA) (Cristianini et al., 2002), which can then be seen as a similar generalisation but for the univariate cosine similarity. To the best of our knowledge, KA and CKA in general have never been applied before to measure semantic similarity between sets of word embeddings; therefore this work seeks to introduce them as standard definitions for squared Pearson's r and cosine similarity for such sets.

5 Experiments

We now empirically demonstrate the power of the methods and statistical analysis presented in Section 4, through a set of evaluations on the Semantic Textual Similarity (STS) tasks series 2012-2016 (Agirre et al., 2012, 2013, 2014, 2015, 2016; Cer et al., 2017). For methods involving pretrained word embeddings, we use fastText (Bojanowski et al., 2017) trained on Common Crawl (600B tokens), as previous evaluations have indicated that fastText vectors have uniformly the best performance on these tasks out of commonly-used pretrained unsupervised word vectors (Conneau et al., 2017; Perone et al., 2018; Zhelezniak et al., 2019a,b). We provide experiments and significance analysis for additional word vector in the Appendix. The success metric for the STS tasks is the Pearson correlation between the sentence similarity scores provided by human annotators and the scores generated by a candidate algorithm. Note that the dataset for the STS13 SMT subtask is no longer publicly available, so the mean Pearson correlation for STS13 reported in our experiments has been re-calculated accordingly. The code for our experiments builds on the SentEval toolkit (Conneau and Kiela, 2018) and is available on GitHub[1].

We first conduct a set of experiments to validate the observations of Sections 4.1 and 4.2 regarding the performance of cosine similarity and various univariate correlation coefficients when applied to pooled word vectors. These results are depicted in Figure 2, for which we can make the following observations.

First, max and min-pooled vectors consistently outperform mean-pooled vectors when all three representations are compared with Pearson correlation. We hypothesise that this is in part because max and min-pooling remove the outliers (to which Pearson's r is very sensitive) from at least one tail of the distribution whereas mean-pooled vectors have outliers in both tails. This outlier-removing property, however, cannot be taken as a sole explanation behind excellent performance of max-pooled vectors, as max-pooling still tends to outperform mean-pooling when both are compared with correlations that are robust to outliers, as well as on word vectors that have very few outliers to begin with (e.g. word2vec).

In addition, the strong performance of rank correlation coefficients (Spearman's ρ and Kendall's τ) comes solely from their robustness to outliers, as clipping (winsorizing) the top and

[1] https://github.com/Babylonpartners/corrsim

bottom 5% of the values and then proceeding with Pearson's r closes the gap almost completely. Consistently, on vectors with few outliers (word2vec), Pearson's r achieves the same performance as rank correlations even without winsorization. However, unlike outliers, positive (negative) skew of max- (min-) pooled vectors does not seem to hurt Pearson's r on STS tasks.

Next, we conduct evaluations of the methods proposed in this work alongside other deep learning and set-based similarity measures for STS from the literature. The methods we compare are as follows:

- *Deep representation approaches:* BoW with ELMo embeddings (Peters et al., 2018), Skip-Thought (Kiros et al., 2015), InferSent (Conneau et al., 2017), Universal Sentence Encoder both DAN and Transformer (Cer et al., 2018), STN multitask embeddings (Subramanian et al., 2018), and BERT 12- and 24-layer models (Devlin et al., 2018).

- *Set-based similarity measures:* Word Mover's Distance (WMD) (Kusner et al., 2015), soft-cardinality with Jaccard coefficient (Jimenez et al., 2012), DynaMax with Jaccard (Zhelezniak et al., 2019b), mean- and max-pooled word vectors with cosine similarity (COS), and mean-pooled word vectors with Spearman correlation (SPR) (Zhelezniak et al., 2019a).

- *Proposed set-based approaches:* max-pooled word vectors with Spearman correlation, CKA with linear kernel (also known as RV-coefficient), CKA with Gaussian kernel (median estimation for σ^2), and CKA with distance kernel (distance correlation).

Note that for BERT we evaluated all pooling strategies available in bert-as-service (Xiao, 2018) applied to either the last or second-to-last layers and report results for the best-performing combination, which was mean-pooling on the last layer for both model sizes. Our results are presented in Table 1. We can clearly see that deep learning-based methods do not shine on STS tasks, while simple compositions of word vectors can perform extremely well, especially when an appropriate correlation coefficient is used as the similarity measure. Indeed, the performance of max-pooled vectors with Spearman correlation approaches or exceeds that of more expensive or offline methods like that of Arora et al. (2017), which performs PCA computations on the entire test set. Additionally, while the multivariate correlation methods such as CKA are more computationally expensive than pooling-based approaches (see Table 2), they can provide performance boost on some tasks, making the cost worth it depending on the application. Finally, we conducted an exploratory error analysis and found that many errors are due to the well-known inherent weaknesses of word embeddings. For example, the proposed approaches heavily overestimate similarity when two sentences contain antonyms or when one sentence is the negation of the other. We illustrate these and other cases in the Appendix.

Approach	**Time complexity**
MaxPool+SPR	$O(nd + d \log d)$
CKA	$O(nd^2 + d^2)$
DynaMax	$O(n^2 d)$
SoftCard	$O(n^2 d)$
WMD	$O(n^3 \log n \cdot d)$
WMD (relaxed)	$O(n^2 d)$

Table 2: Computational complexity of some of the set-based STS methods discussed in this paper. Here n is the sentence length and d is the dimensionality of the word embeddings.

6 Conclusion

In this work we investigate the application of statistical correlation coefficients to sets of word vectors as a method for computing semantic textual similarity (STS). This can be done either by pooling these word vectors and computing univariate correlations between the resulting representations, or by applying multivariate correlation coefficients to the sets of vectors directly.

We provide further empirical evidence that outliers in word vector distributions disrupt performance of set-based similarity metrics as previously shown (Zhelezniak et al., 2019a). We also show working methods for solving or avoiding the issue through vector pooling operations, robust correlations or winsorization. In addition, we found that pooling operations in conjunction with univariate correlation coefficients yield one of the strongest results on downstream STS tasks, while being computationally much more efficient than competing set-based methods. Our findings are

supported by a combination of statistical analysis, practical examples and visualisations, and empirical evaluation on standard benchmark datasets.

Both proposed families of approaches serve as strong baselines for future research into STS, as well as useful algorithms for the practitioner, being efficient and simple to implement.

We believe our findings speak to the efficacy of the statistical perspective on word embeddings, which we hope will encourage others to explore further implications of not only this particular framework, but also completely novel interpretations of textual representations.

Game Theory Meets Embeddings: a Unified Framework for Word Sense Disambiguation

Rocco Tripodi

Abstract

Game-theoretic models, thanks to their intrinsic ability to exploit contextual information, have shown to be particularly suited for the Word Sense Disambiguation task. They represent ambiguous words as the players of a non-cooperative game and their senses as the strategies that the players can select in order to play the games. The interaction among the players is modeled with a weighted graph and the payoff as an embedding similarity function, which the players try to maximize. The impact of the word and sense embedding representations in the framework was tested and analyzed extensively: experiments on standard benchmarks show state-of-art performances and different tests hint at the usefulness of using disambiguation to obtain contextualized word representations.

1 Introduction

Word Sense Disambiguation (WSD), the task of linking the appropriate meaning from a sense inventory to words in a text, is an open problem in Natural Language Processing (NLP). It is particularly challenging because it deals with the semantics of words and, by their very nature, words are ambiguous and can be used with different meanings in different situations. Among the key tasks aimed at enabling Natural Language Understanding (Navigli, 2018), WSD provides a basic, solid contribution since it is able to identify the intended meaning of the words in a sentence (Kim et al., 2010).

WSD can be seen as a classification task in which words are the objects to be classified and senses are the classes into which the objects have to be classified (Navigli, 2009); therefore it is possible to use supervised learning techniques to solve the WSD problem. One drawback with this idea is that it requires large amounts of data that are difficult to obtain. Furthermore, in the WSD context, the production of annotated data is even more complicated and excessively time-consuming compared to other tasks. This arises because of the variability in lexical use. Furthermore, the number of different meanings to be considered in a WSD task is in the order of thousands, whereas classical classification tasks in machine learning have considerably fewer classes.

We decided to adopt a semi-supervised approach to overcome the knowledge acquisition bottleneck and innovate the strand of research introduced by Tripodi and Pelillo (2017). These researchers developed a flexible game-theoretic WSD model that exploits word and sense similarity information. This combination of features allows the textual coherence to be maintained: in fact, in this model the disambiguation process is relational, and the sense assigned to a word must always be compatible with the senses of the words in the same text. It can be seen as a constraint satisfaction model which aims to find the best configuration of senses for the words in context. This is possible because the payoff function of the games is modeled in a way in which, when a game is played between two players, they are emboldened to select the senses that have the highest compatibility with the senses that the co-player is choosing. Another appealing feature of this model is that it offers the possibility to configure many components of the system: it is possible to use any word and sense representation; also, one can model the interactions of the players in different ways by exploiting word similarity information, the syntactic structure of the sentence and the importance provided by specific relations. Furthermore, it is possible to use different priors on the sense distributions and to use different game dynamics to find the equilibrium state of the model. Traditional WSD methods have only some of these

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 88–99,
Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

properties.

The main difference between our model and the model proposed by Tripodi and Pelillo (2017) is that they did not use state-of-the-art models for word and sense representations. They used word co-occurrence measures for word similarity and *tf-idf* vectors for sense similarity, resulting in sparse graphs in which nodes can be disjoint or some semantic area is not covered. Instead, we are advocating the use of dense vectors, which provide a completely different perspective not only in terms of representation but also in terms of dynamics. Each player is involved in many more games and this affects the computation of the payoffs and the convergence of the system. The interaction among the players is defined in a different way and the priors are modeled with a more realistic distribution to avoid the skewness typical of word sense distributions. Furthermore, our model is evaluated on recent standard benchmarks, facilitating comparison with other models.

The main contributions of this paper are as follows:

1. the release of a general framework for WSD;
2. the evaluation of different word and sense embeddings;
3. state-of-the-art performances on standard benchmarks (in different cases performing better than recent supervised models);
4. the use of disambiguated sense vectors to obtain contextualized word representations.

2 Word Sense Disambiguation

WSD approaches can be divided into two main categories: supervised, which require human intervention in the creation of sense-annotated datasets, and the so-called knowledge-based approaches (Navigli, 2009), which require the construction of a task-independent lexical-semantic knowledge resource, but which, once that work is available, use models that are completely autonomous.

As regards supervised systems, a popular system is *It makes sense* (Zhong and Ng, 2010), a model which takes advantage of standard WSD features such as POS-tags, word co-occurrences, and collocations and creates individual support vector machine classifiers for each ambiguous word. Newer supervised models exploit deep neural networks and especially long short-term memory (LSTM) networks, a type of recurrent neural network particularly suitable for handling arbitrary-length sequences. Yuan et al. (2016) proposed a deep neural model trained with large amounts of data obtained in a semi-supervised fashion. This model was re-implemented by Le et al. (2018), reaching comparable results with a smaller training corpus. Raganato et al. (2017) introduced two approaches for neural WSD using models developed for machine translation and substituting translated words with sense-annotated ones. A recent work that combines labeled data and knowledge-based information has been proposed by Luo et al. (2018). Uslu et al. (2018) proposed *fastSense*, a model inspired by *fastText* (Joulin et al., 2017) which – rather than predicting context words – predicts word senses.

Knowledge-based models, instead, exploit the structural properties of a lexical-semantic knowledge base, and typically use the relational information between concepts in the semantic graph together with the lexical information contained therein (Navigli and Lapata, 2010). A popular algorithm used to select the sense of each word in this graph is PageRank (Page et al., 1999) that performs random walks over the network to identify the most important nodes (Haveliwala, 2002; Mihalcea et al., 2004; De Cao et al., 2010). An extension of these models was proposed by Agirre et al. (2014) in which the Personalized PageRank algorithm is applied. Another knowledge-based approach is Babelfy (Moro et al., 2014), which defines a semantic signature for a given context and compares it with all the candidate senses in order to perform the disambiguation task. Chaplot and Salakhutdinov (2018) proposed a method that uses the whole document as the context for the words to be disambiguated, exploiting topical information (Ferret and Grau, 2002). It models word senses using a variant of the Latent Dirichlet Allocation framework (Blei et al., 2003), in which the topic distributions of the words are replaced with sense distributions modeled with a logistic normal distribution according to the frequencies obtained from WordNet.

3 Word and Sense Embeddings

A good machine-interpretable representation of lexical features is fundamental for every NLP system. A system's performance, however, depends

on the quality of the input representations. Furthermore, the inclusion of semantic features, in addition to lexical ones, has been proven effective in many NLP approaches (Li and Jurafsky, 2015).

Word embeddings, the current paradigm for lexical representation of words, were popularized with word2vec (Mikolov et al., 2013). The main idea is to exploit a neural language model which learns to predict a word occurrence given its surroundings. Another well-known word embedding model was presented by Pennington et al. (2014), which shares the idea of word2vec, but with the difference that it uses explicit latent representations obtained from statistical calculation on word co-occurrences. However, all word embedding models share a common issue: they cannot capture polysemy since they conflate the various word senses into a single vector representation. Several efforts have been presented so far to deal with this problem. SensEmbed (Iacobacci et al., 2015) uses a knowledge-based disambiguation system to build a sense-annotated corpus that, in its turn, is used to train a vector space model for word senses with word2vec. AutoExtend (Rothe and Schütze, 2015), instead, is initialized with a set of pre-trained word embeddings, and induces sense and synset vectors in the same semantic space using an autoencoder. The vectors are induced by constraining their representation given the assumption that synsets are sums of their lexemes. Camacho-Collados et al. (2015) presented NASARI, an approach that learns sense vectors by exploiting the hyperlink structure of the English Wikipedia, linking their representations to the semantic network of BabelNet (Navigli and Ponzetto, 2012). More recent works, such as ELMo (Peters et al., 2018) and BERT (Devlin et al., 2019), are based on language models learned using complex neural network architectures. The advantage of these models is that they can produce different representations of words according to the context in which they appear.

4 Game Theory and Game Dynamics

In this work we take a different approach to WSD by employing a model based on game theory (GT). This discipline was introduced by Neuman and Morgenstern (1944) in order to develop a mathematical framework able to model the essentials of decision making in interactive situations. In its *normal-form* representation (Weibull, 1997), it consists of a finite set of players $N = (1, .., n)$, a finite set of pure strategies $S_i = \{1, ..., m_i\}$ for each player $i \in N$, and a payoff (utility) function $u_i : S \rightarrow \mathbb{R}$, that associates a payoff with each combination of strategies in $S = S_1 \times S_2 \times ... \times S_n$. A fundamental assumption in game theory is that each player i tries to maximize the value of u_i. Furthermore, in *non-cooperative games* the players choose their strategies independently, considering what choices other players can make and trying to find the best response to the strategy of the co-players.

A player i, in addition to playing single (pure) strategies from S_i, can also use *mixed strategies*, that are probability distributions over pure strategies. A mixed strategy over S_i is defined as a vector $\mathbf{x_i} = (x_1, \ldots, x_{m_i})$, such that $x_j \geq 0$ and $\sum x_j = 1$. Each mixed strategy corresponds to a point in the simplex Δ_m, whose corners correspond to pure strategies. The intuition is that player i randomises over strategies according to the probabilities in $\mathbf{x_i}$. Each mixed strategy profile lives in the mixed strategy space of the game, given by the Cartesian product $\Theta = \Delta_{m_1} \times \Delta_{m_2} \times \cdots \times \Delta_{m_n}$.

In a *two-player game*, a strategy profile can be defined as a pair $(\mathbf{x}_i, \mathbf{x}_j)$. The expected payoff for this strategy profile is computed as:

$$u(\mathbf{x}_i, \mathbf{x}_j) = \mathbf{x}_i^T \cdot A_{ij}\mathbf{x}_j$$

where A_{ij} is the $m_i \times m_j$ payoff matrix between players i and j.

In evolutionary game theory (Weibull, 1997), the games are played repeatedly and the players update their mixed strategy distributions over time until no player can improve the payoff obtained with the current mixed strategy. This situation corresponds to the equilibrium of the system.

The payoff corresponding to the h-th pure strategy is computed as:

$$u(x_i^h) = x_i^h \cdot \sum_{j=1}^{n_i} (A_{ij}\mathbf{x}_j)^h \quad (1)$$

It is important to note here that the payoff in Equation 1 is additively separable, in fact, the summation is over all the n_i players with whom i is playing the games. The average payoff of player i is calculated as:

$$u(\mathbf{x}_i) = \sum_{h=1}^{m_i} u(x_i^h) \quad (2)$$

To find the Nash equilibrium of the game it is common to use the discrete time version of the *replicator dynamics* equation (Weibull, 1997) for each player $i \in N$,

$$x_i^h(t+1) = x_i^h(t)\frac{u(x_i^h)}{u(\mathbf{x}_i)} \qquad \forall\, h \in \mathbf{x}_i \qquad (3)$$

This equation allows better than average strategies to grow at each iteration. It can be considered as an *inductive learning* process, in which the players learn from past experiences how to play their best strategy. We note that each player optimizes their individual strategy space, but this operation is done according to what other players simultaneously are doing, so the local optimization is the result of a global process.

Game-theoretic models are appealing because they are versatile, interpretable and have a solid mathematical foundation. Furthermore, it is always possible to find the Nash equilibrium in non-cooperative games in mixed strategies (Nash, 1951). In fact, starting from an interior point of Θ, a point $\mathbf{x}$ is a Nash equilibrium only if it is the limit of a trajectory of Equation 3 (Weibull, 1997).

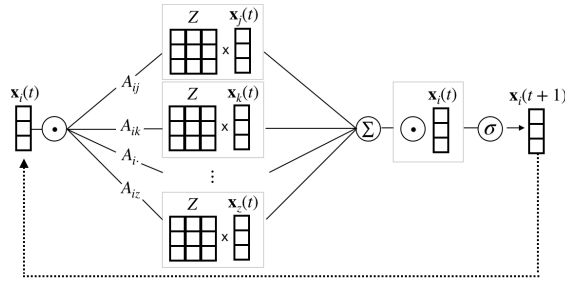

Figure 1: Generic scheme of the model. $\cdot$, $\times$ and σ refer to elementwise multiplication, matrix multiplication and normalization, respectively.

5 The Model

The model used in this paper, Word Sense Disambiguation Games (*WSDG*), was introduced by Tripodi and Pelillo (2017). It is based on graph-theoretic principles to model the geometry of the data and on game theory to model the learning algorithm which disambiguates the words in a text. It represents the words as the players of a non-cooperative game and their senses as the strategy that the players can select in order to play the games. The players are arranged in a graph whose edges determine the interactions and carry word similarity information. The payoff matrix is encoded as a sense similarity function. The players play the games repeatedly and – at each iteration – update their strategy preferences according to what strategy has been effective in previous games. These preferences, as introduced previously, are encoded as a probability distribution over strategies (senses).

Formally, for a text T we select its content words $W = (1, \ldots, n)$ as the players of the game $I = (1, \ldots, n)$. For each word we use a knowledge base to determine its possible senses. Each sense is represented as a strategy that the player can select from the set $S_i = \{1, ..., m_i\}$, where m_i is the number of senses of word w_i. The set of all different senses in the text, $C = \{1, ..., m\}$, is the strategy space of the games. The strategy space is modeled, for each player, as a probability distribution, $\mathbf{x}_i$, of length m. It takes non-zero values only on the entries corresponding to the elements of S_i. It can be initialized with a normal distribution in the case of unsupervised learning or with information obtained from sense-labeled corpora in the case of semi-supervised learning.

The payoff of a game depends on a payoff matrix Z in which the rows are indexed according to the strategies of player i and the columns according to the strategies of player j. Its entries $Z_{r,t}$ are the payoff obtained when player i selects strategy r and player j selects strategy t. It is important to note here that the payoff of a game does not depend on the single strategy taken individually by a player, but always by the combination of two simultaneous actions. In WSD this means that the sense selected by a word influences the choices of the other words in the text and this allows the textual coherence to be maintained.

The disambiguation games to build a payoff function require: a word similarity matrix A, a sense similarity matrix Z and a sense distribution $\mathbf{x}_i$ for each player i. A models the players' interactions, so that similar players play together and the more similar they are the more reciprocal influence they have. It can be interpreted as an attention mechanism (Vaswani et al., 2017) since it weights the payoffs. Z is used to create the payoff matrices of the games so that the more similar the senses of the words are the more the corresponding players are encouraged to select them, since they give a high payoff. A and Z are obtained by computing vector representations of word and sense (see Section 3) and then calculating their pairwise sim-

ilarity.

The strategy space of each player, i, is represented as a column vector of length m. It is initialized with:

$$x_i^h = \begin{cases} |m_i|^{-1} & \text{if sense } h \text{ is in } S_i, \\ 0 & \text{otherwise.} \end{cases} \quad (4)$$

This initialization is used in the case of unsupervised WSD, since it does not use information from sense-tagged corpora. If instead this information is available, $|m_i|^{-1}$ in Equation 4 is substituted with the frequency of the corresponding sense and then $\mathbf{x}_i$ is normalized in order to sum up to one.

Once these sources of information are computed, the *WSDG* are run by using the replicator dynamic equation (Taylor and Jonker, 1978) in Equation 3, where the payoff of strategy h for player i is calculated as:

$$u(x_i^h) = x_i^h \cdot \sum_{j=1}^{n_i} (A_{ij} Z \mathbf{x}_j)^h \quad (5)$$

where n_i are the neighbours of player i as in the graph A. The average payoff is calculated as:

$$u(\mathbf{x}_i) = \sum_{h=1}^{m_i} u(x_i^h) \quad (6)$$

The complexity of *WSDG* scales linearly with the number of words to be disambiguated. Differently from other models based on PageRank, it is possible to disambiguate all the words at the same time. As an example, *WSDG* can disambiguate 200 words (1650 senses) in 7 seconds, on a single CPU core. A generic representation of the model is proposed in Figure 1.

Implementation details The cosine similarity was used as similarity measure for both words and senses. The A matrix was treated as the adjacency matrix of an undirected weighted graph and, to reduce the complexity of the model, the edges with weight lower than 0.1 were removed. The symmetric normalized Laplacian of this graph was calculated as $D^{-1/2}AD^{-1/2}$, where D is the degree matrix of graph A. Since the algorithm operates on an entire text, local information is added to matrix A. The mean value of the matrix is added to the $\lceil log(n) \rceil$ cells on the left of the main diagonal. For BERT, this operation was replaced with its attention layer, adding to matrix A the mean attention distribution of all the heads of the last layer. The choice of the last layer is motivated by the fact that it stores semantic information and its attention distributions have high entropy (Clark et al., 2019). The first singular vector was removed from A in the case of word vectors whose length exceeded 500. This was done to reduce the redundancy of the representations in line with Arora et al. (2017). The distributions for each $\mathbf{x}$ were computed according to SemCor (Miller et al., 1993) and normalized using the softmax function. The replicator dynamics were run until a maximum number of iterations was reached (100) or the difference between two consecutive iterations was below a small threshold (10^{-3}), calculated as $\sum_{i=1}^{n} \|\mathbf{x_i}(t-1) - \mathbf{x_i}(t)\|$. The code of the model is available at `https://github.com/roccotrip/wsd_games_emb`.

6 Evaluation

The evaluation of our model was conducted using the framework proposed by Raganato et al. (2017). This consists of five datasets which were unified to the same WordNet 3.0 inventory: Senseval-2 (S2), Senseval-3 (S3), SemEval-2007 (SE7), SemEval-2013 (SE13) and SemEval-2015 (SE15). These datasets have in total 26 texts and 10,619 words to be disambiguated. Our objective was to test our game-theoretic model with different settings and to evaluate its performances. To this end we performed experiments comparing 16 different sets of pretrained word embeddings and 7 sets of sense embeddings.

Word embeddings As word embedding models we included 4 pre-word2vec models: the *hierarchical log-bilinear* model (Mnih and Hinton, 2007, HLBL), a probabilistic linear neural model which aims to predict the embedding of a word given the concatenation of the previous words; CW (Collobert and Weston, 2008), an embeddings model with a deep unified architecture for multitask NLP; Distributional Memory (Baroni and Lenci, 2010, DM), a semantically enriched count-based model; leskBasile (Basile et al., 2014), a model based on Latent Semantic Analysis reduced via Singular-Value Decomposition; 3 models obtained with word2vec: GoogleNews, a set of 300-dimensions vectors trained with the Google News dataset; BNC-*, vectors of different dimensions trained on the British National Corpus including POS information during training; and w2vR, trained with word2vec on the 2014

dump of the English Wikipedia, enriched with retrofitting (Faruqui et al., 2015), a technique to enhance pre-trained embeddings with semantic information. The enrichment was performed using retrofitting's best configuration, based on the Paraphrase Database (Ganitkevitch et al., 2013, PPDB). We also tested GloVe (Pennington et al., 2014), trained with the concatenation of the 2014 dump of the English Wikipedia and Gigaword 5, and fastText (Bojanowski et al., 2017) trained on Wikipedia 2017, UMBC corpus and the statmt.org news dataset.

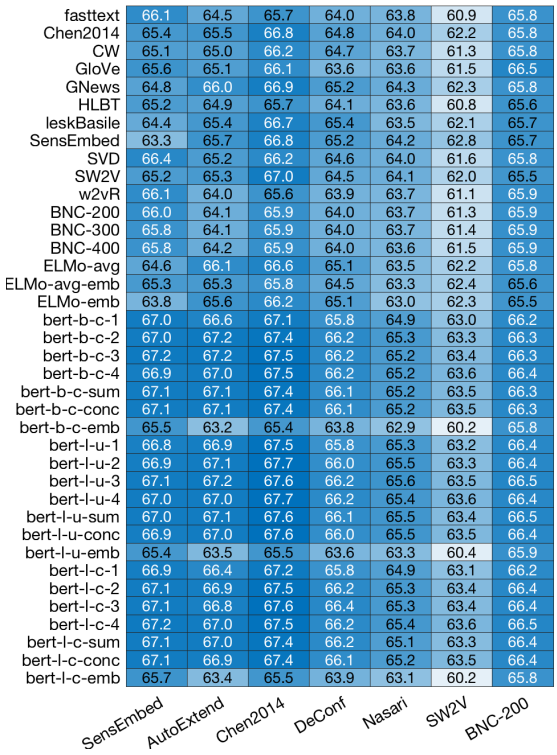

Figure 2: Performances of the model on the union of all datasets. The results are presented as F1 for all combinations of word and sense embeddings. Word vectors are on the rows and sense vectors on the columns.

Contextualized word embeddings As contextualized embeddings we used ELMo (Peters et al., 2018) in three different configurations, namely: ELMo-avg, weighted sum of its three layers; ELMo-avg emb, weighted sum of its three layers and the embeddings it produces; and ELMo-emb, the word embeddings produced by the model[1]. We also tested three implementations of BERT (Devlin et al., 2019): base cased (b-c); large uncased (l-u) and large cased (l-c). They offer pre-trained deep bidirectional representations of words in context[2]. We used seven configurations for each model: one for each of the last four layers (numbered from 1 to 4), the sum of these layers, their concatenation and the embedding layer. We fed all these models with the entire texts of the datasets. Since BERT uses WordPiece tokenization, we averaged sub-token embeddings to obtain token-level representations.

We also included three models which were built together with the sense embeddings introduced below.

Sense embeddings As sense embeddings, in addition to the three models introduced in Section 3 (AutoExtend, NASARI and SensEmbed), we included four models: Chen et al. (2014), a unified model which learns sense vectors by training a sense-annotated corpus disambiguated with a framework based on semantic similarity of WordNet sense definitions; meanBNC, created using a weighted combination of the words from WordNet glosses, using, as word vectors, the set of BNC-200 mentioned earlier; DeConf (Pilehvar and Collier, 2016), also linked to WordNet, a model where sense vectors are inferred in the same semantic space of pre-trained word embeddings by decomposing the given word representation into its constituent senses; and finally SW2V (Mancini et al., 2017), a model linked to BabelNet which uses a shallow disambiguation step and which, by extending the word2vec architecture, learns word and sense vectors jointly in the same semantic space as an emerging feature.

Results The results of these models are reported in Figure 2. One of the most interesting patterns that emerges from the heat map is that there are some combinations of word and sense embeddings that always work better than others. Sense vectors drive the performance of the system, contributing in great part to the accumulation of payoffs during the games. The sense vectors that maintain high performances are SensEmbed, AutoExtended and Chen2014. In particular Chen2014 has high performances with all the word embedding combinations. While these models are specific sense embedding techniques, the construction of BNC-200 follows a very simple method, which in view of these results can be refined using more principled gloss embedding techniques. Table 1: Comparison with state-of-the-art algorithms: unsupervised or knowledge-based (*unsup.*), and supervised (*sup.*). *MFS* refers to the MFS heuristic computed on SemCor on each dataset. The results are provided as F1 and the first result of the semi supervised systems with a statistically significant difference from the best of each dataset is marked with * (χ^2, $p < 0.1$). † indicates the same statistics but including also supervised models.

NASARI are lower compared to lexical vectors: this may be due to our choice to use NASARI-embed, whose vectors have low dimensionality.

The word vectors that have consistently high performances in association with the three sense vectors mentioned above are BERT, Chen2014, SensEmbed and SW2V. This is not surprising since they are able to produce contextualised word representations, performing, in fact, a preliminary disambiguation of the words. In particular, SW2V is specifically tailored for WSD. ELMo and fastText perform slightly worse. The vectors constructed using syntactic information and trained on the BNC corpus have similar performances to the their counterparts trained on larger corpora without the use of syntactic information. If we focus on BERT, we can see that it is able to maintain high performances ($F1 \approx 67$) with all its configurations, except for the embedding layers of all the models (*-emb). The contribution of the sum and concatenation operations is not significant.

Comparison We performed a comparison with 3 configurations of our model, one for each of the three best sense vectors: WSDG$_\alpha$, obtained using Chen2014 as sense vectors and BERT-l-u-4 as word vectors; WSDG$_\beta$, obtained using SensEmbed as sense vectors and BERT-l-c-4 as word vectors; and WSDG$_\gamma$, obtained using AutoExtended as sense vectors and BERT-l-u-3 as word vectors.

As comparison systems we included three semi-supervised approaches mentioned above, Babelfy (Moro et al., 2014), ppr$_{w2w}$, the best configuration of UKB (Agirre et al., 2018), and WSD-TM, introduced by Chaplot and Salakhutdinov (2018) (for this model we did not have the possibility to verify the results since its code is not available). In addition, we also report the performances of relevant supervised models, namely: It Makes Sense (Zhong and Ng, 2010, IMS), Iacobacci et al. (2016), Yuan et al. (2016), Raganato et al. (2017), Joulin et al. (2017) and Uslu et al. (2018).

The results of our evaluation are shown in Table 1. As we can see our model achieves state-of-the-art performances on four datasets and on S13 and S15 it performs better than many supervised systems. In general the gap between supervised and semi-supervised systems is reducing. This encourages new research in this direction. Our model fares particularly well on the disambiguation of nouns and verbs. However, the main gap between our models and supervised systems relies upon the disambiguation of verbs.

7 Analysis

Polysemy As expected, most of the errors made by WSDG$_\alpha$ are on highly polysemous words. Figure 3 shows that the number of wrong answers increases as the number of senses grows, and that the number of wrong answers starts to be higher than that of correct answers when the number of senses for a target word is in the range of 10-15 senses. The words with the highest number of errors are polysemous verbs such as: *say* (34), *make* (24), *find* (21), *have*, (17), *take* (15), *get*, (15) and *do* (13). These are words that in many NLP applications (especially those based on distributional models) are treated as stopwords.

Sense rank Mancini et al. (2017) show that senses which are not the most frequent ones are particularly challenging and most sense-based approaches fail to represent them properly. In Figure 4 we report the results of WSDG$_\alpha$ divided per sense rank, where it is possible to see how the performances of the system deteriorate as the rank of the correct sense increases. It is interesting to see that, in the first part of the plot, the performances follow a regular pattern that resembles a power-law distribution. This requires further analysis beyond the scope of this work, along the lines of Ferrer-i Cancho and Vitevitch (2018).

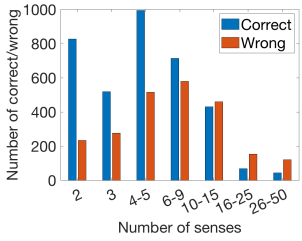

Figure 3: Correct and wrong answers given by WSDG$_\alpha$ grouped by number of senses

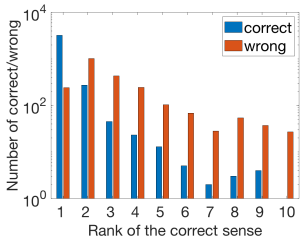

Figure 4: Correct and wrong answers given by WSDG$_\alpha$ per sense rank.

Priors Corroborating the findings of Pilehvar and Navigli (2014), Postma et al. (2016) conducted a series of experiments to study the effect that the variation of sense distributions in the training set has on the performances of *It makes sense* (Zhong and Ng, 2010). Specifically, they increased the volume of training examples (V) by enriching SemCor with senses inferred from BabelNet; increased the number of least frequent senses (LFS) (V+LFS); and overfitted the model constructing a training set proportional to the correct sense distribution of the test set (GOLD,GOLD+LFS). We used the same training sets to compute the priors for our system. The results of this analysis are reported in Table 2. These experiments show that increasing the number of training examples has a small beneficial effect. Increasing the number of LFS examples leads to worse results because this is a deviation from a real sense distribution. Further, to work with better semantic representations, this operation should also be accompanied by a similar selection on the training set of sense and word embeddings, otherwise LFS remain underrepresented. Finally, mimicking the distribution of the test set is more beneficial for *WSDG*$_\alpha$ than for IMS, especially when LFS examples are added, suggesting that semi-supervised systems can better adapt to specific domains than supervised systems.

System	V	V+LFS	GOLD	GOLD+LFS
IMS	68.9	62.0	86.8	85.4
WSDG$_\alpha$	66.4	57.5	88.4	90.8

Table 2: Comparison using different priors.

8 Exploratory study

We now present three WSD applications in as many tasks: selection of context-sensitive embeddings; sentence similarity; paraphrases detection.

Context-sensitive embeddings We used the Word in Context (WiC) dataset (Pilehvar and Camacho-Collados, 2019) for this task. It contains 7466 sentence pairs in which a target word appears in two different contexts. The task consisted of predicting if a target word has the same sense in the two sentences or not. The aim of this experiment was twofold: we wanted to show the usefulness of contextualized word embeddings obtained from WSD systems and to demonstrate that the model was able to maintain the textual coherence. The experiments on this dataset were conducted on the development set (1400 sentence pairs). The comparison was conducted against state-of-the-art models for contextualized word embeddings and sense embeddings: Context2Vec (Melamud et al., 2016) based on a bidirectional LSTM language model; ELMo$_1$, the first LSTM hidden state; ELMo$_3$, the weighted sum of the 3 LSTM layers; BERT$_{\text{base}}$; BERT$_{\text{large}}$. The results of these systems were taken from Pilehvar and Camacho-Collados (2019). We note here that all these models, including WSDG$_\alpha$, do not use training data. They are based on a simple threshold-based classifier, tuned on the development set (638 sentence pairs). WSDG$_\alpha$ disambiguates all the words in each pair of sentences separately and, if the cosine

C2V	ELMo$_1$	ELMo$_3$	BERT$_{base}$	BERT$_{large}$	WSDG$_\alpha$
59.7	57.1	56.3	63.6	63.8	**66.2**

Table 3: Performance on the WiC dataset.

	Pearson	Spearman	MSE
sense	46.5	43.9	7.9
word	39.8	39.9	8.6

Table 4: *WSDG*$_\alpha$ results on the SICK dataset.

similarity among the senses assigned to the target words is below a threshold (0.9), it classifies the pair as different senses, and as the same sense otherwise. As shown in Table 3 the disambiguation step has a big impact on the results.

Sentence similarity We used the SICK dataset (Marelli et al., 2014) for this task. It consists of 9841 sentence pairs that had been annotated with relatedness scores on a 5-point rating scale. We used the test split of this dataset that contains 4906 sentence pairs. The aim of this experiment was to test if disambiguated sense vectors can provide a better representation of sentences than word vectors. We used a simple method to test the two representations: it consisted of representing a sentence as the sum of the disambiguated sense vectors in one case and as the sum of word vectors in the other case. Once the sentence representations had been obtained for both methods the cosine similarity was used to measure their relatedness. The results of this experiment are reported in Table 4 as Pearson and Spearman correlation and Mean Squared Error (MSE). We used the α configuration of our model with Chen2014 to represent senses and BERT-l-u-4 to represent words. As we can see the simplicity of the method leads to low performances for both representations, but sense vectors correlate better than word vectors.

Paraphrase detection We used the test set of the Microsoft Research Paraphrase Corpus (Dolan et al., 2004, MRPC) for this task. The corpus contains 1621 sentence pairs that have been annotated with a binary label: 1 if the two sentences constitute a paraphrase and 0 otherwise. In this task we also used the sum of word vectors and the sum of disambiguated sense vectors to represent the sentences, and used part of the training set (10%) in order to tune the threshold parameter below which the sentences are not considered paraphrase. The classification accuracy for the word vectors used by *WSDG*$_\alpha$ was 58.1 whereas the disambiguated sense vectors obtained 66.9.

9 Conclusion

In this work we have presented *WSDG*, a flexible game-theoretic model for WSD. It combines game dynamics with most successful word and sense embeddings, therefore showing the potential of an effective combination of the two areas of game theory and word sense disambiguation.

Our approach achieves state-of-the-art performances on four datasets performing particularly well on the disambiguation of nouns and verbs. Beyond the numerical results, in this paper we have presented a model able to construct and evaluate word and sense representations. This is particularly useful since it can serve as a test bed for new word and sense embeddings. In particular, it will be interesting to test new sense embedding models based on contextual embeddings.

Thanks to the flexibility and scalability of our model, as future work we plan to explore in depth its use in different tasks, such as the creation of sentence (document) embeddings and lexical substitution. In fact, we believe that using disambiguated sense vectors, as shown in the context-sensitive embeddings and paraphrase detection studies, can offer a more accurate representation and improve the quality of downstream applications such as sentiment analysis and text classification (see, e.g., (Pilehvar et al., 2017)), machine translation and topic modelling. Encouraged by the good results achieved in our exploratory studies, we plan to develop a new model for contextualised word embeddings based on a game-theoretic framework.

Acknowledgments

Guided Dialog Policy Learning: Reward Estimation for Multi-Domain Task-Oriented Dialog

Ryuichi Takanobu[1], **Hanlin Zhu**[2], **Minlie Huang**[1*]

Abstract

Dialog policy decides what and how a task-oriented dialog system will respond, and plays a vital role in delivering effective conversations. Many studies apply Reinforcement Learning to learn a dialog policy with the reward function which requires elaborate design and pre-specified user goals. With the growing needs to handle complex goals across multiple domains, such manually designed reward functions are not affordable to deal with the complexity of real-world tasks. To this end, we propose Guided Dialog Policy Learning, a novel algorithm based on Adversarial Inverse Reinforcement Learning for joint reward estimation and policy optimization in multi-domain task-oriented dialog. The proposed approach estimates the reward signal and infers the user goal in the dialog sessions. The reward estimator evaluates the state-action pairs so that it can guide the dialog policy at each dialog turn. Extensive experiments on a multi-domain dialog dataset show that the dialog policy guided by the learned reward function achieves remarkably higher task success than state-of-the-art baselines.

1 Introduction

Dialog policy, deciding the next action that the dialog agent should take at each turn, is a crucial component of a task-oriented dialog system. Among many models, Reinforcement Learning (RL) is commonly used to learn dialog policy (Fatemi et al., 2016; Peng et al., 2017; Chen et al., 2017; Yarats and Lewis, 2018; Lei et al., 2018; He et al., 2018; Su et al., 2018), where users are modeled as a part of the environment and the policy is learned through interactions with users.

While it is too expensive to learn directly from real users since RL requires a large number of samples to train, most existing studies use data-driven approaches to build a dialog system from conversational corpora (Zhao and Eskenazi, 2016; Dhingra et al., 2017; Shah et al., 2018; Shi and Yu, 2018), where a common strategy is to build a user simulator, and then to learn dialog policy through making simulated interactions between an agent and the simulator. A typical reward function on policy learning consists of a small negative penalty at each turn to encourage a shorter session, and a large positive reward when the session ends successfully if the agent completes the user goal.

U:	I'm looking for a hotel to stay that has 5 stars and cheap price range.
S:	I am sorry that there is no such hotel, would you like to reserve a 3-star hotel as an alternative?
U:	I'd prefer a 4-star hotel even if it's a bit expensive. Oh, and I need parking.
S:	OK, I find a moderately priced 4-star hotel that includes parking and free wifi.
U:	Are there any places to eat around it?
S:	Many. Japanese, Indian, French, etc. What kind of food would you like?

Table 1: An example of the multi-domain task-oriented dialog between the user (U) and the system (S). The dialog proceeds successfully because the system informs the user that no matching hotel exists (the first turn), identifies the new user goal about parking (the second turn), and shifts the topic to the restaurant domain (the third turn), which well understands the user's demand.

However, specifying an effective reward function is challenging in task-oriented dialog. On one hand, the short dialogs resulted from the negative constant rewards are not always efficient. The agent may end a session too quickly to complete the task properly. For example, it is inappropriate to book a 3-star hotel without confirming with the user at the first turn in Table 1. On the other hand, an explicit user goal is essential to evaluate the task success in the reward design, but user goals are hardly available in real situations (Su et al.,

2016). In addition, the user goal may change as the conversation proceeds. For instance, the user introduces a new requirement for the parking information at the second turn in Table 1.

Unlike a handcrafted reward function that only evaluates the task success at the end of a session, a good reward function should be able to guide the policy dynamically to complete the task during the conversation. We refer to this as the *reward sparsity* issue. Furthermore, the reward function is often manually tweaked until the dialog policy performs desired behaviors. With the growing needs for the system to handle complex tasks across multiple domains, a more sophisticated reward function would be designed, which poses a serious challenge to manually trade off those different factors.

In this paper, we propose a novel model for learning task-oriented dialog policy. The model includes a robust dialog reward estimator based on Inverse Reinforcement Learning (IRL). The main idea is to automatically infer the reward and goal that motivates human behaviors and interactions from the real human-human dialog sessions. Different from conventional IRL that learns a reward function first and then trains the policy, we integrate Adversarial Learning (AL) into the method so that the policy and reward estimator can be learned simultaneously in an alternate way, thus improving each other during training. To deal with reward sparsity, the reward estimator evaluates the generated dialog session using state-action pairs instead of the entire session, which provides reward signals at each dialog turn and guides dialog policy learning better.

To evaluate the proposed approach, we conduct our experiments on a multi-domain, multi-intent task-oriented dialog corpus. The corpus involves large state and action spaces, multiple decision making in one turn, which makes it more challenging for the reward estimator to infer the user goal. Furthermore, we experiment with two different user simulators. The contributions of our work are in three folds:

- We build a reward estimator via Inverse Reinforcement Learning (IRL) to infer an appropriate reward from multi-domain dialog sessions, in order to avoid manual design of reward function.
- We integrate Adversarial Learning (AL) to train the policy and estimator simultaneously, and evaluate the policy using state-action pairs to better guide dialog policy learning.
- We conduct experiments on the multi-domain, multi-intent task-oriented dialog corpus, with different types of user simulators. Results show the superiority of our model to the state-of-the-art baselines.

2 Related Work

2.1 Multi-Domain Dialog Policy Learning

Some recent efforts have been paid to multi-domain task-oriented dialog systems where users converse with the agent across multiple domains. A natural way to handle multi-domain dialog systems is to learn multiple independent single-domain sub-policies (Wang et al., 2014; Gašić et al., 2015; Cuayáhuitl et al., 2016). Multi-domain dialog completion was also addressed by hierarchical RL which decomposes the task into several sub-tasks in terms of temporal order (Peng et al., 2017) or space abstraction (Casanueva et al., 2018), but the hierarchical structure can be very complex and constraints between different domains should be considered if an agent conveys multiple intents.

2.2 Reward Learning in Dialog Systems

Handcrafted reward functions for dialog policy learning require elaborate design. Several reward learning algorithms have been proposed to find better rewards, including supervised learning on expert dialogs (Li et al., 2014), online active learning from user feedback (Su et al., 2016), multi-object RL to aggregate measurements of various aspects of user satisfaction (Ultes et al., 2017), etc. However, these methods still require some knowledge about user goals or annotations of dialog ratings from real users. Boularias et al. (2010) and Barahona and Cerisara (2014) learn the reward from dialogs using linear programming based on IRL, but do not scale well in real applications. Recently, Liu and Lane (2018) use adversarial rewards as the only source of reward signal. It trains a Bi-LSTM as a discriminator that works on the entire session to predict the task success.

2.3 Adversarial Inverse Reinforcement Learning

IRL aims to infer the reward function $\mathcal{R}$ underlying expert demonstrations sampled from humans

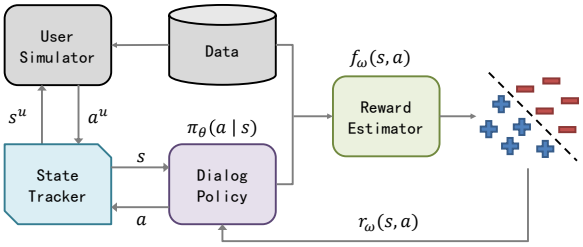

Figure 1: Architecture of GDPL. The dialog policy π decides the dialog act a according to the dialog state s provided by the state tracker, and the reward estimator f evaluates the dialog policy by comparing the generated state-action pair (s, a) with the human dialog.

or the optimal policy π^*. This is similar to the discriminator network in AL that evaluates how realistic the sample looks. Finn et al. (2016) draw a strong connection between GAN and maximum entropy causal IRL (Ziebart et al., 2010) by replacing the estimated data density in AL with the Boltzmann distribution in IRL, i.e. $p(x) \propto \exp(-E(x))$. Several approaches (Ho and Ermon, 2016; Fu et al., 2018) obtain a promising result on automatic reward estimation in large, high-dimensional environments by combining AL with IRL. Inspired by this, we apply AIRL to complex, multi-domain task-oriented dialog, which faces new issues such as discrete action space and language understanding.

3 Guided Dialog Policy Learning

We propose Guided Dialog Policy Learning (GDPL), a flexible and practical method on joint reward learning and policy optimization for multi-domain task-oriented dialog systems.

3.1 Overview

The overview of the full model is depicted in Fig. 1. The framework consists of three modules: a multi-domain Dialog State Tracker (DST) at the dialog act level, a dialog policy module for deciding the next dialog act, and a reward estimator for policy evaluation.

Specifically, given a set of collected human dialog sessions $\mathcal{D} = \{\tau_1, \tau_2, \dots\}$, each dialog session τ is a trajectory of state-action pairs $\{s_0^u, a_0^u, s_0, a_0, s_1^u, a_1^u, s_1, a_1, \dots\}$. The user simulator $\mu(a^u, t^u|s^u)$ posts a response a^u according to the user dialog state s^u where t^u denotes a binary terminal signal indicating whether the user wants to end the dialog session. The dialog policy $\pi_\theta(a|s)$ decides the action a according to the current state s and interacts with the simulator μ. During the conversation, DST records the action from one dialog party and returns the state to the other party for deciding what action to take in the next step. Then, the reward estimator $f_\omega(s, a)$ evaluates the quality of the response from the dialog policy, by comparing it with sampled human dialog sessions from the corpus. The dialog policy π and the reward estimator f are MLPs parameterized by θ, ω respectively. Note that our approach does not need any human supervision during training, and modeling a user simulator is beyond the scope of this paper.

In the subsequent subsections, we will first explain the state, action, and DST used in our algorithm. Then, the algorithm is introduced in a session level, and last followed by a decomposition of state-action pair level.

3.2 Multi-Domain Dialog State Tracker

A dialog state tracker keeps track of the dialog session to update the dialog state (Williams et al., 2016; Zhang et al., 2019). It records *informable* slots about the constraints from users and *requestable* slots that indicates what users want to inquiry. DST maintains a separate *belief state* for each slot. Given a user action, the belief state of its slot type is updated according to its slot value (Roy et al., 2000). Action and state in our algorithm are defined as follows:

Action : Each system action a or user action a^u is a subset of dialog act set $\mathcal{A}$ as there may be multiple intents in one dialog turn. A *dialog act* is an abstract representation of an intention (Stolcke et al., 2000), which can be represented in a quadruple composed of *domain*, *intent*, *slot type* and *slot value* in the multi-domain setting (e.g. [*restaurant*, *inform*, *food*, *Italian*]). In practice, dialog acts are delexicalized in the dialog policy. We replace the slot value with a count placeholder and refill it with the true value according to the entity selected from the external database, which allows the system to operate on unseen values.

State : At dialog turn t[1], the system state $s_t = [a_t^u; a_{t-1}; b_t; q_t]$ consists of (I) user action at current turn a_t^u; (II) system action at the last turn a_{t-1}; (III) all belief state b_t from DST; and (IV) embedding vectors of the number of query results q_t from the external database.

[1]We regard a user turn and a system turn as one dialog turn throughout the paper.

As our model works at the dialog act level, DST can be simply implemented by extracting the slots from actions.

3.3 Session Level Reward Estimation

Based on maximum entropy IRL (Ziebart et al., 2008), the reward estimator maximizes the log likelihood of observed human dialog sessions to infer the underlying goal,

$$\omega^* = \arg\max_{\omega} \mathbb{E}_{\tau\sim\mathcal{D}}[f_\omega(\tau)],$$

$$f_\omega(\tau) = \log p_\omega(\tau) = \log \frac{e^{R_\omega(\tau)}}{Z_\omega},$$

$$R_\omega(\tau) = \sum_{t=0}^{T} \gamma^t r_\omega(s_t, a_t),$$

$$Z_\omega = \sum_{\tau} e^{R_\omega(\tau)}.$$

where f models human dialogs as a Boltzmann distribution (Ziebart et al., 2008), R stands for the *return* of a session, i.e. γ-discounted cumulative rewards, and Z is the corresponding partition function.

The dialog policy is encouraged to mimic human dialog behaviors. It maximizes the expected entropy-regularized return $\mathbb{E}_\pi[R] + H(\pi)$ (Ziebart et al., 2010) based on the *principle of maximum entropy* through minimizing the KL-divergence between the policy distribution and Boltzmann distribution,

$$\begin{aligned} J_\pi(\theta) &= -KL(\pi_\theta(\tau)||p_\omega(\tau)) \\ &= \mathbb{E}_{\tau\sim\pi}[f_\omega(\tau) - \log \pi_\theta(\tau)] \\ &= \mathbb{E}_{\tau\sim\pi}[R_\omega(\tau)] - \log Z_\omega + H(\pi_\theta), \end{aligned}$$

where the term $\log Z_\omega$ is independent to θ, and $H(\cdot)$ denotes the entropy of a model. Intuitively, maximizing entropy is to resolve the ambiguity of language that many optimal policies can explain a set of natural dialog sessions. With the aid of the likelihood ratio trick, the gradient for the dialog policy is

$$\nabla_\theta J_\pi = \mathbb{E}_{\tau\sim\pi}[(f_\omega(\tau) - \log \pi_\theta(\tau))\nabla_\theta \log \pi_\theta(\tau)].$$

In the fashion of AL, the reward estimator aims to distinguish real human sessions and generated sessions from the dialog policy. Therefore, it minimizes KL-divergence with the empirical distribution, while maximizing the KL-divergence with the policy distribution,

$$\begin{aligned} J_f(\omega) &= -KL(p_\mathcal{D}(\tau)||p_\omega(\tau)) + KL(\pi_\theta(\tau)||p_\omega(\tau)) \\ &= \mathbb{E}_{\tau\sim\mathcal{D}}[f_\omega(\tau)] + H(p) - \mathbb{E}_{\tau\sim\pi}[f_\omega(\tau)] - H(\pi_\theta). \end{aligned}$$

Algorithm 1: Guided Dialog Policy Learning

Require: Dialog corpus $\mathcal{D}$, User simulator μ

foreach *training iteration* **do**
- Sample human dialog sessions D_H from $\mathcal{D}$ randomly
- Collect the dialog sessions D_Π by executing the dialog policy π and interacting with μ, $a^u \sim \mu(\cdot|s^u)$, $a \sim \pi(\cdot|s)$, where s is maintained by DST
- Update the reward estimator f by maximizing J_f w.r.t. ω adversarially (Eq. 2)
- Compute the estimated reward of each state-action pair in D_Π, $\hat{r} = f_\omega(s, a) - \log \pi_\theta(a|s)$
- Update π, V using the estimated reward $\hat{r}$ by maximizing J_π, J_V w.r.t. θ (Eq. 3 and Eq. 4)

end

Similarly, $H(p)$ and $H(\pi_\theta)$ is independent to ω, so the gradient for the reward estimator yields

$$\nabla_\omega J_f = \mathbb{E}_{\tau\sim\mathcal{D}}[\nabla_\omega f_\omega(\tau)] - \mathbb{E}_{\tau\sim\pi}[\nabla_\omega f_\omega(\tau)].$$

3.4 State-Action Level Reward Estimation

So far, the reward estimation uses the entire session τ, which can be very inefficient because of reward sparsity and may be of high variance due to the different lengths of sessions. Here we decompose a session τ into state-action pairs (s, a) in the reward estimator to address the issues. Therefore, the loss functions for the dialog policy and the reward estimator become respectively as follows:

$$\begin{aligned} J_\pi(\theta) = \mathbb{E}_{s,a\sim\pi}[&\sum_{k=t}^{T} \gamma^{k-t}(f_\omega(s_k, a_k) \\ &- \log \pi_\theta(a_k|s_k))], \end{aligned} \tag{1}$$

$$J_f(\omega) = \mathbb{E}_{s,a\sim\mathcal{D}}[f_\omega(s, a)] - \mathbb{E}_{s,a\sim\pi}[f_\omega(s, a)], \tag{2}$$

where T is the number of dialog turns. Since the reward estimator evaluates a state-action pair, it can guide the dialog policy at each dialog turn with the predicted reward $\hat{r}_\omega(s, a) = f_\omega(s, a) - \log \pi_\theta(a|s)$.

Moreover, the reward estimator f_ω can be transformed to a reward approximator g_ω and a shaping term h_ω according to (Fu et al., 2018) to recover

an interpretable and robust reward from real human sessions. Formally,

$$f_\omega(s_t, a_t, s_{t+1}) = g_\omega(s_t, a_t) + \gamma h_\omega(s_{t+1}) - h_\omega(s_t),$$

where we replace the state-action pair (s_t, a_t) with the state-action-state triple (s_t, a_t, s_{t+1}) as the input of the reward estimator. Note that, different from the objective in (Fu et al., 2018) that learns a discriminator in the form $D_\omega(s,a) = \frac{p_\omega(s,a)}{p_\omega(s,a)+\pi(a|s)}$, GDPL directly optimizes f_ω, which avoids unstable or vanishing gradient issue in vanilla GAN (Arjovsky et al., 2017).

In practice, we apply Proximal Policy Optimization (PPO) (Schulman et al., 2017), a simple and stable policy based RL algorithm using a constant clipping mechanism as the soft constraint for dialog policy optimization,

$$J_\pi(\theta) = \mathbb{E}_{s,a\sim\pi}[\min\{\beta_t \hat{A}_t, clip(\beta_t, 1-\epsilon, 1+\epsilon)\hat{A}_t\}], \tag{3}$$

$$\begin{aligned} \hat{A}_t &= \delta_t + \gamma\lambda\hat{A}_{t+1}, \\ \delta_t &= \hat{r}_t + \gamma V_\theta(s_{t+1}) - V_\theta(s_t), \end{aligned}$$

$$J_V(\theta) = -(V_\theta(s_t) - \sum_{k=t}^{T} \gamma^{k-t}\hat{r}_k)^2, \tag{4}$$

where V_θ is the approximate value function, $\beta_t = \frac{\pi_\theta(a_t|s_t)}{\pi_{\theta_{old}}(a_t|s_t)}$ is the ratio of the probability under the new and old policies, $\hat{A}$ is the estimated advantage, δ is TD residual, λ and ϵ are hyper-parameters.

In summary, a brief script for GPDL algorithm is shown in Algorithm 1.

4 Experimental Setting

4.1 Data and Simulators

We use MultiWOZ (Budzianowski et al., 2018), a multi-domain, multi-intent task-oriented dialog corpus that contains 7 domains, 13 intents, 25 slot types, 10,483 dialog sessions, and 71,544 dialog turns in our experiments. Among all the sessions, 1,000 each are used for validation and test. During the data collection process, a user is asked to follow a pre-specified user goal, but it encourages the user to change its goal during the session and the changed goal is also stored, so the collected dialogs are much closer to reality. The corpus also provides the ontology that defines all the entity attributes for the external database.

We apply two user simulators as the interaction environment for the agent. One is the agenda-based user simulator (Schatzmann et al., 2007) which uses heuristics, and the other is a data-driven neural model, namely, Variational Hierarchical User Simulator (VHUS) derived from (Gür et al., 2018). Both simulators initialize a user goal when the dialog starts[2], provide the agent with a simulated user response at each dialog turn, and work at the dialog act level. Since the original corpus only annotates the dialog acts at the system side, we use the annotation at the user side from ConvLab (Lee et al., 2019) to implement the two simulators.

4.2 Evaluation Metrics

Evaluation of a task-oriented dialog mainly consists of the cost (dialog turns) and task success (inform F1 & match rate). The definition of inform F1 and match rate is explained as follows.

Inform F1 : This evaluates whether all the **requested information** (e.g. address, phone number of a hotel) has been informed. Here we compute the F1 score so that a policy which greedily answers all the attributes of an entity will only get a high *recall* but a low *precision*.

Match rate : This evaluates whether the booked entities match all the **indicated constraints** (e.g. Japanese food in the center of the city) for all domains. If the agent fails to book an entity in one domain, it will obtain 0 score on that domain. This metric ranges from 0 to 1 for each domain, and the average on all domains stands for the score of a session.

Finally, a dialog is considered successful only if all the information is provided (i.e. inform recall = 1) and the entities are correctly booked (i.e. match rate = 1) as well[3]. Dialog success is either 0 or 1 for each session.

4.3 Implementation Details

Both the dialog policy $\pi(a|s)$ and the value function $V(s)$ are implemented with two hidden layer MLPs. For the reward estimator $f(s,a)$, it is split into two networks $g(s,a)$ and $h(s)$ according to the proposed algorithm, where each is a one hidden layer MLP. The activation function is all *Relu*

[2]Refer to the appendix for user goal generation.

[3]If the user does not request any information in the session, this will just compute match rate, and similarly for inform recall.

Hyper-parameter	Value
Learning rate	1e-4
Mini-batch size	32
Discount factor γ	0.99
Clipping factor ϵ in PPO	0.2
GAE factor λ in PPO	0.95

Table 2: Hyper-parameter settings.

for MLPs. We use Adam as the optimization algorithm. The hyper-parameters of GDPL used in our experiments are shown in Table 2.

4.4 Baselines

First of all, we introduce three baselines that use handcrafted reward functions. Following (Peng et al., 2017), the agent receives a positive reward of $2L$ for success at the end of each dialog, or a negative reward of $-L$ for failure, where L is the maximum number of turns in each dialog and is set to 40 in our experiments. Furthermore, the agent receives a reward of -1 at each turn so that a shorter dialog is encouraged.

GP-MBCM (Gašić et al., 2015): Multi-domain Bayesian Committee Machine for dialog management based on Gaussian process, which decomposes the dialog policy into several domain-specific policies.

ACER (Wang et al., 2017): Actor-Critic RL policy with Experience Replay, a sample efficient learning algorithm that has low variance and scales well with large discrete action spaces.

PPO (Schulman et al., 2017): The same as the dialog policy in GDPL.

Then, we also compare with another strong baseline that involves reward learning.

ALDM (Liu and Lane, 2018): Adversarial Learning Dialog Model that learns dialog rewards with a Bi-LSTM encoding the dialog sequence as the discriminator to predict the task success. The reward is only estimated at the end of the session and is further used to optimize the dialog policy.

For a fair comparison, each method is pre-trained for 5 epoches by simple imitation learning on the state-action pairs.

5 Result Analysis

5.1 Main Results

The performance of each approach that interacts with the agenda-based user simulator is shown in Table 3. GDPL achieves extremely high performance in the task success on account of the substantial improvement in inform F1 and match rate over the baselines. Since the reward estimator of GDPL evaluates state-action pairs, it can always guide the dialog policy during the conversation thus leading the dialog policy to a successful strategy, which also indirectly demonstrates that the reward estimator has learned a reasonable reward at each dialog turn. Surprisingly, GDPL even outperforms human in completing the task, and its average dialog turns are close to those of humans, though GDPL is inferior in terms of match rate. Humans almost manage to make a reservation in each session, which contributes to high task success. However, it is also interesting to find that human have low inform F1, and that may explain why the task is not always completed successfully. Actually, there have high recall (*86.75%*) but low precision (*54.43%*) in human dialogs when answering the requested information. This is possibly because during data collection human users forget to ask for all required information of the task, as reported in (Su et al., 2016).

Method	Agenda			
	Turns	Inform	Match	Success
GP-MBCM	2.99	19.04	44.29	28.9
ACER	10.49	77.98	62.83	50.8
PPO	9.83	83.34	69.09	59.1
ALDM	12.47	81.20	62.60	61.2
GDPL-sess	**7.49**	88.39	77.56	76.4
GDPL-discr	7.86	93.21	80.43	80.5
GDPL	7.64	**94.97**	**83.90**	**86.5**
Human	*7.37*	*66.89*	*95.29*	*75.0*

Table 3: Performance of different dialog agents on the multi-domain dialog corpus by interacting with the agenda-based user simulator. All the results except "dialog turns" are shown in percentage terms. Real human-human performance computed from the test set (i.e. the last row) serves as the upper bounds.

ACER and PPO obtain high performance in inform F1 and match rate as well. However, they obtain poor performance on the overall task success, even when they are provided with the designed reward that already knows the real user goals. This is because they only receive the reward about the success at the last turn and fail to understand what the user needs or detect the change of user goals.

Though ALDM obtains a lower inform F1 and match rate than PPO, it gets a slight improvement

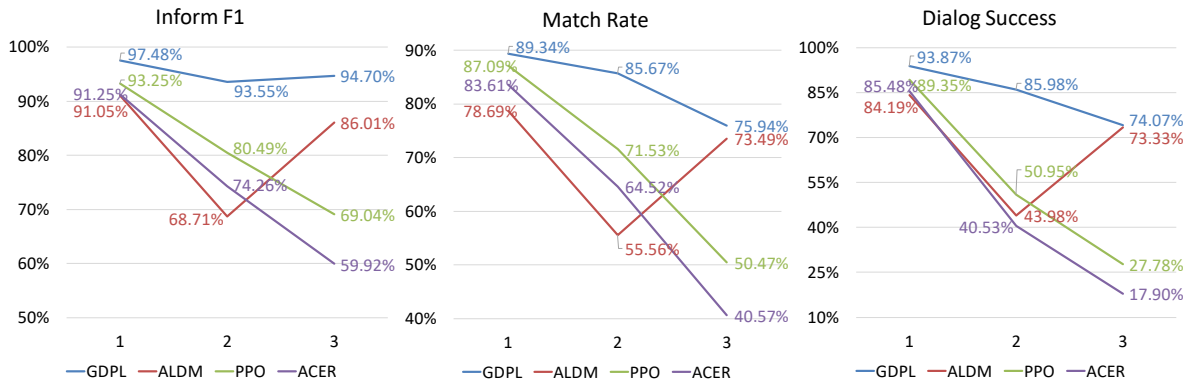

Figure 2: Performance of dialog agents according to the different number of domains in the dialog session. The ratio of the sessions with 1:2:3 domains is 310:528:162 respectively.

GP-MBCM	ACER	PPO	ALDM	GDPL
1.666	0.775	0.639	1.069	**0.238**

Table 4: KL-divergence between different dialog policy and the human dialog $KL(\pi_{turns}||p_{turns})$, where π_{turns} denotes the discrete distribution over the number of dialog turns of simulated sessions between the policy π and the agenda-based user simulator, and p_{turns} for the real human-human dialog.

Method	VHUS			
	Turns	Inform	Match	Success
ACER	22.35	55.13	33.08	18.6
PPO	**19.23**	**56.31**	33.08	18.3
ALDM	26.90	54.37	24.15	16.4
GDPL	22.43	52.58	**36.21**	**19.7**

Table 5: Performance of different agents on the neural user simulator.

on task success by encoding the entire session in its reward estimator. This demonstrates that learning effective rewards can help the policy to capture user intent shift, but the reward sparsity issue remains unsolved. This may explain why the gain is limited, and ALDM even has longer dialog turns than others. In conclusion, the dialog policy benefits from the guidance of the reward estimator per dialog turn.

Moreover, GDPL can establish an efficient dialog thanks to the learned rewards that infer human behaviors. Table 4 shows that GDPL has the smallest KL-divergence to the human on the number of dialog turns over the baselines, which implies that GDPL behaves more like the human. It seems that all the approaches generate many more *short dialogs* (dialog turns less than 3) than human, but GDPL generates far less *long dialogs* (dialog turns larger than 11) than other baselines except GP-MBCM. Most of the long dialog sessions fail to reach a task success.

We also observe that GP-MBCM tries to provide many dialog acts to avoid the negative penalty at each turn, which results in a very low inform F1 and short dialog turns. However, as explained in the introduction, a shorter dialog is not always the best. The dialog generated by GP-MBCM is too short to complete the task successfully. GP-MBCM is a typical case that focuses too much on the cost of the dialog due to the handcrafted reward function and fails to realize the true target that helps the users to accomplish their goals.

5.2 Ablation Study

Ablation test is investigated in Table 3. GDPL-sess sums up all the rewards at each turn to the last turn and does not give any other reward before the dialog terminates, while GDPL-discr is to use the discriminator form as (Fu et al., 2018) in the reward estimator. It is perceptible that GDPL has better performance than GDPL-sess on the task success and is comparable regarding the dialog turns, so it can be concluded that GDPL does benefit from the guidance of the reward estimator at each dialog turn, and well addresses the reward sparsity issue. GDPL also outperforms GDPL-discr which means directly optimizing f_ω improves the stability of AL.

5.3 Interaction with Neural Simulator

The performance that the agent interacts with VHUS is presented in Table 5. VHUS has poor performance on multi-domain dialog. It sometimes becomes insensible about the dialog act so

VS.	Efficiency			Quality			Success		
	W	D	L	W	D	L	W	D	L
ACER	55	25	20	44	32	24	52	30	18
PPO	74	13	13	56	26	18	59	31	10
ALDM	69	19	12	49	25	26	61	24	15

Table 6: The count of human preference on dialog session pairs that GDPL wins (W), draws with (D) or loses to (L) other methods based on different criteria. One method wins the other if the majority prefer the former one.

Type	Inform		Match		Success	
	Mean	Num	Mean	Num	Mean	Num
Full	8.413	903	10.59	450	11.18	865
Other	-99.95	76	-48.15	99	-71.62	135

Table 7: Return distribution of GDPL on each metric. The first row counts the dialog sessions that get the full score of the corresponding metric, and the results of the rest sessions are included in the second row.

it often gives unreasonable responses. Therefore, it is more laborious for the dialog policy to learn a proper strategy with the neural user simulator. All the methods cause a significant drop in performance when interacting with VHUS. ALDM even gets worse performance than ACER and PPO. In comparison, GDPL is still comparable with ACER and PPO, obtains a better match rate, and even achieves higher task success. This indicates that GDPL has learned a more robust reward function than ALDM.

5.4 Goal across Multiple Domains

Fig. 2 shows the performance with the different number of domains in the user goal. In comparison with other approaches, GDPL is more scalable to the number of domains and achieves the best performance in all metrics. PPO suffers from the increasing number of the domain and has remarkable drops in all metrics. This demonstrates the limited capability for the handcrafted reward function to handle complex tasks across multiple domains in the dialog.

ALDM also has a serious performance degradation with 2 domains, but it is interesting to find that ALDM performs much better with 3 domains than with 2 domains. We further observe that ALDM performs well on the taxi domain, most of which appear in the dialogs with 3 domains. Taxi domain has the least slots for constraints and requests, which makes it easier to learn a reward about that domain, thus leading ALDM to a local optimal. In general, our reward estimator has higher effectiveness and scalability.

5.5 Human Evaluation

For human evaluation, we hire Amazon Mechanical Turkers to state their preferences between GDPL and other methods. Because all the policies work at dialog act level, we generate the texts from dialog acts using hand-crafted templates to make the dialog readable. Given a certain user goal, Turkers first read two simulated dialog sessions, one from the interaction between GDPL and the agenda-based user simulator, the other from another baseline with the same simulator. Then, they are asked to judge which dialog is better (win, draw or lose) according to different subjective assessments. In addition to *Task Success*, we examine another two measures concerning *Dialog Cost* in the human evaluation: *Efficiency* such as dialog turn cost or response delay, and *Quality* such as redundant information or inappropriate reply (Walker et al., 1997). Since the text is generated by templates for all policies, we do not evaluate language generation here (including grammar, diversity, etc.). We randomly sample 300 user goals from the test set, 100 each for one baseline, and each session pair is evaluated by 3 Turkers.

Table 6 presents the results of human evaluation. GDPL outperforms three baselines significantly in all aspects (sign test, p-value < 0.01) except for the quality compared with ACER. Among all the baselines, GDPL obtains the most preference against PPO. Note that the difference between PPO and GDPL is only in the reward signal. This again demonstrates the advantage of reward learning in GDPL over the handcrafted reward function. The agreement on the superiority of GDPL between objective rating in Table 3 and human preference here also indicates that the automatic metrics used in our experiments is reliable to reflect user satisfaction to some extent.

5.6 Reward Evaluation

To provide an insight into the learned reward function itself, Table 7 provides a quantitative evaluation on the learned rewards by showing the distribution of the return $R = \sum_t \gamma^t r_t$ according to each metric. It should be noted that some sessions do not have inform F1 because the user does not request any information, and similarly for match

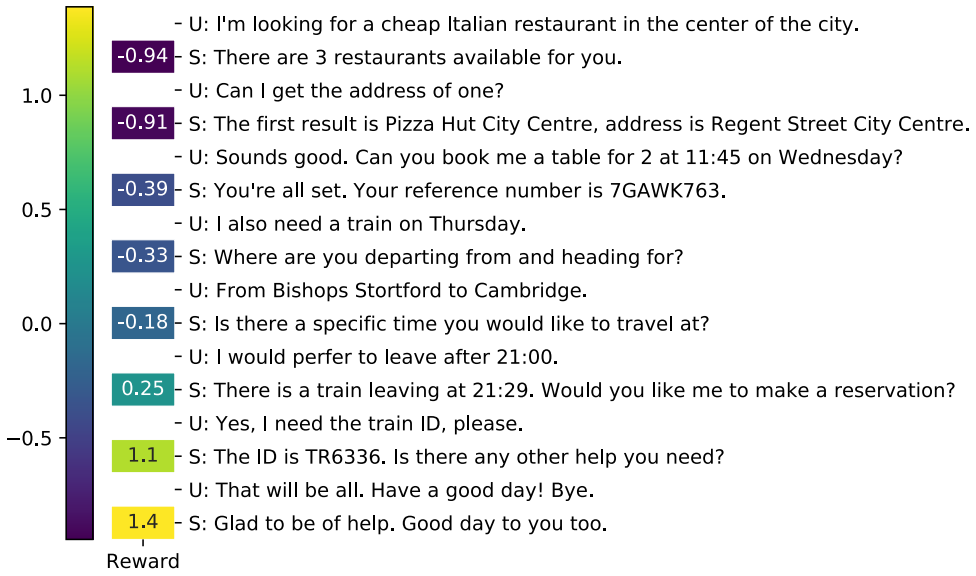

Figure 3: Reward visualization of a dialog session simulated between GDPL and the agenda-based user simulator that contains restaurant and train domains.[4]

rate. It can be observed that the learned reward function has good interpretability in that the reward is positive when the dialog gets a full score on each metric, and negative otherwise.

Fig. 3 gives an illustration of the learned reward at each dialog turn as a qualitative evaluation. In the beginning, the agent is unaware of the user goal thus it starts with a low reward. As the dialog proceeds, the agent has collected enough information from the user, then books the restaurant successfully and the reward remarkably increases at the third turn. The reward continues to grow stably after the topic shifts to the train domain. Again, the agent offers the correct train ID given sufficient information. Since the user has been informed all the requested information and the restaurant and train are both booked successfully, the user leaves the session with satisfaction at last, and the reward rises to the top as well. In brief, the learned reward can well reflect the current state of the dialog. It is also noticeable that the dialog policy manages to express multiple intents during the session.

6 Discussion

In this paper, we propose a guided policy learning method for joint reward estimation and policy optimization in multi-domain task-oriented dialog. The method is based on Adversarial Inverse Reinforcement Learning. Extensive experiments demonstrate the effectiveness of our proposed approach and that it can achieve higher task success and better user satisfaction than state-of-the-art baselines.

Though the action space $\mathcal{A}$ of the dialog policy is defined as the set of all dialog acts, it should be noted that GDPL can be equipped with NLU modules that identify the dialog acts expressed in utterance, and with NLG modules that generate utterances from dialog acts. In this way, we can construct the framework in an end-to-end scenario.

The agenda-based user simulator is powerful to provide a simulated interaction for the dialog policy learning, however, it needs careful design and is lack of generalization. While training a neural user simulator is quite challenging due to the high diversity of user modeling and the difficulty of defining a proper reward function, GDPL may offer some solutions for multi-agent dialog policy learning where the user is regarded as another agent and trained with the system agent simultaneously. We leave this as the future work.

Abstract

Multi-turn retrieval-based conversation is an important task for building intelligent dialogue systems. Existing works mainly focus on matching candidate responses with every context utterance on multiple levels of granularity, which ignore the side effect of using excessive context information. Context utterances provide abundant information for extracting more matching features, but it also brings noise signals and unnecessary information.

In this paper, we will analyze the side effect of using too many context utterances and propose a multi-hop selector network (MSN) to alleviate the problem. Specifically, MSN firstly utilizes a multi-hop selector to select the relevant utterances as context. Then, the model matches the filtered context with the candidate response and obtains a matching score. Experimental results show that MSN outperforms some state-of-the-art methods on three public multi-turn dialogue datasets.

1 Introduction

Building a dialogue system that can naturally and consistently converse with humans has drawn increasing research interests in past years. Existing works on building dialogue systems include generation-based and retrieval-based methods. Compared with generation-based methods, retrieval-based methods have advantages in providing fluent and informative responses. Many industrial products have applied retrieval-based dialogue system, e.g., the E-commerce assistant AliMe Assist from Alibaba Group (Li et al., 2017) and the XiaoIce (Shum et al., 2018) from Microsoft.

Early studies (Tan et al., 2015; Yan et al., 2016; Wan et al., 2016) of retrieval-based dialogue system focus on response selection for single-turn conversation. Recently, researchers have begun to pay attention to the multi-turn conversation, aiming at selecting the most related response from a set of candidates given the context utterances of a conversation. Some effective models, such as Sequential Matching Network (SMN) (Wu et al., 2017), Deep Attention Matching network (DAM) (Zhou et al., 2018c), Multi-Representation Fusion Network (MFRN) (Tao et al., 2019), have been proposed to capture the matching features on multiple levels of granularity (words, phrases, sentences, etc.) and short-term and long-term dependencies among words.

Previous works have shown that utilizing multi-turn utterances can further improve the matching performance than only using single-turn utterance (i.e., last utterance). But context utterance is a "double-edged sword", it also provides a lot of noise while providing abundant information, which would influence the performance due to the sensitivity of these matching-based methods.

Table 1: An error case of SMN (Wu et al., 2017), DAM (Zhou et al., 2018c) from E-commerce Corpus. The scores in the table are matching scores predicted by the models.

Turns	Dialogue Text	SMN	DAM
Turn-1	A: Are there any **discounts** activities recently?		
Turn-2	B: No. Our product have been **cheaper** than before.		
Turn-3	A: Oh.		
Turn-4	B: Hum!		
Turn-5	A: I'll buy these nuts. Can you sell me **cheaper**?		
Turn-6	B: You can get some **coupons** on the homepage.		
Turn-7	A: Will you give me some nut **clips**?		
Turn-8	B: Of course **we will**.		
Turn-9	A: **How many clips** will you give?		
Resp-1	**One clip** for every package. (True)	0.832	0.854
Resp-2	OK, **we will** give you a **coupons** worth $1. (False)	0.925	0.947

To illustrate the problem, we show an error case of SMN (Wu et al., 2017) and DAM (Zhou et al., 2018c) from E-commerce Corpus in Table 1. We can see that although "Resp-1" is the right answer for utterance "Turn-9", the SMN and DAM mod-

els still choose "Resp-2". Because it has more words overlap with context utterances, thus accumulating a larger similarity score. We can easily observe that "Resp-2" is relevant to former utterances (Turn-1 to Turn-6), but the topic has changed after "Turn-6". Besides, we can see that "Turn-3" and "Turn-4" do not provide any useful information for selecting candidate response. From this example, irrelevant context utterances may cause the models making simple mistakes that humans would not make. Furthermore, we conduct several adversarial experiments and the results show that these matching-based models are very sensitive to the adversarial samples.

In this paper, we propose a multi-hop selector network to tackle the above problem. Intuitively, the closer the utterance to the response is, the more it reflects the intention of the last dialogue session. Thus, we firstly use the last utterance as key to select context utterances that are relevant to it on the word and sentence level. However, we find that there are many samples whose last utterance is very short and contains very limited information (such as "good", "ok"), which will cause the selectors to lose too much useful context information. Therefore, we propose multi-hop selectors to select more relevant context utterances, yielding k different context. Then, we fuse these selected context utterances and match it with candidate response. During the matching stage, the convolution neural network (CNN) is applied to extract matching features and the gated recurrent unit (GRU) is applied to learn the temporal relationship of utterances.

The contributions of this paper are summarized as follows:

- We find the noises in context utterances could influence the matching performance and design adversarial experiments to verify it.
- We propose a unified network MSN to select relevant context utterances from word and utterance level and fuse the selected context to generate a better context representation.
- Experimental results on three public datasets achieve significant improvement, which shows the effectiveness of MSN.

The outline of the paper is as follows. Section 2 introduces related works. Section 3 describes adversarial experiment to check how sensitivity of previous models to the context utterances. Section 4 describes every component of MSN model. Section 5 discusses the experiments and corresponding results. Section 6 discusses some experiments to explore the influence of hyper-parameters on performance. We conclude our work in Section 7.

2 Related Work

With the development of natural language processing, building intelligent chatbots with data-driven approaches has drawn increasing attention in recent years. Existing works can be generally categorized into retrieval-based methods (Wan et al., 2016; Wu et al., 2017; Zhang et al., 2018; Tao et al., 2019) and generation-based methods (Shang et al., 2015; Serban et al., 2016; Xing et al., 2017; Wu et al., 2018; Zhou et al., 2018a,b). In this work, we focus on retrieval-based method and study context-based response selection.

Early retrieval-based chatbots are devoted to response selection for single-turn conversation (Wang et al., 2013; Tan et al., 2015; Yan et al., 2016). Recently, researchers have begun to turn to the multi-turn conversation. Lowe et al. (2015) use RNN to read context and response, use the last hidden states to represent context and response as two semantic vectors to measure their relevance. Zhou et al. (2016) perform context-response matching with a multi-view model on both word and utterance levels. Considering concatenating utterances in context may lose relationships among utterances or important contextual information, Wu et al. (2017) separately match the response with each utterance based on a convolutional neural network. This paradigm is applied in many subsequent works. Zhou et al. (2018c) consider the dependency relation among utterances based on the attention mechanism. Tao et al. (2019) fuse words, n-grams, and sub-sequences of utterances representations and capture both short-term and long-term dependencies among words.

Different from previous works, (i) we study the influence of using excessive context utterances, (ii) we explore how to filter out irrelevant context to improve the robustness of matching-based methods.

3 Adversarial experiments

To study how sensitive of the previous models (Wu et al., 2017; Zhang et al., 2018; Zhou et al., 2018c; Tao et al., 2019) to the context utterances, we conduct several adversarial experiments inspired

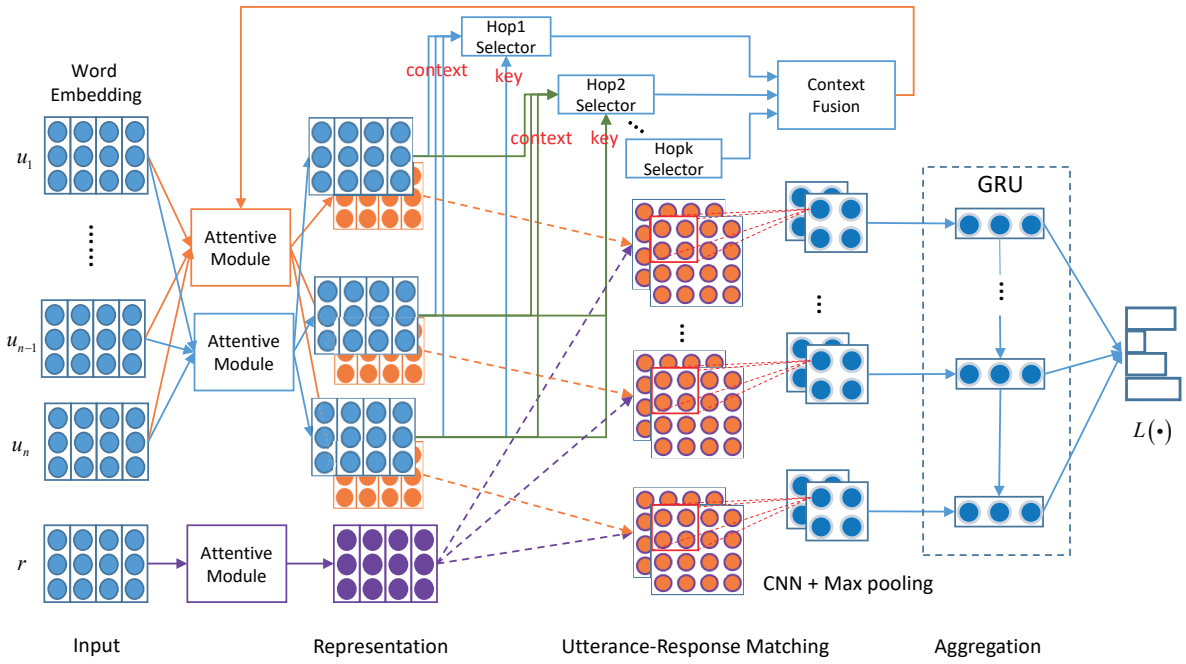

Figure 1: Architecture of multi-hop selector network.

by (Jia and Liang, 2017). We keep the training set unchanged and add some noises to the original test set. To be specific, we randomly sample 1∼3 words from context utterances and append them on every candidate response. In this way, we can obtain 3 different adversarial test sets: adversarial_set1, adversarial_set2, adversarial_set3.

Then, we evaluate the models again to see how much will the performance change. To ensure the fairness of the experiments, we use the results from their papers for the original test set. Moreover, we use their open source code for adversarial experiments. We employ recall at position k in n candidates ($R_n@k$) as the evaluation metric, which is the same as previous works.

Table 2: Adversarial experimental results on Ubuntu Dialogue Corpus. The results of SMN (Wu et al., 2017), DUA (Zhang et al., 2018), DAM (Zhou et al., 2018c), MFRN (Tao et al., 2019) on original test set are cited from their papers.

Models	original test set		adversarial_set1		adversarial_set2		adversarial_set3	
	$R_{10}@1$	$R_{10}@2$	$R_{10}@1$	$R_{10}@2$	$R_{10}@1$	$R_{10}@2$	$R_{10}@1$	$R_{10}@2$
SMN	72.6	84.7	66.2	82.1	63.8	79.4	57.1	75.0
DUA	75.2	86.8	64.0	80.4	58.0	75.6	52.7	70.8
DAM	76.7	87.4	67.5	82.3	61.2	76.8	54.3	71.6
MRFN	78.6	88.6	65.4	81.7	65.1	76.4	58.2	72.3
MSN	80.0	89.9	70.7	84.6	66.2	81.4	64.6	79.9

The experimental results are shown in Table 2. From the table, we can observe that the one-word noise will bring about 7% ∼ 13% absolute decrease on $R_{10}@1$ and the three-word noise brings about 20% $R_{10}@1$ decrease. Thus, we can see that matching-based models (Wu et al., 2017; Zhang et al., 2018; Zhou et al., 2018c; Tao et al., 2019) are very sensitive to small noises of the dataset. Moreover, using too many context utterances will greatly increase the probability of introducing noise. The results of MSN also show that filtering irrelevant utterances can effectively alleviate this problem and improve the robustness of matching-based models.

4 Model

4.1 Problem Formalization

Suppose that we have a data set $D = \{U_i, r_i, y_i\}_{i=1}^{N}$, where $U_i = \{u_{i1}, u_{i2}, \ldots, u_{iL}\}$ represents a conversation context with L utterances and every utterance u_{ij} contains T words. r_i is a response candidate and $y_i \in \{0, 1\}$ denotes a label. $y_i = 1$ means r_i is a proper response for U_i, otherwise $y_i = 0$. Our goal is to learn a matching model $g(\cdot, \cdot)$ with D. For any context-response pair (U_i, r_i), $g(U_i, r_i)$ measures the matching degree between U_i and r_i.

To this end, we need to address two problems: (1) how to select proper context utterances from U_i; and (2) how to fuse these selected utterances together for a better representation.

4.2 Model Overview

We propose a multi-hop selector network (MSN) to model $g(\cdot, \cdot)$. Figure 1 gives the architecture, which generally follows the representation-matching-aggregation framework (Wu et al., 2017; Zhang et al., 2018; Zhou et al., 2018c; Tao et al., 2019) to match response with multi-turn context.

Different from previous works, we add a selection process before the above framework. MSN first constructs semantic representations at word level by an Attentive Module. Then, each utterance are packed as context or key and sent to the "Hopk Selector" to calculate relevance scores. The scores of k different selectors are fused together by a Context Fusion module. Finally, the fused scores are performed over original context utterances to filter out irrelevant context. The rest context utterances are applied for response matching.

4.3 Attentive Module

We use the Attentive Module to learn the context information for word representation. Attentive Module is proposed in DAM (Zhou et al., 2018c) and it is a variant of Multi-head Attention (Vaswani et al., 2017). Figure 2 shows its structure.

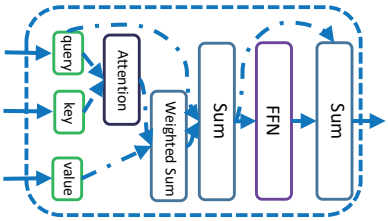

Figure 2: Architecture of Attentive Module.

The $\mathbf{AttentiveModule}(Q, K, V)$ has three input sentences: the query sentence, the key sentence and the value sentence, namely $Q \in \mathbb{R}^{n_q \times d}$, $K \in \mathbb{R}^{n_k \times d}$, and $V \in \mathbb{R}^{n_v \times d}$ respectively, where n_q, n_k, and n_v denote the number of words in each sentence, and d is the dimension of the embedding.

The Attentive Module first takes each word in the query sentence to attend to words in the key sentence via Scaled Dot-Product Attention (Vaswani et al., 2017), and then applies those attention weights upon the value sentence:

$$\mathbf{V}_{att} = softmax\left(\frac{QK^T}{\sqrt{d}}\right)V\,. \quad (1)$$

Then, a feed-forward network (FFN) with RELU (LeCun et al., 2015) activation is applied upon the normalization result, to further process the fused embeddings:

$$\mathbf{FFN}(x) = \max(0, x\mathbf{W}_1 + b_1)\mathbf{W}_2 + b_2\,, \quad (2)$$

where x is a 2D matrix in the same shape of query sentence Q and $\mathbf{W}_1$, b_1,$\mathbf{W}_2$, b_2 are learnt parameters. The result $\mathbf{FFN}(x)$ is a 2D matrix that has the same shape as x, $\mathbf{FFN}(x)$ is then residually added to x, and the fusion result is then normalized as the final outputs.

4.4 Context Selector

Given $\mathbf{U}_i = [\mathbf{u}_{i1}, \ldots, \mathbf{u}_{ij}, \ldots, \mathbf{u}_{iL}]$, the word-level embedding representations for utterance $\mathbf{u}_{ij} \in \mathbb{R}^{T \times d}$, where d is the dimension of word vector, we use the Attentive Module to reconstruct the word representations of each utterance to encode the context and dependency information into word, which is formulated as:

$$\mathbf{u}'_{ij} = \mathbf{AttentiveModule}(\mathbf{u}_{ij}, \mathbf{u}_{ij}, \mathbf{u}_{ij})\,, \quad (3)$$

where $\mathbf{u}'_{ij} \in \mathbb{R}^{T \times d}$. $\mathbf{U}'_i = [\mathbf{u}'_{i1}, \mathbf{u}'_{i2}, \ldots, \mathbf{u}'_{iL}] \in \mathbb{R}^{L \times T \times d}$.

We first discuss how to construct "Hop1 Selector", which consists of word and utterance selector. To capture matching features at multiple levels of granularity, we leverage word and utterance level matching features to select relevant context.

4.4.1 Word Selector

At word level, we utilize cross attention to obtain a matching feature map for each context utterance $\mathbf{u}'_{ij}$ and key $\mathbf{K}_1 = \mathbf{u}'_{iL}$, which is formulated as:

$$\mathbf{A} = \mathbf{v}^T \mathbf{tanh}(\mathbf{K}_1^T \mathbf{W} \mathbf{U}'_i + \mathbf{b})\,, \quad (4)$$

where $\mathbf{W} \in \mathbb{R}^{d \times d \times h}$, $\mathbf{b} \in \mathbb{R}^h$ and $\mathbf{v} \in \mathbb{R}^{h \times 1}$. And we get a word alignment matrix $\mathbf{A} \in \mathbb{R}^{L \times T \times T}$.

Then, we extract the most prominent matching features from $\mathbf{A}$ by max pooling over row and column. Then, they are concatenated together:

$$m_1(\mathbf{K}_1, \mathbf{U}'_i) = [\max_{dim=2} \mathbf{A}; \max_{dim=3} \mathbf{A}]\,, \quad (5)$$

where $m_1(\mathbf{K}_1, \mathbf{U}'_i) \in \mathbb{R}^{L \times 2T}$, which reflects which words have identical or similar meaning between utterances $\mathbf{u}_{ij}$ and key $\mathbf{u}_{iL}$. The matching features are transformed to the relevance score by a linear layer:

$$\mathbf{s}_1 = \mathbf{softmax}(m_1(\mathbf{K}_1, \mathbf{U}'_i)\mathbf{c} + b)\,, \quad (6)$$

where $\mathbf{c} \in \mathbb{R}^{2T\times 1}$ and $b \in \mathbb{R}^{L\times 1}$.

The word selector can only capture word-level relevance between key and utterances. It can not reflect whether key and context are compatible on the overall semantic level. Thus, we continue to evaluate the relevance on the utterance level.

4.4.2 Utterance Selector

Firstly, the word-level representations $\mathbf{U}'_i$ are transformed to utterance-level representations by mean pooling over word dimension:

$$\widetilde{\mathbf{U}}_i = \mathbf{mean}(\mathbf{U}'_i)\,, \tag{7}$$

where $\widetilde{\mathbf{U}}_i \in \mathbb{R}^{L\times d}$.

We use cosine similarity to measure the relevance between key $\mathbf{K}_2 = \widetilde{\mathbf{U}}_{iL}$ and context utterances $\widetilde{\mathbf{U}}_i$, which is formulated as:

$$s_2 = \frac{\widetilde{\mathbf{U}}_i \mathbf{K}_2^T}{||\widetilde{\mathbf{U}}_i||_2 \, ||\mathbf{K}_2||_2}\,, \tag{8}$$

where $\mathbf{s}_2 \in \mathbb{R}^{L\times 1}$ is the relevance score at utterance level.

Both the scores of word selector and utterance selector are important to measure the relevance of last utterance and context. In order to make full use of word and utterance selectors, we design a combined strategy to fuse two scores. Specifically, we use the weighted sum of two scores for selection:

$$\mathbf{s}^{(1)} = \alpha * \mathbf{s}_1 + (1-\alpha) * \mathbf{s}_2\,, \tag{9}$$

where α is a hyper-parameter and $\mathbf{s}^{(1)}$ is the final score that hop1 selector produces. The default value of α is set to 0.5.

4.4.3 Hopk Selector

Although "Hop1 Selector" can choose proper context utterances that are related to the last dialogue session, we find that there are many samples whose last utterance contains very little information (such as "good", "ok"), which will cause the selector lose too much useful context information. Thus, we combine it with $\widetilde{u}_{i,L-1}$, $\widetilde{u}_{i,L-2}$, ..., $\widetilde{u}_{i,L-k}$ by mean pooling. Then, we treat them as key to conduct the same process as "Hop1 Selector" for context selection. In this way, we can get k different selectors, yielding k different scores $\mathbf{S} = [\mathbf{s}^{(1)}, \mathbf{s}^{(2)}, \ldots, \mathbf{s}^{(k)}] \in \mathbb{R}^{L\times k}$.

4.5 Context Fusion

Then we fuse the similarity scores from different selectors and apply it to select relevant context utterances for matching.

Firstly, we combine the similarity scores $\mathbf{S} \in \mathbb{R}^{L\times k}$ to form the final scores for each context utterances and filter out irrelevant context, which is formulated as:

$$\begin{aligned} \mathbf{s}' &= \mathbf{S}\mathbf{W}^T\,, \\ \widetilde{\mathbf{s}} &= \mathbf{s}' \odot (\mathbf{sigmoid}(\mathbf{s}') \geq \gamma)\,, \end{aligned} \tag{10}$$

where $\mathbf{W} \in \mathbb{R}^{1\times k}$ is a dynamic weight vector and will be tuned by the gradient. γ is the threshold and will be tuned according to the dataset. The default value of γ can be set to 0.5. The utterances whose scores are below γ will be allocated lower weights or filtered out.

Then, we multiply the mask weight $\widetilde{\mathbf{s}}$ and context utterances to filter irrelevant context:

$$\hat{\mathbf{U}}_i = \widetilde{\mathbf{s}} \odot \mathbf{U}_i\,, \tag{11}$$

and generate $\hat{\mathbf{U}}_i \in \mathbb{R}^{L\times T\times d}$, where $\mathbf{U}_i \in \mathbb{R}^{L\times T\times d}$ is the original utterances tensor.

4.6 Utterance-Response Matching

Similar to DAM (Zhou et al., 2018c), we utilize the self and cross matching paradigm to construct better matching feature maps.

4.6.1 Origin Matching

Given the filtered utterances $\hat{\mathbf{U}}_i = [\hat{\mathbf{u}}_{i1}, \ldots, \hat{\mathbf{u}}_{ij}, \ldots, \hat{\mathbf{u}}_{iL}]$ and candidate response $\mathbf{r}_i \in \mathbb{R}^{T\times d}$, they are then used to construct a word-word similarity matrix $\mathbf{M_1} \in \mathbb{R}^{L\times 2\times T\times T}$ by dot product and cosine similarity. Both of them are stacked together as the channel dimension. The process can be formulated as:

$$\mathbf{M_1} = [\hat{\mathbf{U}}_i \mathbf{A_1} \mathbf{r}_i^T; \mathbf{cos}(\hat{\mathbf{U}}_i, \mathbf{r}_i)]\,. \tag{12}$$

where $\mathbf{A_1} \in \mathbb{R}^{d\times d}$ is a linear transformation matrix.

4.6.2 Self Matching

Then, we use the Attentive Module over word dimension to construct multi-grained representations, which is formulated as:

$$\begin{aligned} \hat{\mathbf{U}}_i^{self} &= \mathbf{AttentiveModule}(\hat{\mathbf{U}}_i, \hat{\mathbf{U}}_i, \hat{\mathbf{U}}_i)\,, \\ \mathbf{r}_i^{self} &= \mathbf{AttentiveModule}(\mathbf{r}_i, \mathbf{r}_i, \mathbf{r}_i)\,. \end{aligned} \tag{13}$$

By this means, the words in each utterance or candidate response are connected together repeatedly to

combine more and more overall characterizations. Different from DAM (Zhou et al., 2018c), we do not stack many Attentive Module layers because it will drastically increase the computational expense.

Then, we use them to construct $\mathbf{M_2} \in \mathbb{R}^{L\times 2\times T\times T}$, whose element is

$$\mathbf{M}_2 = [\hat{\mathbf{U}}_i^{self}\mathbf{A_2}(\mathbf{r}_i^{self})^T; \mathbf{cos}(\hat{\mathbf{U}}_i^{self}, \mathbf{r}_i^{self})]\,, \tag{14}$$

where $\mathbf{A_2} \in \mathbb{R}^{d\times d}$ is a linear transformation matrix.

4.6.3 Cross Matching

Similarly, we build the semantic association between every utterance and response by the attentive module:

$$\begin{aligned}\hat{\mathbf{U}}_i^{cross} &= \mathbf{AttentiveModule}(\hat{\mathbf{U}}_i, \mathbf{r}_i, \mathbf{r}_i)\,,\\ \mathbf{r}_i^{cross} &= \mathbf{AttentiveModule}(\mathbf{r}_i, \hat{\mathbf{U}}_i, \hat{\mathbf{U}}_i)\,.\end{aligned} \tag{15}$$

In this way, we can make the inter-dependent segment pairs close to each other, and aliment scores between those latently inter-dependent pairs could get increased, which will better encode the dependency relation into representation.

Finally, we use $\hat{\mathbf{U}}_i^{cross}$ and $\mathbf{r}_i^{cross}$ to construct $\mathbf{M}_3 \in \mathbb{R}^{L\times 2\times T\times T}$, whose element is

$$\mathbf{M}_3 = [\hat{\mathbf{U}}_i^{cross}\mathbf{A_3}(\mathbf{r}_i^{cross})^T; \mathbf{cos}(\hat{\mathbf{U}}_i^{cross}, \mathbf{r}_i^{cross})]\,, \tag{16}$$

where $\mathbf{A_3} \in \mathbb{R}^{d\times d}$ is a linear transformation.

4.7 Aggregation

MSN aggregates all the matching matrices together $\mathbf{M} = [\mathbf{M}_1; \mathbf{M}_2; \mathbf{M}_3] \in \mathbb{R}^{L\times 6\times T\times T}$ and applies 2D CNN and max pooling for matching feature extraction and use GRU to model the temporal relationship of utterances in the context, which is the same as SMN (Wu et al., 2017).

Then we compute matching score $g(U_i, r_i)$ based on the matching features. Specifically, we use the final state of GRU output h_L as features and apply a single-layer perceptron to obtain score:

$$g(U_i, r_i) = \sigma(\mathbf{W}h_L + b)\,, \tag{17}$$

where $\mathbf{W}$ and b are learnt parameters, $\sigma(\cdot)$ is sigmoid activation function.

Finally, the negative log-likelihood is used as a loss function to optimize the training process.

5 Experiment

5.1 Dataset

We test MSN on three widely used multi-turn response selection datasets, the Ubuntu Corpus (Lowe et al., 2015), the Douban Corpus (Wu et al., 2017) and the E-commerce Corpus (Zhang et al., 2018). Data statistics are in Table 3.

Table 3: Data statistics for Ubuntu, Douban and E-commerce datasets.

Models	Ubuntu			Douban			E-commerce		
	Train	Val	Test	Train	Val	Test	Train	Val	Test
#context-response pairs	1M	500K	500K	1M	50K	50K	1M	10K	10K
#candidates per context	2	10	10	2	2	10	2	2	10
Avg #turns per context	10.13	10.11	10.11	6.69	6.75	6.45	5.51	5.48	5.64
Avg #words per utterance	11.35	11.34	11.37	18.56	18.50	20.74	7.02	6.99	7.11

Ubuntu Corpus consists of English multi-turn conversations about technical support collected from chat logs of the Ubuntu forum.

Douban Corpus contains dyadic dialogs (conversation between two persons) longer than 2 turns from the Douban group [1] which is a popular social networking service in China.

E-commerce Corpus is collected from real-world conversations between customers and customer service staff from Taobao[2], the largest e-commerce platform in China. The dataset contains diverse types of conversations (e.g. commodity consultation, logistics express, recommendation, and chitchat) concerning various commodities.

5.2 Evaluation Metric

Following the previous works (Wu et al., 2017; Zhang et al., 2018; Chaudhuri et al., 2018; Tao et al., 2019), we employ recall at position k in n candidates ($R_n@k$) as evaluation metrics. Apart from $R_n@k$, we use MAP (Mean Average Precision), MRR (Mean Reciprocal Rank), and Precision-at-one P@1 especially for Douban corpus, which is the same as previous works (Wu et al., 2017; Tao et al., 2019). For some dialogues in Douban corpus have more than one true candidate response.

5.3 Baseline Models

Single-turn matching models: Basic models in (Lowe et al., 2015; Kadlec et al., 2015) including RNN, CNN are used in early works. Some advanced single-turn matching models, such as DL2R (Yan et al., 2016), Atten-LSTM (Tan et al.,

[1] https://www.douban.com/group
[2] https://www.taobao.com

Table 4: Experimental results on Ubuntu, Douban and E-commerce datasets. MRFN is the state-of-the-art model until this submission.

Models	Ubuntu Corpus			Douban Corpus						E-commerce Corpus		
	R_{10}@1	R_{10}@2	R_{10}@5	MAP	MRR	P@1	R_{10}@1	R_{10}@2	R_{10}@5	R_{10}@1	R_{10}@2	R_{10}@5
TF-IDF (Lowe et al., 2015)	41.0	54.5	70.8	33.1	35.9	18.0	9.6	17.2	40.5	15.9	25.6	47.7

Multi-View (Zhou et al., 2016)	66.2	80.1	95.1	50.5	54.3	34.2	20.2	35.0	72.9	42.1	60.1	86.1
SMN (Wu et al., 2017)	72.6	84.7	96.1	52.9	56.9	39.7	23.3	39.6	72.4	45.3	65.4	88.6
DUA (Zhang et al., 2018)	75.2	86.8	96.2	55.1	59.9	42.1	24.3	42.1	78.0	50.1	70.0	92.1
DAM (Zhou et al., 2018c)	76.7	87.4	96.9	55.0	60.1	42.7	25.4	41.0	75.7	-	-	-
MRFN (Tao et al., 2019)	78.6	88.6	97.6	57.1	61.7	44.8	27.6	43.5	78.3	-	-	-
MSN	**80.0**	**89.9**	**97.8**	**58.7**	**63.2**	**47.0**	**29.5**	**45.2**	**78.8**	**60.6**	**77.0**	**93.7**

2015), and MV-LSTM (Wan et al., 2016) are also explored in this work. These models concatenate all context utterances together to match a response.

Multi-turn matching models: Multi-view (Zhou et al., 2016) models utterances from word level view and utterance level view; DL2R model (Yan et al., 2016) reformulates the message with other utterances in the context; SMN (Wu et al., 2017) matches a response with each utterance in the context; DUA (Zhang et al., 2018) formulates previous utterances into context using a proposed deep utterance aggregation model; DAM (Zhou et al., 2018c) constructs representations of utterances in the context and the response with stacked self-attention and cross attention; MRFN (Tao et al., 2019) fuses multiple types of representations with a multi-representation fusion network for response matching.

5.4 Model Training

Our model was implemented by PyTorch (Paszke et al., 2017). Word embeddings were initialized by the results of word2vec (Mikolov et al., 2013) which ran on the dataset, and the dimensionality of word vectors is 200. The hyper-parameter k of selectors is set to 3. We use three convolution layers to extract matching features. The 1st convolution layer has 16 [3,3] filters with [1,1] stride, and its max-pooling size is [2,2] with [2,2] stride. The 2nd convolution layer has 32 [3,3] filters with [1,1] stride, and its max pooling size is also [2,2] with [2,2] stride. The 3rd convolution layer has 64 [3,3] filters with [1,1] stride, and its max pooling size is also [3,3] with [3,3] stride. We set the dimension of the hidden states of GRU as 300. The parameters were updated by Adam algorithm (Kingma and Ba, 2014) and the parameters of Adam, β_1 and β_2 are 0.9 and 0.999 respectively. The learning rate is initialized as 1e-3 and gradually decreased during training. Same as previous works (Wu et al., 2017; Zhang et al., 2018), the maximum utterance length is 50 and the maximum context length (i.e., number of utterances) as 10.

5.5 Experiment Result

Table 4 shows the results of MSN and all baseline models on the datasets. All the experimental results are cited from previous works (Zhang et al., 2018; Chaudhuri et al., 2018; Tao et al., 2019).

Referring to the table, MSN significantly outperforms all other models in terms of most of the metrics on the three datasets, including MRFN, which is the state-of-the-art model until this submission. MSN extends from SMN (Wu et al., 2017) and DAM (Zhou et al., 2018c), and it achieves more than 3% absolute improvement on R_{10}@1 compared with SMN and DAM. The improvement also shows the importance of filtering irrelevant context before matching.

6 Further Analysis

6.1 Ablation Study

We perform a series of ablation experiments over the different parts of the model to investigate their relative importance. Firstly, we use the complete

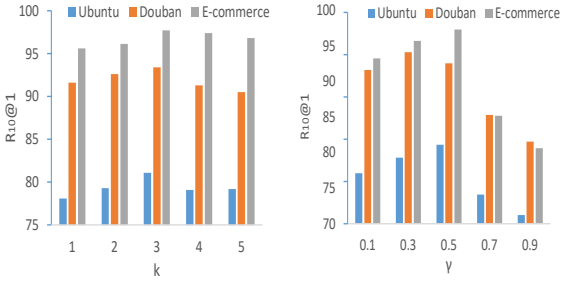
MSN as the baseline. Then, we gradually remove its modules as follows:

- **w/o Word Selector**: A model that is trained using the utterance selector but without the word selector.
- **w/o Utterance Selector**: A model which is trained without the utterance selector.
- **Only Hop1 (Hop2, Hop3) Selector**: A model which is trained only with hop1 or hop2 or hop3 selector.
- **w/o Selector**: Removing all selector modules and only use the attention module for matching.

Table 5: Ablation study on E-commerce corpus.

Model	$R_{10}@1$	$R_{10}@2$	$R_{10}@5$
MSN$_{base}$	60.6	77.0	93.7
w/o Selector	55.4	74.2	92.5
w/o Word Selector	59.3	76.5	92.4
w/o Utterance Selector	58.6	75.3	92.8
Only Hop1 Selector	58.3	74.9	93.3
Only Hop2 Selector	56.8	76.7	94.6
Only Hop3 Selector	56.6	74.7	94.0

From experimental results in Table 5, we can observe that:



(1) Compared with MSN$_{base}$, removing selectors leads to performance degradation, which shows that the multi-hop selectors are indeed help to improve the selection performance.

(2) The performances decay a large margin when the word selector and utterance selector are removed, which proves that both word selector and utterance selector play an important role in selecting relevant context utterances.

(3) For E-commerce dataset, the context selected by Hop1 selector is more important than other selectors. We think the main reason is that the dialogs in E-commerce corpus happen between buyers and sellers on the Taobao platform. The intent of the dialogue is very clear and the dialogue is mainly in the form of one question and one answer. So the last dialogue session has little dependency on the very far context. However, the fusion of these hop selectors' results still brings more performance improvement.

6.2 Parameter Sensitivity

The choices of k for selectors and threshold γ in formula (10) may influence the performance. Thus, we conduct a series of sensitivity analysis experiments on the development dataset to study how different choices of parameters influence the performance of the model.

(a) Effects of k. (b) Effects of threshold γ.

Figure 3: Parameter sensitivity analysis on the development datasets of Ubuntu, Douban, and E-commerce Corpus.

The k decides how many selectors that MSN uses to select relevant context utterances. Referring to Figure 3 (a), only using hop1 selector is not better than using multiple selectors. However, the performance does not increase when $k > 3$. It is easy to see that when k is too large, the key will contain too many noises and cannot reflect the intention of the last dialogue session.

Figure 3 (b) shows the performance with different threshold γ. Intuitively, when γ is too large, the selectors will filter out too much context, which may hurt performance. However, when γ is too small, the selectors do not work very well. We can observe that MSN achieves the best performance when $\gamma = 0.3$ or 0.5.

7 Conclusion and Future Work

In this paper, we analyze the side effect of using unnecessary context utterances and verify matching-based models are very sensitive to the context. We propose a multi-hop selector network to alleviate this problem. Empirical results on three large-scale datasets demonstrate the effectiveness of the model in multi-turn response selection and yield new state-of-the-art results at the same time.

In the future, we will study how to solve the logical consistency problem between utterances and candidate responses to improve selection performance.

Abstract

Previous research on empathetic dialogue systems has mostly focused on generating responses given certain emotions. However, being empathetic not only requires the ability of generating emotional responses, but more importantly, requires the understanding of user emotions and replying appropriately. In this paper, we propose a novel end-to-end approach for modeling empathy in dialogue systems: Mixture of Empathetic Listeners (MoEL). Our model first captures the user emotions and outputs an emotion distribution. Based on this, MoEL will *softly combine* the output states of the *appropriate* Listener(s), which are each optimized to react to certain emotions, and generate an empathetic response. Human evaluations on *empathetic-dialogues* (Rashkin et al., 2018) dataset confirm that MoEL outperforms multitask training baseline in terms of empathy, relevance, and fluency. Furthermore, the case study on generated responses of different Listeners shows high interpretability of our model.

1 Introduction

Neural network approaches for conversation models have shown to be successful in scalable training and generating fluent and relevant responses (Vinyals and Le, 2015). However, it has been pointed out by Li et al. (2016a,b,c); Wu et al. (2018b) that only using Maximum Likelihood Estimation as the objective function tends to lead to *generic* and *repetitive* responses like "I am sorry". Furthermore, many others have shown that the incorporation of additional inductive bias leads to a more engaging chatbot, such as understanding commonsense (Dinan et al., 2018), or modeling consistent persona (Li et al., 2016b; Zhang et al., 2018a; Mazare et al., 2018a).

Meanwhile, another important aspect of an engaging human conversation that received relatively less focus is emotional understanding and empathy (Rashkin et al., 2018; Dinan et al., 2019; Wolf et al., 2019). Intuitively, ordinary social conversations between two humans are often about their daily lives that revolve around happy or sad experiences. In such scenarios, people generally tend to respond in a way that acknowledges the feelings of their conversational partners.

Emotion: Angry	
Situation	I was furious when I got in my first car wreck.
Speaker	I was driving on the interstate and another car ran into the back of me.
Listener	Wow. Did you get hurt? Sounds scary.
Speaker	No just the airbags went off and I hit my head and got a few bruises.
Listener	I am always scared about those airbags! I am so glad you are ok!

Table 1: One conversation from empathetic dialogue, a speaker tells the situation he(she) is facing, and a listener try to understand speaker's feeling and respond accordingly

Table 1 shows an conversation from the *empathetic-dialogues* dataset (Rashkin et al., 2018) about how an empathetic person would respond to the stressful situation the *Speaker* has been through. However, despite the importance of empathy and emotional understanding in human conversations, it is still very challenging to train a dialogue agent able to recognize and respond with the correct emotion.

So far, to solve the problem of empathetic dialogue response generation, which is to understand the user emotion and respond appropriately (Bertero et al., 2016), there have been mainly two lines

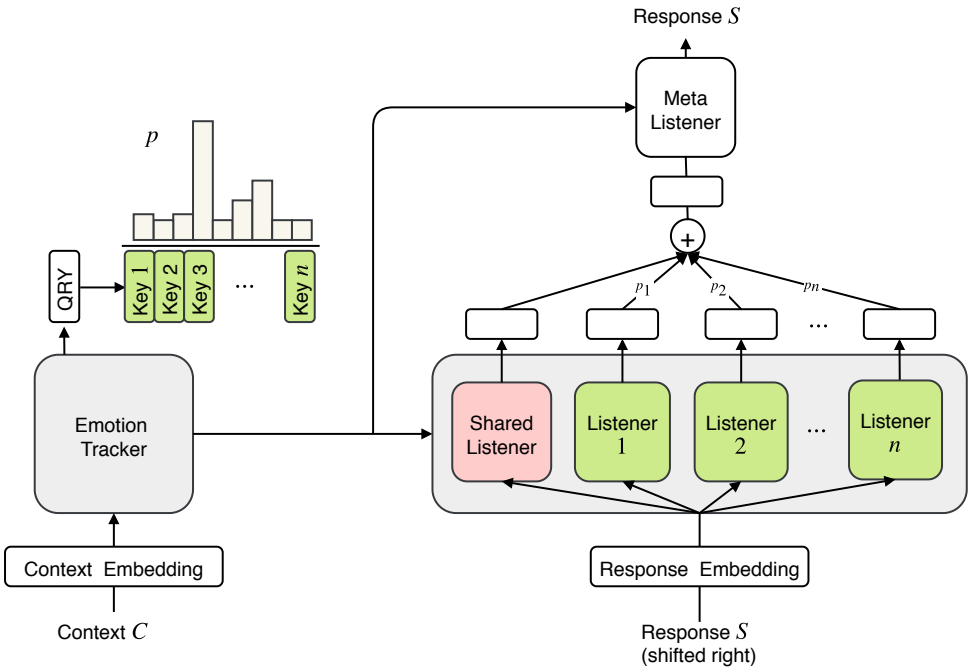

Figure 1: The proposed model Mixture of Empathetic Listeners, which has an emotion tracker, n empathetic listeners along with a shared listener, and a meta listener to fuse the information from listeners and produce the empathetic response.

of work. The first is a multi-task approach that jointly trains a model to predict the current emotional state of the user and generate an appropriate response based on the state (Lubis et al., 2018; Rashkin et al., 2018). Instead, the second line of work focuses on conditioning the response generation to a certain fixed emotion (Hu et al., 2017; Wang and Wan, 2018; Zhou and Wang, 2018; Zhou et al., 2018).

Both cases have succeeded in generating empathetic and emotional responses, but have neglected some crucial points in empathetic dialogue response generation. 1) The first assumes that by understanding the emotion, the model implicitly learns how to respond appropriately. However, without any additional inductive bias, a single decoder learning to respond for all emotions will not only lose interpretability in the generation process, but will also promote more generic responses. 2) The second assumes that the emotion to condition the generation on is given as input, but we often do not know which emotion is appropriate in order to generate an empathetic response.

Therefore, in this paper, to address the above issues, we propose a novel end-to-end empathetic dialogue agent, called Mixture of Empathetic Listeners [1] (MoEL). Similar to Rashkin et al. (2018), we first encode the dialogue context and use it to recognize the emotional state (n possible emotions). However, the main difference is that our model consists of n decoders, further denoted as *listeners*, which are optimized to react to each context emotion accordingly. The listeners are trained along with a Meta-listener that *softly combines* the output decoder states of each listener according to the emotion classification distribution. Such design allows our model to explicitly learn how to choose an appropriate reaction based on its understanding of the context emotion. A detailed illustration of MoEL is shown in Figure 1.

The proposed model is tested against several competitive baseline settings (Vaswani et al., 2017; Rashkin et al., 2018), and evaluated with human judges. The experimental results show that our approach outperforms the baselines in both empathy and relevance. Finally, our analysis demonstrates that not only MoEL effectively attends to the right listener, but also each listener learns how to properly react to its corresponding emotion, hence allowing a more interpretable generative process.

[1] The code will be released at https://github.com/HLTCHKUST/MoEL

2 Related Work

Conversational Models: Open domain conversational models has been widely studied (Serban et al., 2016; Vinyals and Le, 2015; Wolf et al., 2019). A recent trend is to produce personalized responses by conditioning the generation on a persona profile to make the response more consistent through the dialogue (Li et al., 2016b). In particular, PersonaChat (Zhang et al., 2018b; Kulikov et al., 2018) dataset was created, and then extended in ConvAI 2 challenge (Dinan et al., 2019), to show that by adding persona information as input to the model, the produced responses elicit more consistent personas. Based on such, several follow-up work has been presented (Mazare et al., 2018b; Hancock et al., 2019; Joshi et al., 2017; Kulikov et al., 2018; Yavuz et al., 2018; Zemlyanskiy and Sha, 2018; Madotto et al., 2019). However, such personalized dialogue agents focus only on modeling a consistent persona and often neglect the feelings of their conversation partners.

Another line of work combines retrieval and generation to promote the response diversity (Cai et al., 2018; Weston et al., 2018; Wu et al., 2018b). However, only fewer works focus on emotion (Winata et al., 2017, 2019; Xu et al., 2018; Fan et al., 2018a,c,b; Lee et al., 2019) and empathy in the context of dialogues systems (Bertero et al., 2016; Chatterjee et al., 2019a,b; Shin et al., 2019). For generating emotional dialogues, Hu et al. (2017); Wang and Wan (2018); Zhou and Wang (2018) successfully introduce a framework of controlling the sentiment and emotion of the generated response, while (Zhou and Wang, 2018) also introduces a new Twitter conversation dataset and propose to distantly supervised the generative model with emojis. Meanwhile, (Lubis et al., 2018; Rashkin et al., 2018) also introduce new datasets for empathetic dialogues and train multi-task models on it.

Mixture of Experts: The idea of having specialized parameters, or so-called experts, has been widely studied topics in the last two decades (Jacobs et al., 1991; Jordan and Jacobs, 1994). For instance, different architectures and methodologies have been used such as SVM (Collobert et al., 2002), Gaussian Processes (Tresp, 2001; Theis and Bethge, 2015; Deisenroth and Ng, 2015), Dirichlet Processes (Shahbaba and Neal, 2009), Hierarchical Experts (Yao et al., 2009), Infinite Number of Experts (Rasmussen and Ghahramani, 2002) and sequential expert addition (Aljundi et al., 2017). More recently, the Mixture Of Expert (Shazeer et al., 2017; Kaiser et al., 2017) model was proposed which added a large number of experts in between of two LSTM (Schmidhuber, 1987) layers to enhance the capacity of the model. This idea of having independent specialized experts inspires our approach to model the reaction to each emotion with a separate expert.

3 Mixture of Empathetic Listeners

The dialogue context is an alternating set of utterances from speaker and listener. We denote the dialogue context as $C = \{U_1, S_1, U_2, S_2, \cdots, U_t\}$ and the speaker emotion state at each utterance as $Emo = \{e_1, e_2, \cdots, e_t\}$ where $\forall e_i \in \{1, \ldots, n\}$. Then, our model aims to track the speaker emotional state e_t from the dialogue context C, and generates an empathetic response S_t.

Overall, MoEL is composed of three components: an *emotion tracker*, *emotion-aware listeners*, and a *meta listener* as shown in Figure 1. The emotion tracker (which is also the context encoder) encodes C and computes a distribution over the possible user emotions. Then all the listeners independently attend to this distribution to compute their own representation. Finally, the meta listener takes the weighted sum of representations from the listeners and generates the final response.

3.1 Embedding

We define the context embedding $E^C \in \mathbb{R}^{|V| \times d_{emb}}$, and the response embedding $E^R \in \mathbb{R}^{|V| \times d_{emb}}$ which are used to convert tokens into embeddings. In multi-turn dialogues, ensuring that the model is able to distinguish among turns is essential, especially when multiple emotion are present in different turns. Hence, we incorporate a dialogue state embedding in the input. This is used to enable the encoder to distinguish speaker utterances and listener utterances (Wolf et al., 2019). As shown in Figure 2, our context embedding E^C is the positional sum of the word embedding E^W, the positional embedding E^P (Vaswani et al., 2017) and the dialogue state embedding E^D.

$$E^C(C) = E^W(C) + E^P(C) + E^D(C) \quad (1)$$

3.2 Emotion Tracker

MoEL uses a standard transformer encoder (Vaswani et al., 2017) for the emotion

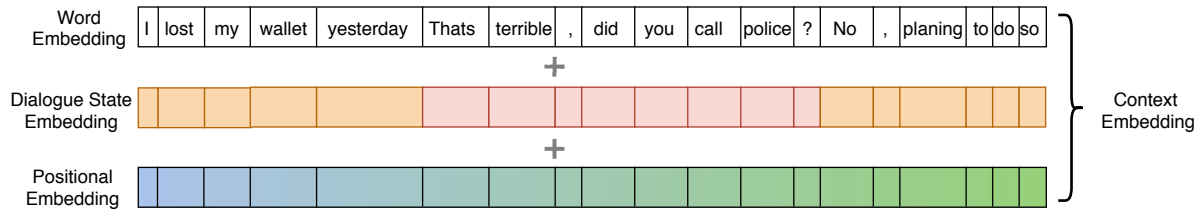

Figure 2: Context embedding is computed by summing up the word embedding, dialogue state embedding and positional embedding for each token.

tracker. We first flatten all dialogue turns in C, and map each token into its vectorial representation using the context embedding E^C. Then the encoder encodes the context sequence into a context representation. We add a query token QRY at the beginning of each input sequence as in BERT (Devlin et al., 2018), to compute the weighted sum of the output tensor. Denoting a transformer encoder as TRS_{Enc}, then corresponding context representation become:

$$H = TRS_{Enc}(E^C([QRY; C])) \quad (2)$$

where $[;]$ denotes concatenation, $H \in \mathbb{R}^{L \times d_{model}}$ where L is the sequence length. Then, we define the final representation of the token QRY as

$$q = H_0 \quad (3)$$

where $q \in \mathbb{R}^{d_{model}}$, which is then used as the query for generating the emotion distribution.

3.3 Emotion Aware Listeners

The emotion aware listeners mainly consist of 1) a *shared listener* that learns shared information for all emotions and 2) n independently parameterized Transformer decoders (Vaswani et al., 2017) that learn how to appropriately react given a particular emotional state. All the listeners are modeled by a standard transformer decoder layer block, denoted as TRS_{Dec}, which is made of three sub-components: a multi-head self-attention over the response input embedding, a multi-head attention over the output of the emotion tracker, and a position-wise fully connected feed-forward network.

Thus, we define the set of listeners as $L = [TRS^0_{Dec}, \ldots, TRS^n_{Dec}]$. Given the target sequence shifted by one $r_{0:t-1}$, each listener compute its own emotional response representation V_i:

$$V_i = TRS^i_{Dec}(H, E^R(r_{0:t-1})) \quad (4)$$

where TRS^i_{Dec} refers to the i-th listener, including the shared one. Conceptually, we expect that the output from the shared listener, TRS^0_{Dec}, to be a general representation which can help the model to capture the dialogue context. On the other hand, we expect that each empathetic listener learns how to respond to a particular emotion. To model this behavior, we assign different weights to each empathetic listener according to the user emotion distribution, while assigning a fixed weight of 1 to the shared listener.

To elaborate, we construct a Key-Value Memory Network (Miller et al., 2016) and represent each memory slot as a vector pair (k_i, V_i), where $k_i \in \mathbb{R}^{d_{model}}$ denotes the key vector and V_i is from Equation 4. Then, the encoder informed query q is used to address the key vectors k by performing a dot product followed by a Softmax function. Thus, we have:

$$p_i = \frac{e^{q^\top k_i}}{\sum_{j=1}^{n} e^{q^\top k_j}} \quad (5)$$

each p_i is the score assigned to V_i, thus used as the weight of each listener. During training, given the speaker emotion state e_t, we supervise each weight p_i by maximizing the probability of the emotion state e_t with a cross entropy loss function:

$$\mathcal{L}_1 = -\log p_{e_t} \quad (6)$$

Finally, the combined output representation is compute by the weighted sum of the memory values V_i and the shared listener output V_0.

$$V_M = V_0 + \sum_{i=1}^{n} p_i V_i \quad (7)$$

3.4 Meta Listener

Finally, the Meta Listener is implemented using another transformer decoder layer, which further transform the representation of the listeners and

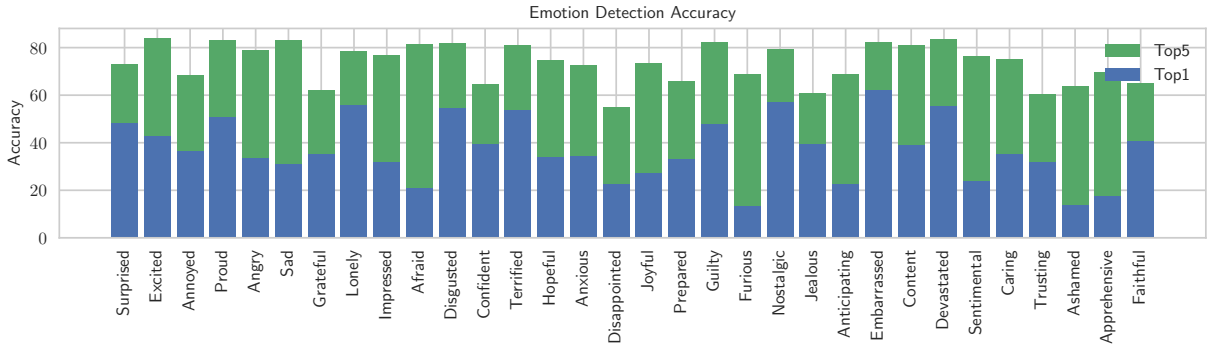

Figure 3: Top-1 and Top-5 emotion detection accuracy over 32 emotions at each turn

	Params.	BLEU	Empathy	Relevance	Fluency
Gold	-	-	3.93	3.93	3.35
TRS	16.94M	3.02	3.32	3.47	**3.52**
MultiTRS	16.95M	2.92	3.36	3.57	3.31
MoEL	23.1M	2.90	**3.44**	**3.70**	3.47

Table 2: Comparison between our proposed methods and baselines. All of models receive close BLEU score. MoEL achieve highest *Empathy* and *Relevance* score, while TRS achieve better *Fluency* score. The number of parameters for each model is reported.

generates the final response. The intuition is that each listener specializes to a certain emotion and the Meta Listener gathers the opinions generated by multiple listeners to produce the final response. Hence, we define another TRS^{Meta}_{Dec}, and an affine transformation $W \in \mathbb{R}^{d_{model} \times |V|}$ to compute:

$$O = TRS^{Meta}_{Dec}(H, V_M) \tag{8}$$

$$p(r_{1:t}|C, r_{0:t-1}) = \text{softmax}(O^\top W) \tag{9}$$

where $O \in \mathbb{R}^{d_{model} \times t}$ is the output of meta listener and $p(r_{1:t}|C, r_{0:t-1})$ is a distribution over the vocabulary for the next tokens. We then use a standard maximum likelihood estimator (MLE) to optimize the response prediction:

$$\mathcal{L}_2 = -\log p\left(S_t|C\right) \tag{10}$$

Lastly, all the parameters are jointly trained end-to-end to optimize the listener selection and response generation by minimizing the weighted-sum of two losses:

$$\mathcal{L} = \alpha\mathcal{L}_1 + \beta\mathcal{L}_2 \tag{11}$$

Where α and β are hyperparameters to balance two loss.

Model	Win	Loss	Tie
MoEL vs TRS	37.3%	18.7%	44%
MoEL vs Multi-TRS	36.7%	32.6%	30.7%

Table 3: Result of human A/B test. Tests are conducted pairwise between MoEL and baseline models

4 Experiment

4.1 Dataset

We conduct our experiment on the *empathetic-dialogues* (Rashkin et al., 2018) dataset which consist of 25k one-to-one open-domain conversation grounded in emotional situations. The dataset provides 32, evenly distributed, emotion labels. Table 1 shows an example from the training set. The speakers are talking about their situation and the listeners is trying to understand their feeling and reply accordingly. At training time the emotional labels of the speakers are given, while we hide the label in test time to evaluate the *empathy* of our model.

4.2 Training

We train our model using Adam optimizer (Kingma and Ba, 2014) and varied the learning rate during training following (Vaswani et al., 2017). The weight of both losses α and β are set to 1 for simplicity. We use pre-trained Glove vectors (Pennington et al., 2014) to initialize the word embedding and we share it across the encoder and the decoder. The rest of the parameters are randomly initialized.

In the early training stage, emotion tracker randomly assign weights to the listeners, and may send noisy gradient flow back to the wrong listeners, which can make the model convergence harder. To stabilize the learning process, we replace the distribution p of the listeners with the or-

acle emotion e_t information using a certain probability ϵ_{oracle}, and we gradually anneal it during the training. We set an annealing rate $\gamma = 1 \times 10^{-3}$, and a threshold t_{thd} equal to 1×10^4, thus at each iteration t iteration we compute:

$$\epsilon_{oracle} = \gamma + (1 - \gamma)e^{-\frac{t}{t_{thd}}} \quad (12)$$

4.3 Baseline

We compare our model with two baselines:

Transformer (TRS) The standard Transformer model (Vaswani et al., 2017) that is trained to minimize MLE loss as in Equation 10.

Multitask Transformer (Multi-TRS) A Multitask Transformer trained as (Rashkin et al., 2018) to incorporate additional supervised information about the emotion. The encoder of multitask transformer is the same as our emotion tracker, and the context representation Q, from Equation 3, is used as input to an emotion classifier. The whole model is jointy trained by optimizing both the classification and generation loss.

4.4 Hyperparameter

In all of our experiments we used 300 dimensional word embedding and 300 hidden size everywhere. We use 2 self-attention layers made up of 2 attention heads each with embedding dimension 40. We replace Positionwise Feedforward sub-layer with 1D convolution with 50 filters of width 3. We train all of models with batch size 16 and we use batch size 1 in the test time.

4.5 Evaluation Metrics

BLEU We compute BLEU scores (Papineni et al., 2002) to compare the generated response against human responses. However, in open-domain dialogue response generation, BLEU is not a good measurement of generation quality (Liu et al., 2016), so we use BLEU only as a reference.

Human Ratings In order to measure the quality of the generated responses, we conduct human evaluations with Amazon Mechanical Turk. Following Rashkin et al. (2018), we first randomly sample 100 dialogues and their corresponding generations from MoEL and the baselines. For each response, we assign three human annotators to score the following aspect of models: *Empathy*, *Relevance*, and *Fluency*. Note that we evaluate each metric independently and the scores range between 1 and 5, in which 1 is "not at all" and 5 is "very much".

We ask the human judges to evaluate each of the following categories from a 1 to 5 scale, where 5 is the best score.

- Empathy / Sympathy: Did the responses from the LISTENER show understanding of the feelings of the SPEAKER talking about their experience?
- Relevance: Did the responses of the LISTENER seem appropriate to the conversation? Were they on-topic?
- Fluency: Could you understand the responses from the LISTENER? Did the language seem accurate?

Human A/B Test In this human evaluation task, we aim to directly compare the generated responses with each other. We randomly sample 100 dialogues each for *MoEL vs* {*TRS, Multi-TRS*}. Three workers are given randomly ordered responses from either MoEL or {TRS, Multi-TRS}, and are prompted to choose the better response. They can either choose one of the responses or select *tie* when the provided options are either both good or both bad.

5 Results

Emotion detection To verify whether our model can attend to the appropriate listeners, we compute the emotion detection accuracy for each turn. Our model achieve 38%, 63%, 74% in terms of top-1, top-3, top-5 detection accuracy over 32 emotions. We notice that some emotions frequently appear in similar context (e.g., Annoyed, Angry, Furious) which might degrade the detection accuracy. Figure 3 shows the per class accuracy in the test set. We can see that by using top-5 the majority of the emotion achieve around 80% accuracy.

Response evaluation Both automatic and human evaluation results are shown in Table 2. TRS achieves the highest BLEU score and *Fluency* score but the lowest *Empathy* and *Relevance* score. This shows us that the responses generated by TRS are more generic but cannot accurately capture the user emotions. With the additional supervision on user emotions, multi-task training improves both *Empathy* and *Relevance* score, but it still degrades *Fluency*. In contrast, MoEL achieves the highest

Emotion	Disgusted
Context	**Speaker**: i had to dog-sit for my dad about a week ago . i had to clean up dog poop at least 10 times , it was awful .
TRS	that is **horrible** . i hope you did not have to clean it up .
Multi-TRS	oh my goodness , that must have been so **scary** !
MoEL	oh wow , that is pretty **gross** .
Goal	ohh , cleaning dog poop is always been annoying , yet petting the dog is always amusing
Emotion	Disappointed
Context	**Speaker**: i was turned down for a job i really thought i would be a good fit at . **Listener**: did they give you any reason for not giving you the job ? **Speaker**: someone else interviewed who had much more experience than i did .
TRS	that is good . i hope you have a good time .
Multi-TRS	that is a good idea . i hope it was a good idea .
MoEL	i am sorry to hear that . i am sure you will do great again
Goal	well , at least a candidate that deserved the job got it .

Speaker: so my friend 's baby fell down and scraped his knee yesterday and i was trying so hard to cheer him up. **Listener**$_{caring}$: that was really nice of you. I am glad you were able to help him.	
Listener$_{terrified}$	oh wow ! that must have been so scary .
Listener$_{sad}$	oh no , i am so sorry to hear that .
Listener$_{excited}$	that sounds like a good idea .
Listener$_{proud}$	that was awesome ! did he get any good at you ?
Speaker: my husband lost a job but I am hoping he can find a full-time job soon. **Listener**$_{hopeful}$: what kind of job is it?	
Listener$_{terrified}$	oh that sucks . you should have been together .
Listener$_{sad}$	i am so sorry . i am sure he will be fine .
Listener$_{excited}$	that sounds awesome . what kind of job did he get you for ?
Listener$_{proud}$	oh wow ! congratulations to him . you must be proud of him .

Table 4: Generated responses from TRS, Multi-TRS and MoEL in 2 different user emotion states (**top**) and comparing generation from different listeners (**bottom**). We use hard attention on Terrified, Sad, Excited and Proud listeners.

Empathy and *Relevance* score. This suggests that the multi-expert strategy helps to capture the user emotional states and context simultaneously, and elicits a more appropriate response. The human A/B tests also confirm that the responses from our model are more preferred by human judges.

6 Analysis

In order to understand whether or how MoEL can effectively improve other baselines, learn each emotion, and properly react to them, we conduct three different analyses: model response comparison, listener analysis, and visualization of the emotion distribution p.

Model response comparison The top part of Table 4 compares the generated responses from MoEL and the two baselines on two different speaker emotional states. In the first example, MoEL captures the exact emotion of the speaker, by replying with "cleaning up dog poop is pretty **gross**", instead of "**horrible**" and "**scary**". In the second example, both TRS and Multi-TRS fail to understand that the speaker is disappointed about the failure of his interview, and they generate inappropriate responses. On the other hand, MoEL shows an empathetic response by comforting the speaker with "I am sure you will do great again". More examples can be find in the Appendix.

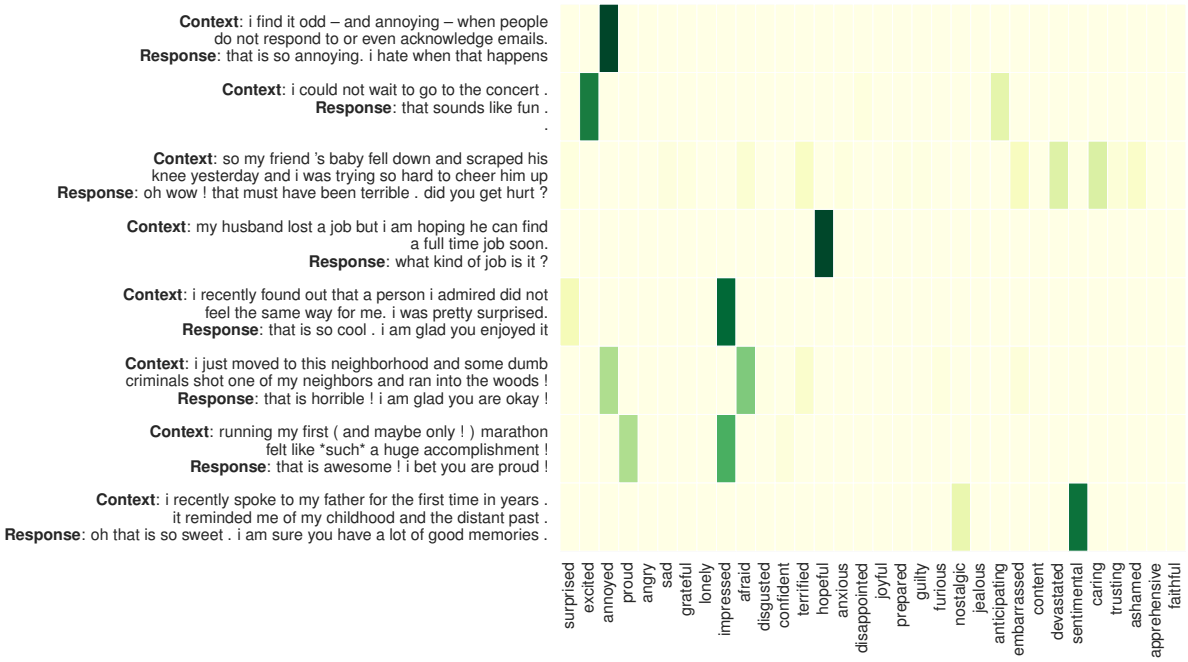

Figure 4: The visualization of attention on the listeners: The left side is the context followed by the responses generated by MoEL. The heat map illustrate the attention weights on 32 listeners

Listener analysis To have a better understanding of how each listener learned to react to different context, we conduct a study of comparing responses produced by different listeners. To do so, we *fix* the input dialogue context and we manually modify the attention vector distribution p used to produce the response. We experiment with the correct listener and four other listeners: **Listener**$_{terrified}$, **Listener**$_{sad}$, **Listener**$_{excited}$, **Listener**$_{proud}$. Given the same context, we expect that different listeners will react differently, as this is our inductive bias. For example, **Listener**$_{sad}$ is optimized to comfort sad people, and **Listener**$_{\{excited,proud\}}$ share the positive emotions from the user. From the generation results in the bottom parts of Table 4 we can see that the corresponding listeners can produce empathetic and relevant responses when they reasonably match the speaker emotions. However, when the expected emotion label is opposite to the selected listener, such as *caring* and *sad*, the response becomes emotionally inappropriate.

Interestingly, in the last example, the *sad* listener actually produces a more meaningful response by encouraging the speaker. This is due to the first part of the context which conveys a sad emotion. On the other hand, for the same example, the *excited* listener responds with very relevant yet unsympathetic response. In addition, as many dialogue contexts contain multiple emotions, being able to capture them would lead to a better understanding of the speaker emotional state.

Visualization of Emotion Distribution Finally, to understand how MoEL chooses the listener according to the context, we visualize the emotion distribution p in Figure 4. In most of the cases, the model attends to the proper listeners (emotions), and generate a proper responses. This is confirmed also by the accuracy results shown in Figure 3. However, our model is sometimes focuses on parts of the dialogue context. For example, in the fifth example in Figure 4, the model fails to detect the real emotion of speaker as the context contains "I was pretty **surprised**" in its last turn.

On the other hand, the last three rows of the heatmap indicate that the model learns to leverage **multiple** listeners to produce an empathetic response. For example, when the speaker talks about some criminals that shot one of his neighbors, MoEL successfully detects both *annoyed* and *afraid* emotions from the context, and replies with an appropriate response "that is horrible! i am glad you are okay!" that addresses both emotions. However, in the third row, the model produces "you" instead of "he" by mistake. Although the model is able to capture relevant emotions for this case, other emotions also have non-negligible weights which results in a smooth emotion distri-

bution p that confuses the meta listener from accurately generating a response.

7 Conclusion & Future Work

In this paper, we propose a novel way to generate empathetic dialogue responses by using Mixture of Empathetic Listeners (MoEL). Differently from previous works, our model understands the user feelings and responds accordingly by learning specific listeners for each emotion. We benchmark our model in *empathetic-dialogues* dataset (Rashkin et al., 2018), which is a multi-turn open-domain conversation corpus grounded on emotional situations. Our experimental results show that MoEL is able to achieve competitive performance in the task with the advantage of being more interpretable than other conventional models. Finally, we show that our model is able to automatically select the correct emotional decoder and effectively generate an empathetic response.

One of the possible extensions of this work would be incorporating it with Persona (Zhang et al., 2018a) and task-oriented dialogue systems (Gao et al., 2018; Madotto et al., 2018; Wu et al., 2019, 2017, 2018a; Reddy et al., 2018; Raghu et al., 2019). Having a persona would allow the system to have more consistent and personalized responses, and combining open-domain conversations with task-oriented dialogue systems would equip the system with more engaging conversational capabilities, hence resulting in a more versatile dialogue system.

Abstract

Querying the knowledge base (KB) has long been a challenge in the end-to-end task-oriented dialogue system. Previous sequence-to-sequence (Seq2Seq) dialogue generation work treats the KB query as an attention over the entire KB, without the guarantee that the generated entities are consistent with each other. In this paper, we propose a novel framework which queries the KB in two steps to improve the consistency of generated entities. In the first step, inspired by the observation that a response can usually be supported by a single KB row, we introduce a KB retrieval component which explicitly returns the most relevant KB row given a dialogue history. The retrieval result is further used to filter the irrelevant entities in a Seq2Seq response generation model to improve the consistency among the output entities. In the second step, we further perform the attention mechanism to address the most correlated KB column. Two methods are proposed to make the training feasible without labeled retrieval data, which include distant supervision and Gumbel-Softmax technique. Experiments on two publicly available task oriented dialog datasets show the effectiveness of our model by outperforming the baseline systems and producing entity-consistent responses.

1 Introduction

Task-oriented dialogue system, which helps users to achieve specific goals with natural language, is attracting more and more research attention. With the success of the sequence-to-sequence (Seq2Seq) models in text generation (Sutskever et al., 2014; Bahdanau et al., 2014; Luong et al., 2015a; Nallapati et al., 2016b,a), several works tried to model the task-oriented dialogue as the Seq2Seq generation of response from the dialogue history (Eric and Manning, 2017; Eric et al., 2017; Madotto et al., 2018). This kind of modeling scheme frees the task-oriented dialogue system from the manually designed pipeline modules and heavy annotation labor for these modules. Different from typical text generation, the successful conversations for task-oriented dialogue system heavily depend on accurate knowledge base (KB) queries. Taking the dialogue in Figure 1 as an example, to answer the driver's query on the gas station, the dialogue system is required to retrieve the entities like "`200 Alester Ave`" and "`Valero`". For the task-oriented system based on Seq2Seq generation, there is a trend in recent study towards modeling the KB query as an attention network over the entire KB entity representations, hoping to learn a model to pay more attention to the relevant entities (Eric et al., 2017; Madotto et al., 2018; Reddy et al., 2018; Wen et al., 2018).

Address	Distance	POI type	POI	Traffic info
638 Amherst St	3 miles	grocery store	Sigona Farmers Market	car collision nearby
269 Alger Dr	1 miles	coffee or tea place	Cafe Venetia	car collision nearby
5672 barringer street	5 miles	certain address	5672 barringer street	no traffic
200 Alester Ave	2 miles	gas station	Valero	road block nearby
899 Ames Ct	5 miles	hospital	Stanford Childrens Health	moderate traffic
481 Amaranta Ave	1 miles	parking garage	Palo Alto Garage R	moderate traffic
145 Amherst St	1 miles	coffee or tea place	Teavana	road block nearby
409 Bollard St	5 miles	grocery store	Willows Market	no traffic

Driver Address to the gas station.
Car Valero is located at 200 Alester Ave.
Driver OK , please give me directions via a route that avoids all heavy traffic.
Car Since there is a road block nearby, I found another route for you and I sent it on your screen.
Driver Awesome thank you.

Figure 1: An example of a task-oriented dialogue that incorporates a knowledge base (KB). The fourth row in KB supports the second turn of the dialogue. A dialogue system will produce a response with *conflict entities* if it includes the POI in the fourth row and the address in the fifth row, like "*Valero is located at 899 Ames Ct*".

Though achieving good end-to-end dialogue generation with over-the-entire-KB attention mechanism, these methods do not guarantee the generation consistency regarding KB entities and

* Email corresponding.

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 133–142, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

sometimes yield responses with conflict entities, like "*Valero is located at 899 Ames Ct*" for the gas station query (as shown in Figure 1). In fact, the correct address for *Valero* is *200 Alester Ave*. A consistent response is relatively easy to achieve for the conventional pipeline systems because they query the KB by issuing API calls (Bordes and Weston, 2017; Wen et al., 2017b,a), and the returned entities, which typically come from a single KB row, are consistently related to the object (like the "gas station") that serves the user's request. This indicates that *a response can usually be supported by a single KB row*. It's promising to incorporate such observation into the Seq2Seq dialogue generation model, since it encourages KB relevant generation and avoids the model from producing responses with conflict entities.

To achieve entity-consistent generation in the Seq2Seq task-oriented dialogue system, we propose a novel framework which query the KB in two steps. In the first step, we introduce a retrieval module — KB-retriever to explicitly query the KB. Inspired by the observation that a single KB row usually supports a response, given the dialogue history and a set of KB rows, the KB-retriever uses a memory network (Sukhbaatar et al., 2015) to select the most relevant row. The retrieval result is then fed into a Seq2Seq dialogue generation model to filter the irrelevant KB entities and improve the consistency within the generated entities. In the second step, we further perform attention mechanism to address the most correlated KB column. Finally, we adopt the copy mechanism to incorporate the retrieved KB entity.

Since dialogue dataset is not typically annotated with the retrieval results, training the KB-retriever is non-trivial. To make the training feasible, we propose two methods: 1) we use a set of heuristics to derive the training data and train the retriever in a distant supervised fashion; 2) we use Gumbel-Softmax (Jang et al., 2017) as an approximation of the non-differentiable selecting process and train the retriever along with the Seq2Seq dialogue generation model. Experiments on two publicly available datasets (**Camrest** (Wen et al., 2017b) and **InCar Assistant** (Eric et al., 2017)) confirm the effectiveness of the KB-retriever. Both the retrievers trained with distant-supervision and Gumbel-Softmax technique outperform the compared systems in the automatic and human evaluations. Analysis empirically verifies our assumption that more than 80% responses in the dataset can be supported by a single KB row and better retrieval results lead to better task-oriented dialogue generation performance.

2 Definition

In this section, we will describe the input and output of the end-to-end task-oriented dialogue system, and the definition of Seq2Seq task-oriented dialogue generation.

2.1 Dialogue History

Given a dialogue between a user (u) and a system (s), we follow Eric et al. (2017) and represent the k-turned *dialogue utterances* as $\{(u_1, s_1), (u_2, s_2), ..., (u_k, s_k)\}$. At the i^{th} turn of the dialogue, we aggregate dialogue context which consists of the tokens of $(u_1, s_1, ..., s_{i-1}, u_i)$ and use $\mathbf{x} = (x_1, x_2, ..., x_m)$ to denote the whole *dialogue history* word by word, where m is the number of tokens in the dialogue history.

2.2 Knowledge Base

In this paper, we assume to have the access to a relational-database-like KB B, which consists of $|\mathcal{R}|$ rows and $|\mathcal{C}|$ columns. The value of entity in the j^{th} row and the i^{th} column is noted as $v_{j,i}$.

2.3 Seq2Seq Dialogue Generation

We define the Seq2Seq task-oriented dialogue generation as finding the most likely response $\mathbf{y}$ according to the input dialogue history $\mathbf{x}$ and KB B. Formally, the probability of a response is defined as

$$p(\mathbf{y} \mid \mathbf{x}, B) = \prod_{t=1}^{n} p(y_t \mid y_1, ..., y_{t-1}, \mathbf{x}, B),$$

where y_t represents an output token.

3 Our Framework

In this section, we describe our framework for end-to-end task-oriented dialogues. The architecture of our framework is demonstrated in Figure 2, which consists of two major components including an memory network-based retriever and the seq2seq dialogue generation with KB Retriever. Our framework first uses the KB-retriever to select the most relevant KB row and further filter the irrelevant entities in a Seq2Seq response generation model to improve the consistency among the

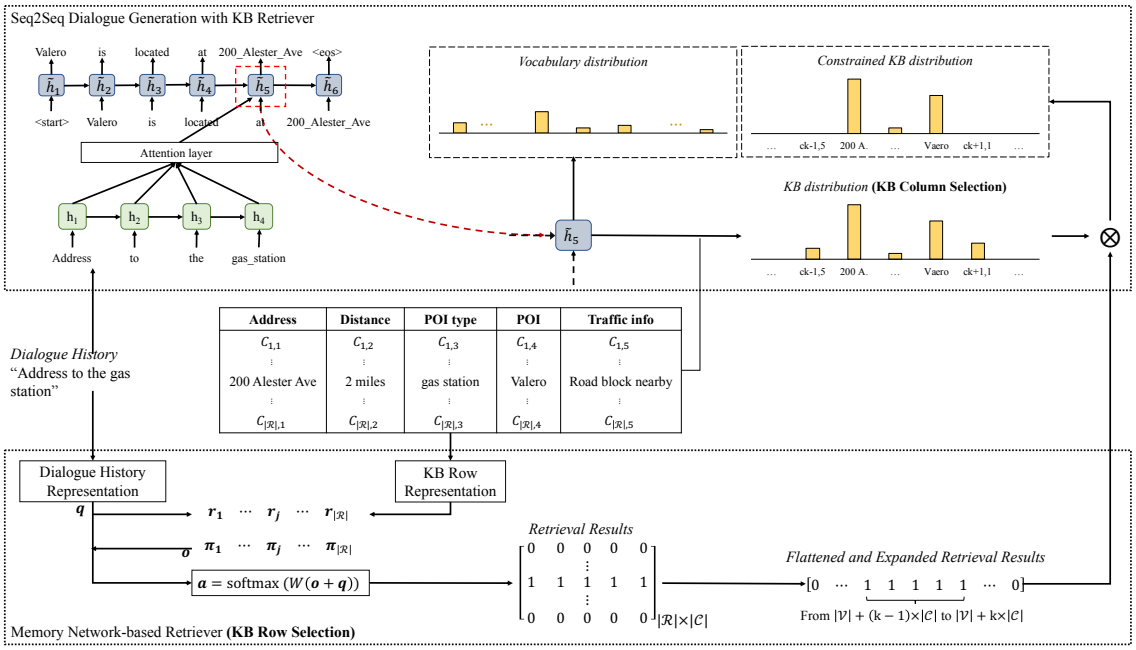

Figure 2: The workflow of our Seq2Seq task-oriented dialogue generation model with KB-retriever. For simplification, we draw the single-hop memory network instead of the multiple-hop one we use in our model.

output entities. While in decoding, we further perform the attention mechanism to choose the most probable KB column. We will present the details of our framework in the following sections.

3.1 Encoder

In our encoder, we adopt the bidirectional LSTM (Hochreiter and Schmidhuber, 1997, BiLSTM) to encode the dialogue history $\mathbf{x}$, which captures temporal relationships within the sequence. The encoder first map the tokens in $\mathbf{x}$ to vectors with embedding function ϕ^{emb}, and then the BiLSTM read the vector forwardly and backwardly to produce context-sensitive hidden states $(\mathbf{h}_1, \mathbf{h}_2, ..., \mathbf{h}_m)$ by repeatedly applying the recurrence $\mathbf{h}_i = \text{BiLSTM}\left(\phi^{\text{emb}}\left(x_i\right), \mathbf{h}_{i-1}\right)$.

3.2 Vanilla Attention-based Decoder

Here, we follow Eric et al. (2017) to adopt the attention-based decoder to generation the response word by word. LSTM is also used to represent the partially generated output sequence $(y_1, y_2, ..., y_{t-1})$ as $(\tilde{\mathbf{h}}_1, \tilde{\mathbf{h}}_2, ..., \tilde{\mathbf{h}}_t)$. For the generation of next token y_t, their model first calculates an attentive representation $\tilde{\mathbf{h}}_t'$ of the dialogue history as

$$\mathbf{u}_i^t = W_2 \tanh(W_1 [\mathbf{h}_i, \tilde{\mathbf{h}}_t]),$$
$$\mathbf{a}_i^t = \text{softmax}(\mathbf{u}_i^t),$$
$$\tilde{\mathbf{h}}_t' = \sum_{i=1}^{m} \mathbf{a}_i^t \cdot \mathbf{h}_i.$$

Then, the concatenation of the hidden representation of the partially outputted sequence $\tilde{\mathbf{h}}_t$ and the attentive dialogue history representation $\tilde{\mathbf{h}}_t'$ are projected to the vocabulary space $\mathcal{V}$ by U as

$$\mathbf{o}_t = U\,[\tilde{\mathbf{h}}_t, \tilde{\mathbf{h}}_t'],$$

to calculate the score (logit) for the next token generation. The probability of next token y_t is finally calculated as

$$p(y_t \mid y_1, ..., y_{t-1}, \mathbf{x}, B) = \text{softmax}(\mathbf{o}_t).$$

3.3 Entity-Consistency Augmented Decoder

As shown in section 3.2, we can see that the generation of tokens are just based on the dialogue history attention, which makes the model ignorant to the KB entities. In this section, we present how to query the KB explicitly in two steps for improving the entity consistence, which first adopt the KB-retriever to select the most relevant KB row and the generation of KB entities from the entities-augmented decoder is constrained to the entities

within the most probable row, thus improve the entity generation consistency. Next, we perform the column attention to select the most probable KB column. Finally, we show how to use the copy mechanism to incorporate the retrieved entity while decoding.

3.3.1 KB Row Selection

In our framework, our KB-retriever takes the dialogue history and KB rows as inputs and selects the most relevant row. This selection process resembles the task of selecting one word from the inputs to answer questions (Sukhbaatar et al., 2015), and we use a memory network to model this process. In the following sections, we will first describe how to represent the inputs, then we will talk about our memory network-based retriever

Dialogue History Representation: We encode the dialogue history by adopting the neural bag-of-words (BoW) followed the original paper (Sukhbaatar et al., 2015). Each token in the dialogue history is mapped into a vector by another embedding function $\phi^{\text{emb}'}(x)$ and the dialogue history representation $\mathbf{q}$ is computed as the sum of these vectors: $\mathbf{q} = \sum_{i=1}^{m} \phi^{\text{emb}'}(x_i)$.

KB Row Representation: In this section, we describe how to encode the KB row. Each KB cell is represented as the cell value v embedding as $\mathbf{c}_{j,k} = \phi^{\text{value}}(v_{j,k})$, and the neural BoW is also used to represent a KB row $\mathbf{r}_j$ as $\mathbf{r}_j = \sum_{k=1}^{|\mathcal{C}|} \mathbf{c}_{j,k}$.

Memory Network-Based Retriever: We model the KB retrieval process as selecting the row that most-likely supports the response generation. Memory network (Sukhbaatar et al., 2015) has shown to be effective to model this kind of selection. For a n-hop memory network, the model keeps a set of input matrices $\{R^1, R^2, ..., R^{n+1}\}$, where each R^i is a stack of $|\mathcal{R}|$ inputs $(\mathbf{r}_1^i, \mathbf{r}_2^i, ..., \mathbf{r}_{|\mathcal{R}|}^i)$. The model also keeps query $\mathbf{q}^1$ as the input. A single hop memory network computes the probability $\mathbf{a}_j$ of selecting the j^{th} input as

$$\boldsymbol{\pi}^1 = \text{softmax}((\mathbf{q}^1)^T R^1),$$
$$\mathbf{o}^1 = \sum_i \boldsymbol{\pi}_i^1 \mathbf{r}_i^2,$$
$$\mathbf{a} = \text{softmax}(W^{\text{mem}} (\mathbf{o}^1 + \mathbf{q}^1)).$$

For the multi-hop cases, layers of single hop memory network are stacked and the query of the $(i+1)^{\text{th}}$ layer network is computed as

$$\mathbf{q}^{i+1} = \mathbf{q}^i + \mathbf{o}^i,$$

and the output of the last layer is used as the output of the whole network. For more details about memory network, please refer to the original paper (Sukhbaatar et al., 2015).

After getting $\mathbf{a}$, we represent the retrieval results as a 0-1 matrix $T \in \{0,1\}^{|\mathcal{R}|\times|\mathcal{C}|}$, where each element in T is calculated as

$$T_{j,*} = \mathbb{1}[j = \underset{i}{\text{argmax}}\, \mathbf{a}_i]. \quad (1)$$

In the retrieval result, $T_{j,k}$ indicates whether the entity in the j^{th} row and the k^{th} column is relevant to the final generation of the response. In this paper, we further flatten T to a 0-1 vector $\mathbf{t} \in \{0,1\}^{|\mathcal{E}|}$ (where $|\mathcal{E}|$ equals $|\mathcal{R}| \times |\mathcal{C}|$) as our retrieval row results.

3.3.2 KB Column Selection

After getting the retrieved row result that indicates which KB row is the most relevant to the generation, we further perform column attention in decoding time to select the probable KB column. For our KB column selection, following the Eric et al. (2017) we use the decoder hidden state $(\tilde{\mathbf{h}}_1, \tilde{\mathbf{h}}_2, ..., \tilde{\mathbf{h}}_t)$ to compute an attention score with the embedding of column attribute name. The attention score $\mathbf{c} \in R^{|\mathcal{E}|}$ then become the logits of the column be selected, which can be calculated as

$$\mathbf{c}_j = W_2^{'} \tanh(W_1^{'} [\mathbf{k}_j, \tilde{\mathbf{h}}_t]),$$

where $\mathbf{c}_j$ is the attention score of the j^{th} KB column, $\mathbf{k}_j$ is represented with the embedding of word embedding of KB column name. $W_1^{'}$, $W_2^{'}$ and $\mathbf{t}^T$ are trainable parameters of the model.

3.3.3 Decoder with Retrieved Entity

After the row selection and column selection, we can define the final retrieved KB entity score as the element-wise dot between the row retriever result and the column selection score, which can be calculated as

$$\mathbf{v}^t = \mathbf{t} * \mathbf{c}, \quad (2)$$

where the v^t indicates the final KB retrieved entity score. Finally, we follow Eric et al. (2017) to

use copy mechanism to incorporate the retrieved entity, which can be defined as

$$\mathbf{o}_t = U\,[\tilde{\mathbf{h}}_t, \tilde{\mathbf{h}'}_t] + \mathbf{v}^t,$$

where $\mathbf{o}_t$'s dimensionality is $|\mathcal{V}| + |\mathcal{E}|$. In $\mathbf{v}^t$, lower $|\mathcal{V}|$ is zero and the rest $|\mathcal{E}|$ is retrieved entity scores.

4 Training the KB-Retriever

As mentioned in section 3.3.1, we adopt the memory network to train our KB-retriever. However, in the Seq2Seq dialogue generation, the training data does not include the annotated KB row retrieval results, which makes supervised training the KB-retriever impossible. To tackle this problem, we propose two training methods for our KB-row-retriever. 1) In the first method, inspired by the recent success of distant supervision in information extraction (Zeng et al., 2015; Mintz et al., 2009; Min et al., 2013; Xu et al., 2013), we take advantage of the similarity between the surface string of KB entries and the reference response, and design a set of heuristics to extract training data for the KB-retriever. 2) In the second method, instead of training the KB-retriever as an independent component, we train it along with the training of the Seq2Seq dialogue generation. To make the retrieval process in Equation 1 differentiable, we use Gumbel-Softmax (Jang et al., 2017) as an approximation of the argmax during training.

4.1 Training with Distant Supervision

Although it's difficult to obtain the annotated retrieval data for the KB-retriever, we can "guess" the most relevant KB row from the reference response, and then obtain the weakly labeled data for the retriever. Intuitively, for the current utterance in the same dialogue which usually belongs to one topic and the KB row that contains the largest number of entities mentioned in the whole dialogue should support the utterance. In our training with distant supervision, we further simplify our assumption and assume that one dialogue which is usually belongs to one topic and can be supported by the most relevant KB row, which means for a k-turned dialogue, we construct k pairs of training instances for the retriever and all the inputs $(u_1, s_1, ..., s_{i-1}, u_i \mid i \leq k)$ are associated with the same weakly labeled KB retrieval result T^*.

In this paper, we compute each row's similarity to the whole dialogue and choose the most similar row as T^*. We define the similarity of each row as the number of matched spans with the surface form of the entities in the row. Taking the dialogue in Figure 1 for an example, the similarity of the 4th row equals to 4 with "`200 Alester Ave`", "`gas station`", "`Valero`", and "`road block nearby`" matching the dialogue context; and the similarity of the 7th row equals to 1 with only "`road block nearby`" matching.

In our model with the distantly supervised retriever, the retrieval results serve as the input for the Seq2Seq generation. During training the Seq2Seq generation, we use the weakly labeled retrieval result T^* as the input.

4.2 Training with Gumbel-Softmax

In addition to treating the row retrieval result as an input to the generation model, and training the kb-row-retriever independently, we can train it along with the training of the Seq2Seq dialogue generation in an end-to-end fashion. The major difficulty of such a training scheme is that the discrete retrieval result is not differentiable and the training signal from the generation model cannot be passed to the parameters of the retriever. Gumbel-softmax technique (Jang et al., 2017) has been shown an effective approximation to the discrete variable and proved to work in sentence representation. In this paper, we adopt the Gumbel-Softmax technique to train the KB retriever. We use

$$T^{\text{approx}}_{j,*} = \frac{\exp((\log(\mathbf{a}_j) + \mathbf{g}_j)/\tau)}{\sum_i \exp((\log(\mathbf{a}_i) + \mathbf{g}_i)/\tau)},$$

as the approximation of T, where $\mathbf{g}_j$ are i.i.d samples drawn from Gumbel$(0, 1)$[1] and τ is a constant that controls the smoothness of the distribution. T^{approx}_j replaces T_j in equation 1 and goes through the same flattening and expanding process as $\mathbf{V}$ to get $\mathbf{v}^{\mathbf{t}^{\text{approx}'}}$ and the training signal from Seq2Seq generation is passed via the logit

$$\mathbf{o}^{\text{approx}}_t = U\,[\tilde{\mathbf{h}}_t, \tilde{\mathbf{h}}'_t] + \mathbf{v}^{\mathbf{t}^{\text{approx}'}}.$$

To make training with Gumbel-Softmax more stable, we first initialize the parameters by pre-training the KB-retriever with distant supervision and further fine-tuning our framework.

[1] We sample $\mathbf{g}$ by drawing $u \sim \text{Uniform}(0, 1)$ then computing $\mathbf{g} = -\log(-\log(u))$.

4.3 Experimental Settings

We choose the InCar Assistant dataset (Eric et al., 2017) including three distinct domains: navigation, weather and calendar domain. For weather domain, we follow Wen et al. (2018) to separate the highest temperature, lowest temperature and weather attribute into three different columns. For calendar domain, there are some dialogues without a KB or incomplete KB. In this case, we padding a special token "-" in these incomplete KBs. Our framework is trained separately in these three domains, using the same train/validation/test split sets as Eric et al. (2017).[2] To justify the generalization of the proposed model, we also use another public CamRest dataset (Wen et al., 2017b) and partition the datasets into training, validation and testing set in the ratio 3:1:1.[3] Especially, we hired some human experts to format the CamRest dataset by equipping the corresponding KB to every dialogues.

All hyper-parameters are selected according to validation set. We use a three-hop memory network to model our KB-retriever. The dimensionalities of the embedding is selected from $\{100, 200\}$ and LSTM hidden units is selected from $\{50, 100, 150, 200, 350\}$. The dropout we use in our framework is selected from $\{0.25, 0.5, 0.75\}$ and the batch size we adopt is selected from $\{1, 2\}$. L2 regularization is used on our model with a tension of 5×10^{-6} for reducing overfitting. For training the retriever with distant supervision, we adopt the weight typing trick (Liu and Perez, 2017). We use Adam (Kingma and Ba, 2014) to optimize the parameters in our model and adopt the suggested hyper-parameters for optimization.

We adopt both the automatic and human evaluations in our experiments.

4.4 Baseline Models

We compare our model with several baselines including:

- **Attn seq2seq** (Luong et al., 2015b): A model with simple attention over the input context at each time step during decoding.
- **Ptr-UNK** (Gulcehre et al., 2016): Ptr-UNK is the model which augments a sequence-to-sequence architecture with attention-based copy mechanism over the encoder context.
- **KV Net** (Eric et al., 2017): The model adopted and argumented decoder which decodes over the concatenation of vocabulary and KB entities, which allows the model to generate entities.
- **Mem2Seq** (Madotto et al., 2018): Mem2Seq is the model that takes dialogue history and KB entities as input and uses a pointer gate to control either generating a vocabulary word or selecting an input as the output.
- **DSR** (Wen et al., 2018): DSR leveraged dialogue state representation to retrieve the KB implicitly and applied copying mechanism to retrieve entities from knowledge base while decoding.

In InCar dataset, for the *Attn seq2seq*, *Ptr-UNK* and *Mem2seq*, we adopt the reported results from Madotto et al. (2018). In CamRest dataset, for the *Mem2Seq*, we adopt their open-sourced code to get the results while for the *DSR*, we run their code on the same dataset to obtain the results.[4]

5 Results

Follow the prior works (Eric et al., 2017; Madotto et al., 2018; Wen et al., 2018), we adopt the *BLEU* and the *Micro Entity F1* to evaluate our model performance. The experimental results are illustrated in Table 1.

In the first block of Table 1, we show the Human, rule-based and KV Net (with*) result which are reported from Eric et al. (2017). We argue that their results are not directly comparable because their work uses the entities in thier canonicalized forms, which are not calculated based on real entity value. It's noticing that our framework with two methods still outperform KV Net in InCar dataset on whole BLEU and Entity F metrics, which demonstrates the effectiveness of our framework.

[2]We obtain the BLEU and Entity F1 score on the whole InCar dataset by mixing all generated response and evaluating them together.

[3]The dataset can be available at: https://github.com/yizhen20133868/Retriever-Dialogue

[4]We adopt the same pre-processed dataset from Madotto et al. (2018). We can find that experimental results is slightly different with their reported performance (Wen et al., 2018) because of their different tokenized utterances and normalization for entities.

Model	InCar					CamRest	
	BLEU	F1	Navigate F1	Weather F1	Calendar F1	BLEU	F1
Human* (Eric et al., 2017)	13.5	60.7	55.2	61.6	64.3	-	-
Rule-Based* (Eric et al., 2017)	6.6	43.8	40.4	39.5	61.3	-	-
KV Net* (Eric et al., 2017)	13.2	48.0	41.3	47.0	62.9	-	-
Attn seq2seq (Luong et al., 2015b)	9.3	11.9	10.8	25.6	23.4	-	-
Ptr-UNK (Gulcehre et al., 2016)	8.3	22.7	14.9	26.7	26.9	-	-
Mem2Seq (Madotto et al., 2018)	12.6	33.4	20.0	32.8	49.3	16.6	42.4
DSR (Wen et al., 2018)	12.7	51.9	52.0	50.4	52.1	18.3	53.6
w/ distant supervision	**14.1**	51.9	51.6	49.6	54.2	17.4	58.0
w/ Gumbel-Softmax	13.9	**53.7**	**54.5**	**52.2**	**55.6**	**18.5**	**58.6**

Table 1: Comparison of our model with baselines

In the second block of Table 1, we can see that our framework trained with both the distant supervision and the Gumbel-Softmax beats all existing models on two datasets. Our model outperforms each baseline on both BLEU and F1 metrics. In InCar dataset, Our model with Gumbel-Softmax has the highest BLEU compared with baselines, which which shows that our framework can generate more fluent response. Especially, our framework has achieved 2.5% improvement on navigate domain, 1.8% improvement on weather domain and 3.5% improvement on calendar domain on F1 metric. It indicates that the effectiveness of our KB-retriever module and our framework can retrieve more correct entity from KB. In CamRest dataset, the same trend of improvement has been witnessed, which further show the effectiveness of our framework.

Besides, we observe that the model trained with Gumbel-Softmax outperforms with distant supervision method. We attribute this to the fact that the KB-retriever and the Seq2Seq module are fine-tuned in an end-to-end fashion, which can refine the KB-retriever and further promote the dialogue generation.

5.1 The proportion of responses that can be supported by a single KB row

In this section, we verify our assumption by examining the proportion of responses that can be supported by a single row.

We define a response being supported by the most relevant KB row as all the responded entities are included by that row. We study the proportion of these responses over the test set. The number is 95% for the navigation domain, 90% for the CamRest dataset and 80% for the weather domain. This confirms our assumption that most responses can be supported by the relevant KB row.

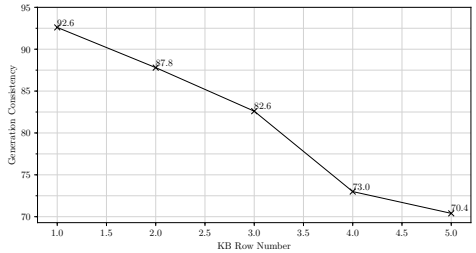

Figure 3: Correlation between the number of KB rows and generation consistency on navigation domain.

Correctly retrieving the supporting row should be beneficial.

We further study the weather domain to see the rest 20% exceptions. Instead of being supported by multiple rows, most of these exceptions cannot be supported by any KB row. For example, there is one case whose reference response is "*It 's not rainy today*", and the related KB entity is `sunny`. These cases provide challenges beyond the scope of this paper. If we consider this kind of cases as being supported by a single row, such proportion in the weather domain is 99%.

5.2 Generation Consistency

In this paper, we expect the consistent generation from our model. To verify this, we compute the consistency recall of the utterances that have multiple entities. An utterance is considered as consistent if it has multiple entities and these entities belong to the same row which we annotated with distant supervision.

The consistency result is shown in Table 2. From this table, we can see that incorporating retriever in the dialogue generation improves the consistency.

5.3 Correlation between the number of KB rows and generation consistency

To further explore the correlation between the number of KB rows and generation consistency, we conduct experiments with distant manner to study the correlation between the number of KB rows and generation consistency.

We choose KBs with different number of rows on a scale from 1 to 5 for the generation. From Figure 3, as the number of KB rows increase, we can see a decrease in generation consistency. This indicates that irrelevant information would harm the dialogue generation consistency.

5.4 Visualization

To gain more insights into how the our retriever module influences the whole KB score distribution, we visualized the KB entity probability at the decoding position where we generate the entity `200_Alester_Ave`. From the example (Fig 4), we can see the 4^{th} row and the 1^{th} column has the highest probabilities for generating `200_Alester_Ave`, which verify the effectiveness of firstly selecting the most relevant KB row and further selecting the most relevant KB column.

5.5 Human Evaluation

We provide human evaluation on our framework and the compared models. These responses are based on distinct dialogue history. We hire several human experts and ask them to judge the quality of the responses according to correctness, fluency, and humanlikeness on a scale from 1 to 5. In each judgment, the expert is presented with the dialogue history, an output of a system with the name anonymized, and the gold response.

The evaluation results are illustrated in Table 2. Our framework outperforms other baseline models on all metrics according to Table 2. The most significant improvement is from correctness, indicating that our model can retrieve accurate entity from KB and generate more informative information that the users want to know.

6 Related Work

Sequence-to-sequence (Seq2Seq) models in text generation (Sutskever et al., 2014; Bahdanau et al., 2014; Luong et al., 2015a; Nallapati et al., 2016b,a) has gained more popular and they are applied for the open-domain dialogs (Vinyals and Le, 2015; Serban et al., 2016) in the end-to-end training method. Recently, the Seq2Seq can be used for learning task oriented dialogs and how to query the structured KB is the remaining challenges.

Properly querying the KB has long been a challenge in the task-oriented dialogue system. In the pipeline system, the KB query is strongly correlated with the design of language understanding, state tracking, and policy management. Typically, after obtaining the dialogue state, the policy management module issues an API call accordingly to query the KB. With the development of neural network in natural language processing, efforts have been made to replacing the discrete and predefined dialogue state with the distributed representation (Bordes and Weston, 2017; Wen et al., 2017b,a; Liu and Lane, 2017). In our framework, our retrieval result can be treated as a numeric representation of the API call return.

Instead of interacting with the KB via API calls, more and more recent works tried to incorporate KB query as a part of the model. The most popular way of modeling KB query is treating it as an attention network over the entire KB entities (Eric et al., 2017; Dhingra et al., 2017; Reddy et al., 2018; Raghu et al., 2019; Wu et al., 2019) and the return can be a fuzzy summation of the entity representations. Madotto et al. (2018)'s practice of modeling the KB query with memory network can also be considered as learning an attentive prefer-

w/ distant supervision	65.8	4.53	4.71	4.64
w/ Gumble-Softmax	**72.1**	**4.64**	**4.73**	**4.69**

Table 2: The generation consistency and Human Evaluation on navigation domain. *Cons.* represents *Consistency*. *Cor.* represents *Correctness*. *Flu.* represents *Fluency* and *Hum.* represents *Humanlikeness.*

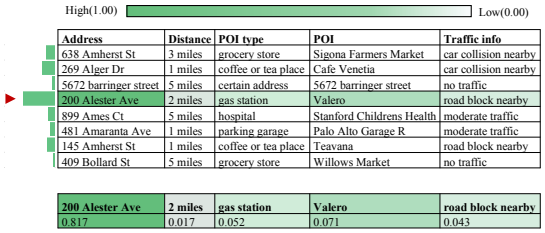

Figure 4: KB score distribution. The distribution is the timestep when generate entity `200_Alester_Ave` for response " *Valero is located at 200_Alester_Ave*"

ence over these entities. Wen et al. (2018) propose the implicit dialogue state representation to query the KB and achieve the promising performance. Different from their modes, we propose the KB-retriever to explicitly query the KB, and the query result is used to filter the irrelevant entities in the dialogue generation to improve the consistency among the output entities.

7 Conclusion

In this paper, we propose a novel framework to improve entities consistency by querying KB in two steps. In the first step, inspired by the observation that a response can usually be supported by a single KB row, we introduce the KB retriever to return the most relevant KB row, which is used to filter the irrelevant KB entities and encourage consistent generation. In the second step, we further perform attention mechanism to select the most relevant KB column. Experimental results show the effectiveness of our method. Extensive analysis further confirms the observation and reveal the correlation between the success of KB query and the success of task-oriented dialogue generation.

Building Task-Oriented Visual Dialog Systems Through Alternative Optimization Between Dialog Policy and Language Generation

Mingyang Zhou **Josh Arnold** **Zhou Yu**

Abstract

Reinforcement learning (RL) is an effective approach to learn an optimal dialog policy for task-oriented visual dialog systems. A common practice is to apply RL on a neural sequence-to-sequence (seq2seq) framework with the action space being the output vocabulary in the decoder. However, it is difficult to design a reward function that can achieve a balance between learning an effective policy and generating a natural dialog response. This paper proposes a novel framework that alternatively trains a RL policy for image guessing and a supervised seq2seq model to improve dialog generation quality. We evaluate our framework on the GuessWhich task and the framework achieves the state-of-the-art performance in both task completion and dialog quality.

1 Introduction

Visually-grounded conversational artificial intelligence (AI) is an important field that explores the extent intelligent systems are able to hold meaningful conversations regarding visual content. Visually-grounded conversational AI can be applied to a wide range of real-world tasks, including assisting blind people to navigate their surroundings, online recommendation systems, and analysing mass amounts of visual media through natural language. Current approaches to these tasks involve an end-to-end framework that maps the multi-modal context to a deep vector and in order to decode a natural dialog response. This framework can be trained through supervised learning (SL) with the objective to maximize the distribution of the response given a human-human dialog history. Given a large conversational data, the neural end-to-end system can effectively learn to generate coherent and natural language.

While much success has been achieved by applying neural sequence to sequence models to open visual grounding conversation, the visual dialog system also needs to learn an optimal strategy to efficiently accomplish an external goal through natural conversations. To address this issue, various image guessing tasks such us GuessWhich (Chattopadhyay et al., 2017) and GuessWhat (de Vries et al., 2016) are proposed to evaluate a visual-grounded conversational agent on its ability to retrieve visual content via conversing in natural language. To obtain an optimal dialog policy, reinforcement learning (RL) is introduced to enable the neural end-to-end framework to model a more effective action distribution by exploring different dialog strategies. With the application of RL, the visual dialog system can generate more consistent responses and achieve a higher level of engagement in the conversation when compared to a dialog system trained via SL (Das et al., 2017b; Zhang et al., 2017). A typical way to apply RL on a dialog system is to assign a task-related reward to influence the utterance generation process by treating each output word as the action step. A significant limitation of this approach is that it is difficult to achieve an optimal dialog policy that can both effectively complete the external goal and generate natural utterances (Zhao et al., 2019; Das et al., 2017b). As there is no ground truth reference during the RL training stage, the dialog system can only leverage the reward signal when generating the response. However, this approach often deviates from natural language as it is challenging to define a comprehensive reward that considers all aspects of the dialog quality, and in addition, assigns appropriate rewards to the large word vocabulary action space.

In this paper we propose a novel learning curriculum to address the challenge of joint learning between the dialog policy and language generation for task-oriented dialog systems. In our framework, we separate the training of the image re-

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 143–153,

trieval policy from dialog generation by applying RL, with the goal of achieving an optimal policy for guessing the target image at every turn. In addition, we apply a language model objective function to optimize the utterance generator to mitigate language degeneration. We specifically study this framework in the image guessing task GuessWhich, where a conversational agent attempts to guess a target image by asking a series of questions. When compared to state-of-art RL visual dialog systems, our method achieves superior performance in both task-accomplishment and dialog quality.

2 Related Work

2.1 Visual Dialog System

Visual dialog systems are an emerging area of interdisciplinary research that attracts both the vision and language communities due to the potential applications. Das et al. (2017a) proposed a visual dialog task in which a conversational agent attempts to answer questions regarding an assigned image based on a dialog history. To approach this task, they initially collected data by having two people chat about an image with one person acting as the questioner and the other as the answerer. GuessWhich (Chattopadhyay et al., 2017) extends VisDial with the goal to build an agent that learns how to identify a target image through question and answers. (de Vries et al., 2016) additionally introduced a game in which a series of yes-or-no questions are asked by an agent in order to locate an object in an image. Many researchers approached these tasks via reinforcement learning (RL), with the goal of obtaining an optimal dialog policy. Zhang et al. (2017), for example, designed three rewards with respect to the goals of task achievement, efficiency, and question informativeness, in order to help the agent to achieve an effective question generation policy for GuessWhat game. Das et al. (2017b) applies reinforcement learning in the GuessWhich task and demonstrates a moderate improvement in accuracy compared to the supervised learning approach. Both methods apply RL on a neural end-to-end pipeline to jointly influence the language generation and dialog policy. Due the challenge of designing an appropriate reward for language generation, these methods generate responses that deviate from human natural language. Zhang et al. (2018), proposed an approach involving hierarchical reinforcement learning and state-adaptation techniques that enable the agent to learn an optimal and efficient multi-modal policy. The bottleneck of (Zhang et al., 2018)'s method, however, is that the system response is retrieved from a predefined human-written or system-generated utterance. The number of predefined responses are limited, therefore, this method does not easily generalize to other tasks in real-world settings. We address these limitations by applying RL on a reduced, yet more relevant action space, while optimizing the dialog generator in a supervised fashion. We alternatively optimize policy learning to language generation to combine the two tasks together.

2.2 RL on Task-oriented Dialog System

Various RL-based models have been proposed to train task-oriented dialog systems (Williams and Young, 2007). In order to build a traditional modular-based dialog system, researchers first identify the semantic representation, such as the dialog acts and slots in user utterances. Then they accumulate these semantic representations over time to track the dialog state. Finally they apply RL to learn an optimized dialog policy given the dialog state (Raux et al., 2005; Shi and Yu, 2018). Such modular-based dialog systems are effective in narrow task domains, such as searching a bus route schedule and reserving a restaurant through natural language, but they fail to generalize to complex settings where the size of the action space increases. Owing to the development of deep learning, RL on neural sequence-to-sequence models has been explored in more complex dialog domains such as open-domain conversation (Li et al., 2016) and negotiation (Lewis et al., 2017). However, due to the difficulty of assigning appropriate rewards when operating in a large action space, these frameworks cannot generate fluent dialog utterances. Zhao et al. (2019) proposed a novel latent action RL framework to marry the advantage of a module based approach and sequence-to-sequence approach. They learned the optimal dialog policy in a complex task-oriented dialog domain while achieving decent conversation quality. We study the similar issue in a multi-modal task-oriented dialog scenario. We propose an iterative approach to optimize dialog policy using RL methods and system response generation via SL.

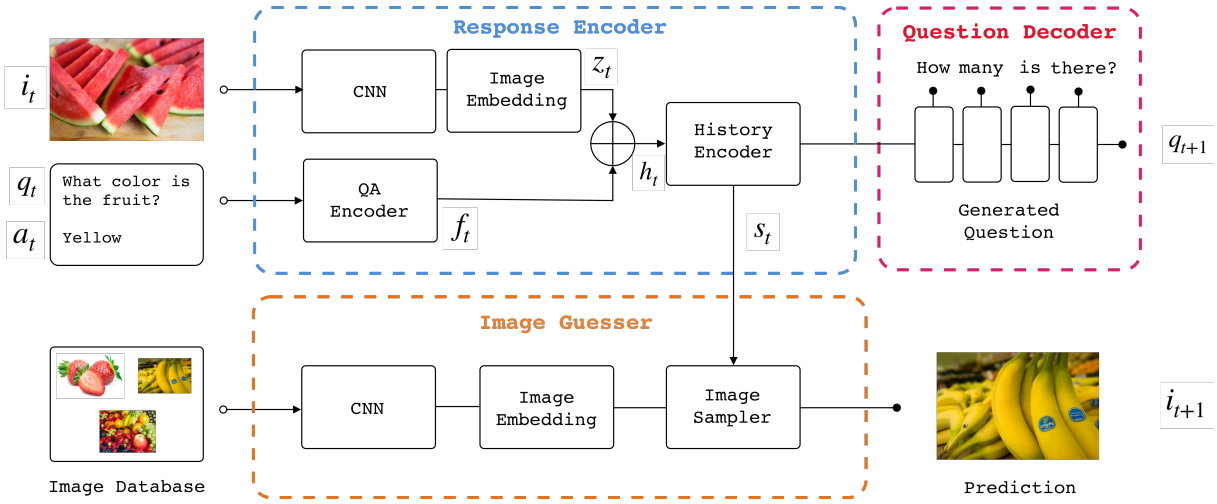

Figure 1: The proposed end-to-end framework of the conversation agent for GuessWhich task-oriented visual dialog task

3 Method

3.1 Problem Setting

In the GuessWhich problem, we aim to build an agent (Q-Bot) that attempts to guess an image i_{tgt} that another agent (A-Bot) knows by asking it a series of questions. At the beginning of the conversation, the Q-Bot is primed with a short caption c of the target image that is only known by A-Bot. At every round t, the Q-Bot generates a question q_t to elicit as much information as possible about the target image and the A-Bot provides an appropriate answer a_t with regard to q_t and the target image. In the end, the agent guesses the target image among a set of images considering the entire conversation.

In addition, our dialog system also guesses a candidate image i_t out of an image database $\mathcal{I} = \{i_k\}_{k=0}^{m}$ at every turn. This action models the process of sequentially updating the visual belief state on the target image based on the latest dialog history. Conditioned on the current guessed image and the prior dialog contexts, the system will generate an optimal question in order to get the maximum information from A-Bot that can strengthen the system's belief on the target image. At the end of the conversation, our Q-Bot will guess the target image based on the multimodal contexts $s_n = (q_{1:n}, a_{1:n}, i_{1:n}, c)$ consisting of the dialog history and the trajectory of guessed images.

3.2 Model Architecture

Our Q-Bot is constructed on top of a hierarchical encoder-decoder framework (Serban et al., 2015), which consists of three major components: The **Response Encoder**, the **Question Decoder**, and the **Image Guesser**. We introduce each component as follows:

Response Encoder The goal of the response encoder is to append the question q_t, the answer a_t, and the guessed image i_t received at current round to the dialog history and obtain an updated vector representation of the multimodal context s_t. The image i_t is encoded with a pre-trained convolutional neural network VGG-16 (Simonyan and Zisserman, 2015) followed by a linear embedding layer and the image feature vector denoted as z_t. For the question and answer pair at the current round (q_t, a_t), we map them to a hidden state vector f_t through the LSTM based *QA Encoder*. We then apply a linear projection on the concatenation of f_t and z_t in order to obtain the multi-modal context vector h_t for the current round. The context vector is then passed through another LSTM encoder: *History Encoder* generates an updated dialog history representation $s_t = \text{HistoryEnc}(h_t, s_{t-1})$. We denote the trainable parameters for Response Encoder as θ_e.

Question Decoder The question decoder is a two-layer LSTM network initialized with the most updated dialog history representation vector s_t from the response encoder. It will sequentially sample the words to come up with the next question q_t. The learned parameters for question decoder are denoted as θ_d.

Image Guesser The Image Guesser attempts to identify the candidate image that best aligns with the dialog history. Given a image database $\mathcal{I} = \{i_k\}_{k=0}^{m}$ where we sample the candidate image, we first extract the image feature representations $\{z_k\}_{k=0}^{m}$ for all candidate images with the convolutional neural network and image embedding layer defined in response encoder. Then, we can sample a candidate image i_k for the current turn based on the euclidean distance $d(z_k, s_t)$ between the image feature of the candidate image and the current dialog history vector. The image with the smallest euclidean distance is selected as the guess i_t at the current round. The associated parameters for image guesser are defined as θ_g.

3.3 Training Dialog System

We follow a two-stage training fashion as introduced in many previous end-to-end RL dialog systems (Das et al., 2017b; Zhang et al., 2017; Zhao et al., 2019), where we first pre-train the dialog framework with a supervised objective then apply reinforcement learning to learn an optimal policy to retrieve the target image. The Supervised pre-training is a critical step that facilitates an effective policy exploration for RL training, as it is difficult to explore a complex action space with limited prior knowledge. During RL training, we introduce an alternative learning method between dialog policy exploration and natural utterance generation that addresses the issue of language degeneration in previous RL based visual dialog systems (Das et al., 2017b). We introduce each training method as follows.

3.3.1 Supervised Pre-training

During the supervised pre-training process, we jointly optimize the objective to generate questions and also predict target image features from dialog contexts. The task of question generation is optimized by maximizing the log conditional probability of the next question dependent on a ground truth dialog for every round of the conversation. For the image feature prediction, we minimize the mean square error (MSE) between the target image feature z_{tgt} and the dialog context vector s_t at each round. The joint loss function for supervised pre-training is:

$$\mathcal{L}_{SL}(\theta_r, \theta_d, \theta_g) = \alpha \sum_{t=0}^{n} \log p(q_t|s_t) + \beta \sum_{t=0}^{n} \text{MSE}(z_{tgt}, s_t) \quad (1)$$

Where α and β are weights assigned to the objective function of each task in the joint objective function. With SL pre-training process, the dialog system is facilitated with the ability to estimate a visual object and emit a natural language sentence given a dialog context.

3.3.2 Reinforcement Learning on Image Retrieval

In our framework, we treat the sequence of image guess through out the conversation as a partially observable markov decision process and train a policy network via RL to obtain an optimal strategy to retrieve the target image. We formally describe state, policy, action, rewards, and the training procedures in our pipeline.

State The dialog states in our framework consist of a combination of multimodal contexts, including the image caption c, the dialog history with A-Bot $[q_1, a_2, \ldots, q_t, a_t]$, and the image guessing trajectories $[i_1, i_2, \ldots, i_t]$.

Policy The dialog policy $\pi_{\theta_r,\theta_g}(i_t|S_t)$ is a stochastic policy that samples the candidate image to guess from an image set based on the previous dialog histories. The policy is learned from response encoder and image generator which is parameterized via θ_r and θ_g.

Action The full action space is the number of images in the database that we can sample to guess an image. As the pre-trained process already enables the system to approximate a target image feature z_{tgt} with the dialog history representation vector s_t, we reduce the action space to the top-K nearest images, s_t, based upon the euclidean distance. The probability to sample an image i_j is gained by applying a softmax function over the top-K candidates on their distance to s_t: $\pi(j) = \frac{e^{-d_j}}{\sum_{k=1}^{K} e^{-d_k}}$. d_j represents the mean-square-distance between the j-th image and the dialog history state vector s_t.

Rewards We use the ranking percentile of the target image with respect to the dialog history vector s_t as the reward signal to credit the guess at each turn. The goal is to maximize the expectation value of the discounted return $\mathbb{E}[\sum_{t=1}^{n} \gamma^t r_t]$ over the n-round conversation. r_t is the ranking percentile of target image at round t and γ is the discounted factor between $(0, 1)$.

Training Procedure Inspired from the RL training process on the iterative image retrieval framework (Guo et al., 2018), we apply the policy improvement theory (Sutton and Barto, 1998) to estimate an improved policy $\pi^*(s_t)$ from an existing policy $\pi(s_t)$ obtained from the pre-trained dialog system. Given a dialog state s_t and the action a_t derived from the existing policy, the value estimated by the current policy for taking the action a_t is $Q_\pi(s_t, a_t) = \mathbb{E}[\sum_{t'=t}^{n} \gamma^t r_t]$. To improve this, we explore a different action $a_t^* \neq a_t$ such that a larger policy value $Q_\pi(s_t, a_t^*) > Q_\pi(s_t, a_t)$ estimated with the current policy is achieved. Then we can adjust the existing policy $\pi(s_t)$ to a new policy $\pi^*(s_t)$ that executes that optimal action a_t^* given the current dialog state. The parameters of the policy can be effectively optimized via a cross entropy loss function conditioned on the derived optimal action a_t^*:

$$\mathcal{L}_{RL}(\theta_r, \theta_g) = \mathbb{E}[-\sum_{t=1}^{n} \log(\pi_{\theta_r, \theta_g}(a_t^*|s_t))] \quad (2)$$

Compared to the previous RL visual-grounded conversational agent, (Das et al., 2017b), there are several advantages of conducting policy learning on the action level of guessing the image. First, the action space of the top-k nearest neighbors are much smaller compared to the vocabulary size of the output words which reduces the difficulty to explore optimal strategies. Second, only the parameters of response encoder and image generator will be optimized during the RL training stage. The question decoder stays intact so that it is less likely for the dialog system to suffer from language deviation.

3.3.3 Alternating Policy Learning and Language Generation

Although the parameters of the decoder won't be impacted during the RL training stage, the shared response encoder of the dialog context is still optimized with policy learning. The language distribution captured by both the response encoder and question decoder will gradually be differentiated from the original human dialog distribution. To prevent the potential language degeneration behavior, we alternatively optimize the dialog system with a policy learning objective in equation 2 and the language model objective function in equation 1 at every other epoch. It assures the dialog system maintains a good estimation of the human language distribution while also effectively exploring various dialog actions in order to achieve the task of guessing the right image.

4 Experiments

4.1 AI-AI Image Guessing Game

We evaluate the performance of our task-oriented dialog system by playing the image guessing game, GuessWhich with an automatic answer bot. Our conversational agent's goal is to locate the target image out of the 9,628 test images by interacting with the other player in five conversation exchanges. We evaluate agent on both goal achievement and utterance generation quality using two automatic evaluation metrics Percentile Mean Rank (PMR) and perplexity respectively. PMR estimates how good the agent can rank the target image against other candidates in the test database based on its current dialog state. Perplexity estimates the closeness of the generated response to a reference utterance given a dialog context from the VisDial dataset.

4.2 Human-AI Image Guessing Game

To evaluate the ability of our task-oriented dialog system in a realistic conversational scenario, we also make our agent play the image guessing game with human users. The games are set up as 20-image guessing games where the agent attempts to guess a target image outside of a pool of 20 candidate images by asking a human player 5 rounds of questions. The objective of the human player is to play the role of answer bot and answer agent's question with respect to the target image.

In this setting, the performance of the agent on task accomplishment is evaluated by the game win rates. The quality of the dialogs are manually rated on four criteria: fluency, comprehension, diversity and relevance. Fluency defines the naturalness and readability of the generated question in English. Comprehension represents the consistency of the generated question with respect to the previous dialog context. Diversity evaluates the uniqueness

Image	RL-Q-IG	SL-Q-IG	RL-Q
	Q: are bananas in bunch? A: yes it's in bunch Q: are they on table? A: yes they are Q: is this in kitchen? A: I'm not sure Q: any people? A: Yes there are several people Q: any other fruits? A: NO, only bananas	Q: what color are planes? A: no planes there Q: are they in city? A: yes it is Q: are they in baskets? A: yes they are Q: any people? A: yes there are Q: animals? A: no animals	Q: is this outside? A: yes it is Q: is there any people? A: yes ... Q: is this in zoo? A: no it is not Q: are there any people? A: yes there are Q: is there any people? A: yes ...

Table 1: A dialog example with the ground truth caption: **bunches of bananas hang on a wall and arranged for sale.** blue indicates ideal relevant questions and orange indicates less relevant questions.

of the questions generated within one game. Relevance presents how well the asked question is related to the target image and the given caption.

4.3 Comparative Models

We compare the performance of our model with state-of-the-art task-oriented visual dialog systems. Meanwhile we also perform an ablation study to evaluate the contribution of different designs in our framework. We introduce each model as follows:

SL-Q: The dialog agent from (Das et al., 2017b), which is trained with a joint supervised learning objective function for language generation and image prediction.

RL-Q: The dialog agent from (Das et al., 2017b) which is fine-tuned on a trained SL-Q by applying RL to the action space of output word vocabulary.

SL-Q-IG: The dialog agent from this framework is build on top of the SL-Q. Compared to SL-Q, SL-Q-IG has an additional image guesser module that makes a guess on target image at every round. SL-Q-IG also has an image encoder which fuses the guessed candidate image into the dialog history tracker. We only train this model with the supervised learning objective introduced equation 1.

RL-Q-IG: We use RL method to fine-tune SL-Q-IG. The RL method used is applied on action space of guessing candidate image. We alternate the model to optimize towards dialog policy learning and language generation.

RL-Q-IG-NA: We fine-tune SL-Q-IG by applying RL to the action space of guessing candidate image and only optimized with policy learning objective function alone.

RL-Q-IG-W: The dialog agent from our framework, which is fine-tuned on a trained SL-Q-IG by applying reinforcement learning on output word vocabulary. It follows the same training procedures as RL-Q to conduct policy learning.

All the SL dialog agents are trained on the VisDial Dataset with the default setting from (Das et al., 2017b) for 40 epochs. The RL dialog agents are then fine-tuned on their corresponding SL dialog agents for another 20 epochs. We evaluate every model on AI-AI image guessing games with the same answer bot, trained on the Visdial Dataset with the objective of visual question answering. We only evaluate RL-Q, SL-Q-IG and RL-Q-IG in human evaluation.

4.4 Human-AI Evaluation Implementation

In order to evaluate the effectiveness of the model, we designed three human evaluation tasks. Six college students were recruited to conduct the evaluation. Each student evaluated 100 games using the ground truth captions and 30 games using human generated captions. An additional three evaluators each completed 30 rounds of the relevancy experiment.

Ground Truth Captions We generated 100 image guessing games that used the ground truth captions to ensure a consistent amount of information is supplied across all human evaluators. Each game consists of a randomly selected set of 20 images from the VisDial Dataset, with one image randomly chosen as the target. For each game, we test three different models, each twice, resulting in a total of 600 evaluated games from the 100 generated games. We keep the identity of the models anonymous to the evaluator.

During each game, the human evaluator is pre-

sented with a target image the agent is trying to guess. Five rounds of Q&A take place in which the agent asks a question to elicit information and the human evaluator responds with a relevant truthful answer. At the end of each game, the evaluator is asked to rate the conversation on four criteria: fluency, relevance, comprehension and diversity.

Human Generated Captions In order to distinguish SL-Q-IG and RL-Q-IG in a more natural setting, we generate an additional 30 games, similar to the previous human evaluation task, except when beginning the game, the evaluator is asked to provide the caption for the target image instead of using the ground truth.

Relevance Experiment We noticed that the human evaluators found rating dialogues on the relevance criteria challenging and nuanced. In order to reduce the difficulty of rating dialogues using the relevance criteria, we designed a separate experiment in which, using the conversations obtained from the previous 600 evaluated ground truth games, a human evaluator is presented with three complete conversations side by side at each round. The evaluator then selects the most relevant conversation out of the three that corresponds to the image caption. Each of the three conversations have the same caption, however, correspond to a different model, thus allowing for an effective comparison between the relevancy of each model.

5 Results

5.1 Results on AI-AI Image Guess Game

Image Retrieval It is clear from Fig 2 that our dialog system significantly outperforms the baseline models from (Das et al., 2017b) in terms of PMR on every round of the dialog. PMR estimates how good the agent can rank the target image against other candidates in the test database. The biggest improvement gap is observed between SL-Q-IG and SL-Q. In comparison to SL-Q, SL-Q-IG tracks the additional context from the previously guessed images which leads to a better estimation of the target image. RL-Q-IG has better performance compared to SL-Q-IG in terms of PMR. This suggests that fine-tuning dialog systems with RL can further improve the success of guessing the correct image. The best image retrieval result is achieved by RL-Q-IG-NA, as the objective function of RL-Q-IG-NA is based solely on policy learning without consideration for the dialog generation quality.

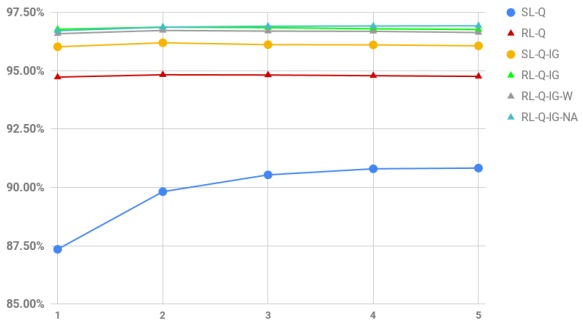

Figure 2: The percentile mean rank (PMR) over the 5-round dialog in the AI-AI image guessing game

Model	PMR	Perplexity
SL-Q	90.07%	79.49
SL-Q-IG	96.09%	61.42
RL-Q	94.78%	544.97
RL-Q-IG	96.81%	**54.66**
RL-Q-IG-NA	**96.88%**	363.88
RL-Q-IG-W	96.65%	227.35

Table 2: RL-Q-IG-NA performs best in PMR and RL-Q-IG perform best in perplexity

Although our framework achieved an improved image retrieval accuracy, we observed, however, that there is little improvement gained in PMR after additional rounds of conversation. We suspect this is partially due to the fact that images from MSCOCO are composed of a diverse selection objects and background scenes, thus making images easily distinguishable with a detailed caption. In cases where candidate images are visually similar or the given caption is not informative, additional rounds of dialog are necessary to identify the target image.

Language Generation We observe a marginal increase of perplexity from SL-Q to RL-Q in Table 2, thus demonstrating that there is a bottleneck when applying RL to improve the language generation. By decoupling the policy learning from the language generation and alternatively optimizing the dialog policy and language model, our RL-Q-IG avoids language deviation while still achieving an optimal dialog policy for the image retrieval task. To further evaluate the contribution from the RL and alternative training curriculum, we conduct two ablation studies. RL-Q-IG-NA is fine-tuned with a policy learning objective that excludes alternatively applying the language model loss. While RL-Q-IG-NA only achieves an in-

Model	Win	Fluency	Relevance	Comprehension	Diversity
RL-Q	59.6	4.19	3.22	2.60	2.50
SL-Q-IG	62.7	4.18	3.96	3.18	3.22
RL-Q-IG	**67.5**	**4.40**	**4.02**	**3.50**	**3.25**

Table 3: Evaluation results on the human-AI image guessing game initialized with ground truth captions

Model	Win	Fluency	Relevance	Comprehension	Diversity
RL-Q	29.2	4.04	2.88	2.71	2.29
SL-Q-IG	40.6	4.16	3.19	2.75	2.69
RL-Q-IG	**67.6**	**4.23**	**3.74**	**3.32**	**3.06**

Table 4: Evaluation results on the human-AI image guessing game initialized with human generated captions

cremental improvement over the full framework RL-Q-IG in terms of the PMR rate with less than 0.1%, it suffers from a dramatic increase of perplexity from 61.42 to 363.88, thus suggesting that alternatively applying the supervised learning objective can prevent the language model from deviating from the human language distribution. We additionally apply policy learning on the question decoder of SL-Q-IG and follow the RL fine-tuning process in (Das et al., 2017b) to train the agent, RL-Q-IG-W. While applying word-level RL enables RL-Q to achieve a moderate improvement over SL-Q in terms of PMR, we did not observe, the same degree of advantage in RL-Q-IG-W over SL-Q-IG. Additionally, RL-Q-IG-W is affected by a marginal increase in perplexity in comparison to the SL pre-trained agent, which approves the drawbacks of applying RL on a large action space in language generation.

5.2 Results on Human-AI Image Guess Game

The performance of a dialog agent evaluated with a user simulator does not necessarily reflect its performance on real human (de Vries et al., 2016). We conduct human evaluation on different dialog agents. From the results summarized in Table 3 and Table 4, we observe a consistent optimal performance of our method from conversations with AI agent to conversations with real human. Our RL-Q-IG significantly outperforms the baseline RL agent in all criteria for both settings. RL-Q-IG's advantage over SL-Q-IG is not significant in the game when agents are primed with ground truth image caption. This observation correlates with the result in the Human-AI game, as both RL-Q-IG and SL-Q-IG achieve superior PMR over 96% when presented with the ground truth caption. However, if a human generated caption is given, the performance of the SL pre-trained agent suffers a big drop in all metrics except fluency while our RL agent maintains similar performance. Applying RL to fine-tune the dialog system enables the agent to generate more consistent dialogs in unseen scenarios. We also notice a degradation of the baseline RL agent from its performance with the user simulator, which suggests deviation from natural language is due to the sub-optimal RL training on a large action space.

We conduct a qualitative analysis on the generated dialogs from the three models with human players. Besides a marginal improvement over the RL baseline model and SL pretrained agent in terms of decreased repetition and grammar mistakes, there is a distinct superiority in regards to the relevance to the image caption in the questions generated from our RL agent. For example, in Table 9, we demonstrate the three dialogs generated by RL-Q-IG, SL-Q-IG and RL-Q on one game. Given the image caption *bunches of bananas hang on a wall and arranged for sale.*, RL-Q and SL-Q-IG ask very general questions that are not related to the caption such as *"planes"*, *"zoo"* and *"animals"*. In comparison, our agent asks high-quality questions regarding the caption that covers *"bananas"* and *"fruits"*. These questions help our RL agent obtain useful information to guess the target image. This advantage is also evident from the results of comparative evaluation on the degree of relevance of the questions in Table 5. We credit the positive result to the dialog policy, which explores multiple paths to conduct the conversation. The optimal path will involve a set of questions that obtains the maximum information of the target image such that it can construct the best estimation of the target image.

Model	Prefered (%)
RL-Q	8.93
SL-Q-ImGuess	39.90
RL-Q-IG	**51.20**

Table 5: Results on comparative evaluation of relevance on the human-AI image guessing dialogs

6 Conclusion and Future Work

We present a novel framework for building a task-oriented visual dialog system. We model the agent to simultaneously optimize two actions: guessing the image and generating effective questions. We achieve this simultaneous optimization through alternatively applying reinforcement learning to obtain an effective image guessing policy, whilst also applying supervised learning to enhance the quality of generated questions. By decoupling the policy learning from language generation, we overcome language degeneration in the word-level reinforcement learning framework. Both analytical and human evaluation suggests our proposed framework leads to a higher task completion rate and an improved dialog quality.

In the future, we plan to collect a fashion retrieval visual dialog dataset which simulates a realistic application for multi-modal dialog systems. To address the limitation of a high image retrieval rate with just the use of captions from the VisDial dataset, we plan to format a challenging candidate image pool in which images are visually similar to each other. This will incentivize the dialog system to conduct multiple rounds of dialog in order to retrieve the target image successfully. Furthermore, we will explore additional task-oriented settings where we can decouple task accomplishment from language generation to evaluate the extent our framework can generalize to other conversational tasks.

A Human Evaluation Interface

We demonstrate our web interface for our Human-AI guessing game in Fig 3. At the beginning of every game the human player is presented with a random sampled target image. For the trained Q-bot, 20 images are sampled as the candidate pool with the objective of retrieving the target image. At the end of the conversation, the Q-Bot's guess is revealed to the human player followed by a request to evaluate the quality of the conversation in the four aspects introduced in section 4.4 on a scale from 1 to 5.

Our human relevancy evaluation interface is demonstrated in Fig 4. We present side-by-side questions generated in the same game from each of the three different models and ask the human evaluators to pick the conversation that is most semantically relevant to the target image caption.

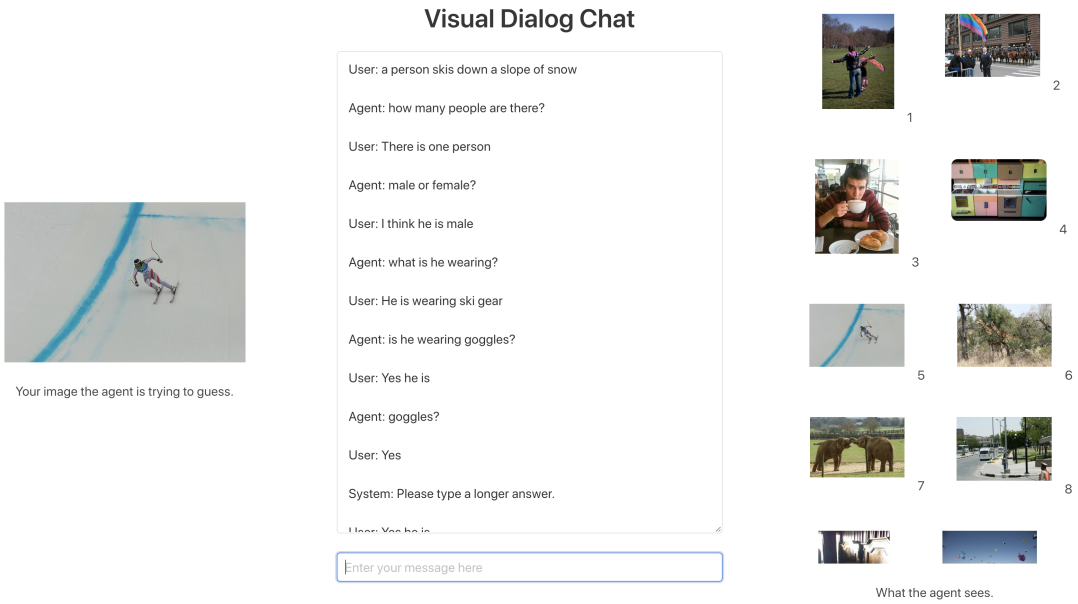

Figure 3: The web interface for human-AI guessing game. The left image is a target image randomly sampled from (Das et al., 2017a). The center section is a chat platform for human to communicate with a trained Q-Bot. On the right hand side are the 20 candidate images sampled for the Q-Bot to retrieve the target image.

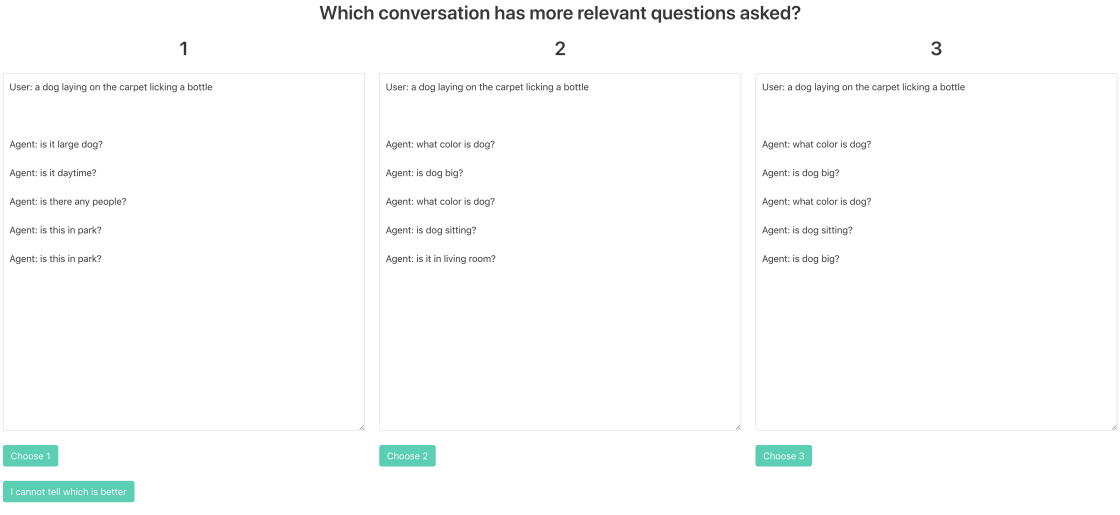

Figure 4: The user interface for human relevancy experiment. The conversation from the three different models on the same game setting are presented in the three boxes. On top of every conversation is the caption for the target image. Followed by that are the five questions asked by the Q-Bot in that game.

Abstract

Emotion recognition in conversation (ERC) has received much attention, lately, from researchers due to its potential widespread applications in diverse areas, such as health-care, education, and human resources. In this paper, we present Dialogue Graph Convolutional Network (DialogueGCN), a graph neural network based approach to ERC. We leverage self and inter-speaker dependency of the interlocutors to model conversational context for emotion recognition. Through the graph network, DialogueGCN addresses context propagation issues present in the current RNN-based methods. We empirically show that this method alleviates such issues, while outperforming the current state of the art on a number of benchmark emotion classification datasets.

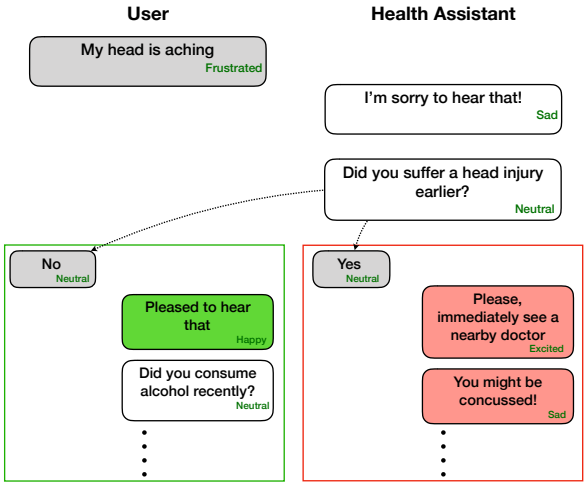

Figure 1: Illustration of an affective conversation where the emotion depends on the context. Health assistant understands affective state of the user in order to generate affective and empathetic responses.

1 Introduction

Emotion recognition has remained an active research topic for decades (K. D'Mello et al., 2006; Busso et al., 2008; Strapparava and Mihalcea, 2010). However, the recent proliferation of open conversational data on social media platforms, such as Facebook, Twitter, Youtube, and Reddit, has warranted serious attention (Poria et al., 2019b; Majumder et al., 2019; Huang et al., 2019) from researchers towards emotion recognition in conversation (ERC). ERC is also undeniably important in affective dialogue systems (as shown in Fig. 1) where bots understand users' emotions and sentiment to generate emotionally coherent and empathetic responses.

Recent works on ERC process the constituent utterances of a dialogue in sequence, with a recurrent neural network (RNN). Such a scheme is illustrated in Fig. 2 (Poria et al., 2019b), that relies on propagating contextual and sequential information to the utterances. Hence, we feed the conversation to a bidirectional gated recurrent unit (GRU) (Chung et al., 2014). However, like most of the current models, we also ignore intent modelling, topic, and personality due to lack of labelling on those aspects in the benchmark datasets. In theory, RNNs like long short-term memory (LSTM) (Hochreiter and Schmidhuber, 1997) and GRU should propagate long-term contextual information. However, in practice it is not always the case (Bradbury et al., 2017). This affects the efficacy of RNN-based models in various tasks, including ERC.

To mitigate this issue, some variants of the state-of-the-art method, DialogueRNN (Majumder et al., 2019), employ attention mechanism that pools information from entirety or part of the conversation per target utterance. However, this pooling mechanism does not consider speaker information of the utterances and the relative position of other utterances from the target utterance. Speaker information is necessary for mod-

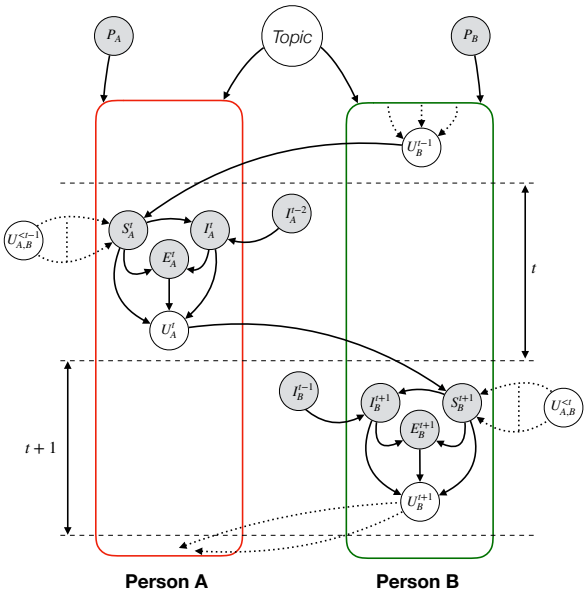

Figure 2: Interaction among different controlling variables during a dyadic conversation between persons A and B. Grey and white circles represent hidden and observed variables, respectively. P represents personality, U represents utterance, S represents interlocutor state, I represents interlocutor intent, E represents emotion and *Topic* represents topic of the conversation. This can easily be extended to multi-party conversations.

elling inter-speaker dependency, which enables the model to understand how a speaker coerces emotional change in other speakers. Similarly, by extension, intra-speaker or self-dependency aids the model with the understanding of emotional inertia of individual speakers, where the speakers resist the change of their own emotion against external influence. On the other hand, consideration of relative position of target and context utterances decides how past utterances influence future utterances and vice versa. While past utterances influencing future utterances is natural, the converse may help the model fill in some relevant missing information, that is part of the speaker's background knowledge but explicitly appears in the conversation in the future. We leverage these two factors by modelling conversation using a directed graph. The nodes in the graph represent individual utterances. The edges between a pair of nodes/utterances represent the dependency between the speakers of those utterances, along with their relative positions in the conversation. By feeding this graph to a graph convolution network (GCN) (Defferrard et al., 2016), consisting of two consecutive convolution operations, we propagate contextual information among distant utterances. We surmise that these representations hold richer context relevant to emotion than DialogueRNN. This is empirically shown in Section 5.

The remainder of the paper is organized as follows — Section 2 briefly discusses the relevant and related works on ERC; Section 3 elaborates the method; Section 4 lays out the experiments; Section 5 shows and interprets the experimental results; and finally, Section 6 concludes the paper.

2 Related Work

Emotion recognition in conversation is a popular research area in natural language processing (Kratzwald et al., 2018; Colneriĉ and Demsar, 2018) because of its potential applications in a wide area of systems, including opinion mining, health-care, recommender systems, education, etc.

However, emotion recognition in conversation has attracted attention from researchers only in the past few years due to the increase in availability of open-sourced conversational datasets (Chen et al., 2018; Zhou et al., 2018; Poria et al., 2019a). A number of models has also been proposed for emotion recognition in multimodal data i.e. datasets with textual, acoustic and visual information. Some of the important works include (Poria et al., 2017; Chen et al., 2017; Zadeh et al., 2018a,b; Hazarika et al., 2018a,b), where mainly deep learning-based techniques have been employed for emotion (and sentiment) recognition in conversation, in only textual and multimodal settings. The current state-of-the-art model in emotion recognition in conversation is (Majumder et al., 2019), where authors introduced a party state and global state based recurrent model for modelling the emotional dynamics.

Graph neural networks have also been very popular recently and have been applied to semi-supervised learning, entity classification, link prediction, large scale knowledge base modelling, and a number of other problems (Kipf and Welling, 2016; Schlichtkrull et al., 2018; Bruna et al., 2013). Early work on graph neural networks include (Scarselli et al., 2008). Our graph model is closely related to the graph relational modelling work introduced in (Schlichtkrull et al., 2018).

3 Methodology

One of the most prominent strategies for emotion recognition in conversations is contextual mod-

elling. We identify two major types of context in ERC – sequential context and speaker-level context. Following Poria et al. (2017), we model these two types of context through the neighbouring utterances, per target utterance.

Computational modeling of context should also consider emotional dynamics of the interlocutors in a conversation. Emotional dynamics is typically subjected to two major factors in both dyadic and multiparty conversational systems — inter-speaker dependency and self-dependency. Inter-speaker dependency refers to the emotional influence that counterparts produce in a speaker. This dependency is closely related to the fact that speakers tend to mirror their counterparts to build rapport during the course of a dialogue (Navaretta et al., 2016). However, it must be taken into account, that not all participants are going to affect the speaker in identical way. Each participant generally affects each other participants in unique ways. In contrast, self-dependency, or emotional inertia, deals with the aspect of emotional influence that speakers have on themselves during conversations. Participants in a conversation are likely to stick to their own emotional state due to their emotional inertia, unless the counterparts invoke a change. Thus, there is always a major interplay between the inter-speaker dependency and self-dependency with respect to the emotional dynamics in the conversation.

We surmise that combining these two distinct yet related contextual information schemes (sequential encoding and speaker level encoding) would create enhanced context representation leading to better understanding of emotional dynamics in conversational systems.

3.1 Problem Definition

Let there be M speakers/parties $p_1, p_2, \ldots, p_M$ in a conversation. The task is to predict the emotion labels (*happy*, *sad*, *neutral*, *angry*, *excited*, *frustrated*, *disgust*, and *fear*) of the constituent utterances $u_1, u_2, \ldots, u_N$, where utterance u_i is uttered by speaker $p_{s(u_i)}$, while s being the mapping between utterance and index of its corresponding speaker. We also represent $u_i \in \mathbb{R}^{D_m}$ as the feature representation of the utterance, obtained using the feature extraction process described below.

3.2 Context Independent Utterance-Level Feature Extraction

A convolutional neural network (Kim, 2014) is used to extract textual features from the transcript of the utterances. We use a single convolutional layer followed by max-pooling and a fully connected layer to obtain the feature representations for the utterances. The input to this network is the 300 dimensional pretrained 840B GloVe vectors (Pennington et al., 2014). We use filters of size 3, 4 and 5 with 50 feature maps in each. The convoluted features are then max-pooled with a window size of 2 followed by the ReLU activation (Nair and Hinton, 2010). These are then concatenated and fed to a 100 dimensional fully connected layer, whose activations form the representation of the utterance. This network is trained at utterance level with the emotion labels.

3.3 Model

We now present our Dialogue Graph Convolutional Network (DialogueGCN[1]) framework for emotion recognition in conversational setups. DialogueGCN consists of three integral components — Sequential Context Encoder, Speaker-Level Context Encoder, and Emotion Classifier. An overall architecture of the proposed framework is illustrated in Fig. 3.

3.3.1 Sequential Context Encoder

Since, conversations are sequential by nature, contextual information flows along that sequence. We feed the conversation to a bidirectional gated recurrent unit (GRU) to capture this contextual information: $g_i = \overleftrightarrow{GRU_S}(g_{i(+,-)1}, u_i)$, for i = 1, 2,..., N, where u_i and g_i are context-independent and sequential context-aware utterance representations, respectively.

Since, the utterances are encoded irrespective of its speaker, this initial encoding scheme is speaker agnostic, as opposed to the state of the art, DialogueRNN (Majumder et al., 2019).

3.3.2 Speaker-Level Context Encoder

We propose the Speaker-Level Context Encoder module in the form of a graphical network to capture speaker dependent contextual information in a conversation. Effectively modelling speaker level context requires capturing the inter-dependency

[1]Implementation available at https://github.com/SenticNet/conv-emotion

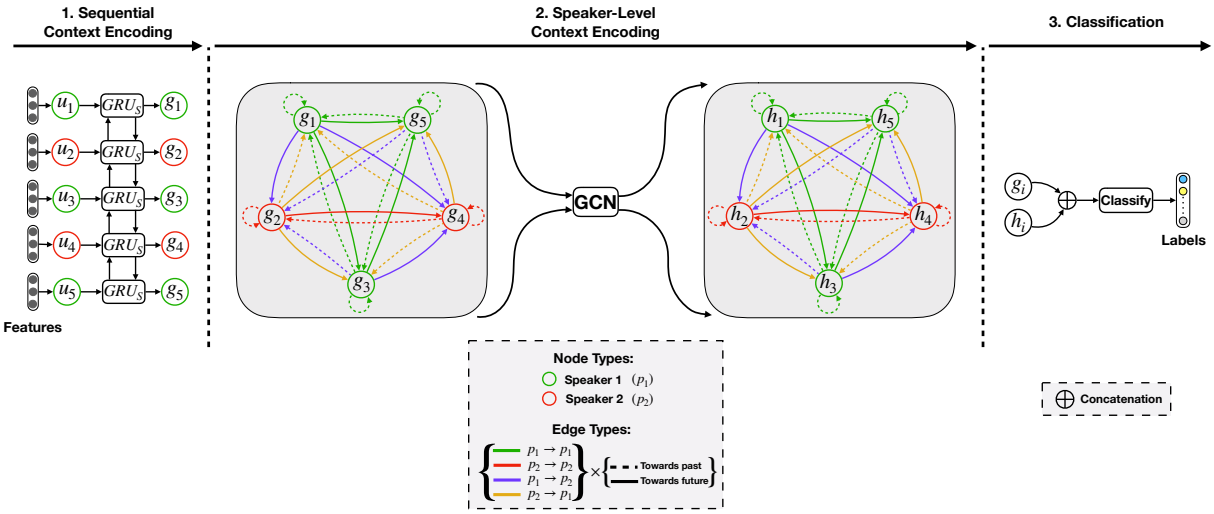

Figure 3: Overview of DialogueGCN, congruent to the illustration in Table 1.

and self-dependency among participants. We design a directed graph from the sequentially encoded utterances to capture this interaction between the participants. Furthermore, we propose a local neighbourhood based convolutional feature transformation process to create the enriched speaker-level contextually encoded features. The framework is detailed here.

First, we introduce the following notation: a conversation having N utterances is represented as a directed graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{R}, \mathcal{W})$, with vertices/nodes $v_i \in \mathcal{V}$, labeled edges (relations) $r_{ij} \in \mathcal{E}$ where $r \in \mathcal{R}$ is the relation type of the edge between v_i and v_j and α_{ij} is the weight of the labeled edge r_{ij}, with $0 \leqslant \alpha_{ij} \leqslant 1$, where $\alpha_{ij} \in \mathcal{W}$ and $i, j \in [1, 2, ..., N]$.

Graph Construction: The graph is constructed from the utterances in the following way,

Vertices: Each utterance in the conversation is represented as a vertex $v_i \in \mathcal{V}$ in $\mathcal{G}$. Each vertex v_i is initialized with the corresponding sequentially encoded feature vector g_i, for all $i \in [1, 2, ..., N]$. We denote this vector as the vertex feature. Vertex features are subject to change downstream, when the neighbourhood based transformation process is applied to encode speaker-level context.

Edges: Construction of the edges $\mathcal{E}$ depends on the context to be modeled. For instance, if we hypothesize that each utterance (vertex) is contextually dependent on all the other utterances in a conversation (when encoding speaker level information), then a fully connected graph would be constructed. That is each vertex is connected to all the other vertices (including itself) with an edge. However, this results in $O(N^2)$ number of edges, which is computationally very expensive for graphs with large number of vertices. A more practical solution is to construct the edges by keeping a past context window size of p and a future context window size of f. In this scenario, each utterance vertex v_i has an edge with the immediate p utterances of the past: $v_{i-1}, v_{i-2}, ..v_{i-p}$, f utterances of the future: $v_{i+1}, v_{i+2}, ..v_{i+f}$ and itself: v_i. For all our experiments in this paper, we consider a past context window size of 10 and future context window size of 10.

As the graph is directed, two vertices can have edges in both directions with different relations.

Edge Weights: The edge weights are set using a similarity based attention module. The attention function is computed in a way such that, for each vertex, the incoming set of edges has a sum total weight of 1. Considering a past context window size of p and a future context window size of f, the weights are calculated as follows,

$$\alpha_{ij} = \text{softmax}(g_i^T W_e [g_{i-p}, \ldots, g_{i+f}]), \quad \text{for } j = i-p, \ldots, i+f. \tag{1}$$

This ensures that, vertex v_i which has incoming edges with vertices $v_{i-p}, \ldots, v_{i+f}$ (as speaker-level context) receives a total weight contribution of 1.

Relations: The relation r of an edge r_{ij} is set depending upon two aspects:

Speaker dependency — The relation depends on both the speakers of the constituting vertices: $p_{s(u_i)}$ (speaker of v_i) and $p_{s(u_j)}$ (speaker of v_j).

Temporal dependency — The relation also de-

pends upon the relative position of occurrence of u_i and u_j in the conversation: whether u_i is uttered before u_j or after. If there are M distinct speakers in a conversation, there can be a maximum of M (speaker of u_i) $*M$ (speaker of u_j) $*2$ (u_i occurs before u_j or after) = $2M^2$ distinct relation types r in the graph $\mathcal{G}$.

Each speaker in a conversation is uniquely affected by each other speaker, hence we hypothesize that explicit declaration of such relational edges in the graph would help in capturing the inter-dependency and self-dependency among the speakers in play, which in succession would facilitate speaker-level context encoding.

As an illustration, let two parties p_1, p_2 participate in a dyadic conversation having 5 utterances, where u_1, u_3, u_5 are uttered by p_1 and u_2, u_4 are uttered by p_2. If we consider a fully connected graph, the edges and relations will be constructed as shown in Table 1.

Feature Transformation: We now describe the methodology to transform the sequentially encoded features using the graph network. The vertex feature vectors (g_i) are initially speaker independent and thereafter transformed into a speaker dependent feature vector using a two-step graph convolution process. Both of these transformations can be understood as special cases of a basic differentiable message passing method (Gilmer et al., 2017).

In the first step, a new feature vector $h_i^{(1)}$ is computed for vertex v_i by aggregating local neighbourhood information (in this case neighbour utterances specified by the past and future context window size) using the relation specific transformation inspired from (Schlichtkrull et al., 2018):

$$h_i^{(1)} = \sigma\Big(\sum_{r\in\mathcal{R}}\sum_{j\in N_i^r}\frac{\alpha_{ij}}{c_{i,r}}W_r^{(1)}g_j + \alpha_{ii}W_0^{(1)}g_i\Big), \quad \text{for } i = 1,2,\ldots,N, \tag{2}$$

where, α_{ij} and α_{ii} are the edge weights, N_i^r denotes the neighbouring indices of vertex i under relation $r \in \mathcal{R}$. $c_{i,r}$ is a problem specific normalization constant which either can be set in advance, such that, $c_{i,r} = |N_i^r|$, or can be automatically learned in a gradient based learning setup. σ is an activation function such as ReLU, $W_r^{(1)}$ and $W_0^{(1)}$ are learnable parameters of the transformation. In the second step, another local neighbourhood based transformation is applied over the output of the first step,

$$h_i^{(2)} = \sigma\Big(\sum_{j\in N_i^r} W^{(2)}h_j^{(1)} + W_0^{(2)}h_i^{(1)}\Big), \quad \text{for } i = 1,2,\ldots,N, \tag{3}$$

where, $W^{(2)}$ and $W_0^{(2)}$ are parameters of these transformation and σ is the activation function.

This stack of transformations, Eqs. (2) and (3), effectively accumulates normalized sum of the local neighbourhood (features of the neighbours) i.e. the neighbourhood speaker information for each utterance in the graph. The self connection ensures self dependent feature transformation.

Emotion Classifier: The contextually encoded feature vectors g_i (from sequential encoder) and $h_i^{(2)}$ (from speaker-level encoder) are concatenated and a similarity-based attention mechanism is applied to obtain the final utterance representation:

$$h_i = [g_i, h_i^{(2)}], \tag{4}$$

$$\beta_i = \text{softmax}(h_i^T W_\beta[h_1, h_2 \ldots, h_N]), \tag{5}$$

$$\tilde{h}_i = \beta_i[h_1, h_2, \ldots, h_N]^T. \tag{6}$$

Finally, the utterance is classified using a fully-connected network:

$$l_i = \text{ReLU}(W_l\tilde{h}_i + b_l), \tag{7}$$

$$\mathcal{P}_i = \text{softmax}(W_{smax}l_i + b_{smax}), \tag{8}$$

$$\hat{y}_i = \underset{k}{\text{argmax}}(\mathcal{P}_i[k]). \tag{9}$$

Relation	$p_s(u_i), p_s(u_j)$	$i < j$	(i, j)
1	p_1, p_1	Yes	(1,3), (1,5), (3,5)
2	p_1, p_1	No	(1,1), (3,1), (3,3) (5,1), (5,3), (5,5)
3	p_2, p_2	Yes	(2,4)
4	p_2, p_2	No	(2,2), (4,2), (4, 4)
5	p_1, p_2	Yes	(1,2), (1,4), (3,4)
6	p_1, p_2	No	(3,2), (5,2), (5,4)
7	p_2, p_1	Yes	(2,3), (2,5), (4,5)
8	p_2, p_1	No	(2,1), (4,1), (4,3)

Table 1: $p_s(u_i)$ and $p_s(u_j)$ denotes the speaker of utterances u_i and u_j. 2 distinct speakers in the conversation implies $2 * M^2 = 2 * 2^2 = 8$ distinct relation types. The rightmost column denotes the indices of the vertices of the constituting edge which has the relation type indicated by the leftmost column.

Training Setup: We use categorical cross-entropy along with L2-regularization as the measure of loss (L) during training:

$$L = -\frac{1}{\sum_{s=1}^{N} c(s)} \sum_{i=1}^{N} \sum_{j=1}^{c(i)} \log \mathcal{P}_{i,j}[y_{i,j}] + \lambda \|\theta\|_2 , \tag{10}$$

where N is the number of samples/dialogues, $c(i)$ is the number of utterances in sample i, $\mathcal{P}_{i,j}$ is the probability distribution of emotion labels for utterance j of dialogue i, $y_{i,j}$ is the expected class label of utterance j of dialogue i, λ is the L2-regularizer weight, and θ is the set of all trainable parameters.

We used stochastic gradient descent based Adam (Kingma and Ba, 2014) optimizer to train our network. Hyperparameters were optimized using grid search.

4 Experimental Setting

4.1 Datasets Used

We evaluate our DialogueGCN model on three benchmark datasets — IEMOCAP (Busso et al., 2008), AVEC (Schuller et al., 2012), and MELD (Poria et al., 2019a). All these three datasets are multimodal datasets containing textual, visual and acoustic information for every utterance of each conversation. However, in this work we focus on conversational emotion recognition only from the textual information. Multimodal emotion recognition is outside the scope of this paper, and is left as future work.

IEMOCAP (Busso et al., 2008) dataset contains videos of two-way conversations of ten unique speakers, where only the first eight speakers from session one to four belong to the trainset. Each video contains a single dyadic dialogue, segmented into utterances. The utterances are annotated with one of six emotion labels, which are happy, sad, neutral, angry, excited, and frustrated.

AVEC (Schuller et al., 2012) dataset is a modification of SEMAINE database (McKeown et al., 2012) containing interactions between humans and artificially intelligent agents. Each utterance of a dialogue is annotated with four real valued affective attributes: valence ($[-1, 1]$), arousal ($[-1, 1]$), expectancy ($[-1, 1]$), and power ($[0, \infty)$). The annotations are available every 0.2 seconds in the original database. However, in order to adapt the annotations to our need of utterance-level annotation, we averaged the attributes over the span of an utterance.

MELD (Poria et al., 2019a) is a multimodal emotion/sentiment classification dataset which has been created by the extending the EmotionLines dataset (Chen et al., 2018). Contrary to IEMOCAP and AVEC, MELD is a multiparty dialog dataset. MELD contains textual, acoustic and visual information for more than 1400 dialogues and 13000 utterances from the Friends TV series. Each utterance in every dialog is annotated as one of the seven emotion classes: anger, disgust, sadness, joy, surprise, fear or neutral.

Dataset	# dialogues			# utterances		
	train	val	test	train	val	test
IEMOCAP	120		31	5810		1623
AVEC	63		32	4368		1430
MELD	1039	114	280	9989	1109	2610

Table 2: Training, validation and test data distribution in the datasets. No predefined train/val split is provided in IEMOCAP and AVEC, hence we use 10% of the training dialogues as validation split.

4.2 Baselines and State of the Art

For a comprehensive evaluation of DialogueGCN, we compare our model with the following baseline methods:

CNN (Kim, 2014) This is the baseline convolutional neural network based model which is identical to our utterance level feature extractor network (Section 3.2). This model is context independent as it doesn't use information from contextual utterances.

Memnet (Sukhbaatar et al., 2015) This is an end-to-end memory network baseline (Hazarika et al., 2018b). Every utterance is fed to the network and the memories, which correspond to the previous utterances, is continuously updated in a multi-hop fashion. Finally the output from the memory network is used for emotion classification.

c-LSTM (Poria et al., 2017) Context-aware utterance representations are generated by capturing the contextual content from the surrounding utterances using a Bi-directional LSTM (Hochreiter and Schmidhuber, 1997) network. The context-aware utterance representations are then used for emotion classification. The contextual-LSTM

model is speaker independent as it doesn't model any speaker level dependency.

c-LSTM+Att (Poria et al., 2017) In this variant of c-LSTM, an attention module is applied to the output of c-LSTM at each timestamp by following Eqs. (5) and (6). Generally this provides better context to create a more informative final utterance representation.

CMN (Hazarika et al., 2018b) CMN models utterance context from dialogue history using two distinct GRUs for two speakers. Finally, utterance representation is obtained by feeding the current utterance as query to two distinct memory networks for both speakers. However, this model can only model conversations with two speakers.

ICON (Hazarika et al., 2018b) ICON which is an extension of CMN, connects outputs of individual speaker GRUs in CMN using another GRU for explicit inter-speaker modeling. This GRU is considered as a memory to track the overall conversational flow. Similar to CMN, ICON can not be extended to apply on multiparty datasets e.g., MELD.

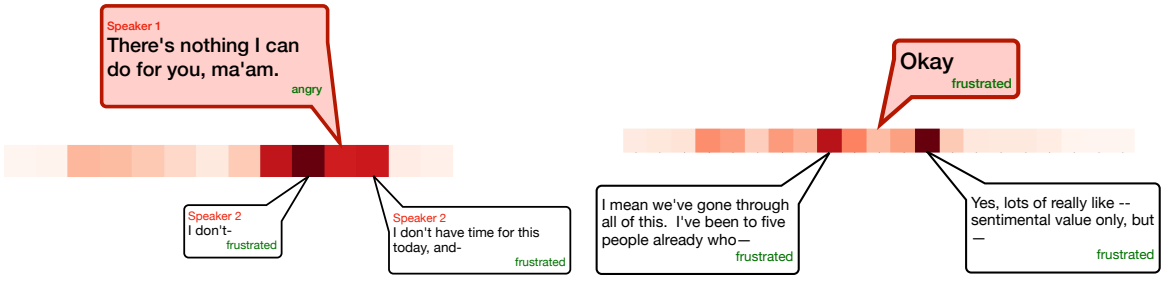
DialogueRNN (Majumder et al., 2019) This is the state-of-the-art method for ERC. It is a recurrent network that uses two GRUs to track individual speaker states and global context during the conversation. Further, another GRU is employed to track emotional state through the conversation. DialogueRNN claims to model inter-speaker relation and it can be applied on multiparty datasets.

5 Results and Discussions

5.1 Comparison with State of the Art and Baseline

We compare the performance of our proposed DialogueGCN framework with the state-of-the-art DialogueRNN and baseline methods in Tables 3 and 4. We report all results with average of 5 runs. Our DialogueGCN model outperforms the SOTA and all the baseline models, on all the datasets, while also being statistically significant under the paired t-test ($p < 0.05$).

IEMOCAP and AVEC: On the IEMOCAP dataset, DialogueGCN achieves new state-of-the-art average F1-score of 64.18% and accuracy of 65.25%, which is around 2% better than DialogueRNN, and at least 5% better than all the other baseline models. Similarly, on AVEC dataset, DialogueGCN outperforms the state-of-the-art on all the four emotion dimensions: valence, arousal, expectancy, and power.



To explain this gap in performance, it is important to understand the nature of these models. DialogueGCN and DialogueRNN both try to model speaker-level context (albeit differently), whereas, none of the other models encode speaker-level context (they only encode sequential context). This is a key limitation in the baseline models, as speaker-level context is indeed very important in conversational emotion recognition.

As for the difference of performance between DialogueRNN and DialogueGCN, we believe that this is due to the different nature of speaker-level context encoding. DialogueRNN employs a gated recurrent unit (GRU) network to model individual speaker states. Both IEMOCAP and AVEC dataset has many conversations with over 70 utterances (the average conversation length is 50 utterances in IEMOCAP and 72 in AVEC). As recurrent encoders have long-term information propagation issues, speaker-level encoding can be problematic for long sequences like those found in these two datasets. In contrast, DialogueGCN tries to overcome this issue by using neighbourhood based convolution to model speaker-level context.

MELD: The MELD dataset consists of multiparty conversations and we found that emotion recognition in MELD is considerably harder to model than IEMOCAP and AVEC - which only consists of dyadic conversations. Utterances in MELD are much shorter and rarely contain emotion specific expressions, which means emotion modelling is highly context dependent. Moreover, the average conversation length is 10 utterances, with many conversations having more than 5 participants, which means majority of the participants only utter a small number of utterances per conversation. This makes inter-dependency and self-dependency modeling difficult. Because of these reasons, we found that the difference in results between the baseline models and DialogueGCN is not as contrasting as it is in the case of IEMOCAP and AVEC. Memnet, CMN, and ICON are not suitable for this dataset as they exclusively work in dyadic conversations. Our DialogueGCN model achieves new state-of-the-art F1 score of 58.10% outperforming DialogueRNN by more than 1%.

Table 3: Comparison with the baseline methods on IEMOCAP dataset; Acc. = Accuracy; bold font denotes the best performances. Average(w) = Weighted average.

(a) (b)

Figure 4: Visualization of edge-weights in Eq. (1) — (a) Target utterance attends to other speaker's utterance for correct context; (b) Short utterance attends to appropriate contextual utterances to be classified correctly.

We surmise that this improvement is a result of the speaker dependent relation modelling of the edges in our graph network which inherently improves the context understanding over DialogueRNN.

5.2 Effect of Context Window

We report results for DialogueGCN model in Tables 3 and 4 with a past and future context window size of (10, 10) to construct the edges. We also carried out experiments with decreasing context window sizes of (8, 8), (4, 4), (0, 0) and found that performance steadily decreased with F1 scores of 62.48%, 59.41% and 55.80% on IEMOCAP. DialogueGCN with context window size of (0, 0) is equivalent to a model with only sequential encoder (as it only has self edges), and performance is expectedly much worse. We couldn't perform extensive experiments with larger windows because of computational constraints, but we expect performance to improve with larger context sizes.

5.3 Ablation Study

We perform ablation study for different level of context encoders, namely sequential encoder and speaker-level encoder, in Table 5. We remove them one at a time and found that the speaker-level encoder is slightly more important in overall performance. This is due to speaker-level encoder mitigating long distance dependency issue of sequential encoder and DialogueRNN. Removing both of them results in a very poor F1 score of 36.7 %, which demonstrates the importance of contextual modelling in conversational emotion recognition.

Further, we study the effect of edge relation modelling. As mentioned in Section 3.3.2, there are total $2M^2$ distinct edge relations for a conversation with M distinct speakers. First we removed only the temporal dependency (resulting in M^2 distinct edge relations), and then only the speaker dependency (resulting in 2 distinct edge relations) and then both (resulting in a single edge relation all throughout the graph). The results of these tests in Table 6 show that having these different relational edges is indeed very important for modelling emotional dynamics. These results support our hypothesis that each speaker in a conversation is uniquely affected by the others, and hence, modelling interlocutors-dependency is rudimentary. Fig. 4a illustrates one such instance where target utterance attends to other speaker's utterance for context. This phenomenon is com-

monly observable for DialogueGCN, as compared to DialogueRNN.

5.4 Performance on Short Utterances

Emotion of short utterances, like "okay", "yeah", depends on the context it appears in. For example, without context "okay" is assumed 'neutral'. However, in Fig. 4b, DialogueGCN correctly classifies "okay" as 'frustration', which is apparent from the context. We observed that, overall, DialogueGCN correctly classifies short utterances, where DialogueRNN fails.

5.5 Error Analysis

We analyzed our predicted emotion labels and found that misclassifications are often among similar emotion classes. In the confusion matrix, we observed that our model misclassifies several samples of 'frustrated' as 'angry' and 'neutral'. This is due to subtle difference between frustration and anger. Further, we also observed similar misclassification of 'excited' samples as 'happy' and 'neutral'. All the datasets that we use in our experiment are multimodal. A few utterances e.g., 'ok. yes' carrying *non-neutral* emotions were misclassified as we do not utilize audio and visual modality in our experiments. In such utterances, we found audio and visual (in this particular example, high pitched audio and frowning expression) modality providing key information to detect underlying emotions (*frustrated* in the above utterance) which DialogueGCN failed to understand by just looking at the textual context.

6 Conclusion

In this work, we present Dialogue Graph Convolutional Network (DialogueGCN), that models inter and self-party dependency to improve context understanding for utterance-level emotion detection in conversations. On three benchmark ERC datasets, DialogueGCN outperforms the strong baselines and existing state of the art, by a significant margin. Future works will focus on incorporating multimodal information into DialogueGCN, speaker-level emotion shift detection, and conceptual grounding of conversational emotion reasoning. We also plan to use DialogueGCN in dialogue systems to generate affective responses.

Abstract

Messages in human conversations inherently convey emotions. The task of detecting emotions in textual conversations leads to a wide range of applications such as opinion mining in social networks. However, enabling machines to analyze emotions in conversations is challenging, partly because humans often rely on the context and commonsense knowledge to express emotions. In this paper, we address these challenges by proposing a Knowledge-Enriched Transformer (KET), where contextual utterances are interpreted using hierarchical self-attention and external commonsense knowledge is dynamically leveraged using a context-aware affective graph attention mechanism. Experiments on multiple textual conversation datasets demonstrate that both context and commonsense knowledge are consistently beneficial to the emotion detection performance. In addition, the experimental results show that our KET model outperforms the state-of-the-art models on most of the tested datasets in F1 score.

1 Introduction

Emotions are "generated states in humans that reflect evaluative judgments of the environment, the self and other social agents" (Hudlicka, 2011). Messages in human communications inherently convey emotions. With the prevalence of social media platforms such as Facebook Messenger, as well as conversational agents such as Amazon Alexa, there is an emerging need for machines to understand human emotions in natural conversations. This work addresses the task of detecting emotions (e.g., happy, sad, angry, etc.) in textual conversations, where the emotion of an utterance is detected in the conversational context. Being able to effectively detect emotions in conversations leads to a wide range of applications ranging from opinion mining in social media platforms (Chatterjee et al., 2019) to building emotion-aware conversational agents (Zhou et al., 2018a).

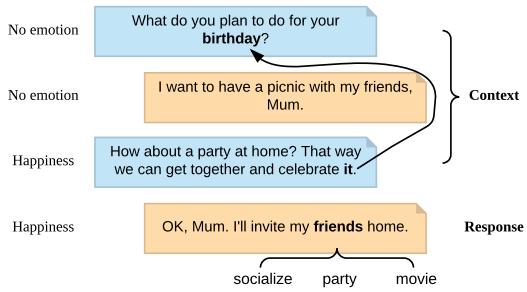

Figure 1: An example conversation with annotated labels from the DailyDialog dataset (Li et al., 2017). By referring to the context, "it" in the third utterance is linked to "birthday" in the first utterance. By leveraging an external knowledge base, the meaning of "friends" in the forth utterance is enriched by associated knowledge entities, namely "socialize", "party", and "movie". Thus, the implicit "happiness" emotion in the fourth utterance can be inferred more easily via its enriched meaning.

However, enabling machines to analyze emotions in human conversations is challenging, partly because humans often rely on the context and commonsense knowledge to express emotions, which is difficult to be captured by machines. Figure 1 shows an example conversation demonstrating the importance of context and commonsense knowledge in understanding conversations and detecting implicit emotions.

There are several recent studies that model contextual information to detect emotions in conversations. Poria et al. (2017) and Majumder et al. (2019) leveraged recurrent neural networks (RNN) to model the contextual utterances in sequence, where each utterance is represented by a feature vector extracted by convolutional neural networks (CNN) at an earlier stage. Similarly, Hazarika et al. (2018a,b) proposed to use extracted CNN

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 165–176, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

features in memory networks to model contextual utterances. However, these methods require separate feature extraction and tuning, which may not be ideal for real-time applications. In addition, to the best of our knowledge, no attempts have been made in the literature to incorporate commonsense knowledge from external knowledge bases to detect emotions in textual conversations. Commonsense knowledge is fundamental to understanding conversations and generating appropriate responses (Zhou et al., 2018b).

To this end, we propose a Knowledge-Enriched Transformer (KET) to effectively incorporate contextual information and external knowledge bases to address the aforementioned challenges. The Transformer (Vaswani et al., 2017) has been shown to be a powerful representation learning model in many NLP tasks such as machine translation (Vaswani et al., 2017) and language understanding (Devlin et al., 2018). The self-attention (Cheng et al., 2016) and cross-attention (Bahdanau et al., 2014) modules in the Transformer capture the intra-sentence and inter-sentence correlations, respectively. The shorter path of information flow in these two modules compared to gated RNNs and CNNs allows KET to model contextual information more efficiently. In addition, we propose a hierarchical self-attention mechanism allowing KET to model the hierarchical structure of conversations. Our model separates context and response into the encoder and decoder, respectively, which is different from other Transformer-based models, e.g., BERT (Devlin et al., 2018), which directly concatenate context and response, and then train language models using only the encoder part.

Moreover, to exploit commonsense knowledge, we leverage external knowledge bases to facilitate the understanding of each word in the utterances by referring to related knowledge entities. The referring process is dynamic and balances between relatedness and affectiveness of the retrieved knowledge entities using a context-aware affective graph attention mechanism.

In summary, our contributions are as follows:

- For the first time, we apply the Transformer to analyze conversations and detect emotions. Our hierarchical self-attention and cross-attention modules allow our model to exploit contextual information more efficiently than existing gated RNNs and CNNs.
- We derive dynamic, context-aware, and emotion-related commonsense knowledge from external knowledge bases and emotion lexicons to facilitate the emotion detection in conversations.
- We conduct extensive experiments demonstrating that both contextual information and commonsense knowledge are beneficial to the emotion detection performance. In addition, our proposed KET model outperforms the state-of-the-art models on most of the tested datasets across different domains.

2 Related Work

Emotion Detection in Conversations: Early studies on emotion detection in conversations focus on call center dialogs using lexicon-based methods and audio features (Lee and Narayanan, 2005; Devillers and Vidrascu, 2006). Devillers et al. (2002) annotated and detected emotions in call center dialogs using unigram topic modelling. In recent years, there is an emerging research trend on emotion detection in conversational videos and multi-turn Tweets using deep learning methods (Hazarika et al., 2018b,a; Zahiri and Choi, 2018; Chatterjee et al., 2019; Zhong and Miao, 2019; Poria et al., 2019). Poria et al. (2017) proposed a long short-term memory network (LSTM) (Hochreiter and Schmidhuber, 1997) based model to capture contextual information for sentiment analysis in user-generated videos. Majumder et al. (2019) proposed the DialogueRNN model that uses three gated recurrent units (GRU) (Cho et al., 2014) to model the speaker, the context from the preceding utterances, and the emotions of the preceding utterances, respectively. They achieved the state-of-the-art performance on several conversational video datasets.

Knowledge Base in Conversations: Recently there is a growing number of studies on incorporating knowledge base in generative conversation systems, such as open-domain dialogue systems (Han et al., 2015; Asghar et al., 2018; Ghazvininejad et al., 2018; Young et al., 2018; Parthasarathi and Pineau, 2018; Liu et al., 2018; Moghe et al., 2018; Dinan et al., 2019; Zhong et al., 2019), task-oriented dialogue systems (Madotto et al., 2018; Wu et al., 2019; He et al., 2019) and question answering systems (Kiddon et al., 2016; Hao et al., 2017; Sun et al., 2018; Mihaylov and Frank, 2018). Zhou et al. (2018b) adopted structured

knowledge graphs to enrich the interpretation of input sentences and help generate knowledge-aware responses using graph attentions. The graph attention in the knowledge interpreter (Zhou et al., 2018b) is static and only related to the recognized entity of interest. By contrast, our graph attention mechanism is dynamic and selects context-aware knowledge entities that balances between relatedness and affectiveness.

Emotion Detection in Text: There is a trend moving from traditional machine learning methods (Pang et al., 2002; Wang and Manning, 2012; Seyeditabari et al., 2018) to deep learning methods (Abdul-Mageed and Ungar, 2017; Zhang et al., 2018b) for emotion detection in text. Khanpour and Caragea (2018) investigated the emotion detection from health-related posts in online health communities using both deep learning features and lexicon-based features.

Incorporating Knowledge in Sentiment Analysis: Traditional lexicon-based methods detect emotions or sentiments from a piece of text based on the emotions or sentiments of words or phrases that compose it (Hu et al., 2009; Taboada et al., 2011; Bandhakavi et al., 2017). Few studies investigated the usage of knowledge bases in deep learning methods. Kumar et al. (2018) proposed to use knowledge from WordNet (Fellbaum, 2012) to enrich the text representations produced by LSTM and obtained improved performance.

Transformer: The Transformer has been applied to many NLP tasks due to its rich representation and fast computation, e.g., document machine translation (Zhang et al., 2018a), response matching in dialogue system (Zhou et al., 2018c), language modelling (Dai et al., 2019) and understanding (Radford et al., 2018). A very recent work (Rik Koncel-Kedziorski and Hajishirzi, 2019) extends the Transformer to graph inputs and propose a model for graph-to-text generation.

3 Our Proposed KET Model

In this section we present the task definition and our proposed KET model.

3.1 Task Definition

Let $\{X_j^i, Y_j^i\}, i = 1, ...N, j = 1, ...N_i$ be a collection of $\{$*utterance*, *label*$\}$ pairs in a given dialogue dataset, where N denotes the number of conversations and N_i denotes the number of utterances in the ith conversation. The objective of the task is to maximize the following function:

$$\Phi = \prod_{i=1}^{N} \prod_{j=1}^{N_i} p(Y_j^i | X_j^i, X_{j-1}^i, ..., X_1^i; \theta), \quad (1)$$

where $X_{j-1}^i, ..., X_1^i$ denote contextual utterances and θ denotes the model parameters we want to optimize.

We limit the number of contextual utterances to M. Discarding early contextual utterances may cause information loss, but this loss is negligible because they only contribute the least amount of information (Su et al., 2018). This phenomenon can be further observed in our model analysis regarding context length (see Section 5.2). Similar to (Poria et al., 2017), we clip and pad each utterance X_j^i to a fixed m number of tokens. The overall architecture of our KET model is illustrated in Figure 2.

3.2 Knowledge Retrieval

We use a commonsense knowledge base ConceptNet (Speer et al., 2017) and an emotion lexicon NRC_VAD (Mohammad, 2018a) as knowledge sources in our model.

ConceptNet is a large-scale multilingual semantic graph that describes general human knowledge in natural language. The nodes in ConceptNet are concepts and the edges are relations. Each $\langle$*concept1*, *relation*, *concept2*$\rangle$ triplet is an assertion. Each assertion is associated with a confidence score. An example assertion is $\langle$*friends*, *CausesDesire*, *socialize*$\rangle$ with confidence score of 3.46. Usually assertion confidence scores are in the $[1, 10]$ interval. Currently, for English, ConceptNet comprises 5.9M assertions, 3.1M concepts and 38 relations.

NRC_VAD is a list of English words and their VAD scores, i.e., valence (negative-positive), arousal (calm-excited), and dominance (submissive-dominant) scores in the $[0, 1]$ interval. The VAD measure of emotion is culture-independent and widely adopted in Psychology (Mehrabian, 1996). Currently NRC_VAD comprises around 20K words.

In general, for each non-stopword token t in X_j^i, we retrieve a connected knowledge graph $g(t)$ comprising its immediate neighbors from ConceptNet. For each $g(t)$, we remove concepts that are stopwords or not in our vocabulary. We further remove concepts with confidence scores less

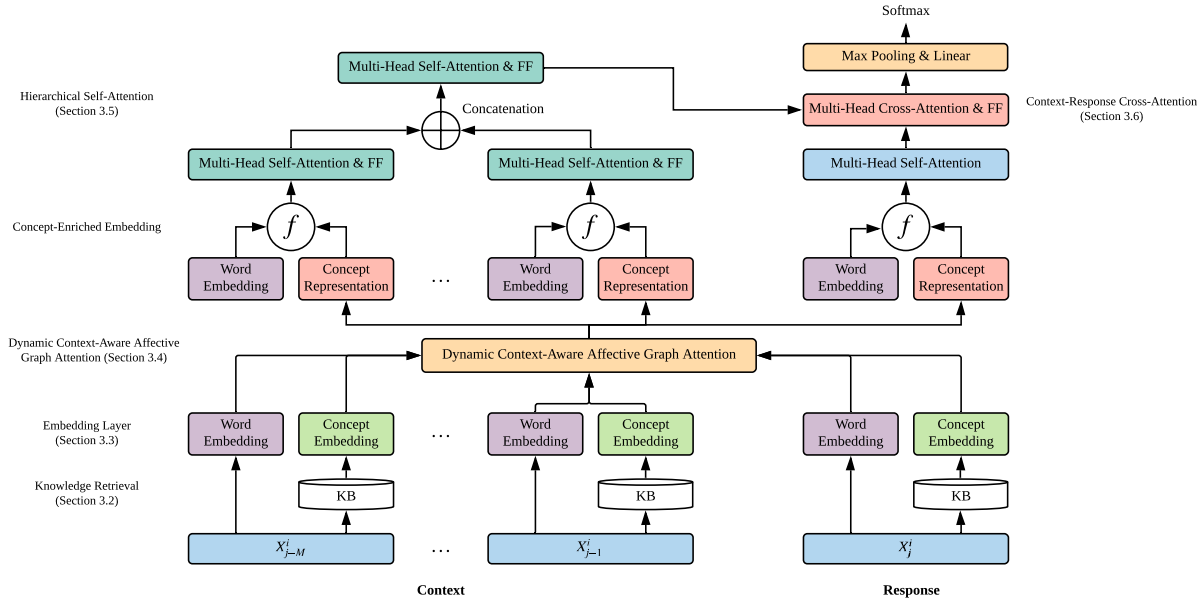

Figure 2: Overall architecture of our proposed KET model. The positional encoding, residual connection, and layer normalization are omitted in the illustration for brevity.

than 1 to reduce annotation noises. For each concept, we retrieve its VAD values from NRC_VAD. The final knowledge representation for each token t is a list of tuples: $(c_1, s_1, \mathit{VAD}(c_1))$, $(c_2, s_2, \mathit{VAD}(c_2))$, ..., $(c_{|g(t)|}, s_{|g(t)|}, \mathit{VAD}(c_{|g(t)|}))$, where $c_k \in g(t)$ denotes the kth connected concept, s_k denotes the associated confidence score, and $\mathit{VAD}(c_k)$ denotes the VAD values of c_k. The treatment for tokens that are not associated with any concept and concepts that are not included in NRC_VAD are discussed in Section 3.4. We leave the treatment on relations as future work.

3.3 Embedding Layer

We use a word embedding layer to convert each token t in X^i into a vector representation $\mathbf{t} \in \mathbb{R}^d$, where d denotes the size of word embedding. To encode positional information, the position encoding (Vaswani et al., 2017) is added as follows:

$$\mathbf{t} = \mathit{Embed}(t) + \mathit{Pos}(t). \tag{2}$$

Similarly, we use a concept embedding layer to convert each concept c into a vector representation $\mathbf{c} \in \mathbb{R}^d$ but without position encoding.

3.4 Dynamic Context-Aware Affective Graph Attention

To enrich word embedding with concept representations, we propose a dynamic context-aware affective graph attention mechanism to compute the concept representation for each token. Specifically, the concept representation $\mathbf{c}(t) \in \mathbb{R}^d$ for token t is computed as

$$\mathbf{c}(t) = \sum_{k=1}^{|g(t)|} \alpha_k * \mathbf{c_k}, \tag{3}$$

where $\mathbf{c_k} \in \mathbb{R}^d$ denotes the concept embedding of c_k and α_k denotes its attention weight. If $|g(t)| = 0$, we set $\mathbf{c}$(t) to the average of all concept embeddings. The attention α_k in Equation 3 is computed as

$$\alpha_k = \mathit{softmax}(w_k), \tag{4}$$

where w_k denotes the weight of c_k.

The derivation of w_k is crucial because it regulates the contribution of $\mathbf{c}_k$ towards enriching $\mathbf{t}$. A standard graph attention mechanism (Velikovi et al., 2018) computes w_k by feeding $\mathbf{t}$ and $\mathbf{c}_k$ into a single-layer feedforward neural network. However, not all related concepts are equal in detecting emotions given the conversational context. In our model, we make the assumption that important concepts are those that relate to the conversational context and have strong emotion intensity. To this end, we propose a context-aware affective graph attention mechanism by incorporating two factors when computing w_k, namely relatedness and affectiveness.

Relatedness: Relatedness measures the strength of the relation between c_k and the conversational context. The relatedness factor in w_k is computed as

$$rel_k = \textit{min-max}(s_k) * \textit{abs}(\cos(\mathbf{CR}(X^i), \mathbf{c_k})), \quad (5)$$

where s_k is the confidence score introduced in Section 3.2, *min-max* denotes min-max scaling for each token t, *abs* denotes the absolute function, cos denotes the cosine similarity function, and $\mathbf{CR}(X^i) \in \mathbb{R}^d$ denotes the context representation of the ith conversation X^i. Here we compute $\mathbf{CR}(X^i)$ as the average of all sentence representations in X^i as follows:

$$\mathbf{CR}(X^i) = \textit{avg}(\mathbf{SR}(X^i_{j-M}), ..., \mathbf{SR}(X^i_j)), \quad (6)$$

where $\mathbf{SR}(X^i_j) \in \mathbb{R}^d$ denotes the sentence representation of X^i_j. We compute $\mathbf{SR}(X^i_j)$ via hierarchical pooling (Shen et al., 2018) where n-gram ($n \leq 3$) representations in X^i_j are first computed by max-pooling and then all n-gram representations are averaged. The hierarchical pooling mechanism preserves word order information to certain degree and has demonstrated superior performance than average pooling or max-pooling on sentiment analysis tasks (Shen et al., 2018).

Affectiveness: Affectiveness measures the emotion intensity of c_k. The affectiveness factor in w_k is computed as

$$\textit{aff}_k = \textit{min-max}(||[V(c_k)-1/2, A(c_k)/2]||_2), \quad (7)$$

where $||.||_k$ denotes l_k norm, $V(c_k) \in [0, 1]$ and $A(c_k) \in [0, 1]$ denote the valence and arousal values of $VAD(c_k)$, respectively. Intuitively, $\textit{aff}_k$ considers the deviations of valence from neutral and the level of arousal from calm. There is no established method in the literature to compute the emotion intensity based on VAD values, but empirically we found that our method correlates better with an emotion intensity lexicon comprising 6K English words (Mohammad, 2018b) than other methods such as taking dominance into consideration or taking l_1 norm. For concept c_k not in NRC_VAD, we set $\textit{aff}_k$ to the mid value of 0.5.

Combining both rel_k and $\textit{aff}_k$, we define the weight w_k as follows:

$$w_k = \lambda_k * rel_k + (1 - \lambda_k) * \textit{aff}_k, \quad (8)$$

where λ_k is a model parameter balancing the impacts of relatedness and affectiveness on computing concept representations. Parameter λ_k can be fixed or learned during training. The analysis of λ_k is discussed in Section 5.2.

Finally, the concept-enriched word representation $\hat{\mathbf{t}}$ can be obtained via a linear transformation:

$$\hat{\mathbf{t}} = \mathbf{W}[\mathbf{t}; \mathbf{c}(t)], \quad (9)$$

where $[;]$ denotes concatenation and $\mathbf{W} \in \mathbb{R}^{d \times 2d}$ denotes a model parameter. All m tokens in each X^i_j then form a concept-enriched utterance embedding $\hat{\mathbf{X}}^i_j \in \mathbb{R}^{m \times d}$.

3.5 Hierarchical Self-Attention

We propose a hierarchical self-attention mechanism to exploit the structural representation of conversations and learn a vector representation for the contextual utterances $X^i_{j-1}, ..., X^i_{j-M}$. Specifically, the hierarchical self-attention follows two steps: 1) each utterance representation is computed using an utterance-level self-attention layer, and 2) a context representation is computed from M learned utterance representations using a context-level self-attention layer.

At step 1, for each utterance X^i_n, n=$j-1$, ..., $j-M$, its representation $\hat{\mathbf{X}}'^i_n \in \mathbb{R}^{m \times d}$ is learned as follows:

$$\hat{\mathbf{X}}'^i_n = \textit{FF}(L'(\textit{MH}(L(\hat{\mathbf{X}}^i_n), L(\hat{\mathbf{X}}^i_n), L(\hat{\mathbf{X}}^i_n)))), \quad (10)$$

where $L(\hat{\mathbf{X}}^i_n) \in \mathbb{R}^{m \times h \times d_s}$ is linearly transformed from $\hat{\mathbf{X}}^i_n$ to form h heads ($d_s = d/h$), L' linearly transforms from h heads back to 1 head, and

$$\textit{MH}(Q, K, V) = \textit{softmax}(\frac{QK^T}{\sqrt{d_s}})V, \quad (11)$$

$$\textit{FF}(x) = \textit{max}(0, xW_1 + b_1)W_2 + b_2, \quad (12)$$

where Q, K, and V denote sets of queries, keys and values, respectively, $W_1 \in \mathbb{R}^{d \times p}, b_1 \in \mathbb{R}^p, W_2 \in \mathbb{R}^{p \times d}$ and $b_2 \in \mathbb{R}^d$ denote model parameters, and p denotes the hidden size of the point-wise feedforward layer (FF) (Vaswani et al., 2017). The multi-head self-attention layer (MH) enables our model to jointly attend to information from different representation subspaces (Vaswani et al., 2017). The scaling factor $\frac{1}{\sqrt{d_s}}$ is added to ensure the dot product of two vectors do not get overly large. Similar to (Vaswani et al., 2017), both MH and FF layers are followed by residual connection and layer normalization, which are omitted in Equation 10 for brevity.

Dataset	Domain	#Conv. (Train/Val/Test)	#Utter. (Train/Val/Test)	#Classes	Evaluation
EC	Tweet	30160/2755/5509	90480/8265/16527	4	Micro-F1
DailyDialog	Daily Communication	11118/1000/1000	87170/8069/7740	7	Micro-F1
MELD	TV Show Scripts	1038/114/280	9989/1109/2610	7	Weighted-F1
EmoryNLP	TV Show Scripts	659/89/79	7551/954/984	7	Weighted-F1
IEMOCAP	Emotional Dialogues	100/20/31	4810/1000/1523	6	Weighted-F1

Table 1: Dataset descriptions.

At step 2, to effectively combine all utterance representations in the context, the context-level self-attention layer is proposed to hierarchically learn the context-level representation $\mathbf{C}^i \in \mathbb{R}^{M\times m\times d}$ as follows:

$$\mathbf{C}^i = FF(L^{'}(MH(L(\hat{\mathbf{X}}^i), L(\hat{\mathbf{X}}^i), L(\hat{\mathbf{X}}^i)))), \quad (13)$$

where $\hat{\mathbf{X}}^i$ denotes $[\hat{\mathbf{X}}^{'i}_{j-M}; ...; \hat{\mathbf{X}}^{'i}_{j-1}]$, which is the concatenation of all learned utterance representations in the context.

3.6 Context-Response Cross-Attention

Finally, a context-aware concept-enriched response representation $\mathbf{R}^i \in \mathbb{R}^{m\times d}$ for conversation X^i is learned by cross-attention (Bahdanau et al., 2014), which selectively attends to the concept-enriched context representation as follows:

$$\mathbf{R}^i = FF(L^{'}(MH(L(\hat{\mathbf{X}}^{'i}_j), L(\mathbf{C}^i), L(\mathbf{C}^i)))), \quad (14)$$

where the response utterance representation $\hat{\mathbf{X}}^{'i}_j \in \mathbb{R}^{m\times d}$ is obtained via the MH layer:

$$\hat{\mathbf{X}}^{'i}_j = L^{'}(MH(L(\hat{\mathbf{X}}^i_j), L(\hat{\mathbf{X}}^i_j), L(\hat{\mathbf{X}}^i_j))), \quad (15)$$

The resulted representation $\mathbf{R}^i \in \mathbb{R}^{m\times d}$ is then fed into a max-pooling layer to learn discriminative features among the positions in the response and derive the final representation $\mathbf{O} \in \mathbb{R}^d$:

$$\mathbf{O} = max_pool(\mathbf{R}^i). \quad (16)$$

The output probability p is then computed as

$$p = softmax(\mathbf{O}W_3 + b_3), \quad (17)$$

where $W_3 \in \mathbb{R}^{d\times q}$ and $b_3 \in \mathbb{R}^q$ denote model parameters, and q denotes the number of classes. The entire KET model is optimized in an end-to-end manner as defined in Equation 1. Our model is available at here[1].

[1]https://github.com/zhongpeixiang/KET

4 Experimental Settings

In this section we present the datasets, evaluation metrics, baselines, our model variants, and other experimental settings.

4.1 Datasets and Evaluations

We evaluate our model on the following five emotion detection datasets of various sizes and domains. The statistics are reported in Table 1.

EC (Chatterjee et al., 2019): Three-turn Tweets. The emotion labels include happiness, sadness, anger and other.

DailyDialog (Li et al., 2017): Human written daily communications. The emotion labels include neutral and Ekman's six basic emotions (Ekman, 1992), namely happiness, surprise, sadness, anger, disgust and fear.

MELD (Poria et al., 2018): TV show scripts collected from *Friends*. The emotion labels are the same as the ones used in DailyDialog.

EmoryNLP (Zahiri and Choi, 2018): TV show scripts collected from *Friends* as well. However, its size and annotations are different from MELD. The emotion labels include neutral, sad, mad, scared, powerful, peaceful, and joyful.

IEMOCAP (Busso et al., 2008): Emotional dialogues. The emotion labels include neutral, happiness, sadness, anger, frustrated, and excited.

In terms of the evaluation metric, for EC and DailyDialog, we follow (Chatterjee et al., 2019) to use the micro-averaged F1 excluding the majority class (neutral), due to their extremely unbalanced labels (the percentage of the majority class in the test set is over 80%). For the rest relatively balanced datasets, we follow (Majumder et al., 2019) to use the weighted macro-F1.

4.2 Baselines and Model Variants

For a comprehensive performance evaluation, we compare our model with the following baselines:

cLSTM: A contextual LSTM model. An utterance-level bidirectional LSTM is used to encode each utterance. A context-level unidirectional LSTM is used to encode the context.

Model	EC	DailyDialog	MELD	EmoryNLP	IEMOCAP
cLSTM	0.6913	0.4990	0.4972	0.2601	0.3484
CNN (Kim, 2014)	0.7056	0.4934	0.5586	0.3259	0.5218
CNN+cLSTM (Poria et al., 2017)	0.7262	0.5024	0.5687	0.3289	0.5587
BERT_BASE (Devlin et al., 2018)	0.6946	0.5312	0.5621	0.3315	0.6119
DialogueRNN (Majumder et al., 2019)	0.7405	0.5065	0.5627	0.3170	**0.6121**
KET_SingleSelfAttn (ours)	0.7285	0.5192	0.5624	0.3251	0.5810
KET_StdAttn (ours)	**0.7413**	0.5254	0.5682	0.3353	0.5861
KET (ours)	0.7348	**0.5337**	**0.5818**	**0.3439**	0.5956

Table 2: Performance comparisons on the five test sets. Best values are highlighted in bold.

Dataset	M	m	d	p	h
EC	2	30	200	100	4
DailyDialog	6	30	300	400	4
MELD	6	30	200	100	4
EmoryNLP	6	30	100	200	4
IEMOCAP	6	30	300	400	4

Table 3: Hyper-parameter settings for KET. M: context length. m: number of tokens per utterance. d: word embedding size. p: hidden size in FF layer. h: number of heads.

CNN (Kim, 2014): A single-layer CNN with strong empirical performance. This model is trained on the utterance-level without context.

CNN+cLSTM (Poria et al., 2017): An CNN is used to extract utterance features. An cLSTM is then applied to learn context representations.

BERT_BASE (Devlin et al., 2018): Base version of the state-of-the-art model for sentiment classification. We treat each utterance with its context as a single document. We limit the document length to the last 100 tokens to allow larger batch size. We do not experiment with the large version of BERT due to memory constraint of our GPU.

DialogueRNN (Majumder et al., 2019): The state-of-the-art model for emotion detection in textual conversations. It models both context and speakers information. The CNN features used in DialogueRNN are extracted from the carefully tuned CNN model. For datasets without speaker information, i.e., EC and DailyDialog, we use two speakers only. For MELD and EmoryNLP, which have 260 and 255 speakers, respectively, we additionally experimented with clipping the number of speakers to the most frequent ones (6 main speakers + an universal speaker representing all other speakers) and reported the best results.

KET_SingleSelfAttn: We replace the hierarchical self-attention by a single self-attention layer to learn context representations. Contextual utterances are concatenated together prior to the single self-attention layer.

KET_StdAttn: We replace the dynamic context-aware affective graph attention by the standard graph attention (Velikovi et al., 2018).

4.3 Other Experimental Settings

We preprocessed all datasets by lower-casing and tokenization using Spacy[2]. We keep all tokens in the vocabulary[3]. We use the released code for BERT_BASE and DialogueRNN. For each dataset, all models are fine-tuned based on their performance on the validation set.

For our model in all datasets, we use Adam optimization (Kingma and Ba, 2014) with a batch size of 64 and learning rate of 0.0001 throughout the training process. We use GloVe embedding (Pennington et al., 2014) for initialization in the word and concept embedding layers[4]. For the class weights in cross-entropy loss for each dataset, we set them as the ratio of the class distribution in the validation set to the class distribution in the training set. Thus, we can alleviate the problem of unbalanced dataset. The detailed hyper-parameter settings for KET are presented in Table 3.

5 Result Analysis

In this section we present model evaluation results, model analysis, and error analysis.

5.1 Comparison with Baselines

We compare the performance of KET against that of the baseline models on the five afore-introduced datasets. The results are reported in Table 2. Note that our results for CNN, CNN+cLSTM and DialogueRNN on EC, MELD and IEMOCAP are slightly different from the reported results in (Majumder et al., 2019; Poria et al., 2019).

[2]https://spacy.io/

[3]We keep tokens with minimum frequency of 2 for DailyDialog due to its large vocabulary size

[4]We use GloVe embeddings from Magnitude Medium: https://github.com/plasticityai/magnitude

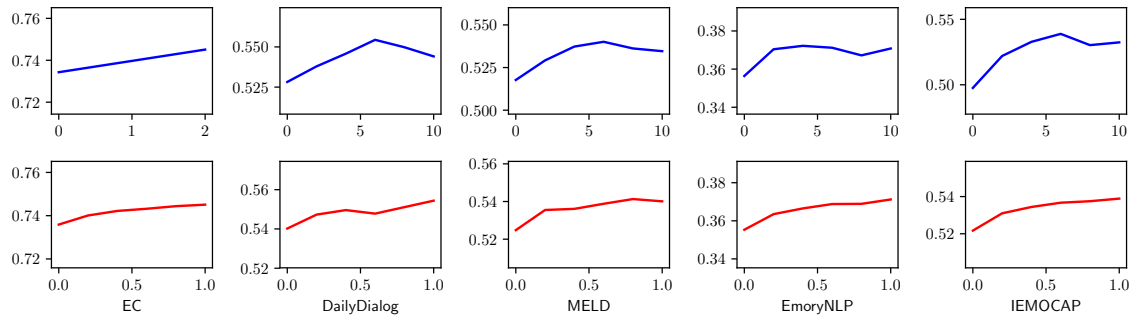

Figure 3: Validation performance by KET. Top: different context length (M). Bottom: different sizes of random fractions of ConceptNet.

cLSTM performs reasonably well on short conversations (i.e., EC and DailyDialog), but the worst on long conversations (i.e., MELD, EmoryNLP and IEMOCAP). One major reason is that learning long dependencies using gated RNNs may not be effective enough because the gradients are expected to propagate back through inevitably a huge number of utterances and tokens in sequence, which easily leads to the vanishing gradient problem (Bengio et al., 1994). In contrast, when the utterance-level LSTM in cLSTM is replaced by features extracted by CNN, i.e., the CNN+cLSTM, the model performs significantly better than cLSTM on long conversations, which further validates that modelling long conversations using only RNN models may not be sufficient. BERT_BASE achieves very competitive performance on all datasets except EC due to its strong representational power via bi-directional context modelling using the Transformer. Note that BERT_BASE has considerably more parameters than other baselines and our model (110M for BERT_BASE versus 4M for our model), which can be a disadvantage when deployed to devices with limited computing power and memory. The state-of-the-art DialogueRNN model performs the best overall among all baselines. In particular, DialogueRNN performs better than our model on IEMOCAP, which may be attributed to its detailed speaker information for modelling the emotion dynamics in each speaker as the conversation flows.

It is encouraging to see that our KET model outperforms the baselines on most of the datasets tested. This finding indicates that our model is robust across datasets with varying training sizes, context lengths and domains. Our KET variants KET_SingleSelfAttn and KET_StdAttn perform comparably with the best baselines on all datasets except IEMOCAP. However, both variants perform noticeably worse than KET on all datasets except EC, validating the importance of our proposed hierarchical self-attention and dynamic context-aware affective graph attention mechanism. One observation worth mentioning is that these two variants perform on a par with the KET model on EC. Possible explanations are that 1) hierarchical self-attention may not be critical for modelling short conversations in EC, and 2) the informal linguistic styles of Tweets in EC, e.g., misspelled words and slangs, hinder the context representation learning in our graph attention mechanism.

5.2 Model Analysis

We analyze the impact of different settings on the validation performance of KET. All results in this section are averaged over 5 random seeds.

Analysis of context length: We vary the context length M and plot model performance in Figure 3 (top portion). Note that EC has only a maximum number of 2 contextual utterances. It is clear that incorporating context into KET improves performance on all datasets. However, adding more context is contributing diminishing performance gain or even making negative impact in some datasets. This phenomenon has been observed in a prior study (Su et al., 2018). One possible explanation is that incorporating long contextual information may introduce additional noises, e.g., polysemes expressing different meanings in different utterances of the same context. More thorough investigation of this diminishing return phenomenon is a worthwhile direction in the future.

Analysis of the size of ConceptNet: We vary the size of ConceptNet by randomly keeping only a fraction of the concepts in ConceptNet when train-

Dataset	0	0.3	0.7	1
EC	0.7345	0.7397	**0.7426**	0.7363
DailyDialog	0.5365	0.5432	**0.5451**	0.5383
MELD	0.5321	**0.5395**	0.5366	0.5306
EmoryNLP	0.3528	**0.3624**	0.3571	0.3488
IEMOCAP	0.5344	**0.5367**	0.5314	0.5251

Table 4: Analysis of the relatedness-affectiveness tradeoff on the validation sets. Each column corresponds to a fixed λ_k for all concepts (see Equation 8).

Dataset	KET	-context	-knowledge
EC	**0.7451**	0.7343	0.7359
DailyDialog	**0.5544**	0.5282	0.5402
MELD	**0.5401**	0.5177	0.5248
EmoryNLP	**0.3712**	0.3564	0.3553
IEMOCAP	**0.5389**	0.4976	0.5217

Table 5: Ablation study for KET on the validation sets.

ing and evaluating our model. The results are illustrated in Figure 3 (bottom portion). Adding more concepts consistently improves model performance before reaching a plateau, validating the importance of commonsense knowledge in detecting emotions. We may expect the performance of our KET model to improve with the growing size of ConceptNet in the future.

Analysis of the relatedness-affectiveness tradeoff: We experiment with different values of $\lambda_k \in [0, 1]$ (see Equation 8) for all k and report the results in Table 4. It is clear that λ_k makes a noticeable impact on the model performance. Discarding relatedness or affectiveness completely will cause significant performance drop on all datasets, with one exception of IEMOCAP. One possible reason is that conversations in IEMOCAP are emotional dialogues, therefore, the affectiveness factor in our proposed graph attention mechanism can provide more discriminative power.

Ablation Study: We conduct ablation study to investigate the contribution of context and knowledge as reported in Table 5. It is clear that both context and knowledge are essential to the strong performance of KET on all datasets. Note that removing context has a greater impact on long conversations than short conversations, which is expected because more contextual information is lost in long conversations.

5.3 Error Analysis

Despite the strong performance of our model, it still fails to detect certain emotions on certain datasets. We rank the F1 score of each emotion per dataset and investigate the emotions with the worst scores. We found that disgust and fear are generally difficult to detect and differentiate. For example, the F1 score of fear emotion in MELD is as low as 0.0667. One possible cause is that these two emotions are intrinsically similar. The VAD values of both emotions have low valence, high arousal and low dominance (Mehrabian, 1996). Another cause is the small amount of data available for these two emotions. How to differentiate intrinsically similar emotions and how to effectively detect emotions using limited data are two challenging directions in this field.

6 Conclusion

We present a knowledge-enriched transformer to detect emotions in textual conversations. Our model learns structured conversation representations via hierarchical self-attention and dynamically refers to external, context-aware, and emotion-related knowledge entities from knowledge bases. Experimental analysis demonstrates that both contextual information and commonsense knowledge are beneficial to model performance. The tradeoff between relatedness and affectiveness plays an important role as well. In addition, our model outperforms the state-of-the-art models on most of the tested datasets of varying sizes and domains.

Given that there are similar emotion lexicons to NRC_VAD in other languages and ConceptNet is a multilingual knowledge base, our model can be easily adapted to other languages. In addition, given that NRC_VAD is the only emotion-specific component, our model can be adapted as a generic model for conversation analysis.

Abstract

Multiple emotions with different intensities are often evoked by events described in documents. Oftentimes, such event information is hidden and needs to be discovered from texts. Unveiling the hidden event information can help to understand how the emotions are evoked and provide explainable results. However, existing studies often ignore the latent event information. In this paper, we proposed a novel interpretable relevant emotion ranking model with the event information incorporated into a deep learning architecture using the event-driven attentions. Moreover, corpus-level event embeddings and document-level event distributions are introduced respectively to consider the global events in corpus and the document-specific events simultaneously. Experimental results on three real-world corpora show that the proposed approach performs remarkably better than the state-of-the-art emotion detection approaches and multi-label approaches. Moreover, interpretable results can be obtained to shed light on the events which trigger certain emotions.

1 Introduction

The advent and prosperity of social media enable users to share their opinions, feelings and attitudes online. Apart from directly expressing their opinions on social media posts, users can also vote for their emotional states after reading an article online. An example of a news article crawled from Sina News Society Channel together with its associated emotion votes received from readers is illustrated in Figure 1. Treating these emotion votes as labels for the news article, we can define the emotion detection problem as an emotion ranking problem that ranks emotions based on their intensities. Moreover, some of the emotion labels

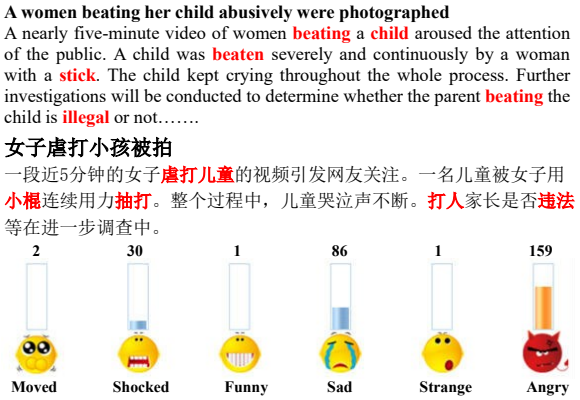

Figure 1: An example of an online news article with the readers' votes on various emotion categories. Words highlighted in red are event-indicative words.

could be considered as irrelevant emotions. For example, the emotion categories '*Moved*', '*Funny*' and '*Strange*' in Figure 1 only received one or two votes. These emotion votes could be noises (e.g., readers accidentally clicked on a wrong emotion button) and hence can be considered as irrelevant emotions. We need to separate the relevant emotions from irrelevant ones and only predict the ranking results for the relevant emotion labels. Therefore, the task we need to perform is the relevant emotion ranking. Understanding and automatically ranking users' emotional states would be potentially useful for downstream applications such as dialogue systems (Picard and Picard, 1997). Multiple emotion detection from texts has been previously addressed in (Zhou et al., 2016) which predicted multiple emotions with different intensities based on emotion distribution learning. A relevant emotion ranking framework was proposed in (Yang et al., 2018) to predict multiple relevant emotions as well as the rankings based on their intensities. However, existing emotion detection approaches do not model the events in texts

which are crucial for emotion detection. Moreover, most of the existing approaches only produce emotion classification or ranking results, and they do not provide interpretations such as identifying which event triggers a certain emotion.

We argue that emotions may be evoked by latent events in texts. Let us refer back to the example shown in Figure 1 and read the text more carefully. We notice that words such as '*beat*', '*child*' and '*stick*' marked in red are event-related words indicating the event of "*child abuse*" which may evoke the emotions of "*Anger*", "*Sadness*" and "*Shock*".

The above example shows that it is important to simultaneously consider the latent events in texts for relevant emotion ranking. In this paper we proposed an interpretable relevant emotion ranking model with event-driven attention (IRER-EA). We focus on relevant emotion ranking (RER) by discriminating relevant emotions from irrelevant ones and only learn the rankings of the relevant emotions based on their intensities.

Our main contributions are summarized below:

- A novel interpretable relevant emotion ranking model with event-driven attention (IRER-EA) is proposed. The latent event information is incorporated into a deep learning architecture through event-driven attentions which can provide clues of how the emotions are evoked with interpretable results. To the best of our knowledge, it is the first deep event-driven neural approach for RER.

- To consider event information comprehensively, corpus-level event embeddings are incorporated to consider global events in corpus and document-level event distributions are incorporated to learn document-specific event-related attention respectively.

- Experimental results on three different real-world corpora show that the proposed method performs better than the state-of-the-art emotion detection methods and multi-label learning methods. Moreover, the event-driven attention enables dynamically highlighting important event-related parts evoking the emotions in texts.

2 Related Work

In general, emotion detection methods can mainly be categorized into two classes: lexicon-based methods and learning-based methods. Lexicon-based approaches utilize emotion lexicons including emotion words and their emotion labels for detecting emotions from texts. For example, emotion lexicons are used in (Aman and Szpakowicz, 2007) to distinguish emotional and non-emotional sentences. Emotion dictionaries could also be used to predict the readers' emotion of new articles (Rao et al., 2012; Lei et al., 2014). Wang et al. (2015) proposed a model with several constraints using non-negative matrix factorization based on emotion lexicon for multiple emotion detection. However, these approaches often suffer from low recall.

Learning-based approaches can be further categorized into unsupervised and supervised learning methods. Unsupervised learning approaches do not require labeled training data (Blei et al., 2003). Supervised learning methods typically frame emotion detection as a classification problem by training supervised classifiers from texts with emotion categories (Rao et al., 2014; Wang and Pal, 2015; Rao, 2016). Lin et al. (2008) studied the readers' emotion detection with various kinds of feature sets on news articles. Quan et al. (2015) detected emotions from texts with a logistic regression model introducing the intermediate hidden variables to model the latent structure of input text corpora. Zhou et al. (2016) predicted multiple emotions with intensities based on emotion distribution learning. A relevant label ranking framework for emotion detection was proposed to predict multiple relevant emotions as well as the rankings of emotions based on their intensities (Yang et al., 2018; Zhou et al., 2018). However, these approaches do not model the latent events in texts.

In recent years, deep neural network models have been widely used for text classification. In particular, the attention-based recurrent neural networks (RNNs) (Schuster and Paliwal, 2002; Yang et al., 2016) prevail in text classification. However, these approaches ignore the latent events in texts thus fail to attend on event-related parts. Moreover, they are lack of interpretation.

Our work is partly inspired by (Yang et al., 2018) for relevant emotion ranking, but with the following significant differences: (1) our model incorporates corpus-level event embeddings and document-level event distributions by an event-driven attention mechanism attending to event-related words, which are ignored in the mod-

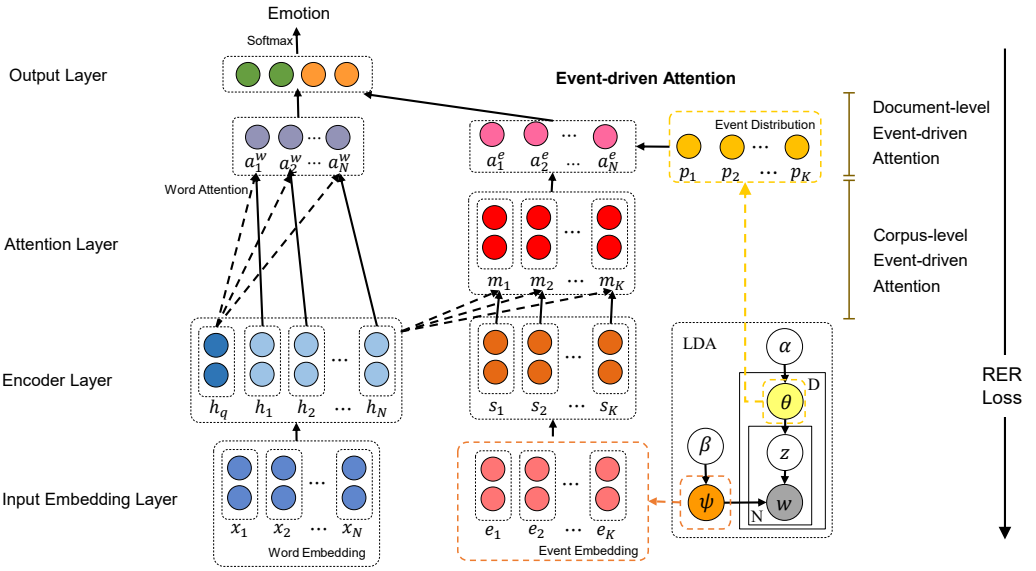

Figure 2: The IRER-EA model.

el (Yang et al., 2018) simply using a Kullback-Leibler (KL) divergence to approximatively learning the documents' topic distributions; (2) our model incorporates the event information into a deep learning architecture thus can consider the sequential information of texts which is ignored in the model (Yang et al., 2018) based on shallow bag-of-words representations.

3 The IRER-EA Model

3.1 Problem Setting

Assuming a set of T emotions, $L = \{l_1, l_2, ...l_T\}$, and a set of Q document instances, $\mathbb{D} = \{d_1, d_2, d_3, ..., d_Q\}$, each instance d_i is associated with a list of its relevant emotions $R_i \subseteq L$ ranked by their intensities and also a list of irrelevant emotions $\overline{R_i} = L - R_i$. Relevant emotion ranking aims to learn a score function $\mathbf{g}(d_i) = [g_1(d_i), ..., g_T(d_i)]$ which assigns a score $g_j(d_i)$ to each emotion $l_j, (j \in \{1, ..., T\})$. Relevant emotions and their rankings can be obtained simultaneously according to the scores assigned by the learned ranking function $\mathbf{g}$.

The learning objective of relevant emotion ranking (RER) is to both discriminate relevant emotions from irrelevant ones and to rank relevant emotions according to their intensities. Therefore, to fulfil the requirements of RER, the global objective function is defined as follows:

$$E = \sum_{i=1}^{Q} \sum_{l_t \in R_i} \sum_{l_s \in \prec(l_t)} \frac{1}{norm_{t,s}} [\exp(-(g_t(d_i) - g_s(d_i))) + \omega_{ts}(g_t(d_i) - g_s(d_i))^2] \quad (1)$$

Here, $l_s \in \prec (l_t)$ represents that emotion l_s is less relevant than emotion l_t. The normalization term $norm_{t,s}$ is used to avoid terms dominated by the sizes of emotion pairs. The term $g_t(d_i) - g_s(d_i)$ measures the difference between two emotions. ω_{ts} represents the relationship between two emotions l_t and l_s which is calculated by Pearson correlation coefficient (Nicewander, 1988).

We present the overall architecture of the proposed interpretable relevant emotion ranking with event-driven attention (IRER-EA) model in Figure 2. It consists of four layers: (1) the *Input Embedding Layer* including both word embeddings and event embeddings; (2) the *Encoder Layer* including both the word encoder and the event encoder; (3) the *Attention Layer* which computes the word-level attention scores and the event-driven attention scores taking into account of the corpus-level and document-level event information, respectively; (4) the *Output Layer* which generates the emotion ranking results.

3.2 Input Embedding Layer

The *Input Embedding Layer* contains word embeddings and event embeddings. Assuming a document d_i consisting of N words represented as

$d_i = \{w_1, w_2, ..., w_N\}$, the pre-trained word vector, GloVe (Pennington et al., 2014), is used to obtain the fixed word embedding of each word and d_i can be represented as $d_i = \{x_1, x_2, ..., x_N\}$ as shown in Figure 2.

Since nouns and verbs are more important than other word types in referring to specific events, they are utilized as inputs of topic model such as Latent Dirichlet Allocation (LDA) (Blei et al., 2003) to generate events automatically. Therefore, the granularity of extracted events is controlled by the predefined K, the number of events. For the corpus $\mathbb{D}$ consisting of K events $\{e_1, e_2, ..., e_K\}$, the event embedding of the kth event e_k can be obtained from the output event-word distribution matrix E of the topic model. For the single document d_i, the event distribution $p = (p_1, p_2, ..., p_K)$ obtained from the topic model represents the probability of the text expressing each event.

3.3 Encoder Layer

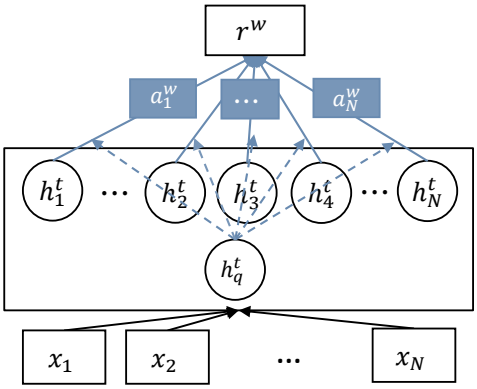

Figure 3: Word Encoder.

The *Encoder Layer* contains both the word encoder and event encoder. As for the word encoder, an alternative RNN structure (Zhang et al., 2018) is used to encode texts into semantic representations since it has been shown to be more effective in encoding longer texts. For document d_i, formally, a state at time step t can be denoted by:

$$H^t = < h_1^t, ..., h_N^t, h_q^t > \quad (2)$$

which consists of sub-states h_i^t for the ith word w_i in document d_i and a document-level sub-state h_q^t as shown in Figure 3. The hidden states are independent of each other at the present recurrent step and are connected across recurrent steps, which can capture long-range dependencies. The recurrent state transition process is used to model information exchange between those sub-states to enrich state representations incrementally. The state transition is similar to LSTM (Hochreiter and Schmidhuber, 1997) and a recurrent cell c_i^t for each word w_i and a cell c_q^t for document-level sub-state h_q are used. The value of each h_i^t is computed based on the values of x_i, h_{i-1}^{t-1}, h_i^{t-1}, h_{i+1}^{t-1}, h_q^{t-1} at two adjacent recurrent time steps. Note that the number of window size between two adjacent steps can be set manually. Hence, the hidden sub-states h_i for individual words w_i and a global document hidden state h_q for d_i are obtained.

As for event encoder, event representations are produced by the ReLU-actived neural perceptrons taking the event-word weight matrix $E \in V \times K$ as inputs. Hence, each event representation s_k representing event k is obtained according to the event embedding e_k, $k \in \{1, 2, 3, ..., K\}$.

3.4 Attention Layer

Given a word w_n in document d_i, h_n is the hidden representation of w_n after encoder. Given an event embedding e_k in the corpus, s_k is the event representation of e_k generated by the event encoder. Then we utilize attention weights to enhance the word representations and event representations from different aspects.

Our model contains two kinds of attention mechanisms including the word-level attentions and the event-driven attentions.

3.4.1 Word-Level Attention

As for word-level attentions, since not all words contribute equally to the meaning of a document, we introduce an attention mechanism to extract words with greater importance and aggregate the representations of those informative words to form the document representation, which is shown in the left part of Figure 2. More concretely,

$$\begin{aligned} \varphi_{w_i} &= tanh(W_w(h_i + h_q) + b_w) \\ a_i^w &= \frac{exp(\varphi_{w_i}^\top u_w)}{\sum_i exp(\varphi_{w_i}^\top u_w)} \\ r^w &= \sum_i a_i^w h_i \end{aligned} \quad (3)$$

where the weight a_i^w is the attention of the word w_i and W_w, b_w and u_w are parameters similar to (Pappas and Popescu-Belis, 2017). Note that we further incorporate the global information of the document representation h_q obtained from the encoder to strengthen the word attention.

3.4.2 Event-Driven Attention

In our model, we use the event-driven attention mechanism to attend to event-related words, which can discover words more important for text-related events. The event-driven attention leverages the corpus-level event information based on each event representation $s_k, k \in \{1, 2, 3, ..., K\}$ obtained from the corpus and the document-level event information based on the document's event distribution $p = (p_1, p_2, ..., p_K)$.

Corpus-level Event-Driven Attention

The model utilizes the corpus-level event information by a joint attention mechanism to consider global events in corpus, which aggregates the semantic representations $h = (h_1, h_2, ..., h_N)$ of an input text obtained and measures the interaction the words in the text with the event representations $s = (s_1, s_2, ..., s_K)$ by the event-driven attention. The corpus-level event-driven attention is calculated as follows:

$$\begin{aligned} \varphi^c &= tanh(W_c h + b_c) \\ m_k^c &= (\varphi^c)^\top s_k \\ a^c &= softmax(\sum_{k=1}^{K} m_k^c) \\ r^c &= (a^c)^\top h \end{aligned} \tag{4}$$

where $h = (h_1, h_2, ..., h_N)^\top$stands for the combination of all the hidden states of words in the document and W_c and b_c are parameters needed to be learnt for corpus-level event-driven attention. $\varphi^c = (\varphi_1^c, \varphi_2^c, ..., \varphi_N^c)$ refers to the hidden representation of state h through a fully connected layer. Given the event representation s_k, we measure the interaction of the words in the document and the event by an attention weight vector m_k^c which can be computed as the inner product of event s_k and φ^c followed by a softmax layer. $a^c = (a_1^c, a_2^c, ..., a_N^c)$ stands for the average attention weights of all the events for words which contribute to discover event keywords of a document according to different events in corpus. Then we construct the text representation r^c with the sum of hidden states weighted by a^c.

Document-level Event-driven Attention

We further incorporate the document-level event-driven attention mechanism. Our model can attend to the event distributions of the current document in order to strengthen the effect of the current document expressing each event and learn document-specific event related attention. For each document, $p = (p_1, p_2, ..., p_K)$ denotes the event distributions of the document, with each dimension representing the level of prominence of the corresponding event occurred in the document. The corpus-level event-driven attention weights can be further strengthened by including document-level event distributions. The document-level event-driven attention is calculated as follows:

$$\begin{aligned} \varphi^d &= tanh(W_d h + b_d) \\ m_k^d &= (\varphi^d)^\top s_k \\ a^e &= softmax(\sum_{k=1}^{K} m_k^d p_k) \\ r^e &= (a^e)^\top h \end{aligned} \tag{5}$$

where $h = (h_1, h_2, ..., h_N)^\top$ stands for the aggregation of all the hidden states of words in the document and W_d and b_d are parameters needed to be learnt for the document-level event-driven attention. $\varphi^d = (\varphi_1^d, \varphi_2^d, ..., \varphi_N^d)$ refers to the hidden representation of state h through a fully connected layer. m_k^d represents the interaction of the words in the document and the event which can be computed as the inner product of event s_k and φ^d. Then m_k^d is weighted by the document-level event distribution, $p = (p_1, p_2, ..., p_K)$, followed by a softmax layer, and $a^e = (a_1^e, a_2^e, ..., a_N^e)$ stands for the attention weight after incorporating the document-level event distributions. Then we construct the text representation r^e with the sum of hidden states weighted by a^e. Finally, r^e is used as the final text representation obtained by the event-driven attention which simultaneously takes into account both the corpus-level event information and the document-level event information.

3.5 Output Layer

At last, we concatenate both the representations calculated by the word-level attention and the event-driven attention to obtain the final representation $r = [r^w, r^e]$, which is fed to a multi-layer perceptron and a softmax layer for identifying relevant emotions and their rankings.

4 Experiments

To evaluate our proposed approach, we conducted experiments on the following three corpora:

Sina Social News (News) (Zhou et al., 2018) consists of 5,586 news articles collected from the Sina

news *Society* channel. Each document was kept together with the readers' emotion votes of the six emotions including *Funny*, *Moved*, *Angry*, *Sad*, *Strange*, and *Shocked*.

Ren-CECps corpus (Blogs) (Quan and Ren, 2010) is a Chinese data set containing 1,487 blogs annotated with eight basic emotions from writer's perspective, including *Anger*, *Anxiety*, *Expect*, *Hate*, *Joy*, *Love*, *Sorrow* and *Surprise*. The emotions are represented by their emotion scores in the range of $[0, 1]$. Higher scores represent higher emotion intensities.

SemEval (Strapparava and Mihalcea, 2007) contains 1,250 English news headlines extracted from Google news, CNN, and many other portals, which are manually annotated with a fine-grained valence scale of 0 to 100 across 6 emotions, including *Anger*, *Disgust*, *Fear*, *Joy*, *Sad* and *Surprise*.

News		Blogs		SemEval	
Category	#Votes	Category	#Scores	Category	#Scores
Touching	694,006	Joy	349.2	anger	12042
Shock	572,651	Hate	174.2	disgust	7634
Amusement	869,464	Love	610.6	fear	20306
Sadness	837,431	Sorrow	408.4	joy	23613
Curiosity	212,559	Anxiety	422.6	sad	24039
Anger	1,109,315	Surprise	59.2	surprise	21495
		Anger	116.4		
		Expect	385.5		
All	4,295,426	All	2526.1	All	109,129

Table 1: Statistics for the three corpora used in our experiments.

The statistics for the three corpora used in our experiments are shown in Table 1.

In our experiments, the News and Blog corpora were preprocessed using the python jieba segmenter[1] for word segmentation and filtering. The third corpus SemEval is in English and was tokenized by white space. Stanford CoreNLP[2] was applied for parts of speech tagging to obtain the nouns and verbs of the documents. Stop words and words appeared less than twice were removed from documents. We used the pre-trained Chinese GloVe and English GloVe[3] vectors as the word embeddings in the experiments and the dimension of the word embeddings was 300.

Name	Definition
PRO Loss	$\frac{1}{n}\sum_{i=1}^{n}\sum_{e_t\in R_i\cup\{\Theta\}}\sum_{e_s\in\prec(e_t)}\frac{1}{norm_{t,s}}l_{t,s}$ $l_{t,s}$ is a modified 0-1 error; $norm_{t,s}$is the set size of label pair(e_t, e_s)
Hamming Loss	$\frac{1}{nT}\sum_{i=1}^{n}\lvert\hat{R}_i\triangle R_i\rvert$ The predicted relevant emotions: $\hat{R}_i$.
Ranking Loss	$\frac{1}{n}\sum_{i=1}^{n}\frac{(\sum_{(e_t,e_s)\in R_i\times\overline{R_i}}\delta[g_t(x_i)<g_s(x_i)])}{(\lvert R_i\rvert\times\lvert\overline{R_i}\rvert)}$ where δ is the indicator function.
One Error	$\frac{1}{n}\sum_{i=1}^{n}\delta[\underset{e_t}{\operatorname{argmax}}\, g_t(x_i)\notin R_i]$
Average Precision	$\frac{1}{n}\sum_{i=1}^{n}\frac{1}{\lvert R_i\rvert}\times\sum_{t:e_t\in R_i}\frac{\lvert\{e_s\in R_i\lvert g_s(x_i)>g_t(x_i)\}\rvert}{\lvert\{e_s\lvert g_s(x_i)>g_t(x_i)\}\rvert}$
Coverage	$\frac{1}{n}\sum_{i=1}^{n}\max_{t:e_t\in R_i}\lvert\{e_s\lvert g_s(x_i)>g_t(x_i)\}\rvert$
$F1_{exam}$	$\frac{1}{n}\sum_{i=1}^{n}\frac{2\lvert R_i\cap\hat{R}_i\rvert}{(\lvert R_i\rvert+\lvert\hat{R}_i\rvert)}$
MicroF1	$F1(\sum_{t=1}^{T}TP_t,\sum_{t=1}^{T}FP_t,\sum_{t=1}^{T}TN_t,\sum_{t=1}^{T}FN_t)$
MacroF1	$\frac{1}{T}\sum_{t=1}^{T}F1(TP_t,FP_t,TN_t,FN_t)$

Table 2: Evaluation criteria for the Multi-Label Learning (MLL) methods. TP_t, FP_t, TN_t, FN_t represent the number of true positive, false positive, true negative, and false negative test examples with respect to emotion t respectively. $F1(TP_t, FP_t, TN_t, FN_t)$ represent specific binary classification metric F1 (Manning et al., 2008).

The event embeddings and event distributions used in the proposed method are derived in different ways. For long documents including News and Blogs, LDA was employed to generate event embeddings and event distributions using verbs and nouns as the input. For short texts in SemEval with the sparsity problem, Bi-term Topic Model (BTM) (Cheng et al., 2014) was chosen. The number of topics was 60. The parameters were chosen from the validation set which is 10% of the training set. The encoder was trained using a learning rate of 0.001, a dropout rate of 0.5, a window size of 1 and a layer number of 3. The number of epochs was 10 and the mini batch (Cotter et al., 2011) size was 16. For each method, 10-fold cross validation was conducted to get the final results.

The baselines can be categorized into two classes, emotion detection methods and multi-label methods. Most these baselines are either re-implemented or cited from published papers. For instance, the results of multi-label methods are re-implemented, since they are not proposed for relevant emotion ranking. The performances of some emotion detection methods, such as EDL, EmoDetect, RER and INNRER, are cited from the pub-

lished paper (Yang et al., 2018) as they use the same experimental data as ours.

Evaluation metrics typically used in multi-label learning and label ranking are employed in our experiments which are different from those of classical single-label learning systems (Sebastiani, 2001). The detailed explanations of evaluation metrics are presented in Table 2.

4.1 Compared Methods

There are several emotion detection approaches addressing multiple emotions detection from texts.

- **Emotion Distribution Learning(EDL)** (Zhou et al., 2016) learns a mapping function from sentences to their emotion distributions.
- **EmoDetect** (Wang and Pal, 2015) employs a constraint optimization framework with several constraints to obtain multiple emotions.
- **RER** (Zhou et al., 2018) uses support vector machines to predict relevant emotions and rankings in one text based on their intensities.
- **INN-RER** (Yang et al., 2018) designs a three-layer network combined with topic model to solve relevant emotion ranking.

Relevant emotion ranking can be treated as an extension of multi-label learning, so we also com-

Table 4: Comparison of different IRER-EA components."↓" indicates "the smaller the better", while "↑" indicates "the larger the better". The best performance on each evaluation measure is highlighted by boldface.

pare the proposed IRER-EA with several widely-used multi-label learning methods.

- **LIFT** (Zhang, 2011) constructs features specific to each label.
- **Rank-SVM** (Zhang and Zhou, 2014) distinguishes relevant labels from irrelevant ones with large margin strategy.
- **MLLOC** (Huang and Zhou, 2012) exploits local emotion correlations in expression data.
- **BP-MLL** (Zhang and Zhou, 2006) employs a novel error function into back propagation algorithm to capture the characteristics of multi-label learning.

For the MLL methods, linear kernel is used in LIFT. Rank-SVM uses the RBF kernel with the width σ equals to 1.

Experimental results on three corpora are shown in Table 3. It can be summarized from the table that: (1) IRER-EA performs better than state-of-art emotion detection baselines on almost all evaluation metrics across three corpora, which obviously shows the effectiveness of incorporating event information to obtain event-driven attentions for relevant emotion ranking; (2) IRER-EA achieves remarkably better results than MLL methods. It further confirms the effectiveness of IRER-EA, which uses a deep learning architecture incorporating event-driven attention for better performance.

4.2 Model Analysis

To further validate the effectiveness of event-driven attention components, we compare IRER-EA with two sub-networks based on our architectures.

- **IRER-EA(-EA)**: removes event-driven attention from IRER-EA.
- **IRER-EA(-DEA)**: removes document-level event-driven attention from IRER-EA.

Experimental results on three corpora are shown in Table 4. It can be summarized from the table that: (1) All the sub-networks cannot compete with IRER-EA on three corpora, which indicates the corpus-level and document-level event information are effective for relevant emotion ranking task; (2) IRER-EA(-DEA) performs better than IRER-EA(-EA) on most of the evaluation metrics, which verifies the effectiveness of incorporating corpus-level event-driven attention; (3) IRER-EA achieves better results than IRER-EA(-DEA) on almost all the evaluation metrics which further proves the effectiveness of document-level event-driven attention.

4.3 Case Study of Interpretability

To further investigate whether the event-driven attention is able to capture the event-associated words in a given document and provide interpretable results, we compare the results of the attention mechanisms of the word-level attentions and event-driven attentions by visualizing the weights of words in the same documents as shown in Figure 4. As the document of the News corpus and Blogs corpus are too long, we manually simplified the texts for better visualization results and provided English translations of the texts. The words marked in red represent highly-weighted ones according to the event-driven attentions, while the words with blue underlines are the

Angry Sad Shocked
Blog	**地震**过后两百个小时里，每一张前沿的照片，每一段**获救**的视频，每个爸爸妈妈发自心底的痛哭，都令我心痛。 During the two hundred hours after the **earthquake**, each photo and video about **rescue** process and the **crying** from the parents make my heart broken.	Sorrow Love
SemEval	teacher in hide after **attack** on islam stir **threat**	Fear Sad

Figure 4: Case Study of Interpretability on Three Corpora.

ones with higher attention weights according to the word-level attentions.

From the visualization results on an example News article, it can be observed that different from word-level attention that pays more attentions to emotion-associated words, such as '**chill**' which may only evoke the emotion "*Sad*", the event-driven attentions can find words indicating latent events in the document, such as '**drown**', '**death**', '**no one rescue**' which are all closely related to the event "*Suicide without rescue*', which may evoke emotions such as "*Angry*" and "*Shocked*". In an example Blog article, word-level attentions highlight emotion-associated words such as '**crying**' and '**broken**' which may evoke the emotion "*Sorrow*", while event-driven attentions focus on the event-related words such as '**earthquake**' and '**rescued**' representing the event "*Earthquake Relief*'. Finally, in an example from the SemEval corpus, we can see that the word-level attention mechanism only gives a higher attention weight to the word '**threat**' and ignores the word '**attack**', which is also an important indicator of the emotions "*Fear*" and "*Sad*". On the contrary, the event-driven attention mechanism highlights both '**attack**' and '**threat**', representing the event "*Terrorist attack*'.

In summary, we can observe from Figure 4 that: (1) Event-driven attention can capture words representing latent events in texts; (2) Compared with the word-level attention which is prone to attend on emotion-associated keywords, event-driven attention can find words representing one or more hidden events in a document, which can provide more explainable clues of which event triggers certain emotions; (3) Event-driven attention can achieve better performance especially in documents without any emotion-associated words.

5 Conclusion

In this paper, we have proposed an interpretable relevant emotion ranking model with event-driven attention. The event information is incorporated into a neural model through event-driven attentions which can provide clues of how the emotions are evoked with explainable results. Moreover, corpus-level event embeddings and document-level event distributions are incorporated respectively to consider event information comprehensively. Experimental results show that the proposed method performs better than the state-of-the-art emotion detection methods and multi-label learning methods.

Justifying Recommendations using Distantly-Labeled Reviews and Fine-Grained Aspects

Jianmo Ni, Jiacheng Li, Julian McAuley
University of California, San Diego
{jin018,j9li,jmcauley}@ucsd.edu

Abstract

Several recent works have considered the problem of generating reviews (or 'tips') as a form of *explanation* as to why a recommendation might match a user's interests. While promising, we demonstrate that existing approaches struggle (in terms of both quality and content) to generate *justifications* that are relevant to users' decision-making process. We seek to introduce new datasets and methods to address this *recommendation justification* task. In terms of data, we first propose an 'extractive' approach to identify review segments which justify users' intentions; this approach is then used to distantly label massive review corpora and construct large-scale personalized recommendation justification datasets. In terms of generation, we design two personalized generation models with this data: (1) a reference-based Seq2Seq model with aspect-planning which can generate justifications covering different aspects, and (2) an aspect-conditional masked language model which can generate diverse justifications based on templates extracted from justification histories. We conduct experiments on two real-world datasets which show that our model is capable of generating convincing and diverse justifications.

1 Introduction

Explaining, or justifying, recommendations to users has the potential to increase their transparency and reliability. However providing meaningful interpretations remains a difficult task, partly due to the black-box nature of many recommendation models, but also because we simply lack ground-truth datasets specifying what 'good' justifications ought to look like.

Previous work has sought to learn user preferences and writing styles from crowd-sourced reviews (Dong et al., 2017; Ni and McAuley, 2018) to generate explanations in the form of natural language, e.g. generating synthesized reviews similar to those that users would write about a product. However, a large portion of review text (or text from 'tips') is often of little relevance to most users' decision making (e.g. they describe verbose experiences or general endorsements) and may not be appropriate to use as explanations in terms of content and language style. As a result, existing models that learn directly from reviews (or tips) may not capture crucial information that explains users' purchases. Table 1 shows examples of reviews, tips and ideal justifications. More recently, there has been work studying the task of tip generation where tips are concise summaries of reviews (Li et al., 2017). Though tips are concise and some subset of them might be suitable as candidates for recommendation justifications, only a few e-commerce systems provide tips accompanied with reviews. Even in systems where tips are available, the number of tips is usually far smaller than the number of reviews. These approaches hence suffer from generalizability issues, especially in settings

Review examples:
I love this little stand! **The coconut mocha chiller and caramel macchiato are delicious.**
Wow what a special find. One of the most unique and special date nights my husband and I have had.
Tip examples:
Great food. Nice ambiance. Gnocchi were very good.
I can't get enough of this place.
Justification examples:
The food portions were huge.
Plain cheese quesadilla is very good and very cheap.

Table 1: In contrast to reviews and tips, we seek to automatically generate *recommendation justifications* that are more concise, concrete, and helpful for decision making. Examples of justifications from reviews, tips, and our annotated dataset are marked in bold.

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 188–197, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

where user interactions are highly sparse.

On the other hand, generating *diverse* responses is essential in personalized content generation scenarios such as justification generation. Instead of always predicting the most popular reasons, it's preferable to present diverse justifications for different users based on their personal interests. Recent work has shown that incorporating prior knowledge into generation frameworks can greatly improve diversity. Prior knowledge could include story-lines in story generation (Yao et al., 2019), or historical responses in dialogue systems (Weston et al., 2018).

In this work, our goal is to generate convincing and diverse justifications. To address the challenge of lacking ground-truth data about 'good' justifications, we propose a pipeline that can identify justifications from massive corpora of reviews or tips. We extract fine-grained aspects from justifications and build user personas and item profiles consisting of sets of representative aspects. To improve generation quality and diversity, we propose two generation models (1) a reference-based Seq2Seq model with aspect-planning, which takes previous justifications as a reference and can produce justifications based on different aspects, and (2) an aspect-conditional masked language model that can generate diverse justifications from templates extracted from previous justifications.

Our contributions are threefold:

- To facilitate recommendation justification generation, we propose a pipeline to identify justification candidates and build aspect-based user personas and item profiles from massive corpora of reviews. With this approach, we are able to build large-scale personalized justification datasets. We use these extractive justification segments in the task of explainable recommendation and show that these are better training sources instead of whole reviews.
- We propose two models based on reference attention, aspect-planning techniques and a persona-conditional masked language model. We show that adding such personalized information enables the models to generate justifications with high quality and diversity.
- We conduct extensive experiments on two real-world datasets from *Yelp* and *Amazon Clothing*. We provide an annotated dataset about 'good' justifications on the Yelp dataset and show that the binary classifier trained on this dataset generalizes well to the Amazon Clothing dataset. We study different decoding strategies and compare their effect on generation performance.

2 Dataset Generation

In this section, we introduce the pipeline to extract high quality justifications from raw user reviews. Specifically, our goal here is to identify review segments that can be used as justifications and build a personalized justification dataset upon them. Our pipeline consists of three steps:

1. Annotating a set of review segments with binary labels, *i.e.,* to determine whether they are 'good' or 'bad' justifications.
2. Training a classifier on the annotated subset and applying it to distantly label all the review segments to extract 'good' justifications for each user and item pair.
3. Applying fine-grained aspect extraction for the extracted justifications, and building user personas and item profiles.

2.1 Identifying Justifications From Reviews

The first step is to extract text segments from reviews that are appropriate to use as justifications. Instead of a complete sentence or phrase, we define each segment as an Elementary Discourse Unit (EDU; (Mann and Thompson, 1988)) which corresponds to a sequence of clauses. We use the model of Wang et al. (2018) to obtain EDUs from reviews. Recent works have shown that EDUs can improve the performance of document-level summarization (Bhatia et al., 2015) and opinion summarizaiton (Angelidis and Lapata, 2018).

After preprocessing the reviews into EDUs, we analyzed the linguistic differences between recommendation justifications and reviews, and built two rules to filter the segments that are unlikely to be suitable justifications: (1) segments with first-person or third-person pronouns, and (2) too long or short. Next, two expert annotators were exposed to 1,000 segments among those not filtered out and asked to determine whether they are 'good' justifications. Labeling was performed iteratively, followed by feedback and discussion, until the quality was aligned between the two annotators. At the end of the process, the inter-annotator agreement for the binary labeling task (*good* vs. *bad*), measured by Cohen's kappa (Cohen, 1960), was 0.927 after alignment. Then, the annotators further labeled 600 segments. Overall,

Method	F1	Recall	Precision
BOW-Xgboost	0.559	0.679	0.475
CNN	0.644	0.596	0.700
LSTM-MaxPool	0.675	0.703	0.650
BERT	**0.747**	0.700	**0.800**
BERT-SA (one epoch)	0.481	0.975	0.320
BERT-SA (three epoch)	0.491	**1.000**	0.325

Table 2: Performance for classifying review segments as good or bad for recommendation justification.

24.8% of the segments were labeled *good*.

2.2 Automatic Classification

Our next step is to propagate labels to the complete review corpus. Here we adopt BERT (Devlin et al., 2019) to fine-tune on our classification task, where a [CLS] token is added to the beginning of each segment and the final hidden state (i.e., output of BERT) corresponding to this token is fed into a linear layer to obtain the binary prediction. Cross entropy is used as the training loss.

We split the annotated dataset into Train, Dev, and Test sets with a 0.8/0.1/0.1 ratio, fine-tune the BERT classifier on the Train set and choose the best model on the Dev set. After three epochs of fine-tuning, BERT can achieve an F1-score of 0.80 on the Test set. We compare the performance of BERT with multiple baseline models: (1) a XGBoost model which uses Bags-of-Words as sentence features (2) a convolutional neural network (CNN) with three convolution layers and one linear layer (3) a long short-term memory (LSTM) (Hochreiter and Schmidhuber, 1997) network with a max-pooling layer, and a linear layer (4) a BERT sentiment classifier (BERT-SA) trained on the complete Yelp dataset for one epoch and three epochs. To obtain the pre-trained word embeddings for the CNN and LSTM models, we applied fastText (Bojanowski et al., 2016) on the *Yelp* Review dataset. We set the embedding dimension to 200 and used default values for other hyper-parameters.

Table 2 presents results for our binary classification task. The BERT classifier has higher F1-score and precision than other classifiers. The BERT-SA model after three epochs only achieves an F1-score of 0.491, which confirms the difference between sentiment analysis and our *good/bad* task, i.e., even if the segment has positive sentiment, it might be not suitable as a justification.

Yelp
The *Tuna* is pretty amazing
Appetizers and *pasta* are excellent here
An excellent *selection* of both *sweet* and savory *crepes*
It was filled with delicious *food*, fantastic *music* and *dancing*
Amazon-Cloth

Table 3: Examples of justifications with fine-grained aspects in our annotated dataset. The fine-grained aspects are italic and underlined.

2.3 Fine-grained Aspect Extraction

Finally, we extract the fine-grained aspects that each justification covers. Fine-grained aspects are properties of products that appear among a user's opinions. We adopt the method proposed by Zhang et al. (2014) to build a sentiment lexicon which includes a set of fine-grained aspects from the whole dataset. We then use simple rules to determine which aspects appear in each justification.[1] Table 3 presents a set of examples from our dataset. Each example consists of a justification that a user has written about an item, and multiple fine-grained aspects mentioned in the justification. **Note that** we only annotated the Yelp dataset, trained a classifer on that and applied the model on both Yelp and Amazon Clothing dataset. As shown in Table 3, the trained classifier works well on both datasets.

3 Approach

3.1 Problem Definition

For each user u (or item i), we build a justification reference $D = \{d_1, \ldots, d_{l_r}\}$ consisting of justifications that the user has written (or justifications about the item) on the training set, where l_r is the maximum number of justifications. We also obtain a user persona (or item profile) $A = \{a_1, \ldots, a_K\}$ based on the fine-grained aspects that the user's (or item's) previous justifications have covered, where K is the maximum number of aspects.

Given a user u and an item i, as well as the their justification reference D_u and D_i, and u's persona A_u and i's profile A_i, **our target** is to predict the

[1]For each aspect, if its singular or plural exists in the tokenized justification, then we consider that this aspect exists in that justification.

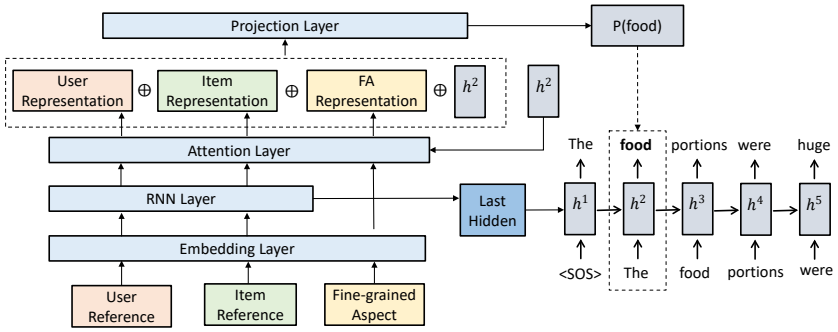

Figure 1: Structure of the reference-based Seq2Seq model with Aspect Planning

justifications $J_{u,i} = \{w_1, w_2, \ldots, w_T\}$ that would explain why item i fits user u's interests, where T is the length of the justification.

3.2 Reference-based Seq2Seq Model

Our base model follows the structure of a standard Seq2Seq (Sutskever et al., 2014) model. Our framework, called 'Ref2Seq', views the historical justifications of users and items as references and learns latent personalized features from them. Figure 1 shows the structure of our Reference-based Seq2Seq Model. It includes two components: (1) two sequence encoders that learn user and item latent representations by taking previous justifications as references; (2) a sequence decoder incorporating representations from users and items to generate personalized justifications.

Sequence Encoders. Our user encoder and sequence encoder share the same structure, which includes an embedding layer, a two-layer bi-directional GRU (Cho et al., 2014), and a projection layer. The inputs are a user (or item) reference D consisting of a set of historical justifications. These justifications pass a word embedding layer, then go through the GRU and yield a sequence of hidden states $\mathbf{e} \in \mathbb{R}^{l_s \times l_r \times n}$:

$$\mathrm{E} = \mathrm{Embedding}(D), \mathbf{e} = \mathrm{GRU}(\mathrm{E}) = \overrightarrow{\mathrm{e}} + \overleftarrow{\mathrm{e}}, \tag{1}$$

where l_s denotes the length of the sequence, n is the hidden size of the encoder GRU, $\mathrm{E} \in \mathbb{R}^{l_s \times l_r \times n}$ is the embedded sequence representation, and $\overrightarrow{e}$ and $\overleftarrow{e}$ are the hidden vectors produced by a forward and a backward GRU (respectively).

To combine information from different 'references' (i.e. justifications), the hidden states are then projected via a linear layer:

$$\hat{\mathbf{e}} = W_e \cdot \mathbf{e} + \mathbf{b}_e, \tag{2}$$

where $\hat{\mathbf{e}} \in \mathbb{R}^{l_s \times n}$ is the final output of the encoder, and $W_e \in \mathbb{R}^{l_r}$, $\mathbf{b}_e \in \mathbb{R}$ are learned parameters.

Sequence decoder. The decoder is a two-layer GRU that predicts the target words given a start token. The hidden state of the decoder is initialized using the sum of the last hidden state of the user and item encoders. The hidden state at time-step t is updated via the GRU unit based on the previous hidden state and the input word. Specifically:

$$\mathbf{h}_0 = \mathbf{e}^u_{l_s} + \mathbf{e}^i_{l_s}, \mathbf{h}_t = \mathbf{GRU}(w_t, \mathbf{h}_{t-1}), \tag{3}$$

where $\mathbf{e}^u_{l_s}$ and $\mathbf{e}^i_{l_s}$ are the last hidden states of the user and item encoder output $\hat{\mathbf{e}}_u$ and $\hat{\mathbf{e}}_i$.

To explore the relation between the reference and generation, we apply an attention fusion layer to summarize the output of each encoder. For the user and item reference encoder, the attention vector is defined as:

$$\mathbf{a}^1_t = \sum_{j=1}^{l_s} \alpha^1_{tj} \mathbf{e}_j,$$
$$\alpha^1_{tj} = \exp(\tanh({\mathbf{v}^1_\alpha}^\top (W^1_\alpha [\mathbf{e}_j; \mathbf{h}_t] + \mathbf{b}^1_\alpha)))/Z, \tag{4}$$

where $\mathbf{a}^1_t \in \mathbb{R}^n$ is an attention vector on the sequence encoder at time-step t, α^1_{tj} is an attention score over the encoder hidden state $\mathbf{e}_j$ and decoder hidden state $\mathbf{h}_t$, and Z is a normalization term.

Aspect-Planning Generation. One of the challenges for generating justifications is how to improve controllability, i.e., directly manipulate the content being generated. Inspired by 'plan-and-write' (Yao et al., 2019), we extend the base model to an Aspect-Planning Ref2Seq (AP-Ref2Seq) model where we plan a fine-grained aspect before generation. This aspect planning can be considered as an extra form of supervision instead of a hard constraint to make justification generation more controllable.

When generating the justification for user u and item i, we first provide a fine-grained aspect a as a plan. The aspect a is fed into the word embedding layer to obtain the aspect embedding $\mathrm{E_a}$. Then, we compute the scores between the embedding of the aspect and the decoder hidden state as:

$$\mathbf{a}_t^2 = \alpha_t^2 \mathrm{E}_a,$$
$$\alpha_t^2 = \exp(\tanh(\mathbf{v}_\alpha^2{}^\top (W_\alpha^2[\mathrm{E}_a; \mathbf{h}_t] + \mathbf{b}_\alpha^2)))/Z, \quad (5)$$

where $\mathbf{a}_t^2 \in \mathbb{R}^n$ is an attention vector and α_t^2 is an attention score.

The attention vectors $\mathbf{a}_{ut}^1$ of user u, $\mathbf{a}_{it}^1$ of item i, and $\mathbf{a}_t^2$ of fine-grained aspect a, are concatenated with the decoder hidden state at time-step t and projected to obtain the output word distribution P. The output probability for word w at time-step t is given by:

$$p(w_t) = \tanh(W_1[\mathbf{h}_t; \mathbf{a}_{ut}^1; \mathbf{a}_{it}^1; \mathbf{a}_t^2] + \mathbf{b}_1), \quad (6)$$

where w_t is the target word at time-step t. Given the probability $p(w_t)$ at each time step t, the model is trained using a cross-entropy loss compared against the ground-truth sequence.

3.3 Aspect Conditional Masked Language Model

Though Seq2Seq-based models can achieve high quality output, they often fail to generate *diverse* content. Recent works in natural language generation (NLG) tried to combine generation methods with information retrieval techniques to increase the generation diversity (Li et al., 2018; Baheti et al., 2018). The basic idea follows the paradigm of retrieve-and-edit—which is to first retrieve historical responses as templates, and then edit the template into new content. Since our data is annotated with fine-grained aspects, it naturally fits into this type of retrieve-and-edit paradigm. Meanwhile, masked language models have shown great performance in language modeling. Recent work (Wang and Cho, 2019; Mansimov et al., 2019) has shown that by sampling from the masked language model (e.g. BERT), it is able to generate coherent sentences.

Inspired by this work, we want to extend such an approach into a conditional version—we explore the use of an Aspect Conditional Masked Language Model (ACMLM) to generate diverse personalized justifications. Figure 2 shows the structure of our Aspect Conditional Masked Language Model. For a justification $J_{u,i}$ that user u wrote about item i, we adapt the pre-trained BERT model (Devlin et al., 2019) into an encoder-decoder network with (1) an aspect encoder which encodes the user persona and item profile into latent representations and (2) a masked language model sequence decoder that takes in a masked justification and predicts the masked tokens.

Aspect Encoder. Our aspect encoder shares the same WordPiece embeddings (Wu et al., 2016) as BERT. The encoder feeds the intersection of fine-grained aspects from the user persona and item profile $A_{ui} = \{a_1, \ldots, a_{K'}\}$ into the embedding layer and obtains the aspect embedding $\mathbf{A}_{ui} \in \mathbb{R}^{K' \times n}$, where K' is the number of common fine-grained aspects and n is the dimension of the WordPiece embeddings.

Masked Language Model Sequence Decoder. We use the masked language model in the pre-trained BERT model as our sequence decoder and add attention over the aspect encoder's output. As shown in Figure 2, the input to the decoder is a masked justification $J_{u,i}^M = \{w_1, \ldots, w_T\}$ with multiple tokens be replaced as [MASK]. The decoder's output $\mathbf{T} \in \mathbb{R}^{T \times n}$ is then fed to the attention layer to calculate an attention score with the output of the encoder:

$$\mathbf{a}_t^3 = \sum_{j=1}^{K'} \alpha_{tj}^3 \mathbf{A}_j,$$
$$\alpha_{tj}^3 = \exp(\tanh(\mathbf{v}_\alpha^3{}^\top (W_\alpha^3[\mathbf{A}_j; \mathbf{T}_t] + \mathbf{b}_\alpha^3)))/Z. \quad (7)$$

The attention vector $\mathbf{a}_t^3$ is then concatenated with the decoder hidden state at time-step t and sent to a linear projection layer to obtain the output word distribution P. The output probability for word w at time-step t is given by:

$$p(w_t) = \tanh(W_2[\mathbf{T}_t; \mathbf{a}_t^3] + \mathbf{b}_2) \quad (8)$$

where w_t is the target word at time-step t.

Masking Procedure. The original BERT paper applies a flat rate (15%) to decide whether to mask a token. Unlike their approach, we adopt a higher rate to mask fine-grained aspects since they are more important in justifications. Specifically, if we encounter a fine-grained aspect, we will replace it with a [MASK] token 30% of the time; while for other words, we will replace them with a [MASK] token 15% of the time.

During training, the model will only predict those masked tokens and calculate a cross-entropy loss on them.

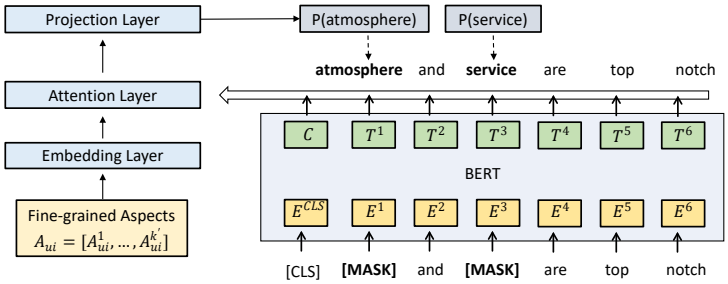

Figure 2: Structure of the Aspect Conditional Masked Language Model

Iter 0	universe [MASK] is extremely friendly and persona ##ble
Iter 5	the [MASK] is extremely friendly and persona ##ble
Iter 10	the [MASK] is extremely friendly and persona ##ble
Iter 15	the staff are extremely cool and persona ##ble
Iter 20	the staff are extra kind , persona ##ble

Table 4: Examples of the generation output of ACMLM at different iterations.

Generation by Sampling from Masked Templates. We next discuss how to generate justifications from the trained ACMLM. We follow the sampling strategy of Wang and Cho (2019) to generate justifications. Instead of generating from a sequence of all [MASK] tokens, we start with masked templates generated from historical justifications about the target item. These masked templates include prior knowledge about the item and can increase the speed of sampling convergence.

Table 4 shows an example of the generation process. We initialize the template sequence X^0 as (universe, [MASK], ..., ##ble) with length T. At each iteration i, a position t_i is sampled uniformly at random from $\{1, \ldots, T\}$ and the token at t_i (i.e. $x^i_{t_i}$) of the current sequence X^i is replaced by [MASK]. After that, we obtain the conditional probability of x_{t_i} as

$$p(x_{t_i}|X^i_{\setminus t_i} = \frac{1}{Z(X^i_{\setminus t_i})} \exp(1\mathrm{h}(x_{t_i})^\top f_\theta(X^i_{\setminus t_i}))), \quad (9)$$

where $1\mathrm{h}(x_{t_i})$ is a one-hot vector with index x_{t_i} set to 1, $X^i_{\setminus t_i}$ is the sequence we obtain after replacing the token at position t_i of X^i by [MASK], $f_\theta(X^i_{\setminus t_i})$ is the output after feeding $X^i_{\setminus t_i}$ into the ACMLM as in Equation (8), and Z is the normalization term. We then sample $\tilde{x}_{ti}$ from Equation (9), and construct the next sequence by $X^{i+1} = (x^i_1, \ldots, \tilde{x}_{ti}, \ldots, x^i_T)$. After repeating this procedure N times, the final output is considered as the generation output.[2]

4 Experiments

4.1 Datasets

With our proposed pipeline (Section 2), we construct two personalized justification datasets from existing review data—Yelp and Amazon Clothing.[3][4] We further filter those users with fewer than five justifications. For each user, we randomly hold out two samples from all of their justifications to construct the Dev and Test sets. Table 5 shows the statistics of our two datasets.

4.2 Baselines

For automatic evaluation, we consider three baselines: Item-Rand is a baseline which randomly chooses a justification from the item's historical justifications. LexRank is a strong unsupervised baseline that is widely used in text summarization (Erkan and Radev, 2004). Given all historical justifications about an item, LexRank can select one justification as the summary. We then use that as the justification for all users. Attr2Seq (Dong et al., 2017) is a Seq2Seq baseline that uses attributes (i.e. user and item identity) as input.

By default, all models use beam search during generation. Recently, there have been works showing that the generation output of sampling methods is more diverse and suitable on high-entropy tasks (Holtzman et al., 2019). To this end, we explore another decoding strategy— 'Top-k sampling' (Radford et al., 2019) in experiments

[2]We set N proportional to the length T of the initial masked template to prevent the generation diverging too much from the original template.

and include a variant of our model: Ref2Ref (Top-k).[5]

For human evaluation, we include two baselines: Ref2Seq (Review) and Ref2Seq (Tip), both of which are the same model as Ref2Seq model but trained on the original review and tip data, respectively. Comparisons with these two baselines demonstrates that training on our annotated dataset tends to generate text more suitable as justifications.

Model	R	I	D
Ref2Seq (Review)	3.02	2.39	2.10
Ref2Seq (Tip)	3.25	2.35	2.34
Ref2Seq	3.87	3.13	2.96

ACMLM	3.23	3.29	**3.42**

Table 7: Performance on Human Evaluation, where R,I,D represents Relevance, Informativeness and Diversity, respectively.

4.3 Implementation Detail

We use PyTorch[6] to implement our models.

For Req2Seq and AP-Ref2Seq, we set the hidden size and word embedding size as 256. We apply a dropout rate of 0.5 for the encoder and 0.2 for the decoder. The size of the justification reference l_r is set to 5 and the number of fine-grained aspects K in the user persona and item profile is set to 30. We train the model using Adam with learning rate $2e^{-4}$ and stop training either when it reaches 20 epochs or the perplexity does not improve (on the Dev set). For ACMLM, we build our model based on the BERT implementation from HuggingFace.[7] We initialize our decoder using the pre-trained 'Bert-base' model and set the max sequence length to 30. We train the model for 5 epochs using Adam with learning rate $2e^{-5}$. For models using beam search, we set the beam size as 10. For models using 'top-k' sampling, we set k to 5. For ACMLM, we use a burn-in step equal to the length of the initial sequence. Our data and code are available online.[8]

4.4 Automatic Evaluation

For automatic evaluation, we use BLEU, Distinct-1, and Distinct-2 (Li et al., 2015) to measure the performance of our model. As shown in Table 6, our reference-based models achieve the highest BLEU scores on both datasets except for BLEU-3 on Yelp. This confirms that Ref2Seq is able to capture user and item content to generate the most relevant content, compared with unpersonalized models such as LexRank and personalized models that do not leverage historical justifications such as Attr2Seq.

On the other hand, recent works have reported that models achieving higher diversity scores will have lower scores on overlap-based metrics (e.g. BLEU) for open-domain generation tasks (Baheti et al., 2018; Gao et al., 2018). We make a similar observation for our personalized justifi-

[5] At each time step, the next word is sampled from the top k possible next tokens, according to their probabilities.

Model	Shake Shack	Teharu Sushi	MGM Grand Hotel
Ground Truth	The burger was good	The rolls are pretty great , typical rolls not that many specials	Room was very clean comfortable
LexRank	A great burger and fries.	Sushi ?	Great rooms.
Ref2Seq (Review)	i love trader joe 's , i love trader joe 's	the food was good and the service was great	i love this place ! the food is always good and the service is always great
Ref2Seq (Tip)	this place is awesome	love this place	come here
Ref2Seq	this place has some of the best burgers	the sushi is delicious	the room was nice
Ref2Seq (Top-k)	the fries are amazing	fresh and delicious sushi	open hotel for hours
ACMLM	breakfast sandwiches are overall very filling	overall fun experience with half price sushi	family style dinner , long time shopping trip to vegas, family dining , cheap lunch

Table 8: Comparisons of the generated justifications from different models for three businesses on the Yelp dataset.

cation generation task. As shown in Table 6, both sampling-based methods Ref2Seq (Top-k) and ACMLM achieve higher Distinct-1 and Distinct-2, while their BLEU scores are lower than Seq2Seq based models using beam search. Therefore, we also perform human evaluation to validate the generation quality of our proposed methods.

4.5 Human Evaluation

We conduct human evaluation on three aspects: (1) *Relevance* measures whether the generated output contains information relevant to an item; (2) *Informativeness* measures whether the generated justification includes specific information that is helpful to users; and (3) *Diversity* measures how distinct the generated output is compared with other justifications.

We focus on the Yelp dataset and sample 100 generated examples from each of the five models as shown in Table 7. Human annotators are asked to give a score in the range [1,5] (lowest to highest) for each metric. Each example is rated by at least three annotators. The results show that both Ref2Seq (Top-k) and ACMLM achieve higher scores on Diversity and Informativeness compared to other models.

4.6 Qualitative Analysis

Here we study the following two qualitative questions:

RQ1: How do training data and methods affect generation? As Table 8 shows, models trained on reviews and tips tend to generate generic phrases (such as 'i love this place') which often do not include information that helps users to make decisions. Other models trained on the justification datasets tend to mention concrete information (e.g. different aspects). LexRank tends to generate relevant but short content. Meanwhile, sampling-based models are able to generate more diverse content.

Dataset	Aspects	Generated Output
Yelp	dining	the dining room is nice
	pastry	the pastries were pretty good
	chicken	the chicken fried rice is the best
	sandwich	the pulled pork sandwich is the best thing on the menu
Amazon-Clothing	product	great product , fast shippong
	price	design is nice , good price
	leather	comfortable leather sneakers . classic
	walking	sturdy , great city walking shoes

Table 9: Generated justifications from AP-Ref2Seq. The planned aspects are randomly selected from users' personas.

RQ2: How does aspect planning affect generation? To mitigate the trade-off between diversity and relevance, one approach is to add more constraints during generation such as constrained Beam Search (Anderson et al., 2017). In our work, we extend our base model Ref2Seq by incorporating aspect-planning to guide generation. As shown in Table 9, most planned aspects are present in the generated outputs of AP-Req2Seq.

5 Related Work

Explainable Recommendation There has been a line of work that studies how to improve the

explainability of recommender systems. Catherine and Cohen (2017) learn latent representations of review text to predict ratings. These representations are then used to find the most helpful reviews for given a particular user and item pair. Another popular direction is to generate text to justify recommendations. Dong et al. (2017) proposed an attribute-to-sequence model to generate product reviews which utilizes categorical attributes. Ni et al. (2017) developed a multi-task learning method that considers collaborative filter and review generation. Li et al. (2019b) generated tips by considering 'persona' information which can capture the language style of users and characteristics of items. However, these works use whole reviews or tips as training examples, which may not be appropriate due to the quality of review text. More recently, Liu et al. (2019) proposed a framework to generate fine-grained explanations for text classification. To achieve labels for human-readable explanations, they constructed a dataset from a website which provides ratings and fine-grained summaries written by users. Unfortunately, most websites do not provide such fine-grained information. On the other hand, our work identifies justifications from reviews, uses them as training examples and shows these are better data source for explainable recommendation via extensive experiments.

Diversity-aware NLG Diversity is an important aspect of NLG systems. Recent works have focused on digesting prior knowledge to improve generation diversity. Yao et al. (2019) proposed a method to incorporate planned story-lines in story generation. Li et al. (2019a) developed an aspect-aware coarse-to-fine review generation method. They predict an aspect for each sentence in the review to capture the content flow. Given the aspects, a sequence of sentence sketches is generated and a decoder will fill in the slots of each sketch. In dialogue systems, several works have studied frameworks to extract templates from historical responses, which are then edited to form new responses (Weston et al., 2018; Wu et al., 2018). Similarly, the extract-and-edit paradigm has been studied in style transfer tasks in NLG (Li et al., 2018). Wu et al. (2019) proposed an attribute aware masked language model for non-parallel sentiment transfer. They first mask out the sentimental tokens and then train a masked language model to infill the masked positions for target sentiment. In this work, we also introduces a conditional masked language model but considers more fine-grained aspects.

6 Conclusion

In this work, we studied the problem of personalized justification generation. To build high quality justification datasets, we provided an annotated dataset and proposed a pipeline to extract justifications from massive review corpora. To generate convincing and diverse justifications, we developed two models: (1) Ref2Seq which leverages historical justifications as references during generation; and (2) ACMLM, which is an aspect conditional model built on a pre-trained masked language model. Our experiments showed that Ref2Seq achieves higher scores (in terms of BLEU) and ACMLM achieves higher diversity scores compared with baselines. Human evaluation showed that reference-based models obtain high relevance scores and sampling based methods led to more diverse and informative outputs. Finally, we showed that aspect-planning is a promising way to guide generation to produce personlized and relevant justifications.

Abstract

Customers ask questions and customer service staffs answer their questions, which is the basic service model via multi-turn customer service (CS) dialogues on E-commerce platforms. Existing studies fail to provide comprehensive service satisfaction analysis, namely satisfaction polarity classification (e.g., well satisfied, met and unsatisfied) and sentimental utterance identification (e.g., positive, neutral and negative). In this paper, we conduct a pilot study on the task of service satisfaction analysis (SSA) based on multi-turn CS dialogues. We propose an extensible Context-Assisted Multiple Instance Learning (CAMIL) model to predict the sentiments of all the customer utterances and then aggregate those sentiments into service satisfaction polarity. After that, we propose a novel Context Clue Matching Mechanism (CCMM) to enhance the representations of all customer utterances with their matched context clues, i.e., sentiment and reasoning clues. We construct two CS dialogue datasets from a top E-commerce platform. Extensive experimental results are presented and contrasted against a few previous models to demonstrate the efficacy of our model. [1]

1 Introduction

In the past decades, E-commerce platforms, such as Amazon.com and Taobao.com[2], have evolved into the most comprehensive and prosperous business ecosystems. They not only deeply involve other traditional businesses such as payment and logistics, but also largely transform every aspect of retailing. Taking the customer service on Taobao as an example, third-party retailers are always online to answer any question at any stage of pre-sale, sale and after-sale, through an instant messenger within the platform. The topics of relevant customer service dialogues involve various aspects of online shopping, such as product information, return or exchange, logistics, etc. Based on a previous survey, over 77% of buyers on Taobao communicated with sellers before placing an order (Gao and Zhang, 2011). Therefore, such service dialogue data contain very important clues for sellers to improve their service quality.

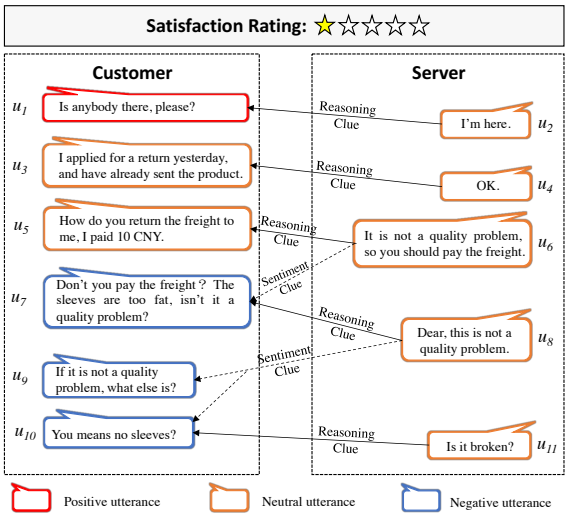

Figure 1: Customer utterance and context clues (i.e., sentiment and reasoning clues) alignments in multi-turn dialogue utterances of an *unsatisfied* customer service. The utterances (u_i) with *positive/neutral/negative* sentiments are denoted by *red*/*orange*/*blue* boxes.

Figure 1 depicts an exemplar dialogue of online customer service, which has a form of multi-turn dialogue between the customer and the customer service staff (or "the server" for short). In this dialogue, the customer is asking for refunding the freight he/she paid for sending back the product. At the end of service dialogue, the E-commerce platform invites the customer to score the service quality (e.g., using 1-5 stars denoting the extent of

[1]We have released the dataset at https://github.com/songkaisong/ssa.
[2]Taobao is a top E-commerce platform in China.

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 198–207, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

satisfaction from "*very unsatisfied*" to "*very satisfied*") via instant messages or a grading interface. Evidently, the customer feels unsatisfied with the response. Automatically detecting such unsatisfactory service is important. For the retail shopkeepers, they can quickly locate such service dialogue and find out the reason to take remedial actions. For the platform, by detecting and analyzing such cases, the platform can define clear-cut rules, say "*not fitting well is not a quality issue, and the buyers should pay the freight for freight.*"

In this paper, we define a new task named **Service Satisfaction Analysis (SSA)**: *Given a service dialogue between the customer and the service staff, the task aims at predicting the customer's satisfaction, i.e., if the customer is satisfied by the responses from the service staff, meanwhile locating possible sentiment reasons, i.e., sentiment identification of the customer utterances*. For example, Figure 1 gives the satisfaction prediction of the service as "*unsatisfied*" and identifies the detailed sentiments of all customer utterances. Obviously, SSA focuses on two special cases of text classification over predefined satisfaction labels ("*well satisfied/met/unsatisfied*") and predefined sentiment labels ("*positive/neutral/negative*"). Text classification has been widely studied for decades, such as sentiment classification on product reviews (Song et al., 2017; Chen et al., 2017; Li et al., 2018, 2019), stance classification on tweets or blogs (Du et al., 2017; Liu, 2010), emotion classification for chit-chat (Majumder et al., 2018), etc. However, all these methods cannot deal with these two classification tasks simultaneously in a unified framework. Although recent studies on multi-task learning framework suggest that closely related tasks can improve each other mutually from separated supervision information (Ma et al., 2018; Cerisara et al., 2018; Wang et al., 2018b), the acquisition of sentence (or utterance)-level sentiment labels, which is required by multi-task learning, remains a laborious and expensive endeavor. In contrast, coarse-grained document (or dialogue)-level annotations are relatively easy to obtain due to the widespread use of opinion grading interfaces (e.g., ratings).

Recently, *Multiple Instance Learning* (MIL) framework is adopted for performing document-level and sentence-level sentiment classification simultaneously while only using document-level sentiment annotations (Zhou et al., 2009; Wang and Wan, 2018). However, these models are trained based on plain textual data which are in a much simpler form than our multi-turn dialogue structure. Specifically, customer service dialogue has unique characteristics. Customer utterances tend to have more sentiment changes during the customer service dialogue which affect customer's final satisfaction. Figure 1 illustrates that satisfaction polarity ("*unsatisfied*") is mostly embedded in the last few customer utterances (i.e., u_7, u_9 and u_{10})[3]. On the other hand, a well-trained server varies less by always expressing positive/neutral utterances which contain helpful sentiment clues and reasoning clues. In this work, both sentiment clue and reasoning clue are called context clues which can directly or indirectly influence satisfaction polarity and need to be given special treatments in the model.

To deal with the issues, we propose a novel and extensible Context-Assisted Multiple Instance Learning (CAMIL) model for the new SSA task, and utterance-level sentiment classification and dialogue-level satisfaction classification will be done simultaneously only under the supervision of satisfaction labels. We motivate the idea of our context-assisted modeling solution based on the hypothesis that if a customer utterance does not have enough information to create a sound vector representation for sentiment prediction, we try to enhance it with a complementary representation derived from context clues via our position-guided Context Clue Matching Mechanism (CCMM). Overall, our contributions are three-fold:

- We introduce a new SSA task based on customer service dialogues. We thus propose a novel CAMIL model to predict the sentiment distributions of all customer utterances, and then aggregate those distributions to determine the final satisfaction polarity.
- We further propose an automatic CCMM to associate each customer utterance with its most relevant context clues, and then generate a complementary vector which enhances the customer utterance representation for better sentiment classification to boost the final satisfaction classification.

[3]Given a specific customer utterance (u_7) in Figure 1, the server utterance (u_6) triggers the change of customer sentiment from "*neutral*" to "*negative*", and the server utterance (u_8) answers the question "*this is not a quality problem*".

- Two real-world CS dialogue datasets are collected from a top E-commerce platform. The experimental results demonstrate that our model is effective for the SSA task.

2 Related Work

Service satisfaction analysis (SSA) is closely related to sentiment analysis (SA), because the sentiment of the customer utterances is a basic clue signaling the customer's satisfaction. Existing SA works aim to predict sentiment polarities (*positive*, *neutral* and *negative*) for subjective texts in different granularities, such as word (Feng et al., 2015; Song et al., 2016), sentence (Ma et al., 2017), short text (Song et al., 2015) and document (Yang et al., 2018a). In these studies, subjective texts are always considered as a sequence of words[4]. More recently, some researchers started to explore the utterance-level structure for sentiment classification, such as modeling dialogues via a hierarchical RNN in both word level and utterance level (Cerisara et al., 2018) or keeping track of sentiment states of dialogue participants (Majumder et al., 2018). However, none of these works can do dialogue-level satisfaction classification and utterance-level sentiment classification simultaneously. Recent studies (Cerisara et al., 2018; Ma et al., 2018; Wang et al., 2018b) employing multi-task learning open a possibility to address this issue. However, these models must be trained under the supervision of both document-level and sentence-level sentiment labels in which the later are generally not easy to obtain.

Sentiment classification based on Multiple Instance Learning (MIL) frameworks (Wang and Wan, 2018; Angelidis and Lapata, 2018) aims to perform document-level and sentence-level sentiment classification tasks simultaneously with the supervision of document labels only. Angelidis and Lapata (2018) proposed an MIL model for fine-grained sentiment analysis. Wang and Wan (2018) further applied the model to peer-reviewed research papers by integrating a memory built from abstracts. However, their models are not suitable for our SSA task because they ignore the dialogue structure of arbitrary interactions between customers and servers. In contrast, we consider complex multi-turn interactions within dialogues and explore context clue matching between customer utterances and server utterances for multi-tasking in the SSA task. Specifically, we improve the basic MIL models by proposing a position-guided automatic context clue matching mechanism (CCMM) to conduct customer utterance and context clues alignments for better sentiment classification to boost satisfaction classification. Other related work related to sentiment analysis for subjective texts in different granularities include (Yang et al., 2016; Wu and Huang, 2016; Yang et al., 2018b; Du et al., 2017; Wang et al., 2018a; Song et al., 2019).

[4]From plain sentiment analysis viewpoint, sentence and utterance are treated the same since a dialogue is considered as a chunk of plain texts and the matching between utterances is ignored. So, an utterance is seen as a sentence and a dialogue as a document. Here, we use sentence and utterance interchangeably when it comes to plain sentiment analysis models.

3 Context-Assisted MIL Network

In order to predict service satisfaction and identify sentiments of all customer utterances with available satisfaction labels, we propose a CAMIL model based on multiple instance learning approach. Figure 2 shows the architecture of our model which consists of three layers: *Input Representation Layer*, *Sentiment Classification Layer* and *Satisfaction Classification Layer*. In this section, we will describe the model in detail.

3.1 Input Representation Layer

Let each utterance $u_i = \left[w_1, ..., w_{|u_i|}\right]$ be a sequence of words. By adopting word embeddings and semantic composition models such as Recurrent Neural Network (RNN), we can learn the utterance representation. In this work, we adopt a standard LSTM model (Hochreiter and Schmidhuber, 1997) to learn a fixed-size utterance representation $\boldsymbol{v}_{u_i} \in \mathbb{R}^k$, where k is the size of LSTM hidden state. Specifically, we first convert the words in each utterance u_i to the corresponding word embeddings $\boldsymbol{E}_{u_i} \in \mathbb{R}^{d \times |u_i|}$ which are then fed into a LSTM for obtaining the last hidden state as the $\boldsymbol{v}_{u_i}$, where d is the dimensionality of word embeddings. Formally, we have $\boldsymbol{v}_{u_i} = \mathrm{LSTM}(\boldsymbol{E}_{u_i})$.

We conjecture that the participants (i.e., customer and server) play different roles in CS dialogue. Our hypothesis is that satisfaction polarity can be more or less conveyed by the sentiments of key customer utterances, and meanwhile the sentiments of server utterances are generally polite or non-negative and contain text with context clues which complement the target customer's ut-

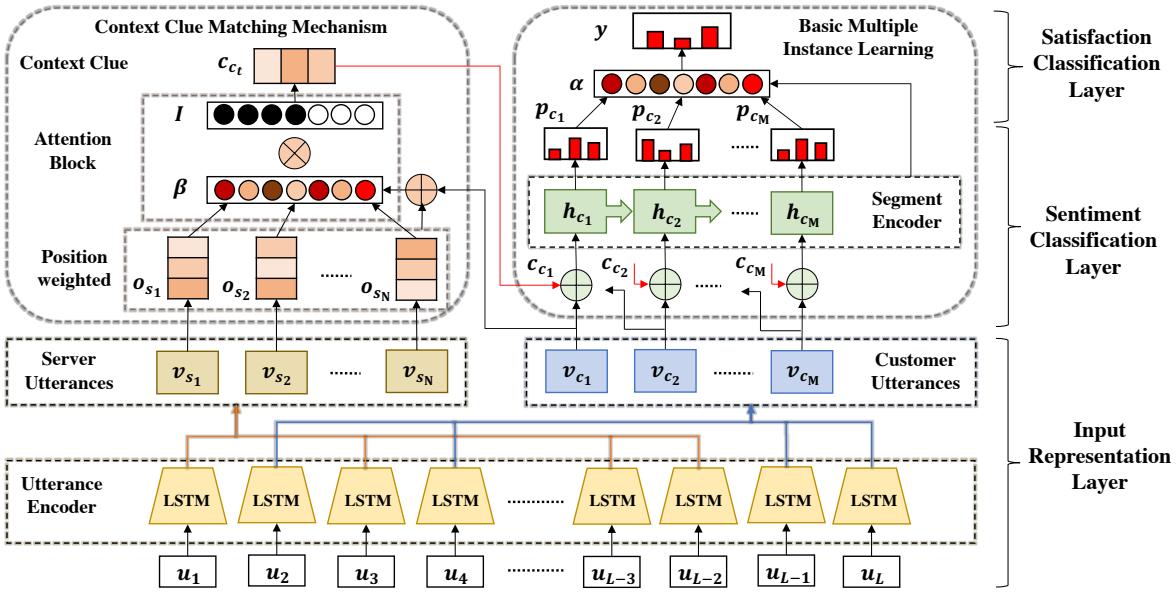

Figure 2: The architecture of our Context-Assisted Multiple Instance Learning (CAMIL) network. The model consists of four modules: Input Representation Layer, Sentiment Classification Layer, Satisfaction Classification Layer and Context Clue Matching Mechanism.

terances and indirectly affect satisfaction polarity. Thus, we separately denote the customer utterance representations as $\{\boldsymbol{v}_{c_1}, \boldsymbol{v}_{c_2}, ..., \boldsymbol{v}_{c_M}\}$ and server utterance representations as $\{\boldsymbol{v}_{s_1}, \boldsymbol{v}_{s_2}, ..., \boldsymbol{v}_{s_N}\}$, where $M + N = L$ and L is the total number of utterances in the dialogue.

3.2 Sentiment Classification Layer

Customer utterances tend to have more direct impact on the dominating satisfaction polarity. However, short utterance texts may not contain enough information for semantic representation. Thus, considering context to enhance utterance representation is a natural and reasonable choice. Given a specific customer utterance vector $\boldsymbol{v}_{c_t}$, we use a context clue matching mechanism, namely CCMM (see Section 4), to produce matched context representation $\boldsymbol{c}_{c_t} \in \mathbb{R}^k$ as below:

$$\boldsymbol{c}_{c_t} = \text{CCMM}\left(\boldsymbol{v}_{c_t}, \{\boldsymbol{v}_{s_{t'}} | 1 \leq t' \leq N\}\right) \quad (1)$$

where $\boldsymbol{v}_{s_{t'}}$ is any server utterance representation.

After that, $\boldsymbol{v}_{c_t}$ can be enhanced by $\boldsymbol{c}_{c_t}$ via concatenation for a combined representation $\bar{\boldsymbol{v}}_{c_t} = \boldsymbol{v}_{c_t} \oplus \boldsymbol{c}_{c_t}$. Compared to $\boldsymbol{v}_{c_t}$, $\bar{\boldsymbol{v}}_{c_t} \in \mathbb{R}^{2k}$ contains more evidence for sentiment prediction. Then, we feed the representation sequence $\{\bar{\boldsymbol{v}}_{c_1}, \bar{\boldsymbol{v}}_{c_2}, ..., \bar{\boldsymbol{v}}_{c_M}\}$ into a standard LSTM for obtaining a segment representation $\boldsymbol{h}_{c_t} \in \mathbb{R}^k$ at each time step t, i.e., $\boldsymbol{h}_{c_t} = \text{LSTM}\left(\bar{\boldsymbol{v}}_{c_t}\right)$.

Finally, each segment representation $\boldsymbol{h}_{c_t}$ is fed into a linear layer and then a softmax function for predicting its sentiment distribution over sentiment labels $\mathcal{G} = \{\textit{positive, neutral, negative}\}$:

$$\boldsymbol{p}_{c_t} = \text{softmax}(\mathbf{W}^s \boldsymbol{h}_{c_t} + \boldsymbol{b}^s) \quad (2)$$

where $\mathbf{W}^s \in \mathbb{R}^{|\mathcal{G}| \times k}$ and $\boldsymbol{b}^s \in \mathbb{R}^{|\mathcal{G}|}$ are trainable parameters shared across all segments, and $\boldsymbol{p}_{c_t} \in \mathbb{R}^{|\mathcal{G}|}$ is the sentiment distribution for utterance u_{c_t}.

3.3 Satisfaction Classification Layer

In the simplest case, satisfaction polarities $\mathcal{C} = \{\textit{well satisfied, met, unsatisfied}\}$ can be computed by averaging all predicted sentiment distributions of customer utterances as $\boldsymbol{y} = \frac{1}{M} \sum_{t \in [1,M]} \boldsymbol{p}_{c_t}$. However, it is a crude way of combining sentiment distributions uniformly, as not all distributions convey equally important sentiment clues. In Figure 1, for example, the satisfaction polarity ("unsatisfied") is mostly determined by customer utterances u_7, u_9 and u_{10} which are relatively more crucial than other ones. We opt for an attention mechanism to reward segments that are more likely to be good sentiment predictors. Therefore, we measure the importance of each segment representation $\boldsymbol{h}_{c_t}$ through a scoring function using feed forward neural network as below:

$$\alpha_{c_t} = \text{softmax}\left(\boldsymbol{v}^{\mathrm{T}} \tanh(\boldsymbol{W}^u \boldsymbol{h}_{c_t} + \boldsymbol{b}^u)\right) \quad (3)$$

where $\mathbf{W}^u \in \mathbb{R}^{k\times k}$, $\boldsymbol{b}^u \in \mathbb{R}^k$ and $\boldsymbol{v} \in \mathbb{R}^k$ are trainable parameters, $\boldsymbol{v}$ can be seen as a high-level representation of a fixed query "*what is the informative segment*" like that used in (Yang et al., 2016). Finally, we obtain the satisfaction distribution $\boldsymbol{y} \in \mathbb{R}^{|\mathcal{C}|}$ as the weighted sum of sentiment distributions of all the customer utterances by:

$$\boldsymbol{y} = \sum_{t\in[1,\mathrm{M}]} \alpha_{c_t} \boldsymbol{p}_{c_t} \tag{4}$$

3.4 Training and Parameter Learning

Note that in the training dataset, our approach only needs the dialogue's satisfaction labels while the utterance sentiment labels are unobserved. Therefore, we use the categorical cross-entropy loss to minimize the error between the distribution of the output satisfaction polarity and that of the gold-standard satisfaction label of the dialogue by:

$$\mathcal{L}(\Theta) = -\sum_{j\in[1,T]} \sum_{i\in\mathcal{C}} g_i^j \log(y_i^j) \tag{5}$$

where g_i^j is 1 or 0 indicating whether the i^{th} class is a correct answer for the j^{th} training instance, y_i^j is the predicted satisfaction probability distribution, and Θ denotes the trainable parameter set.

After learning Θ, we feed each test instance into the final model, and the label with the highest probability stands for the predicted satisfaction polarity. We use back propagation to calculate the gradients of all the model parameters, and update them with Momentum optimizer (Qian, 1999).

4 Context Clue Matching Mechanism

Server utterances provide helpful context clues which can be defined as sentiment and reasoning clues by the positions of server utterances. Thus, we introduce the position-guided automatic context clue matching mechanism (CCMM) used to match each customer utterance with its most related server utterances, which contain two layers: the *position attention layer* and the *utterance attention layer*.

Sentiment and Reasoning Clues: Server utterances provide helpful context clues for each targeted customer utterance. Here, we aim to locate helpful context clues in server utterances which are categorized as sentiment clues and reasoning clues. Sentiment clues refer to the server utterances that appear preceding the targeted customer utterance and trigger its sentiment expression, such as server utterance u_6 leading to customer displeasure of the utterance u_7 in the Figure 1. Reasoning clues are the server utterances that appear following the targeted customer utterance and respond to its concerns, such as server utterance u_6 responding to the customer utterance u_5 in the Figure 1. Both types of clues are identified by the proposed attention layers along with position information.

Position Attention Layer: Typically, customer utterances are more likely to be triggered or answered by the server utterances near them. Let $p(\cdot)$ denote the position function of any utterance in the original dialogue, such as $p(u_{c_2}) = 3$ in Figure 1. For any customer utterance u_{c_t}, the preceding server utterances $\{u_{s_{t'}} | p(u_{s_{t'}}) < p(u_{c_t})\}$ may provide sentiment clues, and the following server utterances $\{u_{s_{t'}} | p(u_{s_{t'}}) > p(u_{c_t})\}$ may contain reasoning clues. By considering both directions, we compute the position attention weight $g(\cdot)$ by:

$$g(u_{c_t}, u_{s_{t'}}) = 1 - \frac{|p(u_{c_t}) - p(u_{s_{t'}})|}{L} \tag{6}$$

Then, the weighted output after this layer is formulated as below:

$$\boldsymbol{o}_{s_{t'}} = g(u_{c_t}, u_{s_{t'}}) * \boldsymbol{h}_{s_{t'}} * I(u_{c_t}, u_{s_{t'}}) \tag{7}$$

where $\boldsymbol{o}_{s_{t'}} \in \mathbb{R}^k$ is the weighted $\boldsymbol{h}_{s_{t'}}$ for $t' \in [1, N]$, the notation $I(\cdot)$ denotes a masking function which can be used to reserve either only sentiment clues (i.e., if $p(u_{c_t}) > p(u_{s_{t'}})$, $I(u_{c_t}, u_{s_{t'}})$ equals to 1, or 0 otherwise) or only reasoning clues (i.e., if $p(u_{c_t}) < p(u_{s_{t'}})$, $I(u_{c_t}, u_{s_{t'}})$ equals to 1, or 0 otherwise). Here, we suggest to consider both sentiment and reasoning clues, so $I(u_{c_t}, u_{s_{t'}})$ is a constant 1. Finally, we construct memory $\boldsymbol{O} \in \mathbb{R}^{k\times N}$ as below:

$$\boldsymbol{O} = [\boldsymbol{o}_{s_1}; \boldsymbol{o}_{s_2}; \ldots; \boldsymbol{o}_{s_\mathrm{N}}] \tag{8}$$

Utterance Attention Layer: Only a fraction of server utterances can match every customer utterance in sentiment or content, such as the exemplar dialogue in Figure 1. So, we introduce an attention strategy which enables our model to attend on server utterances of different importance when constructing a complementary context representation for any customer utterance. Considering customer utterance representation $\boldsymbol{h}_{c_t}$ as an index, we can produce a context vector $\boldsymbol{c}_{c_t} \in \mathbb{R}^k$ using a weighted sum of each piece $\boldsymbol{o}_{s_{t'}}$ of memory $\mathbf{O}$:

$$\boldsymbol{c}_{c_t} = \sum_{t'\in[1,N]} \beta_{s_{t'}} \boldsymbol{o}_{s_{t'}} \tag{9}$$

Statistics items	Clothes	Makeup
# Dialogues	10,000	3,540
# US (unsatisfied)	2,302	1,180
# MT (met)	6,399	1,180

Table 1: Statistics of the datasets we collected.

where $\beta_{s_{t'}} \in [0, 1]$ is the attention weight calculated based on a scoring function using a feed forward neural network as follow:

$$\beta_{s_{t'}} = \text{softmax}\left(\bar{\mathbf{v}}^{\mathrm{T}} \tanh(\mathbf{W}^c \begin{bmatrix} \boldsymbol{o}_{s_{t'}} \\ \boldsymbol{h}_{c_t} \end{bmatrix} + \boldsymbol{b}^c)\right) \tag{10}$$

where $\mathbf{W}^c \in \mathbb{R}^{2k \times 2k}$, $\bar{\mathbf{v}} \in \mathbb{R}^{2k}$ and $\boldsymbol{b}^c \in \mathbb{R}^{2k}$ are trainable parameters.

5 Experiments and Results

5.1 Dataset and Experimental Settings

Our experiments are conducted based on two Chinese CS dialogue datasets, namely **Clothes** and **Makeup**, collected from a top E-commerce platform. Note that our proposed method is language independent and can be applied to other languages directly. **Clothes** is a corpus with 10K dialogues in the *Clothes* domain and **Makeup** is a balanced corpus with 3,540 dialogues in the *Makeup* domain. Both datasets have service satisfaction ratings in 1-5 stars from customer feedbacks. Meanwhile, we also annotate all the utterances in both datasets with sentiment labels for testing. In this study, we conduct two classification tasks: one is to predict in three satisfaction classes, i.e., "*unsatisfied*" (1-2 stars), "*met*" (3 stars) and "*satisfied*" (4-5 stars), and the other is to predict in three sentiment classes, i.e., "*negative/neutral/positive*". All texts are tokenized by a popular Chinese word segmentation utility called jieba[5]. After preprocessing, the datasets are partitioned for training, validation and test with a 80/10/10 split. A summary of statistics for both datasets are given in Table 1.

For all the methods, we apply fine-tuning for the word vectors, which can improve the performance. The word vectors are initialized by word embeddings that are trained on both datasets with CBOW (Mikolov et al., 2013), where the dimension is 300 and the vocabulary size is 23.3K. Other trainable model parameters are initialized by sampling values from a uniform distribution $\mathcal{U}(-0.01, 0.01)$. The size of LSTM hidden states k is set as 128. The hyper-parameters are tuned on the validation set. Specifically, the initial learning rate is fixed as 0.1, the dropout rate is 0.2, the batch size is 32 and the number of epochs is 20. The performances of both satisfaction and sentiment classifications are evaluated using standard *Macro F1* and *Accuracy*.

5.2 Comparative Study

We compare our proposed approach with the following state-of-the-art Sentiment Analysis (SA) methods which can be grouped into two types: plain SA models and dialogue SA models.

Plain SA models consider dialogue as plain text and ignore utterance matching, say, utterance is seen as sentence and dialogue as document.

1) **LSTM**: We use word vectors as the input of a standard LSTM (Hochreiter and Schmidhuber, 1997) and feed the last hidden state into a softmax layer for satisfaction prediction.

2) **HAN**: A hierarchical attention network for document classification (Yang et al., 2016), which has two levels of attention mechanisms applied at word- and utterance-level, enabling it to attend differentially to more and less important content when constructing the dialogue representation and feeding it into a softmax layer for classification.

3) **HRN**: A hierarchical recurrent network for joint sentiment and act sequence recognition (Cerisara et al., 2018). It uses a bi-directional LSTM to represent utterances which are then fed into a standard LSTM for dialogue representation as the input of a softmax layer for classification.

4) **MILNET**: A multiple instance learning network for document-level and sentence-level sentiment analysis (Angelidis and Lapata, 2018). The original method is designed for plain textual data, which does not consider CS dialogue structure. In addition, their method ignores long-range dependencies among customer sentiments (i.e., without segment encoder in Figure 2).

Dialogue SA models consider utterance matching between customer and server utterances.

5) **HMN**: A hierarchical matching network for sentiment analysis, which uses a question-answer bidirectional matching layer to learn the matching

[5] https://pypi.org/project/jieba/

vector of each QA pair (i.e., customer utterance, server utterance) and then characterizes the importance of the generated matching vectors via a self-matching attention layer (Shen et al., 2018). However, the amount of pairs within a dialogue is huge, which leads to expensive calculations. Meanwhile, it considers the sentiments of server utterances, which will mislead final prediction.

6) **CAMIL**$_s$, **CAMIL**$_r$ and **CAMIL**$_{full}$: Our CAMIL models with only sentiment clues, only reasoning clues, and both of them, respectively, by setting masking function (see Equation 7).

All the methods are implemented by ourselves with TensorFlow[6] and run on a server configured with a Tesla V100 GPU, 2 CPU and 32G memory.

Results and Analysis: The results of comparisons are reported in Table 2. It indicates that LSTM cannot compete with other methods because it simply considers dialogues as word sequences but ignores the utterance matching. HAN and HRN perform much better by using a two-layer architecture (i.e., utterance and dialogue), but they ignore the utterance interactions. Besides, HRN treats the sentiment analysis task and the service satisfaction analysis task separately, and ignores their sentiment dependence. HMN uses a heuristic question-answering matching strategy, which is not enough flexible and easily causes mismatching issues. MILNET is the most related work, but its simplistic alignment model weakens prediction performance when facing on our complex customer service dialogue structure. MILNET however does not consider the dialogue structure and introduces unrelated sentiments from server utterances. CAMIL$_r$ and CAMIL$_s$ only consider either sentiment or reasoning clues, so they cannot compete with CAMIL$_{full}$ which considers both in dialogues. Partially configured model CAMIL_r (or CAMIL_s) only considers sentiment (or reasoning) clues and performs worse than our full model CAMIL. This verifies that both types of clues are helpful and complementary, and they should be employed simultaneously.

On Clothes corpus, compared to the *met* class, the performances of all models on the *satisfied* class are much worse, because when the two classes cannot be well distinguished the models tend to predict the majority class (i.e., *met*) to minimize the loss. On Makeup corpus which is a balanced dataset, the performances on the *met* and *satisfied* classes are less distinctive, but both are consistently worse than the *unsatisfied* class.

5.3 Ablation Study

Different model configurations can largely affect the performance. We implement several model variants for ablation tests: **Server** and **Customer** consider only server and customer utterances in a dialogue, respectively. **NoPos** ignores the prior position information. **Average** takes the average of all the sentiment distributions for classification. **Voting** directly maps the majority sentiment into satisfaction prediction, i.e., negative $\rightarrow$ unsatisfied, neutral $\rightarrow$ met, positive $\rightarrow$ well-satisfied. The results of comparisons are reported in Table 3.

In Table 3, we can observe that **Customer** outperforms **Server** by a large margin, which indicates that service satisfaction is mostly related to

the sentiments embedded in the customer utterances. However, its performance is still lower than CAMIL$_{full}$, suggesting that server utterances can provide helpful context clues. NoPos performs well but worse than CAMIL$_{full}$ since the position information provides prior knowledge for guiding context clue matching. Average and Voting are sub-optimal choices because not all the sentiment distributions contribute equally to the satisfaction polarity and the majority sentiment polarity also does not correlate strongly with it.

5.4 Results on Sentiment Classification

Table 4 shows another statistics of our datasets, i.e., the distribution of sentiment labels over each service satisfaction polarity, which reflects the imbalanced situation of utterance-level sentiments in real customer service dialogues.

In Table 5, we compare the sentiment prediction results of MILNET, CAMIL$_r$, CAMIL$_s$ and CAMIL$_{full}$. CAMIL$_r$ and CAMIL$_s$ perform worse than CAMIL$_{full}$ because they only consider partial context information. CAMIL$_{full}$ is the best mainly due to its accurate context clue matching. Thus, our proposed approach is more adaptive to the service satisfaction analysis task based on the customer service dialogues.

5.5 Case Study

Figure 1 illustrates our prediction results with an example dialogue which is translated from Chinese text. For brevity, we use **C/S** to denote customer/server utterance. Our model predicts the label "*unsatisfied*" correctly and also predicts reasonable sentiment polarities for customer utterances. Considering the context, customer utterances $\mathbf{C}_{1,5,6}$ are "*negative*" but predicted as "*neutral*" by MILNET because MILNET predicts sentiments only from target utterance itself and ignores context information. In addition, the sentiments of the customer utterances $\mathbf{C}_{4,5}$ and $\mathbf{C}_9$ tend to have larger influences on deciding the satisfaction polarity because $\mathbf{C}_4$ clearly conveys "*unsatisfied*" attitude, $\mathbf{C}_5$ complains about delay and $\mathbf{C}_9$ criticizes the low service quality.

We also visualize the attention weights in Figure 4 to explain our prediction results. For each customer utterance $\mathbf{C}_i$, we give the attention weights $\beta_{s_{t'}}$ on all the server utterances (see Formula 10). Furthermore, we also visualize the attention rates α_{c_t} on the customer utterances (see Formula 3). *Lighter colors denote smaller values*. From Figure 4, we can see that the customer utterances $\mathbf{C}_{4,5,9}$ have higher attention weights because customer attitudes are intuitively formed at the end of the dialogues (i.e., $\mathbf{C}_9$) or determined by explicit sentiments (i.e., $\mathbf{C}_4$). In this example, the customer is finally unhappy with the provided solution, and the sentiments did not change through the whole dialogue. We can also see that customer

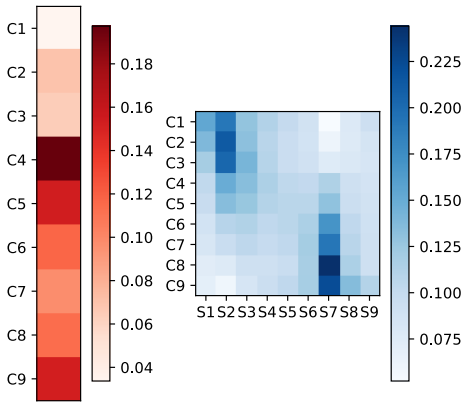

Figure 4: The visualization of attention rates α_{c_t} (Left in *red*) and $\beta_{s_{t'}}$ (Right in *blue*) for the given example.

utterances are influenced by server utterances. For example, $\mathbf{C}_{1-3}$ are related to $\mathbf{S}_2$, $\mathbf{C}_{4,5}$ are related to $\mathbf{S}_{2,3,7}$, and $\mathbf{C}_{6-9}$ are related to $\mathbf{S}_7$. This again validates the fact that customer utterances are related to the server utterances near them. Meanwhile, customer utterances may provide different types of context clues (i.e., sentiment and reasoning). For a specific server utterance $\mathbf{S}_7$, it provides explicit sentiment clue for $\mathbf{C}_9$ and also gives reasoning clue for $\mathbf{C}_8$.

In-depth Analysis: CAMIL$_{full}$ is only trained based on satisfaction labels, thus the laborious acquisition of sentiment labels is unnecessary. However, we would point out that lack of sentiment labels will inevitably lead to difficulties on identifying positive/negative utterances from those neutral ones. We will study to alleviate it in the future.

Our general observation is that the sentiment of customers at the beginning cannot largely determine the service satisfaction at the end. This is because the sentiment of the customers can vary with different quality of service during the dialogue, and the final service satisfaction results from the overall sentiments of important customer utterances in the dialogue (see the attention weights in Figure 4). To verify this, we design a heuristic baseline called Mapping which directly maps the initial *negative*, *neutral* and *positive* sentiment of customer to the corresponding service satisfaction, i.e., *unsatisfied*, *met* and *satisfied*. The satisfaction classification results are displayed in the Table 6.

In Table 6, we can observe that the Mapping method is far worse than our model. One reason is that the service dialogues in our datasets have more than 25 utterances in average (See the statistics in Table 1) and contain a large proportion

Methods	Clothes		Makeup	
	MacroF1	Acc.	MacroF1	Acc.
Mapping	0.625	0.487	0.471	0.430

Table 6: Satisfaction classification comparison between our method and a heuristic mapping method.

of complex interactions. Besides, the sentiment change is closely related to the quality of service and it is very common in our datasets. Thus, using such simple correlation does not work well in our complex dialogue scenarios.

6 Conclusions and Future Work

In this paper, we propose a novel CAMIL model for the SSA task. We first propose a basic MIL approach with the inputs of context-matched customer utterances, then predict the utterance-level sentiment polarities and dialogue-level satisfaction polarities simultaneously. In addition, we propose a context clue matching mechanism (CCMM) to match any customer utterance with the most related server utterances. Experimental results on two real-world datasets indicate our method clearly outperforms some state-of-the-art baseline models on the two SSA subtasks, i.e., service satisfaction polarity classification and utterance sentiment classification, which are performed simultaneously. We have made our datasets publicly available.

In the future, we will further improve our method by learning the correlation between the customer utterances and the server utterances. In addition, we will study other interesting tasks in customer service dialogues, such as outcome prediction or opinion change.

Abstract

Medical relation extraction discovers relations between entity mentions in text, such as research articles. For this task, dependency syntax has been recognized as a crucial source of features. Yet in the medical domain, 1-best parse trees suffer from relatively low accuracies, diminishing their usefulness. We investigate a method to alleviate this problem by utilizing dependency forests. Forests contain many possible decisions and therefore have higher recall but more noise compared with 1-best outputs. A graph neural network is used to represent the forests, automatically distinguishing the useful syntactic information from parsing noise. Results on two biomedical benchmarks show that our method outperforms the standard tree-based methods, giving the state-of-the-art results in the literature.

1 Introduction

The sheer amount of medical articles and their rapid growth prevent researchers from receiving comprehensive literature knowledge by direct reading. This can hamper both medical research and clinical diagnosis. NLP techniques have been used for automating the knowledge extraction process from the medical literature (Friedman et al., 2001; Yu and Agichtein, 2003; Hirschman et al., 2005; Xu et al., 2010; Sondhi et al., 2010; Abacha and Zweigenbaum, 2011). Along this line of work, a long-standing task is relation extraction, which mines factual knowledge from free text by labeling relations between entity mentions. As shown in Figure 1, the sub-clause "previously observed cytochrome P450 3A4 (CYP3A4) interaction of the dual orexin receptor antagonist almorexant" contains two entities, namely "orexin receptor" and "almorexant". There is an "adversary" relation between these two entities, denoted as"CPR:6".

*Yue Zhang is the corresponding author

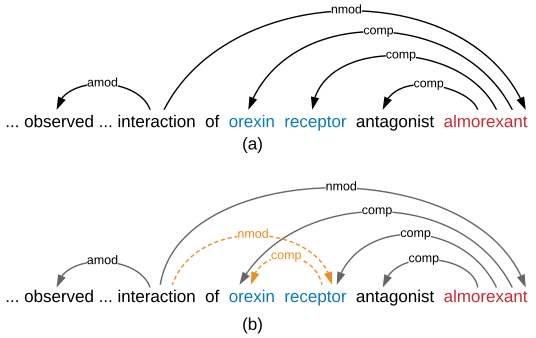

Figure 1: (a) 1-best dependency tree and (b) dependency forest for a medical-domain sentence, where edge label "comp" represents "compound". Associated mentions are in different colors. Some irrelevant words and edges are omitted for simplicity.

Previous work has shown that dependency syntax is important for guiding relation extraction (Culotta and Sorensen, 2004; Bunescu and Mooney, 2005; Liu et al., 2015; Gormley et al., 2015; Xu et al., 2015a,b; Miwa and Bansal, 2016; Zhang et al., 2018b), especially in biological and medical domains (Quirk and Poon, 2017; Peng et al., 2017; Song et al., 2018b). Compared with sequential surface-level structures, such as POS tags, dependency trees help to model word-to-word relations more easily by drawing direct connections between distant words that are syntactically correlated. Take the phrase "effect on the medicine" for example; "effect" and "medicine" are directly connected in a dependency tree, regardless of how many modifiers are added in between.

Dependency parsing has achieved an accuracy over 96% in the news domain (Liu and Zhang, 2017; Kitaev and Klein, 2018). However, for the medical literature domain, parsing accuracies can drop significantly (Lease and Charniak, 2005; McClosky and Charniak, 2008; Sagae et al., 2008; Candito et al., 2011). This can lead to severe er-

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 208–218, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

ror propagation in downstream relation extraction tasks, offsetting much of the benefit that relation extraction models can obtain by exploiting dependency trees as a source of external features.

We address the low-accuracy issue in biomedical dependency parsing by considering dependency forests as external features. Instead of 1-best trees, dependency forests consist of dependency arcs and labels that a parser is relatively confident about, therefore having better recall of gold-standard arcs by offering more candidate choices with noise. Our main idea is to let a relation extraction system learn automatically from a forest which arcs are the most relevant through end-task training, rather than relying solely on the decisions of a noisy syntactic parser. To this end, a graph neural network is used for encoding a forest, which in turn provides features for relation extraction. Back-propagation passes loss gradients from the relation extraction layer to the graph encoder, so that the more relevant edges can be chosen automatically for better relation extraction.

Results on BioCreative VI ChemProt (CPR) (Krallinger et al., 2017) and a recent dataset focused on phenotype-gene relations (PGR) (Sousa et al., 2019) show that our method outperforms a strong baseline that uses 1-best dependency trees as features, giving the state-of-the-art accuracies in the literature. To our knowledge, we are the first to study dependency forests for medical information extraction, showing their advantages over 1-best tree structures. Our code is available at `http://github.com/freesunshine/dep-forest-re`.

2 Related work

Syntactic forests There have been previous studies leveraging constituent forests for machine translation (Mi et al., 2008; Ma et al., 2018; Zaremoodi and Haffari, 2018), sentiment analysis (Le and Zuidema, 2015) and text generation (Lu and Ng, 2011). However, the usefulness of dependency forests is relatively rarely studied, with one exception being Tu et al. (2010), who use dependency forests to enhance long-range word-to-word dependencies for statistical machine translation. To our knowledge, we are the first to study the usefulness of dependency forests for relation extraction under a strong neural framework.

Graph neural network Graph neural networks (GNNs) have been successful in encoding dependency trees for downstream tasks, such as semantic role labeling (Marcheggiani and Titov, 2017), semantic parsing (Xu et al., 2018), machine translation (Song et al., 2019; Bastings et al., 2017), relation extraction (Song et al., 2018b) and sentence ordering (Yin et al., 2019). In particular, Song et al. (2018b) showed that GNNs are more effective than DAG networks (Peng et al., 2017) for modeling syntactic trees in relation extraction, which cause loss of important structural information. We are the first to exploit GNNs for encoding search spaces in the form of dependency forests.

3 Task

Formally, the input to our task is a sentence $\boldsymbol{s} = w_1, w_2, \ldots, w_N$, where N is the number of words in the sentence and w_i represents the i-th input word. $\boldsymbol{s}$ is annotated with boundary information ($\xi_1 : \xi_2$ and $\zeta_1 : \zeta_2$) of target entity mentions (ξ and ζ). We focus on the classic binary relation extraction setting (Quirk and Poon, 2017), where the number of associated mentions is two. The output is a relation from a predefined relation set $\boldsymbol{R} = (r_1, \ldots, r_M, \text{None})$, where "None" means that no relation holds for the entities.

Two steps are taken for predicting the correct relation given an input sentence. First, a dependency parser is used to label the syntactic structure of the input. Here our baseline system takes the standard approach, using the 1-best parser output tree $\boldsymbol{D}_T$ as features. In contrast, our proposed model uses the most confident parser forest $\boldsymbol{D}_F$ as features. Given $\boldsymbol{D}_T$ or $\boldsymbol{D}_F$, the second step is to encode both s and $\boldsymbol{D}_T/\boldsymbol{D}_F$ using a neural network, before making a prediction.

We make use of the same graph neural network encoder structure to represent dependency syntax information for both the baseline and our model. In particular, a graph recurrent neural network architecture (Beck et al., 2018; Song et al., 2018a; Zhang et al., 2018a) is used, which has been shown effective in encoding graph structures (Song et al., 2019), giving competitive results with alternative graph networks such as graph convolutional neural networks (Marcheggiani and Titov, 2017; Bastings et al., 2017).

4 Baseline: DEPTREE

As shown in Figure 2, our baseline model stacks a bidirectional LSTM layer to encode an input sentence $w_1, \ldots, w_N$ with a graph recurrent network

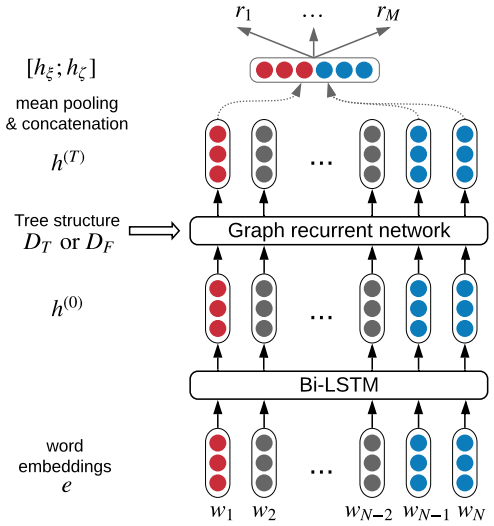

Figure 2: Framework of our baseline and model.

(GRN) to encode a 1-best dependency tree, which extracts features from the sentence and the dependency tree $\boldsymbol{D}_T$, respectively. Similar model frameworks have shown highly competitive performances in previous relation extraction studies (Peng et al., 2017; Song et al., 2018b).

4.1 Bi-LSTM layer

Given the input sentence $w_1, w_2, \ldots, w_N$, we represent each word with its embedding to generate a sequence of embeddings $\boldsymbol{e}_1, \boldsymbol{e}_2, \ldots, \boldsymbol{e}_N$. A Bi-LSTM layer is used to encode the sentences:

$$\overleftarrow{\boldsymbol{h}}_i^{(0)} = \text{LSTM}_l(\overleftarrow{\boldsymbol{h}}_{i+1}^{(0)}, \boldsymbol{e}_i) \quad (1)$$

$$\overrightarrow{\boldsymbol{h}}_i^{(0)} = \text{LSTM}_r(\overrightarrow{\boldsymbol{h}}_{i-1}^{(0)}, \boldsymbol{e}_i), \quad (2)$$

where the state of each word w_i is generated by concatenating the states of both directions:

$$\boldsymbol{h}_i^{(0)} = [\overleftarrow{\boldsymbol{h}}_i^{(0)}; \overrightarrow{\boldsymbol{h}}_i^{(0)}] \quad (3)$$

4.2 GRN layer

A 1-best dependency tree can be represented as a directed graph $\boldsymbol{D}_T = \langle \boldsymbol{V}, \boldsymbol{E} \rangle$, where $\boldsymbol{V}$ includes all words $w_1, w_2, \ldots, w_N$ and $\boldsymbol{E} = \{(w_j, l, w_i)\}|_{w_j \in V, w_i \in V}$ represents all dependency edges (Marcheggiani and Titov, 2017). Each triple (w_j, l, w_i) corresponds to a dependency edge, where w_j modifies w_i with an arc label l. Each word w_i is associated with a hidden state that is initialized with the Bi-LSTM output $\boldsymbol{h}_i^{(0)}$. The state representation of the entire tree consists of all word states:

$$\boldsymbol{h}^{(0)} = \{\boldsymbol{h}_i^{(0)}\}_{w_i \in V} \quad (4)$$

In order to capture non-local interactions between words, the GRN layer adopts a message passing framework that performs iterative information exchange between directly connected words. As a result, each word state is updated by absorbing larger contextual information through the message passing process, and a sequence of state transitions $\boldsymbol{h}^{(0)}, \boldsymbol{h}^{(1)}, \ldots$ is generated for the entire tree. The final state $\boldsymbol{h}^{(T)} = \text{GRN}(\boldsymbol{h}^{(0)}, T)$, where T is a hyperparameter representing the number of state transitions.

Message passing The message passing framework takes two main steps within each iteration: message calculation and state update. Take w_i and iteration t as the example. In the first step, separate messages $\boldsymbol{m}_i^{\uparrow}$ and $\boldsymbol{m}_i^{\downarrow}$ are calculated by summing up the messages of its children and parent in the dependency tree, respectively:

$$\boldsymbol{m}_i^{\uparrow} = \sum_{(w_j, l, w_i) \in \boldsymbol{E}_{(\cdot,\cdot,i)}} [\boldsymbol{h}_j^{(t-1)}; \boldsymbol{e}_l] \quad (5)$$

$$\boldsymbol{m}_i^{\downarrow} = \sum_{(w_i, l, w_k) \in \boldsymbol{E}_{(i,\cdot,\cdot)}} [\boldsymbol{h}_k^{(t-1)}; \boldsymbol{e}_{l_{rev}}], \quad (6)$$

where $\boldsymbol{E}_{(\cdot,\cdot,i)}$ and $\boldsymbol{E}_{(i,\cdot,\cdot)}$ represent all edges with a head word w_i and a modifier word w_i, respectively, and $\boldsymbol{e}_{l_{rev}}$ represents the embedding of label l_{rev}, the reverse version of original label l (such as "amod-rev" is the reverse version of "amod"). The message from a child or a parent is obtained by simply concatenating its hidden state with the corresponding edge label embedding.

In the second step, GRN uses standard gated operations of LSTM (Hochreiter and Schmidhuber, 1997) to update hidden state $\boldsymbol{h}_i^{(t-1)}$ with the previously integrated message. In particular, a cell $\boldsymbol{c}_i^{(t)}$ is taken to record memory for $\boldsymbol{h}_i^{(t)}$; an input gate $\boldsymbol{i}_i^{(t)}$, an output gate $\boldsymbol{o}_i^{(t)}$ and a forget gate $\boldsymbol{f}_i^{(t)}$ are used to control information flow from the inputs and to the output $\boldsymbol{h}_i^{(t)}$:

$$\begin{aligned}
\boldsymbol{i}_i^{(t)} &= \sigma(\boldsymbol{W}_1^{\uparrow}\boldsymbol{m}_i^{\uparrow} + \boldsymbol{W}_1^{\downarrow}\boldsymbol{m}_i^{\downarrow} + \boldsymbol{b}_1) \\
\boldsymbol{o}_i^{(t)} &= \sigma(\boldsymbol{W}_2^{\uparrow}\boldsymbol{m}_i^{\uparrow} + \boldsymbol{W}_2^{\downarrow}\boldsymbol{m}_i^{\downarrow} + \boldsymbol{b}_2) \\
\boldsymbol{f}_i^{(t)} &= \sigma(\boldsymbol{W}_3^{\uparrow}\boldsymbol{m}_i^{\uparrow} + \boldsymbol{W}_3^{\downarrow}\boldsymbol{m}_i^{\downarrow} + \boldsymbol{b}_3) \\
\boldsymbol{u}_i^{(t)} &= \tanh(\boldsymbol{W}_4^{\uparrow}\boldsymbol{m}_i^{\uparrow} + \boldsymbol{W}_4^{\downarrow}\boldsymbol{m}_i^{\downarrow} + \boldsymbol{b}_4) \\
\boldsymbol{c}_i^{(t)} &= \boldsymbol{f}_i^{(t)} \odot \boldsymbol{c}_i^{(t-1)} + \boldsymbol{i}_i^{(t)} \odot \boldsymbol{u}_i^{(t)} \\
\boldsymbol{h}_i^{(t)} &= \boldsymbol{o}_i^{(t)} \odot \tanh(\boldsymbol{c}_i^{(t)}),
\end{aligned} \quad (7)$$

where $\boldsymbol{W}_x^{\uparrow}$, $\boldsymbol{W}_x^{\downarrow}$, and $\boldsymbol{b}_x$ ($x \in \{1, 2, 3, 4\}$) are

model parameters, and $\boldsymbol{c}_i^{(0)}$ is initialized as a vector of zeros.

The same process repeats for T iterations. Starting from $\boldsymbol{h}^{(0)}$ of the Bi-LSTM layer, increasingly more informed hidden states $\boldsymbol{h}^{(t)}$ are obtained as the iteration increases, and $\boldsymbol{h}^{(T)}$ is used as the final representation of each word.

4.3 Relation prediction

Given $\boldsymbol{h}^{(T)}$ of the GRN encoding, we calculate the representation vector of the two related entity mentions ξ and ζ (such as "almorexant" and "orexin receptor" in Figure 1) with mean pooling:

$$\boldsymbol{h}_\xi = f_{\text{mean}}(\boldsymbol{h}^{(T)}_{\xi_1:\xi_2}) \quad (8)$$

$$\boldsymbol{h}_\zeta = f_{\text{mean}}(\boldsymbol{h}^{(T)}_{\zeta_1:\zeta_2}) \quad (9)$$

where $\xi_1 : \xi_2$ and $\zeta_1 : \zeta_2$ represent the span of ξ and ζ, respectively, and f_{mean} is the mean-pooling function.

Finally, the representations of both mentions are concatenated to be the input of a logistic regression classifier:

$$\boldsymbol{y} = \text{softmax}(\boldsymbol{W}_5[\boldsymbol{h}_\xi; \boldsymbol{h}_\zeta] + \boldsymbol{b}_5), \quad (10)$$

where $\boldsymbol{W}_5$ and $\boldsymbol{b}_5$ are model parameters.

5 Model

In this section, we first discuss how to generate high-quality dependency forests, before showing how to adapt GRN to consider the parser probability of each dependency edge.

5.1 Forest generation

Given a dependency parser, generating dependency forests with high recall and low noise is a non-trivial problem. On the one hand, keeping the whole search space gives 100% recall, but introduces maximum noise. On the other hand, using the 1-best dependency tree can result in low recall given an imperfect parser. We investigate two algorithms to generate high-quality forests by judging "quality" from different perspectives: one focusing on arcs, and the other focusing on trees.

EDGEWISE This algorithm focuses on the local relation of each individual edge and uses parser probabilities as confidence scores to assess edge qualities. Starting from the whole parser search space, it keeps all the edges with scores greater than a threshold γ. The time complexity is $O(N^2)$, where N represents the sentence length.[1]

KBESTEISNER This algorithm extends the Eisner algorithm (Eisner, 1996) with cube pruning (Huang and Chiang, 2005) for finding K highest-scored tree structures. The Eisner algorithm is a standard method for decoding 1-best trees for graph-based dependency parsing. Based on bottom-up dynamic programming, it stores the 1-best subtree for each span and takes $O(N^3)$ time complexity for decoding a sentence of N words.

KBESTEISNER keeps a sorted list of K-best hypotheses for each span. Cube pruning (Huang and Chiang, 2005) is adopted to generate the K-best list for each larger span from the K-best lists of its sub-spans. After the bottom-up decoding, we merge the final K-bests by combining identical dependency edges to make the forest. As a result, KBESTEISNER takes $O(N^3K \log K)$ time.

Discussions EDGEWISE is much simpler and faster than KBESTEISNER. Compared with the $O(N^3K \log K)$ time complexity of KBESTEISNER, EDGEWISE only takes $O(N^2)$ running time, and each step (storing an edge) runs faster than KBESTEISNER (making a new hypothesis by combining two from sub-spans). Besides, the forests of EDGEWISE can be denser and provide richer information than those from KBESTEISNER. This is because KBESTEISNER only merges K trees, where many edges are shared among them. Also, K cannot be set to a large number (such as 100), because that will cause a dramatic increase of running time.

Compared with KBESTEISNER, EDGEWISE suffers from two potential problems. First, EDGEWISE does not guarantee to produce a 1-best tree in a generated forest, as it makes decisions by considering the individual edges. Second, it does not guarantee to generate spanning forests, which can happen when the threshold γ is high. On the other hand, no previous work has shown that the information from the whole tree is crucial for relation extraction. In fact, many previous studies use only the dependency path between the target entity mentions (Bunescu and Mooney, 2005; Airola et al., 2008; Chowdhury et al., 2011; Gormley et al., 2015; Mehryary et al., 2016). We study

[1] More accurately, it is $O(N^2L)$ and L s a *constant* factor, denoting the number of distinct dependency labels. We omit it for simplicity.

the effectiveness of both algorithms in our experiments.

5.2 GRN encoding with parser confidence

As illustrated by Figure 1(b), our dependency forests are directed graphs that can be consumed by GRN without any structural changes. For fair comparison, we use the same model as the baseline to encode sentences and forests. Thus our model uses **the same number of parameters** as our baseline taking 1-best trees.

Since forests contain more than one tree, it is intuitive to consider parser confidence scores for potentially better feature extraction. To this end, we slightly adjust the GRN encoding process without introducing additional parameters. In particular, we enhance the original message sum function (Equations 5 and 6) by applying the edge probabilities in calculating weighted message sums:

$$\boldsymbol{m}_i^{\uparrow} = \sum_{\epsilon \in \boldsymbol{E}_{(\cdot,\cdot,i)}} p_\epsilon [\boldsymbol{h}_j^{(t-1)}; \boldsymbol{e}_l] \quad (11)$$

$$\boldsymbol{m}_i^{\downarrow} = \sum_{\epsilon \in \boldsymbol{E}_{(i,\cdot,\cdot)}} p_\epsilon [\boldsymbol{h}_k^{(t-1)}; \boldsymbol{e}_{l_{rev}}], \quad (12)$$

where ϵ (instead of a triple) is used to represent an edge for simplicity, and p_ϵ is the parser probability for edge ϵ. The edge probabilities are *not* adjusted during end-task training.

6 Training

Relation loss Given a set of training instances, each containing a sentence $\boldsymbol{s}$ with two target mentions ξ and ζ, and a dependency structure $\boldsymbol{D}$ (tree or forest), we train our models with a cross-entropy loss between the gold-standard relations r and model distribution:

$$l_R = -\log p(r|\boldsymbol{s}, \xi, \zeta, \boldsymbol{D}; \boldsymbol{\theta}), \quad (13)$$

where $\boldsymbol{\theta}$ represents the model parameters.

Using additional NER loss For training on BioCreative VI CPR, we follow previous work (Liu et al., 2017; Verga et al., 2018) to take NER loss as additional supervision, though the mention boundaries are known during testing.

$$l_{NER} = -\frac{1}{N} \sum_{n=1}^{N} \log p(t_n|\boldsymbol{s}, \boldsymbol{D}; \boldsymbol{\theta}), \quad (14)$$

where t_n is the gold NE tag of w_n with the "BIO" scheme. Both losses are conditionally independent given the deep features produced by our model, and the final loss for BioCreative VI CPR training is $l = l_R + l_{NER}$.

7 Experiments

We conduct experiments on two medical benchmarks to test the usefulness of dependency forest.

7.1 Data

BioCreative VI CPR (Krallinger et al., 2017) This task[2] focuses on the relations between chemical compounds (such as drugs) and proteins (such as genes). The full corpus contains 1020, 612 and 800 extracted PubMed[3] abstracts for training, development and testing, respectively. All abstracts are manually annotated with the boundaries of entity mentions and the relations. The data provides three types of NEs: "CHEMICAL", "GENE-Y" and "GENE-N", and the relation set $\boldsymbol{R}$ contains 5 regular relations ("CPR:3", "CPR:4", "CPR:5", "CPR:6" and "CPR:9") and the "None" relation.

For efficient generation of dependency structures, we segment each abstract into sentences, keeping only the sentences that contain at least a chemical mention and a protein mention. For any sentence containing several chemical mentions or protein mentions, we keep multiple copies of it with each copy having different target mention pairs. As a result, we only consider the relations of mentions in the same sentence, assigning all cross-sentence chemical-protein pairs as "None" relation. By doing this, we effectively sacrifice cross-sentence relations, which has a negative effect on our systems; but this is necessary for efficient generation of dependency structures since directly parsing a short paragraph is slow and erroneous.[4] In general, we obtain 16,107 training, 10,030 development and 14,269 testing instances, in which around 23% have regular relations. The highest recalls for relations on our development and test sets are 92.25 and 92.54, respectively, because of the exclusion of cross-sentence relations in preprocessing. We report F1 scores of the full test set for a fair comparison, using all gold regular relations to calculate recalls.

Phenotype-Gene relation (PGR) (Sousa et al., 2019) This dataset concerns the relations between

[2] https://biocreative.bioinformatics.udel.edu/tasks/biocreative-vi/track-5/

[3] https://www.ncbi.nlm.nih.gov/pubmed/

[4] Peng et al. (2017) describe a solution for cross-sentence cases, which joins different dependency structures by connecting their roots. We leave it for future work.

human phenotypes (such as diseases) with human genes, where the relation set is a *binary* class on whether a phenotype is related to a gene. It has 18,451 silver training instances and 220 high-quality test instances, with each containing mention boundary annotations. We separate the first 15% training instances as our development set. Unlike *BioCreative VI CPR*, almost every relation of PGR is within a single sentence.

7.2 Models

We compare the following models:

- TEXTONLY: It does not take dependency structures and directly uses the Bi-LSTM outputs ($\boldsymbol{h}^{(0)}$ in Eq. 3) to make predictions.
- DEPTREE: Our baseline using 1-best dependency trees, as shown in Section 4.
- EDGEWISEPS and EDGEWISE: Our models using the forests generated by our EDGEWISE algorithm with or without parser scores.
- KBESTEISNERPS and KBESTEISNER: Our model using the forests generated by our KBESTEISNER algorithm with or without parser scores, respectively.

7.3 Settings

We take a state-of-the-art deep biaffine parser (Dozat and Manning, 2017), trained on the Penn Treebank (PTB) (Marcus and Marcinkiewicz, 1993) converted to Universal Dependency, to obtain 1-best trees and full search spaces for generating forests. Using standard PTB data split (02–21 for training, 22 for development and 23 for testing), it gives UAS and LAS scores of 95.7 and 94.6, respectively.

For the other hyper-parameters, word embeddings are initialized with the 200-dimensional BioASQ vectors[5], pretrained on 10M abstracts of biomedical articles, and are fixed during training. The dimension of hidden vectors in Bi-LSTM is set to 200, and the number of message passing steps T is set to 2 based on Zhang et al. (2018b). We use Adam (Kingma and Ba, 2014), with a learning rate of 0.001, as the optimizer. The batch size, coefficient for $l2$ normalization loss and dropout rate are 20, 10^{-8} and 0.1, respectively.

γ	#Edge/#Node	LAS	Conn. Ratio(%)
0.05	2.09	92.5	100.0
0.1	1.57	91.2	99.5
0.2	1.34	90.5	94.2
0.3	1.04	88.0	77.6
K	#Edge/#Node	LAS	Conn. Ratio(%)
1	1.00	86.4	100.0
2	1.03	87.3	100.0
5	1.09	89.1	100.0
10	1.14	89.8	100.0

Table 1: Statistics on forests generated with various γ (upper half) and K (lower half) on the development set.

7.4 Analyses of generated forests

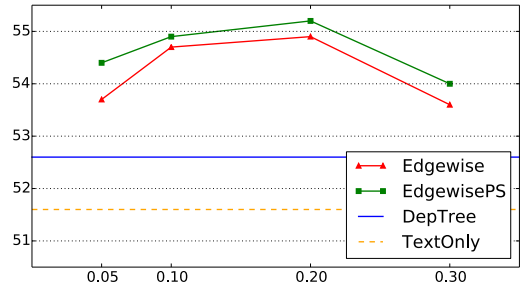

Table 1 demonstrates several characteristics of the generated forests of both the EDGEWISE and KBESTEISNER algorithms in Section 5.1, where "#Edge/#Sent" measures the forest density with the number of edges divided by the sentence length, "LAS" represents the oracle LAS score on 100 biomedical sentences with manually annotated dependency trees, and "Conn. Ratio (%)" shows the percentage of forests where both related entity mentions are connected.

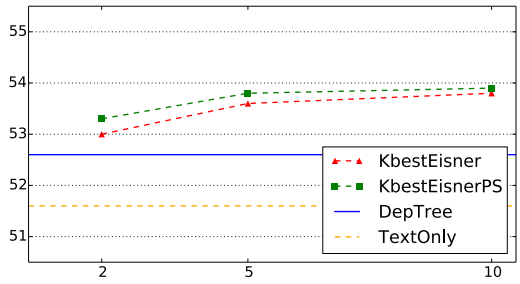
Regarding the forest density, forests produced by EDGEWISE generally contain more edges than those from KBESTEISNER. Due to the combinatorial property of forests, EDGEWISE can give much more candidate trees (and sub-trees) for the whole sentence (and each sub-span). This coincides with the fact that the forests generated by EDGEWISE have higher oracle scores than these generated by KBESTEISNER.



For connectivity, KBESTEISNER guarantees to generate spanning forests. On the other hand, the connectivity ratio for the forests produced by EDGEWISE drops when increasing the threshold γ. We can have more than 94% being connected with $\gamma \leq 0.2$. Later we will show that good end-task performance can still be achieved with the 94% connectivity ratio. This indicates that losing connectivity for a small potion of the data may not hurt the overall performance.

7.5 Development results

Figure 3 shows the development experiments for our forest generation algorithms, where both EDGEWISE and KBESTEISNER give consistent

(a) EDGEWISE

(b) KBESTEISNER

Figure 3: Development results (F1 score) for our forest generation methods.

improvements over DEPTREE and TEXTONLY. Generally, EDGEWISE gives more improvements than KBESTEISNER. The main reason may be that EDGEWISE generates denser forests, providing richer features. On the other hand, KBESTEISNER shows a marginal improvement by increasing K from 5 to 10. This indicates that only merging 10-best trees may be far from sufficient. However, using a much larger K (such as 100) is not practical due to dramatically increased computation time. In particular, the running time of KBESTEISNER with $K = 10$ is already much longer than that of EDGEWISE. As a result, EDGEWISE better serves our goal compared to KBESTEISNER. This may sound surprising, as EDGEWISE does not consider tree-level scores. It suggests that relation extraction may not require full dependency tree features. This coincides with previous relation extraction research (Bunescu and Mooney, 2005; Airola et al., 2008), which utilizes the shortest path connecting the two candidate entities in the dependency tree.

Leveraging parser confidence scores also consistently helps both methods. It is especially effective for EDGEWISE when $\gamma = 0.05$. This is likely because the parser confidence scores are useful for distinguishing some erroneous dependency arcs, when noise is large (e.g. when γ is too small). Following the development results, we directly report the performances of EDGEWISEPS and KBESTEISNERPS, setting γ and K to 0.2 and 10, respectively, in our remaining experiments.

Model	F1 score

EDGEWISEPS	**53.4****

Table 2: Test results of Biocreative VI CPR. † indicates previously reported numbers. ** means significant over DEPTREE at $p < 0.01$ with 1000 bootstrap tests (Efron and Tibshirani, 1994).

7.6 Main results on BioCreative VI CPR

Table 2 shows the main comparison results on the BioCreative CPR testset, with comparisons to the previous state-of-the-art and our baselines. *GRU+Attn* (Liu et al., 2017) stacks a self-attention layer on top of GRU (Cho et al., 2014) and embedding layers; *Bran* (Verga et al., 2018) adopts a biaffine self-attention model to simultaneously extract the relations of all mention pairs. Both methods use only textual knowledge.

TEXTONLY gives a performance comparable with *Bran*. With 1-best dependency trees, our DEPTREE baseline gives better performances than the previous state of the art. This confirms the usefulness of dependency structures and the effectiveness of GRN on encoding these structures. Using dependency forests and parser confidence scores, both KBESTEISNERPS and EDGEWISEPS obtain significantly higher numbers than DEPTREE. Consistent with the development experiments, EDGEWISEPS has a higher testset performance than KBESTEISNERPS.

7.7 Analysis

Effectiveness on parsing accuracy We have shown in Sections 7.5 and 7.6 that a dependency parser trained using a domain-general treebank can produce high-quality dependency forests in a target domain (biomedical) for helping relation extraction. This is based on the assumption of there being a high-quality treebank in a descent scale, which may not be true for low-resource languages. We simulate this low-resource effect by training our parser in much smaller treebanks of 1K or 5K

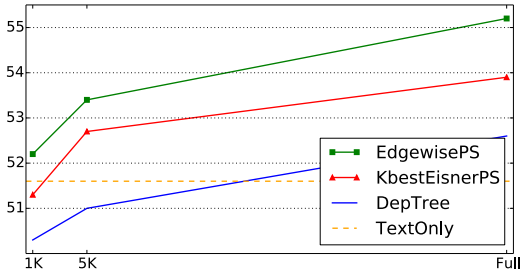

Figure 4: DEV results of BioCreative CPR regarding the dependency parsers trained on different number (1K, 5K or Full) of dependency trees.

dependency trees, respectively. The LAS scores for the resulting parsers on our 100 manually annotated biomedical dependency trees are 79.3 and 84.2, respectively, while the LAS score for the parser trained with the full treebank is 86.4, as shown in Table 1.

Figure 4 shows the results on the Biocreative CPR development set, where the performance of TEXTONLY is 51.6. DEPTREE fails to outperform TEXTONLY when only 1K or 5K dependency trees are available for training our parser. This is due to the low parsing recall and subsequent noise caused by the weak parsers. It confirms the previous conclusion that dependency structures are highly influential to the performance of relation extraction. Both EDGEWISEPS and KBESTEISNERPS are still more effective than DEPTREE. In particular, KBESTEISNERPS significantly improves TEXTONLY with 5K dependency trees, and EDGEWISEPS is helpful even with 1K dependency trees.

KBESTEISNER shows relatively smaller gaps than EDGEWISE when only a limited number of dependency trees are available. This is probably because considering whole-tree quality helps to better eliminate noise.

Case study Figure 5 illustrates two major types of errors in BioCreative CPR, which are caused by inaccurate 1-best dependency trees. As shown in Figure 5(a), the baseline system mistakenly predicts a "None" relation for that instance. This is mainly because "STAT3" is incorrectly linked to the main verb "inhibited" with a "punct" relation, but it should be linked to "AKT". In contrast, our forest contains the correct relation and with a probability of 0.18. This is possibly because "AKT and STAT3" fits the common pattern of "A and B" that conjunct two nouns.

Figure 5(b) shows another type of parsing errors that cause end-task mistakes. In this example, the multi-token mention "calcium modulated cyclases" is incorrectly segmented in the 1-best dependency tree, where "modulated" is used as the main verb of the whole sentence, leaving "cyclases" and "calcium" as the object and the modifier of the subject, respectively. However, this mention ought to be a noun phrase with "cyclases" being the head. Our forest helps in this case by providing a more reasonable structure (shown as the yellow dashed arcs), where both "calcium" and "modulated" modify "cyclases". This is likely because "modulated" can be interpreted as an adjective in addition to being a verb. It shows the advantage of keeping multiple candidate syntactic arcs.

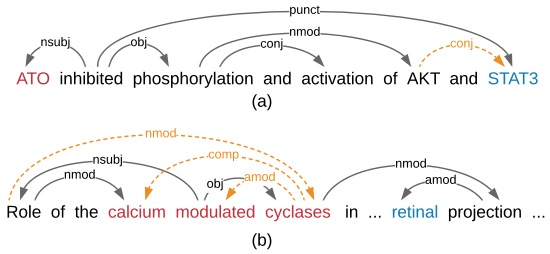

Figure 5: Two representative cases in BioCreative CPR, contrasting 1-best trees and forests, where irrelevant content and arcs are omitted for simplicity.

Model	F1 score

BioBERT (Lee et al., 2019)†	67.2
TEXTONLY	76.0
DEPTREE	78.9
KBESTEISNERPS	83.6*
EDGEWISEPS	**85.7****

Table 3: Main results on PGR testest. † denotes previous numbers rounded into 3 significant digits. * and ** indicate significance over DEPTREE at $p < 0.05$ and $p < 0.01$ with 1000 bootstrap tests.

7.8 Main results on PGR

Table 3 shows the comparison with previous work on the PGR testset, where our models are significantly better than the existing models. This is likely because the previous models do not utilize all the information from inputs: *BO-LSTM* only takes the words (without arc labels) along the shortest dependency path between the target mentions; the pretrained weights of *BioBERT* are kept constant during training for relation extraction.

With 1-best trees, DEPTREE is 2.9 points bet-

ter than TEXTONLY, confirming the usefulness of dependency structures. Leveraging dependency forests, both KBESTEISNERPS and EDGEWISEPS significantly outperform DEPTREE with p-values of 0.003 and 0.024, respectively. This further confirms the usefulness of dependency forests for medical relation extraction.

7.9 Main results on SemEval-2010 task 8

In addition to the biomedical domain, leveraging dependency forests applies to other domains as well. As shown in Table 4, we conduct a preliminary study on SemEval-2010 task 8 (Hendrickx et al., 2009), a widely used benchmark for news-domain relation extraction. It is a public dataset, containing 10,717 instances (8000 for training and development, 2717 for testing) with 19 relations: 9 directed relations and a special "Other" class. Both *C-GCN* and *C-AGGCN* take a similar network as ours by stacking a graph neural network for encoding trees on top of a Bi-LSTM layer for encoding sentences.

DEPTREE achieves similar performance as *C-GCN* and is slightly worse than *C-AGGCN*, with one potential reason being that *C-AGGCN* takes more parameters. Using forests, both KBESTEISNERPS and EDGEWISEPS outperform DEPTREE with the same number of parameters, and they show comparable and slightly better performances than *C-AGGCN*. Again, EDGEWISEPS is better than KBESTEISNERPS, showing that the former is a better way for generating forests.

8 Conclusion

We have proposed two algorithms for generating high-quality dependency forests for relation extraction, and studied a graph recurrent network for effectively distinguishing useful features from noise in parsing forests. Experiments on two biomedical relation extraction benchmarks show the superiority of forests versus tree structures, without introducing any additional model parameters. Our deep analyses indicate that the main advantage comes from alleviating out-of-domain parsing errors.

Abstract

Open relation extraction (OpenRE) aims to extract relational facts from the open-domain corpus. To this end, it discovers relation patterns between named entities and then clusters those semantically equivalent patterns into a united relation cluster. Most OpenRE methods typically confine themselves to unsupervised paradigms, without taking advantage of existing relational facts in knowledge bases (KBs) and their high-quality labeled instances. To address this issue, we propose Relational Siamese Networks (RSNs) to learn similarity metrics of relations from labeled data of pre-defined relations, and then transfer the relational knowledge to identify novel relations in unlabeled data. Experiment results on two real-world datasets show that our framework can achieve significant improvements as compared with other state-of-the-art methods. Our code is available at https://github.com/thunlp/RSN.

1 Introduction

Relation extraction (RE) aims to extract relational facts between two entities from plain texts. For example, with the sentence *"Hayao Miyazaki is the director of the film 'The Wind Rises'"*, we can extract a relation "director_of" between two entities "*Hayao Miyazaki*" and "*The Wind Rises*".

Recent progress in supervised methods to RE has achieved great successes. Supervised methods can effectively learn significant relation semantic patterns based on existing labeled data, but the data constructions are time-consuming and human-intensive. To lower the level of supervision, several semi-supervised approaches have been developed, including bootstrapping, active learning, label propagation (Pawar et al., 2017).

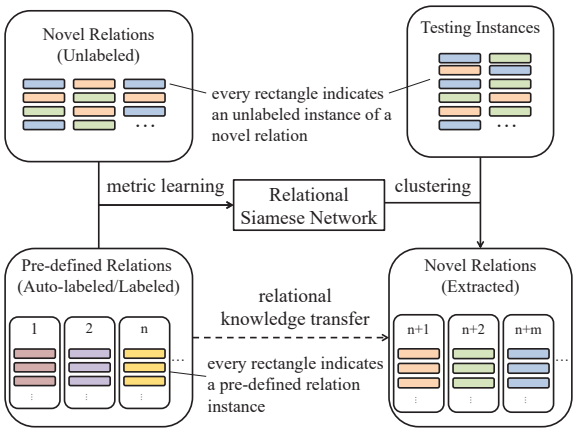

Figure 1: A flowchart of our framework. Our model RSN learns from both labeled instances of pre-defined relations and unlabeled instances of new relations, and tries to cluster testing instances of new relations.[1]

Mintz (2009) also proposes distant supervision to generate training data automatically. It assumes that if two entities have a relation in KBs, all sentences that contain these two entities will express this relation. Still, all these approaches can only extract pre-defined relations that have already appeared either in human-annotated datasets or KBs. It is hard for them to cover the great variety of novel relational facts in the open-domain corpora.

Open relation extraction (OpenRE) aims to extract relational facts on the open-domain corpus, where the relation types may not be predefined. There are some efforts concentrating on extracting triples with new relation types. Banko (2008) directly extracts words or phrases in sentences to represent new relation types. However, some relations cannot be explicitly represented with tokens in sentences, and it is hard to align different relational tokens that exactly have the same meanings. Yao (2011) consid-

ers OpenRE as a clustering task for extracting triples with new relation types. However, previous clustering-based OpenRE methods (Yao et al., 2011, 2012; Marcheggiani and Titov, 2016; Elsahar et al., 2017) are mostly unsupervised, and cannot effectively select meaningful relation patterns and discard irrelevant information.

In this paper, we propose to take advantage of high-quality supervised data of pre-defined relations for OpenRE. The approach is non-trivial, however, due to the considerable gap between the pre-defined relations and novel relations of interest in open domain. To bridge the gap, we propose **Relational Siamese Networks** (RSNs) to learn transferable relational knowledge from supervised data for OpenRE. Specifically, RSNs learn relational similarity metrics from labeled data of pre-defined relations, and then transfer the metrics to measure the similarity of unlabeled sentences for open relation clustering. We describe the flowchart of our framework in Figure 1.

Moreover, we show that RSNs can also be generalized to various weakly-supervised scenarios. We propose **Semi-supervised RSN** to learn from both supervised data of pre-defined relations and unsupervised data with novel relations, and **Distantly-supervised RSN** to learn from distantly-supervised data and unsupervised data.

We conduct experiments on real-world RE datasets, FewRel and FewRel-distant, by splitting relations into seen and unseen set, and evaluate our models in supervised, semi-supervised, and distantly-supervised scenarios. The results demonstrate that our models significantly outperform state-of-the-art baseline methods in all scenarios without using external linguistic tools. To summarize, the main contributions of this work are as follows:

(1) We develop a novel relational knowledge transfer framework RSN for OpenRE, which can effectively transfer existing relational knowledge to novel-relation data and accurately identify novel relations. To the best of our knowledge, RSN is the first model to consider knowledge transfer in clustering-based OpenRE task.

(2) We further propose Semi-supervised RSNs and Distantly-supervised RSNs that can learn from various weakly supervised scenarios. The experimental results show that all these RSN models achieve significant improvements in F-measure compared with state-of-the-art baselines.

2 Related Work

Open Relation Extraction. Relation extraction (RE) is an important task in NLP. Traditional RE methods mainly concentrate on classifying relational facts into pre-defined relation types (Mintz et al., 2009; Yu et al., 2017). Zeng (2014) utilizes CNN encoders to build sentence representations with the help of position embeddings. Lin (2016) further improves RE performance on distantly-supervised data via instance-level attention. These methods take advantage of supervised or distantly-supervised data to learn neural sentence encoders for distributed representations, and have achieved promising results. However, these methods cannot handle the open-ended growth of new relation types in the open-domain corpora.

To solve this problem, recently many efforts have been invested in exploring methods for open relation extraction (OpenRE), which aims to discover new relation types from unsupervised open-domain corpora. OpenRE methods can be roughly divided into two categories: tagging-based and clustering-based. Tagging-based methods cast OpenRE as a sequence labeling problem, and extract relational phrases consisting of words from sentences in unsupervised (Banko et al., 2007; Banko and Etzioni, 2008) or supervised paradigms (Jia et al., 2018; Cui et al., 2018; Stanovsky et al., 2018). However, tagging-based methods often extract multiple overly-specific relational phrases for the same relation type, and cannot be readily utilized for downstream tasks.

In comparison, conventional clustering-based OpenRE methods extract rich features for relation instances via external linguistic tools, and cluster semantic patterns into several relation types (Lin and Pantel, 2001; Yao et al., 2011, 2012). Marcheggiani (2016) proposes a reconstruction-based model discrete-state variational autoencoder for OpenRE via unlabeled instances. Elsahar (2017) utilizes a clustering algorithm over linguistic features. In this paper, we focus on the clustering-based OpenRE methods, which have the advantage of discovering highly distinguishable relation types.

Few-shot Learning. Few-shot learning aims to classify instances with a handful of labeled samples. Many efforts are devoted to few-shot image classification (Koch et al., 2015) and relation classification (Yuan et al., 2017; Han et al., 2018). Notably, (Koch et al., 2015) introduces Convolu-

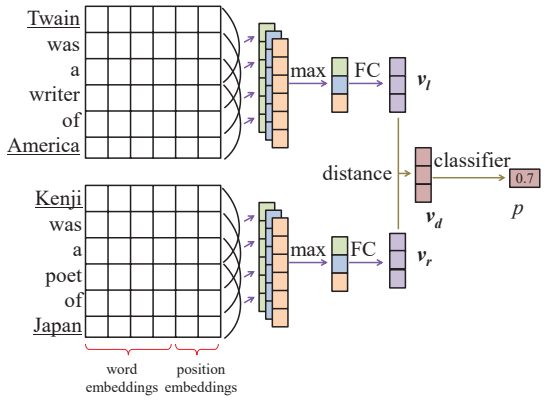

Figure 2: The architecture of Relational Siamese Networks. The output is the similarity between two relational instances.

tional Siamese Neural Network for image metric learning, which inspires us to learn relational similarity metrics for OpenRE.

Semi-supervised Clustering. Semi-supervised clustering aims to cluster semantic patterns given instance seeds of target categories (Bair, 2013; Hongtao Lin, 2019). Differently, our proposed Semi-supervised RSN only leverages labeled instances of pre-defined relations, and does not need any seed of new relations.

3 Methodology

Our OpenRE framework mainly consists of two modules, the relation similarity calculation module and the relation clustering module. For relation similarity calculation, we propose Relational Siamese Networks (RSNs), which learn to predict whether two sentences mention the same relation. To utilize large-scale unsupervised data and distantly-supervised data, we further propose Semi-supervised RSN and Distantly-supervised RSN. Finally, in the relation clustering module, with the learned relation metric, we utilize hierarchical agglomerative clustering (HAC) and Louvain clustering algorithms to cluster target relation instances of new relation types.

3.1 Relational Siamese Network (RSN)

The architecture of our Relational Siamese Networks is shown in Figure 2. CNN modules encode a pair of relational instances into vectors, and several shared layers compute their similarity.

Sentence Encoder. We use a CNN module as the sentence encoder. The CNN module includes an embedding layer, a convolutional layer, a max-pooling layer, and a fully-connected (FC) layer. The embedding layer transforms the words in a sentence x and the positions of entities e_{head} and e_{tail} into pre-trained word embeddings and random-initialized position embeddings. Following (Zeng et al., 2014), we concatenate these embeddings to form a vector sequence. Next, a one-dimensional convolutional layer and a max-pooling layer transform the vector sequence into features. Finally, an FC layer with sigmoid activation maps features into a relational vector $\boldsymbol{v}$. To summarize, we obtain a vector representation $\boldsymbol{v}$ for a relational sentence with our CNN module:

$$\boldsymbol{v} = \mathrm{CNN}(\mathrm{s}), \tag{1}$$

in which we denote the joint information of a sentence x and two entities in it e_{head} and e_{tail} as a data sample s. And with paired input relational instances, we have:

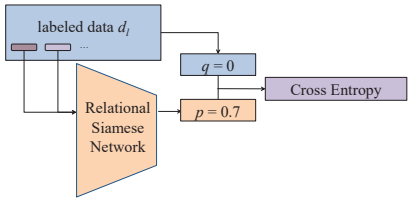
$$\boldsymbol{v_l} = \mathrm{CNN}(\mathrm{s_l}), \boldsymbol{v_r} = \mathrm{CNN}(\mathrm{s_r}), \tag{2}$$

in which two CNN modules are identical and share all the parameters.

Similarity Computation. Next, to measure the similarity of two relational vectors, we calculate their absolute distance and transform it into a real-number similarity $p \in [0, 1]$. First, a distance layer computes the element-wise absolute distance of two vectors:

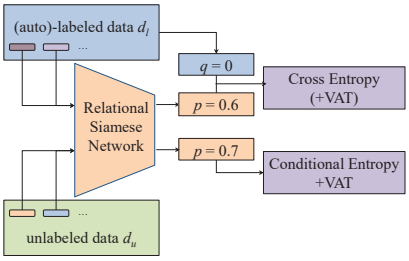
$$\boldsymbol{v_d} = |\boldsymbol{v_l} - \boldsymbol{v_r}|. \tag{3}$$

Then, a classifier layer calculates a metric p for relation similarity. The layer is a one-dimensional-output FC layer with sigmoid activation:



$$p = \sigma(\boldsymbol{k}\boldsymbol{v_d} + b), \tag{4}$$

in which σ denotes the sigmoid function, $\boldsymbol{k}$ and b denote the weights and bias. To summarize, we obtain a good similarity metric p of relational instances.



Cross Entropy Loss. The output of RSN p can also be explained as the probability of two sentences mentioning two different relations. Thus, we can use binary labels q and binary cross entropy loss to train our RSN:

$$\mathcal{L}_l = \mathbb{E}_{d_l \sim \mathcal{D}_l}[q \ln(p_\theta(d_l)) + (1-q)\ln(1-p_\theta(d_l))], \tag{5}$$

in which θ indicates all the parameters in the RSN.

(a) Supervised RSN

(b) Weakly-supervised RSNs

Figure 3: The comparison of (a) Supervised RSN and (b) Weakly-supervised RSNs. Weakly-supervised RSNs, including Semi-supervised RSN and Distantly-supervised RSN, further learn from unlabeled data with conditional entropy minimization and virtual adversarial training (VAT). In figures, p indicates the predicted similarity of two relational sentences, while q indicates the ground-truth label between them.

3.2 Semi-supervised RSN

To discover relation clusters in the open-domain corpus, it is beneficial to not only learn from labeled data, but also capture the manifold of unlabeled data in the semantic space. To this end, we need to push the decision boundaries away from high-density areas, which is known as the cluster assumption (Chapelle and Zien, 2005).

We try to achieve this goal with several additional loss functions. In the following paragraphs, we denote the labeled training dataset as $\mathcal{D}_l$ and a couple of labeled relational instances as d_l. Similarly, we denote the unlabeled training dataset as $\mathcal{D}_u$ and a couple of unlabeled instances as d_u.

Conditional Entropy Loss. In classification problems, a well-classified embedding space usually reserves large margins between different classified clusters, and optimizing margin can be a promising way to facilitate training. However, in clustering problems, type labels are not available during training. To optimize margin without explicit supervision, we can push the data points away from the decision boundaries. Intuitively, when the distance similarity p between two relational instances equals 0.5, there is a high probability that at least one of two instances is near the decision boundary between relation clusters. Thus, we use the conditional entropy loss (Grandvalet and Bengio, 2005), which reaches the maximum when $p = 0.5$, to penalize close-boundary distribution of data points:

$$\begin{aligned}\mathcal{L}_u = \mathbb{E}_{d_u \sim \mathcal{D}_u}[p_\theta(d_u)\ln(p_\theta(d_u)) + \\ (1 - p_\theta(d_u))\ln(1 - p_\theta(d_u))].\end{aligned} \tag{6}$$

Virtual Adversarial Loss. Despite its theoretical promise, conditional entropy minimization suffers from shortcomings in practice. Due to neural networks' strong fitting ability, a very complex decision hyperplane might be learned so as to keep away from all the training samples, which lacks generalizability. As a solution, we can smooth the relational representation space with locally-Lipschitz constraint.

To satisfy this constraint, we introduce virtual adversarial training (Miyato et al., 2016) on both branches of RSN. Virtual adversarial training can search through data point neighborhoods, and penalize most sharp changes in distance prediction. For labeled data, we have

$$\mathcal{L}_{vl} = \mathbb{E}_{d_l \sim \mathcal{D}_l}[\mathrm{D}_{\mathrm{KL}}(p_\theta(d_l)||p_\theta(d_l, t_1, t_2))], \tag{7}$$

in which D_{KL} indicates the Kullback-Leibler divergence, $p_\theta(d_l, t_1, t_2)$ indicates a new distance estimation with perturbations t_1 and t_2 on both input instances respectively. Specifically, t_1 and t_2 are worst-case perturbations that maximize the KL divergence between $p_\theta(d_l)$ and $p_\theta(d_l, t_1, t_2)$ with a limited length. Empirically, we approximate the perturbations the same as the original paper (Miyato et al., 2016). Specifically, we first add a random noise to the input, and calculate the gradient of the KL-divergence between the outputs of the original input and the noisy input. We then add the normalized gradient to the original input and get the perturbed input. And for unlabeled data, we have

$$\mathcal{L}_{vu} = \mathbb{E}_{d_u \sim \mathcal{D}_u}[\mathrm{D}_{\mathrm{KL}}(p_\theta(d_u)||p_\theta(d_u, t_1, t_2))], \tag{8}$$

in which the perturbations t_1 and t_2 are added to word embeddings rather than the words themselves.

To summarize, we use the following loss function to train Semi-supervised RSN, which learns from both labeled and unlabeled data:

$$\mathcal{L}_{all} = \mathcal{L}_l + \lambda_v \mathcal{L}_{vl} + \lambda_u(\mathcal{L}_u + \lambda_v \mathcal{L}_{vu}), \tag{9}$$

in which λ_v and λ_u are two hyperparameters.

3.3 Distantly-supervised RSN

To alleviate the intensive human labor for annotation, the topic of distantly-supervised learning has attracted much attention in RE. Here, we propose Distantly-supervised RSN, which can learn from both distantly-supervised data and unsupervised data for relational knowledge transfer. Specifically, we use the following loss function:

$$\mathcal{L}_{all} = \mathcal{L}_l + \lambda_u(\mathcal{L}_u + \lambda_v \mathcal{L}_{vu}), \tag{10}$$

which treats auto-labeled data as labeled data but removes the virtual adversarial loss on the auto-labeled data.

The reason to remove the loss is simple: virtual adversarial training on auto-labeled data can amplify the noise from false labels. Indeed, we do find that the virtual adversarial loss on auto-labeled data can harm our model's performance in experiments.

We do not use more denoising methods, since we think RSN has some inherent advantages of tolerating such noise. Firstly, the noise will be overwhelmed by the large proportion of negative sampling during training. Secondly, during clustering, the prediction of a new relation cluster is based on areas where the density of relational instances is high. Outliers from noise, as a result, will not influence the prediction process so much.

3.4 Open Relation Clustering

After RSN is learned, we can use RSN to calculate the similarity matrix of testing instances. With this matrix, several clustering methods can be applied to extract new relation clusters.

Hierarchical Agglomerative Clustering. The first clustering method we adopt is hierarchical agglomerative clustering (HAC). HAC is a bottom-up clustering algorithm. At the start, every testing instance is regarded as a cluster. For every step, it agglomerates two closest instances. There are several criteria to evaluate the distance between two clusters. Here, we adopt the complete-linkage criterion, which is more robust to extreme instances.

However, there is a significant shortcoming of HAC: it needs the exact number of clusters in advance. A potential solution is to stop agglomerating according to an empirical distance threshold, but it is hard to determine such a threshold. This problem leads us to consider another clustering algorithm Louvain (Blondel et al., 2008).

Louvain. Louvain is a graph-based clustering algorithm traditionally used for detecting communities. To construct the graph, we use the binary approximation of RSN's output, with 0 indicating an edge between two nodes. The advantage of Louvain is that it does not need the number of potential clusters beforehand. It will automatically find proper sizes of clusters by optimizing community modularity. According to the experiments we conduct, Louvain performs better than HAC.

After running, Louvain might produce a number of singleton clusters with few instances. It is not proper to call these clusters new relation types, so we label these instances the same as their closest labeled neighbors.

Finally, we want to explain the reason why we do not use some other common clustering methods like K-Means, Mean-Shift and Ward's (Ward Jr, 1963) method of HAC: these methods calculate the centroid of several points during clustering by merely averaging them. However, the relation vectors in our model are high-dimensional, and the distance metric described by RSN is non-linear. Consequently, it is not proper to calculate the centroid by simply averaging the vectors.

4 Experiments

In this section, we conduct several experiments on real-world RE datasets to show the effectiveness of our models, and give a detailed analysis to show its advantages.

4.1 Dataset

In experiments, we use FewRel (Han et al., 2018) as our first dataset. FewRel is a human-annotated dataset containing 80 types of relations, each with 700 instances. An advantage of FewRel is that every instance contains a unique entity pair, so RE models cannot choose the easy way to memorize the entities.

We use the original train set of FewRel, which contains 64 relations, as labeled set with predefined relations, and the original validation set of FewRel, which contains 16 new relations, as the unlabeled set with novel relations to extract. We then randomly choose $1,600$ instances from the unlabeled set as the test set, with the rest labeled and unlabeled instances considered as the train set.

The second dataset we use is FewRel-distant, which contains the distantly-supervised data obtained by the authors of FewRel before human an-

notation. We follow the split of FewRel to obtain the auto-labeled train set and unlabeled train set. For evaluation, we use the human-annotated test set of FewRel with $1,600$ instances. Unlabeled instances already existing in this test set are removed from the unlabeled train set of FewRel-distant. Finally, the auto-labeled train set contains $323,549$ relational instances, and the unlabeled train set contains $60,581$ instances.

A previous OpenRE work reports performance on an unpublic dataset called NYT-FB (Marcheggiani and Titov, 2016). However, it has several shortcomings compared with FewRel-distant. First, NTY-FB's test set is distantly-supervised and is noisy for instance-level RE. Moreover, instances in NYT-FB often share entity pairs or relational phrases, which makes it much easier for relation clustering. Therefore, we think the results on FewRel-distant are convincing enough for Distantly-supervised OpenRE.

4.2 Implementation Details

Data Sampling. The input of RSN should be a pair of sampled instances. For the unlabeled set, the only possible sampling method is to select two instances randomly. For the labeled set, however, random selection would result in too many different-relation pairs, and cause severe biases for RSN. To solve this problem, we use down-sampling. In our experiments, we fix the percentage of same-relation pairs in every labeled data batch as 6%.

Let us denote this percentage number as the sample ratio for convenience. Experimental results show that the sample ratio decides RSN's tendency to predict larger or smaller clusters. In other words, it controls the granularity of the predicted relation types. This phenomenon suggests a potential application of our model in hierarchical relation extraction. However, we leave any serious discussion to future work.

Hyperparameter Settings. Following (Lin et al., 2016) and (Zeng et al., 2014), we fix the less influencing hyperparameters for sentence encoding as their reported optimal values. For word embeddings, we use pre-trained 50-dimensional Glove (Pennington et al., 2014) word embeddings. For position embeddings, we use random-initialized 5-dimensional position embeddings. During training, all the embeddings are trainable. For the neural network, the number of feature maps in the convolutional layer is 230. The filter length is 3. The activation function after the max-pooling layer is ReLU, and the activation functions after FC layers are sigmoid. Besides, we adopt two regularization methods in the CNN module. We put a dropout layer right after the embedding layer as (Miyato et al., 2016). The dropout rate is 0.2. We also impose L2 regularization on the convolutional layer and the FC layer, with parameters of 0.0002 and 0.001 respectively. Hyperparameters for virtual adversarial training are just the same as (Miyato et al., 2016) proposed.

At the same time, major hyperparameters are selected with grid search according to the model performance on a validation set. Specifically, the validation set contains 10,000 randomly chosen sentence pairs from the unlabeled set (i.e. 16 novel relations) and does not overlap with the test set. The model is evaluated according to the precision of binary classification of sentence pairs on the validation set, which is an estimation for models' clustering ability. We do not use F1 during model validation because the clustering steps are time-consuming.

For optimization, we use Adam optimizer (Kingma and Ba, 2014) with a learning rate of 0.0001, which is selected from $\{0.1, 0.01, 0.001, 0.0001, 0.00001\}$. The batch size is 100 selected from $\{25, 50, 100\}$. For hyperparameters in Equation 9 and Equation 10, λ_v is 1.0 selected from $\{0.1, 0.5, 1.0, 2.0\}$ and λ_u is 0.03 selected from $\{0.01, 0.02, 0.03, 0.04, 0.05\}$.

For baseline models, original papers do grid search for all possible hyperparameters and report the best result during testing. We follow their settings and do grid search directly on the test set.

4.3 Experiment Results on OpenRE

In this section, we demonstrate the effectiveness of our RSN models by comparing our models with state-of-the-art clustering-based OpenRE methods. We also conduct ablation experiments to detailedly investigate the contributions of different mechanisms of Semi-supervised RSN and Distantly-supervised RSN.

Baselines. Conventional clustering-based OpenRE models usually cluster instances by either clustering their linguistic features (Lin and Pantel, 2001; Yao et al., 2012; Elsahar et al., 2017) or imposing reconstruction constraints (Yao et al., 2011; Marcheggiani and Titov, 2016). To demonstrate

the effectiveness of our RSN models, we compare our models with two state-of-the-art models:

(1) HAC with re-weighted word embeddings (RW-HAC) (Elsahar et al., 2017): RW-HAC is the state-of-the-art feature clustering model for OpenRE. The model first extracts KB types and NER tags of entities as well as re-weighted word embeddings from sentences, then adopts principal component analysis (PCA) to reduce feature dimensionality, and finally uses HAC to cluster the concatenation of reduced feature representations.

(2) Discrete-state variational autoencoder (VAE) (Marcheggiani and Titov, 2016): VAE is the state-of-the-art reconstruction-based model for OpenRE via unlabeled instances. It optimizes a relation classifier by reconstructing entities from pairing entities and predicted relation types. Rich features including entity words, context words, trigger words, dependency paths, and context POS tags are used to predict the relation type.

RW-HAC and VAE both rely on external linguistic tools to extract rich features from plain texts. Specifically, we first align entities to Wikidata and get their KB types. Next, we preprocess the instances with part-of-speech (POS) tagging, named-entity recognition (NER), and dependency parsing with Stanford CoreNLP (Manning et al., 2014). It is worth noting that these features are only used by baseline models. Our models, in contrast, only use sentences and entity pairs as inputs.

Evaluation Protocol. In evaluation, we use B^3 metric (Bagga and Baldwin, 1998) as the scoring function. B^3 metric is a standard measure to balance the precision and recall of clustering tasks, and is commonly used in previous OpenRE works (Marcheggiani and Titov, 2016; Elsahar et al., 2017). To be specific, we use F_1 measure, the harmonic mean of precision and recall.

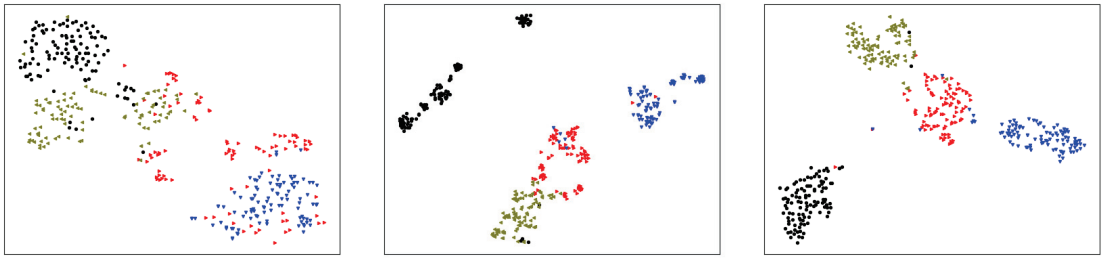
First, we report the result of supervised RSN with different clustering methods. Specifically, **SN** represents the original RSN structure, **HAC** and **L** indicate HAC and Louvain clustering introduced in Sec. 3.3. The result shows that Louvain performs better than HAC, so in the following experiments we focus on using Louvain clustering.

Next, for Semi-supervised and Distantly-supervised RSN, we conduct various combinations of different mechanisms to verify the contribution of each part. **(+C)** indicates that the model is powered up with conditional entropy minimization, while **(+V)** indicates that the model is powered up with virtual adversarial training.

Approach	FewRel P	FewRel R	FewRel F_1	FewRel-distant P	FewRel-distant R	FewRel-distant F_1
VAE	17.9	69.7	28.5	17.9	69.7	28.5
RW-HAC	31.8	46.0	37.6	31.8	46.0	37.6
SN-HAC	36.2	53.3	43.1	34.5	53.3	41.5
SN-L	36.5	69.2	47.8	34.6	59.8	43.9
SN-L+V	46.1	77.3	57.8	40.7	52.4	45.8
SN-L+C	47.1	**78.1**	58.8	**42.3**	66.0	51.5
SN-L+CV[1]	**48.9**	77.5	**59.9**	40.8	**74.0**	**52.6**

Table 1: Precision, recall and F1 results (%) for different models. The first two models are baselines. The next five models are different variants of our model.

Experimental Result Analysis. Table 1 shows the experimental results, from which we can observe that:



(1) RSN models outperform all baseline models on precision, recall, and F1-score, among which Weakly-supervised RSN (SN-L+CV) achieves state-of-the-art performances. This indicates that RSN is capable of understanding new relations' semantic meanings within sentences.

(2) Supervised and distantly-supervised relational representations improve clustering performances. Compared with RW-HAC, SN-HAC achieves better clustering results because of its supervised relational representation and similarity metric. Specifically, unsupervised baselines mainly use sparse one-hot features. RW-HAC uses word embeddings, but integrates them in a rule-based way. In contrast, RSN uses distributed feature representations, and can optimize information integration process according to supervision.

(3) Louvain outperforms HAC for clustering with RSN, comparing SN-HAC with SN-L. One explanation is that our model does not put additional constraints on the prior distribution of relational vectors, and therefore the relation clusters might have odd shapes in violation of HAC's assumption. Moreover, when representations are not distinguishable enough, forcing HAC to find fine-grained clusters may harm recall while contributing minimally to precision. In practice, we do observe that the number of relations SN-L extracts is constantly less than the true number 16.

(4) Both SN-L+V and SN-L+C improve the performance of supervised or distantly-supervised

[1]Here for FewRel-distant we use Equation 10 rather than Equation 9 as loss, which corresponds to Distantly-supervised RSN, and this brings a minor improvement on F_1 from 52.0% to 52.6%.

(a) RSN (b) Semi-supervised RSN (c) Supervised CNN

Figure 4: The t-SNE visualization of the output vectors of CNN modules in our (a) OpenRE model RSN, (b) Semi-supervised RSN facilitated by unlabeled novel-relation data and in (c) a classical RE baseline trained with labeled novel-relation data. All figures visualize the clustering result for 402 instances of 4 novel relations.

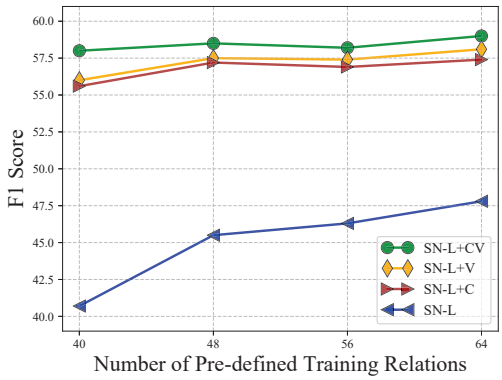


Figure 5: The clustering results with different numbers of pre-defined training relations.

RSN by further utilizing unsupervised corpora. Both semi-supervised approaches bring significant improvements for F_1 scores by increasing the precision and recall, and combining both can further increase the F_1 score.

(5) One interesting observation is that SN-L+V does not outperform SN-L so much on FewRel-distant. This is probably because VAT on the noisy data might amplify the noise. In further experiments, we perform VAT only on unlabeled set and observe improvements on F_1, with SN-L+V from 45.8% to 49.2% and SN-L+CV from 52.0% to 52.6%, which proves this conjecture.

4.4 The Influence of Pre-defined Relation Diversity on Generalizability

In this subsection, we mainly focus on analyzing the influence of pre-defined relation diversity, i.e., the number of relations in the labeled train set. To study this influence, we use FewRel for evaluation and change the number of relations in the labeled train set from 40 to 64 while fixing the total number of labeled instances to $25,000$, and report the clustering results in Figure 5.

Several conclusions can be drawn according to Figure 5. Firstly, a rich variety of labeled relations do improve the performance of our models, especially RSN. The models trained on 64 relations perform better than those trained on 40 relations constantly. Secondly, while the performance of supervised RSN is very sensitive to pre-defined relation diversity, its semi-supervised counterparts suffer much less from the relation number limit. This phenomenon suggests that Semi-supervised RSNs succeed in learning from unlabeled novel-relation data and are more generalizable to novel relations.

4.5 Relational Knowledge Representation Visualization

To intuitively evaluate the knowledge transfer effects of RSN and Semi-supervised RSN, we visualize their relational knowledge representation spaces in the last layer of CNN encoders with t-SNE(Maaten and Hinton, 2008) in Figure 4. We also compare with a supervised CNN trained on $9,600$ labeled instances of novel relations, which suggests the optimal relational knowledge representation. In each figure, we plot 402 relation instances of 4 randomly-chosen relation types in the test set, and points are colored according to their ground-truth labels.

As we can see from Figure 4, RSN is able to roughly distinguish different relations, and Semi-supervised RSN further facilitated knowledge transfer by optimizing the margin between potential relation clusters during training. As a result, Semi-supervised RSN can extract more distinguishable novel relations, and gains comparable

relational knowledge representation ability with supervised CNN.

5 Conclusions and Future Work

In this paper, we propose a new model Relational Siamese Network (RSN) for OpenRE. Different from conventional unsupervised models, our model learns to measure relational similarity from supervised/distantly-supervised data of predefined relations, as well as unsupervised data of novel relations. There are mainly two innovative points in our model. First, we propose to transfer relational similarity knowledge with RSN structure. To the best of our knowledge, we are the first to propose knowledge transfer for OpenRE. Second, we propose Semi/Distantly-supervised RSN, to further perform semi-supervised and distantly-supervised transfer learning. Experiments show that our models significantly surpass conventional OpenRE models and achieve new state-of-the-art performance.

For future research, we plan to explore the following directions: (1) Besides CNN, there are some other popular sentence encoder structures like piecewise convolutional neural network (PCNN) and Long Short-Term Memory (LSTM) for RE. In the future, we can try different sentence encoders in our model. (2) As mentioned above, our model has the potential ability to discover the hierarchical structure of relations. In the future, we will try to explore this application with additional experiments.

Abstract

While attention mechanisms have been proven to be effective in many NLP tasks, majority of them are data-driven. We propose a novel knowledge-attention encoder which incorporates prior knowledge from external lexical resources into deep neural networks for relation extraction task. Furthermore, we present three effective ways of integrating knowledge-attention with self-attention to maximize the utilization of both knowledge and data. The proposed relation extraction system is end-to-end and fully attention-based. Experiment results show that the proposed knowledge-attention mechanism has complementary strengths with self-attention, and our integrated models outperform existing CNN, RNN, and self-attention based models. State-of-the-art performance is achieved on TACRED, a complex and large-scale relation extraction dataset.

1 Introduction

Relation extraction aims to detect the semantic relationship between two entities in a sentence. For example, given the sentence: "*James Dobson* has resigned as chairman of *Focus On The Family*, which he founded thirty years ago.", the goal is to recognize the organization-founder relation held between "*Focus On The Family*" and "*James Dobson*". The various relations between entities extracted from large-scale unstructured texts can be used for ontology and knowledge base population (Chen et al., 2018a; Fossati et al., 2018), as well as facilitating downstream tasks that requires relational understanding of texts such as question answering (Yu et al., 2017) and dialogue systems (Young et al., 2018).

Traditional feature-based and kernel-based approaches require extensive feature engineering (Suchanek et al., 2006; Qian et al., 2008; Rink and Harabagiu, 2010). Deep neural networks such as Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) have the ability of exploring more complex semantics and extracting features automatically from raw texts for relation extraction tasks (Xu et al., 2016; Vu et al., 2016; Lee et al., 2017). Recently, attention mechanisms have been introduced to deep neural networks to improve their performance (Zhou et al., 2016; Wang et al., 2016; Zhang et al., 2017). Especially, the Transformer proposed by Vaswani et al. (2017) is based solely on self-attention and has demonstrated better performance than traditional RNNs (Bilan and Roth, 2018; Verga et al., 2018). However, deep neural networks normally require sufficient labeled data to train their numerous model parameters. The scarcity or low quality of training data will limit the model's ability to recognize complex relations and also cause overfitting issue.

A recent study (Li and Mao, 2019) shows that incorporating prior knowledge from external lexical resources into deep neural network can reduce the reliance on training data and improve relation extraction performance. Motivated by this, we propose a novel knowledge-attention mechanism, which transforms texts from word semantic space into relational semantic space by attending to relation indicators that are useful in recognizing different relations. The relation indicators are automatically generated from lexical knowledge bases which represent keywords and cue phrases of different relation expressions. While the existing self-attention encoder learns internal semantic features by attending to the input texts themselves, the proposed knowledge-attention encoder captures the linguistic clues of different relations based on external knowledge. Since the two attention mechanisms complement each other, we integrate them into a single model to maximize the uti-

lization of both knowledge and data, and achieve optimal performance for relation extraction.

In summary, the main contributions of the paper are: (1) We propose knowledge-attention encoder, a novel attention mechanism which incorporates prior knowledge from external lexical resources to effectively capture the informative linguistic clues for relation extraction. (2) To take the advantages of both knowledge-attention and self-attention, we propose three integration strategies: multi-channel attention, softmax interpolation, and knowledge-informed self-attention. Our final models are fully attention-based and can be easily set up for end-to-end training. (3) We present detailed analysis on knowledge-attention encoder. Results show that it has complementary strengths with self-attention encoder, and the integrated models achieve start-of-the-art results for relation extraction.

2 Related Works

We focus here on deep neural networks for relation extraction since they have demonstrated better performance than traditional feature-based and kernel-based approaches.

Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) are the earliest and commonly used approaches for relation extraction. Zeng et al. (2014) showed that CNN with position embeddings is effective for relation extraction. Similarly, CNN with multiple filter sizes (Nguyen and Grishman, 2015), pairwise ranking loss function (dos Santos et al., 2015) and auxiliary embeddings (Lee et al., 2017) were proposed to improve performance. Zhang and Wang (2015) proposed bi-directional RNN with max pooling to model the sequential relations. Instead of modeling the whole sentence, performing RNN on sub-dependency trees (e.g. shortest dependency path between two entities) has demonstrated to be effective in capturing long-distance relation patterns (Xu et al., 2016; Miwa and Bansal, 2016). Zhang et al. (2018) proposed graph convolution over dependency trees and achieved state-of-the-art results on TACRED dataset.

Recently, attention mechanisms have been widely applied to CNNs (Wang et al., 2016; Han et al., 2018) and RNNs (Zhou et al., 2016; Zhang et al., 2017; Du et al., 2018). The improved performance demonstrated the effectiveness of attention mechanisms in deep neural networks. Particularly, Vaswani et al. (2017) proposed a solely self-attention-based model called Transformer, which is more effective than RNNs in capturing long-distance features since it is able to draw global dependencies without regard to their distances in the sequences. Bilan and Roth (2018) first applied self-attention encoder to relation extraction task and achieved competitive results on TACRED dataset. Verga et al. (2018) used self-attention to encode long contexts spanning multiple sentences for biological relation extraction. However, more attention heads and layers are required for self-attention encoder to capture complex semantic and syntactic information since learning is solely based on training data. Hence, more high quality training data and computational power are needed. Our work utilizes the knowledge from external lexical resources to improve deep neural network's ability of capturing informative linguistic clues.

External knowledge has shown to be effective in neural networks for many NLP tasks. Existing works focus on utilizing external knowledge to improve embedding representations (Chen et al., 2015; Liu et al., 2015; Sinoara et al., 2019), CNNs (Toutanova et al., 2015; Wang et al., 2017; Li and Mao, 2019), and RNNs (Ahn et al., 2016; Chen et al., 2016, 2018b; Shen et al., 2018). Our work is the first to incorporate knowledge into Transformer through a novel knowledge-attention mechanism to improve its performance on relation extraction task.

3 Knowledge-attention Encoder

We present the proposed knowledge-attention encoder in this section. Relation indicators are first generated from external lexical resources (Section 3.1); Then the input texts are transformed from word semantic space into relational semantic space by attending to the relation indicators using knowledge-attention mechanism (Section 3.2); Finally, position-aware attention is used to summarize the input sequence by taking both relation semantics and relative positions into consideration (Section 3.3).

3.1 Relation Indicators Generation

Relation indicators represent the keywords or cue phrases of various relation types, which are essential for knowledge-attention encoder to capture the linguistic clues of certain relation from texts.

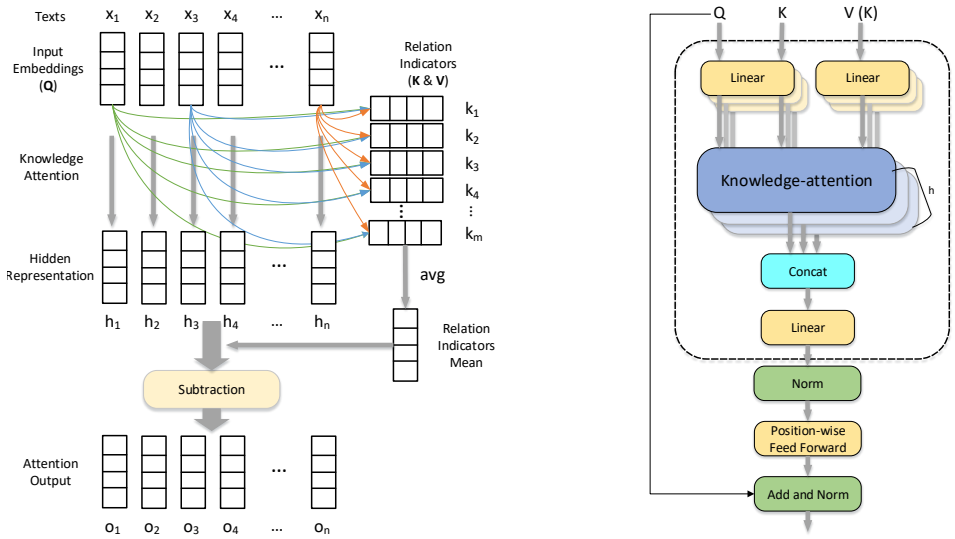

Figure 1: Knowledge-attention process (left) and multi-head structure (right) of knowledge-attention encoder.

We utilize two publicly available lexical resources including FrameNet[1] and Thesaurus.com[2] to find such lexical units.

FrameNet is a large lexical knowledge base which categorizes English words and sentences into higher level semantic frames (Ruppenhofer et al., 2006). Each frame is a conceptual structure describing a type of event, object or relation. FrameNet contains over 1200 semantic frames, many of which represent various semantic relations. For each relation type in our relation extraction task, we first find all the relevant semantic frames by searching from FrameNet (refer Appendix for detailed semantic frames used). Then we extract all the lexical units involved in these frames, which are exactly the keywords or phrases that often used to express such relation. Thesaurus.com is the largest online thesaurus which has over 3 million synonyms and antonyms. It also has the flexibility to filter search results by relevance, POS tag, word length, and complexity. To broaden the coverage of relation indicators, we utilize the synonyms in Thesaurus.com to extend the lexical units extracted from FrameNet. To reduce noise, only the most relevant synonyms with the same POS tag are selected.

Relation indicators are generated based on the word embeddings and POS tags of lexical units. Formally, given a word in a lexical unit, we find its word embedding $\mathbf{w}_i \in \mathbb{R}^{d_w}$ and POS embedding $\mathbf{t}_i \in \mathbb{R}^{d_t}$ by looking up the word embedding matrix $\mathbf{W}^{wrd} \in \mathbb{R}^{d_w \times V^{wrd}}$ and POS embedding matrix $\mathbf{W}^{pos} \in \mathbb{R}^{d_t \times V^{pos}}$ respectively, where d_w and d_t are the dimensions of word and POS embeddings, V^{wrd} is vocabulary size[3] and V^{pos} is total number of POS tags. The corresponding relation indicator is formed by concatenating word embedding and POS embedding, $\mathbf{k}_i = [\mathbf{w}_i, \mathbf{t}_i]$. If a lexical unit contains multiple words (i.e. phrase), the corresponding relation indicator is formed by averaging the embeddings of all words. Eventually, around 3000 relation indicators (including 2000 synonyms) are generated: $\mathbf{K} = \{\mathbf{k}_1, \mathbf{k}_2, ..., \mathbf{k}_m\}$.

3.2 Knowledge Attention

3.2.1 Knowledge-attention process

In a typical attention mechanism, a query (q) is compared with the keys (K) in a set of key-value pairs and the corresponding attention weights are calculated. The attention output is weighted sum of values (V) using the attention weights. In our proposed knowledge-attention encoder, the queries are input texts and the key-value pairs are both relation indicators. The detailed process of knowledge-attention is shown in Figure 1 (left).

Formally, given text input $x = \{x_1, x_2, ..., x_n\}$, the input embeddings $\mathbf{Q} = \{\mathbf{q}_1, \mathbf{q}_2, ..., \mathbf{q}_n\}$ are generated by concatenating each word's word embedding and POS embedding in the same way as relation indicator generation in Section 3.1. The

[1] https://framenet.icsi.berkeley.edu/fndrupal

[2] https://www.thesaurus.com

[3] Same word embedding matrix is used for relation indicators and input texts, hence the vocabulary also includes all the words in the training corpus.

hidden representations $\mathbf{H} = \{\mathbf{h}_1, \mathbf{h}_2, ..., \mathbf{h}_n\}$ are obtained by attending to the knowledge indicators $\mathbf{K}$, as shown in Equation 1. The final knowledge-attention outputs are obtained by subtracting the hidden representations with the relation indicators mean, as shown in Equation 2.

$$\mathbf{H} = softmax(\frac{\mathbf{Q}\mathbf{K}^T}{\sqrt{d_k}})\mathbf{V} \quad (1)$$

$$knwl(\mathbf{Q}, \mathbf{K}, \mathbf{V}) = \mathbf{H} - \sum \mathbf{K}/m \quad (2)$$

where $knwl$ indicates knowledge-attention process, m is the number of relation indicators, and d_k is dimension of key/query vectors which is a scaling factor same as in Vaswani et al. (2017).

The subtraction of relation indicators mean will result in small outputs for irrelevant words. More importantly, the resulted output will be close to the related relation indicators and further apart from other relation indicators in relational semantic space. Therefore, the proposed knowledge-attention mechanism is effective in capturing the linguistic clues of relations represented by relation indicators in the relational semantic space.

3.2.2 Multi-head knowledge-attention

Inspired by the multi-head attention in Transformer (Vaswani et al., 2017), we also have multi-head knowledge-attention which first linearly transforms $\mathbf{Q}$, $\mathbf{K}$ and $\mathbf{V}$ h times, and then perform h knowledge-attentions simultaneously, as shown in Figure 1 (right).

Different from the Transformer encoder, we use the same linear transformation for $\mathbf{Q}$ and $\mathbf{K}$ in each head to keep the correspondence between queries and keys.

$$head_i = knwl(\mathbf{Q}\mathbf{W}_i^Q, \mathbf{K}\mathbf{W}_i^Q, \mathbf{V}\mathbf{W}_i^V) \quad (3)$$

where $\mathbf{W}_i^Q, \mathbf{W}_i^V \in \mathbb{R}^{d_k \times (d_k/h)}$ and $i \in [1, 2, ...h]$. Besides, only one residual connection from input embeddings to outputs of position-wise feed forward networks is used. We also mask the outputs of padding tokens using zero vectors.

The multi-head structure in knowledge-attention allows the model to jointly attend inputs to different relational semantic subspaces with different contributions of relation indicators. This is beneficial in recognizing complex relations where various compositions of relation indicators are needed.

3.3 Position-aware Attention

It has been proven that the relative position information of each token with respective to the two target entities is beneficial for relation extraction task (Zeng et al., 2014). We modify the position-aware attention originally proposed by Zhang et al. (2017) to incorporate such relative position information and find the importance of each token to the final sentence representation.

Assume the relative position of token x_i to target entity is $\hat{p}_i$. We apply position binning function (Equation 4) to make it easier for the model to distinguish long and short relative distances.

$$p_i = \begin{cases} \hat{p}_i & |\hat{p}_i| \leq 2 \\ \frac{\hat{p}_i}{|\hat{p}_i|} \lceil log_2 |\hat{p}_i| + 1 \rceil & |\hat{p}_i| > 2 \end{cases} \quad (4)$$

After getting the relative positions p_i^s and p_i^o to the two entities of interest (subject and object respectively), we map them to position embeddings base on a shared position embedding matrix $\mathbf{W}^p$. The two embeddings are concatenated to form the final position embedding for token x_i: $\mathbf{p}_i = [\mathbf{p}_i^s, \mathbf{p}_i^o]$.

Position-aware attention is performed on the outputs of knowledge-attention $\mathbf{O} \in \mathbb{R}^{n \times d_k}$, taking the corresponding relative position embeddings $\mathbf{P} \in \mathbb{R}^{n \times d_p}$ into consideration:

$$\mathbf{f} = O^T softmax(tanh(\mathbf{O}\mathbf{W}_o + \mathbf{P}\mathbf{W}_p)\mathbf{c}) \quad (5)$$

where $\mathbf{W}_o \in \mathbb{R}^{d_k \times d_a}$, $\mathbf{W}_p \in \mathbb{R}^{d_p \times d_a}$, d_a is attention dimension, and $\mathbf{c} \in \mathbb{R}^{d_a}$ is a context vector learned by the neural network.

4 Integrate Knowledge-attention with Self-attention

The self-attention encoder proposed by Vaswani et al. (2017) learns internal semantic features by modeling pair-wise interactions within the texts themselves, which is effective in capturing long-distance dependencies. Our proposed knowledge-attention encoder has complementary strengths of capturing the linguistic clues of relations precisely based on external knowledge. Therefore, it is beneficial to integrate the two models to maximize the utilization of both external knowledge and training data. In this section, we propose three integration approaches as shown in Figure 2, and each approach has its own advantages.

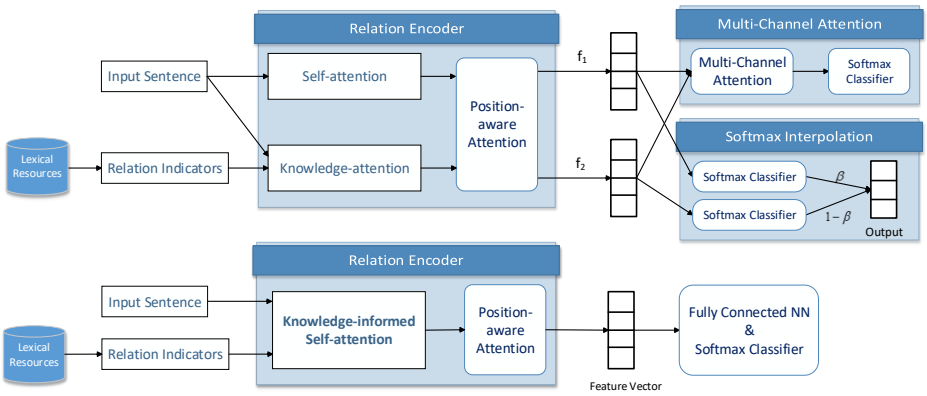

Figure 2: Three ways of integrating knowledge-attention with self-attention: multi-channel attention and softmax interpolation (top), as well as knowledge-informed self-attention (bottom).

4.1 Multi-channel Attention

In this approach, self-attention and knowledge-attention are treated as two separate channels to model sentence from different perspectives. After applying position-aware attention, two feature vectors $\mathbf{f}_1$ and $\mathbf{f}_2$ are obtained from self-attention and knowledge-attention respectively. We apply another attention mechanism called multi-channel attention to integrate the feature vectors.

In multi-channel attention, feature vectors are first fed into a fully connected neural network to get their hidden representations $\mathbf{h}_i$. Then attention weights are calculated using a learnable context vector $\mathbf{c}$, which reflects the importance of each feature vector to final relation classification. Finally, the feature vectors are integrated based on attention weights, as shown in Equation 6.

$$\mathbf{r} = \sum_i softmax(\mathbf{h}_i^T \mathbf{c})\mathbf{h}_i \tag{6}$$

After obtaining the integrated feature vector $\mathbf{r}$, we pass it to a softmax classifier to determine the relation class. The model is trained using stochastic gradient descent with momentum and learning rate decay to minimize the cross-entropy loss.

The main advantage of this approach is flexibility. Since the two channels process information independently, the input components are not necessary to be the same. Besides, we can add more features from other sources (e.g. subject and object categories) to multi-channel attention to make final decision based on all the information sources.

4.2 Softmax Interpolation

Similar as multi-channel attention, we also use two independent channels for self-attention and knowledge-attention in softmax interpolation. Instead of integrating the feature vectors, we make two independent predictions using two softmax classifiers based on the feature vectors from the two channels. The loss function is defined as total cross-entropy loss of the two classifiers. The final prediction is obtained using an interpolation function of the two softmax distributions:

$$\mathbf{p} = \beta \cdot \mathbf{p}_1 + (1 - \beta) \cdot \mathbf{p}_2 \tag{7}$$

where $\mathbf{p}_1$, $\mathbf{p}_2$ are the softmax distributions obtained form self-attention and knowledge-attention respectively, and β is the priority weight assigned to self-attention.

Since knowledge-attention focuses on capturing the keywords and cue phrases of relations, the precision will be higher than self-attention while the recall is lower. The proposed softmax interpolation approach is able to take the advantages of both attention mechanisms and balance the precision and recall by adjusting the priority weight β.

4.3 Knowledge-informed Self-attention

Since knowledge-attention and self-attention share similar structures, it is also possible to integrate them into a single channel. We propose knowledge-informed self-attention encoder which incorporates knowledge-attention into every self-attention head to jointly model the semantic relations based on both knowledge and data.

The structure of knowledge-informed self-attention is shown in Figure 3. Formally, given texts input matrix $\mathbf{Q} \in \mathbb{R}^{n \times d_k}$ and knowledge indicators $\mathbf{K} \in \mathbb{R}^{m \times d_k}$. The output of each attention head is calculated as follows:

$$\begin{aligned} head_i = \; & knwl(\mathbf{Q}\mathbf{W}_i^Q, \mathbf{K}\mathbf{W}_i^Q, \mathbf{K}\mathbf{W}_i^V) + \\ & self(\mathbf{Q}\mathbf{W}_i^{Q_s}, \mathbf{Q}\mathbf{W}_i^{K_s}, \mathbf{Q}\mathbf{W}_i^{V_s}) \end{aligned} \tag{8}$$

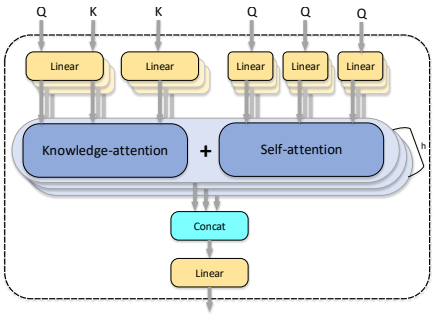

Figure 3: Knowledge-informed self-attention structure. Q, K represent input matrix and knowledge indicators respectively, h is the number of attention heads.

where $knwl$ and $self$ indicate knowledge-attention and self-attention respectively, and all the linear transformation weight matrices have the dimensionality of $\mathbf{W} \in \mathbb{R}^{d_k \times (d_k/h)}$.

Since each self-attention head is aided with prior knowledge in knowledge-attention, the knowledge-informed self-attention encoder is able to capture more lexical and semantic information than single attention encoder.

5 Experiment and Analysis

5.1 Baseline Models

To study the performance of our proposed models, the following baseline models are used for comparison:

CNN-based models including: (1) CNN: the classical convolutional neural network for sentence classification (Kim, 2014). (2) CNN-PE: CNN with position embeddings dedicated for relation classification (Nguyen and Grishman, 2015). (3) GCN: a graph convolutional network over the pruned dependency trees of the sentence (Zhang et al., 2018).

RNN-based models including: (1) LSTM: long short-term memory network to sequentially model the texts. Classification is based on the last hidden output. (2) PA-LSTM: Similar position-aware attention mechanism as our work is used to summarize the LSTM outputs (Zhang et al., 2017).

CNN-RNN hybrid model including contextualized GCN (C-GCN) where the input vectors are obtained using bi-directional LSTM network (Zhang et al., 2018).

Self-attention-based model (Self-attn) which uses self-attention encoder to model the input sentence. Our implementation is based on Bilan and Roth (2018) where several modifications are made on the original Transformer encoder, including the use of relative positional encodings instead of absolute sinusoidal encodings, as well as other configurations such as residual connection, activation function and normalization.

For our model, we evaluate both the proposed knowledge-attention encoder (Knwl-attn) as well as the integrated models with self-attention including multi-channel attention (MCA), softmax interpolation (SI) and knowledge-informed self-attention (KISA).

5.2 Experiment Settings

We conduct our main experiments on TACRED, a large-scale relation extraction dataset introduced by Zhang et al. (2017). TACRED contains over 106k sentences with hand-annotated subject and object entities as well as the relations between them. It is a very complex relation extraction dataset with 41 relation types and a *no_relation* class when no relation is hold between entities. The dataset is suited for real-word relation extraction since it is unbalanced with 79.5% *no_relation* samples, and multiple relations between different entity pairs can be exist in one sentence. Besides, the samples are normally long sentences with an average of 36.2 words.

Since the dataset is already partitioned into train (68124 samples), dev (22631 samples) and test (15509 samples) sets, we tune model hyperparameters using dev set and evaluate model using test set. The evaluation metrics are micro-averaged precision, recall and F_1 score. For fair comparison, we select the model with median F_1 score on dev set from 5 independent runs, same as Zhang et al. (2017). The same "entity mask" strategy is used which replaces subject (or object) entity with special $\langle$NER$\rangle$-SUBJ (or $\langle$NER$\rangle$-OBJ) tokens to avoid overfittting on specific entities and provide entity type information.

Besides TACRED, another dataset called SemEval2010-Task8 (Hendrickx et al., 2009) is used to evaluate the generalization ability of our proposed model. The dataset is significantly smaller and simpler than TACRED, which has 8000 training samples and 2717 testing samples. It contains 9 directed relations and 1 other relation (19 relation classes in total). We use the official macro-averaged F_1 score as evaluation metric.

We use one layer encoder with 6 attention heads for both knowledge-attention and self-attention

since further increasing the number of layers and attention heads will degrade the performance. For softmax interpolation, we choose $\beta = 0.8$ to balance precision and recall. Word embeddings are fine-tuned based on pre-trained GloVe (Pennington et al., 2014) with dimensionality of 300. Dropout (Srivastava et al., 2014) is used during trianing to alleviate overfitting. Other model hyperparameters and training details are described in Appendix due to space limitations.

5.3 Results and Analysis

5.3.1 Results on TACRED dataset

Table 1 shows the results of baseline as well as our proposed models on TACRED dataset. It is observed that our proposed knowledge-attention encoder outperforms all CNN-based and RNN-based models by at least 1.3 F_1. Meanwhile, it achieves comparable results with C-GCN and self-attention encoder, which are the current start-of-the-art single-model systems.

Comparing with self-attention encoder, it is observed that knowledge-attention encoder results in higher precision but lower recall. This is reasonable since knowledge-attention encoder focuses on capturing the significant linguistic clues of relations based on external knowledge, it will result in high precision for the predicted relations similar to rule-based systems. Self-attention encoder is able to capture more long-distance dependency features by learning from data, resulting in better recall. By integrating self-attention and knowledge-attention using the proposed approaches, a more balanced precision and recall can be obtained, suggesting the complementary effects of self-attention and knowledge-attention mechanisms. The integrated models improve performance by at least 0.9 F_1 score and achieve new state-of-the-art results among all the single end-to-end models.

Comparing the three integrated models, softmax interpolation (SI) achieves the best performance. More interestingly, we found that the precision and recall can be controlled by adjusting the priority weight β. Figure 4 shows impact of β on precision, recall and F_1 score. As β increases, precision decreases and recall increases. Therefore, we can choose a small β for relation extraction system which requires high precision, and a large β for the system requiring better recall. F_1 score reaches the highest value when precision and recall are balanced ($\beta = 0.8$).

Model	P	R	F_1
CNN†	**72.1**	50.3	59.2
CNN-PE†	68.2	55.4	61.1
GCN‡	69.8	59.0	64.0
LSTM†	61.4	61.7	61.5
PA-LSTM†	65.7	64.5	65.1
C-GCN‡	69.9	63.3	66.4
Self-attn††	64.6	**68.6**	66.5
Knwl-attn	70.0	63.1	66.4
Knwl+Self (MCA)	68.4	66.1	67.3*
Knwl+Self (SI)	67.1	68.4	**67.8***
Know+Self (KISA)	69.4	66.0	67.7*

Table 1: Micro-averaged precision (P), recall (R) and F_1 score on TACRED dataset. †, ‡ and †† mark the results reported in (Zhang et al., 2017), (Zhang et al., 2018) and (Bilan and Roth, 2018) respectively. $*$ marks statistically significant improvements over Self-attn with $p < 0.01$ under one-tailed t-test.

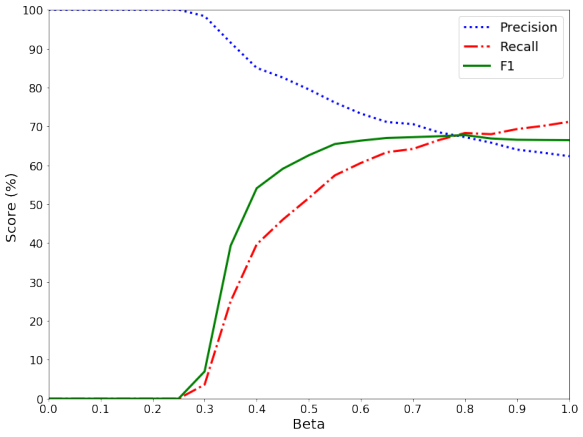

Figure 4: Change of precision, recall and F_1 score on dev set as the priority weight β in softmax interpolation changes.

Knowledge-informed self-attention (KISA) has comparable performance with softmax interpolation, and without the need of hyper-parameter tuning since knowledge-attention and self-attention are integrated into a single channel. The performance gain over self-attention encoder is 1.2 F_1 with much improved precision, demonstrating the effectiveness of incorporating knowledge-attention into self-attention to jointly model the sentence based on both knowledge and data.

Performance gain is the lowest for multi-channel attention (MCA). However, the model is more flexible in the way that features from other information sources can be easily added to the

Model	P	R	F_1
MCA	68.4	66.1	67.3
+ NER	68.7	**66.2**	67.5
+ Entity category	70.0	65.8	67.8
+ Both	**70.1**	66.0	**67.9**

Table 2: Results of adding NER embeddings and entity categorical embeddings to the multi-channel attention (MCA) integrated model.

model to further improve its performance. Table 2 shows the results of adding NER embeddings of each token to self-attention channel, and entity (subject and object) categorical embeddings to multi-channel attention as additional feature vectors. We use dimensionality of 30 and 60 for NER and entity categorical embeddings respectively, and the two embedding matrixes are learned by the neural network. Results show that adding NER and entity categorical information to MCA integrated model improves F_1 score by 0.2 and 0.5 respectively, and adding both improves precision significantly, resulting a new best F_1 score.

5.3.2 Results on SemEval2010-Task8 dataset

We use SemEval2010-Task8 dataset to evaluate the generalization ability of our proposed model. Experiments are conducted in two manners: mask or keep the entities of interest. Results in Table 3 show that the "entity mask" strategy degrades the performance, indicating that there exist strong correlations between entities of interest and relation classes in SemEval2010-Task8 dataset. Although the results of keeping the entities are better, the model tends to remember these entities instead of focusing on learning the linguistic clues of relations. This will result in bad generalization for sentences with unseen entities.

Regardless of whether the entity mask is used, by incorporating knowledge-attention mechanism, our model improves the performance of self-attention by a statistically significant margin, especially the softmax interpolation integrated model. The results on SemEval2010-Task8 are consistent with that of TACRED, demonstrating the effectiveness and robustness of our proposed method.

5.3.3 Ablation study

To study the contributions of specific components of knowledge-attention encoder, we perform ablation experiments on the dev set of TACRED. The results of knowledge-attention encoder with and without certain components are shown in Table 4.

Model	mask entity	keep entity
Self-attn	76.8	83.1
Knwl-attn	76.1	82.3
Knwl+Self (MCA)	77.4*	84.0*
Knwl+Self (SI)	**78.0***	**84.3***
Know+Self (KISA)	77.5*	84.0*

Table 3: Macro-averaged F_1 score on SemEval2010-Task8 dataset. $*$ marks statistically significant improvements over Self-attn with $p < 0.01$ under one-tailed t-test.

Model	Dev F_1
Knwl-attn Encoder	66.5
1. − Multi-head structure	64.6
2. − Synonym relation indicators	64.7
3. − Relation indicators mean	65.0
4. − Output masking	65.8
5. − Entity masking	65.4
6. − Relative positions	63.0

Table 4: Ablation study on knowledge-attention encoder. Results are the median F_1 scores of 5 independent runs on dev set of TACRED.

It is observed that: (1) The proposed multi-head knowledge-attention structure outperforms single-head significantly. This demonstrates the effectiveness of jointly attending texts to different relational semantic subspaces in the multi-head structure. (2) The synonyms improve the performance of knowledge-attention since they are able to broaden the coverage of relation indicators and form a robust relational semantic space. (3) The subtraction of relation indicators mean vector from attention hidden representations helps to suppress the activation of irrelevant words and results in a better representation for each word to capture the linguistic clues of relations. (4-5) The two masking strategies are helpful for our model: the output masking eliminates the effects of the padding tokens and the entity masking avoids entity overfitting while providing entity type information. (6) The relative position embedding term in position-aware attention contributes a significant amount of F_1 score. This shows that positional information is particularly important for relation extraction task.

5.3.4 Attention visualization

Table 5: Attention visualization for knowledge-attention encoder (first) and self-attention encoder (second). Words are highlighted based on the attention weights assigned to them. Best viewed in color.

encoder, we compare the attention weights assigned to words from the two encoders. Table 5 presents the attention visualization results on sample sentences. For each sample sentence, attention weights from knowledge-attention encoder are visualized first, followed by self-attention encoder. It is observed that knowledge-attention encoder focuses more on the specific keywords or cue phrases of certain relations, such as "graduated", "executive director" and "founded"; while self-attention encoder attends to a wide range of words in the sentence and pays more attention to the surrounding words of target entities especially the words indicating the syntactic structure, such as "is", "in" and "of". Therefore, knowledge-attention encoder and self-attention encoder have complementary strengths that focus on different perspectives for relation extraction.

5.3.5 Error analysis

To investigate the limitations of our proposed model and provide insights for future research, we analyze the errors produced by the system on the test set of TACRED. For knowledge-attention encoder, 58% errors are false negative (FN) due to the limited ability in capturing long-distance dependencies and some unseen linguistic clues during training. For our integrated model[4] that takes the benefits of both self-attention and knowledge-attention, FN is reduced by 10%. However, false positive (FP) is not improved due to overfitting that leads to wrong predictions. Many errors are caused by multiple entities with different relations co-occurred in one sentence. Our model may mistake irrelevant entities as a relation pair. We also observed that many FP errors are due to the confusions between related relations such as "city_of_death"and "city_of_residence". More data or knowledge is needed to distinguish "death" and "residence". Besides, some errors are caused by imperfect annotations.

6 Conclusion and Future Work

We introduce knowledge-attention encoder which effectively incorporates prior knowledge from external lexical resources for relation extraction. The proposed knowledge-attention mechanism transforms texts from word space into relational semantic space and captures the informative linguistic clues of relations effectively. Furthermore, we show the complementary strengths of knowledge-attention and self-attention, and propose three different ways of integrating them to maximize the utilization of both knowledge and data. The proposed models are fully attention-based end-to-end systems and achieve state-of-the-art results on TACRED dataset, outperforming existing CNN, RNN, and self-attention based models.

In future work, besides lexical knowledge, we will incorporate conceptual knowledge from encyclopedic knowledge bases into knowledge-attention encoder to capture the high-level semantics of texts. We will also apply knowledge-attention in other tasks such as text classification, sentiment analysis and question answering.

[4]We observed similar error behaviors of the three proposed integrated models.

Abstract

Entity alignment is a viable means for integrating heterogeneous knowledge among different knowledge graphs (KGs). Recent developments in the field often take an embedding-based approach to model the structural information of KGs so that entity alignment can be easily performed in the embedding space. However, most existing works do not explicitly utilize useful relation representations to assist in entity alignment, which, as we will show in the paper, is a simple yet effective way for improving entity alignment. This paper presents a novel joint learning framework for entity alignment. At the core of our approach is a Graph Convolutional Network (GCN) based framework for learning both entity and relation representations. Rather than relying on pre-aligned relation seeds to learn relation representations, we first approximate them using entity embeddings learned by the GCN. We then incorporate the relation approximation into entities to iteratively learn better representations for both. Experiments performed on three real-world cross-lingual datasets show that our approach substantially outperforms state-of-the-art entity alignment methods.

1 Introduction

Knowledge graphs (KGs) transform unstructured knowledge into simple and clear triples of <*head entity, relation, tail entity*> for rapid response and reasoning of knowledge. They are an effective way for supporting various NLP-enabled tasks like machine reading (Yang and Mitchell, 2017), information extraction (Wang et al., 2018a), and question-answering (Zhang et al., 2018b).

Even though many KGs originate from the same resource, e.g., Wikipedia, they are usually created independently. Therefore, different KGs often use different expressions and surface forms to indicate equivalent entities and relations – let alone those built from different resources or languages. This common problem of heterogeneity makes it difficult to integrate knowledge among different KGs. A powerful technique to address this issue is *Entity Alignment*, the task of linking entities with the same real-world identity from different KGs.

Classical methods for entity alignment typically involve a labor-intensive and time-consuming process of feature construction (Mahdisoltani et al., 2013) or rely on external information constructed by others (Suchanek et al., 2011). Recently, efforts have been devoted to the so-called embedding-based approaches. Representative works of this direction include JE (Hao et al., 2016), MTransE (Chen et al., 2017), JAPE (Sun et al., 2017), IPTransE (Zhu et al., 2017), and BootEA (Sun et al., 2018). More recent work (Wang et al., 2018b) uses the Graph Convolutional Network (GCN) (Kipf and Welling, 2017) to jointly embed multiple KGs.

Most of the recent works (e.g., JE, MTransE, JAPE, IPTransE and BootEA) rely on the translation-based models, such as TransE (Bordes et al., 2013), which enable these approaches to encode both entities and relations of KGs. These methods often put more emphasis on the entity embeddings, but do not explicitly utilize relation embeddings to help with entity alignment. Another drawback of such approaches is that they usually rely on pre-aligned relations (JAPE and IPTransE) or triples (MTransE). This limits the scale at which the model can be effectively performed due to the overhead for constructing seed alignments for large KGs. Alternative methods like GCN-based models, unfortunately, cannot directly obtain relation representations, leaving much room for improvement.

Recent studies have shown that jointly modeling entities and relations in a single framework can

* Corresponding author.

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 240–249, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

improve tasks like information extraction (Miwa and Bansal, 2016; Bekoulis et al., 2018). We hypothesize that this will be the case for entity alignment too; that is, the rich relation information could be useful for improving entity alignment as entities and their relations are usually closely related. Our experiments show that this is even a conservative target: by jointly learning entity and relation representations, we can promote the results of both entity and relation alignment.

In this work, we aim to build a learning framework that jointly learns entity and relation representations for entity alignment; and we want to achieve this with only a small set of pre-aligned entities but not relations. Doing so will allow us to utilize relation information to improve entity alignment without paying extra cost for constructing seed relation alignments.

Our work is enabled by the recent breakthrough effectiveness of GCNs (Kipf and Welling, 2017) in extracting useful representations from graph structures. Although GCNs provide a good starting point, applying it to develop a practical and efficient framework to accurately capture relation information across KGs is not trivial. Because a vanilla GCN operates on the undirected and unlabeled graphs, a GCN-based model like (Wang et al., 2018b) would ignore the useful relation information of KGs. While the Relational Graph Convolutional Network (R-GCN) (Schlichtkrull et al., 2018) can model multi-relational graphs, existing R-GCNs use a weight matrix for each relation. This means that an R-GCN would require an excessive set of parameters to model thousands of relations in a typical real-world KG, making it difficult to learn an effective model on large KGs.

A key challenge of our joint learning framework is how to generate useful relation representations at the absence of seed relation alignments, and to ensure the framework can scale to a large number of types of relations. We achieve this by first approximating the relation representations using entity embeddings learned through a small amount of seed entity alignments. We go further by constructing a new joint entity representation consisting of both relation information and neighboring structural information of an entity. The joint representations allow us to iteratively improve the model's capability of generating better entity and relation representations, which lead to not only better entity alignment, but also more accurate relation alignment as a by-product.

We evaluate our approach by applying it to three real-world datasets. Experimental results show that our approach delivers better and more robust results when compared with state-of-the-art methods for entity and relation alignments. The key contribution of this paper is a novel joint learning model for entity and relation alignments. Our approach reduces the human involvement and the associated cost in constructing seed alignments, but yields better performance over prior works.

2 Related Work

2.1 Entity Alignment

Until recently, entity alignment would require intensive human participation (Vrandečić and Krötzsch, 2014) to design hand-crafted features (Mahdisoltani et al., 2013), rules, or rely on external sources (Wang et al., 2017). In a broader context, works in schema and ontology matching also seek help from additional information by using e.g., extra data sources (Nguyen et al., 2011), entity descriptions (Lacoste-Julien et al., 2013; Yang et al., 2015), or semantics of the web ontology language (Hu et al., 2011). Performance of such schemes is bounded by the quality and availability of the extra information about the target KG, but obtaining sufficiently good-quality annotated data could be difficult for large KGs.

Recently, embedding-based entity alignment methods were proposed to reduce human involvement. JE (Hao et al., 2016) was among the first attempts in this direction. It learns embeddings of different KGs in a uniform vector space where entity alignment can be performed. MTransE (Chen et al., 2017) encodes KGs in independent embeddings and learns transformation between KGs. BootEA (Sun et al., 2018) exploits a bootstrapping process to learn KG embeddings. SEA (Pei et al., 2019) proposes a degree-aware KG embedding model to embed KGs. KDCoE (Chen et al., 2018) is a semi-supervised learning approach for co-training embeddings for multilingual KGs and entity descriptions. They all use translation-based models as the backbone to embed KGs.

Non-translational embedding-based methods include recent works on a GCN-based model (Wang et al., 2018b) and NTAM (Li et al., 2018). Additionally, most recent work, RDGCN (Wu et al., 2019), introduces the dual relation graph to model the relation information of KGs. Through

multiple rounds of interactions between the primal and dual graphs, RDGCN can effectively incorporate more complex relation information into entity representations and achieve promising results for entity alignment. However, existing methods only focus on entity embeddings and ignore the help that relation representations can provide on this task.

MTransE and NTAM are two of a few methods that try to perform both relation and entity alignments. However, both approaches require high-quality seed alignments, such as pre-aligned triples or relations, for relation alignment. Our approach advances prior works by jointly modeling entities and relations by using only a *small set* of pre-aligned entities (*but not relations*) to simultaneously perform entity and relation alignments.

2.2 Graph Convolutional Networks

GCNs (Duvenaud et al., 2015; Kearnes et al., 2016; Kipf and Welling, 2017) are neural networks operating on unlabeled graphs and inducing features of nodes based on the structures of their neighborhoods. Recently, GCNs have demonstrated promising performance in tasks like node classification (Kipf and Welling, 2017), relation extraction (Zhang et al., 2018a), semantic role labeling (Marcheggiani and Titov, 2017), etc. As an extension of GCNs, the R-GCNs (Schlichtkrull et al., 2018) have recently been proposed to model relational data for link prediction and entity classification. However, R-GCNs usually require a large number of parameters that are often hard to train, when applied to multi-relational graphs.

In this work, we choose to use GCNs to first encode KG entities and to approximate relation representations based on entity embeddings. Our work is the first to utilize GCNs for jointly aligning entities and relations for heterogeneous KGs.

3 Problem Formulation

We now introduce the notations used in this paper and define the scope of this work.

A KG is formalized as $G = (E, R, T)$, where E, R, T are the sets of entities, relations and triples, respectively. Let $G_1 = (E_1, R_1, T_1)$ and $G_2 = (E_2, R_2, T_2)$ be two different KGs. Usually, some equivalent entities between KGs are already known, defined as *alignment seeds* $\mathbb{L} = \{(e_{i_1}, e_{i_2})|e_{i_1} \in E_1, e_{i_2} \in E_2\}$.

We define the task of entity or relation alignment as automatically finding more equivalent entities or relations based on known alignment seeds. In our model, we only use known *aligned entity pairs* as training data for both entity and relation alignments. The process of relation alignment in our framework is unsupervised, which does not need pre-aligned relation pairs for training.

4 Our Approach

Given two target KGs, G_1 and G_2, and a set of known aligned entity pairs $\mathbb{L}$, our approach uses GCNs (Kipf and Welling, 2017) with highway network (Srivastava et al., 2015) gates to embed entities of the two KGs and approximate relation semantics based on entity representations. By linking entity representations with relation representations, they promote each other in our framework and ultimately achieve better alignment results.

4.1 Overall Architecture

As illustrated in Figure 1, our approach consists of three stages: (1) preliminary entity alignment, (2) approximating relation representations, and (3) joint entity and relation alignment.

In the first stage, we utilize GCNs to embed entities of various KGs in a unified vector space for preliminary entity alignment. Next, we use the entity embeddings to approximate relation representations which can be used to align relations across KGs. In the third stage, we incorporate the relation representations into entity embeddings to obtain the joint entity representations, and continue using GCNs to iteratively integrate neighboring structural information to achieve better entity and relation representations.

4.2 Preliminary Entity Alignment

As shown in Figure 1, we put G_1 and G_2 in one graph $G_a = (E_a, R_a, T_a)$ to form our model's input. We utilize pre-aligned entity pairs to train our model and then discover latent aligned entities.

Graph Convolutional Layers. Our entity alignment model utilizes GCNs to embed entities in G_a. Our model consists of multiple stacked GCN layers so that it can incorporate higher degree neighborhoods. The input for GCN layer l is a node feature matrix, $\mathbf{X}^{(l)} = \{\boldsymbol{x}_1^{(l)}, \boldsymbol{x}_2^{(l)}, ..., \boldsymbol{x}_n^{(l)}|\boldsymbol{x}_i^{(l)} \in \mathbb{R}^{d^{(l)}}\}$, where n is the number of nodes (entities) of G_a, and $d^{(l)}$ is the number of features in layer l. $\mathbf{X}^{(l)}$ is updated us-

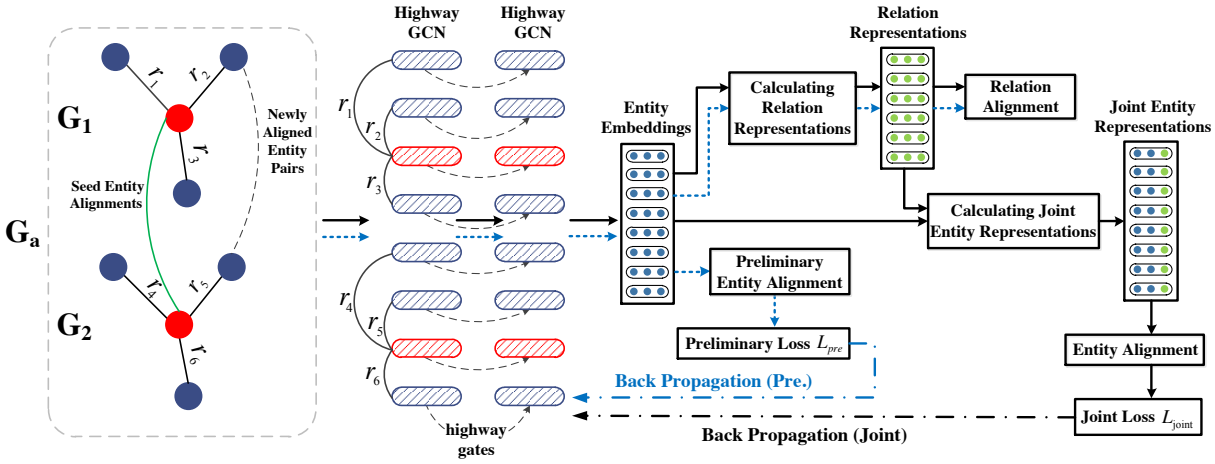

Figure 1: Overall architecture of our model. The blue dotted lines denote the process of preliminary entity alignment and preliminary relation alignment using approximate relation representations, and the black solid lines denote the process of continuing using GCNs to iteratively learn better entity and relation representations.

ing forward propagation as:

$$\mathbf{X}^{(l+1)} = \mathrm{ReLU}(\tilde{D}^{-\frac{1}{2}}\tilde{A}\tilde{D}^{-\frac{1}{2}}\mathbf{X}^{(l)}\mathbf{W}^{(l)}), \quad (1)$$

where $\tilde{A} = A + I$ is the adjacency matrix of G_a with self-connections, I is an identity matrix, $\tilde{D}_{jj} = \sum_k \tilde{A}_{jk}$, and $\mathbf{W}^{(l)} \in \mathbb{R}^{d^{(l)} \times d^{(l+1)}}$ is a layer-specific trainable weight matrix.

Inspired by (Rahimi et al., 2018) that uses highway gates (Srivastava et al., 2015) to control the noise propagation in GCNs for geographic localization, we also employ layer-wise highway gates to build a *Highway*-GCN (HGCN) model. Our layer-wise gates work as follow:

$$T(\mathbf{X}^{(l)}) = \sigma(\mathbf{X}^{(l)}\mathbf{W}_T^{(l)} + \boldsymbol{b}_T^{(l)}), \quad (2)$$

$$\mathbf{X}^{(l+1)} = T(\mathbf{X}^{(l)}) \cdot \mathbf{X}^{(l+1)} + (\mathbf{1} - T(\mathbf{X}^{(l)})) \cdot \mathbf{X}^{(l)} \quad (3)$$

where $\mathbf{X}^{(l)}$ is the input to layer $l+1$; σ is the sigmoid function; $\cdot$ is element-wise multiplication; $\mathbf{W}_T^{(l)}$ and $\boldsymbol{b}_T^{(l)}$ are the weight matrix and bias vector for the transform gate $T(\mathbf{X}^{(l)})$, respectively.

Alignment. In our work, entity alignment is performed by simply measuring the distance between two entity nodes on their embedding space. With the output entity representations $\mathbf{X}' = \{\boldsymbol{x}'_1, \boldsymbol{x}'_2, ..., \boldsymbol{x}'_n | \boldsymbol{x}'_i \in \mathbb{R}^d\}$, for entities e_1 from G_1 and e_2 from G_2, their distance is calculated as:

$$d(e_1, e_2) = \|\boldsymbol{x}'_{e_1} - \boldsymbol{x}'_{e_2}\|_{L_1}. \quad (4)$$

Training. We use a margin-based scoring function as the training objective, to make the distance between aligned entity pairs to be as close as possible, and the distance between positive and negative alignment pairs to be as large as possible. The loss function is defined as:

$$L = \sum_{(p,q)\in\mathbb{L}} \sum_{(p',q')\in\mathbb{L}'} \max\{0, d(p,q) - d(p',q') + \gamma\}, \quad (5)$$

where $\gamma > 0$ is a margin hyper-parameter; $\mathbb{L}'$ stands for the negative alignment set of $\mathbb{L}$.

Rather than simply random sampling for negative instances, we look for more challenging negative samples, e.g., those with subtle differences from the positive ones, to train our model. Given a positive aligned pair (p, q), we choose the $\mathcal{K}$-nearest entities of p (or q) according to Eq. 4 in the embedding space to replace q (or p) as the negative instances.

4.3 Approximating Relation Representations

At this stage, we expect to obtain relation representations, which can be used in the next stage for constructing joint representations and can also be used for preliminary relation alignment. Since we are unable to explicitly modeling relations within our GCN-based framework, we thus approximate the relation representations based on their head and tail entity representations produced by the entity alignment model described in Section 4.2. This strategy is based on our observation that the statistical information of the head and tail entities of a relation can more or less reflect the shallow semantics of the relation itself, such as the head or tail entities' type requirements of a relation. Our

experiments in Section 6 suggest that this is a reasonable assumption.

Given a relation $r \in R_a$, there is a set of triples of r, $\mathbb{T}_r = \{(h_i, r, t_j)|h_i \in H_r, t_j \in T_r\}$, where H_r and T_r are the sets of head entities and tail entities of relation r, respectively. For a relation r, its representation can be approximated as:

$$\boldsymbol{r} = f(\mathbf{H}_r, \mathbf{T}_r), \tag{6}$$

where $\boldsymbol{r}$ is the approximated representation of relation r. $\mathbf{H}_r$ and $\mathbf{T}_r$ are the sets of HGCN-output embeddings of head entities and tail entities of relation r. $f(\cdot)$ is a function to produce relation representations with input entity vectors, which can take many forms such as *mean*, *adding*, *concatenation* or more complex models. In our model, we compute the relation representation for r by first concatenating its averaged head and tail entity representations, and then introducing a matrix $\mathbf{W}_R \in \mathbb{R}^{2\tilde{d}\times m}$ as a learnable shared linear transformation on relation vectors. Here, $\tilde{d}$ is the number of features in each HGCN-output entity embedding and m is the number of features in each relation representation.

With the relation representations in place, relation alignment can be performed by measuring the similarity between two relation vectors. For relation r_1 from G_1 and r_2 from G_2, their similarity is computed as:

$$s(r_1, r_2) = \|\boldsymbol{r}_1 - \boldsymbol{r}_2\|_{L_1} - \beta\frac{|P_{r_1r_2}|}{|HT_{r_1} \cup HT_{r_2}|}, \tag{7}$$

where $\boldsymbol{r}_1$ and $\boldsymbol{r}_2$ are the relation representations for r_1 and r_2. In addition to calculating the distance between the two relation vectors, we believe that the more aligned entities exist in the entities that are connected to the two relations, the more likely the two relations are equivalent. Thus, for r_1 and r_2, we collect the pre-aligned entities existing in the head/tail entities of these two relations as the set $P_{r_1r_2} = \{(e_{i_1}, e_{i_2})|e_{i_1} \in HT_{r_1}, e_{i_2} \in HT_{r_2}, (e_{i_1}, e_{i_2}) \in \mathbb{L}\}$. HT_{r_1} and HT_{r_2} are the sets of head/tail entities for relation r_1 and r_2 respectively. β is a hyper-parameter for balance.

In our framework, relation alignment is explored in an unsupervised fashion, in which we do not have any pre-aligned relations as training data.

4.4 Joint Entity and Relation Alignment

The first two stages of our approach could already produce a set of entity and relation alignments, but we do not stop here. Instead, we attentively fuse the entity and relation representations and further jointly optimize them using the seed entity alignments. Our key insight is that entity and relation alignment tasks are inherently closely related. This is because aligned entities tend to have some relations in common, and similar relations should have similar categories of head and tail entities.

Specifically, we first pre-train the entity alignment model (Section 4.2) until its entity alignment performance has converged to be stable. We assume that both the pre-trained entity and approximate relation representations can provide rich information for themselves. Next, for each entity, we aggregate the representations of its relevant relations into a relation context vector, which is further combined with its pre-trained entity representation to form a new joint entity representation.

Formally, for each entity $e \in E_a$, its new joint representation $\boldsymbol{e}_{joint}$ can be calculated as:

$$\boldsymbol{e}_{joint} = g(\boldsymbol{e}, \mathbf{R}_e), \tag{8}$$

where $\boldsymbol{e}$ is the HGCN-output representation of entity e. $\mathbf{R}_e$ is the set of relation representations of e's relevant relations. $g(\cdot)$ is a function to produce the new joint entity representation by taking $\boldsymbol{e}$ and $\mathbf{R}_e$ as input, which can also take many forms of operations. In our model, we calculate $\boldsymbol{e}_{joint}$ by first summing all relation representations in $\mathbf{R}_e$ and then concatenating $\boldsymbol{e}$ with the summed relation context vector.

After getting the new joint entity representations, $\mathbf{X}_{joint}$, we continue optimizing our model against the seed entity alignments, where we use the joint entity representations to calculate the training loss according to Eq. 5 to continue updating HGCNs[1]. Note that the joint entity representations are composed of entity embeddings and relation representations, while the relation representations are also constructed based on the entity embeddings. Hence, after backpropagation of the loss calculated using the joint entity representations, we optimize the entity embeddings.

5 Experimental Setup

5.1 Datasets

We use DBP15K datasets from (Sun et al., 2017) to evaluate our approach. DBP15K contains three

[1]The training procedure is detailed in Appendix A.

DBP15K		#Ent.	#Rel.	#Rel tr.	Alignments #Ent.	Alignments #Rel.
ZH-EN	ZH	66,469	2,830	153,929	1,5000	890
	EN	98,125	2,317	237,674		
JA-EN	JA	65,744	2,043	164,373	1,5000	529
	EN	95,680	2,096	233,319		
FR-EN	FR	66,858	1,379	192,191	1,5000	212
	EN	105,889	2,209	278,590		

Table 1: Summary of the DBP15K datasets.

cross-lingual datasets that were built from the English version to Chinese, Japanese and French versions of DBpedia. Each contains data from two KGs in different languages and provides 15K pre-aligned entity pairs. Besides, each dataset also provides some pre-aligned relations. We manually aligned more relations from the three datasets and removed the ambiguously aligned relation pairs to construct the test sets for relation alignment. Table 1 shows the statistics of the three datasets. We stress that our approach achieves entity and relation alignments simultaneously using only a small number of pre-aligned entities, and relation alignments are only used for testing. Following the previous works (Sun et al., 2017; Wang et al., 2018b; Sun et al., 2018), we use 30% of the pre-aligned entity pairs as training data and 70% for testing. Our source code and datasets are freely available online[2].

5.2 Implementation Details

We set $\gamma = 1$, $\beta = 20$, and learning rate to 0.001. We sample $\mathcal{K} = 125$ negative pairs every 50 epochs. We use entity names in different KGs for better model initialization. We translate non-English entity names to English via Google Translate, and the entity features are initialized with pre-trained English word vectors *glove.840B.300d*[3] in our model. Note that Google Translate does not always give accurate translations for named entities. We inspected 100 English translations for Japanese and Chinese entity names, and discovered that around 20% of the translations are wrong. The errors are mainly attributed to the missing of titles/modifications and wrong interpretations for person/location names. The inaccurate translation poses further challenges for our model.

5.3 Competitive Approaches

Entity Alignment. For entity alignment, we compare our approach against six embedding-based entity alignment methods discussed in Section 1: JE (Hao et al., 2016), MTransE (Chen et al., 2017), JAPE (Sun et al., 2017)[4], IPTransE (Zhu et al., 2017), BootEA (Sun et al., 2018) and GCN (Wang et al., 2018b). Among those, BootEA is the best-performing model on DBP15K.

Relation Alignment. For relation alignment, we compare our approach with the state-of-the-art BootEA (denoted by BootEA-*R*), and MTransE (denoted by MTransE-*R*). Note that MTransE provides five implementation variants for its alignment model. To provide a fair comparison, we choose the one that does not use pre-aligned relations but gives the best performance for a triple-wise alignment verification (Chen et al., 2017) - a closely related task for relation alignment. Since BootEA and MTransE are translation-based models that encode both entities and relations, relation alignment can be done by measuring the similarities between two relation representations. Furthermore, to evaluate the effectiveness of our proposed relation approximation method, we also build BootEA-*PR* and MTransE-*PR* for relation alignment according to Section 4.3.

5.4 Evaluation Methodology

Model Variants. To evaluate our design choices, we provide different implementation variants with the following denotations. HGCN is our base GCN model with highway gates and entity name initialization. It has several variants, described as follows. HGCN-*PE* (Section 4.2) and HGCN-*PR* (Section 4.3) are our preliminary models for entity and relation alignments, respectively. HGCN-*JE* and HGCN-*JR* are our complete models that use joint representations to further improve entity alignment and relation alignment (Section 4.4). Finally, GCN-*PE* and GCN-*PR* are the preliminary GCN-based models for entity and relation alignments respectively, which use entity name initialization *but no highway gates*; GCN-*JE* and GCN-*JR* are the corresponding joint learning models; and GCN-*JE-r* is the randomly initialized version of GCN-*JE* without entity name initialization.

[2]https://github.com/StephanieWyt/HGCN-JE-JR

[3]http://nlp.stanford.edu/projects/glove/

[4]We note that (Sun et al., 2017) also provides analysis by considering the outputs of a machine translator and JAPE, and using a theoretically perfect *oracle* predictor to correctly choose in between the results given by the machine translator and JAPE. As this only serves as an interesting up-bound analysis, but does not reflect the capability of JAPE (because it is impossible to build such a perfect predictor in the first place), we do not compare to this oracle implementation.

Metrics. Like prior works (Sun et al., 2017; Wang et al., 2018b; Sun et al., 2018), we use Hits@k as our evaluation metric. A Hits@k score is computed by measuring the proportion of correctly aligned entities ranked in the top k list. Hence, we prefer higher Hits@k scores that indicate better performance.

6 Experiment Results

In this section, we first show that our complete model consistently outperforms all alternative methods across datasets, metrics and alignment tasks. We then analyze the impact of prior alignment data size on model performance, showing that our approach requires significantly less training data but achieves better performance over the best-performing prior method. Finally, we use a concrete example to discuss how jointly learned entity and relation representations can be used to improve both entity and relation alignments.

6.1 Entity Alignment

Table 2 reports the performance for entity alignment of all compared approaches. The top part of the table shows the performance of prior approaches. By using a bootstrapping process to expand the training data, BootEA clearly outperforms all prior methods. By capturing the rich neighboring structural information, GCN outperforms all other translation-based models on Hits@1, and over IPTransE, MTransE and JE on Hits@10.

The bottom part of Table 2 shows how our proposed techniques, i.e., entity name initialization, joint embeddings and layer-wise highway gates, can be used within a GCN framework to improve entity alignment. After initialized with the machine-translated entity names, GCN-PE considerably improves GCN on all datasets. The improvement suggests that even rough translations of entity names (see Section 5.2) can still provide important evidence for entity alignment and finally boost the performance. By employing layer-wise highway gates, HGCN-PE further improves GCN-PE, giving a 34.31% improvement on Hits@1 on *DBP15K*$_{FR-EN}$, and also outperforms the strongest baseline BootEA. This substantial improvement indicates that highway gates can effectively control the propagation of noisy information. Our complete framework HGCN-JE gives the best performance across all metrics and datasets. Comparing HGCN-JE with HGCN-PE and GCN-JE with GCN-PE (2.36% and 4.19% improvements of Hits@1 on *DBP15K*$_{ZH-EN}$ respectively), we observe that joining entity and relation alignments improves the model performance. Even without entity name initialization, GCN-JE-r still has obvious advantages over JE, MTransE, JAPE, IPTransE and GCN. The results reinforce our claim that merging the relation information into entities can produce better entity representations. We stress that our proposed methods are not restricted to GCNs or HGCNs, but can be flexibly integrated with other KG representation models as well.

Models	ZH-EN		JA-EN		FR-EN	
	Hits@1	Hits@10	Hits@1	Hits@10	Hits@1	Hits@10

Table 3: Performance on relation alignment.

6.2 Relation Alignment

Table 3 reports the results of relation alignment. Directly using the relation embeddings learned by MTransE to perform relation alignment leads to rather poor performance for MTransE-R, less than 4% for Hits@1 for all datasets. This is because the translation assumption, $head + relation \approx tail$, used by MTransE focuses on modeling the overall relationship among heads, tails, and relations, but capturing little neighboring information and relation semantics. After approximating the relation representations using entity embeddings according to Eq 6, MTransE-PR substantially improves MTransE-R. This confirms our assumption that it is feasible to approximate a relation using the in-

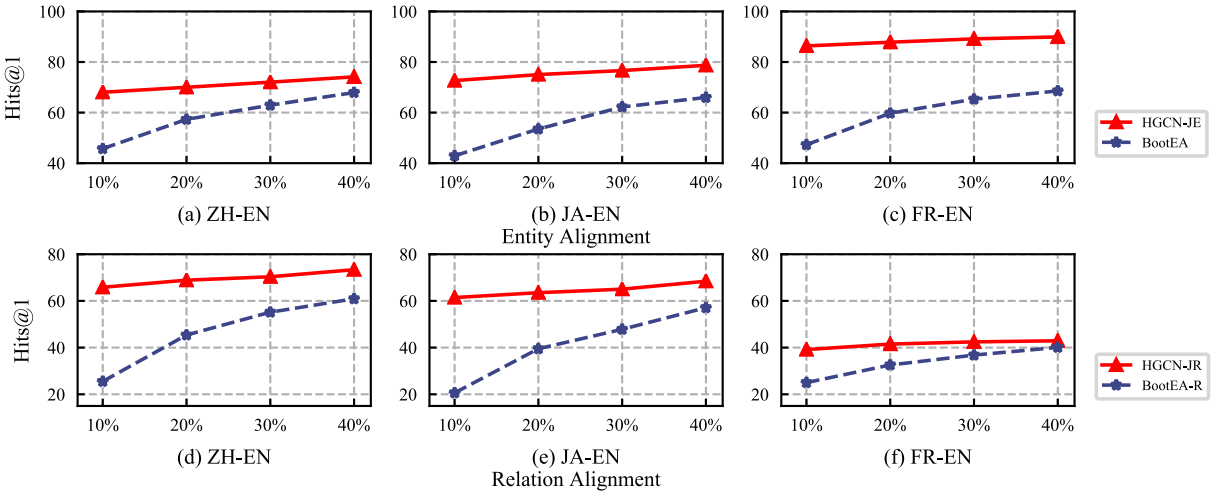

Figure 2: (a)-(c) report the performance for entity alignment of HGCN-JE and BootEA when they are trained with different proportions of seed entity alignments on the three DBP15K datasets. (d)-(f) show the relation alignment performance of HGCN-JR and BootEA-R under corresponding conditions. The x-axes are the proportions of seed alignments, and the y-axes are Hits@1 scores.

formation of its head and tail entities.

The strong entity alignment model BootEA also performs well for relation alignment. Using the relation embeddings from BootEA, BootEA-R delivers the best Hits@1 in MTransE and BootEA variants. Using our approximation strategy hurts BootEA-R in Hits@1, but we see improvements on Hits@10 across all datasets. This suggests that our approximation method can bring more related candidates, but may lack precision to select top-ranked candidates, comparing to explicitly relation modeling in translation-based models.

Our framework, HGCN-JR, delivers the best relation alignment results across datasets and metrics, except for Hits@10 on $DBP15K_{FR-EN}$. Like entity alignment, we also observe that joining entity and relation alignments improves relation alignment, as evidenced by the better performance of HGCN-JR and GCN-JR over HGCN-PR and GCN-PR, respectively. That is, joint modeling produces better entity representations, which in turn provide better relation approximations. This can promote the results of both alignment tasks.

6.3 Analysis

Impact of Available Seed Alignments. To explore the impact of the size of seed alignments on our model, we compare our HGCN with BootEA by varying the proportion of pre-aligned entities from 10% to 40% with a step of 10%. Figure 2 (a-c) illustrate the Hits@1 for entity alignment of HGCN-JE and BootEA on three datasets. As the amount of seed alignments increases, the performances of both models on all three data sets gradually improve. HGCN-JE consistently obtains superior results compared to BootEA, and seems to be insensitive to the proportion of seed alignments. For example, HGCN-JE still achieves 86.40% for Hits@1 on $DBP15K_{FR-EN}$ when only using 10% of training data. This Hits@1 score is 17.84% higher than that of BootEA when BootEA uses 40% of seed alignments.

Figure 2 (d-f) show the Hits@1 for relation alignment of HGCN-JR and BootEA-R. HGCN-JR also consistently outperforms BootEA-R, and gives more stable results with different ratios of seed entity alignments. These results further confirm the robustness of our model, especially with limited seed entity alignments.

Case Study. Figure 3 shows an example from $DBP15K_{FR-EN}$. In the stages of preliminary entity alignment and relation alignment, our model correctly predicts the aligned entity pair (v_2, v_5) and relation pair (r_2, r_5). After examining the full experimental data[5], we find that the entities with more neighbors, such as v_2 and v_5 (indicating *Norway*), and the high-frequency relations, such as r_2 and r_5 (indicating *country*), are easier to align, since such entities and relations have rich structural information that can be exploited by a GCN. After jointly learning entity and relation representations, the extra neighboring relation information

[5] A more detailed analysis of our experimental results can be found in Appendix B in the supplementary material.

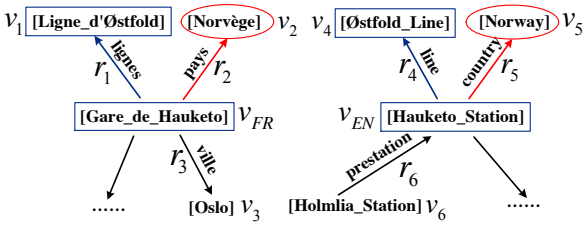

Figure 3: A real-world example from $DBP15K_{FR-EN}$. $[v_2; v_5]$ and $[r_2; r_5]$ are respectively the aligned entities and aligned relations after performing preliminary entity and relation alignments. $[v_{FR}; v_{EN}]$ and $[v_1; v_4]$ are the newly aligned entity pairs, and r_1 and r_4 are the newly aligned relations, which are discovered using jointly learned entity and relation representations. Jointly optimizing alignment tasks leads to the sucessful discovery of new aligned relation and entity pairs.

(e.g., the aligned relations (r_2, r_5)) enables our model to successfully align v_{FR} and v_{EN}. If we keep updating the model to learn better entity and relation representations, our alignment framework can successfully uncover more entity and relation alignments such as (v_1, v_4) and (r_1, r_4). This shows that joint representations can improve both entity and relation alignments.

7 Conclusions

This paper presents a novel framework for entity alignment by jointly modeling entities and relations of KGs. Our approach does not require pre-aligned relations as training data, yet it can simultaneously align entities and relations of heterogeneous KGs. We achieve this by employing gated GCNs to automatically learn high-quality entity and relation representations. As a departure from prior work, our approach constructs joint entity representations that contain both relation information and entity information. We demonstrate that *the whole is greater than the sum of its parts*, as the joint representations allow our model to iteratively improve the learned representations for both entities and relations. Extensive experiments on three real-world datasets show that our approach delivers better and more robust performance when compared to state-of-the-art methods.

Abstract

For large-scale knowledge graphs (KGs), recent research has been focusing on the large proportion of infrequent relations which have been ignored by previous studies. For example few-shot learning paradigm for relations has been investigated. In this work, we further advocate that handling uncommon entities is inevitable when dealing with infrequent relations. Therefore, we propose a meta-learning framework that aims at handling infrequent relations with few-shot learning and uncommon entities by using textual descriptions. We design a novel model to better extract key information from textual descriptions. Besides, we also develop a novel generative model in our framework to enhance the performance by generating extra triplets during the training stage. Experiments are conducted on two datasets from real-world KGs, and the results show that our framework [1] outperforms previous methods when dealing with infrequent relations and their accompanying uncommon entities.

1 Introduction

Modern knowledge graphs (KGs)(Bollacker et al., 2008; Lehmann et al., 2015; Vrandečić and Krötzsch, 2014) consist of a large number of facts, where each fact is represented as a triplet consisting of two entities and a binary relation between them. KGs provide rich information and it has been widely adopted in different tasks, such as question answering (Yih et al., 2015), information extraction (Bing et al., 2017, 2015, 2016) and image classification (Marino et al., 2017). However, KGs still have the issue of incomplete facts. To deal with the problem, Knowledge Graph Completion (KGC) task is introduced to automatically deduce and fill the missing facts. There exist many previous works focusing on this task and embedding-based methods (Bordes et al., 2013; Wang et al., 2014; Trouillon et al., 2016) achieves the best performance among them. Recent works such as (Xiong et al., 2018) have pointed out that relations in KGs follow a long-tailed distribution. To be more precise, a large proportion of relations have only a few facts in KGs. However, previous works of KGC usually focused on small proportions of frequent relations and ignored the remaining ones. One observation is that they often conducted experiments on small datasets such as FB15k and WN18 (Bordes et al., 2013) where a relation typically possesses thousands of facts. Moreover, after analyzing real-world KGs, we find that the more infrequently a relation appears, the entities within its facts are also more uncommon. Figure 1 depicts the relationship between the relation frequency and the proportion of uncommon entities that appear in the facts of these relations in a KG, where an entity is treated as uncommon when it appears less or equal than 5 times in all triplets of the KG. From Figure 1, it is obvious that less frequent relations involve more uncommon entities than frequent relations. Therefore, when dealing with the problem of infrequent relations, the issue of uncommon entities should also be considered simultaneously, where they are two sides of a coin.

Previous works such as (Xiong et al., 2018) only focused on those infrequent relations and ignored the accompanying problem of uncommon entities. When handling uncommon entities, relying only on the structural information of KGs would lead to inferior performance due to data insufficiency,

and thus additional information is required. Some works (Toutanova et al., 2015; Xie et al., 2016) utilize textual description of entities, but they cannot extract different information from entity description if the entity is involved in more than one relations. A recent work (Shi and Weninger, 2018) tries to tackle this problem by using an attention mechanism considering both entity description and relation, but it adopts a heuristic method that cannot generalize well.

In this paper, we consider performing KGC for infrequent relations and uncommon entities as a few-shot learning problem, and we propose a framework that consists of three main components: description encoder, triplet generator, and meta-learner. In the description encoder, we design a novel structure to handle entities involved with multiple relations by automatically locating and extracting relation-specific information. We also simultaneously learn a triplet generator that is able to generate extra triplets in order to relieve the problem of data sparsity in few-shot learning. Moreover, a meta-learner is further adopted to learn a initial representation of the model that can be easily adapted to unseen relations and entities. As a result, our work has three main contributions as follows:

- We formulate the problem of infrequent relations and uncommon entities as a few-shot learning problem and propose a meta-learning framework to solve it.
- We propose a novel model to extract relation-specific information from entity description for entities with multiple relations.
- We propose a generative model that can enhance the performance of few-shot learning by generating extra triplets during the training stage.

2 Related Work

2.1 Knowledge Graph Completion

The knowledge graph completion (KGC) task focuses on automatically inferring and filling the missing facts in KG. The most successful method of KGC is the embedding-based method that learns a latent embedding in a common space for entities and relations. This method only relies on the structural information of entities and relations in KG. There exist a variety of methods (Bordes et al., 2013; Socher et al., 2013; Wang et al., 2014; Trouillon et al., 2016; Nguyen et al., 2018) that have been proposed to learn good embeddings for entities and relations.

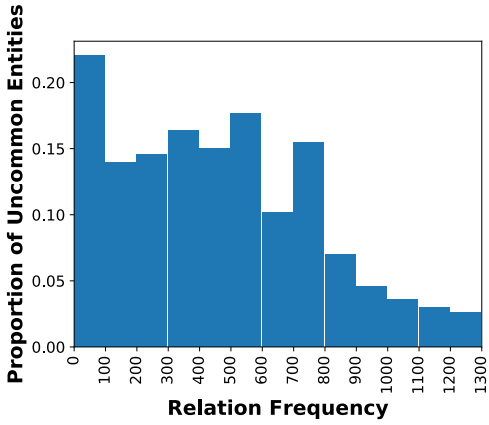

Figure 1: A histogram about relation frequencies and the corresponding proportions of uncommon entities in DBpedia.

However, embedding of uncommon relation or entities can not learn a good representation due to the data insufficiency. Some research has proposed that additional information can be introduced to enhance the learning performance. Among different types of information, textual descriptions is commonly considered by previous works (Zhong et al., 2015; Toutanova et al., 2015; Xie et al., 2016; Shi and Weninger, 2018). Recently, meta-learning is also proposed by (Xiong et al., 2018) to learn infrequent long-tailed relations in KG.

2.2 Meta-Learning

Meta-learning (Lemke et al., 2015) aims at learning common experiences across different tasks and easy adapting the existing model to new tasks. One interesting application of meta-learning is few-shot learning problem where each task has only a few training data available.

Some research focus on learning a general policy for different tasks using a neural network. An early work (Santoro et al., 2016) proposes that the learning policy can be learned by using a global memory network. Recently, temporal convolution and attention have been considered to learn a common representation and pinpoint common experiences (Mishra et al., 2018).

Another direction is to learn a good initial representation where the learned model can be easily adapted to new data. Prototypical Network (Snell

et al., 2017) is proposed to learn a prototype for each category, and thus new data can be classified by distances between data and prototypes. Model-Agnostic Meta-Learning (MAML) (Finn et al., 2017) focuses on learning a good initial point in parameter space of model, hence a trained model can be quickly adapted to new tasks with several updates. More recently, Reptile (Nichol et al., 2018) proposes to be an approximation of MAML. In the Reptile model parameters are updated after a number of steps of inner iteration that can maximize within-task generalization.

3 Background and Overview

3.1 Problem Setting

Knowledge graph (KG) consists of a set of facts. Each fact has the form of a triplet (h, r, t) where h is a head entity, r is a relation and t is a tail entity. KGs are usually sparse, incomplete, and noisy. Therefore Knowledge Graph Completion (KGC) becomes an important task. Given arbitrary two out of three elements within a triplet, the goal of KGC is to predict the remaining one. We focus on predicting t given h and r in this work since our purpose is to deal with uncommon entities.

Previous works usually considered performing KGC given a set of common relations with lots of triplets. On the contrary, we concentrate on performing KGC on those relations that have only a small number of triplets, which can be viewed as a k-shot learning problem for relations when k is a small number. In the limiting case where k equals to 1, we deal with one-shot learning problem in our framework. Besides, unlike the previous work (Xiong et al., 2018) that focuses on common entities, we also consider uncommon entities during operational or testing phase, which means that some entities could appear only several times or be absent before. Moreover, when dealing with uncommon entities, relying only on the structural information of KG would lead to inferior performance due to data insufficiency, and thus additional information is necessary. Textual descriptions have been widely considered in KGC. Typically, textual descriptions are used to describe an entity or a relation, and each of them can be either a short sentence or a paragraph consisting of several sentences. We utilize textual descriptions of entities and relations in our framework.

3.2 Overview of Learning Method

Meta learning is a popular paradigm for solving the few-shot learning problem, and we adopt it to perform KGC. Given a KG, we treat each relation as a task, and the triplets of each relation can be viewed as specific data of each task. We further divide all tasks into three disjoint sets R_{train}, R_{val} and R_{test}. Hence meta-training, meta-validation and meta-testing can be performed on each set respectively. In each iteration of the meta-training phase, we randomly sample B tasks from R_{train} where B is batch size, and then for each task r in the batch we sample some triplets of r to train the model. After meta-training finishes, we obtain a trained model with model parameters W. Next, we follow the procedure in the previous work (Xiong et al., 2018) to perform meta-validation and meta-testing on R_{val} and R_{test}, where the settings are the same. So we only describe meta-testing for short. In the meta-testing phase, given a new task $r^{'} \in R_{test}$ with $H_{r^{'}}$ triplets, we randomly sample k out of $H_{r^{'}}$ triplets. The trained model is further improved via another training stage with only these k samples and the parameters of model become $W^{'}$. Then we keep parameters being fixed as $W^{'}$ and evaluate the performance of model on the remaining $H_{r^{'}} - k$ triplets. These procedures are repeated for all tasks in R_{test}.

Given a triplet, the textual descriptions of h, r and t are respectively d_h, d_r and d_t. With textual descriptions, entities and relations can be mapped into a common semantic space. Therefore, uncommon entities can be tackled in this common space as usual.

4 Model Description

In this section we present the architecture and the learning procedure of our proposed framework.

First, given the textual descriptions of a triplet (h, r, t), the description encoder extracts key information from descriptions and produces corresponding embeddings $O = (o_h, o_r, o_t)$, where o is a u-dimensional vector in the latent semantic space.

Next, the triplet generator participates in the learning procedure. During meta-training phase, it takes O as inputs and learns latent patterns for triplets. However, during the training stage of the meta-testing phase, instead of learning latent patterns, the triplet generator performs triplet aug-

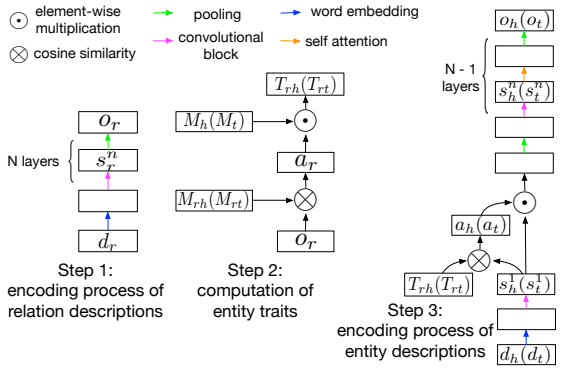

Figure 2: Structure and learning procedures of our description encoder. This figure should be viewed in color.

mentation by generating extra K sets of embeddings $G = \{(g_h, g_r, g_t)\}$. Each set of embeddings (g_h, g_r, g_t) can be viewed as an artificial imitation of O. In the few-shot setting, the size of O is usually too small to learn a good representation for a new task, and thus extra embeddings G is generated for data augmentation.

After previous procedures, we are able to obtain a set of embeddings of triplets $E = \{(e_h, e_r, e_t)\}$, where $E = O$ during meta-training phase and $E = O \cup G$ during training stage of meta-testing phase. With E prepared, a score function F takes E as input and computes the score C for each group of embeddings $(e_h, e_r, e_t) \in E$. Although more sophisticated score functions might be designed, in our framework we adopt a simple formula as follows:

$$C = F(h, r, t) = |e_h + e_r - e_t| \qquad (1)$$

from TransE (Bordes et al., 2013), where L_1-norm is used.

Finally, during the meta-training phase or the training stage of the meta-testing phase, a loss function L related to C is computed, and the meta-learner is adopted to optimize L so that the framework can be easily adapted to new relations and entities. Otherwise, during the testing stage of the meta-testing phase, we collect scores of the correct triplet and other candidates, and then we compute metrics based on the rank of correct triplet within all scores for evaluation.

4.1 Description Encoder

In KG, if an entity is involved in multiple relations, it is natural that different relations are more relevant to different parts in the description of the entity. However, existing works using textual descriptions have not tackled this issue effectively. In order to deal with this issue, we define a new concept "entity trait" ("trait" for short) that represents the common characteristics of some entities related to a special relation. In another word, an entity owns different traits for different relations it involved. In a sense, a trait is similar to an entity type ("type" for short), but it has more advantages when handling KGC. First, types are not relation-specific but traits are. Besides, a trait may consist of semantics of several different types and hence it is more expressive. Moreover, we cannot easily obtain types in some situations, but traits can always be learned properly since they are latent and data-driven. Formally, we assume that a relation r has two traits T_{rh} and T_{rt}, where the previous one for all the head entities of r and the latter one for all the tail entities of r. In our description encoder, a simple but effective method is adopted to learn and utilize traits to extract relation-specific information from description.

The overall structure and learning process of our description encoder are given in Figure 2. Given the descriptions (d_h, d_r, d_t) of a triplet (h, r, t), there are three steps to obtain the embeddings of triplet O as depicted in the figure. For entity, we only describe the process of h for simplicity, but everything stays the same for t. In Step 1, the encoding process of relation descriptions takes d_r as input and outputs a relation embedding o_r. Next, o_r is used to learn the trait T_{rh} for all the head entities of the relation r in Step 2. Finally, in Step 3 both d_h and T_{rh} are fed to the encoding process of the entity descriptions, and the output o_h is the embedding of the head entity. Note that the word embedding layer, convolutional blocks and pooling layers in Step 1 share the same parameters and architectures with the corresponding ones in Step 3.

The core of the encoding process is a N-layer convolutional neural network (CNN) (Conneau et al., 2017), which is shown to have excellent ability of extracting information. In our CNN, the basic convolutional block consists of three consecutive operations: two 1-d convolutions, an instance normalization (Ulyanov et al., 2016), and a non-linear mapping. For the pooling strategy, max pooling with a proper stride is used to distill the key information in the previous $N - 1$ layers, and

mean pooling is used to gather the information in the last layer. Moreover, in Step 3, we also apply self-attention mechanism (Vaswani et al., 2017) before each pooling layer in the last $N-1$ layers. Unlike Step 1, self-attention is necessary here since entity descriptions are often more complex and noisier than relation descriptions according to our observation. Self-attention can assign lower weights to noise, and then those noise would be filtered out in the subsequent pooling layer.

Furthermore, we demonstrate how to compute the trait in Step 2, where the external memories M play an important role. These memories record the global information of relations and entities that can generalize well when encountering new relations and entities. In detail, the o_r computed in Step 1 is transformed to a probability distribution a_r by using m relation memories M_{rh}

$$a_r = softmax(o_r \otimes M_{rh}), \tag{2}$$

where a_r is m-dimensional, $\otimes$ denotes the cosine similarity, $softmax$ is the commonly used softmax function and M_{rh} is a matrix with shape (m, u). After that, the u-dimensional trait T_{rh} can be obtained by computing a linear combination of m latent entity memories M_h

$$T_{rh} = \sum_{i=1}^{m} M_h^i \odot a_r^i, \tag{3}$$

where $\odot$ is the element-wise multiplication between two vectors and M_h^i is a matrix with shape (m, u). Note that each pair of m latent relation memories M_{rh} and m latent entity memories M_h has a one-to-one correspondence.

Finally, we describe how the trait T_{rh} is used to extract the relation-specific information in Step 3. Given the description d_h, the hidden states s_h^1 can be obtained after the first convolutional block, and then the trait T_{rh} is used to locate important hidden states in s_h^1 that have high relevance to r by assigning them higher weights. The procedure here is the same as before: a probability distribution a_h over s_h^1 is computed by

$$a_h = softmax(T_{rh} \otimes s_h^1), \tag{4}$$

and then a_h multiplies with s_h^1 element-wise to weight different hidden states. In this way, the hidden states that are not relevant to r are assigned lower weights, and thus they are more likely to be filtered in the subsequent max-pooling layer.

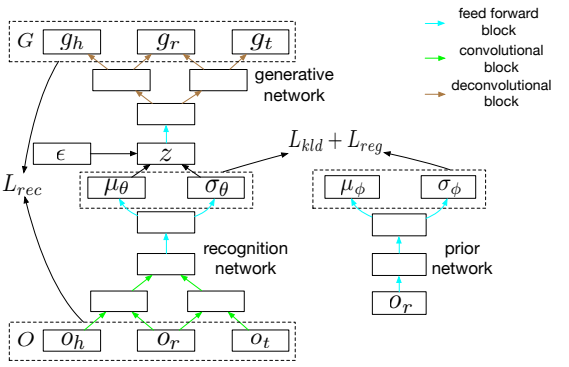

Figure 3: Structure of TCVAE. This figure should be viewed in color.

4.2 Triplet Generator

When handling KGC, learning good representation for infrequent relations and uncommon entities is difficult due to data sparsity. However, recently some research has focused on relieving the data sparsity in few-shot learning by generating extra data with a generative model (Schwartz et al., 2018; Wang et al., 2018). Inspired by these works, we propose a deep generative model that aims at triplet augmentation for k-shot learning. Although the generative adversarial network (Goodfellow et al., 2014) is a popular model that can generate high-quality samples (Frid-Adar et al., 2018), it suffers from an unstable learning process in our framework because of the difficult nature of Nash equilibrium and the influence of meta-learner. On the other hand, VAE is often applied to generate samples and extract latent semantics (Pu et al., 2016; Li et al., 2017) due to its smooth learning procedure. To cope with this issue, we design our triplet generator on the basis of CVAE (Sohn et al., 2015) and we name it triplet CVAE (TCVAE) in this paper. Figure 3 depicts the overall structure of TCVAE that is composed of three important probability distributions:

- Variational posterior distribution $q_\theta(z|O)$ parameterized by θ of the recognition network.
- Conditional prior distribution $p_\phi(z|o_r)$ parameterized by ϕ of the prior network.
- Likelihood distribution $p_\psi(G|z, o_r)$ parameterized by ψ of the generative network.

In the recognition network, there exist two layer of convolutional blocks. Each convolutional block takes two u-dimensional inputs and concatenates

them to form a matrix with shape $(2, u)$, so that 1-d convolution with filter width 2 can be applied to it. Instead of directly concatenate $O = (o_h, o_r, o_t)$ to form a matrix with shape $(3, u)$ and adopt only one layer of convolutional block, such a tree structure of two consecutive layers can better capture the pairwise semantics between any two embeddings in O. Likewise, two layers of the deconvolutional blocks that takes a u-dimensional vector as input and outputs a matrix with shape $(2, u)$ are placed in the generative network. Besides, all feed forward blocks in TCVAE consist of an affine transformation and a non-linear mapping.

During the meta-training phase, the recognition network takes O as input and learns the variational parameters μ_θ and σ_θ of the variational posterior $q_\theta(z|O)$, where the latent semantics z is assumed to follow a Gaussian distribution. Besides, the prior network conditioning on o_r computes the parameters μ_ϕ and σ_ϕ of the prior distribution $p_\phi(z|o_r)$. After that, the generative network samples three u-dimensional embeddings $G = (g_h, g_r, g_t)$ from the likelihood distribution $p_\psi(G|z, o_r)$. In the generative network, firstly, the latent variable z is transformed into a u-dimensional hidden state with the feed forward block after z. Next, the first deconvolutional block receives the hidden state and outputs a matrix with shape $(2, u)$. Finally, the second deconvolutional block receives the matrix before and outputs a matrix with shape $(3, u)$ which is denoted to G. G consists of three u-dimensional embeddings (g_h, g_r, g_t) corresponding to three elements (h, r, t) in the triplet.

Given the procedure, we are able to write down the loss terms of TCVAE: L_{rec}, L_{kld} and L_{rec}. More formally, L_{rec} is the expected log-likelihood that is also the reconstruction loss between the input O and the output G

$$L_{rec} = E_{q_\theta(z|O)} \log p_\psi(G|z, o_r). \quad (5)$$

L_{kld} is the KL-divergence between variational posterior distribution and conditional prior distribution

$$L_{kld} = KL(q_\theta(z|O) \| p_\phi(z|o_r)). \quad (6)$$

And L_{rec} is the regularization term for the prior network proposed in (Ivanov et al., 2019)

$$L_{reg} = -\frac{\mu_\phi^2}{2\sigma_\mu^2} + \sigma_\sigma(\log \sigma_\psi - \sigma_\psi), \quad (7)$$

where $\sigma_\mu = 10000$ and $\sigma_\sigma = 0.0001$ are two hyper-parameters. There terms are jointly optimized with the loss function of KGC that we would demonstrate in the following subsection.

During the training stage of meta-testing phase, TCVAE uses prior network to compute μ_ϕ and σ_ϕ given only the relation embedding $o_r^{'}$ within O where $r^{'} \in R_{test}$. Then it obtains K latent variables z with the following transformation

$$z = \mu_\phi + \sigma_\phi \odot \epsilon \quad \epsilon \sim Gaussian(0, 1). \quad (8)$$

After that, K embeddings of triplet G can be generated from the likelihood distribution $p_\psi(G|z, o_r^{'})$, and G is merged with O to form the final embeddings E. Please note that E is subsequently used to compute the score C with the score function F in Equation 1.

4.3 Loss Function and Meta-Learner

Following previous works, we adopt a simple strategy to compute the loss function of KGC L_{KGC} in both meta-training phase and the training stage of meta-testing phase. Given a randomly sampled relation r, first a positive triplet (h, r, t) is sampled from all triplets of r. Next, a negative triplet $(h, r, t^{'})$ can be produced by replacing t with another entity $t^{'}$ in KG, where the replacement is based on a uniform negative sampling. Note that if the negative triplet exists in KG, the negative sampling needs to be performed again. With a positive triplet and a negative triplet, embeddings of the positive triplet E^+ and embeddings of the negative triplet E^- can be obtained, and then two scores C^+ and C^- can be computed respectively. Finally, a hinge loss related to both scores is minimized for performing KGC

$$L_{KGC} = max(0, \gamma + C^+ - C^-), \quad (9)$$

where γ is a margin hyper-parameter greater than 0. Moreover, during meta-training phase, L_{KGC} is also jointly optimized with TCVAE so that the overall loss L is

$$L = L_{KGC} - L_{rec} - \lambda_1 L_{kld} - \lambda_2 L_{reg}, \quad (10)$$

where the negative loss terms of TCVAE are minimized, and λ_1, λ_2 are two hyper-parameters for weighting terms in the overall loss.

In order to ensure that both description encoder and TCVAE have a good generalization ability when handling infrequent relations and uncommon entities, a meta-learner is further used

to optimize the overall loss L. Among different directions of meta-learning, we construct the meta-learner based on Reptile since we find it has the best performance in our task. In the context of KGC, learning with Reptile is different from previous KGC works. During the meta-training phase, Reptile searches for an initial point W within the parameter space of our framework, but such a framework may not perform well when directly used for performing KGC in R_{test}. Instead, during training stage of the meta-testing phase, the framework parameters can be quickly adapted to a new point $W^{'}$ that is suitable for performing KGC given a new relation $r^{'} \in R_{test}$, and such an adaptation only needs a few training triplets of $r^{'}$ available. The procedure of learning with the meta-learner is depicted in Algorithm 1, where Adam (Kingma and Ba, 2015) is used during the S inner-training steps.

Algorithm 1 Learning Procedure of Meta-Learner

for iteration $= 1, 2, \ldots$ **do**
  Save parameters of our framework W
  for $i = 1, \ldots, B$ **do**
    Sample a relation $r \in R_{train}$, then sample a positive and a negative triplet of r

$\#R_{train}$	130	220
$\#R_{val}$	16	30
$\#R_{test}$	32	69
Avg #words	5.3	170.8

Table 1: Statistics of datasets, where "Avg #words" means the average number of words in descriptions.

Existing datasets for KGC usually select triplets consisting of frequently appearing relations and common entities. Recently two datasets focused on infrequent relations are proposed in (Xiong et al., 2018), but they do not contain textual descriptions for relations and entities. To obtain datasets that fulfill the practical few-shot learning situations as investigated in the problem setting, we manually harvest triplets and their textual descriptions from Wikidata (Vrandečić and Krötzsch, 2014) and DBpedia (Lehmann et al., 2015), and then we construct two datasets called WDtext and DBPtext respectively. The statistics of the two datasets are shown in Table 1. Specifically, the average numbers of words in the textual descriptions have a large variation between two datasets. In WDtext, descriptions are usually short phrases with only several words, on the other hand, descriptions in DBPtext consists of thousands of words, and we use first 200 words so that our model can be processed on GPUs. Such a variation of description length can better reveal the performance of our model in different situations. Besides, in order to collect enough triplets for evaluation, we select those relations whose numbers of triplets are greater than 5 and less than 1000, where the contained entities may exist only several times or even unseen during the meta-training phase. In this way, the problem setting of infrequent relations and uncommon entities is fulfilled in our datasets.

5.2 Experiment Setting

We compare our model with previous KGC models that can make use of textual descriptions, namely, DKRL (Xie et al., 2016) and ConMask (Shi and Weninger, 2018). We adapt their codes with our implementation. Following the experimental protocol of (Shi and Weninger, 2018), we also remove structural features of DKRL so that it can tackle unseen entities. To facilitate fair comparisons, even though these models are designed without using meta-learning, for each relation in R_{val} and R_{test}, we also sample k triplets and put them into R_{train} to ensure that all models make use of similar training data. Besides, the few-shot KGC model GMatching (Xiong et al., 2018) is also used for comparison. We only enable its "neighbor encoder" on WDtext because we cannot collect neighbor information from DBPedia. Moreover, we also design two additional baselines for ablation study. These baselines are constructed by removing specific components and keeping re-

16	0.146	128	0.330
32	0.144	256	0.256

Table 4: MRR results of our framework when using different number of augmentation in TCVAE, where #Gen means the number of triplets being generated.

maining parts in our framework. Specifically, trait is removed in the baseline "Ours - trait" and TCVAE is removed in the baseline "Ours - TCVAE" respectively. The experimental setting of hyperparameters and initialization of our framework and baselines can be found in Appendix A.

To make a fair comparison, we use two categories of common metrics: mean reciprocal rank (MRR) and hits@P which is the percentage of correct tail entities ranked in the top P. Besides, experiments are conducted using four different random seeds and we report the average results of four trials. For each model, we select the epoch that has the best performance when evaluating on R_{val} and report the corresponding results on R_{test}.

5.3 Results of One-Shot Learning

Firstly, we compare our overall framework with baselines by conducting an one-shot KGC experiment, which is the most difficult case in few-shot learning. The results of our overall framework and baselines are shown in Table 2, where we find that our overall framework outperforms the baselines on most metrics. For WDtext, ConMask is a strong baseline and has a better result on Hits@10 and Hits@5, but it performs worse on Hits@1 and MRR compared to our framework. On the other hand, our overall framework outperforms for a large margin compared to all baselines on DBPtext. Since the main difference between the two datasets are the average length of descriptions, we can observe that our framework has a better performance when dealing with long textual descriptions. Besides, the results of the two ablation baselines are significantly worse than our overall framework, and thus we can see both components play an important role in our framework.

5.4 Results of Few-Shot Learning

In real-world KGs, few-shot learning of infrequent relations and uncommon entities are more common than one-shot scenario, so we also conduct four-shot KGC as another experiment. We use the same baselines and metrics as that in the one-shot

KGC experiment. The results are shown in Table 3, where we can see that our overall framework also has the best performance on different comparisons except for Hits@10 on WDtext. By comparing our overall framework with two ablation baselines, the importance of traits and triplet augmentation is demonstrated again. Furthermore, when compared with the previous one-shot KGC results, all baselines in this experiment are able to make use of the extra training data to improve their performances. Our framework also performs better on all metrics in WDtext, but it performs inferior on some metrics in DBPtext when compared with the one-shot scenario. One possible reason is descriptions in DBPtext is longer and more complex than that in WDtext, and thus four descriptions of training triplets are too diverse to learn a good representation.

5.5 Analysis of Triplet Generation

As shown in the previous KGC experiments, the performance of our framework heavily depends on the triplet generation provided by TCVAE. In this subsection, we further explore the effect of triplet generation by comparing the MRR result of our overall framework with different number of generated triplets in one-shot scenario, where the triplet augmentation is particularly helpful. For this analysis, we only conduct experiment and report the result with one trial for simplicity. The results are shown in Table 4, and we can conclude that a proper data augmentation does enhance the performance of our framework when training data available is scarce. Besides, the appropriate number of triplets being generated varies from one dataset to another, and too many or too few generation leads to an inferior performance. In WDtext, generating 8 extra triplets enhances the performance most, but generating 128 triplets is better in DBPtext. One reason for such a difference is that DBPtext has longer descriptions which also increase the variance of the generated triplets, and thus generating more triplets is necessary to learn a stable representation.

6 Conclusions

We consider a new type of KGC where infrequent relations and uncommon entities need to be jointly handled, and we formulate it as a few-shot KGC problem. To tackle the problem, we propose a novel concept ”trait” and adopt it to extract relation-specific information from entity descriptions. Besides, we also design a triplet generator and a meta-learning framework based on Reptile to deal with the issue of few-shot KGC. Moreover, we also conduct two new datasets that focus on this problem setting. The experiments of both one-shot and four-shot scenarios show that our framework has a better performance compared to other baselines.

Abstract

Name tagging in low-resource languages or domains suffers from inadequate training data. Existing work heavily relies on additional information, while leaving those noisy annotations unexplored that extensively exist on the web. In this paper, we propose a novel neural model for name tagging solely based on weakly labeled (WL) data, so that it can be applied in any low-resource settings. To take the best advantage of all WL sentences, we split them into high-quality and noisy portions for two modules, respectively: (1) a classification module focusing on the large portion of noisy data can efficiently and robustly pre-train the tag classifier by capturing textual context semantics; and (2) a costly sequence labeling module focusing on high-quality data utilizes Partial-CRFs with non-entity sampling to achieve global optimum. Two modules are combined via shared parameters. Extensive experiments involving five low-resource languages and fine-grained food domain demonstrate our superior performance (6% and 7.8% F1 gains on average) as well as efficiency[1].

1 Introduction

Name tagging[2] is the task of identifying the boundaries of entity mentions in texts and classifying them into the pre-defined entity types (e.g., person). It serves as a fundamental role as providing the essential inputs for many IE tasks, such as Entity Linking (Cao et al., 2018a) and Relation Extraction (Lin et al., 2017).

Many recent methods utilize a neural network (NN) with Conditional Random Fields (CRFs) (Lafferty et al., 2001) by treating name tagging as a sequence labeling problem (Lample et al., 2016), which has became a basic architecture due to its superior performance. Nevertheless, NN-CRFs require exhaustive human efforts for training annotations, and may not perform well in low-resource settings (Ni et al., 2017). Many approaches thus focus on transferring cross-domain, cross-task and cross-lingual knowledge into name tagging (Yang et al., 2017; Peng and Dredze, 2016; Mayhew et al., 2017; Pan et al., 2017; Lin et al., 2018; Xie et al., 2018). However, they are usually limited by the extra knowledge resources that are effective only in specific languages or domains.

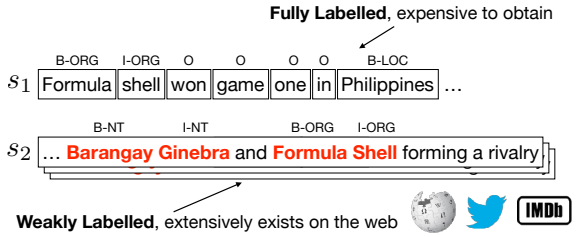

Figure 1: Example of weakly labeled data. B-NT and I-NT denote incomplete labels without types.

Actually, in many low-resource settings, there are extensive noisy annotations that naturally exist on the web yet to be explored (Ni et al., 2017). In this paper, we propose a novel model for name tagging that maximizes the potential of weakly labeled (WL) data. As shown in Figure 1, s_2 is weakly labeled, since only *Formula shell* and *Barangay Ginebra* are annotated, leaving the remaining words unannotated.

WL data is more practical to obtain, since it is difficult for people to accurately annotate those entities that they do not know or are not interested in. We can construct them from online resources, such as the anchors in Wikipedia. However, the following natures of WL data make learning name tagging from them more challenging:

Partially-Labeled Sequence Automatically

[1]Our project can be found in https://github.com/zig-kwin-hu/Low-Resource-Name-Tagging.
[2]Someone may call it Named Entity Recognition (NER).

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 261–270, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

derived WL data does not contain complete annotations, thus can not be directly used for training. Ni et al. (2017) select the sentences with highest confidence, and assume missing labels as O (i.e., non-entity), but it will introduce a bias to recognize mentions as non-entity. Another line of work is to replace CRFs with Partial-CRFs (Täckström et al., 2013), which assign unlabeled words with all possible labels and maximize the total probability (Yang et al., 2018; Shang et al., 2018). However, they still rely on seed annotations or domain dictionaries for high-quality training.

Massive Noisy Data WL corpora are usually generated with massive noisy data including missing labels, incorrect boundaries and types. Previous work filtered out WL sentences by statistical methods (Ni et al., 2017) or the output of a trainable classifier (Yang et al., 2018). However, abandoning training data may exacerbate the issue of inadequate annotation. Therefore, maximizing the potential of massive noisy data as well as high-quality part, yet being efficient, is challenging.

To address these issues, we first differentiate noisy data from high-quality WL sentences via a lightweight scoring strategy, which accounts for the annotation confidence as well as the coverage of all mentions in one sentence. To take best advantages of all WL data, we then propose a unified neural framework that solves name tagging from two perspectives: sequence labeling and classification for two types of data, respectively.

Specifically, the classification module focuses on noisy data to efficiently pretrain the tag classifier by capturing textual context semantics. It is trained only using annotated words without noisy unannotated words, and thus it is robust and efficient during training. The costly sequence labeling module is to achieve sequential optimum among word tags. It further alleviates the burden of seed annotations in Partial-CRFs and increases randomness via Non-entity Sampling strategy, which samples O words according to some linguistic natures. These two modules are combined via shared parameters. Our main contributions are as follows:

- We propose a novel neural name tagging model that merely relies on WL data without feature engineering. It can thus be adapted for both low-resource languages and domains, while no previous work deals with them at the same time.
- We consider name tagging from two perspectives of sequence labeling and classification, to efficiently take the best advantage of both high-quality and noisy WL data.
- We conduct extensive experiments in five low-resource languages and a fine-grained domain. Since few work has been done in two types of low-resource settings simultaneously, we arrive at two types of baselines from state-of-the-art methods. Our model achieves significant improvements (6% and 7.8% F1 on average), yet being efficient demonstrated in further ablation studies.

2 Related Work

Name tagging is an fundamental task of extracting entity information, which shall benefit many applications, such as information extraction (Zhang et al., 2017; Kuang et al., 2019; Cao et al., 2019a) and recommendation (Wang et al., 2019; Cao et al., 2019b). It can be treated as either a multi-class classification problem (Hammerton, 2003; Xu et al., 2017) or a sequence labeling problem (Collobert et al., 2011), but very little work combined them together. The difference between them mainly lies in whether the method models sequential label constraints, which have been demonstrated effective in many NN-CRFs models (Lample et al., 2016; Ma and Hovy, 2016; Chiu and Nichols, 2016). However, they require a large amount of human annotated corpora, which are usually expensive to obtain.

The above issue motivates a lot of work on name tagging in low-resource languages or domains. A typical line of effort focuses on introducing external knowledge via transfer learning (Fritzler et al., 2018; Hofer et al., 2018), such as the use of cross-domain (Yang et al., 2017), cross-task (Peng and Dredze, 2016; Lin et al., 2018) and cross-lingual resources (Ni et al., 2017; Xie et al., 2018; Zafarian et al., 2015; Zhang et al., 2016; Mayhew et al., 2017; Tsai et al., 2016; Feng et al., 2018; Pan et al., 2017). Although they achieve promising results, there are a large amount of weak annotations on the Web, which have not been well studied (Nothman et al., 2008; Ehrmann et al., 2011). Yang et al. (2018); Shang et al. (2018) utilized Partial-CRFs (Täckström et al., 2013) to model incomplete annotations for specific domains, but they still rely on seed annotations or a domain dictionary. Therefore, we aim at filling the gap in low-resource name tagging research by using only WL

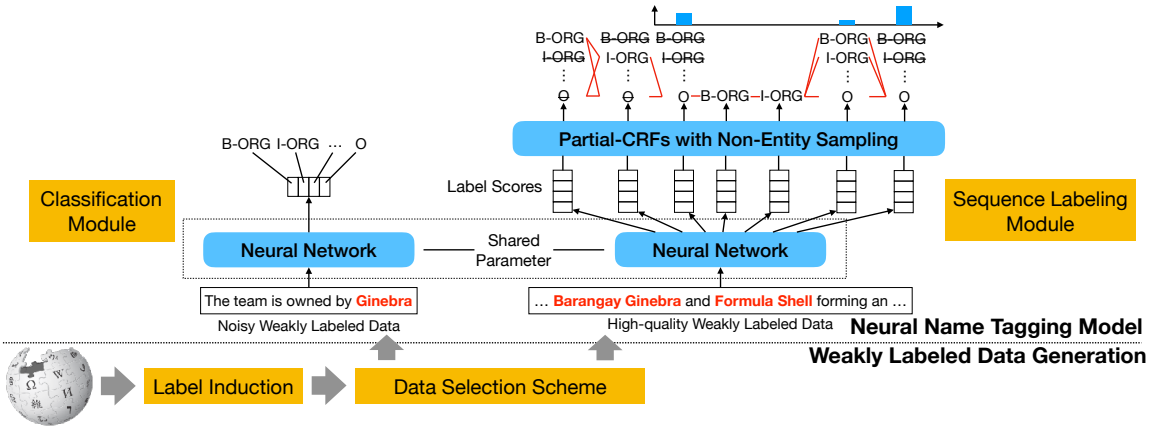

Figure 2: Framework. Rectangles denote the main components for two steps, and rounded rectangles consist of two modules of the neural model. In input sentences, bold fonts denote labeled words, and at the top is corresponding outputs. We use Partial-CRFs to model all possible label sequences (red paths from left to right by picking up one label per column) controlled by non-entity sampling (strikethrough labels according to the distribution). We replace "UN" and "x-NT" label with corresponding possible labels to clarify the principle of PCRF.

data, and adapt it to arbitrary low-resource languages or domains, which can be further improved by the above transfer-based methods.

3 Preliminaries and Framework

3.1 Preliminaries

We formally define the name tagging task as follows: given a sequence of words $X = \langle x_1, \cdots, x_i, \cdots, x_{|X|} \rangle$, it aims to infer a sequence of labels $Y = \langle y_1, \cdots, y_i, \cdots, y_{|X|} \rangle$, where $|X|$ is the length of the sequence, $y_i \in \mathcal{Y}$ is the label of the word x_i, each label consists of the boundary and type information, such as B-ORG indicating that the word is **B**egin of an **ORG**anization entity. To make notations consistent, we use $\tilde{\mathcal{Y}} = \mathcal{Y} \bigcup \{\text{UN,B-NT,I-NT}\}$ to denote the label set of WL data, where UN indicates that the word is unlabeled, and NT denote only the type is unlabeled. In other words, the word with UN may be any one of the label in $\mathcal{Y}$, and the word with NT may be any type. We define $\tilde{\mathcal{Y}}$ for notation clarity.

To deal with the issue of limited annotations, we construct WL data $\mathcal{D} = \{(X, \tilde{Y})\}$ based on Wikipedia anchors and taxonomy, where $\tilde{Y} = \langle \tilde{y}_1, \cdots, \tilde{y}_i, \cdots, \tilde{y}_{|X|} \rangle$ and $\tilde{y}_i \in \tilde{\mathcal{Y}}$. An **anchor** $\langle m, e \rangle \in \mathcal{A}$ links a mention m to an entity $e \in E$, where m contains one or several consecutive words of length $|m|$. Particularly, we define $\mathcal{A}(X)$ as the set of anchors in X. Most entities are mapped to hierarchically organized categories, namely **taxonomy** $\mathcal{T}$, which provides category information $C = \{c\}$. We define $C(e)$ as the category set of e, and $\mathcal{T}_{\downarrow}(c)$ as the children of c.

3.2 Framework

The goal of our method is to extract WL data from Wikipedia and use them as training corpora for name tagging. As shown in Figure 2, there are two steps in our framework:

Weakly Labeled Data Generation generates as many WL data as possible for higher tagging recall. It contains two components of label induction and data selection scheme. First, the label induction assigns each word a label based on Wikipedia anchors and taxonomy. Then, the data selection scheme computes the quality scores for the WL sentences by considering the coverage of mentions as well as the label confidence. According to the scores, we split the entire set into two parts: a small set of high-quality data for the sequence labeling module, and a large amount of noisy data for the classification module.

Neural Name Tagging Model aims at efficiently and robustly utilizing both high-quality and noisy WL data, ensuring satisfying tagging precision. It is to make best use of labeled words via the sequence labeling module and the classification module. More specifically, we pre-train the classification module to capture the textual context semantics from massive noisy data, and then the sequence labeling module further fine-tunes the shared neural networks using a Partial-CRFs layer with Non-Entity Sampling.

4 Weakly Labeled Data Generation

Existing methods use Wikipedia (Ni et al., 2017; Pan et al., 2017; Geiß et al., 2017) to train an extra

classifier to predict entity categories for name tagging training. Instead, we aim at lowering the requirements of additional resources in order to support more low-resource settings. We thus utilize a lightweight strategy to generate WL data including label induction and data selection scheme.

4.1 Label Induction

Given a sentence X including anchors $\mathcal{A}(X)$ and taxonomy $\mathcal{T}$, we aim at inducing a label $\tilde{y} \in \tilde{\mathcal{Y}}$ for each word $x \in X$. Obviously, the words outside of anchors should be labeled with UN, indicating that it is unlabeled and could be O or unannotated mentions. For the words in an anchor $\langle m, e \rangle$, we label it according to the entity categories. For example, words *Formula* and *Shell* (Figure 1) in s_2 are labeled as B-ORG and I-ORG, respectively, because mention *Formula Shell* is linked to entity *Shell Turbo Chargers*, which belongs to category *Basketball teams*. We trace it along the taxonomy $\mathcal{T}$: *Basketball teams*→...→*Organizations*, and find that it is a child of *Organizations*. According to a manually defined mapping $\Gamma(\mathcal{Y}) \rightarrow C$ (e.g., $\Gamma(ORG)$ =*Organizations*), we denote all the classes and their children with the same type (e.g., ORG).

However, there are two minor issues. First, for the entities without category information $C(e) = \emptyset$, we label them as B-NT or I-NT, indicating that they have no type information. Second, for the entities referring to multiple categories, we induce labels that maximizes the conditional probability:

$$\underset{y^*}{\text{argmax}}\, p(y^*|C(e)) = \frac{\sum_{c \in C(e)} \mathbf{1}(c \in \mathcal{T}_{\downarrow}(\Gamma(y^*)))}{|C(e)|} \tag{1}$$

where $\mathbf{1}(\cdot)$ indicates 1 if holds true, otherwise 0.

By doing so, we obtain a set of WL sentences $\mathcal{D} = \{(X, \tilde{Y})\}$. However, the induction process may introduce incorrect boundaries and types of labels due to the crowdsourcing nature of source data. We thus design a data selection scheme to deal with the issues.

4.2 Data Selection Scheme

Following Ni et al. (2017), we compute quality scores for sentences to distinguish high-quality and noisy data from two aspects: the annotation confidence and the annotation coverage.

The annotation confidence measures the likelihood of the text spans being mentions (i.e., correctness of boundaries), and being assigned with the types. We define it as follows:

$$q(X, \tilde{Y}) = \frac{\sum\limits_{(x_i, \tilde{y}_i)} \mathbf{1}(\tilde{y}_i \in \mathcal{Y}) p(\tilde{y}_i|C(e)) p(C(e)|x_i)}{|X|} \tag{2}$$

where $p(C(e)|x_i)$ is the conditional probability of x_i linking to an entity belong to category $C(e)$, we compute it based on its statistical frequency among Wikipedia anchors.

The annotation coverage measures to which ratio the words are being labeled in the sentence:

$$n(X, \tilde{Y}) = \frac{\sum\limits_{(x_i, \tilde{y}_i)} \mathbf{1}(\tilde{y}_i \in \mathcal{Y})}{|X|} \tag{3}$$

We select high-quality sentences $\mathcal{D}^{hq}$ satisfying:

$$q(X, \tilde{Y}) \geq \theta_q; n(X, \tilde{Y}) \geq \theta_n \tag{4}$$

where θ_q and θ_n are the hyperparameters. Thus, the remaining sentences are noisy $\mathcal{D}^{noise}$.

For example (Figure 2), the sentence ... *Barangay Ginebra and Formula Shell* ... is high-quality, and *The team is owned by Ginebra* is noisy. This is because there are more anchors that link *Formula Shell* to an organization entity and the anchors within the sentence account for a large proportion, leading to a higher quality score. Note that *Barangay* and *Ginebra* are labeled with B-NT and I-NT, indicating the type information is missing. Our model may learn the textual semantics for classifying *Ginebra* to ORG from the noisy sentence, where *Ginebra* is labeled with B-ORG.

5 Neural Name Tagging Model

Our neural model contains two modules that share the same NN architecture except the Partial-CRFs layer. Given $\mathcal{D}^{hq}$ and $\mathcal{D}^{noise}$, we first pre-train the classification module using massive noisy data $\mathcal{D}^{noise}$ to efficiently capture the textual semantics. Then, we use the sequence labeling module to fine-tune the classification module on high-quality data $\mathcal{D}^{hq}$ by considering the transitional constraints among sequential labels.

5.1 Sequence Labeling Module

Before describing the NN of the classification module, we first introduce the sequence labeling module. Different from conventional NN-CRFs

models, we utilize the Partial CRFs layer to maximize the probability of all possible sequential labels for the sentence with transitional constraints, where the probability of missing word labels is controlled by non-entity sampling.

Partial-CRFs

Partial-CRFs (PCRFs) was first proposed in the field of Part-of-Speech Tagging (Täckström et al., 2013). It can be trained when the coupled word and label constraints provide only a partial signal by assuming that the uncoupled words may refer to multiple labels. Given $(X, \tilde{Y})$, we traverse all possible labels $\mathcal{Y}$ for each unannotated word $\{x_i|\tilde{y}_i \in$ UN,B-NT,I-NT$\}$ (e.g., the red paths in Figure 2), and compute the total probability of possible fully labeled sentences $\mathcal{Y}(X, \tilde{Y}) = \{(X, Y)\}$:

$$p(\tilde{Y}|X) = \sum_{(X,Y)}^{\mathcal{Y}(X,\tilde{Y})} p(Y|X) \tag{5}$$

where $p(Y|X) = \text{softmax}(s(X, Y))$, the same as in CRFs, and the score function $s(X, Y)$ is:

$$s(X, Y) = \sum_{i=0}^{|X|} A_{y_i,y_{i+1}} + \sum_{i=1}^{|X|} P_{x_i,y_i} \tag{6}$$

where P_{x_i,y_i} is the score indicating how possible x_i is labeled with y_i, which is defined as the output of NN and will be detailed in the next section. $A_{y_i,y_{i+1}}$ is the transition score from label y_i to y_{i+1} that is learned in this layer.

Instead of the single correct label sequence in CRFs, the loss function of partial-CRFs is to minimize the negative log-probability of ground truth over all possible labeled sequences:

$$\mathcal{L} = -\sum_{(X,\tilde{Y})}^{\mathcal{D}^{nq}} \log p(\tilde{Y}|X) \tag{7}$$

Non-entity Sampling

A crucial drawback of using partial CRFs for WL sentences is that there are no words labeled with O (i.e., non-entity words) for training (Section 6.5).

To further alleviate the reliance on seed annotations, we introduce non-entity sampling that samples O from unlabeled words as follows:

$$p(y_i = \text{O}|x_i, \tilde{y}_i = \text{N}) = \frac{\alpha}{3}(\lambda_1 f_1 + \lambda_2(1 - f_2) + \lambda_3 f_3) \tag{8}$$

where α is non-entity ratio to balance how many unlabeled words are sampled as O, we set $\alpha = 0.9$ in experiments according to Augenstein et al. (2017). Weighting parameters satisfy $0 \leq \lambda_1, \lambda_2, \lambda_3 \leq 1$, and f_1, f_2, f_3 are feature scores. We define $f_1 = \mathbf{1}(x_i \text{ adjoins an entity})$, which implies that the words around a mention are possible to be O; f_2 is the ratio of the number of x_i labeled with entities to its total occurrences, reflecting how frequent a word is in a mention; and $f_3 = tf * df$, where tf is term frequency and df is document frequency in Wikipedia articles.

As shown in Figure 2, three words *and*, *forming* and *an* are labeled with N since they are outside of anchors. During training, they should be regarded as all labels of $\mathcal{Y}$ in Partial CRFs, while we sample some of them as O words according to Equation 8. Thus, *and* and *an* are instead treated as O words, because they do not appear in any anchor, and are too general due to a high f_3 value.

5.2 Classification Module

To efficiently utilize the noisy WL sentences, this module regards name tagging as a multi-label classification problem. On one hand, it predicts each word's label separately, naturally addressing the issue of inconsecutive labels. On the other hand, we only focus on the labeled words, so that the module is robust to the noise since most noise arises from the unlabeled words, and enjoy an efficient training procedure.

Formally, given a noisy sentence $(X, \tilde{Y}) \in \mathcal{D}^{noise}$, we classify words $\{x_i|\tilde{y}_i \in \mathcal{Y}\}$ by capturing textual semantics within the context. Independently of languages and domains, we combine the character and word embeddings for each word, then feed them into an encoder layer to capture contextual information for the classification layer.

Character and Word Embeddings

As inputs, we introduce character information to enhance word representations to improve the robustness to morphological and misspelling noise following (Ma and Hovy, 2016). Concretely, we represent a word $\mathbf{x}$ by concatenating word embedding $\mathbf{w}$ and Convolutional Neural Networks (CNN) (LeCun et al., 1989) based character embedding $\mathbf{c}$, which is obtained through convolution operations over characters in a word followed by max pooling and drop out techniques.

Encoder Layer

Given an arbitrary length of sentence X, this component encodes the semantics of words as well as their compositionality into a low-dimensional vector space. The most common encoders are CNN, Long-Short Term Memory (LSTM) (Hochreiter and Schmidhuber, 1997) and Transformer (Vaswani et al., 2017). We use the bi-directional LSTM (Bi-LSTM) due to its superior performance. We discuss it in Section 6.2.

Bi-LSTM (Graves et al., 2013) has been widely used in modeling sequential words, so as to capture both past and future input features for a given word. It stacks a forward LSTM and a backward LSTM, so that the output of a word x_i is $\mathbf{h}_i = [\overleftarrow{\mathbf{h}}_i; \overrightarrow{\mathbf{h}}_i]$, where $\overrightarrow{\mathbf{h}}_i = \text{LSTM}(X_{1:i})$ and $\overleftarrow{\mathbf{h}}_i = \text{LSTM}(X_{i:|X|})$.

Classification Layer

The classification layer makes independent labeling decisions for each word, so that we can only focus on labeled words, while robustly and efficiently skip the noisy unlabeled words.

In this layer, we estimate the score P_{x_i,y_i} (Equation 6) for word x_i being the label y_i. We use a fully connected layer followed by softmax to output a probability-like score:

$$P_{x_i,y_i} = Softmax(W\mathbf{h}_i + b) \tag{9}$$

where $W \in \mathbb{R}^{|\mathcal{Y}|}$. Note that we have no training instance for O words. Thus, we also use the non-entity sampling (Section 5.1). Given $(X, \tilde{Y}) \in \mathcal{D}^{noise}$, this module is trained to minimize cross-entropy of the predicted and ground truth:

$$\mathcal{L}_c = -\sum_{(X,\tilde{Y})}^{\mathcal{D}^{noise}} \mathbf{1}(\tilde{y}_i \in \mathcal{Y}) \tilde{y}_i \log P_{x_i,y_i} \tag{10}$$

5.3 Training and Inference

To distill the knowledge derived from noisy data, we first pre-train the classification module, then share the overall NN with the sequence labeling module. If we choose a loose threshold θ_p and θ_n, there is no noisy data and our model shall degrade to the sequential model without the pre-trained classifier. When the threshold is strict, there is no high-quality data and our model will degrade to the classification module only (Section 6.4).

For inference, we use the sequence labeling module to predict the output label sequence with the largest score as in Equation 6.

6 Experiment

We verify our model using five low-resource languages and a specific domain. Furthermore, we investigate the impacts of the main components as well as hyperparameters in the ablation study.

6.1 Experiment Settings

Datasets Since most datasets on low-resource languages are not publicly available, we use Wikipedia data as the "ground truth" following Pan et al. (2017). Thus, we can test name tagging in low-resource languages as well as domains. We choose five languages: Welsh, Bengali, Yoruba, Mongolian and Egyptian Arabic (or CY, BN, YO, MN and ARZ for short), at different low-resource levels, and select 3 types: Person, Location and Organization. For food domain, we reorganized the entities in Wikipedia category "Food and drink" into 5 types: Drinks, Meat, Vegetables, Condiments and Breads, for name tagging, and extract sentences containing those entities from all English Wikipedia articles for as many data as possible.

	Train		Test	
	#Sent	#Ment	#Sent	# Ment
CY	106,541	146,524	1,193	3,256
BN	66,915	127,932	870	2838
YO	36,548	10,405	77	232
MN	19,250	27,820	173	439
ARZ	18,700	28,928	195	377
Food Domain	27,798	32,155	207	253
Drinks	8,615	9,218	62	67
Meat	7,685	8,841	53	68
Vegetables	6,155	7,235	45	58
Condiments	3,737	4,084	27	30
Breads	2,515	2,777	24	30

Table 1: The statistics of weakly labeled dataset.

We use 20190120 Wikipedia dump for WL data construction, where the ratio of words in anchors to the whole sentence is nearly 0.12, 0.07, 0.14, 0.07 and 0.06 for languages CY, BN, YO, MN and ARZ, and 0.13 for food domain, demonstrating that unlabeled words are dominant. By heuristically setting $\theta_q = 0.1, \theta_n = 0.9$, we obtain 56,571, 16,718, 4,131, 8,332, 6,266, 11,297 high-quality and 49,970, 50,197, 32,417, 10,918, 12,434, 16,501 noisy WL sentences for language

Table 2: Performance (%) on low-resource languages.

CY, BN, YO, MN and ARZ, and food domain, respectively. For correctness, we then pick up test data of 25% sentences that has highest annotation confidence and exceed 0.3 coverage. We randomly choose 25% of high-quality data as validation for early stop, and the rest for training. The statistics[3] is in Table 1.

Training Details

For tuning of hyper-parameters, we set non-entity feature weights to $\lambda_1 = 0, \lambda_2 = 0.9, \lambda_3 = 0.1$ heuristically. We pre-train word embeddings using Glove (Pennington et al., 2014), and fine-tune embeddings during training. We set the dimension of words and characters as 100 and 30, respectively. We use 30 filter kernels, where each kernel has the size of 3 in character CNN, and dropout rate is set to 0.5. For bi-LSTM, the hidden state has 150 dimensions. The batch size is set to 32 and 64 for sequence labeling module and classification module. We adopt Adam with L2 regularization for optimization, and set the learning rate and weight decay to 0.001 and $1e^{-9}$.

Baselines Since most low-resource name tagging methods introduce external knowledge (Section 2), which has limited availability and is out of the scope for this paper, we arrive at two types of baselines from weakly supervised models:

Typical NN-CRFs models (Ni et al., 2017) by selecting high-quality WL data and regarding unlabeled words as O, which usually achieve very competitive results. NN denotes CNN, Transformer (Trans for short) or Bi-LSTM.

NN-PCRFs model (Yang et al., 2018; Shang et al., 2018). Although they achieves state-of-the-art performance, methods of this type are only evaluated in specific domains and require a small set of seed annotations or a domain dictionary. We thus carefully adapt them to low-resource languages and domains by selecting the highest-quality WL data ($\theta_n > 0.3$) as seeds[4].

[3]The statistics includes noisy data, which greatly increases the size but cannot be used for evaluation.

[4]We adopt the common part of their models related to handling weakly labeled data, removing the other parts that are specifically designed for domains, such as instance selector (Yang et al., 2018) which makes it worse since we have already selected the high-quality data.

6.2 Results on Low-Resource Languages

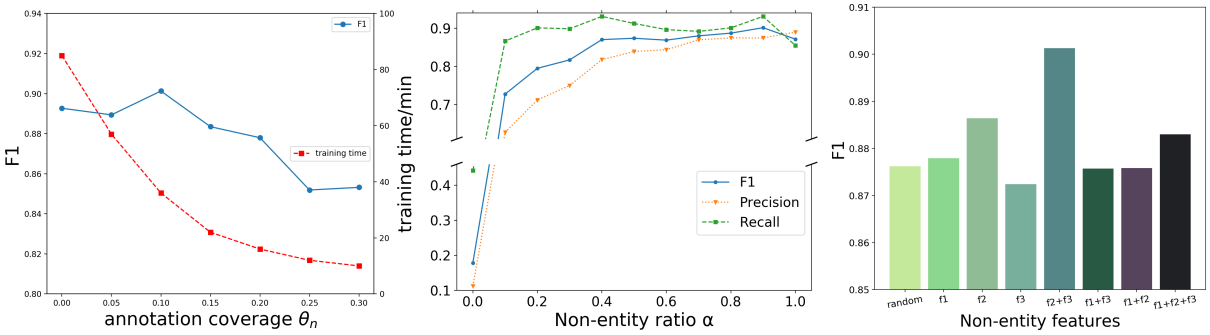

Table 2 shows the overall performance of our proposed model as well as the baseline methods (P and R denote Precision and Recall). We can see:

Our method consistently outperforms all baselines in five languages w.r.t F1, mainly because we greatly improve recall (2.7% to 9.34% on average) by taking best advantage of WL data and being robust to noise via two modules. As for the precision, partial-CRFs perform poorly compared with CRFs due to the uncertainty of unlabeled words, while our method alleviates this issue by introducing linguistic features in non-entity sampling. An exception occurs in CY, because it has the most training data, which may bring more accurate information than sampling. Actually, we can tune hyper-parameter non-entity ratio α to improve precision[5], more studies can be found in Section 6.5. Besides, the sampling technique can utilize more prior features if available, we leave it in future.

Among all encoders, Bi-LSTM has greater ability for feature abstraction and achieves the highest precision in most languages. An unexpected exception is Yoruba, where CNN achieves the higher performance. This indicates that the three encoders capture textual semantics from different perspectives, thus it is better to choose the encoder by considering the linguistic natures.

As for the impacts of resources, all the models perform the worst in Yoruba. Interestingly, we conclude that the performance for name tagging in low-resource languages doesn't depend entirely on the absolute number of mentions in the training data, but largely on the average number of annotations per sentence. For example, Bengali has 1.9 mentions per sentence and all methods achieve their best results, while the opposite is Welsh with

[5]In this table, we show the performance using the same hyper-parameters in different languages for fairness.

(a) Efficiency analysis. (b) Impact of non-entity sampling ratio. (c) Impact of non-entity features.

Figure 3: Ablation study of our model in Mongolian.

1.4 mentions per sentence. This verifies our data selection scheme (e.g., annotation coverage $n(\cdot)$), and we will give more discussion in Section 6.4.

6.3 Results on Low-Resource Domains

	Food					
	D	**M**	**V**	**C**	**B**	**All**
CNN-CRFs	67.8	69.8	57.9	42.8	46.5	60.9
BiLSTM-CRFs	64.9	69.0	62.8	50.0	62.2	63.5
Trans-CRFs	62.1	68.9	59.6	43.4	54.5	60.6
BiLSTM-PCRFs	66.1	70.7	67.2	44.4	58.3	64.4
Ours	**72.0**	**76.4**	**70.0**	**53.5**	**66.6**	**70.1**

Table 3: F1-score (%) on food domain.

Table 3 shows the overall performance in food domain, where D, M, V, C and B denote: Drink, Meat, Vegetables, Condiments and Breads. We can observe that there is a performance drop compared to that in low-resource languages, mainly because of more types and sparse training data. Our model outperforms all of the baselines in all food types by 7.8% on average. The performance in condiments is relatively low, because most of them are composed of meat or vegetables, such as steak sauce, which is overlapped with other types and make the recognition more difficult.

Sentence:	*Maize*	and	*yams*	are	grown	on	its	banks	.
Labels:	B-V	UN	UN	UN	UN	UN	UN	UN	UN
Predictions:	B-V	O	B-V	O	O	O	O	O	O

Figure 4: Our predictions on a noisy WL sentence.

Here is a representative case demonstrating that our model is robust to noise induced by unlabeled words. In Figure 4, the sentence is from the noisy WL training data of food domain, and only *Maize* is labeled as B-V. Although our model is trained on this sentence, it successfully predicts *yams* as B-V. This example shows that our two-modules design can utilize the noisy data while avoiding side effects caused by incomplete annotation.

6.4 Efficiency Analysis

We utilize θ_n, the main factor to annotation quality (Section 6.2), to trade off between high-quality and noisy WL data. As shown in Figure 3(a), the red curve denotes the training time and the blue curve denotes F1. We can see that the performance of our model is relatively stable when $\theta_n \in [0, 0.15)$, while the time cost drops dramatically (from 90 to 20 minutes), demonstrating the robustness and efficiency of two-modules design. When $\theta_n \in [0.15, 0.3]$, the performance decreases greatly due to less available high-quality data for sequence labeling module; meanwhile, little time is saved through classification module. Thus, we pick up $\theta_n = 0.1$ in experiments. A special case happens when $\theta_n = 0$, our model degrades to sequence labeling without pre-trained classifier. We can see the performance is worse than that of $\theta_n = 0.1$ due to massive noisy data.

6.5 Impact of Non-Entity Sampling Ratio

We use non-entity ratio α to control sampling, and a higher α denotes that more unlabeled words are labeled with O. As shown in Figure 3(b), the precision increases as more words are assigned with labels, while the recall achieves two peaks ($\alpha = 0.4, 0.9$), leading to the highest F1 when $\alpha = 0.9$, which conforms to the statistics in Augenstein et al. (2017). There are two special cases. When $\alpha = 0$, our model degrades to a NN-PCRFs model without non-entity sampling and there is no seed annotations for training. We can see the model performs poorly due to the dominant unlabeled words (Section 5.1). When $\alpha = 1$ indicating all unlabeled words are sampled as O, our model

degrades to NN-CRFs model, which has higher precision at the cost of recall. Clearly, the model suffers from the bias to O labeling.

6.6 Impact of Non-Entity Features

We propose three features for non-entity samples: nearby entities (f_1), ever within entities (f_2) and term/document frequency (f_3). We now investigate how effective each feature is. Figure 3(c) shows the performance of our model that samples non-entity words using each feature as well as their combinations. The first bar denotes the performance of sampling without any features. It is not satisfying but competitive, indicating the importance of non-entity sampling to partial-CRFs. The single f_2 contributes the most, and gets enhanced with f_3 because they provide complementary information. Surprisingly, f_1 seems better than f_3, but makes the model worse if we use it combined with f_2, f_3, thus we set $\lambda_1 = 0$.

7 Conclusions

In this paper, we propose a novel name tagging model that consists of two modules of sequence labeling and classification, which are combined via shared parameters. We automatically construct WL data from Wikipedia anchors and split them into high-quality and noisy portions for training each module. The sequence labeling module focuses on high-quality data and is costly due to the partial-CRFs layer with non-entity sampling, which models all possible label combinations. The classification module focuses on the annotated words in noisy data to pretrain the tag classifier efficiently. The experimental results in five low-resource languages and a specific domain demonstrate the effectiveness and efficiency.

In the future, we are interested in incorporating entity structural knowledge to enhance text representation (Cao et al., 2017, 2018b), or transfer learning (Sun et al., 2019) to deal with massive rare words and entities for low-resource name tagging, or introduce external knowledge for further improvement.

Abstract

Despite of the recent success of collective entity linking (EL) methods, these "global" inference methods may yield sub-optimal results when the "all-mention coherence" assumption breaks, and often suffer from high computational cost at the inference stage, due to the complex search space. In this paper, we propose a simple yet effective solution, called Dynamic Context Augmentation (DCA), for collective EL, which requires only one pass through the mentions in a document. DCA *sequentially* accumulates context information to make efficient, collective inference, and can cope with different local EL models as a plug-and-enhance module. We explore both supervised and reinforcement learning strategies for learning the DCA model. Extensive experiments[1] show the effectiveness of our model with different learning settings, base models, decision orders and attention mechanisms.

1 Introduction

Linking mentions of entities in text to knowledge base entries (i.e., entity linking, or EL) is critical to understanding and structuring text corpora. In general, EL is approached by first obtaining candidate entities for each mention, and then identifying the true referent among the candidate entities. Prior distribution and local contexts, either in the form of hand-crafted features (Ratinov et al., 2011; Shen et al., 2015) or dense embeddings (He et al., 2013; Nguyen et al., 2016; Francis-Landau et al., 2016), play key roles in distinguishing different candidates. However, in many cases, local features can be too sparse to provide sufficient information for disambiguation.

To alleviate this problem, various collective EL models have been proposed to globally optimize the inter-entity coherence between mentions in the same document (Hoffart et al., 2011; Cheng and Roth, 2013; Nguyen et al., 2014; Alhelbawy and Gaizauskas, 2014; Pershina et al., 2015). Despite of their success, existing global EL models try to optimize the entire linking configuration of all mentions, with extra assumptions of either all-mention coherence or pairwise coherence (Phan et al., 2018). Such assumptions are against human intuitions, as they imply that no inference can

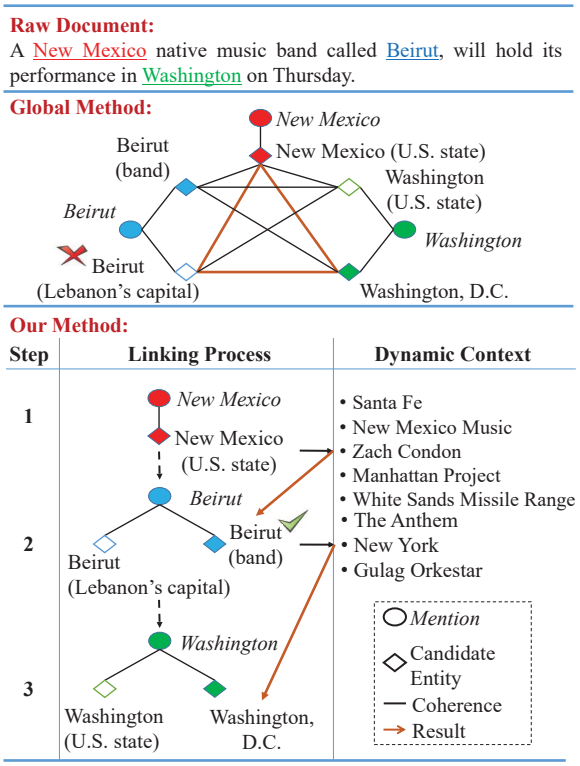

Figure 1: **An Illustration of the Dynamic Context Augmentation process.** A traditional global EL model jointly optimizes the linking configuration after iterative calculations over all mentions, which is computationally expensive. In contrast, the DCA process only requires one pass of the document to accumulate knowledge from previously linked mentions to enhance fast future inference.

be made until all mentions in a document have been observed. Also, there usually exists a trade-off between accuracy and efficiency: state-of-the-art collective/global models suffer from high time complexity. From the perspective of computational efficiency, optimal global configuration inference is NP-hard. Approximation methods, such as loopy belief propagation (Ganea and Hofmann, 2017) or iterative substitutions (Shen et al., 2015), are still computationally expensive due to the huge hypothesis space, and thus can hardly be scaled to handle large corpus. Many previous works have discussed the urgent needs of more efficient linking system for production, both in time complexity (Hughes et al., 2014) and memory consumption (Blanco et al., 2015).

In this paper, we propose a simple yet effective **D**ynamic **C**ontext **A**ugmentation (DCA) process to incorporate global signal for EL. As Figure 1 shows, in contrast to traditional global models, DCA only requires one pass through all mentions to achieve comparable linking accuracy. The basic idea is to accumulate knowledge from previously linked entities as dynamic context to enhance later decisions. Such knowledge come from not only the inherent properties (e.g., description, attributes) of previously linked entities, but also from their closely related entities, which empower the model with important associative abilities. In real scenarios, some previously linked entities may be irrelevant to the current mention. Some falsely linked entities may even introduce noise. To alleviate error propagation, we further explore two strategies: (1) soft/hard attention mechanisms that favour the most relevant entities; (2) a reinforcement learning-based ranking model, which proves to be effective as reported in other information extraction tasks.

Contributions. The DCA model forms a new linking strategy from the perspective of data augmentation and thus can serve as a plug-and-enhance module of existing linking models. The major contributions of this work are as follows: (1) DCA can introduce topical coherence into local linking models without reshaping their original designs or structures; (2) Comparing to global EL models, DCA only requires one pass through all mentions, yielding better efficiency in both training and inference; (3) Extensive experiments show the effectiveness of our model under different learning settings, base models, decision orders and attention mechanisms.

2 Background

2.1 Problem Definition

Given a set of entity mentions $\mathcal{M} = \{m_1, ..., m_T\}$ in corpus $\mathcal{D}$, Entity Linking aims to link each mention m_t to its corresponding gold entity e_t^*. Such a process is usually divided into two steps: *Candidate generation* first collects a set of possible (candidate) entities $\mathcal{E}_t = \{e_t^1, ..., e_t^{|\mathcal{E}_t|}\}$ for m_t; *Candidate ranking* is then applied to rank all candidates by likelihood. The linking system selects the top ranked candidate as the predicted entity $\hat{e}_t$. The key challenge is to capture high-quality features of each entity mention for accurate entity prediction, especially when local contexts are too sparse to disambiguate all candidates.

We build our DCA model based on two existing local EL models. In this section, we first introduce the architecture of the base models, then present the proposed DCA model under the standard supervised learning framework. Since the DCA process can be naturally formed as a sequential decision problem, we also explore its effectiveness under the Reinforcement Learning framework. Detailed performance comparison and ablation studies are reported in Section 6.

2.2 Local Base Models for Entity Linking

We apply the DCA process in two popular local models with different styles: the first is a neural attention model named ETHZ-Attn (Ganea and Hofmann, 2017), the other is the Berkeley-CNN (Francis-Landau et al., 2016) model which is made up of multiple convolutional neural networks (CNN).

ETHZ-Attn. For each mention m_t and a candidate $e_t^j \in \mathcal{E}_t$, three local features are considered: (1) *Mention-entity Prior* $\hat{P}(e_t^j|m_t)$ is the empirical distribution estimated from massive corpus (e.g.Wikipedia); (2) *Context Similarity* $\Psi_C(m_t, e_t^j)$ measures the textual similarity between e_t^j and the local context of m_t; (3) *Type Similarity* $\Psi_T(m_t, e_t^j)$ considers the similarity between the type of e_t^j and contexts around m_t. $\hat{P}(e_t^j|m_t)$ and $\Psi_C(m_t, e_t^j)$ are calculated in the same way as (Ganea and Hofmann, 2017). For $\Psi_T(m_t, e_t^j)$, we first train a typing system proposed by (Xu and Barbosa, 2018) on AIDA-train dataset, yielding 95% accuracy on AIDA-A dataset. In the testing phase, the typing system

predicts the probability distribution over all types (PER, GPE, ORG and UNK) for m_t, and outputs $\Psi_T(m_t, e_t^j)$ for each candidate accordingly. All local features are integrated by a two-layer feed-forward neural network with 100 hidden units, as described in (Ganea and Hofmann, 2017).

Berkeley-CNN. The only difference between **ETHZ-Attn** and **Berkeley-CNN** is that, this model utilizes CNNs at different granularities to capture *context similarity* $\Psi_C(m_t, e_t^j)$ between a mention's context and its target candidate entities.

3 Dynamic Context Augmentation

As Figure 1 demonstrates, the basic idea of DCA is to accumulate knowledge from previously linked entities as dynamic context to enhance later decisions. Formally, denote the list of previously linked entities as $S_t = \{\hat{e}_1, ..., \hat{e}_t\}$, where each $\hat{e}_i$ is represented as an embedding vector. The augmented context can be represented by accumulated features of all previous entities and their neighbors (e.g. by averaging their embeddings, in the simplest way). In actual scenarios, some entities in S_t are irrelevant, if not harmful, to the linking result of m_{t+1}. To highlight the importance of relevant entities while filtering noises, we also try to apply a neural attention mechanism on dynamic contexts (Figure 2). For mention m_{t+1}, candidates that are more coherent with S_t are preferred. More specifically, we calculate the relevance score for each $\hat{e}_i \in S_t$ as

$$u(\hat{e}_i) = \max_{e_{t+1}^j \in \mathcal{E}_{t+1}} {e_{t+1}^j}^\top \cdot A \cdot \hat{e}_i, \quad (1)$$

where A is a parameterized diagonal matrix. Top K entities in S_t are left to form dynamic context while the others are pruned. The relevance scores are transformed to attention weights with

$$a(\hat{e}_i) = \frac{\exp[u(\hat{e}_i)]}{\sum_{\hat{e}_j \in S_t} \exp[u(\hat{e}_j)]}. \quad (2)$$

Thus, we can define a weighted coherence score between $e_{t+1}^j \in \mathcal{E}_{t+1}$ and S_t as

$$\Phi(e_{t+1}^j, S_t) = \sum_{\hat{e}_i \in S_t} a(\hat{e}_i) \cdot {e_{t+1}^j}^\top \cdot R \cdot \hat{e}_i, \quad (3)$$

where R is a learnable diagonal matrix. Such a coherence score will be later incorporated in the final representation of e_{t+1}^j.

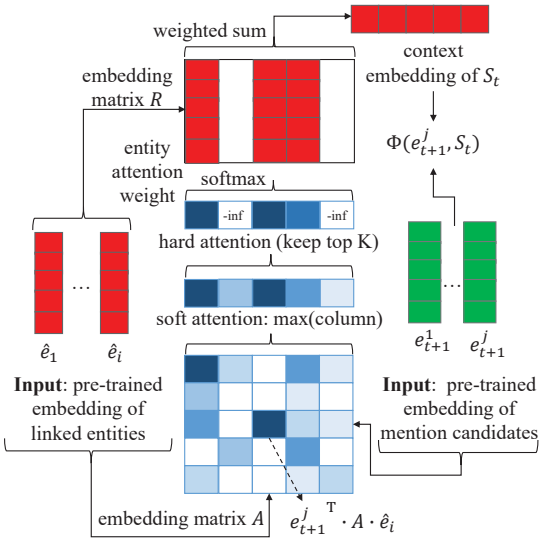

Figure 2: Neural attention mechanism on the dynamic context. The soft attention module assigns higher weights to entities that are more relevant to the target mention. The hard attention module only considers top K entities as dynamic contexts.

To empower the linking model with associative ability, aside from previously linked entities, we also incorporate entities that are closely associated with entities in S_t. Specifically, for each $\hat{e}_i \in S_t$, we collect its neighborhood $\mathcal{N}(\hat{e}_i)$ consisting of Wikipedia entities that have inlinks pointing to $\hat{e}_i$. Denoting S_t' as the union of $\{\mathcal{N}(\hat{e}_i)|\hat{e}_i \in S_t\}$, we define a similar weighted coherence score between $e_{t+1}^j \in \mathcal{E}_{t+1}$ and S_t' as

$$\Phi'(e_{t+1}^j, S_t') = \sum_{\hat{e}_i \in S_t'} a'(\hat{e}_i) \cdot {e_{t+1}^j}^\top \cdot R' \cdot \hat{e}_i, \quad (4)$$

where a' is defined similarly to a, and R' is a learnable diagonal matrix. The final representation $\vec{h}_0(m_{t+1}, e_{t+1}^j)$ is the concatenation of $\Phi(e_{t+1}^j, S_t)$, $\Phi'(e_{t+1}^j, S_t')$, $\Psi_T(m_t, e_{t+1}^j)$, $\Psi_C(m_t, e_{t+1}^j)$ and $\log \hat{P}(e_{t+1}^j|m_{t+1})$.

4 Model Learning for DCA

In this section, we explore different learning strategies for the linking model. Specifically, we present a Supervised Learning model, where the model is given all gold entities for training, and a Reinforcement Learning model, where the model explores possible linking results by itself in a long-term planning task.

4.1 Supervised Ranking Method

Given a mention-candidate pair (m_t, e_t^j), the ranking model parameterized by θ accepts the feature

vector $\vec{h_0}(m_t, e_t^j)$ as input, and outputs the probability $P_\theta(e_t^j|m_t)$. In this work, we use a two-layer feedforward neural network as the ranking model. We apply the max-margin loss as

$$\mathcal{L}_\theta = \sum_{D\in\mathcal{D}} \sum_{m_t\in D} \sum_{e_t^j\in\mathcal{E}_t} g_\theta(e_t^j, m_t),$$

$$g_\theta(e_t^j, m_t) = \max(0, \gamma - P_\theta(e_t^*|m_t) + P_\theta(e_t^j|m_t)).$$

The learning process is to estimate the optimal parameter such that $\theta^* = \arg\min_\theta \mathcal{L}_\theta$.

Note that, in the Supervised Ranking model, dynamic contexts are provided by previous gold entities: $S_t = \{e_1^*, ..., e_t^*\}$, $S'_t = \bigcup_{i=1}^{t} \mathcal{N}(e_i^*)$. In the testing phase, however, we do not have access to gold entities. Wrongly linked entities can introduce noisy contexts to future linking steps. To consider such long-term influences, we introduce an alternative Reinforcement Learning model in the next section.

4.2 Reinforcement Learning Method

Naturally, the usage of dynamic context augmentation forms a sequential decision problem, as each linking step depends on previous linking decisions. Correct linking results provide valuable information for future decisions, while previous mistakes can lead to error accumulation. Reinforcement Learning (RL) algorithms have proven to be able to alleviate such accumulated noises in the decision sequence in many recent works (Narasimhan et al., 2016; Feng et al., 2018). In this work, we propose an RL ranking model for DCA-enhanced entity linking.

Agent: The Agent is a candidate ranking model that has a similar architecture to (Clark and Manning, 2016), aiming to output the action preference $H_\theta(S_{t-1}, S'_{t-1}, A_t^j)$ of each linking action $A_t^j = (m_t \rightarrow e_t^j)$. It is a 2-layer feedforward neural network with following components:

Input Layer: For each (m_t, e_t^j) pair, DCA-RL extracts context-dependent features from S_{t-1}, S'_{t-1}, and concatenates them with other context-independent features to produce an I-dimensional input vector $\vec{h_0}(m_t, e_t^j)$.

Hidden Layers: Let $Drop(\vec{x})$ be the dropout operation (Srivastava et al., 2014) and $ReLU(\vec{x})$ be the rectifier nonlinearity (Nair and Hinton, 2010). So the output $\vec{h}_1$ of the hidden layer is defined as:

$$\vec{h}_1 = Drop(ReLU(\vec{W}_1 \cdot \vec{h}_0 + \vec{b}_1)), \quad (5)$$

where $\vec{W}_1$ is a $H_1 \times I$ weight matrix.

Output Layers: This scoring layer is also fully connected layer of size 1.

$$\vec{h}_2 = \vec{W}_2 \cdot \vec{h}_1 + \vec{b}_2, \quad (6)$$

where $\vec{W}_2$ is a $1 \times H_1$ weight matrix. In the end, all action preference would be normalized together using an exponential softmax distribution, getting their action probabilities $\pi_\theta(A_t^j|S_{t-1}, S'_{t-1})$:

According to policy approximating methods, the best approximate policy may be stochastic. So we randomly sample the actions based on the softmax distribution during the training time, whereas deliberately select the actions with the highest ranking score at the test time.

Reward. The reward signals are quite sparse in our framework. For each trajectory, the Agent can only receive a reward signal after it finishes all the linking actions in a given document. Therefore the immediate reward of action t, $R_t = 0$, where $0 \leq t < T$, and $R_T = -(|\mathbb{M}_e|/T)$, where T is total number of mentions in the source document, and $|\mathbb{M}_e|$ is the number of incorrectly linked mentions. Then the value G_t (expected reward) of each previous state S_t can be retraced back with a discount factor ρ according to R_T:

$$G_t = \rho^{T-t} R_T \quad (7)$$

To maximize the expected reward of all trajectories, the Agent utilizes the REINFORCE algorithm (Sutton and Barto, 1998) to compute Monte Carlo policy gradient over all trajectories, and perform gradient ascent on its parameters:

$$\theta \leftarrow \theta + \alpha \sum_t G_t \nabla_\theta \ln \pi_\theta(A_t^j|S_{t-1}, S'_{t-1}) \quad (8)$$

In following sections, to fully investigate the effectiveness of the proposed method, we report and compare the performances of both the Supervised-learning model and the Reinforcement-learning model.

5 Analysis of Computational Complexity

For each document D, the train and inference of the global EL models are heavily relied on the inter-entity coherence graph Φ_g. Many studies (Ratinov et al., 2011; Globerson et al., 2016; Yamada et al., 2016; Ganea and Hofmann, 2017; Le and Titov, 2018) obtain Φ_g by calculating all

Dataset	# mention	# doc	Mentions per doc	Gold recall
AIDA-train	18448	946	19.5	-
AIDA-A	4791	216	22.1	97.3
AIDA-B	4485	231	19.4	98.3
MSNBC	656	20	32.8	98.5
AQUAINT	727	50	14.5	94.2
ACE2004	257	36	7.1	90.6
CWEB	11154	320	34.8	91.1
WIKI	6821	320	21.3	92.4

Table 1: **Dataset Statistics.** *Gold recall* is the percentage of mentions for which the candidate entities contain the ground truth entity.

pairwise scores between two arbitrary elements ${e_i}^x$ and ${e_j}^y$ sampled independently from candidate sets $\mathcal{E}_i$ and $\mathcal{E}_j$ in the given document. It is obvious that Φ is intractable, and the computational complexity of Φ_g is

$$\mathcal{O}(\Phi_g) = \mathcal{O}(\sum_{i=1}^{T} \sum_{j=1, j\neq i}^{T} \sum_{{e_i}^x \in \mathcal{E}_i}^{|\mathcal{E}_i|} \sum_{{e_j}^y \in \mathcal{E}_j}^{|\mathcal{E}_j|} \Phi({e_i}^x, {e_j}^y)) \tag{9}$$

, where $\Phi({e_i}^x, {e_j}^y)$ is a learnable score function. Thus, $\mathcal{O}(\Phi_g)$ is approximate to $\mathcal{O}(T^2 \times |\mathcal{E}|^2 \times \mathcal{I})$, where $|\mathcal{E}|$ is the average number of candidates per mention and $\mathcal{I}$ is the unit cost of pairwise function Φ. In order to reduce $\mathcal{O}(\Phi_g)$, most previous models (Hoffart et al., 2011; Ganea and Hofmann, 2017; Le and Titov, 2018; Fang et al., 2019) have to hard prune their candidates into an extremely small size (e.g. $|\mathcal{E}|$=5). This will reduce the gold recall of candidate sets and also unsuitable for large scale production (e.g. entity disambiguation for dynamic web data like Twitter).

In contrast, the computational complexity of our model is $\mathcal{O}(T \times |\mathcal{E}| \times \mathcal{I} \times K)$, where K is the key hyper-parameter described in Section 3 and is usually set to a small number. This indicates the response time of our method grow linearly as a function of $T \times |\mathcal{E}|$.

6 Experiment

6.1 Experiment Setup

Datasets. Following our predecessors, we train and test all models on the public and widely used AIDA CoNLL-YAGO dataset (Hoffart et al., 2011). The target knowledge base is Wikipedia. The corpus consists of 946 documents for training, 216 documents for development and 231 documents for testing (AIDA-train/A/B respectively).

System	In-KB acc. (%)
AIDA-light (Nguyen et al., 2014)	84.8

ETHZ-Attn + DCA-SL	**94.64** $\pm$ 0.2
ETHZ-Attn + DCA-RL	93.73 $\pm$ 0.2

Table 2: **In-domain Performance Comparison on the AIDA-B Dataset.** For our method we show 95% confidence intervals obtained over 5 runs. DCA-based models achieve the best reported scores on this benchmark.

To evaluate the generalization ability of each model, we apply cross-domain experiments following the same setting in (Ganea and Hofmann, 2017; Le and Titov, 2018; Yang et al., 2018). Models are trained on AIDA-train, and evaluated on five popular public datasets: AQUAINT (Milne and Witten, 2008), MSNBC (Cucerzan, 2007), ACE2004 (Ratinov et al., 2011), CWEB (Guo and Barbosa, 2016) and WIKI (Guo and Barbosa, 2016). The statistics of these datasets are available in Table 1. In the candidate generation step, we directly use the candidates provided by the Ment-Norm system (Le and Titov, 2018)[2], and their quality is also listed in Table 1.

Compared Methods. We compare our methods with following existing systems that report state-of-the-art results on the test datasets: **AIDA-light** (Nguyen et al., 2014) uses a kind of two-stage collective mapping algorithm and designs several domain or category related coherence features. **WNED** (Guo and Barbosa, 2016) applies random walks on carefully built disambiguation graphs and uses a greedy, iterative and global disambiguation algorithm based on Information Theory. **Global-RNN** (Nguyen et al., 2016) develops a framework based on convolutional neural networks and recurrent neural networks to simultaneously model the local and global features. **MulFocal-Att** (Globerson et al., 2016) adopts a coherence model with a multi-focal attention mechanism. **Deep-ED** (Ganea and Hofmann, 2017) leverages learned neural representa-

Table 3: **Performance Comparison on Cross-domain Datasets using F1 score (%)**. The best results are in bold. Note that our own results all retain two decimal places. Other results with uncertain amount of decimal places are directly retrieved from their original paper.

tions, and uses a deep learning model combined with a neural attention mechanism and graphical models. **Ment-Norm** (Le and Titov, 2018) improving the **Deep-ED** model by modeling latent relations between mentions.

For a fair comparison with prior work, we use the same input as the **WNED**, **Deep-ED** and **Ment-Norm** (models proposed after 2016), and report the performance of our model with both Supervised Learning (**DCA-SL**) and Reinforcement Learning (**DCA-RL**). We won't compare our models with the **RLEL** (Fang et al., 2019) which is a deep reinforcement learning based LSTM model. There are two reasons: 1) **RLEL** uses optimized candidate sets with smaller candidate size and higher gold recall than ours and the listed baselines. 2) **RLEL** uses additional training set from Wikipedia data. (Fang et al., 2019) doesn't release either their candidate sets or updated training corpus, so the comparison with their work would be unfair for us.

Hyper-parameter Setting. We coarsely tune the hyper-parameters according to model performance on AIDA-A. We set the dimensions of word embedding and entity embedding to 300, where the word embedding and entity embedding are publicly released by (Pennington et al., 2014) and (Ganea and Hofmann, 2017) respectively. Hyper-parameters of the best validated model are: $K = 7$, $I = 5$, $H_1 = 100$, and the probability of dropout is set to 0.2. Besides, the rank margin $\gamma = 0.01$ and the discount factor $\rho = 0.9$. We also regularize the *Agent* model as adopted in (Ganea and Hofmann, 2017) by constraining the sum of squares of all weights in the linear layer with $MaxNorm = 4$. When training the model, we use Adam (Kingma and Ba, 2014) with learning rate of 2e-4 until validation accuracy exceeds 92.8%, afterwards setting it to 5e-5.

System	In-KB acc. (%)	
	SL	RL
ETHZ-Attn (Section 2.2)	90.88	-
ETHZ-Attn + 1-hop DCA	93.69	93.20
ETHZ-Attn + 2-hop DCA	94.47	93.76

Table 4: **Ablation Study on Neighbor Entities.** We compare the performance of DCA with or without neighbor entities (i.e., 2-hop vs. 1-hop).

6.2 Overall Performance Comparison

Starting with an overview of the end-task performance, we compare DCA (using SL or RL) with several state-of-the-art systems on in-domain and cross-domain datasets. We follow prior work and report in-KB accuracy for AIDA-B and micro F1 scores for the other test sets.

Table 2 summarizes results on the AIDA-B dataset, and shows that DCA-based models achieve the highest in-KB accuracy and outperforms the previous state-of-the-art neural system by near 1.6% absolute accuracy. Moreover, compared with the base models, dynamic context augmentation significantly improve absolute in-KB accuracy in models Berkeley-CNN (more than

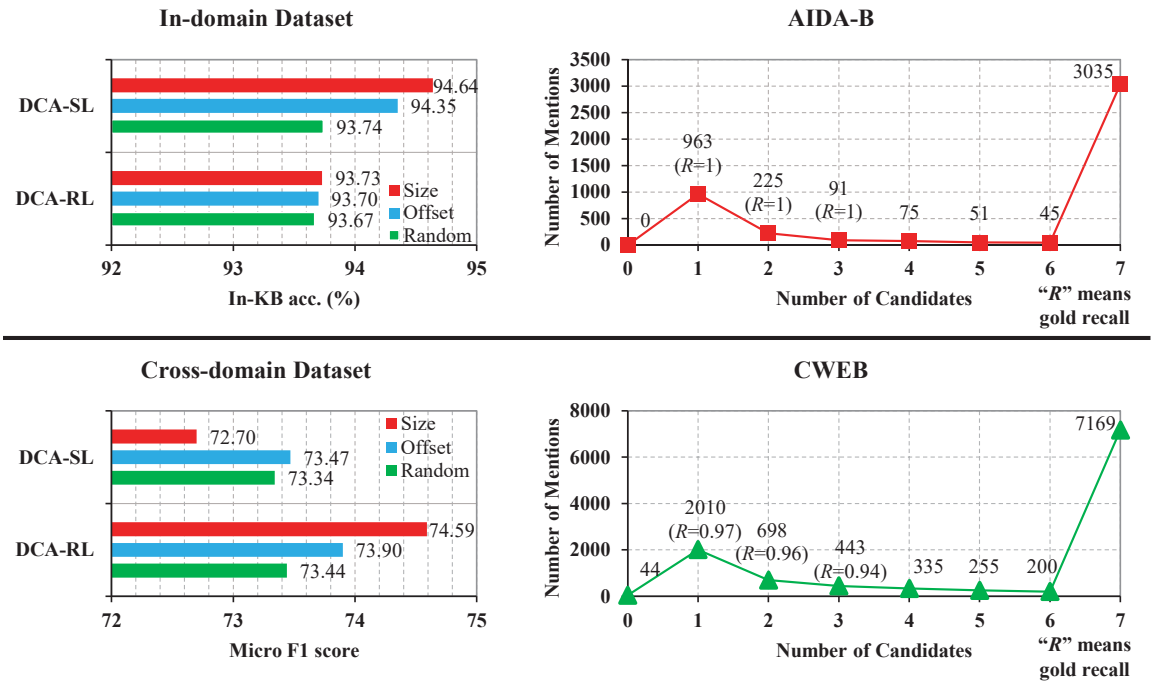

Figure 3: **Ablation Study on Different Decision Orders.** We test on both in-domain (AIDA-B) and cross-domain (CWEB) datasets, using ETHZ-Attn as the local model.

8%) and ETHZ-Attn (3.3% on average). Note that, our DCA model outperforms existing global models with the same local model (**Global-RNN** uses Berkeley-CNN as base model, **Deep-ED** and **Ment-Norm** use ETHZ-Attn as the local model).

Table 3 shows the results on the five cross-domain datasets. As shown, none of existing methods can consistently win on all datasets. DCA-based models achieve state-of-the-art performance on the MSBNC and the ACE2004 dataset. On remaining datasets, DCA-RL achieves comparable performance with other complex global models. In addition, RL-based models show on average 1.1% improvement on F1 score over the SL-based models across all the cross-domain datasets. At the same time, DCA-based methods are much more efficient, both in time complexity and in resource requirement. Detailed efficiency analysis will be presented in following sections.

6.3 Performance Analysis

1. Impact of decision order. As the DCA model consecutively links and adds all the mentions in a document, the linking order may play a key role in the final performance. In this work, we try three different linking orders: *Offset* links all mentions by their natural orders in the original document;

System	In-KB acc. (%)	
	SL	RL
DCA + Average Sum	94.05	93.56
DCA + Soft Attention	94.23	93.69
DCA + Soft&Hard Attention	94.47	93.76

Table 5: **Study on Different Attention Mechanisms on the Dynamic Context.** Results (using ETHZ-Attn as local model) show that different attention mechanisms have similar impact on the performance.

Size first links mentions with smaller candidate sizes, as they tend to be easier to link; The baseline method is to link all mentions in a *Random* order. Figure 3 shows the performance comparison on the AIDA-B and the CWEB dataset. As shown, in general, *Size* usually leads to better performance than *Offset* and *Random*. However, the DCA-SL model shows poor performance on the CWEB dataset with *Size* order. This is mainly because the CWEB dataset is automatically generated rather than curated by human, and thus contains many noisy mentions. Some mentions in CWEB with less than three candidates are actually bad cases , where none of the candidates is the actual gold entity. Thus, such mentions will always introduce wrong information to the model, which leads to a worse performance. In contrast, the AIDA-B dataset does not have such situations.

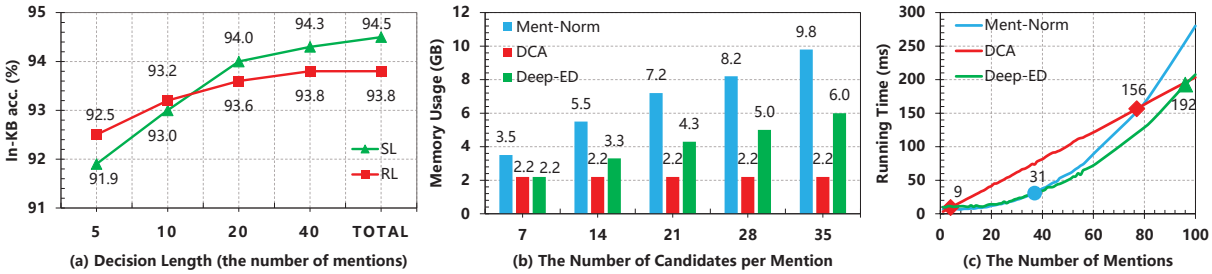

Figure 4: (a) **In-KB accuracy** as a function of decision length on AIDA-B dataset; (b) **Memory usage** as a function of the number of candidates on AIDA-B dataset; (c) **Runtime cost** (at inference time) as a function of the number of mentions. (each dot represents a document of AIDA-B with $|\mathcal{E}| = 35$).

The DCA-RL model, however, still has strong performance on the CWEB dataset, which highlights its robustness to potential noises.

2. Effect of neighbor entities. In contrast to traditional global models, we include both previously linked entities and their close neighbors for global signal. Table 4 shows the effectiveness of this strategy. We observe that incorporating these neighbor entities (2-hop) significantly improve the performance (compared to 1-hop) by introducing more related information. And our analysis shows that on average 0.72% and 3.56% relative improvement of 2-hop DCA-(SL/RL) over 1-hop DCA-(SL/RL) or baseline-SL (without DCA) is statistically significant (with P-value $<$ 0.005). This is consistent with our design of DCA.

3. Study of different attention mechanisms. Table 5 shows the performance comparison by replacing the attention module described in Section 3 with different variants. *Average Sum* treats all previously linked entities equally with a uniform distribution. *Soft Attention* skips the pruning step for entities with low weight scores. *Soft&Hard Attention* stands for the strategy used in our model. It is obvious that the attention mechanism does show positive influence on the linking performance compared with *Average Sum*. Hard pruning brings slight further improvement.

4. Impact of decision length. As wrongly linked entities can introduce noise to the model, there exists a trade-off in DCA: involving more previous entities (longer historical trajectory) provides more information, and also more noise. Figure (4.a) shows how the performance of DCA changes with the number of previous entities involved. We observe that longer historical trajectories usually have a positive influence on the performance of DCA. The reason is that our attention mechanism could effectively assess and select relevant contexts for each entity mention on the fly, thus reducing potential noise.

6.4 Analysis on Time Complexity

As discussed in Sec. 5, the running time of a DCA enhanced model may rise linearly when the average number of candidates per mention (i.e., $|\mathcal{E}|$) increases, while the global EL model increases exponentially. To validate the theory we empirically investigate the scalability of DCA, and carefully select two global EL models Ment-Norm (Le and Titov, 2018) and Deep-ED (Ganea and Hofmann, 2017) as our baselines. The reason for this choice is that our final model shares the same local model as their models, which excludes other confounding factors like implementation details. As Figure (4.c) shows, when $|\mathcal{E}|$ increases, the running time of these two global EL models increases shapely, while our DCA model grows linearly. On the other hand, we also observed that the resources required by the DCA model are insensitive to $|\mathcal{E}|$. For example, as shown in Figure (4.b), the memory usage of Ment-Norm and Deep-ED significantly rises as more candidates are considered, while the DCA model remains a relatively low memory usage all the time. We also measure the power consumption of Ment-Norm and DCA models, and we find that the DCA model saves up to 80% of the energy consumption over the Ment-Norm, which is another advantage for large scale production.

7 Related Work

Local EL methods disambiguate each mention independently according to their local contexts (Yamada et al., 2016; Chen et al., 2017; Globerson et al., 2016; Raiman and Raiman, 2018). The per-

formance is limited when sparse local contexts fail to provide sufficient disambiguation evidence.

To alleviate this problem, global EL models jointly optimize the entire linking configuration. The key idea is to maximize a global coherence/similarity score between all linked entities (Hoffart et al., 2011; Ratinov et al., 2011; Cheng and Roth, 2013; Nguyen et al., 2014; Alhelbawy and Gaizauskas, 2014; Pershina et al., 2015; Guo and Barbosa, 2016; Globerson et al., 2016; Ganea and Hofmann, 2017; Le and Titov, 2018; Yang et al., 2018; Fang et al., 2019; Xue et al., 2019). Despite of its significant improvement in accuracy, such global methods suffer from high complexity. To this end, some works try to relax the assumption of all-mention coherence, e.g. with pairwise coherence, to improve efficiency (Phan et al., 2018), but exact inference remains an NP-hard problem. Approximation methods are hence proposed to achieve reasonably good results with less cost. (Shen et al., 2012) propose the iterative substitution method to greedily substitute linking assignment of one mention at a time that can improve the global objective. Another common practice is to use Loopy Belief Propagation for inference (Ganea and Hofmann, 2017; Le and Titov, 2018). Both approximation methods iteratively improve the global assignment, but are still computationally expensive with unbounded number of iterations. In contrast, the proposed DCA method only requires one pass through the document. Global signals are accumulated as dynamic contexts for local decisions, which significantly reduces computational complexity and memory consumption.

8 Conclusions

In this paper we propose Dynamic Context Augmentation as a plug-and-enhance module for local Entity Linking models. In contrast to existing global EL models, DCA only requires one pass through the document. To incorporate global disambiguation signals, DCA accumulates knowledge from previously linked entities for fast inference. Extensive experiments on several public benchmarks with different learning settings, base models, decision orders and attention mechanisms demonstrate both the effectiveness and efficiency of DCA-based models. The scalability of DCA-based models make it possible to handle large-scale data with long documents. Related code and data has been published and may hopefully benefit the community.

Abstract

To extract the structured representations of open-domain events, Bayesian graphical models have made some progress. However, these approaches typically assume that all words in a document are generated from a single event. While this may be true for short text such as tweets, such an assumption does not generally hold for long text such as news articles. Moreover, Bayesian graphical models often rely on Gibbs sampling for parameter inference which may take long time to converge. To address these limitations, we propose an event extraction model based on Generative Adversarial Nets, called Adversarial-neural Event Model (AEM). AEM models an event with a Dirichlet prior and uses a generator network to capture the patterns underlying latent events. A discriminator is used to distinguish documents reconstructed from the latent events and the original documents. A byproduct of the discriminator is that the features generated by the learned discriminator network allow the visualization of the extracted events. Our model has been evaluated on two Twitter datasets and a news article dataset. Experimental results show that our model outperforms the baseline approaches on all the datasets, with more significant improvements observed on the news article dataset where an increase of 15% is observed in F-measure.

1 Introduction

With the increasing popularity of the Internet, online texts provided by social media platform (e.g. Twitter) and news media sites (e.g. Google news) have become important sources of real-world events. Therefore, it is crucial to automatically extract events from online texts.

Due to the high variety of events discussed online and the difficulty in obtaining annotated data for training, traditional template-based or supervised learning approaches for event extraction are no longer applicable in dealing with online texts. Nevertheless, newsworthy events are often discussed by many tweets or online news articles. Therefore, the same event could be mentioned by a high volume of redundant tweets or news articles. This property inspires the research community to devise clustering-based models (Popescu et al., 2011; Abdelhaq et al., 2013; Xia et al., 2015) to discover new or previously unidentified events without extracting structured representations.

To extract structured representations of events such as *who* did *what*, *when*, *where* and *why*, Bayesian approaches have made some progress. Assuming that each document is assigned to a single event, which is modeled as a joint distribution over the named entities, the date and the location of the event, and the event-related keywords, Zhou *et al.* (2014) proposed an unsupervised Latent Event Model (LEM) for open-domain event extraction. To address the limitation that LEM requires the number of events to be pre-set, Zhou *et al.* (2017) further proposed the Dirichlet Process Event Mixture Model (DPEMM) in which the number of events can be learned automatically from data. However, both LEM and DPEMM have two limitations: (1) they assume that all words in a document are generated from a single event which can be represented by a quadruple <entity, location, keyword, date>. However, long texts such news articles often describe multiple events which clearly violates this assumption; (2) During the inference process of both approaches, the Gibbs sampler needs to compute the conditional posterior distribution and assigns an event for each document. This is time consuming and takes long time to converge.

To deal with these limitations, in this paper, we propose the Adversarial-neural Event Model

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 282–291, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

(AEM) based on adversarial training for open-domain event extraction. The principle idea is to use a generator network to learn the projection function between the document-event distribution and four event related word distributions (entity distribution, location distribution, keyword distribution and date distribution). Instead of providing an analytic approximation, AEM uses a discriminator network to discriminate between the reconstructed documents from latent events and the original input documents. This essentially helps the generator to construct a more realistic document from a random noise drawn from a Dirichlet distribution. Due to the flexibility of neural networks, the generator is capable of learning complicated nonlinear distributions. And the supervision signal provided by the discriminator will help generator to capture the event-related patterns. Furthermore, the discriminator also provides low-dimensional discriminative features which can be used to visualize documents and events.

The main contributions of the paper are summarized below:

- We propose a novel Adversarial-neural Event Model (AEM), which is, to the best of our knowledge, the first attempt of using adversarial training for open-domain event extraction.
- Unlike existing Bayesian graphical modeling approaches, AEM is able to extract events from different text sources (short and long). And a significant improvement on computational efficiency is also observed.
- Experimental results on three datasets show that AEM outperforms the baselines in terms of accuracy, recall and F-measure. In addition, the results show the strength of AEM in visualizing events.

2 Related Work

Our work is related to two lines of research, event extraction and Generative Adversarial Nets.

Event Extraction

Recently there has been much interest in event extraction from online texts, and approaches could be categorized as domain-specific and open-domain event extraction.

Domain-specific event extraction often focuses on the specific types of events (e.g. sports events or city events). Panem *et al.* (2014) devised a novel algorithm to extract attribute-value pairs and mapped them to manually generated schemes for extracting the natural disaster events. Similarly, to extract the city-traffic related event, Anantharam *et al.* (2015) viewed the task as a sequential tagging problem and proposed an approach based on the conditional random fields. Zhang (2018) proposed an event extraction approach based on imitation learning, especially on inverse reinforcement learning.

Open-domain event extraction aims to extract events without limiting the specific types of events. To analyze individual messages and induce a canonical value for each event, Benson *et al.* (2011) proposed an approach based on a structured graphical model. By representing an event with a binary tuple which is constituted by a named entity and a date, Ritter *et al.* (2012) employed some statistic to measure the strength of associations between a named entity and a date. The proposed system relies on a supervised labeler trained on annotated data. In (Abdelhaq et al., 2013), Abdelhaq *et al.* developed a real-time event extraction system called EvenTweet, and each event is represented as a triple constituted by time, location and keywords. To extract more information, Wang *el al.* (2015) developed a system employing the links in tweets and combing tweets with linked articles to identify events. Xia *el al.* (2015) combined texts with the location information to detect the events with low spatial and temporal deviations. Zhou *et al.* (2014; 2017) represented event as a quadruple and proposed two Bayesian models to extract events from tweets.

Generative Adversarial Nets

As a neural-based generative model, Generative Adversarial Nets (Goodfellow et al., 2014) have been extensively researched in natural language processing (NLP) community.

For text generation, the sequence generative adversarial network (SeqGAN) proposed in (Yu et al., 2017) incorporated a policy gradient strategy to optimize the generation process. Based on the policy gradient, Lin *et al.* (2017) proposed RankGAN to capture the rich structures of language by ranking and analyzing a collection of human-written and machine-written sentences. To overcome mode collapse when dealing with discrete data, Fedus *et al.* (2018) pro-

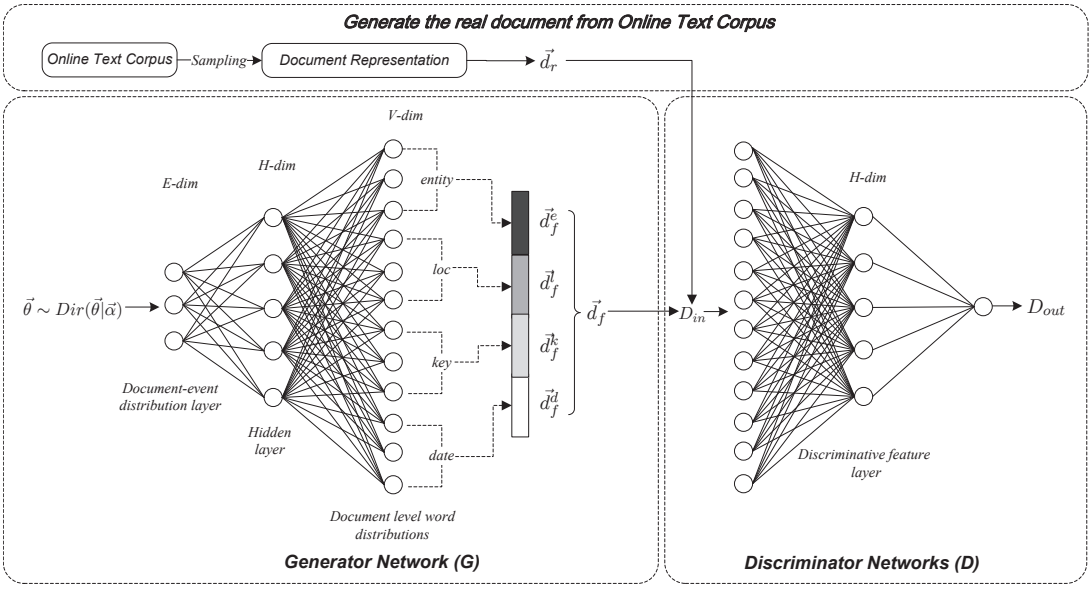

Figure 1: The framework of the Adverarial-neural Event Model (AEM), and $\vec{d}_f^e$, $\vec{d}_f^l$, $\vec{d}_f^k$ and $\vec{d}_f^d$ denote the generated entity distribution, location distribution, keyword distribution and date distribution corresponding to event distribution $\vec{\theta}$.

posed MaskGAN which used an actor-critic conditional GAN to fill in missing text conditioned on the surrounding context. Along this line, Wang *et al.* (2018) proposed SentiGAN to generate texts of different sentiment labels. Besides, Li et al. (2018) improved the performance of semi-supervised text classification using adversarial training, (Zeng et al., 2018; Qin et al., 2018) designed GAN-based models for distance supervision relation extraction.

Although various GAN based approaches have been explored for many applications, none of these approaches tackles open-domain event extraction from online texts. We propose a novel GAN-based event extraction model called AEM. Compared with the previous models, AEM has the following differences: (1) Unlike most GAN-based text generation approaches, a generator network is employed in AEM to learn the projection function between an event distribution and the event-related word distributions (entity, location, keyword, date). The learned generator captures event-related patterns rather than generating text sequence; (2) Different from LEM and DPEMM, AEM uses a generator network to capture the event-related patterns and is able to mine events from different text sources (short and long). Moreover, unlike traditional inference procedure, such as Gibbs sampling used in LEM and DPEMM, AEM could extract the events more efficiently due to the CUDA acceleration; (3) The discriminative features learned by the discriminator of AEM provide a straightforward way to visualize the extracted events.

3 Methodology

We describe Adversarial-neural Event Model (AEM) in this section. An event is represented as a quadruple $<e, l, k, d>$, where e stands for non-location named entities, l for a location, k for event-related keywords, d for a date, and each component in the tuple is represented by component-specific representative words.

AEM is constituted by three components: (1) *The document representation module*, as shown at the top of Figure 1, defines a document representation approach which converts an input document from the online text corpus into $\vec{d}_r \in \mathbb{R}^V$ which captures the key event elements; (2) *The generator* G, as shown in the lower-left part of Figure1, generates a fake document $\vec{d}_f$ which is constituted by four multinomial distributions using an event distribution $\vec{\theta}$ drawn from a Dirichlet distribution as input; (3) *The discriminator* D, as shown in the lower-right part of Figure1, distinguishes the real documents from the fake ones and its output is subsequently employed as a learning signal to update the G and D. The details of each component are presented below.

3.1 Document Representation

Each document doc in a given corpus C is represented as a concatenation of 4 multinomial distributions which are entity distribution ($\vec{d}_r^e$), location distribution ($\vec{d}_r^l$), keyword distribution ($\vec{d}_r^k$) and date distribution ($\vec{d}_r^d$) of the document. As four distributions are calculated in a similar way, we only describe the computation of the entity distribution below as an example.

The entity distribution $\vec{d}_r^e$ is represented by a normalized V_e-dimensional vector weighted by TF-IDF, and it is calculated as:

$$tf^e_{i,doc} = \frac{n^e_{i,doc}}{\sum_{v_e} n^e_{v_e,doc}}$$
$$idf^e_i = \log \frac{|C^e|}{|C^e_i|}$$
$$tf\text{-}idf^e_{i,doc} = tf^e_{i,doc} \times idf^e_i$$
$$d^e_{r,i} = \frac{tf\text{-}idf^e_{i,doc}}{\sum_{v_e} tf\text{-}idf^e_{v_e,doc}}$$

where C^e is the pseudo corpus constructed by removing all non-entity words from C, V_e is the total number of distinct entities in a corpus, $n^e_{i,doc}$ denotes the number of i-th entity appeared in document doc, $|C^e|$ represents the number of documents in the corpus, and $|C^e_i|$ is the number of documents that contain i-th entity, and the obtained $d^e_{r,i}$ denotes the relevance between i-th entity and document doc.

Similarly, location distribution $\vec{d}_r^l$, keyword distribution $\vec{d}_r^k$ and date distribution $\vec{d}_r^d$ of doc could be calculated in the same way, and the dimensions of these distributions are denoted as V_l, V_k and V_d, respectively. Finally, each document doc in the corpus is represented by a V-dimensional (V=V_e+V_l+V_k+V_d) vector $\vec{d}_r$ by concatenating four computed distributions.

3.2 Network Architecture

3.2.1 Generator

The generator network G is designed to learn the projection function between the document-event distribution $\vec{\theta}$ and the four document-level word distributions (entity distribution, location distribution, keyword distribution and date distribution).

More concretely, G consists of a E-dimensional document-event distribution layer, H-dimensional hidden layer and V-dimensional event-related word distribution layer. Here, E denotes the event number, H is the number of units in the hidden layer, V is the vocabulary size and equals to V_e+V_l+V_k+V_d. As shown in Figure 1, G firstly employs a random document-event distribution $\vec{\theta}$ as an input. To model the multinomial property of the document-event distribution, $\vec{\theta}$ is drawn from a Dirichlet distribution parameterized with $\vec{\alpha}$ which is formulated as:

$$p(\vec{\theta}|\vec{\alpha}) = Dir(\vec{\theta}|\vec{\alpha}) \triangleq \frac{1}{\triangle(\vec{\alpha})} \prod_{t=1}^{E} \theta_t^{\alpha_t - 1} \quad (1)$$

where $\vec{\alpha}$ is the hyper-parameter of the dirichlet distribution, E is the number of events which should be set in AEM, $\triangle(\vec{\alpha}) = \frac{\prod_{t=1}^{E}\Gamma(\alpha_t)}{\Gamma(\sum_{t=1}^{E}\alpha_t)}$, $\theta_t \in [0,1]$ represents the proportion of event t in the document and $\sum_{t=1}^{E}\theta_t = 1$.

Subsequently, G transforms $\vec{\theta}$ into a H-dimensional hidden space using a linear layer followed by layer normalization, and the transformation is defined as:

$$\vec{s}_h = LN(W_h\vec{\theta} + \vec{b}_h) \quad (2)$$
$$\vec{o}_h = \max(\vec{s}_h, l_p \times \vec{s}_h) \quad (3)$$

where $W_h \in \mathbb{R}^{H\times E}$ represents the weight matrix of hidden layer, and $\vec{b}_h$ denotes the bias term, l_p is the parameter of LeakyReLU activation and is set to 0.1, $\vec{s}_h$ and $\vec{o}_h$ denote the normalized hidden states and the outputs of the hidden layer, and LN represents the layer normalization.

Then, to project $\vec{o}_h$ into four document-level event related word distributions ($\vec{d}_f^e$, $\vec{d}_f^l$, $\vec{d}_f^k$ and $\vec{d}_f^d$ shown in Figure 1), four subnets (each contains a linear layer, a batch normalization layer and a softmax layer) are employed in G. And the exact transformation is based on the formulas below:

$$\vec{h}^e_w = W^e_w\vec{o}_h + \vec{b}^e_w,\ \vec{d}^e_f = SM(BN(\vec{h}^e_w)) \quad (4)$$
$$\vec{h}^l_w = W^l_w\vec{o}_h + \vec{b}^l_w,\ \vec{d}^l_f = SM(BN(\vec{h}^l_w)) \quad (5)$$
$$\vec{h}^k_w = W^k_w\vec{o}_h + \vec{b}^k_w,\ \vec{d}^k_f = SM(BN(\vec{h}^k_w)) \quad (6)$$
$$\vec{h}^d_w = W^d_w\vec{o}_h + \vec{b}^d_w,\ \vec{d}^d_f = SM(BN(\vec{h}^d_w)) \quad (7)$$

where SM means softmax layer, $W^e_w \in \mathbb{R}^{V_e\times H}$, $W^l_w \in \mathbb{R}^{V_l\times H}$, $W^k_w \in \mathbb{R}^{V_k\times H}$ and $W^d_w \in \mathbb{R}^{V_d\times H}$ denote the weight matrices of the linear layers in subnets, $\vec{b}^e_w$, $\vec{b}^l_w$, $\vec{b}^k_w$ and $\vec{b}^d_w$ represent the corresponding bias terms, $\vec{h}^e_w$, $\vec{h}^l_w$, $\vec{h}^k_w$ and $\vec{h}^d_w$ are state vectors. $\vec{d}^e_f$, $\vec{d}^l_f$, $\vec{d}^k_f$ and $\vec{d}^d_f$ denote the generated entity distribution, location distribution, keyword

distribution and date distribution, respectively, that correspond to the given event distribution $\vec{\theta}$. And each dimension represents the relevance between corresponding entity/location/keyword/date term and the input event distribution.

Finally, four generated distributions are concatenated to represent the generated document $\vec{d}_f$ corresponding to the input $\vec{\theta}$:

$$\vec{d}_f = [\vec{d}_f^e; \vec{d}_f^l; \vec{d}_f^k; \vec{d}_f^d] \tag{8}$$

3.2.2 Discriminator

The discriminator network D is designed as a fully-connected network which contains an input layer, a discriminative feature layer (discriminative features are employed for event visualization) and an output layer. In AEM, D uses fake document $\vec{d}_f$ and real document $\vec{d}_r$ as input and outputs the signal D_{out} to indicate the source of the input data (lower value denotes that D is prone to predict the input data as a fake document and vice versa).

As have previously been discussed in (Arjovsky et al., 2017; Gulrajani et al., 2017), lipschitz continuity of D network is crucial to the training of the GAN-based approaches. To ensure the lipschitz continuity of D, we employ the spectral normalization technique (Miyato et al., 2018). More concretely, for each linear layer $l_d(\vec{h}) = W\vec{h}$ (bias term is omitted for simplicity) in D, the weight matrix W is normalized by $\sigma(W)$. Here, $\sigma(W)$ is the spectral norm of the weight matrix W with the definition below:

$$\sigma(W) := \max_{\vec{h}:\vec{h}\neq\vec{0}} \frac{\|W\vec{h}\|_2}{\|\vec{h}\|_2} = \max_{\|\vec{h}\|_2\leq 1} \|W\vec{h}\|_2 \tag{9}$$

which is equivalent to the largest singular value of W. The weight matrix W is then normalized using:

$$\hat{W_{SN}} := W/\sigma(W) \tag{10}$$

Obviously, the normalized weight matrix $\hat{W_{SN}}$ satisfies that $\sigma(\hat{W_{SN}}) = 1$ and further ensures the lipschitz continuity of the D network (Miyato et al., 2018). To reduce the high cost of computing spectral norm $\sigma(W)$ using singular value decomposition at each iteration, we follow (Yoshida and Miyato, 2017) and employ the power iteration method to estimate $\sigma(W)$ instead. With this substitution, the spectral norm can be estimated with very small additional computational time.

3.3 Objective and Training Procedure

The real document $\vec{d}_r$ and fake document $\vec{d}_f$ shown in Figure 1 could be viewed as random samples from two distributions $\mathbb{P}_r$ and $\mathbb{P}_g$, and each of them is a joint distribution constituted by four Dirichlet distributions (corresponding to entity distribution, location distribution, keyword distribution and date distribution). The training objective of AEM is to let the distribution $\mathbb{P}_g$ (produced by G network) to approximate the real data distribution $\mathbb{P}_r$ as much as possible.

To compare the different GAN losses, Kurach (2018) takes a sober view of the current state of GAN and suggests that the Jansen-Shannon divergence used in (Goodfellow et al., 2014) performs more stable than variant objectives. Besides, Kurach also advocates that the gradient penalty (GP) regularization devised in (Gulrajani et al., 2017) will further improve the stability of the model. Thus, the objective function of the proposed AEM is defined as:

$$L_d = -\mathop{\mathbb{E}}_{\vec{d}_r\sim\mathbb{P}_r}[\log(D(\vec{d}_r))] - \mathop{\mathbb{E}}_{\vec{d}_f\sim\mathbb{P}_g}[\log(1-D(\vec{d}_f))] \tag{11}$$

$$L_{gp} = \mathop{\mathbb{E}}_{\vec{d^*}\sim\mathbb{P}_{d^*}}[(\| \nabla_{\vec{d^*}} D(\vec{d^*}) \|_2 - 1)^2] \tag{12}$$

$$L = L_d + \lambda L_{gp} \tag{13}$$

where L_d denotes the discriminator loss, L_{gp} represents the gradient penalty regularization loss, λ is the gradient penalty coefficient which trade-off the two components of objective, $\vec{d^*}$ could be obtained by sampling uniformly along a straight line between $\vec{d}_r$ and $\vec{d}_f$, $\mathbb{P}_{d^*}$ denotes the corresponding distribution.

The training procedure of AEM is presented in Algorithm 1, where E is the event number, n_d denotes the number of discriminator iterations per generator iteration, m is the batch size, α' represents the learning rate, β_1 and β_2 are hyperparameters of Adam (Kingma and Ba, 2014), p_a denotes $\{\alpha', \beta_1, \beta_2\}$. In this paper, we set $\lambda = 10$, $n_d = 5$, $m = 32$. Moreover, α', β_1 and β_2 are set as 0.0002, 0.5 and 0.999.

3.4 Event Generation

After the model training, the generator G learns the mapping function between the document-event distribution and the document-level event-related word distributions (entity, location, keyword and date). In other words, with an event distribution

Algorithm 1 Training procedure for AEM

    $\omega_d \leftarrow Adam(\nabla_{\omega_d} \frac{1}{m} \sum_{j=1}^{m} L^{(j)}, \omega_d, p_a)$
  end for
  Sample m noise $\left\{\vec{\theta}'^{(j)} \sim Dir(\vec{\theta}|\vec{\alpha})\right\}$
  $\omega_g \leftarrow Adam(\nabla_{\omega_g} \frac{1}{m} \sum_{j=1}^{m} \log[1 - D(G(\vec{\theta}'^{(j)}))], \omega_g, p_a)$
end while

$\vec{\theta}'$ as input, G could generate the corresponding entity distribution, location distribution, keyword distribution and date distribution.

In AEM, we employ event seed $\vec{s}_{t\in\{1,...,E\}}$, an E-dimensional vector with one-hot encoding, to generate the event related word distributions. For example, in ten event setting, $\vec{s}_1 = [1, 0, 0, 0, 0, 0, 0, 0, 0, 0]^\intercal$ represents the event seed of the first event. With the event seed $\vec{s}_1$ as input, the corresponding distributions could be generated by G based on the equation below:

$$[\vec{\phi}_e^1; \vec{\phi}_l^1; \vec{\phi}_k^1; \vec{\phi}_d^1] = G(\vec{s}_1) \tag{14}$$

where $\vec{\phi}_e^1$, $\vec{\phi}_l^1$, $\vec{\phi}_k^1$ and $\vec{\phi}_d^1$ denote the entity distribution, location distribution, keyword distribution and date distribution of the first event respectively.

4 Experiments

In this section, we firstly describe the datasets and baseline approaches used in our experiments and then present the experimental results.

4.1 Experimental Setup

To validate the effectiveness of AEM for extracting events from social media (e.g. Twitter) and news media sites (e.g. Google news), three datasets (FSD (Petrovic et al., 2013), Twitter, and Google datasets[1]) are employed. Details are summarized below:

- *FSD dataset* (social media) is the first story detection dataset containing 2,499 tweets. We filter out events mentioned in less than 15 tweets since events mentioned in very few tweets are less likely to be significant. The final dataset contains 2,453 tweets annotated with 20 events.

- *Twitter dataset* (social media) is collected from tweets published in the month of December in 2010 using Twitter streaming API. It contains 1,000 tweets annotated with 20 events.

- *Google dataset* (news article) is a subset of GDELT Event Database[1], documents are retrieved by event related words. For example, documents which contain 'malaysia', 'airline', 'search' and 'plane' are retrieved for event *MH370*. By combining 30 events related documents, the dataset contains 11,909 news articles.

We choose the following three models as the baselines:

- **K-means** is a well known data clustering algorithm, we implement the algorithm using sklearn[2] toolbox, and represent documents using bag-of-words weighted by TF-IDF.

- **LEM** (Zhou et al., 2014) is a Bayesian modeling approach for open-domain event extraction. It treats an event as a latent variable and models the generation of an event as a joint distribution of its individual event elements. We implement the algorithm

[1] http://data.gdeltproject.org/events/index.html
[2] https://scikit-learn.org/

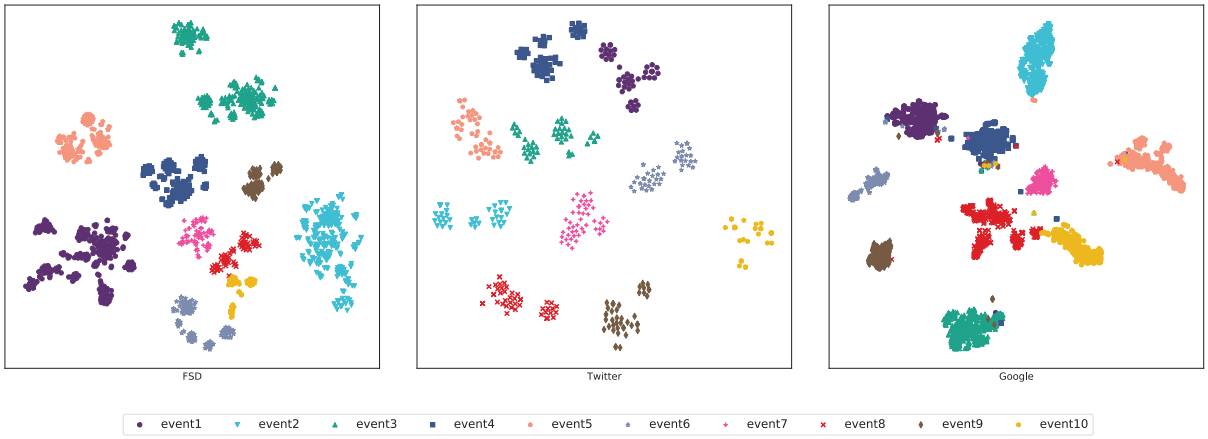

Figure 2: Visualization of the ten randomly selected events on each dataset. Each point denotes a document. Different color denotes different events.

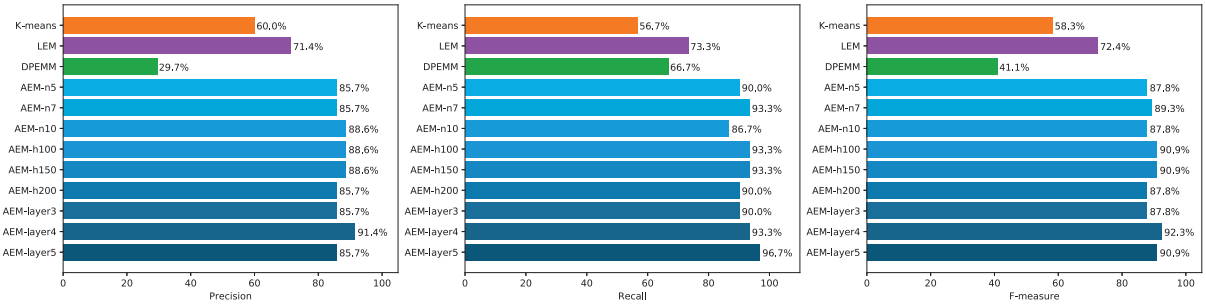

Figure 3: Comparison of methods and parameter settings,'n' and 'h' denote parameter n_d and H, other parameters follow the default setting. The vertical axis represents methods/parameter settings, the horizontal axis denotes the corresponding performance value. All blue histograms with different intensity are those obtained by AEM.

with the default configuration.

- **DPEMM** (Zhou et al., 2017) is a non-parametric mixture model for event extraction. It addresses the limitation of LEM that the number of events should be known beforehand. We implement the model with the default configuration.

For social media text corpus (FSD and Twitter), a named entity tagger[3] specifically built for Twitter is used to extract named entities including locations from tweets. A Twitter Part-of-Speech (POS) tagger (Gimpel et al., 2010) is used for POS tagging and only words tagged with nouns, verbs and adjectives are retained as keywords. For the Google dataset, we use the Stanford Named Entity Recognizer[4] to identify the named entities (organization, location and person). Due to the 'date' information not being provided in the Google dataset, we further divide the non-location named entities into two categories ('person' and 'organization') and employ a quadruple <organization, location, person, keyword> to denote an event in news articles. We also remove common stopwords and only keep the recognized named entities and the tokens which are verbs, nouns or adjectives.

4.2 Experimental Results

To evaluate the performance of the proposed approach, we use the evaluation metrics such as precision, recall and F-measure. Precision is defined as the proportion of the correctly identified events out of the model generated events. Recall is defined as the proportion of correctly identified true events. For calculating the precision of the 4-tuple, we use following criteria:

- (1) Do the entity/organization, location, date/person and keyword that we have extracted refer to the same event?
- (2) If the extracted representation contains

[3]http://fithub.com/aritter/twitter-nlp
[4]https://nlp.stanford.edu/software/CRF-NER.html

keywords, are they informative enough to tell us what happened?

Dataset	Method	Precision (%)	Recall (%)	F-measure (%)
FSD	K-means	84.0	55.0	66.5
	LEM	80.0	80.0	80.0
	DPEMM	84.6	85.0	84.8
	AEM	**88.0**	**85.0**	**86.5**
Twitter	K-means	68.0	75.0	71.3
	LEM	68.0	80.0	73.5
	DPEMM	69.2	80.0	74.2
	AEM	**72.0**	**85.0**	**77.9**
Google	K-Means	60.0	56.7	58.3
	LEM	71.4	73.3	72.4
	DPEMM	29.7	66.7	41.3
	AEM	**85.7**	**90.0**	**87.8**

Table 1: Comparison of the performance of event extraction on the three datasets.

Table 1 shows the event extraction results on the three datasets. The statistics are obtained with the default parameter setting that n_d is set to 5, number of hidden units H is set to 200, and G contains three fully-connected layers. The event number E for three datasets are set to 25, 25 and 35, respectively. The examples of extracted events are shown in Table.2.

It can be observed that K-means performs the worst over all three datasets. On the social media datasets, AEM outpoerforms both LEM and DPEMM by 6.5% and 1.7% respectively in F-measure on the FSD dataset, and 4.4% and 3.7% in F-measure on the Twitter dataset. We can also observe that apart from K-means, all the approaches perform worse on the Twitter dataset compared to FSD, possibly due to the limited size of the Twitter dataset. Moreover, on the Google dataset, the proposed AEM performs significantly better than LEM and DPEMM. It improves upon LEM by 15.5% and upon DPEMM by more than 30% in F-measure. This is because: (1) the assumption made by LEM and DPEMM that all words in a document are generated from a single event is not suitable for long text such as news articles; (2) DPEMM generates too many irrelevant events which leads to a very low precision score. Overall, we see the superior performance of AEM across all datasets, with more significant improvement on the for Google datasets (long text).

We next visualize the detected events based on the discriminative features learned by the trained D network in AEM. The t-SNE (Maaten and Hinton, 2008) visualization results on the datasets are shown in Figure 2. For clarity, each subplot is plotted on a subset of the dataset containing ten randomly selected events. It can be observed that documents describing the same event have been grouped into the same cluster.

To further evaluate if a variation of the parameters n_d (the number of discriminator iterations per generator iteration), H (the number of units in hidden layer) and the structure of generator G will impact the extraction performance, additional experiments have been conducted on the Google dataset, with n_d set to 5, 7 and 10, H set to 100, 150 and 200, and three G structures (3, 4 and 5 layers). The comparison results on precision, recall and F-measure are shown in Figure 3. From the results, it could be observed that AEM with the 5-layer generator performs the best and achieves 96.7% in F-measure, and the worst F-measure obtained by AEM is 85.7%. Overall, the AEM outperforms all compared approaches acorss various parameter settings, showing relatively stable performance.

Finally, we compare in Figure 4 the training time required for each model, excluding the constant time required by each model to load the data. We could observe that K-means runs fastest among all four approaches. Both LEM and DPEMM need to sample the event allocation for each document and update the relevant counts during Gibbs sampling which are time consuming. AEM only requires a fraction of the training time compared to LEM and DPEMM. Moreover, on a larger dataset such as the Google dataset, AEM appears to be far more efficient compared to LEM and DPEMM.

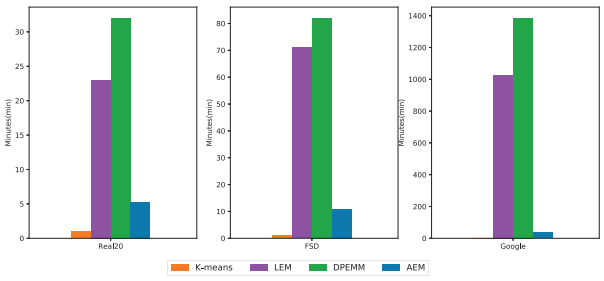

Figure 4: Comparison of training time of models.

5 Conclusions and Future Work

In this paper, we have proposed a novel approach based on adversarial training to extract the structured representation of events from online text. The experimental comparison with the state-of-the-art methods shows that AEM achieves improved extraction performance, especially on

Table 2: The event examples extracted by AEM.

long text corpora with an improvement of 15% observed in F-measure. AEM only requires a fraction of training time compared to existing Bayesian graphical modeling approaches. In future work, we will explore incorporating external knowledge (e.g. word relatedness contained in word embeddings) into the learning framework for event extraction. Besides, exploring nonparametric neural event extraction approaches and detecting the evolution of events over time from news articles are other promising future directions.

Abstract

Bootstrapping for Entity Set Expansion (ESE) aims at iteratively acquiring new instances of a specific target category. Traditional bootstrapping methods often suffer from two problems: 1) *delayed feedback*, i.e., the pattern evaluation relies on both its direct extraction quality and the extraction quality in later iterations. 2) *sparse supervision*, i.e., only few seed entities are used as the supervision. To address the above two problems, we propose a novel bootstrapping method combining the Monte Carlo Tree Search (MCTS) algorithm with a deep similarity network, which can efficiently estimate delayed feedback for pattern evaluation and adaptively score entities given sparse supervision signals. Experimental results confirm the effectiveness of the proposed method.

1 Introduction

Bootstrapping is widely used for Entity Set Expansion (ESE), which acquires new instances of a specific category by iteratively evaluating and selecting patterns, while extracting and scoring entities. For example, given seeds {*London, Paris, Beijing*} for capital entity expansion, a bootstrapping system for ESE iteratively selects effective patterns, e.g., "*the US Embassy in* *", and extracts new capital entities, e.g., *Moscow*, using the selected patterns.

The main challenges of effective bootstrapping for ESE owe to the *delayed feedback* and the *sparse supervision*. Firstly, bootstrapping is an iterative process, where noises brought by currently selected patterns can affect successive iterations (Movshovitz-Attias and Cohen, 2012; Qadir et al., 2015). Indeed, the pattern evaluation relies on not only its direct extraction quality but also the extraction quality in later iterations, which are correspondingly denoted as *instant feedback* and *delayed feedback* in this paper. For instance, as shown in Figure 1, although "* *is a big city*" and "*the US Embassy in* *" have equal direct extraction quality, the former is considered less useful since its later extracted entities are mostly unrelated. As a result, selecting patterns with high instant feedback but low delayed feedback can cause semantic drift problem (Curran et al., 2007), where the later extracted entities belong to other categories. Secondly, the above difficulty is further compounded by sparse supervision, i.e., using only seed entities as supervision, since it provides little evidence for deciding whether an extracted entity belongs to the same category of seed entities or not.

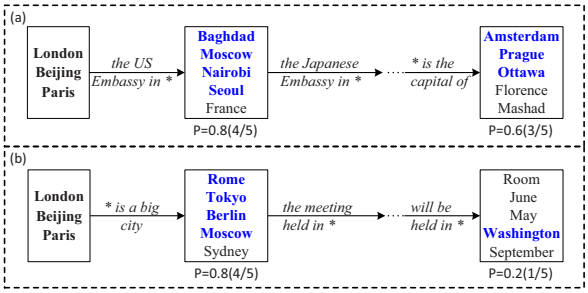

Figure 1: Example of the delayed feedback problem, which expands the capital seeds {*London, Paris, Beijing*}. We demonstrate the top entities extracted by a pattern (correct ones are shown in blue), where P is the precision of extracted entities.

To address the above two challenges, we propose a novel bootstrapping method combining the Monte Carlo Tree Search (MCTS) algorithm with a deep similarity network, aiming to effectively evaluate the delayed feedback of patterns and adaptively score entities given sparse supervision signals. Specifically, our method tackles the delayed feedback problem by enhancing the traditional bootstrapping method using the MCTS algorithm, which effectively estimates each pattern's delayed feedback via efficient multi-step lookahead search. In this way, our method can select the pattern based on its delayed feedback

rather than instant feedback, which is beneficial in that the former feedback is regarded more reliable and accurate for bootstrapping. To resolve the sparse supervision problem, we propose a deep similarity network—pattern mover similarity network (PMSN), which uniformly embeds entities and patterns using the distribution vectors on context pattern embeddings, and measures their semantic similarity to seeds as their ranking scores based on those embeddings; furthermore, we combine the PMSN with the MCTS, and fine-tune the distribution vectors using the estimated delayed feedback. In this way, our method can adaptively embed and score entities.

Major contributions of this paper are tri-fold.

- Enhanced bootstrapping via the MCTS algorithm to estimate delayed feedback in bootstrapping. To our best knowledge, this is the first work to combine bootstrapping with MCTS for entity set expansion.
- A novel deep similarity network to evaluate different categories of entities in the bootstrapping for Entity Set Expansion.
- Adaptive entity scoring by combining the deep similarity network with MCTS.

2 Background

Traditional bootstrapping systems for ESE are usually provided with sparse supervision, i.e., only a few seed entities, and iteratively extract new entities from corpus by performing the following steps, as demonstrated in Figure 2(a).

Pattern generation. Given seed entities and the extracted entities (known entities), a bootstrapping system for ESE firstly generates patterns from the corpus. In this paper, we use lexicon-syntactic surface words around known entities as patterns.

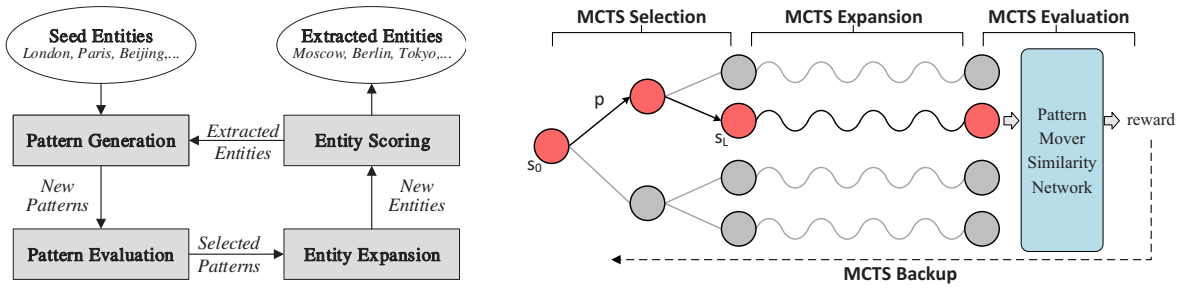
Pattern evaluation. This step evaluates generated patterns using sparse supervision and other sources of evidence, e.g., pattern embedding similarity. Many previous studies (Riloff and Jones, 1999; Curran et al., 2007; Gupta and Manning, 2014) use the RlogF function or its variants to evaluate patterns, which usually estimate the instant feedback of each pattern.

Entity expansion. This step selects top patterns to match new candidate entities from the corpus.

Entity scoring. This step scores candidate entities using sparse supervision, bootstrapping or other external sources of evidence. The top scored entities are then added to the extracted entity set.

As aforementioned, traditional bootstrapping systems for ESE do not consider the delayed feedback when evaluating patterns, leaving considerable potential in further improvement. To estimate the delayed feedback of a pattern, a simple solution is to perform lookahead search for a fixed number of steps and estimate the quality of its successive extracted entities. However, lookahead search may suffer from efficiency issue brought by the enormous search space since there are many candidate patterns at each step. Besides, due to the sparse supervision problem, entity scoring is often unreliable, which in turn influences the delayed feedback estimation.

To address the above two problems, this paper enhances the bootstrapping system using the Monte Carlo Tree Search (MCTS) algorithm for lookahead search, combined with a pattern mover similarity network (PMSN) for better entity scoring. Specifically, we use MCTS for the efficient lookahead search by pruning bad patterns. We additionally estimate the delayed feedback using the PMSN to score entities, given the sparse supervision signals, and fine-tune the PMSN using the delayed feedback estimated by MCTS. In this way, both the MCTS algorithm and the PMSN are devised to enhance each other, resulting in efficient delayed feedback estimation for pattern evaluation and reliable entity scoring.



3 Enhancing Bootstrapping via Monte Carlo Tree Search

In this section, we describe how to enhance the traditional bootstrapping for ESE using the MCTS algorithm for efficient delayed feedback estimation.

3.1 Efficient Delayed Feedback Estimation via MCTS

To estimate the delayed feedback, this paper uses the Monte Carlo Tree Search (MCTS) algorithm for efficient lookahead search.

At each bootstrapping iteration, the MCTS algorithm performs multiple lookahead search procedures (MCTS simulations). Starting from the same root node, each MCTS simulation performs forward search by iteratively constructing sub-nodes, and moving to one of these sub-nodes. Therefore, the whole MCTS algorithm looks like a tree structure (see Figure 2(b)), where the node s represents for known entities, i.e., both seed entities and previously extracted entities, and the edge,

(a) Traditional bootstrapping system for Entity set expansion. The main difference between our method and traditional methods is that we enhance the **pattern evaluation** by the MCTS algorithm, as demonstrated in Figure (b).

(b) The Monte Carlo Tree Search for the pattern evaluation in a bootstrapping system for entity set expansion. The red circles refer to the search node (i.e., seed entities plus extracted entities). A unidirectional edge represents the selection of a pattern to match new entities, which results in a new node.

Figure 2: Traditional Bootstrapping for ESE (a) and the enhanced pattern evaluation using MCTS (b).

linking from a node s to one of its sub-nodes s', represents for selecting a pattern p to expand s. At the very beginning, the root tree node s_0 is constructed using seed entities and the extracted entities from previous iterations, and is fixed among different simulations. Besides, for each (s, p) pair, we store a cumulative reward $Q(s, p)$ and a visit count $N(s, p)$ during tree search for the subsequent reward function defined in Section 3.3.

Specifically, each MCTS simulation contains four stages, as demonstrated in Figure 2(b):

Selection. Starting from s_0, each simulation first traverses the MCTS search tree until reaching the leaf node s_L (which is never reached before) or reaching a fixed depth. Each traversing step i corresponding to selecting a pattern p^i by:

$$p^i = \arg\max_p Q(s, p) + \mu(s, p) \tag{1}$$

where $\mu(s, p) \propto \frac{p_\sigma(s,p)}{1+N(s,p)}$, $p_\sigma(s, p)$ is the prior probability of p returned by the policy network p_σ, which is described in detail in Section 3.2.

Among an MCTS simulation, the lookahead search space is reduced mainly in this stage. Specifically, according to e.q. (1), the lookahead search is more likely to select the potential patterns with high cumulative rewards or high prior probabilities, rather than all patterns.

Expansion. When the traversal reaches a leaf node s_L, we expand this node by selecting a new pattern to match more entities. Due to the lack of the cumulative rewards on the new patterns, we select the new pattern with the highest prior probability returned by p_σ.

Evaluation. Once finishing the above expansion stage or the simulation procedure reaches a fixed depth, the reward R for the leaf node is returned by first quickly selecting multiple patterns to expand the leaf node and then evaluating the quality of all newly extracted entities in this simulation. We herein use the RlogF function to quickly select patterns rather than the policy network (Running RlogF function is much faster than the policy network). And the reward function is described in Section 3.3 in detail.

Backup. At this stage, the returned reward is used to update the cumulative rewards and visit counts of previous (s, p) pairs by:

$$\begin{aligned} N(s, p) &= \sum_j^n \mathbf{1}(s, p, j) \\ Q(s, p) &= \frac{1}{N(s, p)} \sum_{j=1}^n \mathbf{1}(s, p, j) \cdot R \end{aligned} \tag{2}$$

where $\mathbf{1}(s, p, j)$ indicates whether an edge (s, p) was traversed during the j^{th} simulation.

After finishing all MCTS simulations, we use the cumulative reward of each (s_0, p) pair as the delayed feedback for pattern p. Because the cumulative rewards are updated many times using the quality evaluation of their future extracted entities, the cumulative reward of each (s_0, p) pair can be regarded as the precise approximation of the delayed feedback if we have a proper reward function. As a result, our method selects the top patterns with the highest cumulative rewards, which are more likely to extract correct entities.

3.2 Prior Policy using Pattern Mover Similarity Network

The prior policy network is mainly used to prune bad patterns and therefore reduce the search space in the MCTS. Intuitively, if a pattern is not similar

to other patterns around some entities, it is likely a general pattern or noisy pattern to these entities, and therefore should be pruned.

To this end, this paper proposes a novel deep similarity network, namely Pattern Mover Similarity Network (PMSN), which uniformly embeds patterns, entities and entity sets, and estimates their embedding similarities. We describe this model in detail in Section 4.

Particularly, for a pattern p linked from a tree node s, the PMSN is used as the prior policy network to compute the prior probability by:

$$p_\sigma(s,p) = \frac{\text{SIM}(p,E)}{\sum_{p'} \text{SIM}(p',E)} \tag{3}$$

where E is the set of known entities included in node s, and $\text{SIM}(p,E)$ is the similarity of the pattern p to the entity set E using the PMSN.

To further reduce the search space (note that the number of patterns at each step can be tens of thousands), we use the RlogF function to retain only the top k for lookahead search. In the experiments, we set k to a reasonably large value, i.e., 200, to balance between efficiency and effectiveness.

3.3 Reward Function in MCTS

The reward function is critical for efficiently estimating the real delayed feedback of each pattern. Intuitively, a pattern should have higher delayed feedback if it extracts more similar entities and less unrelated entities. Base on this intuition, we devise the reward function as follows:

$$R = \frac{\sum_{e \in E'} \text{SIM}(e,E_0)}{|E'|} \sigma(\frac{|E'|}{a}) \tag{4}$$

where E_0 is the set of known entities in root node, E' is the set of new entities, $\text{SIM}(e,E)$ is the similarity score of newly extracted entity e to known entities, $\sigma(\cdot)$ is the sigmoid function, and a is a "temperature" hyperparameter. The above reward function can be regarded as a trade-off between the extraction quality (the first term) and the extraction amount (the second term). To compute the similarity score, we also exploit the PMSN.

4 Pattern Mover Similarity Network

The pattern mover similarity network (PMSN) is a unified model for adaptively scoring the similarity of entities or patterns to seed entities. Specifically, the pattern mover similarity network contains two components: 1) the adaptive distributional pattern embeddings (ADPE) that adaptively represent patterns, entities, and entity sets in a unified way; 2) the pattern mover similarity (PMS) measurement that estimates the similarity of two ADPEs.

The PMSN model is mainly used in three aspects as follows. 1) The PMSN is used as the prior policy network in the MCTS algorithm to evaluate the similarity of patterns. 2) The PMSN is used to evaluate the newly extracted entities within the MCTS simulation, whose evaluation scores are subsequently used to update rewards. 3) The PMSN is also used as the entity scoring function at the Entity Scoring stage in the bootstrapping process as mentioned in Section 2.

4.1 Adaptive Distributional Pattern Embeddings

In this section, we first describe how to embed patterns; then, we introduce how to obtain the basic distributional pattern embeddings for uniformly representing entities and patterns without adaptation; finally, we introduce the adaptation mechanism combined with the MCTS algorithm.

Pattern Embedding. As a basic step of our PMSN model, we first embed a context pattern of an entity as a single embedding vector. Specifically, we use the average word embeddings, from the pre-trained GloVe (Pennington et al., 2014) embeddings, of a pattern surface text as the pattern embeddings. We filter out patterns containing at least two OOV terms. According to our pilot experiments, replacing the average GloVe word embeddings with alternatives such as Convolutional Neural Network and Recurrent Neural Network does not influence performance.

Basic distributional pattern embeddings without adaptation. Based on the single embedding of each context pattern, this paper represents an entity using a distributional vector on its context pattern embeddings, called distributional pattern embeddings (DPE). The intuition behind is that each context pattern represents one aspect of meanings of an entity according to the distributional hypothesis in linguistics (Harris, 1954), while the importance of different patterns to the semantic of an entity varies from each other. Therefore, we use a distributional vector, which stores the importance score of different patterns, together with the context pattern embeddings to represent the semantic of an entity.

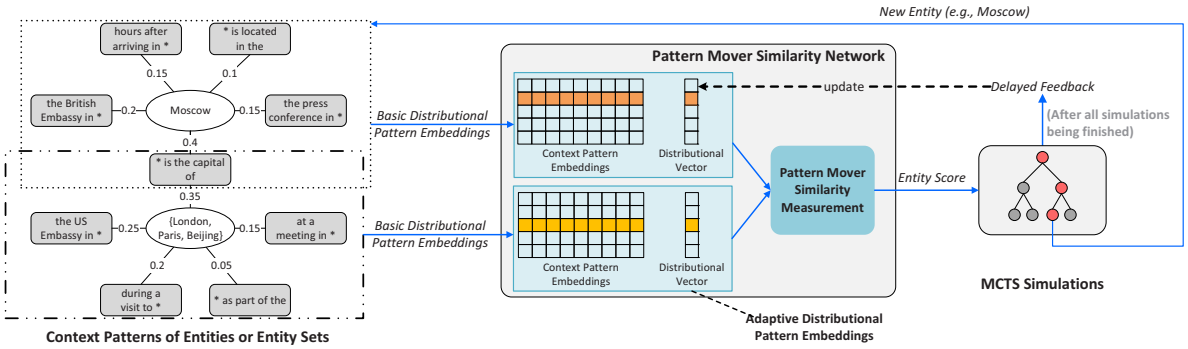


Figure 3: Overall architecture of the Pattern Mover Similarity Network (PMSN), as shown in the rounded square in the middle of the figure.

To estimate each pattern's importance score, we suggest that a context pattern is important to the semantic of an entity if: the pattern matches the entity frequently; the pattern matches as few other entities as possible. Therefore, we design a importance score function for each context pattern p of an entity e as follows:

$$w(p,e) = \frac{N(e,p) \times \log N(e,p)}{C(p)} \tag{5}$$

where $C(p)$ is the number of different entities matched by p, $N(e,p)$ is the frequency of p_i matching entity e. Ultimately, the above importance scores are mapped to the distributional probabilities of each entity's context pattern such that all probabilities sum up to 1.

In addition, we estimate the basic DPE for a single pattern and a whole entity set. Specifically, a single pattern can be regarded as a special "entity", whose context pattern is only the pattern itself. Similarly, as shown in Figure 3, an entity set can be regarded as another special "entity", whose context patterns are the union of all context patterns of entities in this set. Besides, the importance score function for context patterns of an entity set is slightly different from the one in e.q. (5):

$$w(p,E) = \frac{N(E,p) \times \log N(E,p)}{C(p)} \tag{6}$$

where E is the entity set, $N(E,p)$ is the frequency of p matching all entities in E.

Finally, we denote the DPE as $< X, w >$, where X is the context pattern embedding matrix, and w is the vector of distribution probabilities. For efficiency, we only select the top n important patterns. Therefore, X is actually an $n \times d$ matrix, where d is the dimension of each pattern embedding, and w is an n-dimensional vector.

Adaptive distributional pattern embeddings combined with MCTS. Although the basic DPE can provide unified representations for both patterns and entities, it could still fail to represent the underlying semantics of seed entities as unrelated patterns may match many other entities. To address this problem, we combine the MCTS algorithm with the PMSN, to fine-tune the distributional vector of the basic DPE, resulting in an Adaptive Distributional Pattern Embedding (ADPE). As shown in Figure 3, at each iteration, multiple MCTS simulations are performed to accumulate the long-term feedback of selecting a pattern, where the PMSN is used for entity scoring; after that, the delayed feedback can be efficiently calculated for each pattern. Apart from being used to evaluate the reward of selecting a pattern, the delayed feedback can also be used to estimate the importance score of a pattern, since patterns with the high delayed feedback can extract more correct entities and less incorrect entities in the future. Therefore, at each iteration, we fine-tune the distributional probabilities after the MCTS simulations as following:

$$w_t(p,e) \propto w_{t-1}(p,e) \cdot Q(s_0,p) \tag{7}$$

where $w_{t-1}(p,E)$ is the probability of p at iteration $t-1$, $Q(s_0,p)$ is returned cumulative reward of p_i in iteration t.

4.2 Pattern Mover Similarity

The similarity measurement for two ADPEs is important, since it is used for delayed feedback estimation and entity scoring. Intuitively, given two entities embedded by two ADPEs, they can be regarded similarly to each other, if they have similar context patterns and similar distributions on these patterns. Therefore, the similarity measurement should take both context pattern embeddings

and corresponding distributional vectors into consideration. Inspired by Kusner et al. (2015) on the sentence similarity measurement, we devise a similarity measurement for two ADPEs as follows:

$$\begin{aligned} \max_{T \geq 0} \quad & \sum_{i,j=1}^{n} T_{ij} \cdot \text{SIM}(i,j) \\ \text{s.t.} \quad & \sum_{j=1}^{n} T_{ij} = w_i, \quad \forall i \in 1,...,n \\ & \sum_{i=1}^{n} T_{ij} = w_j, \quad \forall j \in 1,...,n \end{aligned} \tag{8}$$

where $\text{SIM}(i,j)$ is the cosine similarity between the i-th pattern embedding of one entity and the j-th pattern embedding of the other entity. We denote the above measurement as the Pattern Mover Similarity (PMS) measurement.

5 Experiments

5.1 Experimental Settings

Category	Description	Category	Description
CAP	Capital name	**FAC**	Man-made structures
ELE	Chemical element	**ORG**	Organizations
FEM	Female first name	**GPE**	Geo-political entities
MALE	Male first name	**LOC**	Non-GPE locations
LAST	Last name	**DAT**	A date or period
TTL	Honorific title	**LANG**	Any named language
NORP	Nationality, Religion, Political		

Table 1: Target categories used on Google Web 1T.

Datasets. We conduct experiments on three public datasets: Google Web 1T (Brants and Franz, 2006), APR, and Wiki (Shen et al., 2017). 1) Google Web 1T contains a large scale of n-grams compiled from a one trillion words corpus. Following Shi et al. (2014), we use 5-grams as the entity context and filter out those 5-grams containing all stopwords or common words. We use 13 categories of entities (see Table 1) list in Shi et al. (2014) and compare our method with traditional bootstrapping methods for ESE on this corpus. 2) APR (2015 news from AP and Reuters) and Wiki (a subset of English Wikipedia) are two datasets published by Shen et al. (2017). Each of them contains about 1 million sentences. We use totally 12 categories of entities as listed in Shen et al. (2017) and compare the final entity scoring performance on both datasets.

Baselines. To evaluate the efficiency of the MCTS and the PMSN, we use several baselines:

1) POS: bootstrapping method which only uses positive seeds without any other constraint;

2) MEB(Curran et al., 2007): mutual exclusion bootstrapping method, which uses the category exclusion as the constraints of bootstrapping;

3) COB(Shi et al., 2014): a probabilistic bootstrapping method which uses both positive and negative seeds.

4) SetExpan(Shen et al., 2017): corpus-based entity set expansion method, which adaptively selects context features and unsupervisedly ensembles them to score entities.

Specifically, we compare baselines (1)-(3) and our method on Google Web 1T; we compare baseline (4) and our method on APR and Wiki [1].

Metrics. We use P@n (precision at top n), and the mean average precision (MAP) on Google Web 1T as in Shi et al. (2014). As for the APR and the Wiki , we use MAP@n (n=10,20,50) to evaluate entity scoring performance of our method. In our experiments, we manually select frequent entities as the seeds from these datasets; the correctness of all extracted entities is manually judged with external supporting resources, e.g., the entity list collected from Wikipedia[2].

5.2 Experimental Results

Comparison with three baseline methods on Google Web 1T. Table 2 shows the performance of different bootstrapping methods on Google Web 1T. We can see that our full model outperforms three baseline methods: comparing with POS, our method achieves 41% improvement in P@100, 35% improvement in P@200 and 45% improvement in MAP; comparing with MEB, our method achieves 24% improvement in P@100 and 18% improvement in P@200; comparing with COB, our method achieves 3% improvement in both P@100 and P@200 metrics, and 2% improvement in MAP. The above findings indicate that our method can extract more correct entities with higher ranking scores than the baselines.

Comparison with SetExpan on APR and Wiki. To further verify that our method can learn a better representation and adaptively score entities in ESE, we compare our method with the state-

[1]Due to scalability issue, we omit the result of SetExpan on Google Web 1T. On the two smaller datasets, results of the under-performing baselines (1-3) are also omitted for space reason. The incompetitive performance of those 3 baselines could be caused by the difficulty in deriving robust statistical features out of the sparse context patterns on the small ARP and Wiki datasets.

Table 4: The performance of our *full* method on different categories on Google Web 1T.

of-the-art entity set expansion method–SetExpan, which is a non-bootstrapping method on the APR and Wik (see Table 3). From Table 3, we can see that our method outperforms SetExpan on both datasets: on the APR, our method achieves 6% improvement in MAP@10 and 2% improvement in MAP@50 ; on the Wiki, our method can achieve 2% improvement in MAP@10 and 4% improvement in MAP@50. The above results further confirm that our method can improve the performance of bootstrapping for Entity Set Expansion.

5.3 Detailed Analysis

Comparison with the Ours^{-MCTS} method and the Ours^{-PMSN} method. From Table 2, we can also see that if we replace the Monte Carlo Tree Search by selecting top-n patterns, the performance decreases by 19% in P@100 and 17% in P@200; if we replace the PMSN with word embedding, the performance decreases by 34% in P@100 and 27% in P@200. The results show that both the PMSN and the MCTS algorithm are critical for our model's performance. Remarkably, the PMSN and the MCTS algorithms can enhance each other in that the PMSN can learn a better representation by combing with the MCTS algorithm, and the MCTS can in turn effectively estimate delayed feedback using the PMSN.

Performance of our full method on different categories of Google Web 1T. From Table 4, We can see that our method achieves high performance in most categories except for ELE, TTL and FAC entities. The lesser performance of our method on ELE entities is likely caused by the data sparseness — there are fewer than 150 elements of the ELE entities in total. The lower performance on TTL and FAC entities is likely due to the fact that the context patterns of TTL and FAC entities are similar to those of person and location names respectively, which makes them easily be regarded as special person names and location names respectively.

Influence of the number of context patterns. Figure 4 shows the performance of our full method under different context pattern numbers. It can be seen that the number of context patterns used to embed entity and entity set heavily influences the performance. Comparing with the settings using fewer context patterns (e.g., 10 and 20, 50), using more context patterns, i.e., 100, in the PMSN has superior performance since it can provide more context information to compare two entities. Besides, further adding context patterns in the PMSN causes the performance decrease for 3%, which is

likely due to the case that noises can be included when considering too many patterns.

Top patterns selected by different methods. To demonstrate the effectiveness of delayed feedback in our method, we illustrate the top 1 pattern in the first five iterations of three methods in Table 5. From Table 5, we can see that the top patterns by our *full* method are more related to seed entities than other two baselines. Besides, we can see that without the MCTS algorithm or the PMSN, most top patterns are less related and easily semantically drifted to other categories.

6 Related Work

Entity set expansion (ESE) is a weakly supervised task, which is often given seed entities as supervision and tries to expand new entities related to them. According to the used corpus, there are two types of ESE: limited corpus (Shi et al., 2014; Shen et al., 2017) and large open corpus, e.g. making use of a search engine for the web search (Wang and Cohen, 2007).

Weakly supervised methods for information extraction (IE) are often provided insufficient supervision signals, such as knowledge base facts as distant supervision (Mintz et al., 2009; Hoffmann et al., 2011; Zeng et al., 2015; Han and Sun, 2016), and light amount of supervision samples in bootstrapping(Riloff and Jones, 1999). As a classical technique, bootstrapping usually exploits pattern (Curran et al., 2007), document (Liao and Grishman, 2010) or syntactic and semantic contextual features (He and Grishman, 2015) to extract and classify new instances.

Limited to the sparse supervision, previous work estimate patterns mainly based on its direct extraction features, e.g., the matching statistics with known entities (Riloff and Jones, 1999; Agichtein and Gravano, 2000), which often suffers from the semantic drift problem. To avoid semantic drift, most existing approaches exploit extra constraints, such as parallel multiple categories (Thelen and Riloff, 2002; Yangarber, 2003; McIntosh, 2010), coupling constraints (Carlson et al., 2010), and mutual exclusion bootstrapping (Curran et al., 2007; McIntosh and Curran, 2008). Besides, graph-based methods (Li et al., 2011; Tao et al., 2015) and the probability-based method (Shi et al., 2014) are also used to improve the bootstrapping performance.

To address the *sparse supervision* problem, many previous studies score entities by leveraging lexical and statistical features (Yangarber et al., 2000; Stevenson and Greenwood, 2005; Pantel and Pennacchiotti, 2006; Paşca, 2007; Pantel et al., 2009), which, despite the promising effectiveness, could often fail since the sparse statistical features provide little semantic information to evaluate entities. Recently word embedding based methods (Batista et al., 2015; Gupta and Manning, 2015) use fixed word embedding learned on external resources and evaluate entities by their similarity to seeds. Recently, Berger et al. (2018) propose to learn custom embeddings at each bootstrapping iteration, to trade efficiency for effectiveness.

7 Conclusions

In this paper, we propose a deep similarity network-based model combined with the MCTS algorithm to bootstrap Entity Set Expansion. Specifically, we leverage the Monte Carlo Tree Search (MCTS) algorithm to efficiently estimate the delayed feedback of each pattern in the bootstrapping; we propose a Pattern Mover Similarity Network (PMSN) to uniformly embed entities

and patterns using a distribution on context pattern embeddings; we combine the MCTS and the PMSN to adaptively learn a better embedding for evaluating both patterns and entities. Experimental results confirm the superior performance of our PMSN combined with the MCTS algorithm.

Abstract

Condition is essential in scientific statement. Without the conditions (e.g., equipment, environment) that were precisely specified, facts (e.g., observations) in the statements may no longer be valid. Existing ScienceIE methods, which aim at extracting factual tuples from scientific text, do not consider the conditions. In this work, we propose a new sequence labeling framework (as well as a new tag schema) to jointly extract the fact and condition tuples from statement sentences. The framework has (1) a multi-output module to generate one or multiple tuples and (2) a multi-input module to feed in multiple types of signals as sequences. It improves F1 score relatively by 4.2% on BioNLP2013 and by 6.2% on a new bio-text dataset for tuple extraction.

1 Introduction

Conditions such as environment and equipment provide validation supports for facts, while the facts focus on scientific observation and hypothesis in scientific literature (Miller, 1947). Existing ScienceIE methods, which extract (subject, relational phrase, object)-tuples from scientific text, do not distinguish the roles of fact and condition. Simply adding a tuple classification module has two weak points: (1) one tuple may have different roles in different sentences; (2) the tuples in one sentence have high dependencies with each other, for example, given a statement sentence in a biochemistry paper (Tomilin et al., 2016):

"*We observed that ... alkaline pH increases the activity of TRPV5/V6 channels in Jurkat T cells.*"

an existing system (Stanovsky et al., 2018) would return one tuple as below:

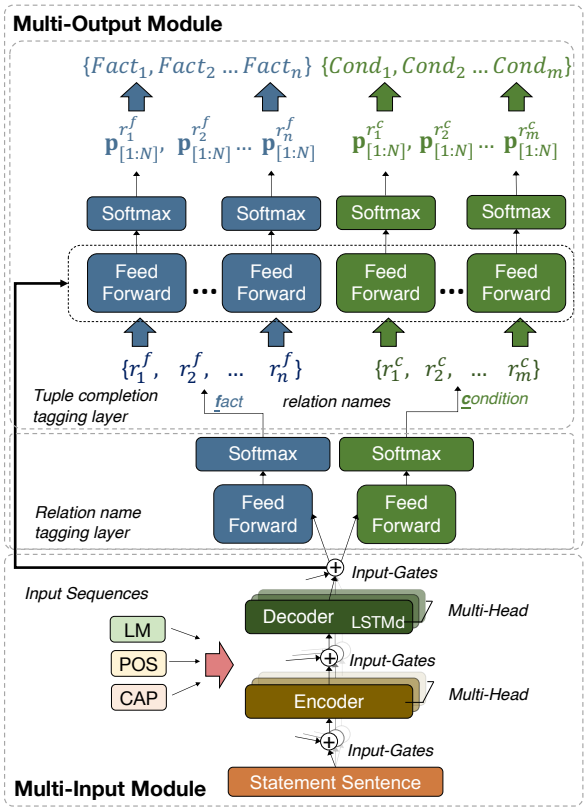

Figure 1: Our framework has two modules: (1) a multi-input module (bottom) based on a multi-head encoder-decoder model with multi-input gates; (2) a multi-output module (top) of a relation name tagging layer and a tuple completion tagging layer.

(alkaline_pH, increases, activity_of_TRPV5/V6 _channels_in_Jurkat_T_cells).

where (a) the object should just be the channel's activity and (b) the condition tuple (TRPV5/V6 _channels, in, Jurkat_T_cells) was not found. Note that the term "TRPV5/V6 _channels" is *not only* the concept in the fact tuple's object *but also* the condition tuple's subject.

In this work, we define the joint tuple extraction task as a *multi-output* sequence labeling problem. First, we create a new tag schema: Non-"O" tags

[1]This work was done when the first author was visiting the University of Notre Dame.

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 302–312, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

are formatted as "B/I-XYZ", where

- X ∈ {fact, condition};
- Y ∈ {1: subject; 2: relation; 3: object};
- Z ∈ {concept, attribute, relational phrase}.

Note that if Y="2" then Z="p". So, the number of non-"O" tags is 20. Now each fact/condition tuple can be represented as a tag sequence. Moreover, it is the first work in sequence labeling that concepts and attributes are separated. The fact tuple in the example will ideally be: (alkaline_pH, increases, {TRPV5/V6_channels : activity}).

Figure 1 shows our framework. Multiple tag sequences are generated after the LSTMd decoder, each of which represents a fact or condition tuple. This multi-output module has two layers: one is a relation name tagging layer that predicts the tags of relational phrases and determines the number of output sequences; the other is a tuple completion tagging layer that generates the tag sequences for completing the fact and condition tuples.

To address the challenge of modeling the complex tag schema, besides language model, we incorporate as much information as possible from upstream tools such as Part-of-Speech tagging (POS), Concept detection, Attribute name extraction, and Phrase mining (CAP). And we transform them into tag sequences as the model input. We observe strong dependencies between the token's POS/CAP tags and target tags. We appreciate the high accuracy of existing techniques making the multi-input sequences available for new datasets.

The multi-input multi-output sequence labeling framework is named as MIMO. Experiments demonstrate that it improves F1 score relatively by 6.2% over state-of-the-art models for tuple extraction on a new bio-text dataset we will introduce in the later section. When transferred to the BioNLP2013 dataset without additional training, it improves F1 score relatively by 4.2%. We apply MIMO to a large set of 15.5M MEDLINE papers and construct a knowledge graph: An example can be found in Figure 4.

2 A New Dataset

We built a system with GUI (Figure 2) to collect a new dataset for the joint tuple extraction purpose, named Biomedical Conditional Fact Extraction (BioCFE). Three participants (experts in biomedical domain) manually annotated the fact and condition tuples from statement sentences from 31 paper abstracts in the MEDLINE database. The annotation procedure took over 30 minutes on average for each paper. Here is a brief guide to the system. First, the users merged the token(s) into a span. Second, they gave a proper number of fact and/or condition tuple(s), where the proper number is not fixed but depends on the concrete sentence. Each tuple has five slots (subject's concept, subject's attribute, relation phrase, object's concept, and object's attribute). Third, they dragged the spans filling into the slots. If the three annotations are inconsistent, we filtered out the case. Eventually we have 756 fact tuples and 654 condition tuples from 336 annotated sentences. It is common to see one sentence having multiple facts and/or conditions, and actually 61%/52% statement sentences have more than one fact/condition tuples.

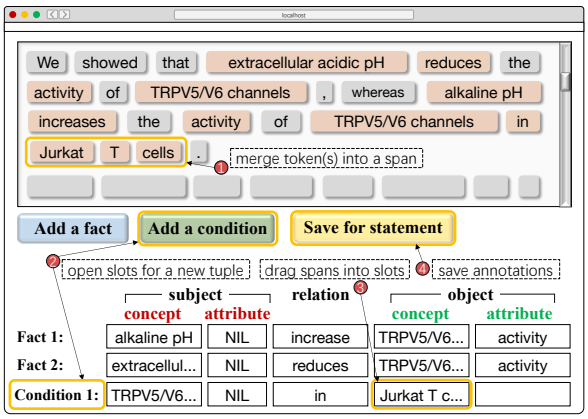

Figure 2: Annotation by four steps: (1) merge token(s) into a span; (2) make slots for a new tuple; (3) drag spans into the slots; (4) save annotations.

3 The Proposed Approach

Our approach has two modules: (1) a multi-input module that harnesses recent NLP development to process the text for input sequences from multiple tasks and feeds them into a multi-head encoder-decoder model with multi-input gates; (2) a multi-output module that generates multiple tuple tag sequences for fact and condition tuples, which consists of a relation name tagging layer and a tuple completion tagging layer, as shown in Figure 1.

3.1 The Multi-Input Module

Preprocessing for input sequences: Following fundamental NLP techniques have achieved high accuracy requiring no additional training with labeled data: Language Model (LM) (Howard and Ruder, 2018), POS (Labeau et al., 2015), CAP (Luan et al., 2018; Jiang et al., 2017; Shang

et al., 2018; Wang et al., 2018a). For any given input sentence, we tokenize it and represent each token by its word embedding (pre-trained GloVe vector in this paper). Then we get another three input sequences by the input sentence and the above three fundamental NLP techniques. (1) A pre-trained LSTM-based language model takes the sentence as input and returns semantic embedding sequence, where the dependencies between a token and its predecessors in distant contexts are preserved. (2) We employ NLTK tool to generate the POS tag sequence for the given sentence. The POS tag sequence indicates syntactic patterns of the words in a sentence, that is the dependencies between POS tags and output tags, like verbs (e.g., VBD) and predicates (e.g., B-f2p). (3) Multiple complementary IE techniques are used to detect concepts, attributes and phrases from the given sentences, being merged and resulting a CAP sequence. We make tags in the format of "B/I - c/a/p" for the tokens of concepts, attributes, and phrases.

Each sequence encodes a specific type of dependencies. A combination of multi-type dependencies learns the complicated dependencies on the 21 tuple tags better than any sole type. LM learns the dependencies between a token and its predecessors in distant contexts, which helps predict the position of subject, relation, and object. POS encodes the syntactic features of words. Dependencies between the POS tag and tuple tag (e.g., "VBD" and "B-f2p") can be modeled. We also spot high dependencies between the CAP tag and tuple tag. For example, the tokens of "B/I-c" (concept) and "B/I-a" (attribute) tags have high probability of being labeled as "B/I-XYc" and "B/I-XYa" in the output sequences, respectively.

Multi-head Encoder-Decoder: We investigate two neural models as encoder: one is bidirectional LSTM (BiLSTM), the other is the renown, bidirectional encoder representations from Transformers (BERT). We adopt a LSTM structure as the decoding layer (LSTMd) (Zheng et al., 2017). We observe that the input sequences may have different tag predictability on different sentences. For short sentences, POS and CAP are more useful (modeling local dependencies); for long sentences, LM is more effective (modeling distant dependencies). In order to secure the model's robustness on massive data, we apply a multi-head mechanism to the encoder-decoder model. Each head of the encoder-decoder is fed with one type of input sequence, and they are combined at the end of decoder layer. Thus, the tag prediction becomes more stable than using a simple encoder-decoder without the multi-head.

Multi-input gates: We adopt the multi-input gates in ResNet (He et al., 2016) to take the most use of the multi-input sequences. We add the gates to the input of BiLSTM or BERT encoder, the input of LSTMd decoder, and the multi-output module.

3.2 Multi-Output Module

We propose to generate multiple output sequences. As annotating multiple tuples from one sentence is common, a token may have different expected tags in the tuples. On BioCFE, we observe that 93.8% statement sentences make multiple tuples: 21.7% of the sentences have at least one token that appears in at least one fact tuple and at least one condition tuple, expecting tags "B/I-fYZ" and "B/I-cYZ"; 18.1% of the sentences have at least one token that appears in one condition tuple as a part of subject and in another condition tuple as a part of object, expecting tags "B/I-c1Z" and "B/I-c3Z". Therefore, we extend the typical one-output sequence labeling to a multi-output design.

Then what is the number of output sequences? We reveal the significant role of relation names in making tuples. If we tagged the relation names out, for each relation name, of tags beginning with "B-f2p" as a fact's and "B-c2p" as a condition's, the module would generate an output sequence, respectively. Then we extract all possible tuples, whose relation has been specified, from every output sequence. Two observations on the annotated data support this idea: We transform each of the 1,410 tuples into a tag sequence. For the same sentence, if the tuples' relation names are the same, we merge their tag sequences into one and then use the matching function in (Stanovsky et al., 2018) to recover the tuples. First, 0 token has conflicting tags among the 240 merged sequences. Second, the recovery has 0 missing or wrong tuple. So, generating one output sequence and completing the tuples per relation name is practical.

The multi-output module has two layers: one is a relation name tagging layer and the other is a tuple completion tagging layer.

Relation name tagging (RNT) layer: It consists of feed-forward neural networks (FFNs) and softmax layers. Decoded vectors are fed into the FFNs

and the softmax predict the probability distribution of tags on fact and condition, respectively:

$$\mathbf{p}_i^f = \text{softmax}(\text{FFN}_{RNT}^f(\mathbf{d}_i)), \quad (1)$$
$$\mathbf{p}_i^c = \text{softmax}(\text{FFN}_{RNT}^c(\mathbf{d}_i)). \quad (2)$$

where f is for fact and c for condition. $\mathbf{d}_i$ denotes the i-th token's vector given by the LSTMd.

Now we have two tag sequences, one for fact and the other for condition. As we have argued with one-output, extracting tuples from the "two-output" sequences cannot resolve the tag conflicts, either. Here we extract only the relation names: $\{r_1^f, r_2^f, \cdots, r_n^f\}$ denotes the n relation names (beginning with "B-f2p" tag) in fact tuples and $\{r_1^c, r_2^c, \cdots, r_m^c\}$ denotes the m relation names (beginning with "B-c2p" tag) in condition tuples.

Tuple completion tagging (TCT) Layer: This layer predicts n fact tag sequences and m condition tag sequences. Each sequence is generated by a FFN and a softmax layer. The FFN obtains the relation name from the RNT layer. The FFN's input also includes the token's vectors from the encoder-decoder model of the multi-input module.

Here we take condition sequences as an example to describe the details of the method. When predicting the j-th tag sequence, we define the position embedding of the i-th token as follows, representing the relative position to the j-th relation name's tag "B-c2p":

$$\mathbf{v}_{i,j}^c = g_{\text{emb}}(r_j^c, i). \quad (3)$$

Thus, the tag probability distributions of the i-th token in the condition tag sequences are:

$$\begin{cases} \mathbf{p}_i^{(r_1^c)} = \text{softmax}(\text{FFN}_{TCT}^c(\mathbf{v}_{i,1}^c + \mathbf{d}_i)), \\ \mathbf{p}_i^{(r_2^c)} = \text{softmax}(\text{FFN}_{TCT}^c(\mathbf{v}_{i,2}^c + \mathbf{d}_i)), \\ \cdots, \\ \mathbf{p}_i^{(r_m^c)} = \text{softmax}(\text{FFN}_{TCT}^c(\mathbf{v}_{i,m}^c + \mathbf{d}_i)). \end{cases} \quad (4)$$

Similarly, we have the following tag distributions for the i-th token in the fact tag sequences:

$$\begin{cases} \mathbf{p}_i^{(r_1^f)} = \text{softmax}(\text{FFN}_{TCT}^f(\mathbf{v}_{i,1}^f + \mathbf{d}_i)), \\ \mathbf{p}_i^{(r_2^f)} = \text{softmax}(\text{FFN}_{TCT}^f(\mathbf{v}_{i,2}^f + \mathbf{d}_i)), \\ \cdots, \\ \mathbf{p}_i^{(r_n^f)} = \text{softmax}(\text{FFN}_{TCT}^f(\mathbf{v}_{i,n}^f + \mathbf{d}_i)), \end{cases} \quad (5)$$

where $\mathbf{v}_{i,j}^f$ is the position embedding of the i-th token in the j-th fact sequence, representing the relative position to the relation name's tag "B-f2p".

Finally, we apply the matching function in (Stanovsky et al., 2018) to complete and extract the tuples (i.e., the concepts and/or attributes in the subjects and objects) for each output sequence.

3.3 Loss Function and Training

Given a sentence s, the loss function of the relation name tagging layer can be written as below:

$$\ell_{RNT}^s = -\sum_{i=1}^{N^s} (\log(p_{i,y_i^f}^f) + \log(p_{i,y_i^c}^c)), \quad (6)$$

where $\mathbf{p}_{i,y}^f$ and $\mathbf{p}_{i,y}^c$ are the probability of predicting y as the tag of the i-th token in the fact and condition tag sequences, respectively. y_i^f and y_i^c are the observed tag of the i-th token in the fact and condition tuple, respectively. N^s is the length of the sentence s.

The loss function of the tuple completion tagging layer is consisted of two parts, loss on fact tuples and loss on condition tuples:

$$\begin{cases} \ell_{TCT}^s = \ell_{fact}^s + \ell_{cond.}^s, \\ \ell_{fact}^s = -\sum_{i=1}^{N^s} \sum_{j=1}^{n} \log(p_{i,y_{i,j}^f}^{(r_j^f)}), \\ \ell_{cond.}^s = -\sum_{i=1}^{N^s} \sum_{j=1}^{m} \log(p_{i,y_{i,j}^c}^{(r_j^c)}), \end{cases} \quad (7)$$

where n and m are the number of fact and condition tag sequences for the sentence s, respectively. $p_{i,y_{i,j}^f}^{(r_j^f)}$ and $p_{i,y_{i,j}^c}^{(r_j^c)}$ are the probability of predicting $y_{i,j}^f$ and $y_{i,j}^c$ as the tag of the i-th token in the j-th fact and condition tag sequence, respectively.

The overall loss function for optimization is:

$$\ell = \ell_{RNT} + \ell_{TCT} = \sum_{s \in \mathcal{S}} (\ell_{RNT}^s + \ell_{TCT}^s), \quad (8)$$

where $\mathcal{S}$ is the set of statement sentences.

Training details: On one hand, Equations (6) and (7) show that the error signal can be propagated from the RNT/TCT layers to the encoder-decoder model. On the other hand, the RNT layer specifies the relation names, or say, the tokens that have tags "B/I-f2p" and "B/I-c2p" for each tag sequence in the TCT layer. So we cannot have smooth gradients for back propagation from the TCT layer to the RNT layer. So, in order to have good learning effectiveness, the quality of predicting relation names has been secured beforehand. We pre-train the RNT layer with the multi-input module till the relation name's tag prediction achieves a higher-than-0.8 F1 score. Then we plug the TCT layer onto the RNT layer and train the entire framework to generate the multi-output tag sequences.

4 Experiments

We evaluate the performance of condition/fact tag prediction and tuple extraction by the proposed MIMO model, its variants, and state-of-the-art models on the newly annotated BioCFE dataset and transferred to the BioNLP2013 dataset.

4.1 Experimental Setup

Datasets: Statistics of BioCFE has been given in the Section 2. Additionally, the attribute-related tags take 11.7% and 9.4% of non-"O" tags in fact and condition tuples, respectively. So, it is important to distinguish concept and attribute. To the best of our knowledge, it is the first time that conditional information was carefully annotated on biomedical literature.

We use the system in Figure 2 to annotate a subset of BioNLP2013 Cancer Genetics (CG) task dataset (Nédellec et al., 2013). We have 197 fact tuples and 173 condition tuples. We use this BioNLP dataset as an extra test set for task of fact and condition tuples extraction, but the model will not be trained on this dataset.

Validation: The ratio of training:validation:test is 60:8:32. For BioCFE, the evaluation set has 242 fact tuples and 209 condition tuples (on average from 108 sentences). We repeat five times, evaluate the performance, and report average results.

Evaluation metrics: For tag prediction, We use standard metrics, precision, recall, and F1 scores. We have similar observations on Micro F1 scores as Macro F1 scores, so we report Macro F1 only. For evaluating tuple extraction, we use pair-wise comparison to match the extracted and ground-truth tuples. We evaluate the correctness on the tuple's five slots using the same metrics.

Baselines: We compare with statistical sequence labeling methods: Structured Support Vector Machine (SVM) (Tsochantaridis et al., 2005) and Conditional random field (CRF) (Lafferty et al., 2001). We compare with a neural sequence labeling method, BiLSTM-LSTMd (Zheng et al., 2017). We replace its encoder with BERT (Devlin et al., 2018) to make it a more competitive baseline. We also compare against two renown OpenIE systems, Stanford OpenIE (Angeli et al., 2015) and AllenNLP OpenIE (Stanovsky et al., 2018) followed by a condition/fact classification.

We enhance statistical sequence labeling models with multi-input signals for fairness, and train them for fact tuple and condition tuple extraction separately. In the neural baselines (BiLSTM-LSTMd and BERT-LSTMd), fact extraction and condition extraction share the encoder-decoder model and use different, proper parameters in the linear-softmax layer.

Hyperparameters: The multi-input module has a BiLSTM/BERT encoder and a LSTM decoder. The word embeddings were obtained from GloVe (Pennington et al., 2014) with the dimension size d_{WE} = 50. The language model dimension size ns d_{LM} = 200. The size of POS tag embedding is d_{POS} = 6. The size of CAP tag embedding is d_{CAP} = 3. The number of LSTM units in the encoding layer is 300. The number of transformer units in the BERT encoding layer is 768.

4.2 Results on BioCFE

In this section, we present overall performance, ablation study, error analysis, and efficiency.

4.2.1 Overall Performance

Table 1 shows that the proposed multi-input multi-output sequence labeling model with a BERT encoder consistently performs the best over all the baselines on tag prediction and tuple extraction. Compared to BiLSTM-LSTMd, BiLSTM-based MIMO improves F1 score relatively by 7.1% on tag prediction and by 8.8% on tuple extraction; compared to BERT-LSTMd, BERT-based MIMO improve F1 by **4.7%** and **6.2%** on the two tasks, respectively. Apparently the BERT encoder significantly improves the performance (by 16.9–17.2% on tag prediction and 7.7–10.3% on tuple extraction). And the MIMO design can further improve it. Neural sequence labeling models perform better than OpenIE systems and statistical methods. Neural sequence labeling models are more adaptive to learning structures with the new tag schema. Open IE method plus a condition/fact classification is not effective.

Compared to BERT-LSTMd, the BERT-based MIMO improves precision and recall relatively by 8.3% and 1.3% on tag prediction; and relatively by 3.1% and 9.3% on tuple extraction, respectively. When the tags were more precisely predicted, the tuple's five slots would be more accurately filled, and we would have more complete tuples.

We also observe that the improvements on condition's tags/tuples are consistently bigger than the improvements on fact's tag/tuples. It demonstrates that the MIMO design recognizes the role of conditions in the statement sentences better.

Methods	Tag Prediction (%)			Tuple Extraction(%)

Table 1: The proposed MIMO outperforms existing methods on tag prediction and tuple extraction in the BioCFE dataset. The MIMO with BERT-based encoder performs the best. Higher score performs better.

4.2.2 Ablation Study

Table 2 compares variants of the proposed model to evaluate the effectiveness of the following components: (1) *multi-input sequences*, such as none, or one (in LM, POS, and CAP), double combination, or triple combination; (2) *multi-input encoder model*, BiLSTM or BERT; (3) *multi-output module*, with the RNT layer only (generating one fact tag sequence and one condition tag sequence) or a combination of RNT and TCT layers (generating multiple sequences for each tuple type).

Multi-input sequences: When the choices of the encoder model and multi-output layers are specified, we observe that triple combination of input sequences performs better than double combinations and the double combinations win over the sole input. An additional sequence makes a relative F1 improvement by 1.0–2.4%. The triple combination improves F1 relatively by 3.2–4.1%. This demonstrates that the three types of input sequences encode *complementary information* for learning dependencies in the proposed tag schema.

First, the language model learns the dependencies between a token and its predecessors in distant contexts. Having the LM sequence recognizes subjects and objects relative to the relation names and reduces the false positives of "B/I-X1Z" and "B/I-X3Z". Second, the POS tag encodes the token's syntactic feature. Having the POS sequence improves the precision of tag prediction. For example, verbs and prepositions (e.g., "in", "during") often act as the relation name of facts and conditions, respectively; conjunction words (e.g., "that", "which") indicate subordinate clauses, so the noun phrase before the conjunction word is likely to be the subject of the tuple given by the clause. Third, the formerly-detected concepts, attribute names, and phrases are absolutely useful for tagging the slots of subjects and objects. In other words, the tags "B/I-c" and "B/I-a" in the CAP sequence are strongly associated with the target tags "B/I-XYc" and "B/I-XYa", respectively.

Encoder in the multi-input module: Comparing the middle three columns (BiLSTM-based encoder) and the right-hand three columns (BERT-based encoder), one can easily tell the significant improvement brought by the BERT model.

Layers in the multi-output module: If the multi-output models have both RNT and TCT layers, the F1 score is relatively 1.4–5.0% higher than the models that have the RNT layer only. Moreover, the recall is improved relatively by 1.5–9.0%. So the TCT layer, which generates multiple tag sequences for each type of tuple (i.e., fact and condition), plays a very important role in recognizing the multiple tuples from one statement sentence.

4.2.3 Error Analysis

Table 3 presents the confusion matrices made by the BERT-based MIMO on predicting non-"O" tags for facts and conditions, respectively. The columns are predicted tags and the rows are actual ones. Perfect results would be diagonal matrices.

We observe that the numbers at the diagonal are consistently bigger than the numbers on the corresponding row and column. The accuracy scores are 0.905 for predicting fact tags and 0.908 for predicting condition tags. Of the 182 actual "B-f2p", the model predicted that 175 were "B-f2p"; of the 186 actual "B-c2p", it predicted that one was "I-c1c" and one was "I-c3c". It demonstrates the high accuracy (0.961 and 0.989) of extracting relation names for multi-output generation.

Table 2: The proposed MIMO that employs (a) multi-input Language Models, POS tags, and Concept-Attribute-Phrase sequences, (b) multi-output tag sequences, (c) BERT-based encoder performs the best on tuple extraction.

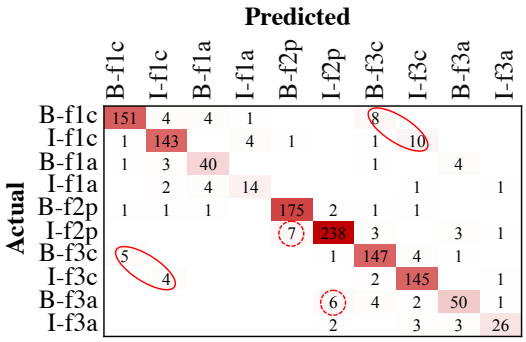
The ovals in each confusion matrix present the most significant type of error. Of a small set of actual subjects, the model predicted them as objects, and vise versa, though the fact/condition role and concept role were correctly predicted.

The dashed circles show the second frequent type of error. Of the actual "I-f2p" tokens, the model predicted that 7 were "B-f2p"; for the actual "I-c2p", it predicted that 6 were "B-c2p". Basically, it was because of missing the beginning word of the relational phrases. Of the actual "B-f3a" tokens, the model predicted 6 were "I-f2p". Future work will aim at improving the prediction of the boundaries of long relational phrases.

4.2.4 Efficiency

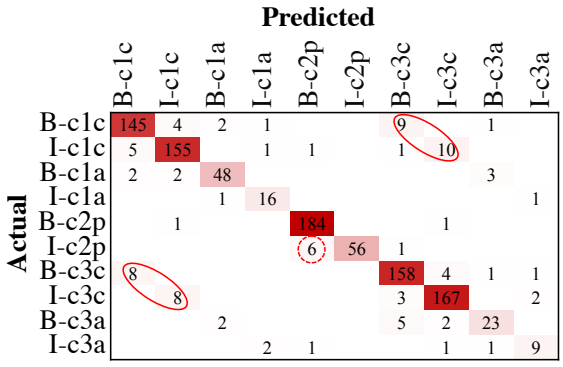
All the experiments were conducted on 16 Graphics Cards (GeForce GTX 1080 Ti), where one individual model only used 1 GPU. Each model was trained for 1,000 epochs. For the BiLSTM-LSTMd MIMOs, the pre-training took 2.4 hours and the re-training (TCT layer) took 0.4 hour. For the BERT-LSTMd MIMOs of the best performance, the pre-training took 3.5 hours and the re-training took 0.9 hour. It took 5.7 hours to extract fact and condition tuples from 141 million sentences in the MEDLINE text data. It is comparable with existing approaches in terms of scalability.

4.3 Results on BioNLP2013



As shown in Table 3, the BERT-LSTMd MIMO model achieves an F1 score of 0.790 on tuple extraction from BioNLP2013. Note that the model was trained on BioCFE that has no overlapping sentence with BioNLP2013. This score is comparable with the testing F1 score on the BioCFE (0.808), which demonstrates the effectiveness and reliability of the proposed model.

Our model improves the F1 score relatively by 4.2% over the best baseline BERT-LSTMd. The improvement on recall is more substantial: It improves recall relatively by 5.8%. It was because of the design of the multi-output module: the TCT layer generates multiple tag sequences based on the relation names predicted by the RNT layer. A token in a statement sentence may have different roles in different tuples of the same type (fact or condition). For example, given the following statement sentence:



"*Immunohistochemical staining of the tumors demonstrated a decreased number of blood vessels in the treatment group versus the controls.*"

The proposed model is able to find one fact tuple and two condition tuples precisely:

-*Fact 1:* ({tumors:immunohistochemical_staining}, demonstrated, {blood_vessels:decreased_number})

(a) Fact tags

(b) Condition tags

Figure 3: Confusion matrices on predicting fact tags (Top) and condition tags (Bottom) in BioCFE data.

-*Condition 1:* (blood_vessels,in,**treatment_group**)
-*Condition 2:* (**treatment_group**,versus,controls)

Note that the concept "treatment_group" acts as the *object* of Condition Tuple 1 (having tags "B/I-c3c") and the *subject* of Condition Tuple 2 (having tags "B/I-c1c"). The multi-output design tackled this issue while other models could not.

Compared with BioCFE: On BioCFE, the F1 score on condition tuple extraction is a bit higher than that on fact tuple extraction (81.64 vs 79.94). On BioNLP2013, we have the opposite observation (78.58 vs 79.42). They are still comparable but if we look at the error cases, we find that most of the false predictions of condition tuple come from long sentences (having more than 30 words). And 35% of the sentences in BioNLP are long sentences, while only 5% in Bio CFE are long. Long dependency modeling is always challenging for IE, especially condition extraction. We will study it in the future work.

4.4 A Visualized Case Study

Scientific knowledge graph enables effective search and exploration. It is certainly important to represent the conditions of the corresponding fact

Methods	*Prec. (%)*	*Rec. (%)*	*F1 (%)*
Allennlp OpenIE	41.84	37.87	39.75
Stanford OpenIE	45.04	42.99	43.99

BERT-LSTMd	76.99	74.74	75.85
MIMO (BERT based)	**78.93**	**79.07**	**79.00**

Table 3: The BERT-LSTMd MIMO model performs the best on tuple extraction in BioNLP2013.

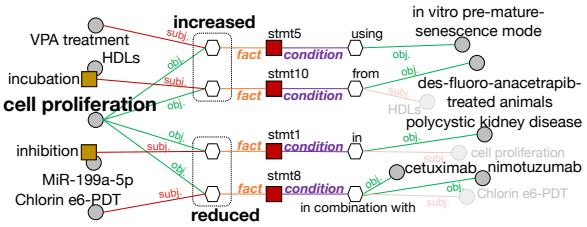

Figure 4: Structuring tuples detected from four statement sentences that mention "cell proliferation" into a snapshot of scientific knowledge graph with fact tuples on the left and condition tuples on the right.

being valid in the graph. As we have applied our model to the large MEDLINE dataset, Figure 4 visualizes the fact and condition tuples extracted from four statement sentences about "cell proliferation". On the left side, we find (1) "VPA treatment" and the "incubation" of "HDLs" increased cell proliferation, while (2)"Chlorin e6-PDT" and the "inhibition" of "MiR-199a-5p" decreased cell proliferation. On the right, we are aware of the conditions of the factual claims. They describe the methodology of the observation (e.g., "using", "in combination with") or the context (e.g., "in" a specific disease or "from" specific animals). In some other cases, we find the temperature and pH values are detected as the conditions of observations.

5 Related Work

5.1 Scientific Information Extraction

Information extraction in scientific literature, e.g., computer science, biology and chemistry, has been receiving much attention in recent years. ScienceIE in computer science focus on concept recognition and factual relation extraction (Luan et al., 2017; Gábor et al., 2018; Luan et al., 2018). ScienceIE in biological literature aims at identifying the relationships between biological concepts

(i.e., proteins, diseases, drugs and genes) (Kang et al., 2012; Liu et al., 2018; Xu et al., 2018). Rule-based approaches were used in early studies (Rindflesch and Fiszman, 2003; Kang et al., 2012). Recently, a wide line of neural network models have been proposed and outperformed traditional methods (Wang et al., 2018b; Liu et al., 2018; Xu et al., 2018; Jiang et al., 2019). Wang *et al.* (2018b) investigated different kinds of word embeddings on different NLP tasks in the biological domain. Liu *et al.* (2018) employed attention-based neural networks to extract chemical-protein relations. Xu *et al.* (2018) used the BiLSTM model to recognize the drug interaction. In our work, we extract biological relational facts as well as their conditions. The condition tuples are essential to interpreting the factual claims.

5.2 Open-Domain IE

Open IE refers to the extraction of (subject, relation, object)-triples from plain text (Angeli et al., 2015; Stanovsky et al., 2018; Saha et al., 2018; Wang et al., 2018a). The schema for the relations does not need to be specified in advance. Distant supervision has been widely used because the size of the benchmark data is often limited (Banko et al., 2007; Wu and Weld, 2010). Stanovsky *et al.* (2018) proposed supervised neural methods for OpenIE. The idea was to transform annotated tuples into tags and learn via sequence tagging. We create a new tag schema and propose a novel sequence labeling framework.

5.3 Sequence Labeling for IE

Statistical models have been studied for long, including Hidden Markov Models (HMM), Support Vector Machine (SVM), and Conditional Random Fields (CRF) (Lafferty et al., 2001; Tsochantaridis et al., 2005; Passos et al., 2014; Luo et al., 2015; Li et al., 2018). However, these methods rely heavily on hand-crafted features. Then neural network models become popular and obtain more promising performance than traditional statistical methods (Yang and Mitchell, 2017; Zheng et al., 2017; Wang et al., 2019; Yu et al., 2019). So, we use them as strong baselines.

6 Conclusions

We present a new problem to find conditional information in scientific statements. We created a new tag schema for jointly extracting condition and fact tuples from scientific text. We proposed a multi-input multi-output sequence labeling model to utilize results from well-established related tasks and extract an uncertain number of fact(s)/condition(s). Our model yields improvement over all the baselines on a newly annotated dataset BioCFE and a public dataset BioNLP2013. We argue that structured representations of knowledge, such as fact/condition tuple, for scientific statements will enable more intelligent downstream applications. In the future work, we will explore the use of the structured tuples to bridge the gap between text content and knowledge-based applications, such as knowledge-based scientific literature search.

Abstract

The identification of complex semantic structures such as events and entity relations, already a challenging Information Extraction task, is doubly difficult from sources written in under-resourced and under-annotated languages. We investigate the suitability of cross-lingual structure transfer techniques for these tasks. We exploit relation- and event-relevant language-universal features, leveraging both symbolic (including part-of-speech and dependency path) and distributional (including type representation and contextualized representation) information. By representing all entity mentions, event triggers, and contexts into this complex and structured multilingual common space, using graph convolutional networks, we can train a relation or event extractor from source language annotations and apply it to the target language. Extensive experiments on cross-lingual relation and event transfer among English, Chinese, and Arabic demonstrate that our approach achieves performance comparable to state-of-the-art supervised models trained on up to 3,000 manually annotated mentions: up to 62.6% F-score for Relation Extraction, and 63.1% F-score for Event Argument Role Labeling. The event argument role labeling model transferred from English to Chinese achieves similar performance as the model trained from Chinese. We thus find that language-universal symbolic and distributional representations are complementary for cross-lingual structure transfer.

1 Introduction

Advanced Information Extraction (IE) tasks entail predicting structures, such as relations between entities, and events involving entities. Given a pair of entity mentions, *Relation Extraction* aims to identify the relation between the mentions and classify it by predefined type. *Event Extraction* aims to identify event triggers and their arguments in unstructured texts and classify them respectively by predefined types and roles. As Figure 1 illustrates, both tasks entail predicting an information network (Li et al., 2014) for each sentence, where the entity mentions and event triggers are nodes, and the relations and event-argument links are edges labeled with their relation and argument roles, respectively.

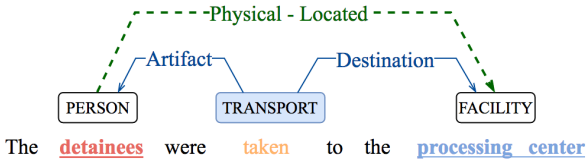

Figure 1: Information Network example constructed by Event (blue) and Relation (green dashed) Extraction.

There are certain relations and events that are of primary interest to a given community and so are reported predominantly in the low-resource language data sources available to that community. For example, though English language news will occasionally discuss the *Person* Aung San Suu Kyi, the vast majority of *Physical-Located* relations and *Meeting* events involving her are only reported locally in Burmese news, and thus, without Burmese relation and event extraction, a knowledge graph of this person will lack this available information. Unfortunately, publicly-available gold-standard annotations for relation and event extraction exist for only a few languages (Doddington et al., 2004; Getman et al., 2018), and Burmese is not among them. Compared to other IE tasks such as name tagging, the annotations for Relation and Event Extraction are also more costly to obtain, because they are structured and require a rich label space.

Recent research (Lin et al., 2017) has found that relational facts are typically expressed by identifiable patterns within languages and has shown

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 313–325,
Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

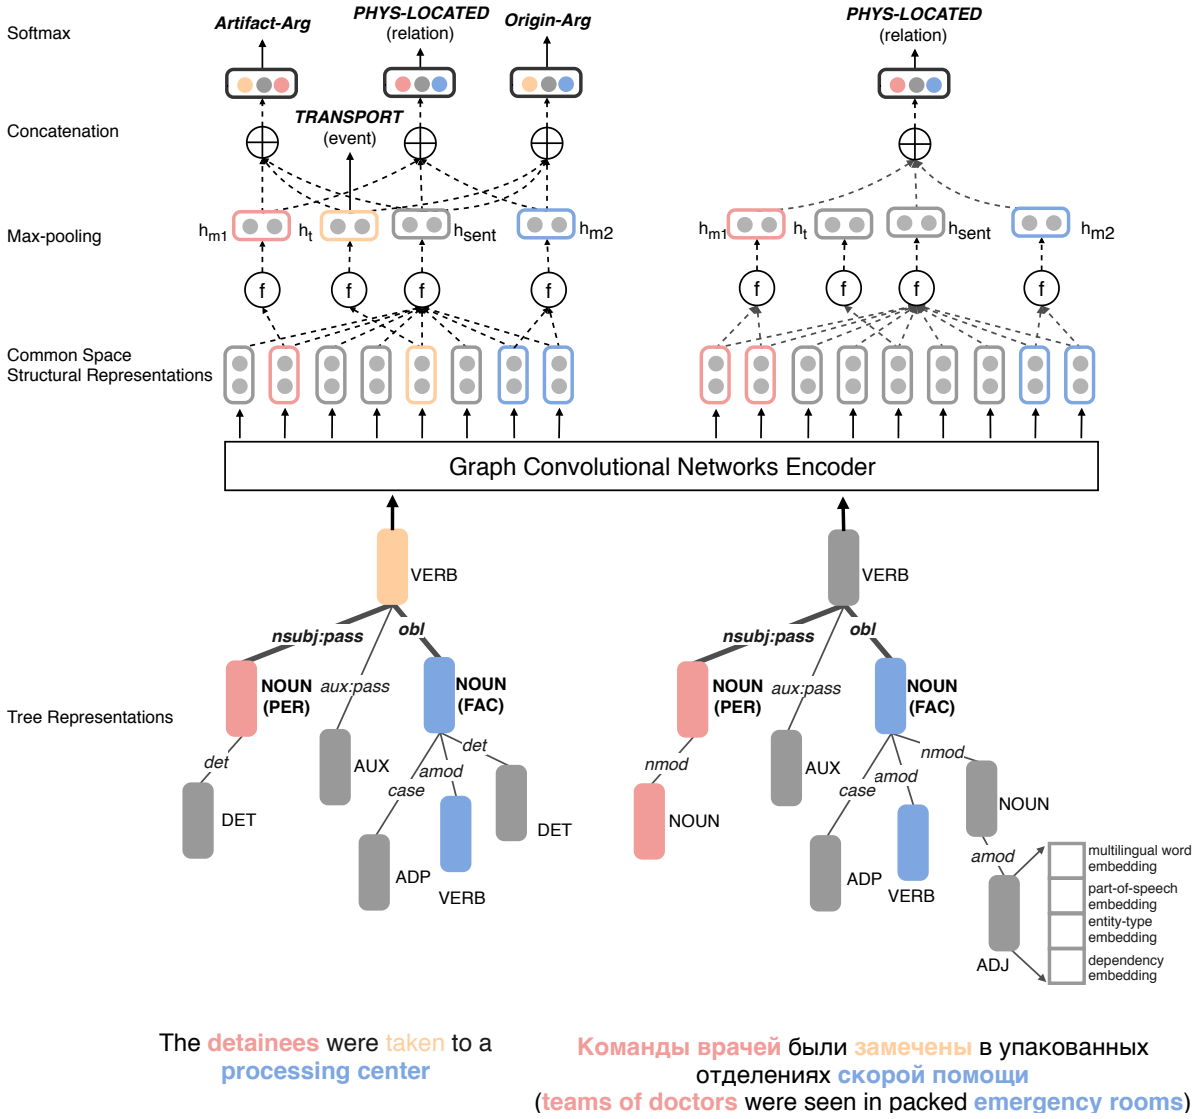

Figure 2: Multilingual common semantic space and cross-lingual structure transfer.

that the consistency in patterns observed across languages can be used to improve relation extraction. Inspired by their results, we exploit language-universal features relevant to relation and event argument identification and classification, by way of both symbolic and distributional representations. For example, language-universal POS tagging and universal dependency parsing is available for 76 languages (Nivre et al., 2018), entity extraction is available for 282 languages (Pan et al., 2017), and multi-lingual word embeddings are available for 44 languages (Bojanowski et al., 2017; Joulin et al., 2018). As shown in Figure 2, even for distinct pairs of entity mentions (colored pink and blue, in both English and Russian), the structures share similar language-universal symbolic features, such as a common labeled dependency path, as well as distributional features, such as multilingual word embeddings.

Based on these language-universal representations, we then project all entity mentions, event triggers and their contexts into one multilingual common space. Unlike recent work on multilingual common space construction that makes use of linear mappings (Mikolov et al., 2013; Rothe et al., 2016; Zhang et al., 2016; Lazaridou et al., 2015; Xing et al., 2015; Smith et al., 2017) or canonical correlation analysis (CCA) (Ammar et al., 2016; Faruqui and Dyer, 2014; Lu et al., 2015) to transfer *surface features* across languages, our major innovation is to convert the text data into structured representations derived from universal dependency parses and enhanced with distributional information to capture individual entities as well

as the relations and events involving those entities, so we can *share structural representations* across multiple languages.

Then we construct a novel cross-lingual structure transfer learning framework to project source language (SL) training data and target language (TL) test data into the common semantic space, so that we can train a relation or event extractor from SL annotations and apply the resulting extractor to TL texts. We adopt graph convolutional networks (GCN) (Kipf and Welling, 2017; Marcheggiani and Titov, 2017) to encode graph structures over the input data, applying graph convolution operations to generate entity and word representations in a latent space. In contrast to other encoders such a Tree-LSTM (Tai et al., 2015), GCN can cover more complete contextual information from dependency parses because, for each word, it captures all parse tree neighbors of the word, rather than just the child nodes of the word. Using this shared encoder, we treat the two tasks of relation extraction and event argument role labeling as mappings from the latent space to relation type and to event type and argument role, respectively.

Extensive experiments on cross-lingual relation and event transfer among English, Chinese, and Arabic show that our approach achieves highly promising performance on both tasks.

2 Model

2.1 Overview

Our cross-lingual structure transfer approach (see Figure 2) consists of four steps: (1) Convert each sentence in any language into a language-universal tree structure based on universal dependency parsing. (2) For each node in the tree structure, create a representation from the concatenation of multilingual word embedding, language-universal POS embedding, dependency role embedding and entity-type embedding, so that all sentences, independent of their language, are represented within one shared semantic space. (3) Adopt GCN to generate contextualized word representations by leveraging information from neighbors derived from the dependency parsing tree, and (4) Using this shared semantic space, train relation and event argument extractors with high-resource language training data, and apply the resulting extractors to texts of low-resource languages that do not have any relation or event argument annotations.

2.2 Tree Representations

Most previous approaches regard a sentence as a linear sequence of words, and incorporate language-specific information such as word order. Unlike sequence representations, tree representations such as constituency trees and dependency trees are typically constructed following a combination of syntactic principles and annotation guidelines designed by linguists. The resulting structures, such as the `verb` – `subject` relation and the `verb` – `object` relation, are found across languages. In this paper, we choose dependency trees as the sentence representations because the community has made great efforts at developing language-universal dependency parsing resources across 83 languages (Nivre et al., 2016).

We define the dependency-based tree representation for a sentence as $G = (V, E)$, where $V = \{v_1, v_2, ..., v_N\}$ is a set of words, and $E = \{e_1, e_2, ..., e_M\}$ is a set of language-universal syntactic relations. N is the number of words in the sentence and M is the number of dependency relations between words. To make this tree representation language-universal, we first convert each tree node into a vector which is a concatenation of three language-universal representations at word-level: multilingual word embedding, POS embedding (Nivre et al., 2016), entity-type embedding, and dependency relation embedding. More details are reported in Section 3.2.

2.3 GCN Encoder

Structural information is important for relation extraction and event argument role labeling, thus we aim to generate contextualized word representations by leveraging neighbors in dependency trees for each node.

Our GCN encoder is based on the monolingual design by Zhang et al. (2018b). The graphical sentence representation obtained from dependency parsing of a sentence with N tokens is converted into an $N \times N$ adjacency matrix $\boldsymbol{A}$, with added self-connections at each node to help capture information about the current node itself, as in Kipf and Welling (2017). Here, $A_{i,j} = 1$ denotes the presence of a directed edge from node i to node j in the dependency tree. Initially, each node contains distributional information about the i^{th} word, including word embedding $\boldsymbol{x}_i^w$, embeddings for symbolic information including its POS tag $\boldsymbol{x}_i^p$, dependency relation $\boldsymbol{x}_i^d$ and entity type $\boldsymbol{x}_i^e$.

We represent this initial representation $\boldsymbol{h}_i^0$ as follows:

$$\boldsymbol{h}_i^{(0)} = \boldsymbol{x}_i^w \oplus \boldsymbol{x}_i^p \oplus \boldsymbol{x}_i^d \oplus \boldsymbol{x}_i^e$$

Then, at the k^{th} layer of convolution, the hidden representation is derived from the representations of its neighbors at the $(k-1)^{th}$ layer. Thus, the hidden representation at the k^{th} layer for the i^{th} node is computed as:

$$\boldsymbol{h}_i^{(k)} = \text{ReLU}\left(\sum_{j=0}^{N} \frac{\boldsymbol{A_{ij}} \boldsymbol{W}^{(k)} \boldsymbol{h}_j^{(k-1)}}{d_i + b^{(k)}}\right)$$

where $\boldsymbol{W}$ is the weight vector, b is the bias term, and d_i represents the degree of the i^{th} node. The denominator in the equation denotes the normalization factor to neutralize the negative impact of node degree (Zhang et al., 2018b). The final hidden representation of each node after the k^{th} layer is the encoding of each word $\boldsymbol{h}_i^{(k)}$ in our language universal common space, and incorporates information about neighbors up to k hops away in the dependency tree.

2.4 Application on Relation Extraction

The GCN encoder generates the final hidden representation, $h_i^{(k)}$, for each of the n nodes. We perform max-pooling over these final node representations to obtain a single vector representation for the sentence, h^s. Similar to previous work (Zhang et al., 2018b), we also use the following recipe to obtain relation type classification results for each mention pair in a sentence: (1) max-pooling over the final representations of the nodes representing entity mentions, to get a single vector representation for each mention in a pair under consideration, $\boldsymbol{h}^{m_1}$ and $\boldsymbol{h}^{m_2}$, (2) a concatenation of three results of max-pooling: $([\boldsymbol{h}^{m_1}; \boldsymbol{h}^s; \boldsymbol{h}^{m_2}])$ to combine contextual sentence information with entity mention information (Santoro et al., 2017; Lee et al., 2017; Zhang et al., 2018b), (3) a linear layer to generate a combined representation of these concatenated results, and (4) a Softmax output layer for relation type classification. The objective function used here is as follows:

$$L^r = \sum_{i=1}^{N} \sum_{j=1}^{L_i} y_{ij} \ \log(\sigma(\boldsymbol{U}^r \cdot [\boldsymbol{h}_i^{m1}; \boldsymbol{h}_{ij}^s; \boldsymbol{h}_j^{m2}])) \quad (1)$$

where $\boldsymbol{U}^r$ is a weight matrix.

2.5 Application on Event Argument Role Labeling

Event argument role labeling distinguishes arguments from non-arguments and classifies arguments by argument role. To label the role of an argument candidate (x_j^a) for an event trigger (x_i^t), we first generate the sentence representation $\boldsymbol{h}^s$, argument candidate representation $\boldsymbol{h}^a$, and trigger representation $\boldsymbol{h}^t$ by applying pooling on sentence, argument candidate x_j^a and event trigger x_i^t respectively, which is the same as that for relation extraction. The mapping function from the latent space to argument roles is composed of a concatenation operation ($[\boldsymbol{h}^t; \boldsymbol{h}^s; \boldsymbol{h}^a]$), a linear layer ($\boldsymbol{U}^a$) and a Softmax output layer:

$$L^a = \sum_{i=1}^{N} \sum_{j=1}^{L_i} y_{ij} \ \log(\sigma(\boldsymbol{U}^a \cdot [\boldsymbol{h}_i^t; \boldsymbol{h}_{ij}^s; \boldsymbol{h}_j^a])) \quad (2)$$

where N is the number of event mentions, L_i is the number of argument candidates for i^{th} event mention and σ is the Sigmoid function.

3 Experiments

3.1 Data and Evaluation Metrics

	Relation Mentions	Event Mentions	Event Arguments
English	8,738	5,349	9,793
Chinese	9,317	3,333	8,032
Arabic	4,731	2,270	4,975

Table 1: Data statistics.

We choose the Automatic Content Extraction (ACE) 2005 corpus (Walker et al., 2006) for our experiments because it contains the most comprehensive gold-standard relation and event annotations for three distinct languages: English, Chinese and Arabic (see Table 1). Our target ontology includes the 7 entity types, 18 relation subtypes and 33 event subtypes defined in ACE. We randomly choose 80% of the corpus for training, 10% for development and 10% for blind test. We downsample the negative training instances by limiting the number of negative samples to be no more than the number of positive samples for each document.

For data preprocessing, we apply the Stanford CoreNLP toolkit (Manning et al., 2014) for Chinese word segmentation and English tokenization, and the API provided by UDPipe (Straka and

Straková, 2017) for Arabic tokenization. We use UDPipe[1] for POS tagging and dependency parsing for all three languages.

We follow the following criteria in previous work (Ji and Grishman, 2008; Li et al., 2013; Li and Ji, 2014) for evaluation:

- A relation mention is considered correct if its relation type is correct, and the head offsets of the two related entity mention arguments are both correct.
- An event argument is correctly labeled if its event type, offsets, and role label match any of the reference argument mentions.

3.2 Training Details

We use the multilingual word embeddings released by (Joulin et al., 2018) which are based on aligning monolingual embeddings learned by fastText (Bojanowski et al., 2017) from Wikipedia. We adopt the universal POS tag set (17 word categories) and 37 categories of dependency relations defined by the *Universal Dependencies* program (Nivre et al., 2016), and seven entity types defined in ACE: person, geopolitical entity, organization, facility, location, weapon and vehicle. Table 2 shows the hyperparameters of our model.

Hyperparameter	**Value**
word embedding size	300
POS embedding size	30
entity embedding size	30
dependency relation embedding size	30
hidden dimension size	200
dropout	0.5
number of layers	2
pooling function	max pooling
mlp layers	2
learning rate	0.1
learning rate decay	0.9
batch size	50
optimization	SGD

Table 2: GCN hyperparameters.

3.3 Overall Performance

In order to fully analyze the cross-lingual learning capabilities of our framework, we assess its performance by applying models trained with various combinations of training and test data from these three languages, as shown in Tables 3 and 4. We can see that the results are promising. For both tasks, the models trained from English are best, followed by Chinese, and then Arabic. We find that extraction task performance degrades as the accuracy of language-dependent tools (for sentence segmentation, POS tagging, dependency parsing) degrades.

Using English as training data, our cross-lingual transfer approach achieves similar performance on Chinese event argument role labeling (59.0%), compared to the model trained from Chinese annotations (59.3%), which is much higher than the best reported English-to-Chinese transfer result on event argument role labeling (47.7%) (Hsi et al., 2016).

We also show polyglot results for event argument role labeling in Table 4, by combing the training data from multiple languages. We observe that our model benefits from the combination of training data of multiple languages. The polyglot transfer learning does not provide further gains to relation extraction because the model converges quickly on a small amount of training data.

Train \ Test	English	Chinese	Arabic
English	68.2	**42.5**	**58.7**
Chinese	**62.6**	69.4	54.0
Arabic	58.6	35.2	67.4

Table 3: Relation Extraction: overall performance (F-score %) using perfect entity mentions.

Train \ Test	English	Chinese	Arabic
English	63.9	**59.0**	**61.8**
Chinese	**51.6**	59.3	60.6
Arabic	43.1	50.1	64.0
English + Chinese	–	–	**63.1**
English + Arabic	–	**60.1**	–
Chinese + Arabic	**51.9**	–	–

Table 4: Event Argument Role Labeling results (F1 %) with perfect event triggers.

[1]Universal Dependencies 2.3 models: english-ewt-ud-2.3-181115.udpipe, chinese-gsd-ud-2.3-181115.udpipe, arabic-padt-ud-2.3-181115.udpipe

Feature	Chinese	Arabic
Multilingual Word Embedding	40.2	53.8
+ POS Embedding	40.1	54.9
+ Entity Embedding	40.8	56.9
+ Dependency Relation Embedding	**42.5**	**58.7**

Table 5: Relation Extraction: Contribution of adding each language-universal feature consecutively for relation extraction on Arabic and Chinese test sets, using the model trained on English (F1 scores (%)).

3.4 Ablation Study

Tables 5 and 6 show the impact of each feature category. We can see that all categories help except Chinese POS features for Relation Extraction and Arabic POS features for Event Argument Role Labeling.

Many Chinese word segmentation errors occur on tokens involved in names. For example, "总统(NOUN, president) 萨姆(PROPN, Samuel) ·(PUNCT) 努乔马(PROPN, Nujoma)" is mistakenly tagged as "总(NOUN) 统萨姆(PROPN) ·(PUNCT) 努乔(NOUN) 马(NOUN)".

In Arabic, sometimes one word is a combination of *Noun* and *Verb*. For example, the single word "الإسرائيلي" means *"Israeli conflict"* in English, including both a trigger and an argument, which are not separated by our tokenizer. In contrast, two entity mentions are unlikely to be combined into one word in Arabic, thus Relation Extraction does not suffer from tokenization errors and corresponding POS features.

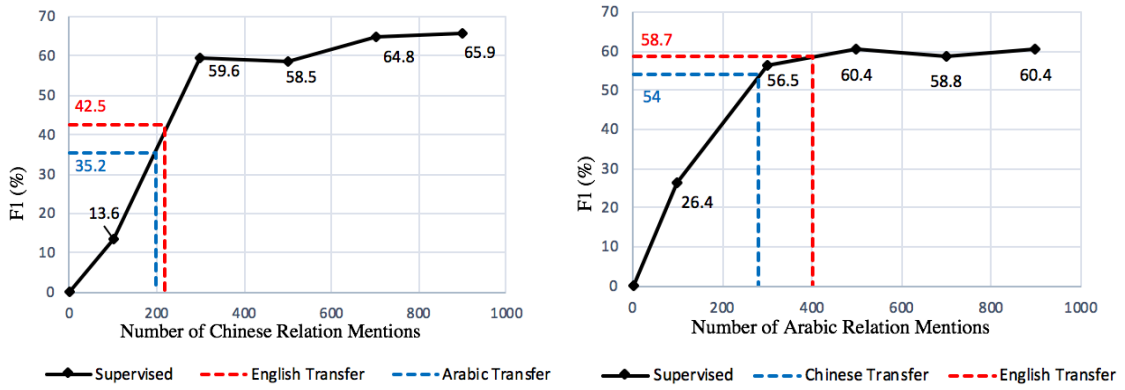
Feature	Chinese	Arabic
Multilingual Word Embedding	52.4	56.6
+ POS Embedding	57.1	37.8
+ Entity Embedding	58.3	41.4
+ Dependency Relation Embedding	**59.0**	**61.8**

Table 6: Event Extraction: Contributions of adding each language-universal feature consecutively for event argument role labeling on Arabic and Chinese test datasets, using a model trained on English (F1 scores (%)).

3.5 Comparison with Supervised Approach

We also compare the results with supervised monolingual models trained from manual annotations in the same language. Figures 3 and 4 show the learning curves of these supervised models. For event argument role labeling, we can see that without using any annotations for the target language, our approach achieves performance comparable to the supervised models trained from more than 3,000 manually annotated event argument mentions, which equal to approximately 1,326 Chinese sentences and 1,141 Arabic sentences based on the statistics of ACE data.

Our model performs particularly well on relation types or argument roles that require deep understanding of wide contexts involving complex syntactic and semantic structures, such as *PART-WHOLE:Artifact*, *PART-WHOLE:Geographical*, *GEN-AFF:Org-Location* and *ORG-AFF:Employment* relations, and *Injure: Victim* argument role. Despite only having 14 training instances, our model achieves near 100% F-score on *PART-WHOLE:Artifact* relations when transferred from English to Chinese. Our model achieves 86% F1 score on *PART-WHOLE:Geographical* relations when transferred from English to Arabic, and 73% and 79% F1 scores on *GEN-AFF:Org-Location* relations when transferred from English to Chinese and to Arabic, respectively. In an *Injure* event, a *Person* can either be an *Agent* or a *Victim*. Surface lexical embedding features are often not sufficient to disambiguate them. Our model is effective at transferring structural information such as dependency relations between words, and obtains 72.97% F1 score on labeling *Injure: Victim* when transferred from English to Chinese, and 75.43 % from English to Arabic.



In addition, our model achieves very high performance on event argument roles for which entity type is a strong indicator. For example, a *weapon* is much more likely to play as an *Instrument* rather than a *Target* in an *Attack*. Our model achieves 89.9% F1 score on *Attack: Instrument* and 91.4% F1 score on *Personnel: POSITION* argument roles when transferred from English to Chinese.

3.6 Using System Extracted Name Mentions

Target Language	F1 score
Chinese	56.9
Arabic	60.1

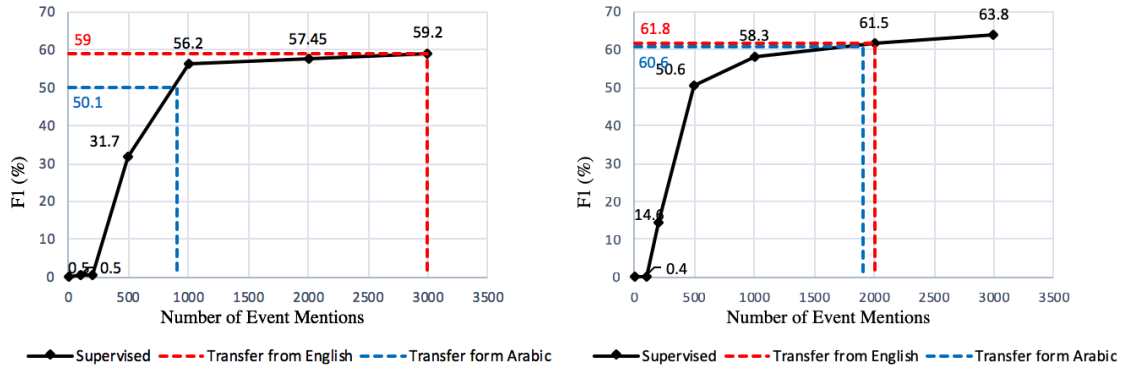


Table 7: Event Argument Role Labeling results (F1 %) on Chinese and Arabic using English as training data (with system generated entity mentions)

Table 7 shows the results of event argument role labeling on Chinese and Arabic entity mentions automatically extracted by Stanford CoreNLP instead of manually annotated mentions. The system extracted entity mentions introduce noise and

(a) Target Language: Chinese (b) Target Language: Arabic

Figure 3: Relation Extraction: Comparison between supervised monolingual GCN model and cross-lingual transfer learning.

(a) Target Language: Chinese (b) Target Language: Arabic

Figure 4: Event Argument Role Labeling: Comparison between supervised monolingual GCN model and cross-lingual transfer learning.

thus decrease the performance of the model, but the overall results are still promising.

4 Related Work

A large number of supervised machine learning techniques have been used for English event extraction, including traditional techniques based on symbolic features (Ji and Grishman, 2008; Liao and Grishman, 2011), joint inference models (Li et al., 2014; Yang and Mitchell, 2016), and recently with neural networks (Nguyen and Grishman, 2015a; Nguyen et al., 2016; Chen et al., 2015; Nguyen and Grishman, 2018; Liu et al., 2018b; Lu and Nguyen, 2018; Liu et al., 2018a; Zhang et al., 2018a, 2019). English relation extraction in the early days also followed supervised paradigms (Li and Ji, 2014; Zeng et al., 2014; Nguyen and Grishman, 2015b; Miwa and Bansal, 2016; Pawar et al., 2017; Bekoulis et al., 2018; Wang et al., 2018b). Recent efforts have attempted to reduce annotation costs using distant supervision (Mintz et al., 2009; Surdeanu et al., 2012; Min et al., 2013; Angeli et al., 2014; Zeng et al., 2015; Quirk and Poon, 2017; Qin et al., 2018; Wang et al., 2018a) through knowledge bases (KBs), where entities and static relations are plentiful. Distant supervision is less applicable for the task of event extraction because very few dynamic events are included in KBs. These approaches, however, incorporate language-specific characteristics and thus are costly in requiring substantial amount of annotations to adapt to a new language (Chen and Vincent, 2012; Blessing and Schütze, 2012; Li et al., 2012; Danilova et al., 2014; Agerri et al., 2016; Hsi et al., 2016; Feng et al., 2016).

Regardless of the recent successes in applying cross-lingual transfer learning to sequence labeling tasks, such as name tagging (e.g., (Mayhew et al., 2017; Lin et al., 2018; Huang et al., 2019)), only limited work has explored cross-lingual relation and event structure transfer. Most previous efforts working with cross-lingual structure trans-

fer rely on bilingual dictionaries (Hsi et al., 2016), parallel data (Chen and Ji, 2009; Kim et al., 2010; Qian et al., 2014) or machine translation (Faruqui and Kumar, 2015; Zou et al., 2018). Recent methods (Lin et al., 2017; Wang et al., 2018b) aggregate consistent patterns and complementary information across languages to enhance Relation Extraction, but they do so exploiting only distributional representations.

Event extraction shares with Semantic Role Labeling (SRL) the task of assigning to each event argument its event role label, in the process of completing other tasks to extract the full event structure (assigning event types to predicates and more specific roles to arguments). Cross-lingual transfer has been very successful for SRL. Early attempts relied on word alignment (Van der Plas et al., 2011) or bilingual dictionaries (Kozhevnikov and Titov, 2013). Recent work incorporates universal dependencies (Prazák and Konopík, 2017) or multilingual word embeddings for Polyglot SRL (Mulcaire et al., 2018). Liu et al. (2019) and Mulcaire et al. (2019) exploit multi-lingual contextualized word embedding for SRL and other Polyglot NLP tasks including dependency parsing and name tagging. To the best of our knowledge, our work is the first to construct a cross-lingual structure transfer framework that combines language-universal symbolic representations and distributional representations for relation and event extraction over texts written in a language without any training data.

GCN has been successfully applied to several individual monolingual NLP tasks, including relation extraction (Zhang et al., 2018b), event detection (Nguyen and Grishman, 2018), SRL (Marcheggiani and Titov, 2017) and sentence classification (Yao et al., 2019). We apply GCN to construct multi-lingual structural representations for cross-lingual transfer learning.

5 Conclusions and Future Work

We show how cross-lingual relation and event argument structural representations may be transferred between languages without any training data for the target language, and conclude that language-universal symbolic and distributional representations are complementary for cross-lingual structure transfer. In the future we will explore more language-universal representations such as visual features from topically-related images and videos and external background knowledge.

Abstract

Distant supervision for relation extraction enables one to effectively acquire structured relations out of very large text corpora with less human efforts. Nevertheless, most of the prior-art models for such tasks assume that the given text can be noisy, but their corresponding labels are clean. Such unrealistic assumption is contradictory with the fact that the given labels are often noisy as well, thus leading to significant performance degradation of those models on real-world data. To cope with this challenge, we propose a novel label-denoising framework that combines neural network with probabilistic modelling, which naturally takes into account the noisy labels during learning. We empirically demonstrate that our approach significantly improves the current art in uncovering the ground-truth relation labels.

1 Introduction

Relation extraction aims at automatically extracting semantic relationships from a piece of text. Consider the sentence "Larry Page, the chief executive officer of Alphabet, Google's parent company, was born in East Lansing, Michigan.". The knowledge triple (*Larry_Page*, *employed_by*, *Google*) can be extracted. Despite various efforts in building relation extraction models (Zelenko et al., 2002; Zhou et al., 2005; Bunescu and Mooney, 2005; Zeng et al., 2014; dos Santos et al., 2015; Yang et al., 2016; Liu et al., 2015; Xu et al., 2015; Miwa and Bansal, 2016; Gábor et al., 2018), the difficulty of obtaining abundant training data with labelled relations remains a challenge, and thus motivates the development of *Distant Supervision* relation extraction (Mintz et al., 2009; Riedel et al., 2010; Zeng et al., 2015; Lin et al., 2016; Ji et al., 2017; Zeng et al., 2018; Feng et al., 2018; Wang et al., 2018b,a; Hoffmann et al., 2011; Surdeanu et al., 2012; Jiang et al., 2016; Ye et al., 2017; Su et al., 2018; Qu et al., 2018). Distant supervision (DS) relation extract methods collect a large dataset with "distant" supervision signal and learn a relation predictor from such data. In detail, each example in the dataset contains a collection, or *bag*, of sentences all involving the same pair of entities extracted from some corpus (e.g., news reports). Although such a dataset is expected to be very noisy, one hopes that when the dataset is large enough, useful correspondence between the semantics of a sentence and the relation label it implies still reinforces and manifests itself. Despite their capability of learning from large scale data, we show in this paper that these DS relation extraction strategies fail to adequately model the characteristic of the noise in the data. Specifically, most of the works fail to recognize that the labels can be noisy in a bag and directly use bag labels as training targets.

This aforementioned observation has inspired us to study a more realistic setting for DS relation extraction. That is, we treat the bag labels as the noisy observations of the ground-truth labels. To that end, we develop a novel framework that jointly models the semantics representation of the bag, the latent ground truth labels, and the noisy observed labels. The framework, probabilistic in nature, allows any neural network, that encodes the bag semantics, to nest within. We show that the well-known Expectation-Maximization (EM) algorithm can be applied to the end-to-end learning of the models built with this framework. As such, we term the framework *Neural Expectation-Maximization*, or the *nEM*.

Since our approach deviates from the conventional models and regards bag labels not as the ground truth, bags with the real ground-truth la-

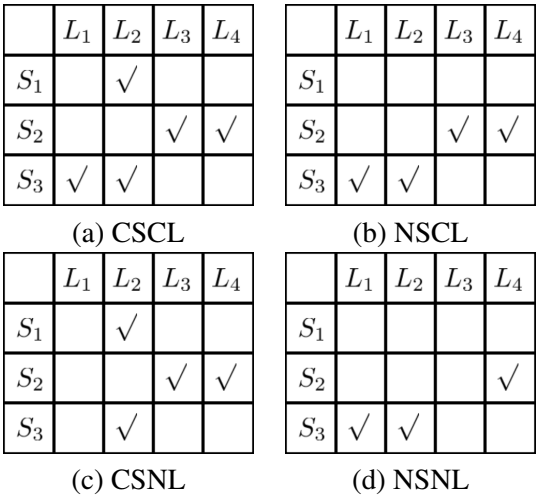

Figure 1: Assumptions on the cleanness of DS dataset. In each matrix, rows correspond to the sentences in a bag, and columns correspond to the labels assigned to the bag. A check mark on (S_i, Lj) indicates that the label L_j is supported by sentence S_i.

bels are required for evaluating our model. To that end, we manually re-annotate a fraction of the testing bags in a standard DS dataset with their real ground-truth labels. We then perform extensive experiments and demonstrate that the proposed nEM framework improves the current state-of-the-art models in uncovering the ground truth relations. To the best of our knowledge, this work is the first that combines a neural network model with EM training under the "noisy-sentence noisy-label" assumption. The re-annotated testing dataset [1], containing the ground-truth relation labels, would also benefit the research community.

2 Problem Statement

Let set $\mathcal{R}$ contain all relation labels of interest. Specifically, each label r in $\mathcal{R}$ corresponds to a candidate relation in which any considered pair (e, e') of entities may participate. Since $\mathcal{R}$ cannot contain all relations that are implied in a corpus, we include in $\mathcal{R}$ an additional relation label "NA", which refers to any relation that cannot be regarded as the other relations in $\mathcal{R}$.

Any subset of $\mathcal{R}$ will be written as a $\{0, 1\}$-valued vector of length $|\mathcal{R}|$, for example, z, where each element of the vector z corresponds to a label $r \in \mathcal{R}$. Specifically, if and only if label r is contained in the subset, its corresponding element $z[r]$ of z equals 1. If two entities e and e' participate in a relation r, we say that the triple (e, r, e') is factual. Let $\mathcal{B}$ be a finite set, in which each $b \in \mathcal{B}$ is a pair (e, e') of entities. Each $b = (e, e') \in \mathcal{B}$ serves as the index for a *bag* x_b of sentences.

The objective of DS is to use a large but noisy training set to learn a predictor that predicts the relations involving two arbitrary (possibly unseen) entities; the predictor takes as input a bag of sentences each containing the two entities of interest, and hopefully outputs the set of all relations in which the two entities participate.

3 Prior Art and Related Works

Relation extraction is an important task in natural language processing. Many approaches with supervised methods have been proposed to complete this task. These works, such as (Zelenko et al., 2002; Zhou et al., 2005; Bunescu and Mooney, 2005), although achieving good performance, rely on carefully selected features and well labelled dataset. Recently, neural network models, have been used in (Zeng et al., 2014; dos Santos et al., 2015; Yang et al., 2016; Liu et al., 2015; Xu et al., 2015; Miwa and Bansal, 2016) for supervised relation extraction. These models avoid feature engineering and are shown to improve upon previous models. But having a large number of parameters to estimate, these models rely heavily on costly human-labeled data.

Distant supervision was proposed in (Mintz et al., 2009) to automatically generate large dataset through aligning the given knowledge base to text corpus. However, such dataset can be quite noisy. To articulate the nature of noise in DS dataset, a sentence is said to be *noisy* if it supports no relation labels of the bag, and a label of the bag is said to be *noisy* if it is not supported by any sentence in the bag. A sentence or label that is not noisy will be called *clean*. The cleanness of a training example may obey the following four assumptions, for each of which an example is given In Figure 1.

- **Clean-Sentence Clean-Label (CSCL)**: All sentences and all labels are clean (Figure 1(a)).
- **Noisy-Sentence Clean-Label (NSCL)**: Some sentences may be noisy but all labels are clean (Figure 1(b)). Note that CSCL is a special case of NSCL.
- **Clean-Sentence Noisy-Label (CSNL)**: All sentences are clean but some labels may be noisy(Figure 1(c)). Note that CSNL includes CSCL as a special case.

[1] Will be released upon the acceptance of the paper

- **Noisy-Sentence Noisy-Label (NSNL)**: Some sentences may be noisy and some labels may also be noisy (Figure 1(d)).

Obviously, CSCL, NSCL, CSNL are all special cases of NSNL. Thus NSNL is the most general among all these assumptions.

The author of (Mintz et al., 2009) creates a model under the CSCL assumption, which is however pointed out a too strong assumption (Riedel et al., 2010). To alleviate this issue, many studies adopt NSCL assumption. Some of them, including (Riedel et al., 2010; Zeng et al., 2015; Lin et al., 2016; Ji et al., 2017; Zeng et al., 2018; Feng et al., 2018; Wang et al., 2018b,a), formulate the task as a multi-instance learning problem where only one label is allowed for each bag. These works take sentence denoising through selecting the max-scored sentence (Riedel et al., 2010; Zeng et al., 2015, 2018), applying sentence selection with soft attention (Lin et al., 2016; Ji et al., 2017), performing sentence level prediction as well as filtering noisy bags (Feng et al., 2018) and redistributing the noisy sentences into negative bags (Wang et al., 2018b,a). Other studies complete this task with multi-instance multi-label learning (Hoffmann et al., 2011; Surdeanu et al., 2012; Jiang et al., 2016; Ye et al., 2017; Su et al., 2018), which allow overlapping relations in a bag. Despite the demonstrated successes, these models ignore the fact that relation labels can be noisy and "noisy" sentences that indeed point to factual relations may also be ignored. Two recent approaches (Liu et al., 2017; Luo et al., 2017) using the NSNL assumption have also been introduced, but these methods are evaluated based on the assumption that the evaluation labels are clean.

We note that this paper is not the first work that combines neural networks with EM training. Very recently, a model also known as Neural Expectation-Maximization or NEM (Greff et al., 2017) has been presented to learn latent representations for clusters of objects (e.g., images) under a complete unsupervised setting. The NEM model is not directly applicable to our problem setting which deals with noisy supervision signals from categorical relation labels. Nonetheless, given the existence of the acronym NEM, we choose to abbreviate our Neural Expecation-Maximization model as the nEM model.

4 The nEM Framework

We first introduce the nEM architecture and its learning strategy, and then present approaches to encode a bag of sentences (i.e., the Bag Encoding Models) needed by the framework.

4.1 The nEM Architecture

Let random variable X denote a random bag and random variable Z denote the label set assigned to X. Under the NSNL assumption, Z, or some labels within, may not be clean for X. We introduce another latent random variable Y, taking values as a subset of $\mathcal{R}$, indicating the set of ground-truth (namely, clean) labels for X. We will write Y again as an $|\mathcal{R}|$-dimensional $\{0,1\}$-valued vector. From here on, we will adopt the convention that a random variable will be written using a capitalized letter, and the value it takes will be written using the corresponding lower-cased letter.

A key modelling assumption in nEM is that random variables X, Y and Z form a Markov chain $X \rightarrow Y \rightarrow Z$. Specifically, the dependency of noisy labels Z on the bag X is modelled as

$$p_{Z|X}(z|x) := \sum_{y \in \{0,1\}^{|\mathcal{R}|}} p_{Y|X}(y|x) p_{Z|Y}(z|y) \quad (1)$$

The conditional distribution $p_{Z|Y}$ is modelled as

$$p_{Z|Y}(z|y) \quad := \quad \prod_{r \in \mathcal{R}} p_{Z[r]|Y[r]}\left(z[r]|y[r]\right) \quad (2)$$

That is, for each ground-truth label $r \in \mathcal{R}$, $Z[r]$ depends only on $Y[r]$. Furthermore, we assume that for each r, there are two parameters ϕ_r^0 and ϕ_r^1 governing the dependency of $Z[r]$ on $Y[r]$ via

$$p_{Z[r]|Y[r]}(z[r]|y[r]) := \begin{cases} \phi_r^0 & y[r]=0, z[r]=1 \\ 1-\phi_r^0 & y[r]=0, z[r]=0 \\ \phi_r^1 & y[r]=1, z[r]=0 \\ 1-\phi_r^1 & y[r]=1, z[r]=1 \end{cases} \quad (3)$$

We will denote by $\{\phi_r^0, \phi_r^1 : r \in \mathcal{R}\}$ collectively by ϕ. .

On the other hand, we model $p_{Y|X}$ by

$$p_{Y|X}(y|x) := \prod_{r \in \mathcal{R}} p_{Y[r]|X}\left(y[r]|\overline{x}\right) \quad (4)$$

where $\overline{x}$ is the encoding of bag x, implemented using any suitable neural network. Postponing explaining the details of bag encoding to a later

section (namely Section 4.3), we here specify the form of $p_{Y[r]|X}\left(y[r]|\overline{x}\right)$ for each r:

$$p_{Y[r]|X}\left(1|\overline{x}\right) = \sigma\left(\overline{r}^T\overline{x} + b_r\right) \tag{5}$$

where $\sigma(\cdot)$ is the sigmoid function, $\overline{r}$ is a $|\mathcal{R}|$-dimensional vector and b_r is bias. That is, $p_{Y[r]|X}$ is essentially a logistic regression (binary) classifier based on the encoding $\overline{x}$ of bag x. We will denote by θ the set of all parameters $\{\overline{r} : r \in \mathcal{R}\}$ and the parameters for generating encoding $\overline{x}$.

At this end, we have defined the overall structure of the nEM framework (summarized in Figure 2). Next, we will discuss the learning of it.

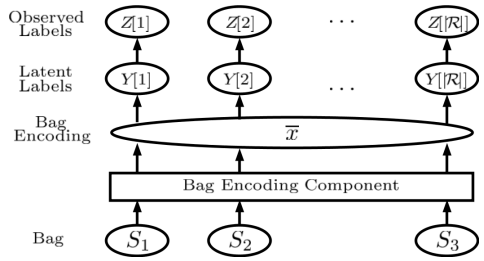

Figure 2: The probabilistic framework of nEM

4.2 Learning with the EM Algorithm

Let $\ell(z|x;\phi,\theta)$ be the log-likelihood of observing the label set z given the bag x, that is,

$$\ell(z|x;\phi,\theta) := \log p_{Z|X}(z|x). \tag{6}$$

The structure of the framework readily enables a principled learning algorithm based on the EM algorithm (Dempster et al., 1977).

Let $\ell_{\text{total}}(\phi,\theta)$ be the log-likelihood defined as

$$\ell_{\text{total}}(\phi,\theta) \;:=\; \sum_{b\in\mathcal{B}} \ell(z_b|x_b;\phi,\theta). \tag{7}$$

The learning problem can then be formulated as maximizing this objective function over its parameters (ϕ,θ), or solving

$$(\widehat{\phi},\widehat{\theta}) := \arg\max_{\phi,\theta} \ell_{\text{total}}(\phi,\theta). \tag{8}$$

Let Q be an arbitrary distribution over $\{0,1\}^{|\mathcal{R}|}$. Then it is possible to show

$$\begin{aligned}
&\ell(z|x;\phi,\theta)\\
&= \log \sum_{y\in\{0,1\}^{|\mathcal{R}|}} Q(y) \frac{\prod_{r\in\mathcal{R}} p_{Y[r]|X}(y[r]|\overline{x}) p_{Z[r]|Y[r]}(z[r]|y[r])}{Q(y)}\\
&\geqslant \sum_{y\in\{0,1\}^{|\mathcal{R}|}} Q(y) \log \frac{\prod_{r\in\mathcal{R}} p_{Y[r]|X}(y[r]|\overline{x}) p_{Z[r]|Y[r]}(z[r]|y[r])}{Q(y)}\\
&= \mathcal{L}(z|x;\phi,\theta,Q)
\end{aligned} \tag{9}$$

where the lower bound $\mathcal{L}(z|x;\phi,\theta,Q)$, often referred to as the variational lower bound. Now we define $\mathcal{L}_{\text{total}}$ as

$$\mathcal{L}_{\text{total}}(\phi,\theta,\{Q_b : b\in\mathcal{B}\}) := \sum_{b\in\mathcal{B}} \mathcal{L}\left(z_b|x_b;\phi,\theta,Q_b\right) \tag{10}$$

where we have introduced a Q_b for each $b \in \mathcal{B}$. Instead of solving the original optimization problem (8), we can turn to solving a different optimization problem by maximizing $\mathcal{L}_{\text{total}}$

$$(\widehat{\phi},\widehat{\theta},\{\widehat{Q_b}\}) := \arg\max_{\phi,\theta,\{Q_b\}} \mathcal{L}_{\text{total}}(\phi,\theta,\{Q_b\}) \tag{11}$$

The EM algorithm for solving the optimization problem (11) is essentially the coordinate ascent algorithm on objective function $\mathcal{L}_{\text{total}}$, where we iterate over two steps, the E-Step and the M-Step. In the E-Step, we maximizes $\mathcal{L}_{\text{total}}$ over $\{Q_b\}$ for the current setting of (ϕ,θ) and in the M-Step, we maximize $\mathcal{L}_{\text{total}}$ (ϕ,θ) for the current setting of $\{Q_b\}$. We now describe the two steps in detail, where we will use superscript t to denote the iteration number.

E-step: In this step, we hold (ϕ,θ) fixed and update $\{Q_b : b\in\mathcal{B}\}$ to maximize the lower bound $\mathcal{L}_{\text{total}}(\phi,\theta,\{Q_b\})$. This boils down to update each factor $Q_{b,r}$ of Q_b according to:

$$\begin{aligned}
Q_{b,r}^{t+1}(y[r]) &:= p_{Y[r]|X,Z}(y_b[r]|x_b, z_b[r]; \theta^t, \phi_r^t)\\
&= \frac{p_{Z|Y}(z_b[r]|y_b[r];\phi_r^t) p_{Y|X}(y_b[r]|x_b;\theta^t)}{p_{Z|X}(z_b[r]|x_b;\theta^t,\phi_r^t)}\\
&= \frac{p_{Z|Y}(z_b[r]|y_b[r];\phi_r^t) p_{Y|X}(y_b[r]|x_b;\theta^t)}{\sum_{y[r]\in\{0,1\}} p_{Z|Y}(z_b[r]|y[r];\phi_r^t) p_{Y|X}(y[r]|x_b;\theta^t)}
\end{aligned} \tag{12}$$

M-step: In this step, we hold $\{Q_b\}$ fixed and update (ϕ,θ), to maximize the lower bound $\mathcal{L}_{\text{total}}(\phi,\theta,\{Q_b\})$. Let

$$M = \prod_{r\in\mathcal{R}} p_{Y[r]|X}(y_b[r]|\overline{x}_b) p_{Z[r]|Y[r]}(z_b[r]|y_b[r]), \tag{13}$$

then (ϕ,θ) is updated according to:

$$\begin{aligned}
&(\theta^{t+1},\phi^{t+1}) := \operatorname*{argmax}_{\theta,\phi} \mathcal{L}_{\text{total}}(\theta,\phi,\{Q_b^{t+1}\})\\
&= \operatorname*{argmax}_{\theta,\phi} \sum_{b\in\mathcal{B}} \sum_{y_b\in\{0,1\}^{|\mathcal{R}|}} Q_b^{t+1}(y) \log \frac{M}{Q_b^{t+1}(y)}\\
&= \operatorname*{argmax}_{\theta,\phi} \sum_{b\in\mathcal{B}} \sum_{y_b\in\{0,1\}^{|\mathcal{R}|}} Q_b^{t+1}(y) \log M - \sum_{b\in\mathcal{B}} \sum_{y_b\in\{0,1\}^{|\mathcal{R}|}} Q_b^{t}(y) \log Q_b^{t+1}(y)\\
&= \operatorname*{argmax}_{\theta,\phi} \sum_{b\in\mathcal{B}} \sum_{r\in\mathcal{R}} \sum_{y_b[r]\in\{0,1\}} Q_{b,r}^{t+1}(y[r]) \big(\log p_{Z|Y}(z_b[r]|y_b[r];\phi_r)\\
&\quad + \log p_{Y|X}(y_b[r]|\overline{x}_b;\theta)\big)
\end{aligned} \tag{14}$$

Overall the EM algorithm starts with initializing $(\phi, \theta, \{Q_b\})$, and then iterates over the two steps until convergence or after some prescribed number of iterations is reached. There are however several caveats on which caution is needed. First, the optimization problem in the M-Step cannot be solved in closed form. As such we take a stochastic gradient descent (SGD) approach[2].

In each M-Step, we perform Δ updates, where Δ is a hyper-parameter. Such an approach is sometimes referred to as "Generalized EM" (Wu, 1983; Jojic and Frey, 2001; Greff et al., 2017). Note that since the parameters θ are parameters for the neural network performing bag encoding, the objective function $\mathcal{L}_{\text{total}}$ is highly non-convex with respect to θ. This makes it desirable to choose an appropriate Δ. Too small Δ results in little change in θ and hence provides insufficient signal to update $\{Q_b\}$; too large Δ, particularly at the early iterations when $\{Q_b\}$ has not been sufficiently optimized, tends to make the optimization stuck in undesired local optimum. In practice, one can try several values of Δ by inspecting their achieved value of $\mathcal{L}_{\text{total}}$ and select the Δ giving rise to the highest $\mathcal{L}_{\text{total}}$. Note that such a tuning of Δ requires no access of the testing data. The second issue is that the EM algorithm is known to be sensitive to initialization. In our implementation, in order to provide a good initial parameter setting, we set each Q_b^0 to z_b. Despite the fact that z contains noise, this is a much better approximation of the posterior of true labels than any random initialization.

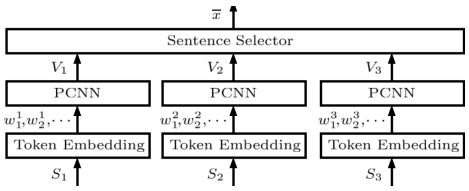

Figure 3: The structure of Bag Encoding component.

The nEM framework needs the encoding of a bag of x as discussed in Equation 4. Any suitable neural network can be deployed to achieve this goal. Next, we present the widely used methods for DS relation extraction strategies: the Bag Encoding Models.

[2]In fact, the approach should be called "stochastic gradient ascent", since we are maximizing the objective function not minimizing it.

4.3 Bag Encoding Models

As illustrated in Figure 3, the Bag Encoding Models include three components: Word-Position Embedding, Sentence Encoding, and Sentence Selectors.

4.3.1 Word-Position Embedding

For the j^{th} word in a sentence, Word-Position Embedding generates a vector representation $\mathbf{w}_j$ as concatenated three components $\left[\mathbf{w}_j^w, \mathbf{w}_j^{p1}, \mathbf{w}_j^{p2}\right]$. Specifically, $\mathbf{w}_j^w$ is the word embedding of the word and $\mathbf{w}_j^{p1}$ and $\mathbf{w}_j^{p2}$ are two position embeddings. Here $\mathbf{w}_j^{p1}$ (resp. $\mathbf{w}_j^{p2}$) are the embedding of the relative location of the word with respect to the first (resp. second) entity in the sentence. The dimensions of word and position embeddings are denoted by d_w and d_p respectively.

4.3.2 Sentence Encoding

Sentence encoding uses Piecewise Convolutional Neural Networks (PCNN) (Zeng et al., 2015; Lin et al., 2016; Ye et al., 2017; Ji et al., 2017), which consists of convolution followed by Piecewise Max-pooling. The convolution operation uses a list of matrix kernels such as $\{\mathbf{K}_1, \mathbf{K}_2, \cdots, \mathbf{K}_{l_{ker}}\}$ to extract *n-gram* features through sliding windows of length l_{win}. Here $\mathbf{K}_i \in \mathbb{R}^{l_{win} \times d_e}$ and l_{ker} is the number of kernels. Let $\mathbf{w}_{j-l_{win}+1:j} \in \mathbb{R}^{l_{win} \times d_e}$ be the concatenated vector of token embeddings in the j^{th} window. The output of convolution operation is a matrix $\mathbf{U} \in \mathbb{R}^{l_{ker} \times (m+l_{win}-1)}$ where each element is computed by

$$\mathbf{U}_{ij} = \mathbf{K}_i \odot \mathbf{w}_{j-l_{win}+1:j} + b_i \qquad (15)$$

where $\odot$ denotes inner product. In Piecewise Max-Pooling, $\mathbf{U}_i$ is segmented to three parts $\left\{\mathbf{U}_i^1, \mathbf{U}_i^2, \mathbf{U}_i^3\right\}$ depending on whether an element in $\mathbf{U}_i$ is on the left or right of the two entities, or between the two entities. Then max-pooling is applied to each segment, giving rise to

$$\mathbf{g}^{ip} = \max(\mathbf{U}_i^p), 1 \leqslant i \leqslant l_{ker}, 1 \leqslant p \leqslant 3 \qquad (16)$$

Let $\mathbf{g} = \left[\mathbf{g}^1, \mathbf{g}^2, \mathbf{g}^3\right]$. Then sentence encoding outputs

$$\mathbf{v} = \text{ReLU}(\mathbf{g}) \circ \mathbf{h}, \qquad (17)$$

where $\circ$ is element-wise multiplication and $\mathbf{h}$ is a vector of Bernoulli random variables, representing dropouts.

4.3.3 Sentence Selectors

Let n be the number of sentences in a bag. We denote a matrix $\mathbf{V} \in \mathbb{R}^{n\times(l_{ker}\times 3)}$consisting of each sentence vector $\mathbf{v}_T$. $\mathbf{V}_{k:}$ and $\mathbf{V}_{:j}$ are used to index the k^{th} row vector and j^{th} column vector of $\mathbf{V}$ respectively. Three kinds of sentence-selectors are used to construct the bag encoding. Mean-selector (Lin et al., 2016; Ye et al., 2017): The bag encoding is computed as

$$\overline{x} = \frac{1}{n}\sum_{k=1}^{n}\mathbf{V}_{k:} \tag{18}$$

Max-selector (Jiang et al., 2016): The j^{th} element of bag encoding $\overline{x}$ is computed as

$$\overline{x}_j = \max(\mathbf{V}_{:j}) \tag{19}$$

Attention-selector Attention mechanism is extensively used for sentence selection in relation extraction by weighted summing of the sentence vectors, such as in (Lin et al., 2016; Ye et al., 2017; Su et al., 2018). However, all these works assume that the labels are *correct* and only use the golden label embeddings to select sentences at training stage. We instead selecting sentences using all label embeddings $\overline{r}$ and construct a bag encoding for each label $r \in \mathcal{R}$. The output is then a list of vectors $\{\overline{x}^r\}$, in which the r^{th} vector is calculated through attention mechanism as

$$e_l = \mathbf{V}_{l:}^T\mathbf{A}\overline{r},\ \alpha_k = \frac{\exp(e_k)}{\sum_{l=1}^{n}\exp(e_l)},\ \overline{x}^r = \sum_{k=1}^{n}\alpha_k\mathbf{V}_{k:} \tag{20}$$

where $\mathbf{A} \in \mathbb{R}^{d_r\times d_r}$ is a diagonal matrix and d_r is the dimension of relation embedding.

5 Experimental Study

We first conduct experiments on the widely used benchmark data set Riedel (Riedel et al., 2010), and then on the TARCED (Zhang et al., 2017) data set. The latter allows us to control the noise level in the labels to observe the behavior and working mechanism of our proposed method. The code for our model is found on the Github page [3].

5.1 Evaluation on the Riedel Dataset

The Riedel dataset[2] is a widely used DS dataset for relation extraction. It was developed in (Riedel et al., 2010) through aligning entity pairs from Freebase with the New York Times (NYT) corpus. There are 53 relations in the Riedel dataset, including "*NA*". The bags collected from the 2005-2006 corpus are used as the training set, and the bags from the 2007 corpus are used as the test set. The training data contains $281,270$ entity pairs and $522,611$ sentences; the testing data contains $96,678$ entity pairs and $172,448$ sentences.

5.1.1 Ground-Truth Annotation

The Riedel dataset contains no ground-truth labels. The held-out evaluation (Mintz et al., 2009) is highly unreliable in measuring a model's performance against the ground truth. Since this study is concerned with discovering the ground-truth labels, the conventional held-out evaluation is no longer appropriate. For this reason, we annotate a subset of the original test data for evaluation purpose. Specifically, we annotate a bag x_b by its all correct labels, and if no such labels exist, we label the bag NA.

In total 3762 bags are annotated, which include all bags originally labelled as non-NA ("Part 1") and 2000 bags ("Part 2") selected from the bags originally labelled as NA but have relatively low score for NA label under a pre-trained PCNN+ATT (Lin et al., 2016) model. The rationale here is that we are interested in inspecting the model's performance in detecting the labels of known relations rather than NA relation.

Table 1: The statistics of ground-truth annotation. *origin* denotes the total number of originally assigned labels of these bags. *correct* and *wrong* denote the total number of correctly assigned and wrongly assigned labels. *added* denote the number of missing labels we added into these bags.

	bags	origin	correct	wrong	added
Part 1	1762	1953	1245	708	804
Part 2	2000	2000	938	1062	1211

The statistics of annotation is shown in Table 1. Through the annotation, we notice that, about 36% of the original labels in original non-NA bags and 53% of labels in original NA bags are wrongly assigned. Similar statistics has been reported in previous works (Riedel et al., 2010; Feng et al., 2018).

5.1.2 Evaluation Metrics and Baselines

For the Riedel dataset, we train the models on the noisy training set and test the models on the manually labeled test set. The precision-recall (PR)

[3] https://github.com/AlbertChen1991/nEM
[2] http://iesl.cs.umass.edu/riedel/ecml/

curve is reported to compare performance of models. Three baselines are considered:

- PCNN+MEAN (Lin et al., 2016; Ye et al., 2017): A model using PCNN to encode sentences and a mean-selector to generate bag encoding.
- PCNN+MAX (Jiang et al., 2016): A model using PCNN to encode sentences and a max-selector to generate bag encoding.
- PCNN+ATT (Lin et al., 2016; Ye et al., 2017; Su et al., 2018): A model using PCNN to encode sentences and an attention-selector to generate bag encoding.

We compare the three baselines with their nEM versions (namely using them as the Bag Encoding component in nEM), which are denoted with a "+nEM" suffix.

5.1.3 Implementation Detail

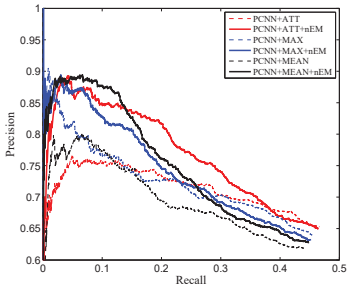
Following previous work, we tune our models using three-fold validation on the training set. As the best configurations, we set $d_w = 50$, $d_p = 5$ and $d_r = 230$. For PCNN, we set $l_{win} = 3$, $l_{ker} = 230$ and set the probability of dropout to 0.5. We use Adadelta (Zeiler, 2012) with default setting ($\rho = 0.95, \varepsilon = 1e^{-6}$) to optimize the models and the initial learning rate is set as 1. The batch size is fixed to 160 and the max length of a sentence is set as 120.

For the noise model $p_{Z|Y}$, we set $\phi^0_{NA} = 0.3, \phi^1_{NA} = 0$ for the NA label and $\phi^0_r = 0, \phi^1_r = 0.9$ for other labels $r \neq NA$. In addition, the number Δ of SGD updates in M-step is set to 2000.

5.1.4 Predictive performance

The evaluation results on manually labeled test set are shown in Figure 4. From which, we observe that the PR-curves of the nEM models are above their corresponding baselines by significant margins, especially in the low-recall regime. This observation demonstrates the effectiveness of the nEM model on improving the extracting performance upon the baseline models. We also observe that models with attention-selector achieve better performance than models with mean-selector and max-selector, demonstrating the superiority of the attention mechanism on sentence selection.

We then analyze the predicting probability of PCNN+ATT and PCNN+ATT+nEM on the ground-truth labels in the test set. We divide the predicting probability values into 5 bins and



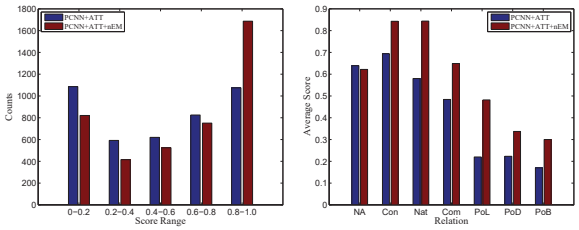


Figure 4: PR curves on DS test set.

count the number of label within each bin. The result is shown in Figure 5(a). We observe that the count for PCNN+ATT in bins $0.0 - 0.2$, $0.2 - 0.4$, $0.4 - 0.6$ and $0.6 - 0.8$ are all greater than PCNN+ATT+nEM. But in bin $0.8 - 1.0$, the count for PCNN+ATT+nEM is about 55% larger than PCNN+ATT. This observation indicates that nEM can promote the overall predicting scores of ground-truth labels.

Figure 5(b) compares PCNN+ATT and PCNN+ATT+nEM in their predictive probabilities on the frequent relations. The result shows that PCNN+ATT+nEM achieves higher average predicting probability on all these relations, except for the NA relation, on which PCNN+ATT+nEM nearly levels with PCNN+ATT. This phenomenon demonstrates that nEM tends to be more confident in predicting the correct labels. In this case, raising the predictive probability on the correct label does increase the models ability to make the correct decision, thereby improving performance.

(a) Score distribution (b) Scores on main relations

Figure 5: Predictive probabilities on the test set. CON, Nat, Com, PoL, PoD and PoB represent 'contains', 'nationality', 'company', 'place lived', 'place of death' and 'place of birth' relations respectively.

5.2 Evaluation on the TACRED Dataset

TACRED is a large supervised relation extraction dataset collected in (Zhang et al., 2017). The text corpus is generated from the TAC KBP evaluation of years 2009 – 2015. Corpus from years

$2009 - 2012$, year 2013 and year 2014 are used as training, validation and testing sets respectively. In all annotated sentences, $68,124$ are used for training, $22,631$ for validation and $15,509$ for testing. There are in total $42,394$ *distinct* entity pairs, where $33,079$ of these entity pairs appear in exactly one sentence. Since these $33,079$ entity pairs dominate the training set, we simply treat each sentence as a bag for training and testing. Another advantage of constructing single-sentence bags is that it allows us to pinpoint the correspondence between the correct label and its supporting sentence. The number of relations in TACRED dataset is 42, including a special relation "*no relation*", which is treated as NA in this study.

5.2.1 Constructing Semi-synthetic Dataset

To obtain insight into the working of nEM, we create a simulated DS dataset by inserting noisy labels into the training set of a supervised dataset, TACRED. Since the training set of TACRED was manually annotated, the labels therein may be regarded as the ground-truth labels. Training using this semi-synthetic dataset allows us to easily observe models' behaviour with respect to the noisy labels and the true labels.

We inject artificial noise into the TACRED training data through the following precedure. For each bag x_b in the training set, we generate a noisy label vector $\tilde{z}_b$ from the observed ground-truth label vector y_b. Specifically, $\tilde{z}_b$ is generated by flipping each element $y_b[r]$ from 0 to 1 or 1 to 0 with a probability p_f. This precedure simulates a DS dataset through introducing wrong labels into training bags, thus corrupts the training dataset.

5.2.2 Experimental Settings

Following (Zhang et al., 2017), the common relation classification metrics Precision, Recall and F1 are used for evaluation. The PCNN model is used to generate the bag encoding since sentence selection is not needed in this setting. The same hyperparameter settings as in Section 5.1.3 are used in this experiment. For the noise model $p_{Z[r]|Y[r]}$ of PCNN +nEM, we set $\phi_r^0 = 0.1, \phi_r^1 = 0.1$ for each label $r \in \mathcal{R}$. The number Δ of SGD updates in each M-step is set to 1600.

5.2.3 Test Results

From Table 2, we see that PCNN+nEM achieves better recall and F1 score than the PCNN model under various noise levels. Additionally, the recall and F1 margins between PCNN and PCNN+nEM increase with noise levels. This suggests that nEM keeps better performance than the corresponding baseline model under various level of training noise. We also observe that the precision of nEM is consistently lower than that of PCNN when noise is injected to TACRED. This is a necessary trade-off present in nEM. The training of nEM regards the training labels with less confidence based on noisy-label assumption. This effectively lowers the probability of seen training labels and considers the unseen labels also having some probability to occur. When trained this way, nEM, at the prediction time, tends to predict more labels than its baseline (PCNN) does. Note that in TACRED, each instance contains only a single ground truth label. Thus the tendency of nEM to predict more labels leads to the reduced precision. However, despite this tendency, nEM, comparing with PCNN, has a stronger capability in detecting the correct label and gives the better recall of nEM. The gain in recall dominates the loss in precision.

Table 2: Test performance on the TACRED dataset.

p_f	PCNN			PCNN+nEM		
	P	**R**	**F1**	**P**	**R**	**F1**
0.02	65.2	30.0	41.1	61.8	34.8	44.5
0.04	63.5	28.9	39.7	60.2	33.8	43.3
0.06	70.5	25.2	37.1	59.9	31.1	41.0
0.08	63.5	23.6	34.4	58.8	29.8	39.6
0.10	66.1	22.7	33.9	56.5	28.9	38.3

5.2.4 Training Label Probabilities

The predicting probabilities for the noise labels and the original true labels are also evaluated under the trained models. The results are shown in Figure 6 (left) which reveals that with increasing noise, the average probability for noisy label sets of PCNN and PCNN+nEM both increase and average scores for original label sets of PCNN and PCNN+nEM both decrease. The performance degradation of PCNN and PCNN+nEM under noise appears different. The average probability for noisy label sets rises with a higher slope in PCNN than in PCNN+nEM. Additionally, the average probability for the original label sets of PCNN+nEM is higher than or equal to PCNN at all noise levels. These observations confirms that the denoising capability of nEM is learned from effectively denoising the training set.

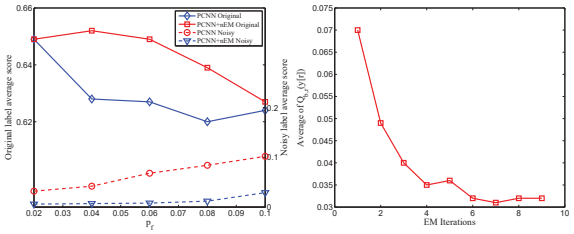

Figure 6: Average probabilities for noisy and original labels (left) and average $Q_{b,r}(y[r])$ over EM iterations (right)

5.2.5 Effectiveness of EM Iterations

For each training bag x_b and each artificial noisy label r, we track the probability $Q_{b,r}(y[r]) = 1$ over EM iterations. This probability, measuring the likelihood of the noise label r being correct, is then averaged over r and over all bags x_b. It can be seen in Figure 6 (right) that the average value of $Q_{b,r}(y[r])$ decreases as the training progresses, leading the model to gradually ignore noisy labels. This demonstrates the effectiveness of EM iterations and validates the proposed EM-based framework.

6 Concluding Remarks

We proposed a nEM framework to deal with the noisy-label problem in distance supervision relation extraction. We empirically demonstrated the effectiveness of the nEM framework, and provided insights on its working and behaviours through data with controllable noise levels. Our framework is a combination of latent variable models in probabilistic modelling with contemporary deep neural networks. Consequently, it naturally supports a training algorithm which elegantly nests the SGD training of any appropriate neural network inside an EM algorithm. We hope that our approach and the annotated clean testing data would inspire further research along this direction.

Abstract

Most existing event extraction (EE) methods merely extract event arguments within the sentence scope. However, such sentence-level EE methods struggle to handle soaring amounts of documents from emerging applications, such as finance, legislation, health, etc., where event arguments always scatter across different sentences, and even multiple such event mentions frequently co-exist in the same document. To address these challenges, we propose a novel end-to-end model, Doc2EDAG, which can generate an entity-based directed acyclic graph to fulfill the document-level EE (DEE) effectively. Moreover, we reformalize a DEE task with the no-trigger-words design to ease document-level event labeling. To demonstrate the effectiveness of Doc2EDAG, we build a large-scale real-world dataset consisting of Chinese financial announcements with the challenges mentioned above. Extensive experiments with comprehensive analyses illustrate the superiority of Doc2EDAG over state-of-the-art methods. Data and codes can be found at https://github.com/dolphin-zs/Doc2EDAG.

1 Introduction

Event extraction (EE), traditionally modeled as detecting trigger words and extracting corresponding arguments from plain text, plays a vital role in natural language processing since it can produce valuable structured information to facilitate a variety of tasks, such as knowledge base construction, question answering, language understanding, etc.

In recent years, with the rising trend of digitalization within various domains, such as finance, legislation, health, etc., EE has become an increasingly important accelerator to the development of business in those domains. Take the financial domain as an example, continuous economic growth has witnessed exploding volumes of digital financial documents, such as financial announcements in a specific stock market as Figure 1 shows, specified as *Chinese financial announcements* (ChFinAnn). While forming up a gold mine, such large amounts of announcements call EE for assisting people in extracting valuable structured information to sense emerging risks and find profitable opportunities timely.

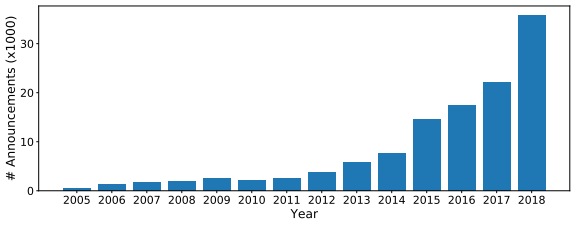

Figure 1: The rapid growth of event-related announcements considered in this paper.

Given the necessity of applying EE on the financial domain, the specific characteristics of financial documents as well as those within many other business fields, however, raise two critical challenges to EE, particularly *arguments-scattering* and *multi-event*. Specifically, the first challenge indicates that arguments of one event record may scatter across multiple sentences of the document, while the other one reflects that a document is likely to contain multiple such event records. To intuitively illustrate these challenges, we show a typical ChFinAnn document with two *Equity Pledge* event records in Figure 2. For the first event, the entity[1] "[SHARE1]" is the correct *Pledged Shares* at the sentence level (*ID 5*). However, due to the capital stock increment (*ID 7*),

[*] This work was done during the internship of Shun Zheng at Microsoft Research Asia, Beijing, China.

[1] In this paper, we use "entity" as a general notion that includes named entities, numbers, percentages, etc., for brevity.

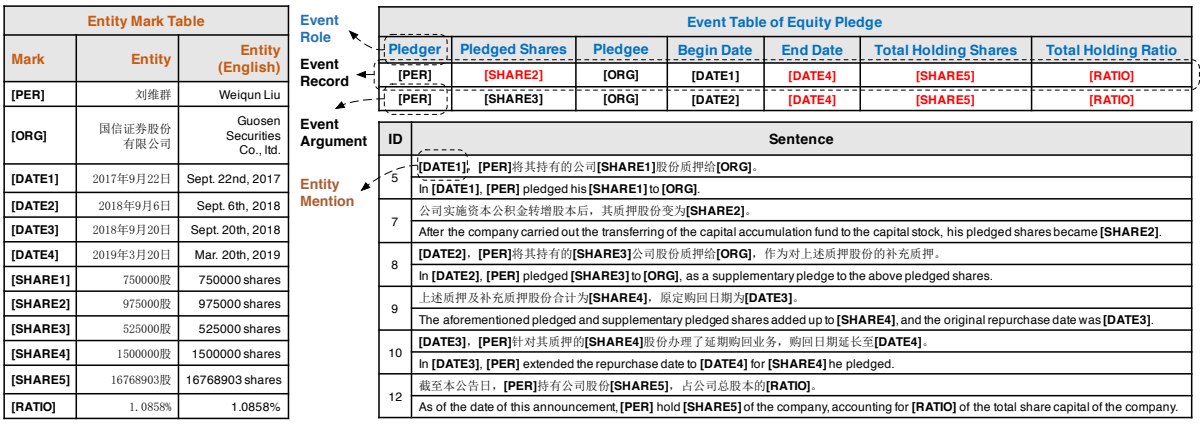

Figure 2: A document example with two *Equity Pledge* event records whose arguments scatter across multiple sentences, where we use *ID* to denote the sentence index, substitute entity mentions with corresponding marks, and color event arguments outside the scope of key-event sentences as red.

the correct *Pledged Shares* at the document level should be "[SHARE2]". Similarly, "[DATE3]" is the correct *End Date* at the sentence level (*ID 9*) but incorrect at the document level (*ID 10*). Moreover, some summative arguments, such as "[SHARE5]" and "[RATIO]", are often stated at the end of the document.

Although a great number of efforts (Ahn, 2006; Ji and Grishman, 2008; Liao and Grishman, 2010; Hong et al., 2011; Riedel and McCallum, 2011; Li et al., 2013, 2014; Chen et al., 2015; Yang and Mitchell, 2016; Nguyen et al., 2016; Liu et al., 2017; Sha et al., 2018; Zhang and Ji, 2018; Nguyen and Nguyen, 2019; Wang et al., 2019) have been put on EE, most of them are based on ACE 2005[2], an expert-annotated benchmark, which only tagged event arguments within the sentence scope. We refer to such task as the **sentence-level EE** (SEE), which obviously overlooks the *arguments-scattering* challenge. In contrast, EE on financial documents, such as ChFinAn, requires **document-level EE** (DEE) when facing *arguments-scattering*, and this challenge gets much harder when coupled with *multi-event*.

The most recent work, DCFEE (Yang et al., 2018), attempted to explore DEE on ChFinAnn, by employing *distant supervision* (DS) (Mintz et al., 2009) to generate EE data and performing a two-stage extraction: 1) a sequence tagging model for SEE, and 2) a key-event-sentence detection model to detect the key-event sentence, coupled with a heuristic strategy that padded missing arguments from surrounding sentences, for DEE. However, the sequence tagging model for SEE cannot handle multi-event sentences elegantly, and even worse, the context-agnostic arguments-completion strategy fails to address the arguments-scattering challenge effectively.

In this paper, we propose a novel end-to-end model, Doc2EDAG, to address the unique challenges of DEE. The key idea of Doc2EDAG is to transform the event table into an *entity-based directed acyclic graph* (EDAG). The EDAG format can transform the hard table-filling task into several sequential path-expanding sub-tasks that are more tractable. To support the EDAG generation efficiently, Doc2EDAG encodes entities with document-level contexts and designs a memory mechanism for path expanding. Moreover, to ease the DS-based document-level event labeling, we propose a novel DEE formalization that removes the trigger-words labeling and regards DEE as directly filling event tables based on a document. This no-trigger-words design does not rely on any predefined trigger-words set or heuristic to filter multiple trigger candidates, and still perfectly matches the ultimate goal of DEE, mapping a document to underlying event tables.

To evaluate the effectiveness of our proposed Doc2EDAG, we conduct experiments on a real-world dataset, consisting of large scales of financial announcements. In contrast to the dataset used by DCFEE where 97%[3] documents just contained one event record, our data collection is ten times larger where about 30% documents include multiple event records. Extensive experiments demonstrate that Doc2EDAG can significantly outper-

[2] https://www.ldc.upenn.edu/collaborations/past-projects/ace

[3] Estimated by their Table 1 as $\frac{2*\text{NO.ANN}-\text{NO.POS}}{\text{NO.ANN}}$.

form state-of-the-art methods when facing DEE-specific challenges.

In summary, our contributions include:

- We propose a novel model, Doc2EDAG, which can directly generate event tables based on a document, to address unique challenges of DEE effectively.
- We reformalize a DEE task without trigger words to ease the DS-based document-level event labeling.
- We build a large-scale real-world dataset for DEE with the unique challenges of *arguments-scattering* and *multi-event*, the extensive experiments on which demonstrate the superiority of Doc2EDAG.

Note that though we focus on ChFinAnn data in this work, we tackle those DEE-specific challenges without any domain-specific assumption. Therefore, our general labeling and modeling strategies can directly benefit many other business domains with similar challenges, such as criminal facts and judgments extraction from legal documents, disease symptoms and doctor instructions identification from medical reports, etc.

2 Related Work

Recent development on information extraction has been advancing in building the joint model that can extract entities and identify structures (relations or events) among them simultaneously. For instance, (Ren et al., 2017; Zheng et al., 2017; Zeng et al., 2018a; Wang et al., 2018) focused on jointly extracting entities and inter-entity relations. In the meantime, the same to the focus of this paper, a few studies aimed at designing joint models for the entity and event extraction, such as handcrafted-feature-based (Li et al., 2014; Yang and Mitchell, 2016; Judea and Strube, 2016) and neural-network-based (Zhang and Ji, 2018; Nguyen and Nguyen, 2019) models. Nevertheless, these models did not present how to handle argument candidates beyond the sentence scope. (Yang and Mitchell, 2016) claimed to handle event-argument relations across sentences with the prerequisite of well-defined features, which, unfortunately, is nontrivial.

In addition to the modeling challenge, another big obstacle for democratizing EE is the lack of training data due to the enormous cost to obtain expert annotations. To address this problem, some researches attempted to adapt distant supervision (DS) to the EE setting, since DS has shown promising results by employing knowledge bases to automatically generate training data for relation extraction (Mintz et al., 2009). However, the vanilla EE required the trigger words that were absent on factual knowledge bases. Therefore, (Chen et al., 2017; Yang et al., 2018) employed either linguistic resources or predefined dictionaries for trigger-words labeling. On the other hand, another recent work (Zeng et al., 2018b) showed that directly labeling event arguments without trigger words was also feasible. However, they only considered the SEE setting and their methods cannot be directly extended to the DEE setting, which is the main focus of this work.

Traditionally, when applying DS to relation extraction, researchers put huge efforts into alleviating labeling noises (Riedel et al., 2010; Lin et al., 2016; Feng et al., 2018; Zheng et al., 2019). In contrast, this work shows that combining DS with some simple constraints can obtain pretty good labeling quality for DEE, where the reasons are two folds: 1) both the knowledge base and text documents are from the same domain; 2) an event record usually contains multiple arguments, while a common relational fact only covers two entities.

3 Preliminaries

We first clarify several key notions: 1) **entity mention**: an entity mention is a text span that refers to an entity object; 2) **event role**: an event role corresponds to a predefined field of the event table; 3) **event argument**: an event argument is an entity that plays a specific event role; 4) **event record**: an event record corresponds to an entry of the event table and contains several arguments with required roles. For example, Figure 2 shows two event records, where the entity "[PER]" is an event argument with the *Pledger* role.

To better elaborate and evaluate our proposed approach, we leverage the ChFinAnn data in this paper. ChFinAnn documents contain firsthand official disclosures of listed companies in the Chinese stock market and have hundreds of types, such as annual reports and earnings estimates. While in this work, we focus on those event-related ones that are frequent, influential, and mainly expressed by the natural language.

4 Document-level Event Labeling

As a prerequisite to DEE, we first conduct the DS-based event labeling at the document level. More specifically, we map tabular records from an event knowledge base to document text and regard well-matched records as events expressed by that document. Moreover, we adopt a no-trigger-words design and reformalize a novel DEE task accordingly to enable end-to-end model designs.

Event Labeling. To ensure the labeling quality, we set two constraints for matched records: 1) arguments of predefined key event roles must exist (non-key ones can be empty) and 2) the number of matched arguments should be higher than a certain threshold. Configurations of these constraints are event-specific, and in practice, we can tune them to directly ensure the labeling quality at the document level. We regard records that meet these two constraints as the well-matched ones, which serve as distantly supervised ground truths. In addition to labeling event records, we assign roles of arguments to matched tokens as token-level entity tags. Note that we do not label trigger words explicitly. Besides not affecting the DEE functionality, an extra benefit of such no-trigger-words design is a much easier DS-based labeling that does not rely on predefined trigger-words dictionaries or manually curated heuristics to filter multiple potential trigger words.

DEE Task Without Trigger Words. We reformalize a novel task for DEE as directly filling event tables based on a document, which generally requires three sub-tasks: 1) **entity extraction**, extracting entity mentions as argument candidates, 2) **event detection**, judging a document to be triggered or not for each event type, and 3) **event table filling**, filling arguments into the table of triggered events. This novel DEE task is much different from the vanilla SEE with trigger words but is consistent with the above simplified DS-based event labeling.

5 Doc2EDAG

The key idea of Doc2EDAG is to transform tabular event records into an EDAG and let the model learn to generate this EDAG based on document-level contexts. Following the example in Figure 2, Figure 3 typically depicts an EDAG generation process and Figure 4 presents the overall workflow of Doc2EDAG, which consists of two key stages:

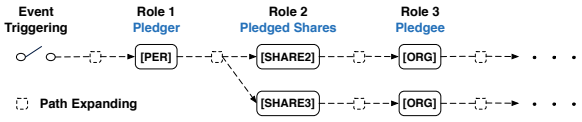

Figure 3: An EDAG generation example that starts from event triggering and expands sequentially following the predefined order of event roles.

document-level entity encoding (Section 5.1) and EDAG generation (Section 5.2). Before elaborating each of them in this section, we first describe two preconditioned modules: input representation and entity recognition.

Input Representation. In this paper, we denote a document as a sequence of sentences. Formally, after looking up the token embedding table $\boldsymbol{V} \in \mathbb{R}^{d_w \times |V|}$, we denote a document $\boldsymbol{d}$ as a sentence sequence $[\boldsymbol{s_1}; \boldsymbol{s_2}; \cdots; \boldsymbol{s_{N_s}}]$ and each sentence $\boldsymbol{s_i} \in \mathbb{R}^{d_w \times N_w}$ is composed of a sequence of token embeddings as $[\boldsymbol{w_{i,1}}, \boldsymbol{w_{i,2}}, \cdots, \boldsymbol{w_{i,N_w}}]$, where $|V|$ is the vocabulary size, N_s and N_w are the maximum lengths of the sentence sequence and the token sequence, respectively, and $\boldsymbol{w_{i,j}} \in \mathbb{R}^{d_w}$ is the embedding of j^{th} token in i^{th} sentence with the embedding size d_w.

Entity Recognition. Entity recognition is a typical sequence tagging task. We conduct this task at the sentence level and follow a classic method, BI-LSTM-CRF (Huang et al., 2015), that first encodes the token sequence and then adds a conditional random field (CRF) layer to facilitate the sequence tagging. The only difference is that we employ the Transformer (Vaswani et al., 2017) instead of the original encoder, LSTM (Hochreiter and Schmidhuber, 1997). Transformer encodes a sequence of embeddings by the multi-headed self-attention mechanism to exchange contextual information among them. Due to the superior performance of the Transformer, we employ it as a primary context encoder in this work and name the Transformer module used in this stage as Transformer-1. Formally, for each sentence tensor $\boldsymbol{s_i} \in \mathbb{R}^{d_w \times N_w}$, we get the encoded one as $\boldsymbol{h_i} = \text{Transformer-1}(\boldsymbol{s_i})$, where $\boldsymbol{h_i} \in \mathbb{R}^{d_w \times N_w}$ shares the same embedding size d_w and sequence length N_w. During training, we employ roles of matched arguments as entity labels with the classic `BIO` (Begin, Inside, Other) scheme and wrap $\boldsymbol{h_i}$ with a CRF layer to get the entity-recognition loss L_{er}. As for the inference, we use the Viterbi

decoding to get the best tagging sequence.

5.1 Document-level Entity Encoding

To address the arguments-scattering challenge efficiently, it is indispensable to leverage global contexts to better identify whether an entity plays a specific event role. Consequently, we utilize document-level entity encoding to encode extracted entity mentions with such contexts and produce an embedding of size d_w for each entity mention with a distinct surface name.

Entity & Sentence Embedding. Since an entity mention usually covers multiple tokens with a variable length, we first obtain a fixed-sized embedding for each entity mention by conducting a max-pooling operation over its covered token embeddings. For example, given l^{th} entity mention covering j^{th} to k^{th} tokens of i^{th} sentence, we conduct the max-pooling over $[\boldsymbol{h_{i,j}}, \cdots, \boldsymbol{h_{i,k}}]$ to get the entity mention embedding $\boldsymbol{e}_l \in \mathbb{R}^{d_w}$. For each sentence $\boldsymbol{s_i}$, we also take the max-pooling operation over the encoded token sequence $[\boldsymbol{h_{i,1}}, \cdots, \boldsymbol{h_{i,N_w}}]$ to obtain a single sentence embedding $\boldsymbol{c_i} \in \mathbb{R}^{d_w}$. After these operations, both the mention and the sentence embeddings share the same embedding size d_w.

Document-level Encoding. Though we get embeddings for all sentences and entity mentions, these embeddings only encode local contexts within the sentence scope. To enable the awareness of document-level contexts, we employ the second Transformer module, Transformer-2, to facilitate the information exchange between all entity mentions and sentences. Before feeding them into Transformer-2, we add them with sentence position embeddings to inform the sentence order. After the Transformer encoding, we utilize the max-pooling operation again to merge multiple mention embeddings with the same entity surface name into a single embedding. Formally, after this stage, we obtain document-level context-aware entity mention and sentence embeddings as $\boldsymbol{e^d} = [\boldsymbol{e^d_1}, \cdots, \boldsymbol{e^d_{N_e}}]$ and $\boldsymbol{c^d} = [\boldsymbol{c^d_1}, \cdots, \boldsymbol{c^d_{N_s}}]$, respectively, where N_e is the number of distinct entity surface names. These aggregated embeddings serve the next stage to fill event tables directly.

5.2 EDAG Generation

After the document-level entity encoding stage, we can obtain the document embedding $\boldsymbol{t} \in \mathbb{R}^{d_w}$ by operating the max-pooling over the sentence tensor $\boldsymbol{c^d} \in \mathbb{R}^{d_w \times N_s}$ and stack a linear classifier over $\boldsymbol{t}$ to conduct the event-triggering classification for each event type. Next, for each triggered event type, we learn to generate an EDAG.

EDAG Building. Before the model training, we need to build the EDAG from tabular event records. For each event type, we first manually define an event role order. Then, we transform each event record into a linked list of arguments following this order, where each argument node is either an entity or a special empty argument `NA`. Finally, we merge these linked lists into an EDAG by sharing the same prefix path. Since every complete path of the EDAG corresponds to one row of the event table, recovering the table format from a given EDAG is simple.

Task Decomposition. The EDAG format aims to simplify the hard table-filling task into several tractable path-expanding sub-tasks. Then, a natural question is how the task decomposition works, which can be answered by the following EDAG recovering procedure. Assume the event triggering as the starting node (the initial EDAG), there comes a series of path-expanding sub-tasks following a predefined event role order. When considering a certain role, for every leaf node of the current EDAG, there is a path-expanding sub-task that decides which entities to be expanded. For each entity to be expanded, we create a new node of that entity for the current role and expand the path by connecting the current leaf node to the new entity node. If no entity is valid for expanding, we create a special `NA` node. When all sub-tasks for the current role finish, we move to the next role and repeat until the last. In this work, we leverage the above logic to recover the EDAG from path-expanding predictions at inference and to set associated labels for each sub-task when training.

Memory. To better fulfill each path-expanding sub-task, it is crucial to know entities already contained by the path. Hence, we design a memory mechanism that initializes a memory tensor $\boldsymbol{m}$ with the sentence tensor $\boldsymbol{c^d}$ at the beginning and updates $\boldsymbol{m}$ when expanding the path by appending either the associated entity embedding or the zero-padded one for the `NA` argument. With this design, each sub-task can own a distinct memory tensor, corresponding to the unique path history.

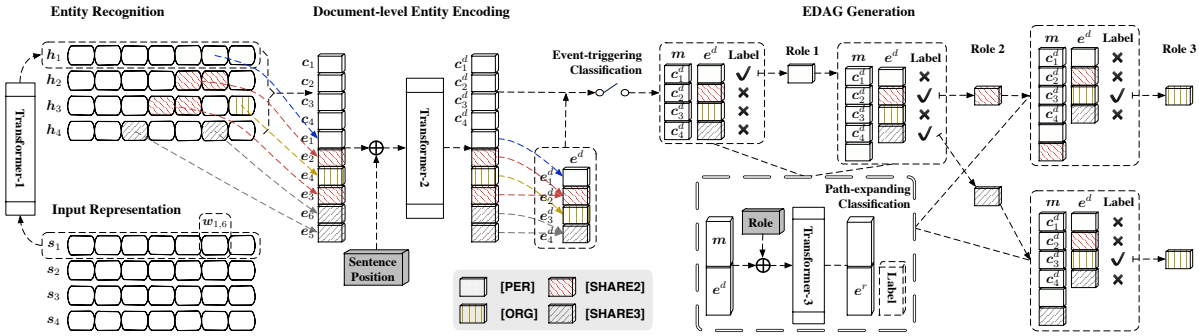

Figure 4: The overall workflow of Doc2EDAG, where we follow the example in Figure 2 and the EDAG structure in Figure 3, and use stripes to differentiate different entities (note that the number of input tokens and entity positions are imaginary, which do not match previous ones strictly, and here we only include the first three event roles and associated entities for brevity).

Path Expanding. For each path-expanding subtask, we formalize it as a collection of multiple binary classification problems, that is predicting *expanding* (1) or *not* (0) for all entities. To enable the awareness of the current path state, history contexts and the current event role, we first concatenate the memory tensor $\boldsymbol{m}$ and the entity tensor $\boldsymbol{e^d}$, then add them with a trainable event-role-indicator embedding, and encode them with the third Transformer module, Transformer-3, to facilitate the context-aware reasoning. Finally, we extract the enriched entity tensor $\boldsymbol{e^r}$ from outputs of Transformer-3 and stack a linear classifier over $\boldsymbol{e^r}$ to conduct the path-expanding classification.

Optimization. For the event-triggering classification, we calculate the cross-entropy loss L_{tr}. During the EDAG generation, we calculate a cross-entropy loss for each path-expanding subtask, and sum these losses as the final EDAG-generation loss L_{dag}. Finally, we sum L_{tr}, L_{dag} and the entity-recognition loss L_{er} together as the final loss, $L_{all} = \lambda_1 L_{er} + \lambda_2 L_{tr} + \lambda_3 L_{dag}$, where λ_1, λ_2 and λ_3 are hyper-parameters.

Inference. Given a document, Doc2EDAG first recognizes entity mentions from sentences, then encodes them with document-level contexts, and finally generates an EDAG for each triggered event type by conducting a series of path-expanding sub-tasks.

Practical Tips. During training, we can utilize both ground-truth entity tokens and the given EDAG structure. While at inference, we need to first identify entities and then expand paths sequentially based on embeddings of those entities to recover the EDAG. This gap between training and inference can cause severe error-propagation problems. To mitigate such problems, we utilize the scheduled sampling (Bengio et al., 2015) to gradually switch the inputs of document-level entity encoding from ground-truth entity mentions to model recognized ones. Moreover, for path-expanding classifications, false positives are more harmful than false negatives, because the former can cause a completely wrong path. Accordingly, we can set $\gamma(> 1)$ as the negative class weight of the associated cross-entropy loss.

6 Experiments

In this section, we present thorough empirical studies to answer the following questions: 1) to what extent can Doc2EDAG improve over state-of-the-art methods when facing DEE-specific challenges? 2) how do different models behave when facing both *arguments-scattering* and *multi-event* challenges? 3) how important are various components of Doc2EDAG?

6.1 Experimental Setup

Data Collection with Event Labeling. We utilize ten years (2008-2018) ChFinAnn[4] documents and human-summarized event knowledge bases to conduct the DS-based event labeling. We focus on five event types: *Equity Freeze* (EF), *Equity Repurchase* (ER), *Equity Underweight* (EU), *Equity Overweight* (EO) and *Equity Pledge* (EP), which belong to major events required to be disclosed by the regulator and may have a huge impact on the company value. To ensure the labeling quality, we set constraints for matched document-record pairs

Precision	Recall	F1	MER (%)
98.8	89.7	94.0	31.0

Table 2: The quality of the DS-based event labeling evaluated on 100 manually annotated documents (randomly select 20 for each event type).

as Section 4 describes. Moreover, we directly use the character tokenization to avoid error propagations from Chinese word segmentation tools.

Finally, we obtain 32,040 documents in total, and this number is ten times larger than 2,976 of DCFEE and about 53 times larger than 599 of ACE 2005. We divide these documents into train, development, and test set with the proportion of 8 : 1 : 1 based on the time order. In Table 1, we show the number of documents and the multi-event ratio (MER) for each event type on this dataset. Note that a few documents may contain multiple event types at the same time.

Data Quality. To verify the quality of DS-based event labeling, we randomly select 100 documents and manually annotate them. By regarding DS-generated event tables as the prediction and human-annotated ones as the ground-truth, we evaluate the labeling quality based on the metric introduced below. Table 2 shows this approximate evaluation, and we can observe that DS-generated data are pretty good, achieving high precision and acceptable recall. In later experiments, we directly employ the automatically generated test set for evaluation due to its much broad coverage.

Evaluation Metric. The ultimate goal of DEE is to fill event tables with correct arguments for each role. Therefore, we evaluate DEE by directly comparing the predicted event table with the ground-truth one for each event type. Specifically, for each document and each event type, we pick one predicted record and one most similar ground-truth record (at least one of them is non-empty) from associated event tables without replacement to calculate event-role-specific true positive, false positive and false negative statistics until no record left. After aggregating these statistics among all evaluated documents, we can calculate role-level precision, recall, and F1 scores (all reported in percentage format). As an event type often includes multiple roles, we calculate micro-averaged role-level scores as the final event-level metric that reflects the ability of end-to-end DEE directly.

Hyper-parameter Setting. For the input, we set the maximum number of sentences and the maximum sentence length as 64 and 128, respectively. During training, we set $\lambda_1 = 0.05$, $\lambda_2 = \lambda_3 = 0.95$ and $\gamma = 3$. We employ the Adam (Kingma and Ba, 2015) optimizer with the learning rate $1e^{-4}$, train for at most 100 epochs and pick the best epoch by the validation score on the development set. Besides, we leverage the decreasing order of the non-empty argument ratio as the event role order required by Doc2EDAG, because more informative entities in the path history can better facilitate later path-expanding classifications.

Note that, due to the space limit, we leave other detailed hyper-parameters, model structures, data preprocessing configurations, event type specifications and pseudo codes for EDAG generation to the appendix.

6.2 Performance Comparisons

Baselines. As discussed in the related work, the state-of-the-art method applicable to our setting is DCFEE. We follow the implementation described in (Yang et al., 2018), but they did not illustrate how to handle multi-event sentences with just a sequence tagging model. Thus, we develop two versions, *DCFEE-O* and *DCFEE-M*, where *DCFEE-O* only produces one event record from one key-event sentence, while *DCFEE-M* tries to get multiple possible argument combinations by the closest relative distance from the key-event sentence. To be fair, the SEE stages of both versions share the same neural architecture as the entity recognition part of Doc2EDAG. Besides, we further employ a simple decoding baseline of Doc2EDAG, *Greedy-Dec*, that only fills one event table entry greedily by using recognized entity roles to verify the necessity of end-to-end modeling.

Main Results. As Table 3 shows, Doc2EDAG achieves significant improvements over all base-

Model	EF			ER			EU			EO			EP		
	P.	R.	F1	P.	R.	F1	P.	R.	F1	P.	R.	F1	P.	R.	F1

DCFEE-M	48.4	43.1	83.8	53.4	48.1	39.6	47.1	42.0	67.0	60.6	58.9	47.7	55.7
GreedyDec	75.9	40.8	81.7	49.8	62.2	34.6	65.7	29.4	**88.5**	42.3	74.8	39.4	60.5
Doc2EDAG	**80.0**	**61.3**	**89.4**	**68.4**	**77.4**	**64.6**	**79.4**	**69.5**	85.5	**72.5**	**82.3**	**67.3**	**76.3**

Table 4: F1 scores for all event types and the averaged ones (Avg.) on single-event (S.) and multi-event (M.) sets.

Model	EF	ER	EU	EO	EP	Avg.
Doc2EDAG	70.2	87.3	71.8	75.0	77.3	76.3
-PathMem	-11.2	-0.2	-10.1	-16.3	-10.9	-9.7
-SchSamp	-5.3	-4.8	-5.3	-6.6	-3.0	-5.0
-DocEnc	-4.7	-1.5	-1.6	-1.1	-1.5	-2.1
-NegCW	-1.4	-0.4	-0.7	-1.3	-0.4	-0.8

Table 5: Performance differences of Doc2EDAG variants for all event types and the averaged ones (Avg.).

lines for all event types. Specifically, Doc2EDAG improves 19.1, 4.2, 26.5, 28.4 and 13.4 F1 scores over DCFEE-O, the best baseline, on EF, ER, EU, EO and EP events, respectively. These vast improvements mainly owe to the document-level end-to-end modeling of Doc2EDAG. Moreover, since we work on automatically generated data, the direct document-level supervision can be more robust than the extra sentence-level supervision used in DCFEE, which assumes the sentence containing most event arguments as the key-event one. This assumption does not work well on some event types, such as EF, EU and EO, on which DCFEE-O is even inferior to the most straightforward baseline, GreedyDec. Besides, DCFEE-O achieves better results than DCFEE-M, which demonstrates that naively guessing multiple events from the key-event sentence cannot work well. By comparing Doc2EDAG with GreedyDec that owns high precision but low recall, we can clearly see the benefit of document-level end-to-end modeling.

Single-Event vs. Multi-Event. We divide the test set into a single-event set, containing documents with just one event record, and a multi-event set, containing others, to show the extreme difficulty when *arguments-scattering* meets *multi-event*. Table 4 shows F1 scores for different scenarios. Although Doc2EDAG still maintains the highest extraction performance for all cases, the multi-event set is extremely challenging as the extraction performance of all models drops significantly. Especially, GreedyDec, with no mechanism for the *multi-event* challenge, decreases most drastically. DCFEE-O decreases less, but is still far away from Doc2EDAG. On the multi-event set, Doc2EDAG increases by 17.7 F1 scores over DCFEE-O, the best baseline, on average.

Ablation Tests. To demonstrate key designs of Doc2EDAG, we conduct ablation tests by evaluating four variants: 1) *-PathMem*, removing the memory mechanism used during the EDAG generation, 2) *-SchSamp*, dropping the scheduled sampling strategy during training, 3) *-DocEnc*, removing the Transformer module used for document-level entity encoding, and 4) *-NegCW*, keeping the negative class weight as 1 when doing path-expanding classifications. From Table 5, we can observe that 1) the memory mechanism is of prime importance, as removing it can result in the most drastic performance declines, over 10 F1 scores on four event types except for the ER type whose MER is very low on the test set; 2) the scheduled sampling strategy that alleviates the mismatch of entity candidates for event table filling between training and inference also contributes greatly, improving by 5 F1 scores on average; 3) the document-level entity encoding that enhances global entity representations contributes

2.1 F1 scores on average; 4) the larger negative class weight to penalize false positive path expanding can also make slight but stable contributions for all event types.

Case Studies. Let us follow the example in Figure 2, Doc2EDAG can successfully recover the correct EDAG, while DCFEE inevitably makes many mistakes even with a perfect SEE model, as discussed in the introduction. Due to the space limit, we leave another three fine-grained case studies to the appendix.

7 Conclusion and Future Work

Towards the end-to-end modeling for DEE, we propose a novel model, Doc2EDAG, associated with a novel task formalization without trigger words to ease DS-based labeling. To validate the effectiveness of the proposed approach, we build a large-scale real-world dataset in the financial domain and conduct extensive empirical studies. Notably, without any domain-specific assumption, our general labeling and modeling strategies can benefit practitioners in other domains directly.

As this work shows promising results for the end-to-end DEE, expanding the inputs of Doc2EDAG from pure text sequences to richly formatted ones (Wu et al., 2018) is appealing, and we leave it as future work to explore.

Abstract

Event detection (ED) aims to locate trigger words in raw text and then classify them into correct event types. In this task, neural network based models became mainstream in recent years. However, two problems arise when it comes to languages without natural delimiters, such as Chinese. First, word-based models severely suffer from the problem of word-trigger mismatch, limiting the performance of the methods. In addition, even if trigger words could be accurately located, the ambiguity of polysemy of triggers could still affect the trigger classification stage. To address the two issues simultaneously, we propose the Trigger-aware Lattice Neural Network (TLNN). (1) The framework dynamically incorporates word and character information so that the trigger-word mismatch issue can be avoided. (2) Moreover, for polysemous characters and words, we model all senses of them with the help of an external linguistic knowledge base, so as to alleviate the problem of ambiguous triggers. Experiments on two benchmark datasets show that our model could effectively tackle the two issues and outperforms previous state-of-the-art methods significantly, giving the best results. The source code of this paper can be obtained from https://github.com/thunlp/TLNN.

1 Introduction

Event Detection (ED) is a pivotal part of Event Extraction, which aims to detect the position of event triggers in raw text and classify them into corresponding event types. Conventionally, the stage of locating trigger words is known as **Trigger Identification (TI)**, and the stage of classifying trigger words into particular event types

(a) An example of trigger-word mismatch.

(b) An example of polysemous trigger.

Figure 1: Examples about trigger-word mismatch and polysemous trigger in Event Detection.

is called **Trigger Classification (TC)**. Although neural network methods have achieved significant progress in event detection (Nguyen and Grishman, 2015; Chen et al., 2015; Zeng et al., 2016), both steps are still exposed to the following two issues.

In the TI stage, the problem of **trigger-word mismatch** could severely impact the performance of event detection systems. Because in languages without natural delimiters such as Chinese, mainstream approaches are mostly word-based models, in which the segmentation should be firstly performed as a necessary preprocessing step. Unfortunately, these word-wise methods neglect an important problem that a trigger could be a specific part of one word or contain multiple words. As shown in Figure 1(a), "射" (shoot) and "杀" (kill)

Datasets	Trigger-word Match		Trigger Polysemy	
	Match	Mismatch	Polysemy	Univocal
ACE 2005	85.39%	14.61%	41.64%	58.36%
KBP 2017	76.28%	23.72%	52.14%	47.86%

Table 1: Proportion of Trigger-word mismatch and Polysemous Triggers on ACE 2005 and KBP 2017.

are two triggers that both are parts of the word "射杀" (shoot and kill) . In the other case, "示威游行" (demonstration) is a trigger that crosses two words. Under this circumstance, triggers could not be located correctly with word-based methods, thereby becoming a serious limitation of the task. Some feature-based methods are proposed (Chen and Ji, 2009; Qin et al., 2010; Li and Zhou, 2012) to alleviate the issue, but they heavily rely on the hand-crafted features. Lin et al. (2018) proposes the nugget proposal networks (NPN) in terms of this issue, which uses a neural network to model character compositional structure of trigger words in a fix-sized window. However, the mechanism of the NPN limits the scope of trigger candidates within a fix-sized window, which is inflexible and suffering from the problem of trigger overlaps.

Even if the locations of triggers can be correctly detected in the TI step, the TC step could still be severely affected by the inherent problem of **ambiguity of polysemy**. Because a trigger word with multiple word senses could be classified into different event types. Take 1(b) as an example, a polysemous trigger word "释放" (release) could represent two distinctly different event types. In the first case, the word 'release' triggers an *Attack* event (release tear gas). But in the second case, the event triggered by 'release' becomes *Release-Parole* (release a man in court).

To further illustrate that the two problems mentioned above do exist, we make manual statistics on the proportion of mismatch triggers and polysemous triggers on two widely used datasets. The statistics are illustrated in Table 1, and we can observe that data with trigger-word mismatch and trigger polysemy do account for a considerable proportion and then affect the task.

In this paper, we propose the Trigger-aware Lattice Network (TLNN), a comprehensive model that can simultaneously tackle both issues. To avoid error propagation by NLP tools like segmentor, we take characters as the basic units of the input sequence. Moreover, we utilize HowNet (Dong and Dong, 2003), an external knowledge base that manually annotates polysemous Chinese and English words, to obtain the sense-level information. Further, we develop the trigger-aware lattice LSTM as the feature extractor of our model, which could leverage character-level, word-level and sense-level information at the same time. More specifically, in order to address the trigger-word mismatch issue, we construct short cut paths to link the cell state between the start and the end characters for each word. It is worth mentioning that the paths are sense-level, which means all the sense information of words that end in one specific character will flow into the memory cell of the character. Hence, with the utilization of multiple granularity of information (character, word and word sense), the problem of polysemous triggers could be effectively alleviated.

We conduct sets of experiments on two real-world datasets in the task of event detection. Empirical results of the main experiments show that our model can efficiently address both mentioned issues. With comprehensive comparisons with other proposed methods, our model achieves the state-of-the-art results on both datasets. Further, sets of subsidiary experiments are conducted to further analyze how TLNN addresses the two issues.

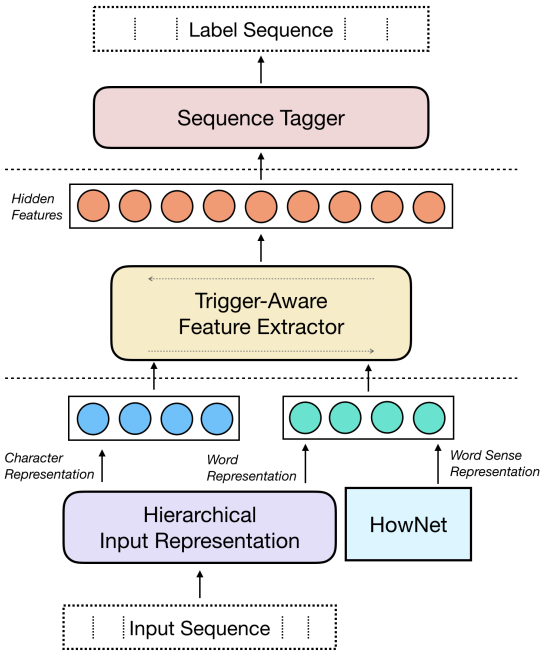

Figure 2: The architecture of TLNN.

2 Methodology

In the paper, event detection is regarded as a sequence labelling task. For each character, the model should identify if it is a part of one trigger and correctly classify the trigger into one specific event type.

The architecture of our model is shown in Figure 2, which primarily includes the following three parts: (1) **Hierarchical Representation Learning**, which reveals the character-level, word-level and sense-level embedding vectors in an unsupervised way. (2) **Trigger-aware Feature Extractor**, which automatically extracts different levels of semantic features by a tree structure LSTM model. (3) **Sequence Tagger**, which calculates the probability of being a trigger for each character candidate.

2.1 Hierarchical Representation Learning

Given an input sequence $S = \{c_1, c_2, ..., c_N\}$, where c_i represents the ith character in the sequence. In character level, each character will be represented as an embedding vector $\boldsymbol{x^c}$ by Skip-Gram method (Mikolov et al., 2013).

$$\boldsymbol{x}_i^c = \boldsymbol{e}(c_i) \tag{1}$$

In the word level, the input sequence S could also be $S = \{w_1, w_2, ..., w_M\}$, where the basic unit is a single word w_i. In this paper, we will use two indexes b and e to represent the start and the end of a word. In this case, the word embeddings are:

$$\boldsymbol{x}_{b,e}^w = \boldsymbol{e}(w_{b,e}) \tag{2}$$

However, the Skip-Gram method maps each word to only one single embedding, ignoring the fact that many words have multiple senses. Hence representation of finer granularity is still necessary to represent deep semantics. With the help of HowNet (Dong and Dong, 2003), we can obtain the representation of each sense of a character or a word. For each character c, there are possible multiple senses $sen^{(c_i)} \in S^{(c)}$ annotated in HowNet. Similarly, for each word w, the senses could be $sen^{(w_i)} \in S^{(w)}$. Consequently, we can obtain the embeddings of senses by jointly learning word and sense embeddings via Skip-gram manner. This mechanism is also applied to (Niu et al., 2017).

$$\boldsymbol{s}_j^{c_i} = \boldsymbol{e}(sen_j^{(c_i)}) \tag{3}$$

$$\boldsymbol{s}_j^{w_{b,e}} = \boldsymbol{e}(sen_j^{(w_{b,e})}) \tag{4}$$

where $sen_j^{(c_i)}$ and $sen_j^{(w_{b,e})}$ represents the jth sense for the character c_i and word $w_{b,e}$ in the sequence. And then $\boldsymbol{s_j^{c_i}}$ and $\boldsymbol{s_j^{w_{b,e}}}$ are the embeddings of c_i and $w_{b,e}$.

2.2 Trigger-Aware Feature Extractor

The trigger-aware feature extractor is the core component of our model. After training, the outputs of the extractor are the hidden state vectors **h** of an input sentence.

Conventional LSTM. LSTM (Hochreiter and Schmidhuber, 1997) is an extension of the recurrent neural network (RNN) with additional gates to control the information. Traditionally, there are following basic gates in LSTM: input gate $\boldsymbol{i}$, output gate $\boldsymbol{o}$ and forget gate $\boldsymbol{f}$. They collectively controls which information will be reserved, forgotten and output. All three gates are accompanied by corresponding weight matrix $\boldsymbol{W}$. Current cell state $\boldsymbol{c}$ records all historical information flow up to the current time. Therefore, the character-based LSTM functions are:

$$\begin{bmatrix} \boldsymbol{i}_i^c \\ \boldsymbol{o}_i^c \\ \boldsymbol{f}_i^c \\ \tilde{\boldsymbol{c}}_i^c \end{bmatrix} = \begin{bmatrix} \sigma \\ \sigma \\ \sigma \\ tanh \end{bmatrix} (\boldsymbol{W}^{c\top} \begin{bmatrix} \boldsymbol{x}_i^c \\ \boldsymbol{h}_{i-1}^c \end{bmatrix} + \boldsymbol{b}^c) \tag{5}$$

$$\boldsymbol{c}_i^c = \boldsymbol{f}_i^c \odot \boldsymbol{c}_{i-1}^c + \boldsymbol{i}_i^c \odot \tilde{\boldsymbol{c}}_i^c \tag{6}$$

$$\boldsymbol{h}_i^c = \boldsymbol{o}_i^c \odot tanh(\boldsymbol{c}_i^c) \tag{7}$$

where h_i^c is the hidden state vector.

Trigger-Aware Lattice LSTM. Trigger-Aware Lattice LSTM is the core feature extractor of our framework, which is an extension of LSTM and lattice LSTM. In this subsection, We will derive and theoretically analyze the model in detail.

In this section, characters and words are assumed to have K senses. As mentioned in 2.1, for the jth sense of the ith character c_i, the embedding would be $\boldsymbol{s_j^{c_i}}$. Then an additional LSTMCell is utilized to integrate all senses of the character, hence the calculation of the cell gate of the multi-sense character $\boldsymbol{c_i}$ would be:

$$\begin{bmatrix} \boldsymbol{i}_j^{c_i} \\ \boldsymbol{f}_j^{c_i} \\ \tilde{\boldsymbol{c}}_j^{c_i} \end{bmatrix} = \begin{bmatrix} \sigma \\ \sigma \\ tanh \end{bmatrix} (\boldsymbol{W}^{c\top} \begin{bmatrix} \boldsymbol{s}_j^{c_i} \\ \boldsymbol{h}^{c_{i-1}} \end{bmatrix} + \boldsymbol{b}^c) \tag{8}$$

$$\boldsymbol{c}_j^{c_i} = \boldsymbol{f}_j^{c_i} \odot \boldsymbol{c}^{c_{i-1}} + \boldsymbol{i}_j^{c_i} \odot \tilde{\boldsymbol{c}}_j^{c_i} \tag{9}$$

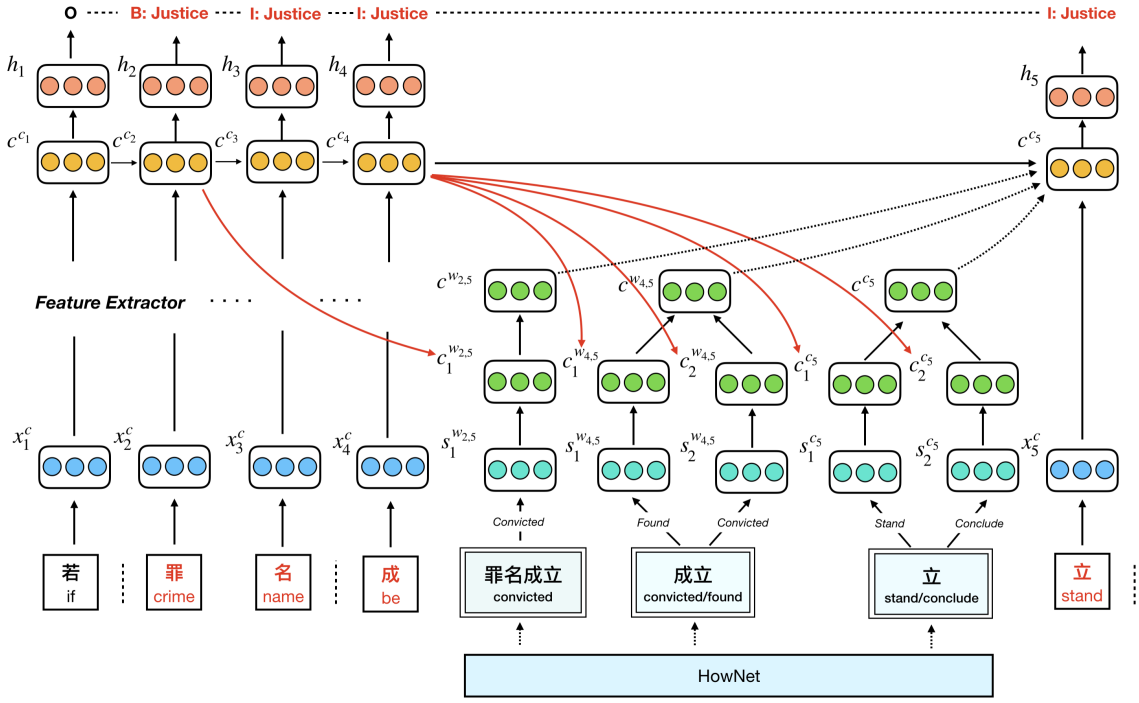

Figure 3: The structure of **Trigger-Aware Feature Extractor**, the input of the example is a part of the sentence "若罪名成立，他将被逮捕" (If convicted, he will be arrested) . In this case, "罪名成立" (convicted) is a trigger with event type *Justice: Sentence*. "成立" (convicted/found) and "立" (stand/conclude) are polysemous words. To keep the figure concise, we (1) only show two senses for each polysemous word; (2) only show the forward direction.

where $\boldsymbol{c}_j^{c_i}$ is the cell state of the jth sense of the ith character, $\boldsymbol{c}^{c_{i-1}}$ is the final cell state of the $i-1$th character. In order to obtain the cell state of the character, an additional gate is used:

$$\boldsymbol{g}_j^{c_i} = \sigma(\boldsymbol{W}^\top \begin{bmatrix} \boldsymbol{x}_i^c \\ \boldsymbol{c}_j^{c_i} \end{bmatrix} + \boldsymbol{b}) \tag{10}$$

Then all the senses should be dynamically integrated into the temporary cell state:

$$\boldsymbol{c}^{*c_i} = \sum_j^K \boldsymbol{\alpha}_j^{c_i} \odot \boldsymbol{c}_j^{c_i} \tag{11}$$

where $\boldsymbol{\alpha}_j^{c_i}$ is the character sense gate after normalization:

$$\boldsymbol{\alpha}_j^{c_i} = \frac{exp(\boldsymbol{g}_j^{c_i})}{\sum_k^K exp(\boldsymbol{g}_k^{c_i})} \tag{12}$$

Eq.11 obtains the temporary cell state of the character c^{*c_i} by incorporating all the senses information of the character. However, word-level information needs to be considered as well. As mentioned in 2.1, $\boldsymbol{s}_j^{w_{b,e}}$ is the embedding for the jth sense of the word out $w_{b,e}$. Similar to characters, extra LSTMCell is used to calculate the cell state of each word that matches the lexicon $\mathbb{D}$.

$$\begin{bmatrix} \boldsymbol{i}_j^{w_{b,e}} \\ \boldsymbol{f}_j^{w_{b,e}} \\ \boldsymbol{c}_j^{w_{b,e}} \end{bmatrix} = \begin{bmatrix} \sigma \\ \sigma \\ tanh \end{bmatrix} (\boldsymbol{W}^{c\top} \begin{bmatrix} \boldsymbol{s}_j^{w_{b,e}} \\ \boldsymbol{h}^{c_{b-1}} \end{bmatrix} + \boldsymbol{b}^c) \tag{13}$$

$$\boldsymbol{c}_j^{w_{b,e}} = \boldsymbol{f}_j^{w_{b,e}} \odot \boldsymbol{c}^{c_{b-1}} + \boldsymbol{i}_j^{w_{b,e}} \odot \tilde{\boldsymbol{c}}_j^{w_{b,e}} \tag{14}$$

Similar to Eq.11, the cell state of the word could be computed by incorporating all the cells of senses.

$$\boldsymbol{g}_j^{w_{b,e}} = \sigma(\boldsymbol{W}^\top \begin{bmatrix} \boldsymbol{x}_b^c \\ \boldsymbol{c}_j^{w_{b,e}} \end{bmatrix} + \boldsymbol{b}) \tag{15}$$

$$\boldsymbol{c}^{w_{b,e}} = \sum_j^K \boldsymbol{\alpha}_j^{w_{b,e}} \odot \boldsymbol{c}_j^{w_{b,e}} \tag{16}$$

where $\boldsymbol{\alpha}_j^{w_{b,e}}$ is the word sense gate after normalization:

$$\boldsymbol{\alpha}_j^{w_{b,e}} = \frac{exp(\boldsymbol{g}_j^{w_{b,e}})}{\sum_k^K exp(\boldsymbol{g}_k^{w_{b,e}})} \tag{17}$$

For a character c_i, the temporary cell state $\boldsymbol{c}^{*c_i}$ that contains sense information is calculated by Eq.11. Moreover, we could calculate all the cell states of words that end in the index i by Eq.16, which are represented as $\{\boldsymbol{c}^{w_{b,i}}|b \in [1,i], w_{b,i} \in \mathbb{D}\}$. In order to ensure the corresponding information could flow into the final cell state of c_i, an extra gate $\boldsymbol{g}^m_{b,i}$ is used to merge character and word cells:

$$\boldsymbol{g}^m_{b,i} = \sigma(\boldsymbol{W}^{l\top} \begin{bmatrix} \boldsymbol{x}^c_i \\ \boldsymbol{c}^w_{b,i} \end{bmatrix} + \boldsymbol{b}^l) \tag{18}$$

and the computation of the final cell state of the character $\boldsymbol{c}^{c_i}$ is:

$$\boldsymbol{c}^{c_i} = \sum_{b \in \{b'|w^d_{b',i} \in \mathbb{D}\}} \boldsymbol{\alpha}^{w_{b,i}} \odot \boldsymbol{c}^{w_{b,i}} + \boldsymbol{\alpha}^{c_i} \odot \boldsymbol{c}^{*c_i} \tag{19}$$

where $\boldsymbol{\alpha}^{w_{b,i}}$ and $\boldsymbol{\alpha}^{c_i}$ are word gate and character gate after normalization. The computation is similar to Eq. 12 and Eq. 17.

Therefore, the final cell state $\boldsymbol{c}^{c_i}$ could represent the ambiguous characters and words in a dynamic manner. Similar to Eq. 7, hidden state vectors could be calculated to transmit to the sequence tagger layer.

2.3 Sequence Tagger

In this paper, the event detection task is regarded as a sequence tagging problem. For an input sequence $S = \{c_1, c_2, ..., c_N\}$, there is a corresponding label sequence $L = \{y_1, y_2, ..., y_N\}$. Hidden vectors $\boldsymbol{h}$ for each character obtained in 2.2 are used as the input. We use a classic CRF layer to perform the sequence tagging, thus the probability distribution is:

$$P(L|S) = \frac{exp(\sum_{i=1}^{N}(S(y_i) + T(y_{i-1}, y_i)))}{\sum_{L' \in \mathbb{C}} exp(\sum_{i=1}^{N}(S(y'_i) + T(y'_{i-1}, y'_i)))}, \tag{20}$$

where S is the score function to compute the emission score from hidden vector $\boldsymbol{h_i}$ to the label y_i:

$$S(y_i) = \boldsymbol{W}^{y_i}_{CRF} \boldsymbol{h}_i + b^{y_i}_{CRF}. \tag{21}$$

$\boldsymbol{W}^{y_i}_{CRF}$ and $b^{y_i}_{CRF}$ are learned parameters specific to y_i. And in Eq. 20, T is the transition function to compute the transition score from y_{i-1} to y_i. $\mathbb{C}$ contains all the possible label sequences on sequence S and L' is a random label sequence in $\mathbb{C}$.

We use standard Viterbi (Viterbi, 1967) algorithm as a decoder to decode the highest scored label sequence. The loss function of our model is log-likelihood in sentence-level.

$$Loss = \sum_{i=1}^{M} log(P(L_i|S_i)) \tag{22}$$

where M is the number of sentences, L_i is the correct label for the sentence S_i.

3 Experiments

3.1 Datasets and Experimental Settings

Datasets. In this paper, we conduct a series of experiments on two real-world datasets: ACE 2005 Chinese dataset (ACE2005) and TAC KBP 2017 Event Nugget Detection Evaluation dataset (KBP2017). For better comparison, we use the same data split as previous works (Chen and Ji, 2009; Zeng et al., 2016; Feng et al., 2018; Lin et al., 2018). Specifically, the ACE2005 (LDC2006T06) contains 697 articles, with 569 articles for training, 64 for validating and the rest 64 for testing. For KBP2017 Chinese dataset (LDC2017E55), we follow the same setup as Lin et al. (2018), using 506/20/167 documents as training/development/test set respectively.

Evaluation Metrics. Standard micro-averaged Precision, Recall and F1 are used as evaluation metrics. For ACE2005 the computation is the same as Chen and Ji (2009). To remain rigorous, we use the official evaluation toolkit [1] to perform the metrics for KBP2017.

Hyper-Parameter Settings. We tune the parameters of our models by grid searching on the validation dataset. Adam (Kingma and Ba, 2014) with a learning rate decay is utilized as the optimizer. The embedding sizes of characters and senses are all 50. To avoid overfitting, Dropout mechanism (Srivastava et al., 2014) is used in the system, and the dropout rate is set to 0.5. We select the best models by early stopping using the F1 results on the validation dataset. Because of the limited influence, we follow empirical settings for other hyper-parameters.

3.2 Overall Results

In this section, we compare our model with previous state-of-the-art methods. The proposed models are as follows:

Table 2: Overall results of proposed methods and TLNN on ACE2005 and KBP2017. * indicates the results adapted from the original paper. For KBP2017, "Trigger Identification" and "Trigger Classification" correspond to the "Span" and "Type" metrics in the official evaluation.

DMCNN (Chen et al., 2015) put forward a dynamic Multi-pooling CNN as a sentence-level feature extractor. Moreover, we add a classifier to DMCNN using IOB encoding.

C-BiLSTM (Zeng et al., 2016) put forward the Convolutional Bi-LSTM model for the event detection task.

HNN (Feng et al., 2018) designed a Hybrid Neural Network model which combines CNN with Bi-LSTM.

HBTNGMA (Chen et al., 2018) put forward a Hierarchical and Bias Tagging Networks with Gated Multi-level Attention Mechanisms to integrate sentence-level and document-level information collectively.

NPN (Lin et al., 2018) proposed a comprehensive model by automatically learning the inner compositional structures of triggers to solve the trigger mismatch problem.

The results of all the models are shown in Table 2. From the results, we can observe that:

(1) Both for ACE2005 and KBP2017, TLNN outperform other proposed models significantly, achieving the best results on two datasets. This demonstrates that the trigger-aware lattice structure could enhance the accuracy of locating triggers. Further, thanks to the usage of sense-level information, triggers could be more precisely classified into correct event types.

(2) On the TI stage, TLNN gives the best performance. By linking shortcut paths of all word candidates with the current character, the model could effectively exploit both character and word information, and then alleviates the issue of trigger-word mismatch.

Model	ACE2005		KBP2017	
	TI	TC	TI	TC
Word baseline	61.13	57.81	56.68	50.98
+char CNN	61.11	57.52	57.14	51.66
+char LSTM	61.51	58.15	56.14	50.46
Char baseline	64.97	61.78	53.95	49.63
+bigram	66.89	62.95	57.01	52.71
+softword	67.79	64.11	60.68	54.57
+softword+bigram	68.22	64.23	60.42	54.85
TLNN	**70.82**	**67.78**	**62.31**	**57.39**

Table 3: F1-score of Word-based and Character-based baselines and TLNN on ACE2005 and KBP2017.

(3) On the TC stage, TLNN still maintain its advantages. The results indicate that the linguistic knowledge of HowNet and the unique structure to dynamically utilize sense-level information could enhance the performance on the TC stage. More located triggers could be classified into correct event types by considering the ambiguity of triggers.

3.3 Effect of Trigger-aware Feature Extractor

In this section, we design a set of experiments to explore the effect of the trigger-aware feature extractor. We implement strong character-based and word-based baselines by replacing the trigger-aware lattice LSTM with the standard Bi-LSTM.

For word-based baselines, the input is segmented into word sequences firstly. Furthermore, we implement extra CNN and LSTM to learn character-level features as additional modules. For character-based baselines, the basic units of the

Model	ACE2005		KBP2017	
	Match	Mismatch	Match	Mismatch
Char Baseline	65.58	63.89	55.65	42.76
Word Baseline	66.30	2.78	64.43	17.63
NPN	65.94	55.56	56.47	41.53
TLNN	**69.93**	**72.22**	**65.52**	**48.56**

Table 4: Recall rates of two trigger-word match splits of two datasets on Trigger Identification task.

input sequence are characters. Then we enhance the character representation by adding external word-level features including bigram and softword (word in which the current character is located). Hence, both baselines could collectively utilize character and word information.

As shown in Table 3, experiments of two types of baselines and our model are conducted on ACE2005 and KBP2017. For the word baseline, although adding character-level features can improve the performance, the effects are relative limited. For the char baseline, it gains considerable improvements when word-level features are taken into account. The results of baselines indicate that integrating different level of information is an effective strategy to improve the performance of models. Compared with baselines, the TLNN achieves the best F1-score compared to all the baselines on both datasets, showing remarkable superiority and robustness. The results show that by dynamically combining multi-grained information, the trigger-aware feature extractor could effectively explore deeper semantic features than the feature-based strategies used in baselines.

3.4 Influence of Trigger Mismatch

In order to explore the influence of trigger mismatch problem, we split the test data of ACE2005 and KBP2017 into two types: match and mismatch. Table 1 shows the proportion of word-trigger match and mismatch on two datasets.

The recall of different methods of each split on Trigger Identification task is shown in Table 4. We can observe that:

(1) The result indicates that the word-trigger mismatch problem could severely impact the performance of the task. All approaches except ours give lower recall rates in the trigger-mismatch part than in the trigger-match part. In contrast, our model could robustly address the word-trigger mismatch problem, reaching the best results on both parts of the two datasets.

Model	ACE2005		KBP2017	
	TI	**TC**	**TI**	**TC**
NPN	67.56	64.21	58.96	52.87
TLNN	**70.82**	**67.78**	**62.31**	**57.39**
- w/o Sense info	68.65	65.83	61.17	56.55

Table 5: F1-score of NPN, TLNN and TLNN - w/o Sense info on ACE2005 and KBP2017.

Model	ACE2005		KBP2017	
	Poly	Mono	Poly	Mono
NPN	66.27	61.08	51.15	48.63
TLNN	**69.11**	62.56	**58.61**	**56.56**
- w/o Sense info	67.53	**62.89**	56.01	55.96

Table 6: F1-score of two splits of two datasets on Trigger Classification task. The splits are based on the polysemy of triggers. "Poly" and "Mono" correspond to polysemous and monosemous trigger splits.

(2) To a certain extent, the NPN model could alleviate the problem by utilizing hybrid representation learning and nugget generator in a fix-sized window. However, the mechanism is still not flexible and robust to integrate character and word information.

(3) The word-based baseline is most severely affected by the trigger-word mismatch problem. This phenomenon is explainable because if one trigger could not be segmented as a specific word in the preprocessing stage, it is impossible to be located correctly.

3.5 Influence of Trigger Polysemy

In this section, we mainly focus on the influence of polysemous triggers. We select NPN model for comparison. And we implement a version of TLNN without sense information, which is denoted as **TLNN - w/o Sense info** in Table 5 and Table 6.

Empirical results in Table 5 show the overall performance on ACE2005 and KBP2017. We can observe that the TLNN is weakened by removing sense information, which indicates the effectiveness of the usage of sense-level information. Even without sense information, our model could still outperform the NPN model on both two datasets.

To further explore and analyze the effect of word sense information, we split the KBP2017 dataset into two parts based on the polysemy of triggers and their contexts. The F1-score of each split is shown in Table 6, in which the TLNN yields the best results on both "Poly" parts. With-

Sentence 1	Word baseline	NPN	TLNN	Answer
立刻/**抗**敌援友 **Resist** the enemies and aid the allies at once	(抗敌援友,Attack)	(刻抗,Attack)	(抗,Attack)	(抗,Attack)
Sentence 2	**NPN**	**TLNN - Sense info**	**TLNN**	**Answer**
送/他/一笔/赴/欧洲/的/旅费 **Send** him money for European tourism	(送,TransferPerson)	(送,TransferPerson)	(送,TransferMoney)	(送,TransferMoney)

Table 7: Two model prediction examples. The first sentence is an example of trigger-word mismatch, while the second one is about polysemous triggers. For each prediction result, (A,B) indicates that A is a trigger with event type B.

out sense information, TLNN - w/o sense info could give comparable F1-scores with TLNN on the "Mono" parts. The results indicate that the trigger-aware feature extractor could dynamically learn all the senses of characters and words, gaining significant improvements under the condition of polysemy.

3.6 Case Study

Table 7 shows two examples comparing the TLNN model with other ED methods. The former example is about trigger-word mismatch, in which the correct trigger "抗"(resist) is part of the idiom word "抗敌援友" (resist the enemies and aid the allies). In this case, the word baseline gives the whole word "抗敌援友" as prediction because it is impossible for word-based methods to detect part-of-word triggers. Additionally, the NPN model recognizes a non-existent word "刻抗". The reason is that the NPN enumerates the combinations of all characters within a window as trigger candidates, which is likely to generate invalid words. In contrast, our model detects the event trigger "抗" accurately.

In the latter example, the trigger "送"(send) is a polysemous word with two different meanings: "送行"(see him off) and "送钱"(give him money). Without considering multiple word senses of polysemes, the NPN and TLNN (w/o Sense info) classify trigger "送" into wrong event type *TransferPerson*. On the contrary, the TLNN can dynamically select word sense for polysemous triggers by utilizing context information. Thus the correct event type *TransferMoney* is predicted.

4 Related Work

Event Detection (ED) is a crucial subtask in Event Extraction task. Feature-based methods (Ahn, 2006; Ji and Grishman, 2008; Liao and Grishman, 2010; Huang and Riloff, 2012; Patwardhan and Riloff, 2009; McClosky et al., 2011) were widely used in the ED task, but these traditional methods are heavily rely on the manual features, limiting the scalability and robustness.

Recent developments in deep learning have led to a renewed interest in neural event detection. Neural networks can automatically learn features of the input sequence and conduct token-level classification. CNN-based models are the seminal neural network models in ED (Nguyen and Grishman, 2015; Chen et al., 2015; Nguyen and Grishman, 2016). However, these models can only capture the local context features in a fixed size window. Some approaches design comprehensive models to explore the interdependency among trigger words (Chen et al., 2018; Feng et al., 2018). To further improve the ED task, some joint models are designed (Nguyen et al., 2016; Lu and Nguyen, 2018; Yang and Mitchell, 2016). These methods have achieved great success in English datasets.

However, in languages without delimiters, such as Chinese, the mismatch of word-trigger become significantly severe. Some feature-based methods are proposed to solve the problem (Chen and Ji, 2009; Qin et al., 2010; Li and Zhou, 2012), but they heavily rely on the hand-crafted features. Lin et al. (2018) proposes NPN, a neural network based method to address the issue. However, the mechanism of NPNs limits the scope of trigger candidates within a fix-sized window, which will cause two problems in the progress. First, the NPNs still cannot take all the possible trigger candidates into account, leading to meaningless computation. Furthermore, the overlap of triggers is serious in NPNs. Lattice-based models were used in other fields to combine character and word information (Li et al., 2019; Zhang and Yang, 2018; Yang et al., 2018). Mainstream methods also suffer from the problem of trigger polysemy. Lu and Nguyen (2018) proposes a multi-task learning model which uses word sense disambiguation to alleviate the effect of the trigger polysemy

problem. But in this work, word disambiguation datasets are necessary. In contrast, our model can solve both word-trigger mismatch and trigger polysemy problems at the same time.

5 Conclusion and Future Work

We propose a novel framework TLNN for event detection, which can simultaneously address the problems of trigger-word mismatch and polysemous triggers. With the hierarchical representation learning and the trigger-aware feature extractor, TLNN efficaciously exploits multi-grained information and learn deep semantic features. Sets of experiments on two real-world datasets show that TLNN could efficiently address the two issues and yield better empirical results than a variety of neural network models.

In future work, we will conduct experiments on more languages with and without explicit word delimiters. In addition, we will try developing a dynamic mechanism to selectively consider the sense-level information rather than take all the senses of characters and words into account.

Abstract

In natural language processing, it is common that many entities contain other entities inside them. Most existing works on named entity recognition (NER) only deal with flat entities but ignore nested ones. We propose a boundary-aware neural model for nested NER which leverages entity boundaries to predict entity categorical labels. Our model can locate entities precisely by detecting boundaries using sequence labeling models. Based on the detected boundaries, our model utilizes the boundary-relevant regions to predict entity categorical labels, which can decrease computation cost and relieve error propagation problem in layered sequence labeling model. We introduce multitask learning to capture the dependencies of entity boundaries and their categorical labels, which helps to improve the performance of identifying entities. We conduct our experiments on nested NER datasets and the experimental results demonstrate that our model outperforms other state-of-the-art methods.

1 Introduction

Named entity recognition (NER) is a task that seeks to locate and classify named entities in unstructured texts into pre-defined categories such as person names, locations or medical codes. NER is generally treated as single-layer sequence labeling problem (Lafferty et al., 2001; Lample et al., 2016) where each token is tagged with one label. The label is composed by an entity boundary label and a categorical label. For example, a token can be tagged with $B\text{-}PER$, where B indicates the boundary of an entity and PER indicates the corresponding entity categorical label. However, when entities are nested within one another, single-layer sequence labeling models can not extract both entities simultaneously. A token contained inside many entities has more than one categorical label. Consider an example in Figure 1 from GENIA corpus (Kim et al., 2003), "Human TR Beta 1" is an $protein$ and it is also a part of a DNA "Human TR Beta 1 mRNA". Both entities contain the same token "Human". Thus the token should have two different categorical labels. In that case, assigning a single categorical label for "Human" is improper.

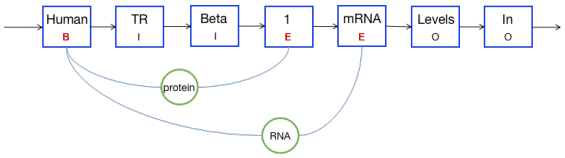

Figure 1: An example of nested entities and their boundary labels. "B" and "E" indicate the beginning and end of an entity. They are the boundary labels. "I" and "O" denote tokens inside and outside entities, respectively. $protein$ and RNA are categories of entities.

Traditional methods coping with nested entities rely on hand-craft features (Shen et al., 2003; Alex et al., 2007) and suffer from heavy feature engineering. Recent studies tackle the nested NER using neural models without relying on linguistics features or external knowledge resources. Ju et al. (2018) propose a layered sequence labeling model and Sohrab and Miwa (2018) propose a exhaustive region classification model.

- Layered sequence labeling model will first extract the inner entities (contained by other entities) and feed them into the next layer to extract outer entities. Thus, this model suffers from error propagation. When the previous layer extracts wrong entities, the performance of next layer will be affected. Moreover, when an outer entity is extracted first, the inner one will not be detected.

- Exhaustive region classification model enumerates all possible regions or spans in sentences to predict entities in a single layer. One issue of their method is the explicit boundary information is ignored, leading to extraction of some non-entities. **We consider an example**. In a sequence of tokens in GENIA dataset, "novel TH protein" is an entity and "a novel TH protein" is not an entity. However, since they share many tokens, the merged region representations of them are similar to each other. "novel" and "protein" are the boundary of the entity. Without the boundary information, both candidate regions are extracted as the entities.

Despite their shortcomings, layered sequence labeling model and exhaustive region classification model are complementary to each other. Therefore, we can combine them to improve the performance of nested NER. We leverage the sequence labeling model to consider the boundary information into locating entities. In the example mentioned above, "novel" is the boundary of the entity "novel TH protein", while "a" is a general token whose representation is different from "novel". With the guidance of boundary information, the model can detect "novel" as a boundary of the entity rather than token "a". We also utilize the region classification model to predict entities without considering the dependencies of inner and outer entities. In such case, Our model will not suffer error propagation problem.

In this paper, we propose a boundary-aware neural model that makes the fusion of sequence labeling model and region classification model. We apply a single-layer sequence labeling model to identify entity boundaries because the tokens in nested entities can share the same boundary labels. For example, as shown in Figure 1, "Human" can be tagged with the label B although it is the beginning of two different entities. Based on the detected entity boundaries, we predict entity categorical labels by classifying boundary-relevant regions. As shown in Figure 1, we match each token with label B to tokens with label E. The regions between them are considered as candidate entities. The representation of candidate entities will be utilized to classify categorical labels.

Our model is advanced than exhaustive region classification model in two ways: (1) we leverage the explicit boundary information to guide the model to locate and classify entities precisely. Exhaustive region classification model classifies entity regions individually, however, our model can consider the context information of boundary tokens with a sequence labeling model. That facilitates the detection of boundaries. (2) Our model only classifies the boundary-relevance regions which are much fewer than all possible regions. That decreases the time cost. Our model is advanced than layered sequence labeling model because we extract entities without distinguishing inner and outer entities.

Multitask learning is considered good at optimising the overall goal via alternatively tuning 2+ objectives, which are reinforced each other (Ruder, 2017). Considering our boundary detection module and entity categorical label prediction module share the same entity boundaries, we apply a multitask loss for training the two tasks simultaneously. The shared features of two modules are extracted by a bidirectional long short-term memory (LSTM) layer. Extensive experiments show the framework of multitask learning improves final performance in a large margin.

In summary, we make the following major contributions in this paper:

- We propose a boundary-aware neural model which leverages entity boundaries to predict categorical labels. Our model can locate entities precisely by detecting boundaries using sequence labeling models. Based on the detected boundaries, our model utilizes boundary-relevant regions to predict entity categorical labels, which can decrease computation cost and relieve error propagation problem.

- We introduce the multitask learning to capture the dependencies of entity boundaries and their categorical labels, which helps to improve the performance of identifying entities.

- We conduct our experiments on public nested NER datasets. The experimental results demonstrate our model outperforms previous state-of-the-art methods and our model is much faster in inference speed.

2 Related Work

NER has drawn the attention of NLP researchers because several downstream tasks such as entity

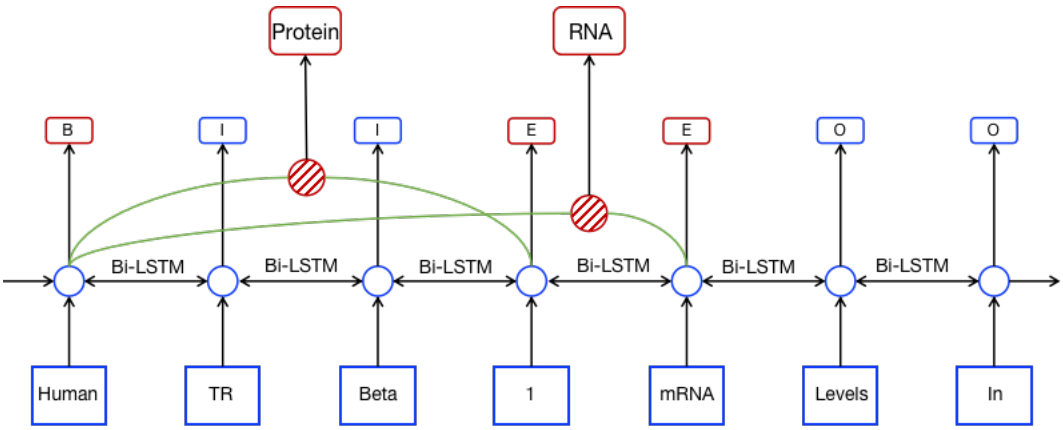

Figure 2: The Architecture of our boundary-aware model. The representation of each token in sentence "Human TR Beta 1 mRNA Levels in.." is feed into a shared bidirectional LSTM layer. We leverage the outputs of Bi-LSTM to detect entity boundaries and their categorical labels. The red circle indicates entity region representations between entity boundaries.

linking (Gupta et al., 2017), relation extraction (Mintz et al., 2009; Liu et al., 2017), co-reference resolution (Chang et al., 2013) and conversation system (Ren et al., 2019) rely on it. Several methods have been proposed on flat named entity recognition (Lample et al., 2016; Ma and Hovy, 2016; Strubell et al., 2017) while few of them address nested entities. Early work on nested entities rely on hand-craft features or rule-based post-processing (Zhang et al., 2004; Zhou et al., 2004; Zhou, 2006). They detect the innermost flat entities with a Hidden Markov Model and then use rule-based post-processing to extract the outer entities.

While most work concerns about named entities, Lu and Roth (2015) present a novel hypergraph-based method to tackle the problem of entity mention detection. One issue of their method is the spurious structure of hyper-graphs. Muis and Lu (2017) improve the method of Lu and Roth (2015) by incorporating mention separators along with features.

Recent studies reveal that stacking sequence model like conditional random filed(CRF) layer can extract entities from inner to outer. Alex et al. (2007) propose several CRF-based methods for the GENIA dataset. However, their approach can not recognize nested entities of the same type. Finkel and Manning (2009) present a chart-based parsing method where each named entity is a constituent in the parsing tree. However, their method is not scalable to larger corpus with a cubic time complexity. Ju et al. (2018) dynamically stack flat NER layers to extract nested entities, each flat layer is based on a Bi-LSTM layer and then a cascaded CRF layer. Their model suffers error propagation from layer to layer, an inner entity can not be detected when a outer entity is identified first.

It is difficult for sequence model, like CRF, to extract nested entities where a token can be included in several entities. Wang et al. (2018) present a transition-based model for nested mention detection using a forest representation. One drawback of their model is the greedy training and decoding. Sohrab and Miwa (2018) consider all possible regions in a sentence and classify them into their entity type or non-entity. However, their exhaustive method considers too many irrelevant regions(non-entity regions) into detecting entity types and the regions are classified individually, without considering the contextual information. Our model focuses on the boundary-relevant regions which is much fewer and the explicit leveraging of boundary information helps to locate entities more precisely.

3 Method

In this paper, we propose a boundary-aware neural model which considers the boundary information into locating and classifying entities. The architecture is illustrated in Figure 2.

Our model is built upon a shared bidirectional LSTM layer. It uses the outputs of LSTM layer to detect entity boundaries and predict categorical labels. We extract entity boundaries as paired tokens with label B and label E, "B" indicates the beginning of an entity and "E" means the end of an entity. We match every detected token with label

B and its corresponding token with label E, the regions between them are identified as candidate entities. We represent entities using the corresponding region outputs of shared LSTM and classify them into categorical labels.

The boundary detection module and entity categorical label prediction module are training simultaneously with a multitask loss function, which can capture the underlying dependencies of entity boundaries and their categorical labels. We will describe each part of our model in detail.

3.1 Token Representation

We represent each token in the sentence following the success of Ma and Hovy (2016) and Lample et al. (2016) that leverages character embedding for the flat NER task.

For a given sentence consisting of n tokens (t_1,t_2,....t_n), we represent the word embedding of i-th token t_i as equation(1):

$$\mathbf{x}_i^w = \mathbf{e}^w(t_i) \tag{1}$$

where $\mathbf{e}^w$ denotes a word embedding lookup table. We use pre-trained word embedding (Chiu et al., 2016) to initialize it.

We capture the orthographic and morphological features of the word by integrating character representations. Denoting the representation of characters within t_i as $\mathbf{x}_i^c$, The embedding of each character within token t_i is denoted as $\mathbf{e}^c(c_j)$. $\mathbf{e}^c$ is the character embedding lookup which is initialized randomly. Then we feed them into a bidirectional LSTM layer to learn hidden states. The forward and backward outputs are concatenated to construct character representations:

$$\mathbf{x}_i^c = [\overrightarrow{\mathbf{h}_i^c}; \overleftarrow{\mathbf{h}_i^c}] \tag{2}$$

where $\overleftarrow{\mathbf{h}_i^c}$ and $\overrightarrow{\mathbf{h}_i^c}$ denote the forward and backward outputs of bidirectional LSTM.

The final token representation is obtained as equation (3), where [;] denotes concatenation.

$$\mathbf{x}_i^t = [\mathbf{x}_i^w; \mathbf{x}_i^c] \tag{3}$$

3.2 Shared Feature Extractor

As shown in Figure 2, we apply the hard parameter sharing mechanism (Ruder, 2017) for multitask training using bidirectional LSTM as shared feature extractor. Hard parameter sharing greatly reduces the risk of overfitting (Baxter, 1997) and increases the correlation of our boundary detection module and categorical label prediction module. Specifically, the hidden state of bidirectional LSTM can be expressed as following:

$$\overrightarrow{\mathbf{h}}_i^t = \overrightarrow{\mathrm{LSTM}}(\mathbf{x}_i^t, \overrightarrow{\mathbf{h}}_{i-1}^t) \tag{4}$$

$$\overleftarrow{\mathbf{h}}_i^t = \overleftarrow{\mathrm{LSTM}}(\mathbf{x}_i^t, \overleftarrow{\mathbf{h}}_{i-1}^t) \tag{5}$$

$$\mathbf{h}_i^t = [\overrightarrow{\mathbf{h}}_i^t; \overleftarrow{\mathbf{h}}_i^t] \tag{6}$$

where $\mathbf{x}_i^t$ is the token representation which is mentioned in section 3.1. We feed $\mathbf{x}_i^t$ into a Dropout layer to prevent overfitting. $\overrightarrow{\mathbf{h}}_i^t$ and $\overleftarrow{\mathbf{h}}_i^t$ denote the i-th forward and backward hidden state of Bi-LSTM layer. Formally, we extract the shared features of each token in a sentence as $\mathbf{h}_i^t$.

3.3 Entity Boundary Detection

Previous works (Lample et al., 2016; Ma and Hovy, 2016) on flat NER (non-nested named entities recognition) predict entity boundaries and categorical labels jointly. However, when entities are nested in other entities, one individual token can be included in many different entities. This means assigning one single categorical label for each token is inappropriate.

We divide nested NER into two subtasks: entity boundary detection and categorical label prediction tasks. Unlike assigning an entity categorical label for each token, we predict the boundary labels first. Formally, given a sentence (t_1,t_2,...t_n), and one entity in the sentence. we represent the entity as $R(i, j)$, which denotes the entity is composed by a continuous token sequence (t_i,t_{i+1},...t_j). Specially, we tag the boundary token t_i as "B" and t_j as "E". The tokens inside entities are assigned with label "I" and non-entity tokens are assigned with "O" labels.

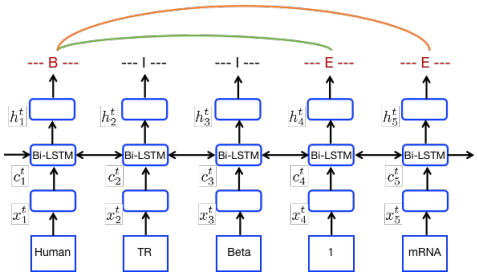

Figure 3: The architecture of entity boundary detection module. We feed the representation of each token in the sentence into a bidirectional LSTM layer, the outputs of LSTM layer are utilized to predict boundary labels.

We detect entity boundaries as shown in Fig-

ure 3. For each token t_i in a sentence, we predict a boundary label by feeding its corresponding shared feature representation $\mathbf{h}_i^t$ (described in section 3.2) into a ReLU activation function and a softmax classifier:

$$\mathbf{o}_i^t = \mathbf{U}\mathbf{h}_i^t + \mathbf{b} \quad (7)$$

$$\mathbf{d}_i^t = \text{softmax}(\mathbf{o}_i^t) \quad (8)$$

where $\mathbf{U}$ and $\mathbf{b}$ are trainable parameters. We compute the KL-divergence multi-label loss between the true distribution $\hat{\mathbf{d}}_i^t$ and the predicted distribution $\mathbf{d}_i^t$ as equation (9):

$$L_{bcls} = -\sum(\hat{\mathbf{d}}_i^t)\log(\mathbf{d}_i^t) \quad (9)$$

Conditional random field (CRF) (Lafferty et al., 2001) is considered good at modeling sequence label dependencies (e.g., label I must be after B). We make a comparison of choosing softmax or CRF as output layer because our sequence labels are different from flat NER models.

3.4 Entity Categorical Label Prediction

Given an input sentence sequence X = (x_1,x_2, ... x_n), and a corresponding boundary label sequence L = (l_1,l_2, ... l_n), we match each token with label B to the token with label E to construct candidate entity regions. Especially, considering there are entities containing one single token, we match tokens with label B to themselves firstly. The representation of entity $R(i,j)$ is obtained as following:

$$\mathrm{R}_{i,j} = \left[\frac{1}{j-i+1}\sum_{k=i}^{j}\mathbf{h}_k^t\right] \quad (10)$$

where $\mathbf{h}_k^t$ denotes the outputs of the shared bidirectional LSTM layer for k-th token in sentence. We simply average the representations for each token within boundary regions. The final representation of entities will be sent into a ReLU activation function and the softmax layer to predict entity categorical labels. We compute the loss of categorical label prediction in equation (11-12):

$$\mathbf{d}_{i,j}^e = \text{softmax}(\mathbf{U}_{i,j}^e\mathrm{R}_{i,j} + \mathbf{b}_{i,j}^e) \quad (11)$$

$$L_{ecls} = -\sum(\hat{\mathbf{d}}_{i,j}^e)\log(\mathbf{d}_{i,j}^e) \quad (12)$$

where $\mathbf{U}_{i,j}^e$ and $\mathbf{b}_{i,j}^e$ are trainable parameters. $\hat{\mathbf{d}}_{i,j}^e$ and $\mathbf{d}_{i,j}^e$ denote the true distribution and predicted distribution of entity categorical labels, respectively.

3.5 Multitask Training

In our model, it is inconvenient and inefficient for the reason that we predict entity categorical labels after all boundary-relative regions have been detected. Considering our boundary detection module and entity categorical label prediction module share the same entity boundaries, we apply a multitask loss for training the two tasks simultaneously.

During training phase, we feed the ground-truth boundary labels into entity categorical label prediction module so that the classifier will be trained without affection from error boundary detection. As for testing phase, the outputs of boundary detection will be collected. The detected boundaries will indicate which entity regions should be considered into predicting categorical labels. The multitask loss function is defined as follows:

$$L_{multi} = \alpha\sum L_{bcls} + (1-\alpha)\sum L_{ecls} \quad (13)$$

where L_{bcls} and L_{ecls} denote the categorical cross-entropy loss for boundary detection module and entity categorical label prediction module, respectively. α is a hyper-parameter which is assigned to control the degree of importance for each task.

4 Experimental Settings

4.1 Dataset

To provide empirical evidence for effectiveness of the proposed model, we employ our experiments on three nested NER datasets: GENIA (Kim et al., 2003), JNLPBA (Kim et al., 2004) and GermEval 2014 (Benikova et al., 2014).

GENIA dataset is constructed based on the GENIA v3.0.2 corpus. We preprocess the dataset following the same settings of (Finkel and Manning, 2009) and (Lu and Roth, 2015). The dataset is split into 8.1:0.9:1 for training, development and testing. The statistics of GENIA dataset is shown as Table 1.

Item	Train	Dev	Test	Overall	Nested
Document	1599	189	212	2000	-
Sentences	15023	1669	1854	18546	-
Percentage	81%	9%	10%	100%	-
DNA	7650	1026	1257	9933	1744
RNA	692	132	109	933	407
Protein	28728	2303	3066	34097	1902
Cell Line	3027	325	438	3790	347
Cell Type	5832	551	604	6987	389
Overall	45929	4337	5474	55740	4789

Table 1: Statistics of GENIA dataset

JNLPBA dataset is originally from GENIA corpus. It contains a training and testing datasets.

However, only the flat and top-most entities are preserved. We collapse the sub-categories into 5 categories following the same settings as GENIA dataset.

GermEval 2014 dataset contains German nested named entities. The dataset covers over 31,000 sentences corresponding to over 590,000 tokens.

4.2 Baseline Methods

We compare our model with several state-of-the-art models on GENIA dataset. These methods can be divided into three groups:

Finkel and Manning (2009) and Ju et al. (2018) propose CRF-based sequence labeling approaches for nested named entity recognition. Finkel and Manning (2009) leverage entity-level features while Ju et al. (2018) propose neural-based method. We rerun the codes of Ju et al. (2018) because they have not shared their pre-processed dataset.

Sohrab and Miwa (2018) propose an exhaustive region classification model for nested NER. We re-implement their method according to their paper because they have not shared the codes.

Lu and Roth (2015) and Muis and Lu (2017) build hyper-graphs to represent both the nested entities and their mentions. Muis and Lu (2017) improve the method of Lu and Roth (2015).

4.3 Parameter Settings

Our model is implemented by PyTorch framework[1] [2]. We use Adam optimizer for training our model. We initialize word vectors with a 200-dimension pre-trained word embedding the same as Ju et al. (2018) and Sohrab and Miwa (2018) while the char embedding is set to 50-dimension and initialized randomly. The learning rate is set to 0.005. We set a 0.5 dropout rate for the Dropout layer employed after token-level LSTM during training phase. The output dimension of our shared bidirectional LSTM is 200. The coefficient α of multitask loss is tuned during development process. All of our experiments are performed on the same machine (NVIDIA 1080ti GPU and Intel i7-8700 CPU).

[1] https://pytorch.org/

[2] Code is available at https://github.com/thecharm/boundary-aware-nested-ner

4.4 Evaluation Metrics

We use a strict evaluation metrics that an entity is confirmed correct when the entity boundary and the entity categorical label are correct simultaneously. We employ precision, recall and F-score to evaluate the performance.

5 Results and Discussion

5.1 Overall Evaluation

We conduct our experiments on GENIA test dataset for nested named entity recognition. Table 2 shows our method outperforms the compared methods both in recall and F-score metrics. The CRF-based model is considered as more efficient in sequence labeling task, we compare the utilization of softmax and CRF as output layer of boundary detection module. The results show they gain comparable scores in precision, recall and F-score. However, the CRF-based model is time-consuming, about 3-5 times slower than the softmax-based model in inference speed.

Model	P(%)	R(%)	F(%)
Finkel and Manning (2009)[3]	75.4	65.9	70.3
Lu and Roth (2015)[3]	72.5	65.2	68.7
Muis and Lu (2017)[3]	75.4	66.8	70.8
Sohrab and Miwa (2018)	73.3	68.3	70.7
Ju et al. (2018)	**76.1**	66.8	71.1
Our model(softmax)	75.9	**73.6**	**74.7**
Our model(CRF)	74.6	73.2	73.9

Table 2: Performance on GENIA test set. Our models with softmax and CRF outperform other state-of-the-art methods.

Our model achieves a recall value of 73.6% and outperforms compared methods in Recall value with a large margin. We think that our model extract entities with a more accurate boundaries comparing to other methods. We evaluate it in experiments on boundary detection module.

Model	P(%)	R(%)	F(%)
Sohrab and Miwa (2018)	**75.0**	60.8	67.2
Ju et al. (2018)	72.9	61.5	66.7
Our model	74.5	**69.1**	**71.7**

Table 3: Performance on GermEval 2014 test set. Our model outperforms two state-of-the-art methods in nested NER.

The GermEval 2014 dataset from KONVENS 2014 shared task is a German NER dataset. It

[3] The results are taken from their papers.

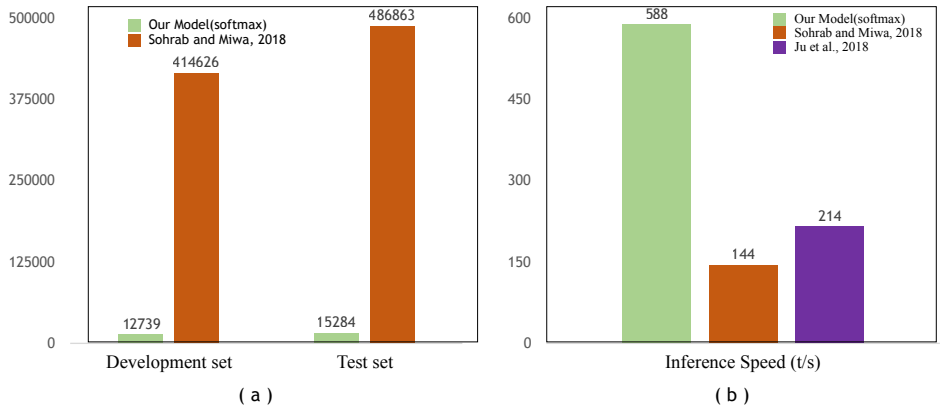

Figure 4: (a): The number of candidate entity regions in our model with softmax and the approach of Sohrab and Miwa (2018) when evaluating on GENIA test and development set; (b): The inference speed of our model and compared models on GENIA test set. t/s indicates token per second.

contains few nested entities. Previous works in this dataset ignore nested entities or extract inner and outer entities in two independent models. Our method can extract nested entities in an end-to-end way. We compare our method with two state-of-the-art approaches in Table 3. Our method outperforms their approaches both in Recall and F-score metrics.

Table 4 describes the performances of our model on the five categories on the test dataset. Our model outperforms the model described in Ju et al. (2018) and Sohrab and Miwa (2018) with F-score value on all categories.

Category	P(%)	R(%)	F(%)	Ju. F(%)	Soh. F(%)
DNA	73.6	67.8	**70.6**	70.1	67.8
RNA	82.2	80.7	**81.5**	80.8	75.9
protein	76.7	76.0	**76.4**	72.7	72.9
cell line	77.8	65.8	**71.3**	66.9	63.6
cell type	73.9	71.2	**72.5**	71.3	69.8
overall	75.8	73.6	**74.7**	71.1	70.7

Table 4: Our results on five categories compared to Ju et al. (2018) and Sohrab and Miwa (2018) on GENIA test set.

5.2 Performance of Boundary Detection

We conduct experiments on boundary detection to illustrate that our model extract entity boundaries more precisely comparing to Sohrab and Miwa (2018) and Ju et al. (2018). Table 5 shows the results of boundary detection on GENIA test dataset. Our model locates entities more accurately with a higher recall value (76.9%) than the comparing methods. It gives a reason why our model outperforms other state-of-the-art methods in recall value. We exploit boundary information explicitly and consider the dependencies of boundaries and entity categorical labels with a multitask loss. While in the method of Sohrab and Miwa (2018), candidate entity regions are classified individually.

Model	Boundary Detection		
	P(%)	R(%)	F(%)
Sohrab and Miwa (2018)	76.6	69.2	72.7
Ju et al. (2018)	79.9	67.08	73.4
Our model(softmax)	79.7	**76.9**	**78.3**

Table 5: Performance of Boundary Detection on GENIA test set.

Table 6 describes the performance of our model in detecting boundary labels for each token in sentences. The results are based on the shared bidirectional LSTM and a softmax classifier. Our model extracts entity boundaries with a relatively high performance. This facilitates the prediction of entity categorical labels because the candidate entity regions are more likely to be true entities.

Boundary Label	P(%)	R(%)	F(%)
O (non-entity)	99.3	99.0	99.2
B (beginning)	84.4	84.3	84.3
E (end)	86.0	87.2	86.6
I (inner-entity)	82.8	88.6	85.6

Table 6: Performance of Boundary Label Prediction with softmax classifier on GENIA test set.

5.3 Inference Time

Figure 4(a) shows the number of candidate entity regions in our model with softmax and the approach of Sohrab and Miwa (2018). Comparing to classifying all possible regions in sentences, our

model only concerns about boundary-relevant regions which is much fewer. We compare the inference speed of our model and the approaches of Sohrab and Miwa (2018) and Ju et al. (2018) in Figure 4(b). Our model is about 4 times faster than Sohrab and Miwa (2018) and about 3 times faster than Ju et al. (2018). The cascaded CRF layers of Ju et al. (2018) are the limitation in inference speed.

5.4 Performance of Multitask Learning

Table 7 shows the performance of our pipeline model and multitask model on GENIA development set and test set. For pipeline model, we train the boundary detection module and entity categorical label prediction module separately. Our multitask model has a higher F value both in development set and test set.

Model	Development Set			Test Set		
	P(%)	R(%)	F(%)	P(%)	R(%)	F(%)
Pipeline	74.5	74.8	74.6	75.4	72.2	73.8
Multitask	74.5	75.6	**75.0**	75.9	73.4	**74.7**

Table 7: Performance Comparison of our pipeline model and multitask model on GENIA development set and test set.

Multitask learning can capture the underlying dependencies of boundaries and entity categorical labels. It helps the model focus its attention on those features that actually matter (Ruder, 2017). In pipeline model, entity categorical prediction module will not share information with boundary detection module because they are trained separately. However, entity categorical prediction module and boundary detection module share the same entity boundaries. We assign a shared feature extractor (the bidirectional LSTM layer) to extract the features utilized in both entity categorical prediction and boundary detection. The results have demonstrated that the framework of multitask learning improves final performance.

5.5 Ablation Study and Flat NER

We conduct ablation experiments on GENIA development set to evaluate the contributions of neural components including dropout layer, pretrained word embedding and the character-level LSTM. The results are listed in Table 8. All these components contribute to the effectiveness of our model. Dropout layer contributes significantly for both precision and recall values.

Setting	P(%)	R(%)	F(%)
Our Model(softmax)	74.5	75.6	**75.0**
without Dropout	72.6	73.1	72.9
without Pre-trained	73.8	**75.7**	74.7
without Char repr.	**75.3**	73.9	74.6

Table 8: Results of Ablation Tests on GENIA development set.

To prove our model can work on nested NER and also flat NER task, we perform experiments on the JNLPBA dataset. We achieve 73.6 in term of F-score which is comparable with the state-of-the-art result of Gridach (2017).

6 Case Study

Table 9 shows a case study comparing our model with exhaustive model (Sohrab and Miwa, 2018) and Layered model (Ju et al., 2018). In the example, "human TATA binding factor" is an entity nested in entity "transcriptionally active human TATA binding factor". Our model with multitask learning extracts both entities with exact boundaries and entity categorical labels. Exhaustive model gets the error boundaries and misses the token "human" in entities. Comparing to layered model only detecting an outer entity, our model extract both inner and outer entities. It demonstrates that our combination of sequence labeling models and region classification models can locate entities precisely and extract both inner and outer entities.

Sentence	Cloning of a transcriptionally active human TATA binding factor.
Gold Label	protein: {human TATA binding factor; transcriptionally active human TATA binding factor}
Exhaustive model	protein: {TATA binding factor; transcriptionally active human TATA binding factor}
Layered model	protein: {transcriptionally active human TATA binding factor}
Our model(pipeline)	protein: {human TATA binding factor;}
Our model(multitask)	protein: {human TATA binding factor; transcriptionally active human TATA binding factor}

Table 9: An example of predicted results in GENIA test dataset.

For our pipeline model, without the dependencies information from entity categorical labels, it misses the outer entity boundaries and only extracts the inner one. It verifies that the multitask learning can share boundary information between boundary detection module and entity categorical

label prediction module, which is very effective for nested NER.

7 Conclusion

This paper presents a boundary-aware model which leverages boundaries to predict entity categorical labels. Our model combines sequence labeling model and region classification model to locate and classify nested entities with high performance. To capture the underlying dependencies of boundary detection module and entity categorical prediction module, we apply a multitask loss for training the two tasks simultaneously. Our model outperforms existing nested models in terms of F-score.

For future work, we consider to model the dependencies among entity regions explicitly and improve the performance of boundary detection module which is important for entity categorical label prediction.

Abstract

The multiple relation extraction task tries to extract all relational facts from a sentence. Existing works didn't consider the extraction order of relational facts in a sentence. In this paper we argue that the extraction order is important in this task. To take the extraction order into consideration, we apply the reinforcement learning into a sequence-to-sequence model. The proposed model could generate relational facts freely. Widely conducted experiments on two public datasets demonstrate the efficacy of the proposed method.

1 Introduction

Relation extraction (RE) is a core task in natural language processing (NLP). RE can be used in information extraction (Wu and Weld, 2010), question answering (Yih et al., 2015; Dai et al., 2016) and other NLP tasks. Most existing works assumed that a sentence only contains one relational facts (a relational fact, or a triplet, contains a relation and two entities). But in fact, a sentence often contains multiple relational facts (Zeng et al., 2018b). The multiple relation extraction task tries to extract all relational facts from a sentence.

Existing works on multiple relation extraction task can be divided into five genres. 1) PseudoPipeline genre, including Miwa and Bansal (2016); Sun et al. (2018). They first recognized all the entities of the sentence, then extracted features for each entity pair and predicted their relation. They trained the entity recognition model and relation prediction model together instead of separately. Therefore, we call them PseudoPipeline methods. 2) TableFilling genre, including Miwa and Sasaki (2014); Gupta et al. (2016) and Zhang et al. (2017). They maintained a entity-relation table and predicted a semantic tag (either entity tags or relation tags) for each cell in the table. According to the predicted tags, they can recognize the entities and the relation between each entity pair. 3) NovelTagging genre, including Zheng et al. (2017). This method can be seen as a development of TableFilling method. They assigned a pre-defined semantic tag to each word of the sentence and collected triplets based on the tags. Their tags include both entity and relation information. Therefore, they don't need to maintain a entity-relation table. 4) MultiHeadSelection genre, including Bekoulis et al. (2018a) and Bekoulis et al. (2018b). They first recognized the entities, then they formulated the relation extraction task as a multi-head selection problem. For each entity, they calculated the score between it and every other entities for a given relation. The combination of the entity pair and relation with the score exceeding a threshold will be kept as a triplet. 5) Generative genre, including Zeng et al. (2018b). They directly generate triplets one by one by a sequence-to-sequence model with copy mechanism (Gu et al., 2016; Vinyals et al., 2015). To generate a triplet, they first generated the relation, then they copy the first entity and the second entity from the source sentence.

However, none of them have considered the extraction order of multiple triplets in a sentence. Given a sentence, the PseudoPipeline methods extract relations of different entity pairs separately. Although they jointly training the entity model and relation model, they ignore the influence between triplets actually. The TableFilling, NovelTagging and MultiHeadSelection methods extract the triplets in the word order of this sentence. They firstly deal with the first word, then the second one and so on. The generative method could generate triplets in any order actually. However, Zeng et al. (2018b) randomly choose the extraction order of the triplets in each sentence. Sorting the triplets in the sentences of training data beforehand with

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 367–377, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

Sentence	Cubanelle is in Arros negre, a dish from the Catalonia region.	
Relational Facts	#1	F_2: <Arros negre, food_region, Catalonia>
	#2	F_1: <Arros negre, ingredient, Cubanelle>

Figure 1: Example of multiple relation extraction. In this example, it's easier to extract F_2 first. The extraction of F_1 can be benefit from F_2.

global rules (e.g., alphabetical order) is straightforward. But one global sorting rule may not fit every sentences.

In this paper, we argue that the extraction order of triplets in a sentence is important. Take Figure 1 as example. It's difficult to extract F_1 first because we don't know what "Arros negre" is in the first place. Extracting F_2 is more straightforward as the key words "dish", "region" in the sentence is helpful. F_2 can help us to extract F_1 because now we are confident that "Arros negre" is some kind of food, so that "ingredient" is a suitable relation between "Arros negre" and "Cubanelle". From this intuitive example, we can see that the extracted triplets could influence the extraction of the remaining triplets.

To automatically learning the extraction order of multiple relational facts in a sentence, we propose a sequence-to-sequence model and apply reinforcement learning (RL) on it. we follow the Generative genre because such a model could extract triplets in various order, which is convenient for us to explore the influence of triplets extraction order. Our model reads in a raw sentence and generates triplets one by one. Thus, all triplets in a sentence could be extracted. To take the triplets extraction order into consideration, we convert the triplets generation process as a RL process. The sequence-to-sequence model is regarded as the RL policy. The action is what we generate in each time step. We assume that a better generation order could lead to more valid generated triplets. The RL reward is related to the generated triplets. In general, the more triplets are correctly generated, the higher the reward. Unlike supervised learning with negative log likelihood (NLL) loss, which forces the model to generate triplets in the order of the ground truth, reinforcement learning allows the model generate triplets freely to achieve higher reward.

The main contributions of this work are:

- We discuss the triplets extraction order problem in the multiple relation extraction task. In our knowledge, this problem has never been addressed before.
- We apply reinforcement learning method on a sequence-to-sequence model to handle this problem.
- We conduct widely experiments on two public datasets. Experimental results show that the proposed method outperform the strong baselines with 3.4% and 5.5% improvements respectively.

2 Related Work

Given a sentence with two annotated entities (an entity pair), the relation classification task aims to identify the predefined relation between these two entities. Zeng et al. (2014) was among the first to apply neural networks in relation classification task. They adopted the Convolutional Neural Network (CNN) to learn the sentence representation automatically. In the following, dos Santos et al. (2015); Xu et al. (2015a) also applied CNN to extract relation. Xu et al. (2015b) utilized shortest dependency path between two entities with a LSTM (Hochreiter and Schmidhuber, 1997) based recurrent neural network. Zhou et al. (2016) applied attention mechanism to learn different weights for each word and used LSTM to represent sentence. These methods all assumed that the entity pair is given beforehand and a sentence only contains two entities.

To extract both entities and relation from sentence, early works like Zelenko et al. (2003); Chan and Roth (2011) adopted pipeline methods. However, such pipeline methods neglect the relevance between entities and relation. Latter works focused on joint models that extract entities and relation jointly. Yu and Lam (2010); Li and Ji (2014); Miwa and Bansal (2016) relied on NLP tools to do feature engineering, which suffered from the error propagation problem. Miwa and Sasaki (2014); Gupta et al. (2016); Zhang et al. (2017) applied neural networks to jointly extract entities and relations. They converted the relation extraction task into a table filling task. Zheng et al. (2017) took a step further and converted this task into a tagging task. They assigned a semantic tag to each word in the sentence and collected triplets according to the tag information. Bekoulis et al. (2018b,a) model the relation extraction task as a multi-head selec-

tion problem. However, these models can not take triplet's extraction order into consideration. Sun et al. (2018) proposed a joint learning paradigm based on minimum risk training. Their method ignore the influence between relational facts. Zeng et al. (2018b) proposed an sequence-to-sequence model with copy mechanism to handle the overlapping problem in multiple relation extraction. They randomly choose a extraction order for each sentence.

RL has attracted lot of attention recently. It has been successfully applied in many games (Mnih et al., 2015; Silver et al., 2016). Narasimhan et al. (2015); He et al. (2016) applied RL on text based games. Narasimhan et al. (2016) employed deep Q-network to optimize a reward function that reflects the extraction accuracy while penalizing extra effort. Li et al. (2016) applied policy gradient method to model future reward in chatbot dialogue. They designed a reward to promote three conversational properties: informativity, coherence and ease of answering. Su et al. (2016) using on-line activate reward learning for policy optimization in spoken dialogue systems because the user feedback is often unreliable and costly to collect. Yu et al. (2017) applied RL method to overcome the limitations that the Generative Adversarial Net (GAN) in generating sequences of discrete tokens. Our work is related to Li et al. (2016); Yu et al. (2017) since we also apply RL to generate better sequences.

There are several works that related to both relation extraction and RL, which are also related to our work. Zeng et al. (2018a); Feng et al. (2018); Qin et al. (2018) applied RL to distantly supervised relation extraction task. Zeng et al. (2018a) turned the bag relation prediction into an RL process. They assumed that the relation of the bag is determined by the relation of sentences from the bag. They set the final reward to +1 or -1 by comparing the predict bag relation with the gold relation. Feng et al. (2018) adopted policy gradient method to select high-quality sentences from the bag. The selected sentences are feed to the relation classifier and the relation classifier provides rewards to the instance selector. Similarly, Qin et al. (2018) explored a deep RL strategy to generate the false-positive indicator. Our work is different from them since we focus on supervised relation extraction task.

3 Method

We first introduce our basic model and then introduce how to apply RL on it. Similar to Zeng et al. (2018b), our neural model is also a sequence-to-sequence model with copy mechanism. It reads in a raw sentence and generates triplets one by one. Instead of training the model with NLL loss, we regard the triplets generation process as a RL process and optimize the model with REINFORCE (Williams, 1992) algorithm. Therefore, we don't have to determine the triplets order of each sentence beforehand, we let the model generate triplets freely. We show the RL process in Figure 2.

3.1 Sequence-to-Sequence Model with Copy Mechanism

The sequence-to-sequence model with copy mechanism is a kind of CopyNet (Gu et al., 2016) or PointerNetwork (Vinyals et al., 2015). Two components included in this model: encoder and decoder. The encoder is a bi-directional recurrent neural network, which is used to encode a variable-length sentence into a fixed-length vector. We denote the outputs of encoder as $\mathbf{O}^E = [\mathbf{o}_1^E, ..., \mathbf{o}_n^E]$, where $\mathbf{o}_i^E$ denotes the output of i-th word of the encoder and n is the sentence length.

The decoder is another recurrent neural network, which is used to generate triplets one by one. The *NA*-triplets will be generated if the valid triplets number is less than the maximum triplets number.[1] It takes three-time steps to generate one triplet. That is, in time step t ($t = 1, 2, 3, ..., T$), if $t\%3 = 1$, we predict the relation. If $t\%3 = 2$, we copy the first entity and if $t\%3 = 0$, we copy the second entity. T is the maximum decode time step. Note that T is always divisible by 3.

Suppose there are m predefined valid relations, in time step t ($t = 1, 4, 7, ...$), we calculate the confidence score for each valid relation:

$$\mathbf{q}_t^r = selu(\mathbf{o}_t^D \cdot \mathbf{W}_t^r + \mathbf{b}_t^r) \quad (1)$$

where $\mathbf{o}_t^D$ is the output of decoder in time step t; $\mathbf{W}_t^r$ is the weight matrix and $\mathbf{b}_t^r$ is the bias in time step t; $selu(\cdot)$ (Klambauer et al., 2017) is activation function. To allow the model to generate *NA*-triplet, we also calculate the confidence score for

[1] *NA*-triplet is a special triplet proposed in Zeng et al. (2018b). It's similar to the "eos" symbol in neural sentence generation.

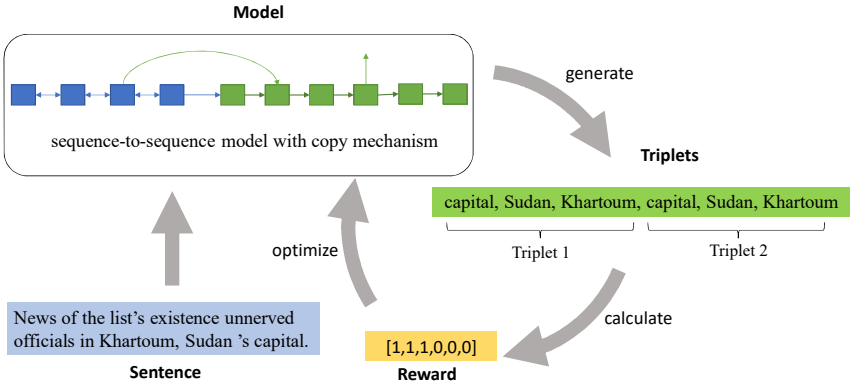

Figure 2: The RL process. The model reads in a raw sentence and generates triplets. Then, a reward is assigned to each time step based on the generated triplets. Lastly, the rewards is used to optimize the model.

NA relation:

$$\mathbf{q}_t^{NA} = selu(\mathbf{o}_t^D \cdot \mathbf{W}_t^{NA} + \mathbf{b}_t^{NA}) \quad (2)$$

where $\mathbf{W}_t^{NA}$ and $\mathbf{b}_t^{NA}$ are parameters in time step t. Then we concatenate $\mathbf{q}_t^r$ and $\mathbf{q}_t^{NA}$ and perform softmax to obtain the probability distribution:

$$\mathbf{p}_t^r = softmax([\mathbf{q}_t^r; \mathbf{q}_t^{NA}]) \quad (3)$$

To copy the first entity in time step t ($t = 2, 5, 8, ...$), we calculate the confidence score of each word in source sentence:

$$q_{ti}^e = selu([\mathbf{o}_t^D; \mathbf{o}_i^E] \cdot \mathbf{w}_t^e) \quad (4)$$

where q_{ti}^e is the confidence score of i-th word and $\mathbf{w}_t^e$ is the weight vector, in time step t. Similarly, to take the *NA*-triplet into consideration, we also calculate the confidence score for *NA* entity with Eq 2. We concatenate them and perform softmax to obtain the probability distribution:

$$\mathbf{p}_t^e = softmax([[q_{t1}^e, ..., q_{tn}^e]; \mathbf{q}_t^{NA}]) \quad (5)$$

Copy the second entity in time step t ($t = 3, 6, 9, ...$) is almost the same as the first entity. The only difference is we also apply the mask (Zeng et al., 2018b) to avoid the copied two entities are the same.

Our model is similar to OneDecoder model and MultiDecoder model in Zeng et al. (2018b). Compared with OneDecoder model, our model using different linear transformation parameters in different decoding time step. Compared with MultiDecoder model, our model using only one decoder cell to decode all triplets. In our model, we didn't using attention mechanism because we found that the attention mechanism makes no difference to the results.

3.2 Reinforcement Learning Process

We regard the triplets generation process as RL process. The loop in Figure 2 represents a RL episode. In each RL episode, the model reads in the raw sentence and generate output sequence. Then we gain triplets from the output sequence and calculate rewards based on them. Finally, we optimize the model with REINFORCE algorithm.

State

We use s_t to denote the state of sentence x in decoding time step t. The state s_t contains the already generated tokens $\hat{y}^{<t}$, the information of source sentence x and the model parameters θ.

$$s_t = (\hat{y}^{<t}, x, \theta) \quad (6)$$

Action

The action is what we predict (or copy) in each time step. In time step t and $t\%3 = 1$, the model (policy) is required to determine the relation of the triplet; In time step t where $t\%3 = 2$ or 0, the model is required to determine the first or second entity, which is copied from the source sentence. Therefore, the action space A is varied in different time step t.

$$A = \begin{cases} R, & t\%3 = 1 \\ P, & t\%3 = 2, 0 \end{cases} \quad (7)$$

where R is the predefined relations and P is the positions of source sentence. We denote the action sequence of the source sentence as $a = [a_1, ..., a_T]$.

Algorithm 1 Reward Assignment

Input: Sampled action sequence $a = [a_1, ..., a_T]$; Gold triplets set G; *NA*-triplet *NA*.
Output: Rewards of each action $r = [r_1, ..., r_T]$.

```
Number of generated triplets K = T/3;
Generated triplets list F = [F_1, ..., F_K];
Already generated triplets set V = {}.
for each i ∈ [1, K] do
    F_i = [a_{3*i-2}, a_{3*i-1}, a_{3*i}]
end for
for each i ∈ [1, K] do
    r_{3*i-2} = r_{3*i-1} = r_{3*i} = 0
    if i ≤ |G| then
        if F_i ∈ G and F_i ∉ V then
            Add F_i to V
            r_{3*i-2} = r_{3*i-1} = r_{3*i} = 1
        end if
    else if F_i = NA then
        r_{3*i-2} = r_{3*i-1} = r_{3*i} = 0.5
    end if
end for
```

Reward

The reward is used to guide the training, which is critical to RL training. However, we can't assign a reward to each step directly during the generation since we don't know whether each action we choose is good or not before we finish the generation. Remind that we could obtain a triplet in every three steps. Once we obtained a triplet, we can compare it with the gold triplets and know if this triplet is good or not. A well generated triplet means it's the same with one of the gold triplets and not the same with any already generated triplets.

When we obtained a good triplet after three steps, we assign reward 1 to each of these three steps. Otherwise, we assign reward 0 to them. After generating valid triplets, we may need to generate *NA*-triplets. We assign reward 0.5 to each of these three steps if we correctly generate *NA*-triplet and reward 0 otherwise. We show the details of the reward assignment in Algorithm 1[2].

3.3 Training

The model can be trained with either supervised learning loss or reinforcement learning loss. However, the supervised learning forces the model to generate triplets in the order of the ground truth while the reinforcement learning allows the model generate triplets freely.

NLL Loss

Training the model with NLL loss requires a predefined ground truth sequence for each sentence. Suppose T is the maximum time step of decoder, we denote the ground truth sequence as $[y_1, ..., y_t, ..., y_T]$. Them the NLL loss for sentence x can be defined as:

$$L = \frac{1}{T}\sum_{t=1}^{T} -log(p(y_t|\hat{y}^{<t}, x, \theta)) \quad (8)$$

where $\hat{y}^{<t}$ is the already generated tokens; $p(\cdot|\cdot)$ is the conditional probability; θ is the parameters of the entire model.

RL Loss

Training the model with reinforcement learning only require the ground truth triplets for each sentence. The RL loss for sentence x is:

$$L = \frac{1}{T}\sum_{t=1}^{T} -log(p(\hat{y}_t|\hat{y}^{<t}, x, \theta)) * r_t \quad (9)$$

where $\hat{y}_t$ is the sampled action and r_t is the reward, in time step t.

4 Experiments

4.1 Dataset

Following Zeng et al. (2018b), we test our method on two open datasets: New York Times (NYT) dataset and WebNLG dataset.

NYT dataset is proposed by Riedel et al. (2010). This dataset is produced by distant supervision method which automatically aligns Freebase with New York Times news articles. Like Zheng et al. (2017); Zeng et al. (2018b) do, we ignore the noise in this dataset and use it as a supervised dataset. We use the pre-processed dataset used in Zeng et al. (2018b), which contains 5000 sentences in the test set and 5000 sentences in the validation set and 56195 sentences in the train set. In the train set, there are 36868 sentences that contain one triplet, 19327 sentences that contain multiple triplets. In the test set, the sentence number are 3244 and 1756, respectively. There are 24 relations in total.

WebNLG dataset is proposed by Gardent et al. (2017). This data set is originally created for Natural Language Generation (NLG) task. Given a

[2]How to determine the reward in RL is difficult. We tried several different reward assignments but only this one works.

group of triplets, annotators are asked to write a sentence which contains the information of all triplets in this group. We use the dataset preprocessed by Zeng et al. (2018b) and the train set contains 5019 sentences, the test set contains 703 sentences and the validation set contains 500 sentences. In the train set, there are 1596 sentences that contain one triplet, 3423 sentences contain multiple triplets. In the test set, the sentence number are 266 and 437, respectively. There are 246 different relations.

4.2 Settings

Zeng et al. (2018b) only use LSTM as the model cell. In this paper, we report the results of both LSTM and GRU (Cho et al., 2014). We follow the most settings from Zeng et al. (2018b). The cell unit number is set to 1000; The embedding dimension is set to 100; The batch size is 100; The maximum time step T is 15, that is, we will extract 5 triplets for each sentence; We use Adam (Kingma and Ba, 2015) to optimize parameters and stop the training when we find the best result in validation set. For the NLL training, the learning rate in both dataset is 0.001. For the RL training, we first pretrain the model with NLL training (pretrain model achieves 80%-90% of the best NLL training performance), then training the model with RL. The RL learning rate is 0.0005.

4.3 Evaluation Metrics

We follow the evaluation metrics in Zeng et al. (2018b). Our model can only copy one word for each entity and we use the last word of each entity to represent them. Triplet is regarded as correct when its relation, the first entity and the second entity are all correct. For example, suppose the gold triplets is $< Barack\ Obama, president, USA >$, $< Obama, president, USA >$ is regarded as correct while $< Obama, locate, USA >$ and $< Barack, prsident, USA >$ are not. A triplet is regarded as *NA*-triplet when and only when its relation is NA relation and it has a NA entity pair. The predicted *NA*-triplet will be excluded. We use the standard micro Precision, Recall and F1 score to evaluate the results.

4.4 Results of Different Extraction Order

To find out if the triplets extraction order of a sentence can make difference in multiple relation extraction task, we conduct widely experiments on both NYT and WebNLG dataset. We show the results of different extraction order of different models with LSTM cell in Table 1. The results of models with GRU cell are shown in Appendix B. We box the best results of a model and the bold values are the best results in this dataset.

CNN denotes the baseline with CNN classifier. We use the NLTK toolkit[3] to recognize the entities first. Then we combine every two entities as an entity pair. Every two entities can lead to two different entity pairs. For each entity pair, we apply a CNN classifier (Zeng et al., 2014) to determine the relation. We leave the details of this model in Appendix A. **ONE** and **MULTI** denotes the OneDecoder model and MultiDecoder model in Zeng et al. (2018b).[4] **NLL** means the model is trained with NLL loss, which requires a predefined ground truth sequence for each sentence. For a sentence with N triplets, there are $N!$ (the factorial of N) possible extraction order, which lead to $N!$ valid sequences. **Shuffle** means we randomly select one valid sequence as the ground truth sequence in every training epoch for a sentence. **FixUnsort** means we randomly select one valid sequence before training, and use the selected one as ground truth sequence during training. This strategy is used in Zeng et al. (2018b). **Alphabetical** means we sort the triplets of a sentence in alphabetical order and build ground truth sequence based on the sorted triplets. **Frequency** means we sort the triplets of a sentence based on the relation frequency. We count the relation frequency from the training set. **RL** means the model is trained with reinforcement learning. In NYT dataset, we using Alphabetical strategy to pretrain the model, and in WebNLG dataset, we pretrain the model wtih Frequency strategy.

Form Table 1, we can observe that: (a) The CNN baseline is not performing well because this model neglect the influence between triplets. (b) Compared with FixUnsort strategy, simply change the ground truth sequence in different training epoch (the Shuffle strategy) is also not good. The performance of OneDecoder drops from 0.566 to 0.552 in NYT dataset and 0.305 to 0.283 in WebNLG dataset. (c) In both dataset and for all models trained with NLL loss, sort the triplets in some order (Alphabetical or Frequency order)

[3] https://www.nltk.org/

[4] We reimplement these two models and find that the attention mechanism is not important. Therefore, we report the results without applying the attention mechanism.

Model	NYT			WebNLG		
	Precision	Recall	F1	Precision	Recall	F1

ONE+NLL (FixUnsort)	0.606	0.530	0.566	0.320	0.291	0.305
ONE+NLL (Alphabetical)	0.616	0.553	0.583	0.305	0.292	0.298
ONE+NLL (Frequency)	0.609	0.546	0.576	0.323	0.311	0.317
ONE+RL	0.715	0.533	0.610	0.668	0.307	0.421
MULTI+NLL (Shuffle)	0.629	0.522	0.570	0.363	0.278	0.315
MULTI+NLL (FixUnsort)	0.600	0.562	0.580	0.434	0.431	0.432
MULTI+NLL (Alphabetical)	0.685	0.647	0.665	0.482	0.481	0.481
MULTI+NLL (Frequency)	0.648	0.604	0.625	0.519	0.518	0.518
MULTI+RL	0.742	0.639	0.687	0.611	0.523	0.564
Our+NLL (Shuffle)	0.670	0.545	0.601	0.417	0.310	0.356
Our+NLL (FixUnsort)	0.645	0.591	0.617	0.490	0.488	0.489
Our+NLL (Alphabetical)	0.717	**0.678**	0.697	0.533	0.537	0.535
Our+NLL (Frequency)	0.688	0.652	0.669	0.581	0.587	0.584
Our+RL	**0.779**	0.672	**0.721**	**0.633**	**0.599**	**0.616**

Table 1: Results of different extraction order of models with LSTM cell.

can lead to better performance. For example, our model achieves 0.617 F1 score under FixUnsort strategy, while 0.697 and 0.669 F1 score under Alphabetical and Frequency strategy in NYT dataset. This observation verifies that the triplets extracting order of a sentence is important in multiple relation extraction task. (d) Another interesting observation is that the NLL trained model can achieve the best F1 score in NYT dataset if we sort the triplets in alphabetical order, while in WebNLG dataset, we need to sort the triplets in relation frequency order. This observation demonstrates that a global sorting rule may not fit for every dataset. The Alphabetical strategy is better for NYT dataset while the Frequency strategy is better for WebNLG dataset. (e) We can also observe that the model trained with RL can achieve better result than any NLL sorting strategy. For example, in WebNLG dataset, MultiDecoder model only achieves 0.481 and 0.518 F1 score with Alphabetical and Frequency strategy, it achieves 0.564 F1 score with RL. Our model trained with RL achieves the best performance on both NYT and WebNLG dataset, which is 0.721 and 0.616. It's 3.4% and 5.5% improvements compared with the best global sorting rule on these two datasets.

4.5 Extraction Order Comparison

This experiment compares the extraction order of our model trained with RL. We test our model on WebNLG dataset. The generated triplets (excluding NA-triplets) sequence of our model which is pretrained with FixUnsort strategy then trained with RL, is denoted as **FURL**. Similarly, the triplets sequence of our model which is pretrained with Frequency strategy then trained with RL is denoted as **FreqRL**. And the triplets sequence of our model which is trained with FixUnsort strategy is denoted as **FUNLL**.

Comparison	LSTM	GRU
FUNLL-FURL	0.326	0.390
FreqRL-FURL	0.446	0.435

Table 2: The extraction order comparison.

Suppose $A = [F_a, F_b, F_c]$ is the generated triplets sequence of FURL for sentence x, $B = [F_a, F_c]$ is the generated triplets sequence of FUNLL for the same sentence x. F_a, as well as F_b and F_c, is a triplet. The first triplet of the sequence A is F_a, which is the same with the first triplet of the sequence B. But the second triplet of A is different from B. Therefore, there are only 1 triplet is in the same position for A and B. The triplets number is the maximum triplets number of A and B, which is 3 in this example. We calculate the order comparison of sentence x as $1/3 = 0.333$. The order comparison of FUNLL and FURL (denote as FUNLL-FURL) is the mean value of all

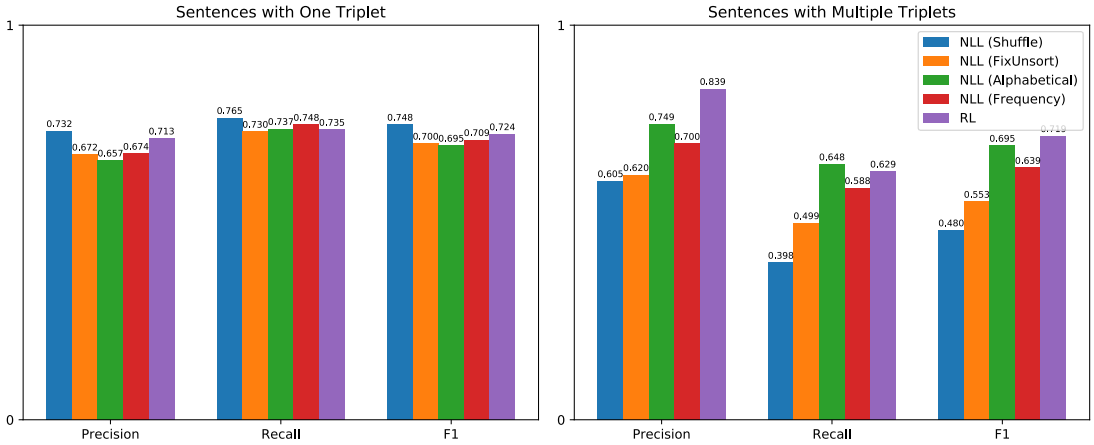

Figure 3: Results of our model with LSTM cell under different training strategies on NYT dataset.

sentences.

We show the order comparison results of our model with LSTM and GRU cell in Table 2. As we can see, although FURL model is pretrained by FUNLL, FURL is more alike FreqRL (0.446 and 0.435), rather then FUNLL (0.326 and 0.390).

This experiment verified that after RL training, the model trend to generate triplets in the same order.

4.6 Multiple Relation Extraction

To verify the ability of extracting multiple relational facts, we conduct the experiment on NYT dataset of our model with LSTM cell. We show the results in Figure 3. The left part of this figure shows the performance of sentences with one triplet. The right part shows the performance of sentences with multiple triplets.

As we can see, when the sentence only contains one triplet, our model trained with RL can achieve comparative performance with the strong baselines. When there are multiple triplets for a sentence, our model trained with RL outperform all baselines significantly. By training with RL, our model could extract triplets more precisely. Although the recall value is slightly lower then NLL training with Frequency strategy, it exceeds other baselines significantly. These observations demonstrate that RL training is effective to handle the multiple relation extraction task.

5 Weakness

Although we overcome all strong baselines by training the model with RL, there are still some weaknesses in our method.

The first weakness is the decrease in recall. Table 1 shows that NLL training with Alphabetical or Frequency strategy achieves the highest recall in most cases. Training the model with RL achieves the highest precision and relatively low recall. This phenomenon demonstrates that the model trained with RL generates relatively fewer triplets. Although we can extract triplets more accurate, it is still a weakness of our method since we try to extract all triplets from a sentence.

The second weakness is our model can only copy one word for each entity. Following Zeng et al. (2018b), we only copy the last word of an entity. But in reality, most entities contains more than one word. In the future, we will consider how to extract the complete entity. For example, we could add the BIO tag prediction in the encoder and train the BIO loss together with current loss. Therefore, we can recognize the complete entity with the help of BIO tags. Or, we can take two steps to generate one entity, one step for the head word and the other for the tail word.

6 Conclusions

In this paper, we discuss the multiple triplets extraction order problem in the multiple relation extraction task. We propose a sequence-to-sequence model with reinforcement learning to take the extraction order into consideration. Widely experiments on NYT dataset and WebNLG dataset are conducted and verified that the proposed method is effective in handling this problem.

A The Details of the CNN Baseline

In this section, we will describe the details of the CNN baseline. This baseline is a pipeline method. For a sentence, we use the NLTK toolkit to recognize the entities first. Then, we combine each two entities as an entity pair and use a CNN relation classifier to predict their relation.

For example, suppose we recognize 3 entities in sentence s, which denoted as e_1, e_2, e_3. There are 6 different entity pairs (remind that $< e_1, e_2 >$ and $< e_2, e_1 >$ are different).

The CNN classifier is basically the same with Zeng et al. (2014). Each word is turned into a embedding which including it's word embedding and position embedding. After the convolution layer, we apply a maxpooling layer on it. Then we apply a two layer softmax classify layer to obtain the final results. We train the model with NLL loss.

Specifically, the word embedding dimension is 100, the position embedding dimension is 5, we use 128 filters and the filter size is 3. The hidden layer size of softmax classifier is 100 and we use tanh as the activation function. We optimize the model with Adam optimizer (Kingma and Ba, 2015).

During evaluation, if the entity pair is classified into *NA* relation, we will exclude this triplet. Otherwise, the triplet will be regarded as a predict triplet. If the predicted triplet is the same as one of the gold triples, it will be regarded as correct triplet. To be fair, when comparing the entities in the triplets, we only compare the last word of each entity. As long as the last word of the extract entity is the same as the gold one, we regard it as correct.

Abstract

Open Information Extraction (OpenIE) methods are effective at extracting (noun phrase, relation phrase, noun phrase) triples from text, e.g., *(Barack Obama, took birth in, Honolulu)*. Organization of such triples in the form of a graph with noun phrases (NPs) as nodes and relation phrases (RPs) as edges results in the construction of Open Knowledge Graphs (OpenKGs). In order to use such OpenKGs in downstream tasks, it is often desirable to learn embeddings of the NPs and RPs present in the graph. Even though several Knowledge Graph (KG) embedding methods have been recently proposed, all of those methods have targeted *Ontological KGs*, as opposed to OpenKGs. Straightforward application of existing Ontological KG embedding methods to OpenKGs is challenging, as unlike Ontological KGs, OpenKGs are not *canonicalized*, i.e., a real-world entity may be represented using multiple nodes in the OpenKG, with each node corresponding to a different NP referring to the entity. For example, nodes with labels *Barack Obama*, *Obama*, and *President Obama* may refer to the same real-world entity *Barack Obama*. Even though canonicalization of OpenKGs has received some attention lately, output of such methods has not been used to improve OpenKG embeddings. We fill this gap in the paper and propose Canonicalization-infused Representations (CaRe) for OpenKGs. Through extensive experiments, we observe that CaRe enables existing models to adapt to the challenges in OpenKGs and achieve substantial improvements for the link prediction task.

1 Introduction

Open Information Extraction (OpenIE) methods such as ReVerb (Fader et al., 2011), OLLIE (Mausam et al., 2012), BONIE (Saha et al., 2017) and CALMIE (Saha and Mausam, 2018) can automatically extract *(noun phrase, relation phrase, noun phrase)* triples from text, e.g., *(Barack Obama, took birth in, Honolulu), (Michelle Obama, wife of, Barack), etc*. An *Open Knowledge Graph* (*OpenKG*) can be constructed out of such triples by representing noun phrases (NPs) as nodes and relation phrases (RPs) as edges connecting them. Example of an OpenKG is shown in Figure 1. OpenKGs do not require pre-specified ontology, making them highly adaptable. In order to use OpenKGs in downstream tasks such as Question Answering, Document Classification, etc., it is often necessary to learn embeddings of NPs and RPs present as nodes and edges in an OpenKG.

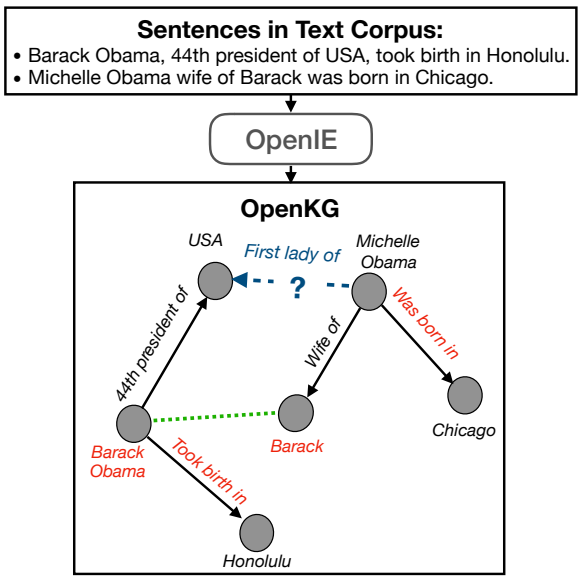

Figure 1: **Challenges in OpenKG**. KG embedding methods are effective in downstream tasks such as Link Prediction. Existing KG embedding methods are ineffective on OpenKGs as they are not canonicalized. CaRe can effectively utilize canonicalization information to learn better embeddings in OpenKGs. Green dotted line represents the missing NP canonicalization information. Please see Section 1 for more details.

Even though Knowledge Graph (KG) embed-

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 378–388, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

ding has been an active area of research (Bordes et al., 2013; Yang et al., 2014), all the proposed KG embedding methods have focused on embedding *Ontological KGs*, such as WikiData (Vrandečić and Krötzsch, 2014), DBpedia (Auer et al., 2007), YAGO (Suchanek et al., 2007), NELL (Mitchell et al., 2018), and Freebase (Bollacker et al., 2008). Existing KG embedding models train representation of each node and edge label based on the context of triples they are present in. Doing this is suitable for ontological KGs as they are *canonicalized*. However, in OpenKGs, the same latent entity may be represented in different nodes labelled with different NPs. Similarly, the same latent relation can be represented with different RPs. For example, in Figure 1, *Barack Obama* the entity is represented using two NP nodes: *Barack Obama* and *Barack*. Similarly, the two RPs – *took birth in* and *was born in* – refer to the same underlying relation. Hence, the paradigm of learning embeddings for each node and edge label only from the context of the triples they appear in is ineffective for OpenKGs.

A possible solution is to canonicalize the OpenKGs. This involves identifying NPs and RPs that refer to the same entity and relation, and assigning them unique IDs. Nodes in the OpenKG having the same ID are *merged*, leading to a clean and canonicalized graph. Recent works that automatically canonicalize OpenKGs, including (Galárraga et al., 2014) and CESI (Vashishth et al., 2018), pose canonicalization as a clustering task of the NPs and RPs. However, due to automatic generation, the output clusters often contain some incorrectly canonicalized elements. Thus, directly merging nodes or relations with the same IDs would result in the propagation of errors in the canonicalization step to down-stream tasks.

Our premise is that the output of these automatic canonicalization models can be utilized to improve OpenKG embedding. Instead of explicitly merging nodes with common IDs, KG embedding models can be designed to judiciously account for mistakes during the canonicalization step. Towards establishing this premise, we propose a flexible OpenKG embedding approach to integrate and utilize the output of a canonicalization model in an error-conscious manner. Our contributions are as follows:

- We draw attention to an important but relatively unexplored problem of learning representations for OpenKGs.
- We propose Canonicalization-infused Representations (CaRe) for Open KGs - a novel approach to enrich OpenKG embedding models with the output of a canonicalization model. To the best of our knowledge, this is the first model of its kind.
- Through extensive experiments on real-world datasets, we establish CaRe's effectiveness in embedding OpenKGs.

CaRe source code is available at `https://github.com/malllabiisc/CaRE`.

2 Related Work

OpenKG extraction and canonicalization: Multiple OpenIE systems have been developed over the years. These include TextRunner (Yates et al., 2007), (Angeli et al., 2015), ReVerb (Fader et al., 2011), OLLIE (Mausam et al., 2012), SRLIE (Christensen et al., 2011), RelNoun (Pal and Mausam, 2016) and ClauseIE (Del Corro and Gemulla, 2013). A recent survey on the progress in OpenIE systems is presented in (Mausam, 2016).

To perform automatic canonicalization of OpenKGs, (Galárraga et al., 2014) first cluster NPs over manually defined feature spaces. These are then passed to AMIE (Galárraga et al., 2013) for RP clustering. Whereas, CESI (Vashishth et al., 2018) jointly learns vector representations of NPs and RPs by infusing side information in KG embedding models which are then used to cluster NPs and RPs. In this work, we use CESI to generate canonicalization clusters for our datasets.

KG Embedding Methods: KG embedding methods aim to learn low dimensional vector representations for the nodes and edge labels encoding the graph topology. All these methods train the embeddings by optimizing a link prediction based objective. They primarily differ in their way of mathematically modelling the likelihood of a triple being true. Translation-based hypothesis which regards relation vector for any *(subject, relation, object)* triple as a translation from the subject vector to the object vector is used in methods like TransE (Bordes et al., 2013) and TransH (Wang et al., 2014). Semantic matching models, such as DistMult (Yang et al., 2014), ComplEx (Trouillon et al., 2016) and HolE (Nickel et al., 2016), use

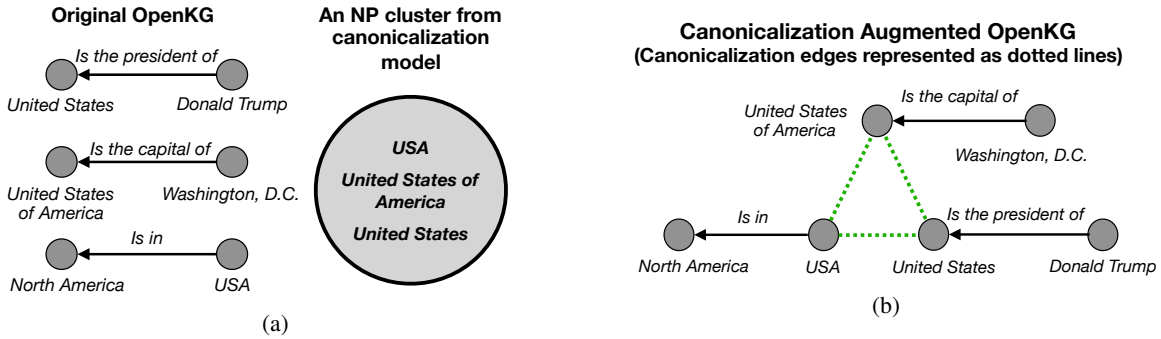

Figure 2: **CaRe Step 1:** First CaRe augments the original OpenKG with the output of a canonicalization model. (a) OpenKG and NP clusters from a canonicalization model. (b) Augmented OpenKG by adding undirected edges between canonical NPs (represented as dotted lines). Please refer to Section 4.2 for more details.

similarity-based scoring functions to measure the likelihood of a fact. Multi-Layer neural network models, ConvE (Dettmers et al., 2018) and R-GCN (Schlichtkrull et al., 2018) have shown better expressive strength. R-GCN adapts graph convolutional network (GCN) (Kipf and Welling, 2016) to a relational graph proposing an auto-encoder model for the link prediction task. Implicit in all these approaches is the assumption that each node in the graph is a different entity, and distinct edge labels refer to distinct relations. This assumption does not hold in OpenKGs. Existing KG embeddings are thus unsuitable for a task like link prediction on OpenKGs. CaRe addresses these limitations by infusing the output of a canonicalization model with the KG embedding models.

3 Background

In this section, we present a quick overview of a few basic methods which are useful for understanding the rest of the paper, especially the experiments section. We first start with the notations.

Notations: OpenKG is denoted as $\mathrm{G} = (\mathrm{N}, \mathrm{R}, \mathrm{T}^+)$, where N and R are the set of NPs and RPs, respectively, and $\mathrm{T}^+ = \{(s, r, o) | s \in \mathrm{N}, r \in \mathrm{R}, o \in \mathrm{N}\}$ is the set of observed triples. Here s, o are the subject and object phrase, respectively.

TransE: Given a triple (s, r, o), consider $e_s, r_r, e_o \in \mathbb{R}^d$ as the d-dimensional vector representations of subject (s), relation (r) and object (o) respectively. TransE follows a translation based triple scoring function $\psi(.)$:

$$\psi(s, r, o) = -\left\| e_s + r_r - e_o \right\|_p .$$

Here, $\|.\|$ denotes norm and p is either 1 or 2. For training parameters, TransE uses margin-based pairwise ranking loss with negative sampling.

ConvE: ConvE (Dettmers et al., 2018) first reshapes e_s and r_r to $\bar{e_s}$ and $\bar{r_r}$, respectively, and passes them through a 2D convolution layer to compute the score corresponding to a triple:

$$\psi(s, r, o) = f(vec(f([\bar{e_s}; \bar{r_r}] * w))W)e_o.$$

Here, $*$ and w denote the convolution operator and convolution filters, f represents an activation function and W, the weights of the final linear layer. For training, ConvE uses binary cross-entropy loss with correct samples considered as positive instances while negative instances are generated through negative sampling.

Graph Neural Networks (GNN): GNNs were introduced in (Gori et al., 2005) and (Scarselli et al., 2009) as a generalization of recursive neural networks. Later, the generalization of CNN to graph-structured data, popularly known as Graph Convolution Network (GCN), was proposed in (Bruna et al., 2014). A first-order formulation of GCN as proposed in (Kipf and Welling, 2016). Under GCN formulation, the representation of a node n after l^{th} layer is defined as follows.

$$e_n^{l+1} = f\left(\sum_{i \in \mathcal{N}(n)} \left(W^l e_i^l + b^l\right)\right), \forall n \in \mathrm{N} \quad (1)$$

Here, W^l, b^l are layer parameters, $\mathcal{N}(n)$ corresponds to the immediate neighborhood of n and f denotes an activation function.

GAT: GAT uses the attention mechanism to determine the weights of a node's neighbors (Veličković et al., 2018). Further, it uses multi-head attentions and defines the representation of

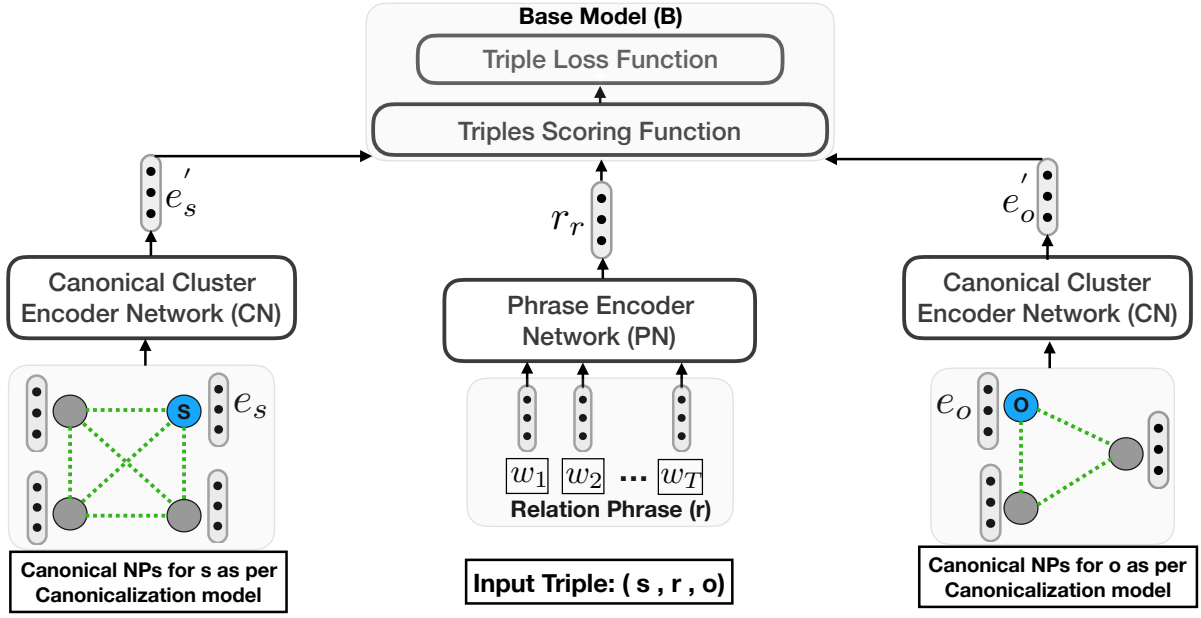

Figure 3: **CaRe Step 2:** In this step, CaRe learns KG embeddings from the augmented OpenKG (Figure 2). Base model can be any existing KG embedding model (e.g., TransE, ConvE). RP embeddings are parameterized by encoding vector representations of the word sequence composing them. This enables CaRe to capture semantic similarity of RPs. Embeddings of NPs are made more context rich by updating them with the represenations of canonical NPs (connected with dotted lines). Please see Section 3 and 4 for details.

n^{th} the node as follows

$$e_n^{l+1} = ||_{k=1}^{K} f\left(\sum_{i \in \mathcal{N}(n)} \left(\alpha_k(e_n^l, e_i^l) W_k^l e_i^l\right)\right). \quad (2)$$

Here, $\alpha(.)$ denotes attention weights and $||$ denotes concatenation.

4 CaRe: Proposed Method

4.1 Overview

CaRe consists of two steps. We first give an overview of the two steps below and then provide a detailed description of each step.

- **Step 1**: In this step, the given OpenKG is augmented by adding edges from a canonicalization model. This step is outlined in Figure 2 and described in detail in Section 4.2.
- **Step 2**: In this step, embeddings of nodes and edges present in the augmented OpenKG obtained in Step 1 are learned. This step is outlined in Figure 3. The system consists of three components: Base Model, Phrase Encoder Network, and Canonical Cluster Encoder Network. We describe these components in Section 4.3, Section 4.4, and Section 4.5, respectively.

CaRe architecture and its components are depicted in Figure 3.

4.2 Step 1: Canonicalization Augmented OpenKG

As discussed in Section 1, based on the automatic clusters generated by a canonicalization model, merging NPs with a single ID can lead to the propagation of errors in the graph. Hence, we propose a soft integration scheme by adding an unlabeled and undirected edge between any two NPs which are canonical as per the canonicalization model as shown in Figure 2. More formally, suppose n_1, n_2 are two NPs that have been identified to be the same in the canonicalization step. We add an undirected and unlabelled edge (n_1, n_2) between the nodes n_1 and n_2, and call them canonicalization edges. If the canonicalization step produces a confidence score for n_1 and n_2 being the same, then this score can be incorporated as a weight on the canonicalization edge. If no such score is produced, then the edges are kept unweighted. We then collect all these canonicalization edges into the set C. Finally, these edges are added to the original OpenKG G to get a *canonicalization augmented OpenKG*, $\mathrm{G}' = (\mathrm{N}, \mathrm{R}, \mathrm{T}^{+} \cup \mathrm{C})$

4.3 Step 2: Base Model (B)

This component decides the way parameters are trained in CaRe based on the relational edges T^+. While CaRe is flexible to accommodate any KG embedding model as the base model, for the experiments in paper, we used TransE and ConvE (please see Section 3).

4.4 Step 2: Phrase Encoder Network (PN)

We generate embeddings of RPs by encoding the vector representations of the words composing them. Consider an RP as a sequence of T words $(w_1, w_2, ..., w_T)$ and their corresponding word vectors as $(x_1, x_2, ..., x_T)$. They are passed through a Phrase Encoder Network module (Figure 3) for which we use a bidirectional GRU (Cho et al., 2014) model with last pooling as described below.

$$(\overrightarrow{h_1}, \overrightarrow{h_2}, ..., \overrightarrow{h_T}) = \overrightarrow{GRU}(x_1, x_2, ..., x_T)$$
$$(\overleftarrow{h_1}, \overleftarrow{h_2}, ..., \overleftarrow{h_T}) = \overleftarrow{GRU}(x_1, x_2, ..., x_T).$$

Finally, $r_r = [\overrightarrow{h_T} : \overleftarrow{h_1}]$ is concatenation of final hidden states in both the directions. This approach allows parameter sharing across RPs with word overlaps while leveraging the rich semantic information from pre-trained word embeddings.

4.5 Step 2: Canonical Cluster Encoder Network (CN)

The canonicalization information is incorporated in the NP embeddings by utilizing the canonicalization-induced edges C.

Each NP $n \in$ N is assigned a vector e_n. As NP canonicalization is expressed as a clustering step, for each NP, its canonical NPs are a single edge away in C (see Figure 3). Hence, a single layer of network aggregation is sufficient. We propose a non-parametric message passing and update network which works in the following two steps:

Context vector: First for each NP, $n \in$ N a context vector e_n^c is generated by the following message passing scheme from its canonical neighbors.

$$e_n^c = \left(\sum_{i \in \mathcal{N}(n)} \frac{1}{|\mathcal{N}(n)|} e_i \right), \forall n \in \text{N}.$$

Here, $\mathcal{N}(n) = \{i | i \in \text{N}, (n, i) \in \text{C}\}$, is the canonical neighborhood of n.

Updating NP embeddings: The updated embeddings for each NP is computed as below:

$$e_n^{'} = \frac{e_n}{2} + \frac{e_n^c}{2}$$

which are passed to the decoding stage. For the case of weighted canonicalization edges, the weights can be used while generating the context vector of an NP, by making the contribution of its canonical NPs proportional to the edge weights joining them. The proposed approach can be interpreted as a *local embedding smoothening* of canonical NPs and we call this network as Local Averaging Network **(LAN)**. We also experimented with more sophisticated attention-based context vector generation and gating mechanism for embedding update stage, but they resulted in a performance drop.

Note that, our approach to embed NPs is inspired by the auto-encoder framework used in R-GCN (Schlichtkrull et al., 2018) but with a key difference. In R-GCN, the same set of edges are utilized at both the encoding and decoding stages. Whereas in CaRe, the canonicalization edges C are used at the encoder (Canonical Cluster Encoder Network) while the decoder (Base Model) operates on the relational edges T^+.

CaRe nomenclature: We introduce a generic nomenclature for the possible variants of the CaRe framework based on the choice of the Base Model (B), Phrase Encoder Network (PN) and Canonical Cluster Encoder Network (CN) as **CaRe(B, PN, CN)**. For e.g., CaRe(B=ConvE, PN=Bi-GRU, CN=LAN) corresponds to a CaRe model with ConvE as base model, Bi-GRU network with last pooling (Section 4.4) as the Phrase Encoder Network and Local Averaging Network (Section 4.5) as the Canonical Cluster Encoder Network. We define Bi-GRU and LAN as default values for the PN and CN arguments respectively. In case, values for these arguments are not explicitly mentioned, they take the default values. Thus, CaRe(B=ConvE) represents the same network as CaRe(B=ConvE, PN=Bi-GRU, CN=LAN).

5 Experiments

5.1 Datasets

Statistics of the two datasets used in the experiments of this paper are summarized in Table 1. In order to build these datasets, we first obtained the three graph datasets – Base, Ambiguous and ReVerb45K. While Base and Ambiguous datasets are created in (Galárraga et al., 2014), ReVerb45K is

Datasets	ReVerb45K	ReVerb20K
# NPs	27K	11.1K
# RPs	21.6K	11.1K
# Gold NP Clusters	18.6K	10.8K
# Train Triples	36K	15.5K
# Test Triples	5.4K	2.4K
# Validation Triples	3.6K	1.6K

Table 1: Details of datasets used. Please see Section 5.1 for details.

introduced in (Vashishth et al., 2018). ReVerb20K is created by combining the two smaller datasets Base and Ambiguous. All the datasets are constructed through ReVerb Open KB (Fader et al., 2011). We refer the readers to the respective papers for the construction details.

To generate the train, validation and test triples the following procedure is adopted. First, the entire set of triples is divided in $80 : 20$ ratio ensuring that each NP and RP in the triples of the smaller set is at least present once in the triples of the bigger set. This consideration is essential because of the transductive nature of existing KG embedding models. The bigger set is considered as the train dataset and the smaller set is further randomly divided in $30 : 70$ to get the validation and test datasets respectively. Both datasets contain gold canonicalization clusters for the NPs extracted through the Freebase entity linking information (Gabrilovich et al., 2013) which enables automatic evaluation in the canonicalization task.

5.2 Open KG Link Prediction Evaluation

In the typical link prediction evaluation, an unseen triple (s, r, o) is taken and partial triples $(s, r, ?)$ and $(?, r, o)$ are shown to the model. It ranks all the entities in the graph for their likelihood to be the missing entity and the rank assigned to the true missing entity is considered.

However, while this is suitable for ontological KGs, it is not valid for our setting. In OpenKGs, instead of entities, NPs are present and several of them can refer to the same entity. This means that, even when predicting correct entity, a model will be unfairly penalized if the prediction is a different canonical form of the entity than the one present in the considered triple. We, therefore propose to rank gold NP clusters, available in the dataset, instead of ranking each NP. We do this in the following manner:

- List all the NPs in decreasing order of their likelihood to be the missing part of the triple.
- Prune this list by keeping the best ranked NPs for each gold cluster. This gives us the ranked list of gold clusters.
- Consider the rank of the cluster to which the true missing NP belongs.

We provide results using three commonly used evaluation metrics: *mean rank* (MR), *mean reciprocal rank* (MRR) and *Hits@n* with $n = \{10, 30, 50\}$. Filtered setting as introduced in (Bordes et al., 2013) is followed.

5.3 Experimental Setup

We run CESI on both the datasets to generate the NP canonical clusters. Note that, none of the existing automatic canonicalization models output edge weights. Hence, for all the experiments, the canonicalization-induced edges are kept unweighted. For Phrase Encoder Network, we found single layer in the Bi-GRU model works best. CaRe allows the use of any pre-trained embeddings. However, (Vashishth et al., 2018) demonstrates the effectiveness of pre-trained GloVE (Pennington et al., 2014) vectors for initializing representations for the same datasets. Hence, the word vectors are initialized with 300-dimensional pre-trained GloVE embeddings and are kept trainable. We use PyTorch Geometric library (Fey and Lenssen, 2019) for the Canonical Cluster Encoder Network module.

The choice of optimizer and regularization based hyper-parameters is directly adopted from the ones proposed in the original work of the base models. Both the NP and RP embedding size is kept fixed at 300, while the learning rate is selected through a grid search over $\{0.1, 0.01, 0.001\}$.

Models like ConvE introduce inverse relations. For our experiments we generate inverse phrase for an RP by adding a phrase *"inverse of"* to that RP. In ComplEx the embeddings have both real and imaginary parts. For this, we use two separate Phrase Encoder Network and Graph Neural Network modules for the real and imaginary parts of RP and NP embeddings respectively.

6 Results

In this section we evaluate the following questions:

Method	ReVerb45K					ReVerb20K				
	MR	MRR	Hits@10	Hits@30	Hits@50	MR	MRR	Hits@10	Hits@30	Hits@50

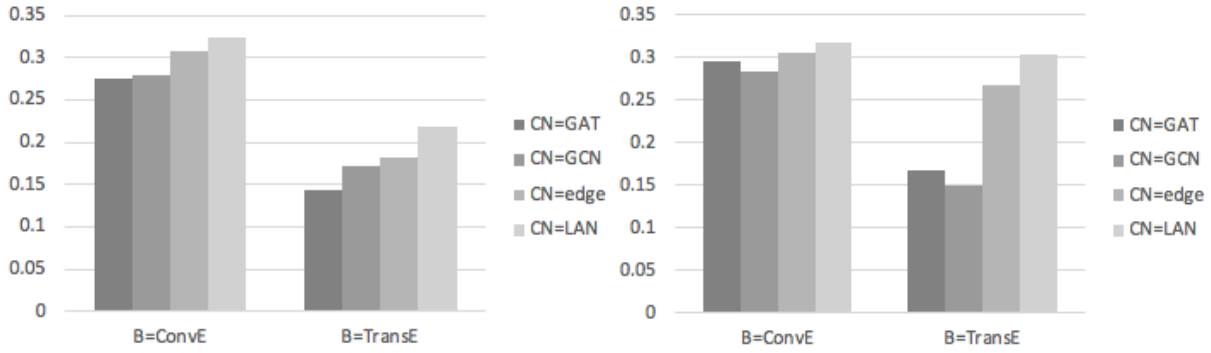
Table 3: Impact of parameterizing RP embeddings. B, CN, PN are the arguments of CaRe framework (Section 4 and Figure 3). ϕ value for CN argument implies that Canonical Cluster Encoder Network module is not used in these experiments. PN=Bi-GRU in all these experiments. Please refer to Section 6.2.

Q1. Is CaRe effective for the link prediction task in OpenKGs? (Section 6.1)

Q2. What is the quantitave and qualitative impact of parameterizing RP embeddings in CaRe? (Section 6.2 and Section 6.4)

Q3. How does the local embedding smoothening approach adopted in CaRe compare against other competitive baselines? (Section 6.3)

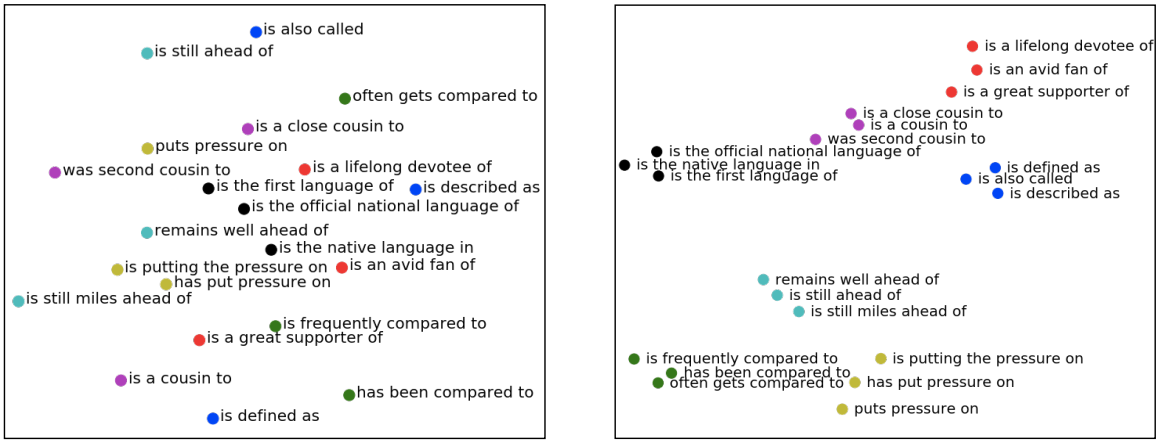
6.1 Overall Performance



As shown in Figure 3, any existing KG embedding model can be used as the base model in the CaRe framework. We experimented with several KG embedding models and found the CaRe achieved substantial improvements in comparison to standalone use of the KG embedding model in each case. We achieved overall best performance working with ConvE as the base model, CaRe(B=ConvE). The experimental results are presented in Table 2.

Table 1 shows that in both the datasets, on an average, the number of train triples for each NP and RP is less than 2. In contrast, FB15k (Bordes et al., 2013), an ontological KG, has on an average 32 triples for each entity and 360 triples for each relation. This highlights the extremely sparse and fragmented nature of OpenKGs. Hence, the superior performance of CaRe supports the hypothesis that the flow of information while learning the representations of canonical NPs and RPs in OpenKGs is beneficial.

Also, a comparison of the number of unique NPs and gold NP clusters for the two datasets (Table 1) shows that the number of NPs canonical to each other is more significant in ReVerb45K than in ReVerb20K. Hence, a more prominent improvement due to CaRe in ReVerb45K as compared to ReVerb20K proves the effectiveness of CaRe in utilizing the canonicalization information.



6.2 Impact of parameterizing RP embeddings

As described in Section 4.4, a Phrase Encoder Network is used to parametrize RP embeddings, which allows parameter sharing while learning embeddings. Table 3 provides a quantitative anal-

(a) ReVerb45K (b) ReVerb20K

Figure 4: Performance comparison of CaRe framework for diffrent values of the CN (as described in Section 6.3). B=ConvE (left group) and B=TransE (right group) in both the plots. PN=Bi-GRU. **Mean Reciprocal Rank (MRR)** is plotted on the y axis (higher is better).

(a) ConvE (b) CaRe(B=ConvE)

Figure 5: **t-SNE visualization of RP embeddings**. RP embeddings learned by CaRe(B=ConvE) are able to capture the semantic similarity of the RPs whereas in ConvE this information is lost. Please refer to Section 6.4.

ysis of the impact of parameterizing RP embeddings across several KG embedding models. In these experiments, the CN argument of CaReis kept ϕ, which implies no canonicalization information is used. The NP embeddings are trained in the same manner as the base KG embedding model.

Comparing the performance of CaRe(B=ConvE,CN=ϕ) in Table 3 with the performance of CaRe(B=ConvE) in Table 2, it can be noticed that a major part of the performance boost of CaRe can be attributed to parameterization of RP embeddings.

6.3 Different ways to utilize Canonicalization edges

There can be several methods through which the canonicalization edges integrated into the graph (as described in Figure 2), can be utilized in the model. In Section 4.5, we described a local embedding smoothening method adopted in CaRe. In this section, we present a comparative analysis with the following competitive baselines:

- **CaRe(CN=GCN)**: A single layer of GCN (Kipf and Welling, 2016) for the Canonical Cluster Encoder Network. Refer to Equation 1.
- **CaRe(CN=GAT)**: A single layer of GAT (Veličković et al., 2018) for the Canonical Cluster Encoder Network. Refer to Equation 2.
- **CaRe(CN=edge)**: Here the canonicalization edges in G' are labelled with a symmetric RP *"is canonical to"*. This adds a new edge type in the graph and is treated by KG embedding models like any other edge type.

We show these comparisons using both TransE and ConvE as base models in Figure 4. The GCN and GAT architectures have an adverse effect on the performance. We believe this can be attributed to the complex nature of these architectures in an already over-parameterized and noisy setting. In CaRe(CN=edge), the model is expected to learn the meaning of two NPs being canonical and encode it in the vector embedding of the new edge type. The local averaging network CaRe(CN=LAN) used in CaRe is a GNN architecture with fixed weights. The choice of weights follows from the prior belief that canonical NP embeddings should be close in the vector space, inducing a useful inductive bias. The above results indicate that this leads to better performance. Additionally, unlike the GNN based methods, CaRe(CN=edge) has a limitation in its modelling capacity as it provides no way to handle the case where canonicalization edges are weighted.

6.4 Qualitative Analysis

Figure 5 demonstrates a qualitative comparison of RP embeddings between ConvE and CaRe(B=ConvE). For this experiment, we selected seven RPs, and for each RP, through human judgement, we selected two more RPs with similar meaning. Thus, there are seven different clusters. The figure shows t-SNE (van der Maaten and Hinton, 2008) visualization of the embeddings learnt for these RPs by CaRe(B=ConvE) and ConvE. t-SNE is a non-linear transformation which tries to map points in high dimensional space to a lower dimension preserving the local relationships between the points. The figure verifies the hypothesis that due to the parameterization of RP embeddings and utilizing pre-trained word embeddings, CaRe is able to better capture the semantic similarity of the RPs in comparison to the base models. Due to the explicit integration of NP canonicalization in CaRe, we observed a similar desirable impact on the embeddings learned for NPs as well.

7 Conclusion

Open Information Extraction (OpenIE) provides an effective way to bootstrap Open Knowledge Graphs (OpenKGs) from text corpus. OpenKGs consist of noun phrases (NPs) as nodes and relations phrases (RPs) as edges. In spite of this advantage, OpenKGs are often sparse and non-canonicalized, i.e., the same entity could be expressed using multiple nodes in the graph (and similarly for relations). This renders existing Ontological KG embedding methods ineffective in learning embeddings of NPs and RPs in OpenKGs. In spite of this limitation, there has been no prior work which has focused on OpenKG embedding. We fill this gap in the paper and propose CaRe. CaRe infuses canonicalization information combined with the neighborhood graph structure to learn rich representations of NPs. Further, it captures the semantic similarity of RPs by utilizing the word sequence information in these relation phrases to parameterize the RP embeddings. Through extensive experiments on real-world datasets, we demonstrate the effectiveness of embeddings learned by CaRe.

As part of future work, we hope to extend CaRe to also utilize RP canonicalization information. Utilizing OpenKG embeddings in tasks beyond link prediction is another avenue of further work.

Abstract

Distance supervision is widely used in relation extraction tasks, particularly when large-scale manual annotations are virtually impossible to conduct. Although Distantly Supervised Relation Extraction (DSRE) benefits from automatic labelling, it suffers from serious mislabelling issues, i.e. some or all of the instances for an entity pair (head and tail entities) do not express the labelled relation. In this paper, we propose a novel model that employs a collaborative curriculum learning framework to reduce the effects of mislabelled data. Specifically, we firstly propose an internal self-attention mechanism between the convolution operations in convolutional neural networks (CNNs) to learn a better sentence representation from the noisy inputs. Then we define two sentence selection models as two relation extractors in order to collaboratively learn and regularise each other under a curriculum scheme to alleviate noisy effects, where the curriculum could be constructed by conflicts or small loss. Finally, experiments are conducted on a widely-used public dataset and the results indicate that the proposed model significantly outperforms baselines including the state-of-the-art in terms of P@N and PR curve metrics, thus evidencing its capability of reducing noisy effects for DSRE.

1 Introduction

Relation Extraction (RE) is vital for NLP tasks such as information extraction, question answering and knowledge base completion. RE aims to identify the relationship between an entity pair (e_1, e_2) in a sentence. For example, in the sentence "$[Bill_Gates_{e_1}]$ is the principal founder of $[Microsoft_{e_2}]$", the relation extractor decodes the relation of *founder* for the entity pair *Bill_Gates* (the person) and *Microsoft* (the company).

Recent supervised relation extraction research can be roughly categorised into two areas: fully supervised and distantly supervised relation extraction. Fully supervised relation extraction mainly depends on manually annotated training dataset (Zeng et al., 2014; dos Santos et al., 2015). Ordinarily, human annotation on large-scale datasets is costly and often practicably impossible. Distance supervision addresses this problem by using an existing knowledge base (e.g. DBpedia) to automatically annotating large-scale datasets, thus reducing the burden of manual annotation (Mintz et al., 2009; Hoffmann et al., 2011; Surdeanu et al., 2012). However, distance supervision often suffers from mislabelling problems.

Figure 1 illustrates this incorrect labelling issue, which shows that not all sentences in a bag with the same entity pair express the labelled relation of *person/company/founder*. The worst case is that all sentences in a bag are mislabelled. Thus, one primary challenge in DSRE is to minimize the noisy labelling effects, which in turn, would let model learn from incorrect labelled datasets.

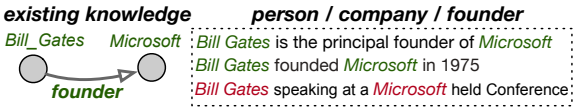

Figure 1: Mislabeling issue example in DSRE: the entity pairs bag containing three sentences is labeled as *person/company/founder*. However, the last sentence marked in red has no extractable pre-defined relation.

In order to design a solution to mitigate the effects of noisy data, we can treat our DSRE model learning procedure as analogous to *two students* training with a *curriculum* to answer a list of multiple-choice questions, where some difficult multiple-choice questions may have no correct answers (false positive). We base our proposed solution on the intuition that two students will compare and rethink their different answers during the learning process, thus regularising each

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 389–398, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

other and improving their final grades. We call this process of two students learning together with a curriculum as *Collaborative Curriculum Learning* (CCL), where each student represents a network.

Inspired by the above intuition, we propose to use a bag-level selective sentence attention model (NetAtt) (Lin et al., 2016) and a maximum probability sentence model (NetMax) (Zeng et al., 2015) as two students learning collaboratively. Meanwhile, highly organised human education methods using a multilevel curriculum, from easy to hard, is an analogy for curriculum learning training, which advocates the adoption of similar multi-stage strategies (Bengio et al., 2009). The curriculum learning training method for DSRE is used with the assumption that entity pair bags contain corrupted labelled sentences, which are difficult components to learn in the curriculum. By disregarding the effects of noisy samples (meaningless knowledge) during the training, the expectation is to boost the model's learning capability. Moreover, in order to accurately obtain the semantic representation of each sentence for our curriculum learning approach, we propose an internal CNNs self-attention mechanism to learn a better sentence representation in the DSRE setting.

The main contributions are summarised as:

(1) We make the first attempt to use the concept of curriculum learning for denoising DSRE and present a novel collaborative curriculum learning model to alleviate the effects of noisy sentences in an entity pair bag. In this model, we define two collaborative relation extractors to regularize each other and boost the model's learning capability.

(2) We propose conflicts and small loss tricks for our collaborative curriculum learning. Instead of using a separated complex noisy sentence filter and two-step training in baseline models, our model can alleviate noise effects during a single training and is easy to implement.

(3) We are the first to apply an internal CNNs self-attention mechanism to enhance a multilayer CNNs model for DSRE.

(4) We conduct thorough experiments on the widely-used NYT dataset, and achieve significant improvements over state-of-the-art models.

2 Related Work

Most DSRE approaches fall under the framework of Multi-Instance Learning (MIL) (Riedel et al., 2010; Surdeanu et al., 2012; Zeng et al., 2015; Lin et al., 2016; Ji et al., 2017; Qin et al., 2018; Feng et al., 2018). At the encoding step, a sentence representation is learned using handcrafted features or neural network models. Afterwards, in the sentence selection step, one or several sentences from an entity pair bag are chosen for further bag representation learning. Previously, statistical models (Mintz et al., 2009; Hoffmann et al., 2011; Surdeanu et al., 2012) have used designed features, such as syntactic and lexical features, and have then been trained by logistic regression or expectation maximization.

When adopting deep learning approaches, a single layer CNNs based model (Zeng et al., 2014) was exploited to extract sentence level features to attain fully supervised relation classification. For DSRE, Zeng et al. (2015) proposed an extended Piece-wise CNN (PCNN) approach and selected the most probable valid sentence to represent an entity pair bag, while the remaining sentences in the bag were ignored. Lin et al. (2016) and Ji et al. (2017) used all the sentences in a bag by assigning higher weights to valid labeled sentences and lower weights to noisy sentences. The selective sentence attention mechanism combined all weighted sentences as a bag representation. In addition, Ji et al. (2017) made use of entity description background knowledge and fused the external information into their PCNN-based model.

The self-attention mechanism (Cheng et al., 2016; Parikh et al., 2016; Vaswani et al., 2017), also called intra-attention, relates to different positions of a single sequence to learn the sequence representation. An internal CNNs states self-attention approach was proposed by Zhang et al. (2018) to improve Generative Adversarial Networks (GANs) (Goodfellow et al., 2014) performance in generating high-quality images. Alt et al. (2019) extended Generative Pre-trained Transformer (GPT) to learn semantic and syntactic features for DSRE. Wang et al. (2019) used pre-trained Transformer for multiple entity-relations extraction task. Du et al. (2018) utilized self-attention mechanisms for better MIL sentence-level and bag-level representations. However, previous work has not considered to use self-attention over the internal CNNs model states for DSRE.

Deeper CNNs have positive effects on noisy NLP tasks (Conneau et al., 2017). Huang and Wang (2017) used residual learning for multilayer deep CNNs to improve DSRE performance.

To better address issues relating to mislabelling, e.g., when *some or all sentence labels* in a bag are falsely positive, schemes to filter out noisy instances have been developed. Takamatsu et al. (2012) proposed a wrong label sentence filter method using linguistic features. Feng et al. (2018) proposed a model comprising of a relation classifier and an instance selector based on reinforcement learning (RL). The instance selector was designed to select possible correctly labelled sentences and was regularised by the rewards from the relation classifier. Qin et al. (2018) used the idea of GANs to develop a separated correct label indicator, which filters high confidence scoring instances for training on existing PCNN/CNN-based relation extractors (DSGAN). *Unlike previous work*, which filters out incorrectly labelled *sentences* to generate an approximate clean training dataset and then retrains on the filtered data to improve models, we instead train our model to actively and purposefully forget noisy entity pair *bags*, based on a collaborative curriculum learning strategy in a single training process. In doing so, we develop an approach to building the curriculum – the identified disagreements and losses of two collaborative student networks in our model.

3 Methodology

The mislabelled sentences from the distance supervision method are normally regarded as unwanted noise that can reduce the performance of relation extraction. To alleviate noisy effects, we propose a collaborative curriculum learning framework for DSRE. The *architecture* is shown in Figure 3, consisting of three main components: (1) input representation; (2) CNNs that are composed of convolution, self-attention and pooling; and (3) collaborative curriculum learning module.

3.1 Inputs: Word and Position Embeddings

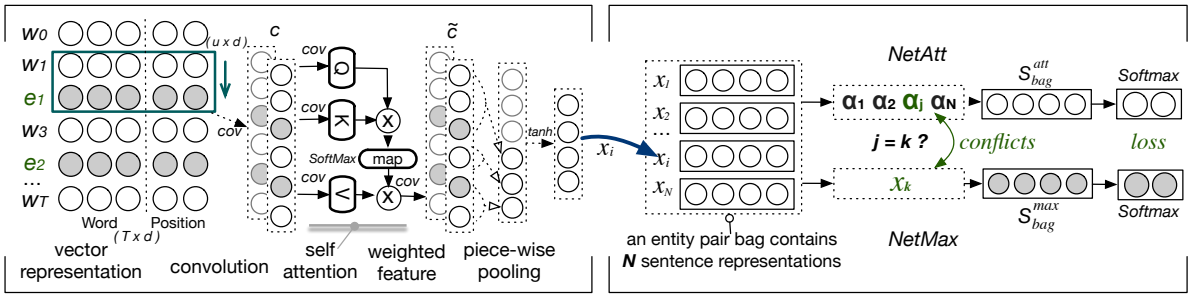
To represent each input token, we use word2vec[1] (Mikolov et al., 2013) to obtain its embedding. Each word embedding (w_t) contains syntactic and semantic information.

Figure 2: relative distances from 'founder' to entities

Similar to (Zeng et al., 2015), we use position embedding to assist the CNNs in measuring distances from the current word to the head and tail entities. As illustrated in Figure 2, in the sentence, the distance of the word *founder* to the head entity is 4 and -2 to the tail entity.

Figure 3(a) further illustrates the use of these embeddings as input representation in CNNs, i.e. the input representation is a concatenation of *word* embedding and *position* embedding. In Figure 3(a), it is assumed that the dimensions of word embedding d_w and position embedding d_p are 3 and 1 (as a simplified example for the sake of the figure), respectively. The total vector representation dimension d is $d_w + 2 \times d_p$.

3.2 Contextualised Representation: Self-attention for CNNs



The sentence embedding matrix is formed by concatenating every vector representation horizontally (left panel Figure 3) and is represented as $s_n = [w_1 : \cdots : w_t : \cdots : w_T]$, where s_n is the input that feeds CNNs to learn a sentence representation. For an input sentence, we use a convolution filter W_p to slide along s_n as $[w_t : \cdots : w_{t+u-1}] * W_p + b$, where $*$ is the convolution symbol, $b \in \mathbb{R}$ is a bias and p represents the p^{th} filter in a filter set. $W_p \subset \mathbb{R}^{u \times d}$, where u is the length of the filter and d is the dimension of a word vector consisting of word and position embeddings.

In order to learn a better sentence representation, we propose a self-attention mechanism which is performed directly over internal CNNs states as shown in Figure 3(a). The self-attention function maps queries (Q) and corresponding keys (K) to compute a weight map. The output is a multiplication of the values (V) and the weight vector. We place this internal CNNs self-attention module after the first convolution state (C). Values, queries, and keys are computed by applying convolution again on C, where $V = C * W^V$, $Q = C * W^Q$ and $K = C * W^K$. The attention map, is calculated using the softmax function, as shown in Equation (1), where Q^T is the transpose of Q and $\otimes$ is the matrix multiplication operator.

$$map = \frac{\exp(Q^T \otimes K)}{\sum \exp(Q^T \otimes K)} \quad (1)$$

Subsequently, the weighted value is computed as $\tau V \otimes map$. $\tilde{C} = cov(C + \tau V \otimes map)$ is then fed into a piece-wise max pooling layer. Where, τ learns gradually from 0 to 1 to assign more weight to the model.

[1] https://code.google.com/p/word2vec/

(a) Self-Attention Piece-wise pooling CNN *(b) Collaborative Learning with Conflicts and Loss*

Figure 3: ***(a)*** A sentence embedding matrix with the entity pair (e_1, e_2) consists of a word vector set of dimension $(T \times d)$. T is the length of the given sentence and d is the length of the word and position vector. A convolution filter with a dimension of $(u \times d)$ is sliding along the sentence representation. cov represents a convolution operation. The internal CNNs states (C) from the first convolution operation are fed into the self-attention module. A piece-wise max-pooling is employed at outputs $(\tilde{C})$ from last convolution layer. A sentence representation x_i is learned after a nonlinear function. ***(b)*** For an entity pair bag B containing N sentence representations, the j^{th} sentence with maximum weight score α_j is selected by NetAtt, while x_k is the k^{th} sentence selected by NetMax. Conflicts between the two subnets are used to form a conflict loss L_{jk}. Each network uses the same sentence representation and generates different bag representations to feed a softmax layer separately. The *conflicts* and *loss* from collaborative training are used as cues for curriculum building in section 3.5.2.

3.3 Entity Position-aware Sentence Representation: Piece-wise Max Pooling

Following the self-attention operations, we use a piece-wise max pooling operation to form the final sentence representation. The max pooling is a variant of pooling in standard CNNs, which applies the pooling to three convolution segments separated by head and tail entities (Zeng et al., 2015). As shown in the column of "piece-wise pooling" in Figure 3(a), the grey dots in $\tilde{c}$, representing head and tail entities, split each vector into three pieces, which are denoted as $\tilde{C}_1, \tilde{C}_2, \tilde{C}_3$, respectively. Thus, the piece-wise max pooling is expressed as $\{x_i^1, x_i^2, x_i^3\} = \text{max-pooling}(\tilde{C}_1, \tilde{C}_2, \tilde{C}_3)$. These three pooled vectors are then concatenated together to form a vector x_i and a nonlinear function is applied to the output vector, such that $x_i = tanh(x_i)$ is the final representation of a sentence.

3.4 Bag Representation for Entity Pairs

After learning representations of all sentences in an entity pair bag, we then use two approaches to form the entity pair bag representation, as illustrated in Figure 3(b), i.e., we employ a mechanism of averaging all sentences using attention scores (NetAtt) (Lin et al., 2016), and a maximum probability sentence selection method (NetMax) (Zeng et al., 2015), respectively, to learn the bag representation. Specifically, NetAtt assigns weight scores $\{\alpha_1, \ldots, \alpha_N\}$ to all sentences in an entity pair bag, while NetMax will select the most reasonable sentence that has the highest probability.

Ideal student networks are equipped with SOTA MIL selection mechanisms and could empirically generate conflicts during the selection, based on this criterion we use NetAtt and NetMax. NetAtt works by considering all sentences in a bag, but it also introduces noisy sentences while learning a bag representation. NetMax works by selecting the sentence with the highest probability in a bag as the bag representation, but it overlooks other valid sentences. Moreover, the two networks use different bag representations to feed classifiers and eventually generate *disagreements*. Therefore, we are motivated by the idea of combining their advantages and disagreements over sentence selection in a single framework to learn better bag representations and to reduce the noise effects.

Before introducing the proposed single framework, we first describe below how NetAtt and NetMax work in bag representation learning. The sentence bag of an entity pair is denoted as B, which consists of representations of N sentences $\{x_1, x_2, \ldots, x_N\}$, where each sentence representation is learned from our self-attention based PCNN. The entity pair is expressed as (e_1, e_2) and the bag's relation is r.

3.4.1 NetAtt: Sentence-Level Attention

To extract information from all sentences in a bag, a sentence-level attention mechanism is used to learn a weight score α_i for each sentence. Subse-

quently, the bag representation S^{att}_{bag} for the entity pair's bag B is computed as: $S^{att}_{bag} = \sum_{i=1}^{N} \alpha_i x_i$.

We can see that the purpose of the weighted factor α_i is to give higher weights to correctly labeled instances and lower weights to wrongly labeled ones. Given the score β_i of a given sentence representation x_i with a relation r, which is measured as: $\beta_i(x_i|r) = x_i A r$ (where A is a weighted diagonal matrix), the attention scores in a given bag B can be calculated as: $\alpha_i(x_i|r, B) = softmax(\gamma\beta_i(x_i|r))$, where γ is set empirically and borrowed from the work by (Sutton and Barto, 1998). Smaller γ will lead to equalisation in all sentences and larger γ will increase bias of the high scored sentence.

3.4.2 NetMax: Maximum Probability

NetMax assumes that at least one sentence in an entity pair bag reflects the bag's relation, and only one sentence with the maximum probability is selected to represent the bag, which is denoted as $S^{max}_{bag} = x_k$, where x_k is the k^{th} sentence representation with maximum probability. As only one sentence is selected, the input o for the *softmax* classifier can be expressed as $o = Kx_k + b$, where K is the transformation matrix and b is the bias. For a bag with relation r, the conditional probability is $p(r|x_k;\theta) = softmax(o_r)$. For all sentences in a bag, the index k is computed by $k = arg\max_k p(r|x_k;\theta)$.

3.5 Collaborative Curriculum Learning

As mentioned above, we consider the advantages and disagreements of sentence selection of NetAtt and NetMax in a single framework so that they can learn to regularise each other so as to reduce the effects of noisy sentences. We propose a collaborative curriculum learning framework where NetAtt and NetMax are defined as two student networks and they learn together under a curriculum scheme. For DSRE, we assume that entity pair bags with wrongly labeled sentences are *hard samples* to be learned, while bags with correctly labeled sentences are *easy samples*. Figure 3(b) shows the architecture of our collaborative curriculum learning framework, where NetAtt and NetMax are trained collaboratively and regularised by each other. The curriculum vector v_i for collaborative learning could be built by various schemes, for example, the *conflicts* (v^c_i) of selecting the valid sentence in a bag between the two student networks, which will be detailed later.

3.5.1 Objective Function

The objective function is defined as $J(S_i;\theta) = \frac{1}{m}\sum_{i=1}^{m} j(S_i;\theta)$, where m is the total number of entity pair's bags in a mini-batch. S_i is a set of $\{S^{att}_{bag_i}, S^{max}_{bag_i}\}$. $j(S_i;\theta)$ is the objective function of one entity pair's bag defined in Equation (2):

$$\begin{aligned} j(S_i;\theta) = \eta \log p(r_i|S^{att}_{bag_i};\theta) + \\ (1-\eta)\log p(r_i|S^{max}_{bag_i};\theta) \end{aligned} \quad (2)$$

where, $0 < \eta < 1$ is an empirical value to assign weights to NetAtt and NetMax. With a curriculum, the model's minimisation problem can be formulated as in Equation (3):

$$\min_{\theta,v} E(\theta, v, \lambda) = \frac{1}{m}\sum_{i=1}^{m} v_i l_i + L_{jk} \quad (3)$$

where, $l_i = l(r_i, j(S_i;\theta))$ is the loss of each bag; r_i is the relation of a bag; v_i is the curriculum weight variable; L_{jk} is the cross entropy loss of conflicts between the highest probability sentence indexes from NetAtt and NetMax, which aims to let them regularise each other during sentence selection; θ and λ are the optimisation parameters of relation extractor and curriculum. The weighted loss is minimised by stochastic gradient descent.

Algorithm 1 Update using conflicts

inputs: mini batch size m; j^i_{att} and k^i_{max}; two students: p_{att} (*NetAtt*), p_{max} (*NetMax*); bag representation: S^{att}_i, S^{max}_i

for *i in* {1,2,3, ..., m} **do**
  if $j^i_{att} = k^i_{max}$ **then**
    # *no conflicts* $v^c_i = 1$
    add S^{att}_i to set $\{S^{att}\}$
    add S^{max}_i to set $\{S^{max}\}$
  end
end
update p_{att} *with* $\{S^{att}\}$ **&** p_{max} *with* $\{S^{max}\}$

3.5.2 Curriculum Construction for Collaborative Learning

Conflicts trick of two students are utlised to build a curriculum (v^c_i): In a mini-batch of size m, where the i^{th} entity pair's bag contains N sentences, j^i_{att}, $k^i_{max} \in [0\ to\ N)$ are the indexes of highest probably sentence selected by NetAtt and NetMax, respectively. For each entity pair bag in the batch, if j^i_{att} is not equal to k^i_{max}, then $v^c_i = 0$, representing a *'hard' sample* (with conflicts). Otherwise $v^c_i = 1$, representing an *'easy' sample*. The

conflicts that occur during the collaborative training between NetAtt and NetMax are shown in Figure 3(b). There is no extra curriculum network ($f(v^c;\lambda)$) required to learn a v_i^c.

When v_i^c is assigned to 0, the training procedure will forget the effects of *'hard'* sample (i^{th} bag) by multiplying 0 and its loss l_i as shown in Eq. (3). Algorithm 1 illustrates the logic to update the training using the conflicts curriculum. In a mini-batch, entity pair bags with conflicts in sentence selection are dropped, the remaining bags are used to update the network parameters.

Furthermore, various curriculum types could be used in CCL to alleviate the noise in DSRE. We utilize the **small loss trick** to build a curriculum which inspired by Jiang et al. (2018). Specifically, to build a curriculum (v_i^l), the loss (l_i) is used as an input constant feature to learn a curriculum vector. We use the MentorNet framework[2] (Jiang et al., 2018) as the curriculum network to learn an approximate predefined curriculum $f(v^l;\lambda)$. The approximation process is to train a curriculum model using synthetic data generated according to the predefined curriculum. The trained model is then used as the curriculum to guide the further model training. We use the predefined curriculum $f(v^l;\lambda) = v_i^l l_i + \frac{1}{2}\lambda_2 (v_i^l)^2 - (\lambda_1 + \lambda_2) v_i^l$ (Jiang et al., 2015) to guide our training.

4 Experiments

4.1 Dataset

We evaluate our model on the widely used New York Times (NYT) DSRE dataset[3], which aligns Freebase entity relation with NYT corpus (Riedel et al., 2010). The dataset uses the data from 2005 to 2006 as the training set and the remaining data, taken from 2007, as the test set. The processed dataset[4] was released by Lin et al. (2016). We use the cleaned version of the processed dataset, which has removed duplicated sentences in training and test sets. In total, the training set consists of *522,611* sentences, 281,270 entity pairs and 18,252 relation facts. The testing set contains 172,448 sentences, 96,678 entity pairs, and 1,950 relation facts. The dataset contains 39,528 unique entities and 53 relations in total including an *NA* relation which represents no existing relation for given entity pairs in sentences.

[2] https://github.com/google/mentornet
[3] http://iesl.cs.umass.edu/riedel/ecml/
[4] https://github.com/thunlp/NRE

4.2 Evaluation Metrics

Instead of obtaining a costly human annotated test data, we conduct a held-out evaluation (Riedel et al., 2010) in the experiments, as in previous work (Riedel et al., 2010; Surdeanu et al., 2012; Zeng et al., 2015; Lin et al., 2016). Held-out evaluation compares relation facts predicted in test data with those relations identified in Freebase. It gives an approximate evaluation of the proposed model. As with the evaluation metrics used in the literature, we report our results using Precision-Recall curve (PR-curve) and Precision at N (P@N) metrics. *PR-curve* is used to understand the trade-off between precision and recall. Using all the test data, the plotted curve expresses the precision as a function of recall. *P@N* considers the cutoff top-most *N* precision values as a set. Each entity pair bag contains one or more instances and P@N considers *all* the multiple instances.

4.3 Baseline Models

We compare our model with both statistical and deep learning baseline models. These baselines were evaluated on the same cleaned dataset. We exclude some recent models due to the dataset and reproducibility issues. Namely, recent models that were trained on a dataset, which was released by mistake, obtained higher results. These results in fact may be inaccurate. From the Github repository commit history and comments[5]: *"It has not deleted the mix part of testing data. The training sentence is 570000+, but in the paper is 520000+."*. The incorrect training dataset was replaced with the corrected one in March 2018, which might be the main reason as to why some MIL DSRE papers in 2018 reported non-reproducible results on the corrected training data. In all probability these works had commenced prior to March 2018 and were likely relying on the erroneous dataset.

(1) Statistical Models: *Mintz* (Mintz et al., 2009) extracted sentence syntactic and lexical features and trained a multiclass logistic regression classifier. *Hoffmann* (Hoffmann et al., 2011) is a probabilistic, graphic model with MIL. *MIMLRE* (Surdeanu et al., 2012) is a MIL model that uses expectation maximization for classification.

(2) Deep Learning Models: both CNN (Zeng et al., 2014) and PCNN (Zeng et al., 2015) based

[5] https://github.com/thunlp/NRE/commit/77025e5cc6b42bc1adf3ec46835101d162013659

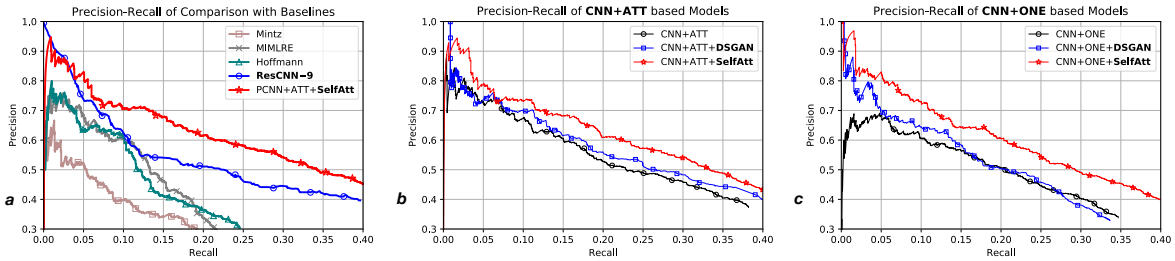


Figure 4: PR curves comparison of CNN/PCNN based models with SelfAtt module and baselines

relation extraction models with bag level selective attention mechanism (*PCNN+ATT*, *CNN+ATT*) (Lin et al., 2016) and multi-instance learning (*PCNN+ONE*, *CNN+ONE*) (Zeng et al., 2015).

(3) ResCNN-9 (Huang and Wang, 2017): 9-layers CNN model with residual identity shortcuts and three fully connected layers. The model outperforms CNN+ATT/ONE models.

(4) State-of-the-art DSRE Noise Filter Systems: DSGAN (Qin et al., 2018) is a model to filter out noise instances. It unitizes GANs to remove potentially inaccurate sentences from original training data and further trains PCNN/CNN models on the filtered data to improve performance.

Number of CNN filters	128, 230, 256
Batch size B	120
Learning rate	0.1, 0.4
Weight decay	0.00001
Burn-in epoch	5
Dropout probability	0.3

Table 1: Parameters setting for best results

We fine-tune our models by validating and selecting the best model parameters. To accomplish this we set the gradient descent learning rate among $\{0.4, 0.2, 0.1, 0.01, 0.001\}$. Batch size B is set to $\{60, 120, 160\}$. The amount of CNN filter is set among $\{64, 128, 230, 256\}$. A dropout rate is in the set $\{0.1, 0.3\}$. All the parameters fine-tuned in our experiments are shown in Table 1. Specifically, the best performance of [CNN+ATT/ONE+SelfAtt] with training parameters of learning rate:0.4 and CNN filters:230; the best performance of [PCNN+ATT/ONE+SelfAtt] with training parameters of learning rate:0.4 and CNN filters:128; and the best performance of [PCNN+ATT/ONE+SelfAtt+CCL] with training parameters of learning rate:0.1 and CNN filters:256. For other parameters, we follow the settings in the work of (Lin et al., 2016), e.g. the maximum sentence length is limited to 70, the word and position embedding size is fixed to 50 and 5 respectively, and the CNNs filter window size is 3.

4.4 Effects of Internal CNNs Self-Attention

Armed by the internal multilayer CNNs self-attention mechanism (named as **SelfAtt**), our model can learn a better representation from noisy data compared with the conventional CNN encoder used in PCNN/CNN. Each model has more than one convolution operation, as illustrated in Figure 3(a). Prior to feeding these outputs from the first convolution operation into the self-attention module, we add a batch normalisation followed by an ReLU activation function.

Figures 4 & 5 show the PR-curve results attained by applying SelfAtt to CNN/PCNN based models. We also report the results of P@100, P@200, P@300 and the Mean for CNN/PCNN+ONE and CNN/PCNN+ATT with SelfAtt in the held-out evaluation. Table 3 shows the P@N values with test settings where all sentences in an entity pair's bag are taken into account. PR-curve and P@N results demonstrate that CNN/PCNN based approaches achieve improved results with the SelfAtt. PCNN/CNN models with SelfAtt also outperform ResCNN-9 in terms of P@N and PR-curve, which indicates that the proposed SelfAtt is beneficial for boosting the performance of the models learning from noisy inputs. The state-of-the-art DSGAN system demonstrates its ability to improve PCNN/CNN + ATT/ONE by filtering out noisy data. By comparing our SelfAtt with DSGAN, Figure 4 shows that SelfAtt significantly outperforms the DSGAN system in terms of CNN-based models.

The intuition of adding an internal CNN states self-attention module to help DSRE task is that, 1/ a deeper CNN has positive effects on noisy NLP tasks (Conneau et al., 2017), 2/ attention enhanced PCNN/CNN is expected to assign various weight scores to different sentence portions and will form a better representation in the DSRE setting.

By applying the SelfAtt it could add more

convolution layers into a model, as the internal self-attention used is placed between two convolution operations. Huang and Wang (2017) demonstrated that multi-layer ResCNNs network does achieve performance improvement by adding residual identity shortcuts, which aligns with the study that deeper CNN has positive effects on noisy NLP tasks (Conneau et al., 2017). However, previous DSRE researches overlooked multilayer CNN/PCNN with ONE/ATT. To investigate multilayer effects of DSRE, we present multilayer CNN with ATT results in Table 2, we observe that with ATT several multilayer models (e.g., 2 layers CNN+ATT) have improvements compared with single layer models, and overfitting occurs when larger convolution layers are employed.

P@N(%)	100	200	300	Mean	AUC
CNN-1+ATT	76.2	68.6	59.8	68.2	0.327
CNN-2+ATT	76.2	**72.1**	**68.4**	**72.2**	**0.348**
CNN-5+ATT	74.2	**72.6**	**66.1**	**71.0**	**0.338**
CNN-9+ATT	66.3	64.2	63.7	64.7	0.315

Table 2: Multilayer CNNs+ATT

Thus, our SelfAtt design is expected to boost a sentence encoder with attention scores and alleviate noise effects by benefiting from a multilayer CNN network. From empirical testing, to apply attention more subtly, placing self-attention after the second convolution operation and followed by one convolution operation works well for all PCNN/CNN + ONE/ATT based models generally. We report results with this setting.

avaya , which was once a division of lucent technologies and att before that , is one of the nation 's top makers of phone equipment , rivaling cisco , nortel and alcatel-lucent in providing internet-based communications to corporations .

By looking at the weight scores from SeftAtt, we observe that different parts of a sentence obtain different attentions. For example, as the heat-map illustrates using attention scores, entities *avaya* and *cisco* obtain more attention than others.

4.5 Effects of Collaborative Curriculum Learning

We refer to the Collaborative Curriculum Learning using Conflicts Trick as CCL-CT, and using the Small Loss trick as CCL-SL. For the following experiments, we expect that by applying our CCL strategies, it will result in further improvements by reducing the undesirable effects of noise. In our framework of integrating collaborative curriculum learning, both NetAtt and NetMax could be used for testing. We report a comparison of NetAtt/NetMax+SelfAtt+CCL, PCNN+ONE/ATT and state-of-the-art DSGAN noise reduction as shown in Table 3 and Figure 5.

P@N (%)	100	200	300	Mean
CNN-based Models				
CNN+ONE	67.3	64.7	58.1	63.4
ResCNN-9	79.0	69.0	61.0	69.7
CNN+ONE+**SelfAtt**	**81.1**	**75.1**	**70.4**	**75.5**
CNN+ATT	76.2	68.6	59.8	68.2
CNN+ATT+**SelfAtt**	**81.1**	**74.1**	**72.4**	**75.9**
PCNN-based Models				
PCNN+ONE	72.3	69.7	64.1	68.7
PCNN+ONE+**SelAtt**	84.1	75.1	69.1	**76.1**
[NetMax+**SelfAtt**]+**CCL-CT**	**85.1**	**78.6**	**74.4**	**79.4**
PCNN+ATT	76.2	73.1	67.4	72.2
PCNN+ATT+**SelfAtt**	81.1	71.6	70.4	**74.4**
[NetAtt+**SelfAtt**]+**CCL-CT**	**82.2**	**79.1**	**73.1**	**78.1**

Table 3: P@N results for models with internal CNNs self-attention and curriculum learning

CCL-CT utilises the conflicts from the collaborative training of NetMax and NetAtt to form a curriculum to guide the training. The two students form different bag representations to feed to Softmax layer separately, and they generate disagreements on the bag-level selection during training. In our experiment, each epoch reveals less than 10.9% disagreement, thus we drop less than 10.9% of the total entity pair bags during each epoch and the drop ratios work well in our experiments.

Model		**+SelfAtt**	**CCL-CT**
PCNN+ATT	0.341	**0.368**	**0.381**
PCNN+ONE	0.325	**0.352**	**0.380**

Table 4: Comparison of AUC Results

From Figures 5(a) and 5(b), we can see that the CCL based models have further improvements in terms of PR-curves compared with PCNN+ATT/ONE+SelfAtt. The P@N results in Table 3 indicate that CCL further improves the model's performance when compared to PCNN+ATT/ONE+SelfAtt as well. Table 4 gives another comparison using AUC with all p-values less than 5e-02 from t-test evaluation. The results indicate that the larger AUC, the better performance. A simple ensemble model of two networks (AUC: 0.371) has a similar result as a single model (NetAtt, AUC: 0.368). The main purpose of adding an additional student network is to introduce conflicts and to build the collaborative curriculum learning scheme. With the CCL strategies, our models improve performances by removing *'hard'* (noisy) entity pair bags during

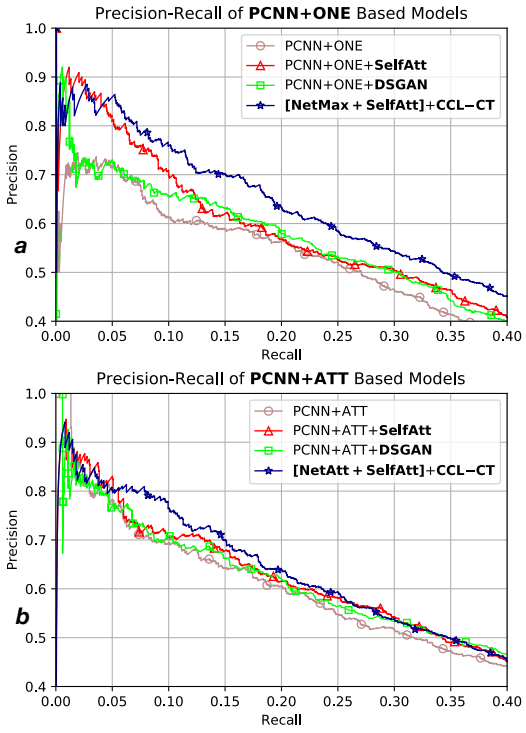

Figure 5: PR curves comparison of PCNN based noise removal models

training. When compared with the state-of-the-art DSGAN system, our models outperform both DSGAN based ONE and ATT models.

We examine the small loss trick based curriculum using MentorNet (Jiang et al., 2018). *CCL-SL* uses the loss from the collaborative training to build the curriculum vector, which commences by guiding the collaborative training from the burn-in epoch (5^{th}) and the optimal epoch result of (AUC:0.382, P@N mean:77.3%), which is reported for held-out evaluation starting at the burn-in epoch. The results also demonstrate that various curriculum types (the conflict and loss tricks) could help to alleviate the noise in DSRE.

Overall, our experimental results demonstrate that the proposed SelfAtt and CCL strategies for PCNN/CNN models significantly outperform baselines in terms of PR-curve and P@N.

5 Conclusion

To deal with the mislabelling issue in distantly supervised relation extraction, this paper details the development of a novel model based on a multi-layer self-attention mechanism for CNNs and collaborative curriculum learning strategies with two students (NetAtt and NetMax). The internal self-attention model can learn a better sentence representation by taking advantage of deeper CNNs in terms of positive effects on noisy inputs. The CCL strategies can perform a collaborative training on NetAtt and NetMax by allowing them to regularize each other, in tandem with the removal of noisy sample effects. Two different tricks, namely conflicts tricks and small loss tricks, are utilized in the CCL framework. Experimental results on the commonly-used NYT dataset indicate that our proposed approaches significantly outperform state-of-the-art baseline models in terms of P@N and PR-curve evaluation metrics.

Neural Cross-Lingual Relation Extraction Based on Bilingual Word Embedding Mapping

Jian Ni and **Radu Florian**
IBM Research AI
1101 Kitchawan Road, Yorktown Heights, NY 10598, USA
{nij, raduf}@us.ibm.com

Abstract

Relation extraction (RE) seeks to detect and classify semantic relationships between entities, which provides useful information for many NLP applications. Since the state-of-the-art RE models require large amounts of manually annotated data and language-specific resources to achieve high accuracy, it is very challenging to transfer an RE model of a resource-rich language to a resource-poor language. In this paper, we propose a new approach for cross-lingual RE model transfer based on bilingual word embedding mapping. It projects word embeddings from a target language to a source language, so that a well-trained source-language neural network RE model can be directly applied to the target language. Experiment results show that the proposed approach achieves very good performance for a number of target languages on both in-house and open datasets, using a small bilingual dictionary with only 1K word pairs.

1 Introduction

Relation extraction (RE) is an important information extraction task that seeks to detect and classify semantic relationships between entities like persons, organizations, geo-political entities, locations, and events. It provides useful information for many NLP applications such as knowledge base construction, text mining and question answering. For example, the entity *Washington, D.C.* and the entity *United States* have a *CapitalOf* relationship, and extraction of such relationships can help answer questions like "What is the capital city of the United States?"

Traditional RE models (e.g., Zelenko et al. (2003); Kambhatla (2004); Li and Ji (2014)) require careful feature engineering to derive and combine various lexical, syntactic and semantic features. Recently, neural network RE models (e.g., Zeng et al. (2014); dos Santos et al. (2015); Miwa and Bansal (2016); Nguyen and Grishman (2016)) have become very successful. These models employ a certain level of automatic feature learning by using word embeddings, which significantly simplifies the feature engineering task while considerably improving the accuracy, achieving the state-of-the-art performance for relation extraction.

All the above RE models are supervised machine learning models that need to be trained with large amounts of manually annotated RE data to achieve high accuracy. However, annotating RE data by human is expensive and time-consuming, and can be quite difficult for a new language. Moreover, most RE models require language-specific resources such as dependency parsers and part-of-speech (POS) taggers, which also makes it very challenging to transfer an RE model of a resource-rich language to a resource-poor language.

There are a few existing weakly supervised cross-lingual RE approaches that require no human annotation in the target languages, e.g., Kim et al. (2010); Kim and Lee (2012); Faruqui and Kumar (2015); Zou et al. (2018). However, the existing approaches require aligned parallel corpora or machine translation systems, which may not be readily available in practice.

In this paper, we make the following contributions to cross-lingual RE:

- We propose a new approach for direct cross-lingual RE model transfer based on bilingual word embedding mapping. It projects word embeddings from a target language to a source language (e.g., English), so that a well-trained source-language RE model can be directly applied to the target language, with no manually annotated RE data needed for the target language.

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 399–409, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

- We design a deep neural network architecture for the source-language (English) RE model that uses word embeddings and generic language-independent features as the input. The English RE model achieves the-state-of-the-art performance without using language-specific resources.

- We conduct extensive experiments which show that the proposed approach achieves very good performance (up to 79% of the accuracy of the supervised target-language RE model) for a number of target languages on both in-house and the ACE05 datasets (Walker et al., 2006), using a small bilingual dictionary with only 1K word pairs. To the best of our knowledge, this is the first work that includes empirical studies for cross-lingual RE on several languages across a variety of language families, without using aligned parallel corpora or machine translation systems.

We organize the paper as follows. In Section 2 we provide an overview of our approach. In Section 3 we describe how to build monolingual word embeddings and learn a linear mapping between two languages. In Section 4 we present a neural network architecture for the source-language (English). In Section 5 we evaluate the performance of the proposed approach for a number of target languages. We discuss related work in Section 6 and conclude the paper in Section 7.

2 Overview of the Approach

We summarize the main steps of our neural cross-lingual RE model transfer approach as follows.

1. Build word embeddings for the source language and the target language separately using monolingual data.

2. Learn a linear mapping that projects the target-language word embeddings into the source-language embedding space using a small bilingual dictionary.

3. Build a neural network source-language RE model that uses word embeddings and generic language-independent features as the input.

4. For a target-language sentence and any two entities in it, project the word embeddings of the words in the sentence to the source-language word embeddings using the linear mapping, and then apply the source-language RE model on the projected word embeddings to classify the relationship between the two entities. An example is shown in Figure 1, where the target language is Portuguese and the source language is English.

We will describe each component of our approach in the subsequent sections.

3 Cross-Lingual Word Embeddings

In recent years, vector representations of words, known as *word embeddings*, become ubiquitous for many NLP applications (Collobert et al., 2011; Mikolov et al., 2013a; Pennington et al., 2014).

A monolingual word embedding model maps words in the vocabulary $\mathcal{V}$ of a language to real-valued vectors in $\mathbb{R}^{d\times 1}$. The dimension of the vector space d is normally much smaller than the size of the vocabulary $V = |\mathcal{V}|$ for efficient representation. It also aims to capture semantic similarities between the words based on their distributional properties in large samples of monolingual data.

Cross-lingual word embedding models try to build word embeddings across multiple languages (Upadhyay et al., 2016; Ruder et al., 2017). One approach builds monolingual word embeddings separately and then maps them to the same vector space using a bilingual dictionary (Mikolov et al., 2013b; Faruqui and Dyer, 2014). Another approach builds multilingual word embeddings in a shared vector space simultaneously, by generating mixed language corpora using aligned sentences (Luong et al., 2015; Gouws et al., 2015).

In this paper, we adopt the technique in (Mikolov et al., 2013b) because it only requires a small bilingual dictionary of aligned word pairs, and does not require parallel corpora of aligned sentences which could be more difficult to obtain.

3.1 Monolingual Word Embeddings

To build monolingual word embeddings for the source and target languages, we use a variant of the Continuous Bag-of-Words (CBOW) word2vec model (Mikolov et al., 2013a).

The standard CBOW model has two matrices, the input word matrix $\tilde{\mathbf{X}} \in \mathbb{R}^{d\times V}$ and the output word matrix $\mathbf{X} \in \mathbb{R}^{d\times V}$. For the ith word w_i in $\mathcal{V}$, let $\mathbf{e}(w_i) \in \mathbb{R}^{V\times 1}$ be a one-hot vector with 1 at index i and 0s at other indexes, so that $\tilde{\mathbf{x}}_i = \tilde{\mathbf{X}}\mathbf{e}(w_i)$

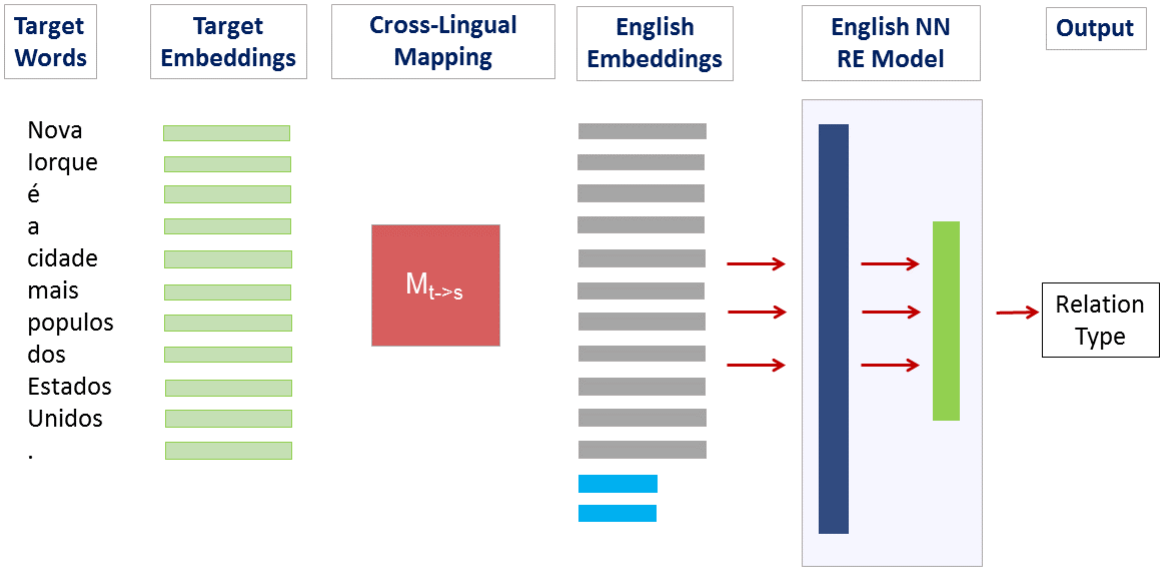

Figure 1: Neural cross-lingual relation extraction based on bilingual word embedding mapping - target language: Portuguese, source language: English.

(the ith column of $\tilde{\mathbf{X}}$) is the input vector representation of word w_i, and $\mathbf{x}_i = \mathbf{X}\mathbf{e}(w_i)$ (the ith column of $\mathbf{X}$) is the output vector representation (i.e., word embedding) of word w_i.

Given a sequence of training words $w_1, w_2, ..., w_N$, the CBOW model seeks to predict a target word w_t using a window of $2c$ context words surrounding w_t, by maximizing the following objective function:

$$\mathcal{L} = \frac{1}{N}\sum_{t=1}^{N} \log P(w_t | w_{t-c}, ..., w_{t-1}, w_{t+1}, ..., w_{t+c})$$

The conditional probability is calculated using a softmax function:

$$P(w_t | w_{t-c}, ..., w_{t+c}) = \frac{\exp(\mathbf{x}_t^{\mathrm{T}} \tilde{\mathbf{x}}_{c(t)})}{\sum_{i=1}^{V} \exp(\mathbf{x}_i^{\mathrm{T}} \tilde{\mathbf{x}}_{c(t)})} \quad (1)$$

where $\mathbf{x}_t = \mathbf{X}\mathbf{e}(w_t)$ is the output vector representation of word w_t, and

$$\tilde{\mathbf{x}}_{c(t)} = \sum_{-c \le j \le c, j \neq 0} \tilde{\mathbf{X}}\mathbf{e}(w_{t+j}) \quad (2)$$

is the sum of the input vector representations of the context words.

In our variant of the CBOW model, we use a separate input word matrix $\tilde{\mathbf{X}}_j$ for a context word at position $j, -c \le j \le c, j \neq 0$. In addition, we employ weights that decay with the distances of the context words to the target word. Under these modifications, we have

$$\tilde{\mathbf{x}}_{c(t)}^{new} = \sum_{-c \le j \le c, j \neq 0} \frac{1}{|j|} \tilde{\mathbf{X}}_j \mathbf{e}(w_{t+j}) \quad (3)$$

We use the variant to build monolingual word embeddings because experiments on named entity recognition and word similarity tasks showed this variant leads to small improvements over the standard CBOW model (Ni et al., 2017).

3.2 Bilingual Word Embedding Mapping

Mikolov et al. (2013b) observed that word embeddings of different languages often have similar geometric arrangements, and suggested to learn a linear mapping between the vector spaces.

Let $\mathcal{D}$ be a bilingual dictionary with aligned word pairs $(w_i, v_i)_{i=1,...,D}$ between a source language s and a target language t, where w_i is a source-language word and v_i is the translation of w_i in the target language. Let $\mathbf{x}_i \in \mathbb{R}^{d \times 1}$ be the word embedding of the source-language word w_i, $\mathbf{y}_i \in \mathbb{R}^{d \times 1}$ be the word embedding of the target-language word v_i.

We find a linear mapping (matrix) $\mathbf{M}_{t \to s}$ such that $\mathbf{M}_{t \to s}\mathbf{y}_i$ approximates $\mathbf{x}_i$, by solving the fol-

lowing least squares problem using the dictionary as the training set:

$$\mathbf{M}_{t\rightarrow s} = \arg\min_{\mathbf{M}\in\mathbb{R}^{d\times d}} \sum_{i=1}^{D} ||\mathbf{x}_i - \mathbf{M}\mathbf{y}_i||^2 \quad (4)$$

Using $\mathbf{M}_{t\rightarrow s}$, for any target-language word v with word embedding $\mathbf{y}$, we can project it into the source-language embedding space as $\mathbf{M}_{t\rightarrow s}\mathbf{y}$.

3.2.1 Length Normalization and Orthogonal Transformation

To ensure that all the training instances in the dictionary $\mathcal{D}$ contribute equally to the optimization objective in (4) and to preserve vector norms after projection, we have tried length normalization and orthogonal transformation for learning the bilingual mapping as in (Xing et al., 2015; Artetxe et al., 2016; Smith et al., 2017).

First, we normalize the source-language and target-language word embeddings to be unit vectors: $\mathbf{x}' = \frac{\mathbf{x}}{||\mathbf{x}||}$ for each source-language word embedding $\mathbf{x}$, and $\mathbf{y}' = \frac{\mathbf{y}}{||\mathbf{y}||}$ for each target-language word embedding $\mathbf{y}$.

Next, we add an orthogonality constraint to (4) such that $\mathbf{M}$ is an orthogonal matrix, i.e., $\mathbf{M}^{\mathrm{T}}\mathbf{M} = \mathbf{I}$ where $\mathbf{I}$ denotes the identity matrix:

$$\mathbf{M}^{O}_{t\rightarrow s} = \arg\min_{\mathbf{M}\in\mathbb{R}^{d\times d}, \mathbf{M}^{\mathrm{T}}\mathbf{M}=\mathbf{I}} \sum_{i=1}^{D} ||\mathbf{x}'_i - \mathbf{M}\mathbf{y}'_i||^2 \quad (5)$$

$\mathbf{M}^{O}_{t\rightarrow s}$ can be computed using singular-value decomposition (SVD).

3.2.2 Semi-Supervised and Unsupervised Mappings

The mapping learned in (4) or (5) requires a seed dictionary. To relax this requirement, Artetxe et al. (2017) proposed a self-learning procedure that can be combined with a dictionary-based mapping technique. Starting with a small seed dictionary, the procedure iteratively 1) learns a mapping using the current dictionary; and 2) computes a new dictionary using the learned mapping.

Artetxe et al. (2018) proposed an unsupervised method to learn the bilingual mapping without using a seed dictionary. The method first uses a heuristic to build an initial dictionary that aligns the vocabularies of two languages, and then applies a robust self-learning procedure to iteratively improve the mapping. Another unsupervised method based on adversarial training was proposed in Conneau et al. (2018).

We compare the performance of different mappings for cross-lingual RE model transfer in Section 5.3.2.

4 Neural Network RE Models

For any two entities in a sentence, an RE model determines whether these two entities have a relationship, and if yes, classifies the relationship into one of the pre-defined relation types. We focus on neural network RE models since these models achieve the state-of-the-art performance for relation extraction. Most importantly, neural network RE models use word embeddings as the input, which are amenable to cross-lingual model transfer via cross-lingual word embeddings. In this paper, we use English as the source language.

Our neural network architecture has four layers. The first layer is the *embedding layer* which maps input words in a sentence to word embeddings. The second layer is a *context layer* which transforms the word embeddings to context-aware vector representations using a recurrent or convolutional neural network layer. The third layer is a *summarization layer* which summarizes the vectors in a sentence by grouping and pooling. The final layer is the *output layer* which returns the classification label for the relation type.

4.1 Embedding Layer

For an English sentence with n words $\mathbf{s} = (w_1, w_2, ..., w_n)$, the *embedding layer* maps each word w_t to a real-valued vector (word embedding) $\mathbf{x}_t \in \mathbb{R}^{d\times 1}$ using the English word embedding model (Section 3.1). In addition, for each entity m in the sentence, the embedding layer maps its entity type to a real-valued vector (entity label embedding) $\mathbf{l}_m \in \mathbb{R}^{d_m\times 1}$ (initialized randomly). In our experiments we use $d = 300$ and $d_m = 50$.

4.2 Context Layer

Given the word embeddings $\mathbf{x}_t$'s of the words in the sentence, the *context layer* tries to build a sentence-context-aware vector representation for each word. We consider two types of neural network layers that aim to achieve this.

4.2.1 Bi-LSTM Context Layer

The first type of context layer is based on Long Short-Term Memory (LSTM) type recurrent neural networks (Hochreiter and Schmidhuber, 1997;

Graves and Schmidhuber, 2005). Recurrent neural networks (RNNs) are a class of neural networks that operate on sequential data such as sequences of words. LSTM networks are a type of RNNs that have been invented to better capture long-range dependencies in sequential data.

We pass the word embeddings $\mathbf{x}_t$'s to a forward and a backward LSTM layer. A forward or backward LSTM layer consists of a set of recurrently connected blocks known as *memory blocks*. The memory block at the t-th word in the forward LSTM layer contains a memory cell $\overrightarrow{\mathbf{c}}_t$ and three *gates*: an input gate $\overrightarrow{\mathbf{i}}_t$, a forget gate $\overrightarrow{\mathbf{f}}_t$ and an output gate $\overrightarrow{\mathbf{o}}_t$ ($\overrightarrow{\cdot}$ indicates the forward direction), which are updated as follows:

$$\begin{aligned}
\overrightarrow{\mathbf{i}}_t &= \sigma(\overrightarrow{W}_i \mathbf{x}_t + \overrightarrow{U}_i \overrightarrow{\mathbf{h}}_{t-1} + \overrightarrow{\mathbf{b}}_i) \\
\overrightarrow{\mathbf{f}}_t &= \sigma(\overrightarrow{W}_f \mathbf{x}_t + \overrightarrow{U}_f \overrightarrow{\mathbf{h}}_{t-1} + \overrightarrow{\mathbf{b}}_f) \\
\overrightarrow{\mathbf{o}}_t &= \sigma(\overrightarrow{W}_o \mathbf{x}_t + \overrightarrow{U}_o \overrightarrow{\mathbf{h}}_{t-1} + \overrightarrow{\mathbf{b}}_o) \\
\overrightarrow{\mathbf{c}}_t &= \overrightarrow{\mathbf{f}}_t \odot \overrightarrow{\mathbf{c}}_{t-1} + \\
&\quad \overrightarrow{\mathbf{i}}_t \odot \tanh\left(\overrightarrow{W}_c \mathbf{x}_t + \overrightarrow{U}_c \overrightarrow{\mathbf{h}}_{t-1} + \overrightarrow{\mathbf{b}}_c\right) \\
\overrightarrow{\mathbf{h}}_t &= \overrightarrow{\mathbf{o}}_t \odot \tanh(\overrightarrow{\mathbf{c}}_t) \qquad (6)
\end{aligned}$$

where σ is the element-wise sigmoid function and $\odot$ is the element-wise multiplication.

The hidden state vector $\overrightarrow{\mathbf{h}}_t$ in the forward LSTM layer incorporates information from the left (past) tokens of w_t in the sentence. Similarly, we can compute the hidden state vector $\overleftarrow{\mathbf{h}}_t$ in the backward LSTM layer, which incorporates information from the right (future) tokens of w_t in the sentence. The concatenation of the two vectors $\mathbf{h}_t = [\overrightarrow{\mathbf{h}}_t, \overleftarrow{\mathbf{h}}_t]$ is a good representation of the word w_t with both left and right contextual information in the sentence.

4.2.2 CNN Context Layer

The second type of context layer is based on Convolutional Neural Networks (CNNs) (Zeng et al., 2014; dos Santos et al., 2015), which applies *convolution-like* operation on successive windows of size k around each word in the sentence. Let $\mathbf{z}_t = [\mathbf{x}_{t-(k-1)/2}, ..., \mathbf{x}_{t+(k-1)/2}]$ be the concatenation of k word embeddings around w_t. The convolutional layer computes a hidden state vector

$$\mathbf{h}_t = \tanh(\mathbf{W}\mathbf{z}_t + \mathbf{b}) \qquad (7)$$

for each word w_t, where $\mathbf{W}$ is a weight matrix and $\mathbf{b}$ is a bias vector, and $\tanh(\cdot)$ is the element-wise hyperbolic tangent function.

4.3 Summarization Layer

After the context layer, the sentence $(w_1, w_2, ..., w_n)$ is represented by $(\mathbf{h}_1, ..., \mathbf{h}_n)$. Suppose $m_1 = (w_{b_1}, .., w_{e_1})$ and $m_2 = (w_{b_2}, .., w_{e_2})$ are two entities in the sentence where m_1 is on the left of m_2 (i.e., $e_1 < b_2$). As different sentences and entities may have various lengths, the *summarization layer* tries to build a *fixed-length* vector that best summarizes the representations of the sentence and the two entities for relation type classification.

We divide the hidden state vectors $\mathbf{h}_t$'s into 5 groups:

- $G_1 = \{\mathbf{h}_1, .., \mathbf{h}_{b_1-1}\}$ includes vectors that are left to the first entity m_1.
- $G_2 = \{\mathbf{h}_{b_1}, .., \mathbf{h}_{e_1}\}$ includes vectors that are in the first entity m_1.
- $G_3 = \{\mathbf{h}_{e_1+1}, .., \mathbf{h}_{b_2-1}\}$ includes vectors that are between the two entities.
- $G_4 = \{\mathbf{h}_{b_2}, .., \mathbf{h}_{e_2}\}$ includes vectors that are in the second entity m_2.
- $G_5 = \{\mathbf{h}_{e_2+1}, .., \mathbf{h}_n\}$ includes vectors that are right to the second entity m_2.

We perform element-wise max pooling among the vectors in each group:

$$\mathbf{h}_{G_i}(j) = \max_{\mathbf{h} \in G_i} \mathbf{h}(j), 1 \le j \le d_h, 1 \le i \le 5 \qquad (8)$$

where d_h is the dimension of the hidden state vectors. Concatenating the $\mathbf{h}_{G_i}$'s we get a fixed-length vector $\mathbf{h}_s = [\mathbf{h}_{G_1}, ..., \mathbf{h}_{G_5}]$.

4.4 Output Layer

The output layer receives inputs from the previous layers (the summarization vector $\mathbf{h}_s$, the entity label embeddings $\mathbf{l}_{m_1}$ and $\mathbf{l}_{m_2}$ for the two entities under consideration) and returns a probability distribution over the relation type labels:

$$\mathbf{p} = \text{softmax}\left(\mathbf{W}_s \mathbf{h}_s + \mathbf{W}_{m_1} \mathbf{l}_{m_1} + \mathbf{W}_{m_2} \mathbf{l}_{m_2} + \mathbf{b}_o\right) \qquad (9)$$

4.5 Cross-Lingual RE Model Transfer

Given the word embeddings of a sequence of words in a target language t, $(\mathbf{y}_1, ..., \mathbf{y}_n)$, we project them into the English embedding space by applying the linear mapping $\mathbf{M}_{t \to s}$ learned in Section 3.2: $(\mathbf{M}_{t \to s}\mathbf{y}_1, \mathbf{M}_{t \to s}\mathbf{y}_2, ..., \mathbf{M}_{t \to s}\mathbf{y}_n)$. The

neural network English RE model is then applied on the projected word embeddings and the entity label embeddings (which are language independent) to perform relationship classification.

Note that our models do not use language-specific resources such as dependency parsers or POS taggers because these resources might not be readily available for a target language. Also our models do not use precise word position features since word positions in sentences can vary a lot across languages.

5 Experiments

In this section, we evaluate the performance of the proposed cross-lingual RE approach on both in-house dataset and the ACE (Automatic Content Extraction) 2005 multilingual dataset (Walker et al., 2006).

5.1 Datasets

Our in-house dataset includes manually annotated RE data for 6 languages: English, German, Spanish, Italian, Japanese and Portuguese. It defines 56 entity types (e.g., *Person*, *Organization*, *Geo-Political Entity*, *Location*, *Facility*, *Time*, *Event_Violence*, etc.) and 53 relation types between the entities (e.g., *AgentOf*, *LocatedAt*, *PartOf*, *TimeOf*, *AffectedBy*, etc.).

The ACE05 dataset includes manually annotated RE data for 3 languages: English, Arabic and Chinese. It defines 7 entity types (*Person*, *Organization*, *Geo-Political Entity*, *Location*, *Facility*, *Weapon*, *Vehicle*) and 6 relation types between the entities (*Agent-Artifact*, *General-Affiliation*, *ORG-Affiliation*, *Part-Whole*, *Personal-Social*, *Physical*).

For both datasets, we create a class label "O" to denote that the two entities under consideration do not have a relationship belonging to one of the relation types of interest.

5.2 Source (English) RE Model Performance

We build 3 neural network English RE models under the architecture described in Section 4:

- The first neural network RE model does not have a context layer and the word embeddings are directly passed to the summarization layer. We call it **Pass-Through** for short.
- The second neural network RE model has a Bi-LSTM context layer. We call it **Bi-LSTM** for short.
- The third neural network model has a CNN context layer with a window size 3. We call it **CNN** for short.

Model	F_1
FCM (S) (Gormley et al., 2015)	55.06

Table 2: Number of documents in the training/dev/test sets of the in-house and ACE05 datasets.

First we compare our neural network English RE models with the state-of-the-art RE models on the ACE05 English data. The ACE05 English data can be divided to 6 different domains: broadcast conversation (bc), broadcast news (bn), telephone conversation (cts), newswire (nw), usenet (un) and webblogs (wl). We apply the same data split in (Plank and Moschitti, 2013; Gormley et al., 2015; Nguyen and Grishman, 2016), which uses news (the union of bn and nw) as the training set, a half of bc as the development set and the remaining data as the test set.

We learn the model parameters using Adam (Kingma and Ba, 2015). We apply dropout (Srivastava et al., 2014) to the hidden layers to reduce overfitting. The development set is used for tuning the model hyperparameters and for early stopping.

In Table 1 we compare our models with the best models in (Gormley et al., 2015) and (Nguyen and Grishman, 2016). Our Bi-LSTM model outperforms the best model (single or ensemble) in (Gormley et al., 2015) and the best single model in (Nguyen and Grishman, 2016), without using any language-specific resources such as dependency

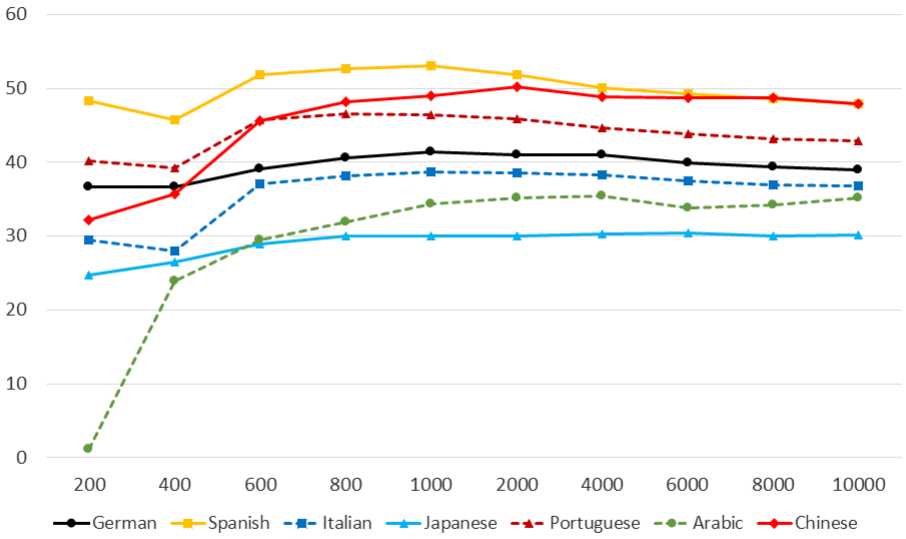

Figure 2: Cross-lingual RE performance (F_1 score) vs. dictionary size (number of bilingual word pairs for learning the mapping (4)) under the Bi-LSTM English RE model on the target-language development data.

Bi-LSTM	66.5	67.7	67.1	65.1	65.8	65.5
CNN	63.4	68.8	66.0	61.7	67.1	64.3

Table 3: Performance of the supervised English RE models on the in-house and ACE05 English test data.

parsers.

While the data split in the previous works was motivated by domain adaptation, the focus of this paper is on cross-lingual model transfer, and hence we apply a random data split as follows. For the source language English and each target language, we randomly select 80% of the data as the training set, 10% as the development set, and keep the remaining 10% as the test set. The sizes of the sets are summarized in Table 2.

We report the Precision, Recall and F_1 score of the 3 neural network English RE models in Table 3. Note that adding an additional context layer with either Bi-LSTM or CNN significantly improves the performance of our English RE model, compared with the simple Pass-Through model. Therefore, we will focus on the Bi-LSTM model and the CNN model in the subsequent experiments.

5.3 Cross-Lingual RE Performance

We apply the English RE models to the 7 target languages across a variety of language families.

5.3.1 Dictionary Size

The bilingual dictionary includes the most frequent target-language words and their translations in English. To determine how many word pairs are needed to learn an effective bilingual word embedding mapping for cross-lingual RE, we first evaluate the performance (F_1 score) of our cross-lingual RE approach on the target-language development sets with an increasing dictionary size, as plotted in Figure 2.

We found that for most target languages, once the dictionary size reaches 1K, further increasing the dictionary size may not improve the transfer performance. Therefore, we select the dictionary size to be 1K.

5.3.2 Comparison of Different Mappings

We compare the performance of cross-lingual RE model transfer under the following bilingual word embedding mappings:

- **Regular-1K**: the regular mapping learned in (4) using 1K word pairs;

Mapping	German	Spanish	Italian	Japanese	Portuguese	Arabic	Chinese	Average
Regular-1K	41.4	53.0	38.7	30.0	46.4	34.4	49.0	41.8
Orthogonal-1K	41.0	49.2	35.7	27.1	44.0	32.1	47.2	39.5
Semi-Supervised-1K	38.1	46.7	31.2	25.3	43.1	37.3	47.1	38.4
Unsupervised	37.8	45.5	28.9	21.2	40.8	37.5	49.1	37.3

Table 4: Comparison of the performance (F_1 score) using different mappings on the target-language development data under the Bi-LSTM model.

- **Orthogonal-1K**: the orthogonal mapping with length normalization learned in (5) using 1K word pairs (in this case we train the English RE models with the normalized English word embeddings);
- **Semi-Supervised-1K**: the mapping learned with 1K word pairs and improved by the self-learning method in (Artetxe et al., 2017);
- **Unsupervised**: the mapping learned by the unsupervised method in (Artetxe et al., 2018).

The results are summarized in Table 4. The regular mapping outperforms the orthogonal mapping consistently across the target languages. While the orthogonal mapping was shown to work better than the regular mapping for the word translation task (Xing et al., 2015; Artetxe et al., 2016; Smith et al., 2017), our cross-lingual RE approach directly maps target-language word embeddings to the English embedding space without conducting word translations. Moreover, the orthogonal mapping requires length normalization, but we observed that length normalization adversely affects the performance of the English RE models (about 2.0 F_1 points drop).

We apply the vecmap toolkit[1] to obtain the semi-supervised and unsupervised mappings. The unsupervised mapping has the lowest average accuracy over the target languages, but it does not require a seed dictionary. Among all the mappings, the regular mapping achieves the best average accuracy over the target languages using a dictionary with only 1K word pairs, and hence we adopt it for the cross-lingual RE task.

5.3.3 Performance on Test Data

The cross-lingual RE model transfer results for the in-house test data are summarized in Table 5 and the results for the ACE05 test data are summarized in Table 6, using the regular mapping learned with a bilingual dictionary of size 1K. In the tables, we also provide the performance of the supervised RE model (Bi-LSTM) for each target language, which is trained with a few hundred thousand tokens of manually annotated RE data in the target-language, and may serve as an upper bound for the cross-lingual model transfer performance.

Among the 2 neural network models, the Bi-LSTM model achieves a better cross-lingual RE performance than the CNN model for 6 out of the 7 target languages. In terms of *absolute* performance, the Bi-LSTM model achieves over 40.0 F_1 scores for German, Spanish, Portuguese and Chinese. In terms of *relative* performance, it reaches over 75% of the accuracy of the supervised target-language RE model for German, Spanish, Italian and Portuguese. While Japanese and Arabic appear to be more difficult to transfer, it still achieves 55% and 52% of the accuracy of the supervised Japanese and Arabic RE model, respectively, without using any manually annotated RE data in Japanese/Arabic.

We apply model ensemble to further improve the accuracy of the Bi-LSTM model. We train 5 Bi-LSTM English RE models initiated with different random seeds, apply the 5 models on the target languages, and combine the outputs by selecting the relation type labels with the highest probabilities among the 5 models. This **Ensemble** approach improves the single model by 0.6-1.9 F_1 points, except for Arabic.

5.3.4 Discussion

Since our approach projects the target-language word embeddings to the source-language embedding space preserving the word order, it is expected to work better for a target language that has more similar word order as the source language. This has been verified by our experiments. The source language, English, belongs to the SVO (Subject, Verb, Object) language family where in a sentence the subject comes first, the verb second, and the object third. Spanish, Italian, Portuguese, German (in conventional typology) and Chinese

also belong to the SVO language family, and our approach achieves over 70% relative accuracy for these languages. On the other hand, Japanese belongs to the SOV (Subject, Object, Verb) language family and Arabic belongs to the VSO (Verb, Subject, Object) language family, and our approach achieves lower relative accuracy for these two languages.

6 Related Work

There are a few weakly supervised cross-lingual RE approaches. Kim et al. (2010) and Kim and Lee (2012) project annotated English RE data to Korean to create weakly labeled training data via aligned parallel corpora. Faruqui and Kumar (2015) translates a target-language sentence into English, performs RE in English, and then projects the relation phrases back to the target-language sentence. Zou et al. (2018) proposes an adversarial feature adaptation approach for cross-lingual relation classification, which uses a machine translation system to translate source-language sentences into target-language sentences. Unlike the existing approaches, our approach does not require aligned parallel corpora or machine translation systems. There are also several multilingual RE approaches, e.g., Verga et al. (2016); Min et al. (2017); Lin et al. (2017), where the focus is to improve monolingual RE by jointly modeling texts in multiple languages.

Many cross-lingual word embedding models have been developed recently (Upadhyay et al., 2016; Ruder et al., 2017). An important application of cross-lingual word embeddings is to enable cross-lingual model transfer. In this paper, we apply the bilingual word embedding mapping technique in (Mikolov et al., 2013b) to cross-lingual RE model transfer. Similar approaches have been applied to other NLP tasks such as dependency parsing (Guo et al., 2015), POS tagging (Gouws and Søgaard, 2015) and named entity recognition (Ni et al., 2017; Xie et al., 2018).

7 Conclusion

In this paper, we developed a simple yet effective neural cross-lingual RE model transfer approach, which has very low resource requirements (a small bilingual dictionary with 1K word pairs) and can be easily extended to a new language. Extensive experiments for 7 target languages across a variety of language families on both in-house and open datasets show that the proposed approach achieves very good performance (up to 79% of the accuracy of the supervised target-language RE model), which provides a strong baseline for building cross-lingual RE models with minimal resources.

Leveraging *2-hop* Distant Supervision from Table Entity Pairs for Relation Extraction

Abstract

Distant supervision (DS) has been widely used to automatically construct (noisy) labeled data for relation extraction (RE). Given two entities, distant supervision exploits sentences that directly mention them for predicting their semantic relation. We refer to this strategy as 1-hop DS, which unfortunately may not work well for long-tail entities with few supporting sentences. In this paper, we introduce a new strategy named *2-hop* DS to enhance distantly supervised RE, based on the observation that there exist a large number of relational tables on the Web which contain entity pairs that share common relations. We refer to such entity pairs as *anchors* for each other, and collect all sentences that mention the anchor entity pairs of a given target entity pair to help relation prediction. We develop a new neural RE method REDS2 in the multi-instance learning paradigm, which adopts a hierarchical model structure to fuse information respectively from 1-hop DS and 2-hop DS. Extensive experimental results on a benchmark dataset show that REDS2 can consistently outperform various baselines across different settings by a substantial margin.[1]

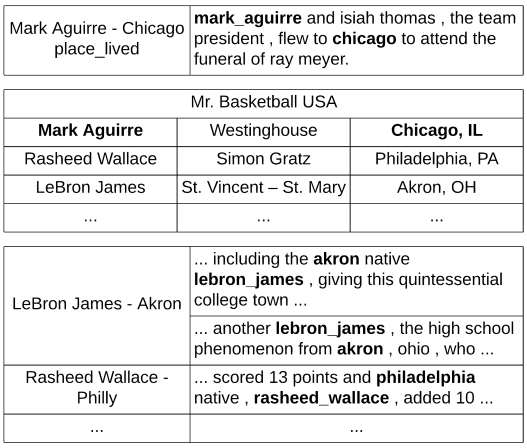

Figure 1: Illustration of *2-hop* distant supervision. The top panel shows a target entity pair, one sentence that mentions it, and the relation under study which cannot be inferred from the sentence. The middle gives part of a table from Wikipedia page "*Mr. Basketball USA*", where we can extract *anchors* for the target entity pair. The bottom shows some sentences that are associated with the anchors, which more clearly indicate the underinvestigated relation and can be utilized to extract relations between the target entity pair.

1 Introduction

Relation extraction (RE) aims to extract semantic relations between two entities from unstructured text and is an important task in natural language processing (NLP). Formally, given an entity pair (e_1, e_2) from a knowledge base (KB) and a sentence (instance) that mentions them, RE tries to predict if a relation r from a predefined relation set exists between e_1 and e_2. A special relation *NA* is used if none of the predefined relations holds.

Given that it is costly to construct large-scale labeled instances for RE, distant supervision (DS) has been a popular strategy to automatically construct (noisy) training data. It assumes that if two entities hold a relation in a KB, all sentences mentioning them express the same relation. Noticing that the DS assumption does not always hold and has the wrong labeling problem, many efforts including (Riedel et al., 2010; Hoffmann et al., 2011; Surdeanu et al., 2012) have adopted the multi-instance learning paradigm to tackle the challenge, and more recently, neural models with attention mechanism have been proposed to de-emphasize the noisy instances (Lin et al., 2016; Ji et al., 2017; Han et al., 2018). Such models tend to work well when there are a large number of sentences talking about the target entity pair (Lin et al., 2016).

[1]Our source code and datasets are at https://github.com/sunlab-osu/REDS2.

Proceedings of the 2019 Conference on Empirical Methods in Natural Language Processing and the 9th International Joint Conference on Natural Language Processing, pages 410–420, Hong Kong, China, November 3–7, 2019. ©2019 Association for Computational Linguistics

However, we observe that there can be a large portion of entity pairs that have very few supporting sentences (e.g., nearly 75% of entity pairs in the Riedel et al. (2010) dataset only have one single sentence mentioning them), which makes distantly supervised RE even more challenging.

The conventional distant supervision strategy only exploits instances that directly mention a target entity pair, and because of this, we refer to it as *1-hop* distant supervision. On the other hand, there are a large number of Web tables that contain relational facts about entities (Cafarella et al., 2008; Venetis et al., 2011; Wang et al., 2012). Owing to the semi-structured nature of tables, we can extract from them sets of entity pairs that share common relations, and sentences mentioning these entity pairs often have similar semantic meanings. Under this observation, we introduce a new strategy named *2-hop* distant supervision: We define entity pairs that potentially have the same relation with a given target entity pair as *anchors*, which can be found through Web tables, and aim to fully exploit the sentences that mention those anchor entity pairs to augment RE for the target entity pair. Figure 1 illustrates the 2-hop DS strategy.

The intuition behind 2-hop DS is if the target entity pair holds a certain relation, one of its anchors is likely to have that relation too and at least one sentence mentioning the anchors should express the relation. Despite being noisy, the 2-hop DS can provide extra, informative supporting sentences for the target entity pair. One straightforward approach is to merge the two bags of sentences respectively derived from 1-hop and 2-hop DS as one single set and apply existing multi-instance learning models. However, the 2-hop DS strategy also has the wrong labeling problem that already exists in 1-hop DS. Simply mixing the two sets of sentences together may mislead the prediction, especially when there is a great disparity in their size. In this paper, we propose REDS2[2], a new neural relation extraction method in the multi-instance learning paradigm, and design a hierarchical model structure to fuse information from 1-hop and 2-hop DS. We evaluate REDS2 on a widely used benchmark dataset and show that it consistently outperforms various baseline models by a large margin.

We summarize our contributions as three-fold:

- We introduce 2-hop distant supervision as an extension to the conventional distant supervision, and leverage entity pairs in Web tables as anchors to find additional supporting sentences to further improve RE.
- We propose REDS2, a new neural relation extraction method based on 2-hop DS and has achieved new state-of-the-art performance in the benchmark dataset (Riedel et al., 2010).
- We release both our source code and an augmented benchmark dataset that has entity pairs aligned with those in Web tables, to facilitate future work.

[2]stands for relation extraction with 2-hop DS.

2 Related Work

Distant Supervision. One main drawback of traditional supervised relation extraction models (Zelenko et al., 2003; Mooney and Bunescu, 2006) is they require adequate amounts of annotated training data, which is time consuming and labor intensive. To address this issue, Mintz et al. (2009) proposes distant supervision (DS) to automatically label data by aligning plain text with Freebase. However, DS inevitably accompanies with the wrong labeling problem. To alleviate the noise brought by DS, Riedel et al. (2010) and Hoffmann et al. (2011) introduce multi-instance learning mechanism, which is originally used to combat the problem of ambiguously-labeled training data when predicting the activity of different drugs (Dietterich et al., 1997).

Neural Relation Extraction. Early stage relation extraction (RE) methods use features extracted by NLP tools and strongly rely on the quality of features. Due to the recent success of neural models in different NLP tasks, many researchers have investigated the possibility of using neural networks to build end-to-end relation extraction models. Zeng et al. (2014) uses convolutional neural network (CNN) to encode sentences, which is further improved through piecewise-pooling (Zeng et al., 2015). Adel and Schütze (2017) and Gupta et al. (2016) use neural networks for joint entity and relation extraction. More advanced network architectures like Tree-LSTM (Miwa and Bansal, 2016) and Graph Convolution Network (Vashishth et al., 2018) are also adopted to learn better representations by using syntactic features like dependency trees. Most recent models also incorporate neural attention technology (Lin et al., 2016) as an

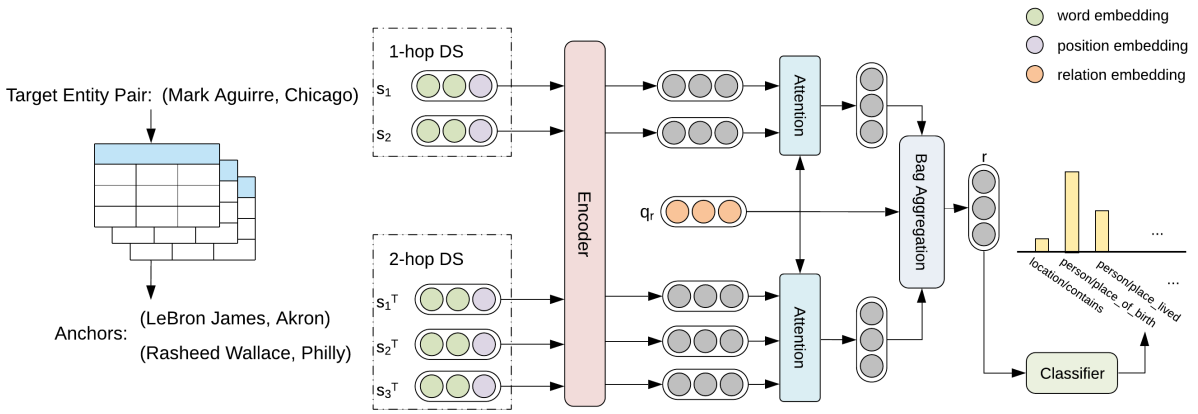

Figure 2: Overview of our method REDS2. REDS2 first obtains *anchors* of the target entity pair and constructs a 2-hop DS bag. Sentences in the 1-hop and 2-hop DS bag are individually encoded with a PCNN sentence encoder (Zeng et al., 2015). We then use selective attention and bag aggregation to get the final representation, based on which a classifier predicts scores for each candidate relation.

improvement to at-least-one multi-instance learning (Zeng et al., 2015). Han et al. (2018) further develops a hierarchical attention scheme to utilize the relation correlations and help predictions for long-tail relations.

Web Table Understanding. Aside from plain texts, there are large amounts of factual knowledge in the Web expressed in hundreds of millions of tables and other structured lists (Cafarella et al., 2008; Venetis et al., 2011), which have not been fully explored yet. Table understanding tries to match tables to KB and parse the schemas. Existing methods for table understanding mainly fall into two categories. One is based on local evidence (Venetis et al., 2011; Muñoz et al., 2014; Ritze et al., 2015). Given one table, the main idea is to first link cells to entities in KB. We can then use existing relations between linked entities to infer relations between columns and extract new facts by generalizing to all rows. However, this method requires a high overlap between table and KB, which is hampered by KB incompleteness. The other approach tries to leverage features extracted from the table header and column names (Ritze and Bizer, 2017; Cannaviccio et al., 2018). Unfortunately, a large portion of Web tables miss such metadata or contain limited information, and the second approach will fail in such cases. Although the focus of this paper is the RE task, we believe the idea of connecting Web tables and plain texts using DS can potentially benefit table understanding as well.

3 Methodology

Given a set of sentences $\mathrm{S} = \{s_1, s_2, ...\}$ and a target entity pair (h, t), we will leverage the directly associated sentence bag $S_{h,t} \subseteq \mathrm{S}$ by 1-hop distant supervision (1-hop DS bag), and the table expanded sentence bag $S^T_{h,t} \subseteq \mathrm{S}$ by 2-hop distant supervision (2-hop DS bag), for relation extraction. $S_{h,t}$ contains all instances mentioning both h and t, while $S^T_{h,t}$ is obtained indirectly through the anchors of (h, t) found in Web tables. Following previous work (Riedel et al., 2010; Hoffmann et al., 2011), we adopt the multi-instance learning paradigm to measure the probability of (h, t) having relation r.

Figure 2 gives an overview of our framework with three major components:

- **Table-aided Instance Expansion:** Given a target entity pair (h, t), we find its *anchor* entity pairs $\{(h_1, t_1), (h_2, t_2), ...\}$ through Web tables. We define an anchor entity pair as two entities co-occurring with (h, t) in some table columns at least once. $S^T_{h,t} = S_{h_1,t_1} \cup S_{h_2,t_2} \cup ...$ is then exploited to augment the directly associated bag $S_{h,t}$.

- **Sentence Encoding:** For each sentence s in bag $S_{h,t}$ or $S^T_{h,t}$, a sentence encoder is used to obtain its semantic representation $\mathbf{s}$.

- **Hierarchical Bag Aggregation:** Once the embedding of each sentence is learned, we first use a sentence-level attention mechanism to get bag representation $\mathbf{h}$ and $\mathbf{h}^T$, and

then aggregate them for final relation prediction.

3.1 Table-aided Instance Expansion

Now we introduce how to construct the table expanded sentence bag $S^T_{h,t}$ for a given target entity pair (h, t) by 2-hop distant supervision.

3.1.1 Web Tables

Web tables have been found to contain rich facts of entities and relations. It is estimated that out of a total of 14.1 billion tables on the Web, 154 million tables contain relational data (Cafarella et al., 2008) and Wikipedia alone is the source of nearly 1.6 million relational tables (Bhagavatula et al., 2015). Columns of a Wikipedia table can be classified into one of the following data types: 'empty', 'named entity', 'number', 'date expression', 'long text' and 'other' (Zhang, 2017). Here we only focus on named entity columns (NE-columns) and the Wikipedia page title, which can be easily linked to KB entities. These entities can be further categorized as:

A topic entity e^t that the table is centered around. We refer to the Wikipedia article where the table is found and take the entity it describes as e^t.

Subject entities $E^s = \{e^s_1, e^s_2, ...\}$ that can act as primary keys of the table. Following previous work on Web table analysis (Venetis et al., 2011), we select the leftmost NE-column as subject column and its entities as E^s.

Body entities $E = \{e_{1,1}, e_{1,2}, ...\}$ that compose the rest of the table. All entities in non-subject NE-columns are considered as E.

3.1.2 2-hop Distant Supervision

In the conventional distant supervision setting, each entity pair (h, t) is associated with a bag of sentences $S_{h,t}$ that directly mention h and t. The intuition behind 2-hop distant supervision is, if (h_i, t_i) and (h_j, t_j) potentially hold the same relation, we can treat them as **anchor entity pairs** for each other, and then use the 1-hop DS bag S_{h_j,t_j} to help with the prediction for (h_i, t_i) and vice versa. In this paper, we extract anchor entity pairs with the help of Web tables.

We notice that owing to the semi-structured nature of tables, (1) subject entities can usually be connected with the topic entity by the same relation. (2) Non-subject columns of a table usually have binary relationships to or are properties of the subject column. Body entities in the same column share common relations with their corresponding subject entities. For example, in Figure 1, the topic entity is "*Mr. Basketball USA*"; column 1 is the subject column and contains a list of winners of "*Mr. Basketball USA*"; column 2 and column 3 are high school and city of the subject entity.

Formally, we consider two entity pairs (h_i, t_i) and (h_j, t_j) as anchored if there exists a Web table such that either criterion below is met:

- $h_i = h_j = e^t$ and $t_i,\ t_j \in E^s$.
- $h_i \in E^s$ or $t_i \in E^s$, (h_i, h_j) is in the same column (and so is (t_i, t_j)), and (h_i, t_i) is in the same row (and so is (h_j, t_j))

The 2-hop DS bag $S^T_{h,t}$ is then constructed as the union of S_{h_i,t_i}'s, where (h_i, t_i) is an anchor entity pair of (h, t).

3.2 Sentence Encoding

Given a sentence s consisting of n words $s = \{w_1, w_2, ..., w_n\}$, we use a neural network with an embedding layer and an encoding layer to obtain its low-dimensional vector representation.

3.2.1 Embedding Layer

Each token is first fed into an embedding layer to embed both semantic and positional information.

Word Embedding maps words to vectors of real numbers which preserve syntactic and semantic information of words. Here we get a vector representation $\mathbf{w}_i \in \mathbb{R}^{k_w}$ for each word from a pre-trained word embedding matrix.

Position Embedding was proposed by Zeng et al. (2014). Position embedding is used to embed the positional information of each word relative to the head and tail mention. A position embedding matrix is learned in training to compute position representation $\mathbf{p}_i \in \mathbb{R}^{k_p \times 2}$.

Finally, we concatenate the word representation $\mathbf{w}_i$ and position representation $\mathbf{p}_i$ to build the input representation $\mathbf{x}_i \in \mathbb{R}^{k_i}$ (where $k_i = k_w + k_p \times 2$) for each word w_i.

3.2.2 Encoding Layer

A sequence of input representations $\mathbf{x} = \{\mathbf{x}_1, \mathbf{x}_2, ...\}$ with a variable length is then fed through the encoding layer and converted to a fixed-sized sentence representation $\mathbf{s} \in \mathbb{R}^{k_h}$. There are many existing neural architectures that can serve as the encoding layer, such as CNN

(Zeng et al., 2014), PCNN (Zeng et al., 2015) and LSTM-RNN (Miwa and Bansal, 2016). We simply adopt PCNN here, which has been shown very powerful and efficient by a number of previous RE works.

PCNN is an extension to CNN, which first slides a convolution kernel with a window size m over the input sequence to get the hidden vectors:

$$\mathbf{h}_i = \text{CNN}(\mathbf{x}_{i-\frac{m-1}{2}:i+\frac{m-1}{2}}), \tag{1}$$

A piecewise max-pooling is then applied over the hidden vectors:

$$\begin{aligned}
[\mathbf{s}^{(1)}]_j &= \max_{1\le i\le i_1}\{[\mathbf{h}_i]_j\},\\
[\mathbf{s}^{(2)}]_j &= \max_{i_i+1\le i\le i_2}\{[\mathbf{h}_i]_j\},\\
[\mathbf{s}^{(3)}]_j &= \max_{i_2+1\le i\le n}\{[\mathbf{h}_i]_j\},
\end{aligned} \tag{2}$$

where i_1 and i_2 are head and tail positions. The final sentence representation $\mathbf{s}$ is composed by concatenating these three pooling results $\mathbf{s} = [\mathbf{s}^{(1)}; \mathbf{s}^{(2)}; \mathbf{s}^{(3)}]$.

3.3 Hierarchical Bag Aggregation

After we get sentence representations $\{\mathbf{s}_1, \mathbf{s}_2, ...\}$ and $\{\mathbf{s}_1^T, \mathbf{s}_2^T, ...\}$ for S and S^T, to fuse key information from these two bags, we adopt a hierarchical aggregation design to obtain the final representation $\mathbf{r}$ for prediction. We first get bag representation $\mathbf{h}$ and $\mathbf{h}^T$ using a sentence-level selective attention, and then employ a bag-level aggregation to compute $\mathbf{r}$.

3.3.1 Sentence-level Selective Attention

Since the wrong labeling problem inevitably exists in both 1-hop and 2-hop distant supervision, here we use selective attention to assign different weights to different sentences given relation r and de-emphasize the noisy sentences. The attention is caculated as follows:

$$\begin{aligned}
e_i &= \mathbf{q}_r^\top \mathbf{s}_i,\\
\alpha_i &= \frac{\exp(e_i)}{\sum_{j=1}^{n}\exp(e_j)},\\
\mathbf{h} &= \sum_{i=1}^{n}\alpha_i \mathbf{s}_i,
\end{aligned} \tag{3}$$

where $\mathbf{q}_r$ is a query vector assigned to relation r. $\mathbf{h}$ and $\mathbf{h}^T$ are computed respectively for the two bags S and S^T.

3.3.2 Bag-level Aggregation

Since 2-hop DS bag S^T is collected indirectly through anchor entity pairs in Web tables, despite that it brings abundant information, it also contains a massive amount of noise. Thus treating S^T equally as S may mislead the prediction, especially when their sizes are extremely imbalanced.

To automatically decide how to balance between S and S^T, we utilize information from $\mathbf{h}$, $\mathbf{h}^T$ and $\mathbf{q}_r$ to predict a weight β:

$$\beta = \sigma(\mathbf{W}[\mathbf{h}; \mathbf{h}^T; \mathbf{q}_r] + \mathbf{b}), \tag{4}$$

where vector $\mathbf{W}$ and scalar $\mathbf{b}$ are learnable variables and σ is the sigmoid function. Next, β is used as a weight to fuse information from 1-hop DS and 2-hop DS, determined by S and S^T of the current target entity pair and relation r. We then obtain the final representation $\mathbf{r}$ as:

$$\mathbf{r} = \beta\mathbf{h} + (1-\beta)\mathbf{h}^T, \tag{5}$$

Finally, we define the conditional probability $P(r|S, S^T, \theta)$ as follows,

$$P(r|S, S^T, \theta) = \frac{\exp(\mathbf{o}_r)}{\sum_{k=1}^{n_r}\exp(\mathbf{o}_k)} \tag{6}$$

where $\mathbf{o}$ is the score vector for current target entity pair having each relation,

$$\mathbf{o} = \mathbf{M}\mathbf{r} + \mathbf{d}, \tag{7}$$

here $\mathbf{M}$ is the representation matrix of relations, which shares weights with $\mathbf{q}_r$'s. $\mathbf{d}$ is a learnable bias term.

3.4 Optimization

We adopt the cross-entropy loss as the training objevtive function. Given a set of target entity pairs with relations $\pi = \{(h_1, t_1, r_1), (h_2, t_2, r_2), ...\}$, we define the loss function as follows:

$$J(\theta) = -\frac{1}{|\pi|}\sum_{i=1}^{|\pi|}\log P(r_i|S_{h_i,t_i}, S^T_{h_i,t_i}, \theta). \tag{8}$$

All models are trained with stochastic gradient descent (SGD) to minimize the objective function. The same sentence encoder is used to encode S and S^T.

	Train		Test	
	Overall	Non-NA	Overall	Non-NA
# Entity Pairs	291699	18144	96678	1761
# Entity Pairs with $\|S^T\| > 0$	17565	6928	4832	824
% Entity Pairs with $\|S^T\| > 0$	6.02	**38.18**	5.00	**46.79**
mean $\|S\|$	1.69	5.24	1.62	2.78
mean $\|S^T\|$	147.65	190.61	131.65	217.23

Table 1: Dataset statistics. We show statistics of entity pairs that hold non-NA relations separately from overall, as they are important relational facts to discover. Among non-NA entity pairs, 38.18% in training and 46.79% in testing have nonempty S^T, which respectively have 190.61 and 217.23 sentences on average.

4 Experiments

4.1 Datasets and Evaluation

We evaluate our model on the New York Times (NYT) dataset developed by Riedel et al. (2010), which is widely used in recent works. The dataset has 53 relations including a special relation NA which indicates none of the other 52 relations exists between the head and tail entity.

We use the WikiTable corpus collected by Bhagavatula et al. (2015) as our table source. It originally contains around 1.65M tables extracted from Wikipedia pages. Since the NYT dataset is already linked to Freebase, we perform entity linking on the table cells and the Wikipedia page titles using existing mapping from Wikipedia URL to Freebase MID (Machine Identifier). We then align the table corpus with NYT and construct S^T for entity pairs as detailed in section 3.1. *For both training and testing, we only use entity pairs and sentences in the original NYT training data for table-aided instance expansion.* We set the max size of S^T as 300, and randomly sample 300 sentences if $|S^T| > 300$. Statistics of our final dataset is summarized in Table 1. One can see that 38.18% and 46.79% of relational facts (i.e., entity pairs holding non-NA relations) respectively in the training and testing set can potentially benefit from leveraging 2-hop DS.

Following prior work (Mintz et al., 2009), we use the testing set for held-out evaluation, and evaluate models by comparing the predicted relational facts with those in Freebase. For evaluation, we rank the extracted relational facts based on model confidence and plot precision-recall curves. In addition, we also show the area under the curve (AUC) and precision values at specific recall rates to conduct a more comprehensive comparison.

Window size m	3
Sentence Representation Size k^h	230
Word Dimension k^w	50
Position Dimension k^p	5
Pre-train Learning Rate λ_P	0.005
Fine-tune Learning Rate λ_F	0.002
Dropout Probability p	0.5

Table 2: Parameter settings in REDS2.

4.2 Baselines

We compare REDS2 with the following baselines:
PCNN+ATT (Lin et al., 2016). This model uses a PCNN encoder combined with selective attention over sentences. Since this is also the base block of our model, we also refer to it as BASE in this paper.
PCNN+HATT (Han et al., 2018). This is another PCNN based relation extraction model, where the authors use hierarchical attention to model the semantic correlations among relations.
RESIDE (Vashishth et al., 2018). It uses Graph Convolutional Networks (GCN) for sentence encoding, and also leverages relevant side information like relation alias and entity type.

Results of PCNN+HATT and RESIDE are directly taken from the code repositories released by the authors. For PCNN+ATT, we report results obtained by our reproduced model, which are close to those shown in (Lin et al., 2016). To simply verify the effectiveness of adding extra supporting sentences from 2-hop DS, we also compare the following vanilla method with PCNN+ATT:
BASE+MERGE. For each target entity pair (h, t), we simply merge S and S^T as one sentence bag, and apply the trained PCNN+ATT (or, BASE) model.

4.3 Implementation Details

We preprocess the WikiTable corpus with PySpark to build index for anchor entity pairs. On a single machine with two 8-core E5 CPUs and 256 GB memory, this processing takes around 20 minutes.

We use word embeddings from (Lin et al., 2016) for initialization, which are learned by word2vec tool[3] on NYT corpus. The vocabulary is composed of words that appear more than 100 times in the corpus and words in an entity mention are concatenated as a single word.

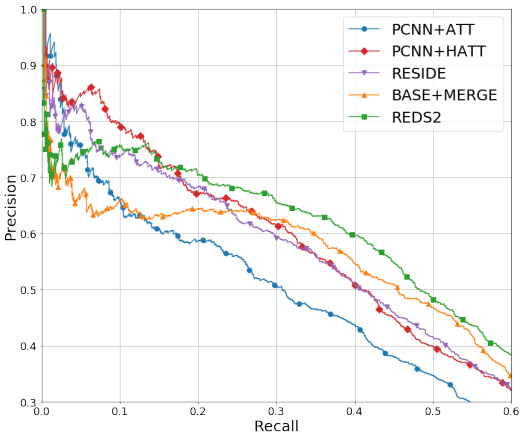

Figure 3: Precision-recall curves for the proposed model and various baselines.

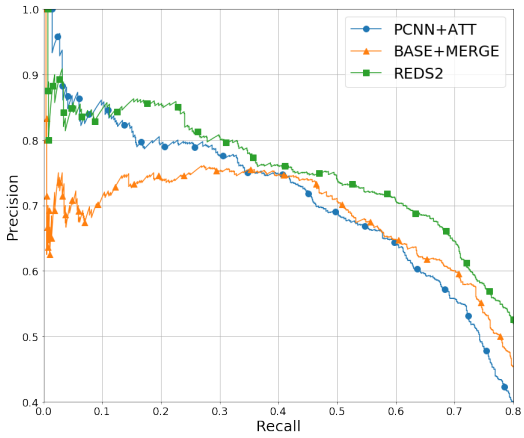

Figure 4: Precision-recall curves on the subset of test entity pairs whose S^T is not empty, to better show the effect of hierarchical bag aggregation design.

Method	P@0.1	P@0.2	P@0.3	AUC
PCNN+ATT	65.9	58.7	50.4	35.8
PCNN+HATT	**79.3**	67.2	61.6	42.0
RESIDE	73.6	68.4	59.5	41.5
BASE+MERGE	65.9	64.5	62.4	41.2
REDS2	75.9	**70.4**	**65.5**	**44.7**

Table 3: Comparison on Precision@recall and AUC.

To see the effect of 2-hop DS more directly, we set most parameters in REDS2 following Lin et al. (2016). Since the original NYT dataset only contains training and testing set, we randomly sample 20% training data for development. We first pre-train a PCNN+ATT model with only S and sentence-level selective attention. This BASE model converges in around 100 epochs. We then fine-tune the entire model with S^T and bag-level aggregation added, which can finish within 50 epochs. Some key parameter settings in REDS2 are summarized in Table 2.

In testing phase, inference using 2-hop DS is slower, because the average size of S^T is about 100 times that of S. With single 2080ti GPU, one full pass of testing data takes around 37s using REDS2, compared with 12s using BASE model.

4.4 Results

4.4.1 Overall Evaluation Results

Evaluation results on all target entity pairs in testing set are shown in Figure 3 and Table 3, from which we make the following observations:

(1) Figure 3 shows all models obtain a reasonable precision when recall is smaller than 0.05. With the recall gradually increasing, the performance of models with 2-hop DS drops slower than those existing methods without. From Figure 3, we can see simply merging S^T with S in BASE+MERGE can boost the performance of basic PCNN+ATT model, and even achieves higher precision than state-of-the-art models like PCNN+HATT when recall is greater than 0.3. This demonstrates that models utilizing 2-hop DS are more robust and remain a reasonable precision when including more lower-ranked relational facts which tend to be more challenging to predict because of insufficient evidence.

(2) As shown in both Figure 3 and Table 3, REDS2 achieves the best results among all the models. Even when compared with PCNN+HATT and RESIDE which adopt extra relation hierarchy and side information from KB, our model still enjoys a significant performance gain. This is because our method can take advantage of the rich entity pair correlations in Web tables and leverage the extra information brought by 2-hop DS. We anticipate our REDS2 model can be further improved by using more advanced sentence encoders and extra mechanisms like reinforcement learning (Feng et al., 2018) and adversarial training (Wu et al., 2017), which we leave for future work.

4.4.2 Effect of Hierarchical Bag Aggregation

To further show the effect of our hierarchical bag aggregation design, here we also plot precision-recall curves in Figure 4 on a subset of entity pairs in the test set (i.e., 4832 in total according to Table 1) whose table expanded sentence bag S^T is not empty.

One main challenge of using 2-hop DS is it brings more noise. As shown in Table 1, for en-

Test Mode	SINGLE				MULTIPLE											
					ONE				TWO				ALL			
Metric	P@0.1	P@0.2	P@0.3	AUC	P@0.1	P@0.2	P@0.3	AUC	P@0.1	P@0.2	P@0.3	AUC	P@0.1	P@0.2	P@0.3	AUC
PCNN+ATT	57.3	53.0	41.3	30.0	72.9	66.4	57.5	39.0	75.3	69.7	63.8	45.9	80.5	68.6	64.2	48.6
RESIDE	66.9	60.5	51.8	36.2	79.7	70.4	57.4	42.1	77.7	76.1	67.6	46.5	83.2	**80.3**	73.2	51.9
PCNN+HATT	**70.1**	59.1	50.8	34.8	74.5	67.4	57.2	40.1	78.4	68.9	65.9	44.5	**86.4**	75.5	70.0	49.7
BASE+MERGE	62.2	58.5	55.2	35.6	71.4	74.9	73.2	51.3	70.0	71.8	73.9	52.0	70.7	71.1	73.2	52.0
REDS2	69.1	**61.1**	**57.4**	**37.5**	**82.4**	**81.9**	**78.1**	**56.3**	**81.4**	**79.6**	**76.9**	**57.2**	82.4	79.6	**76.6**	**57.6**

Table 4: Comparison on Precision@recall and AUC under different testing settings, detailed in Section 4.4.3.

max $\|S^T\|$	P@0.1	P@0.2	P@0.3	AUC
10	57.9	55.8	51.5	36.2
50	69.4	65.7	60.8	42.2
100	70.4	66.7	62.3	43.2
200	72.8	68.4	63.4	44.0
300	**75.9**	**70.4**	**65.5**	**44.7**

Table 5: Effect of the table expanded sentence bag size $|S^T|$ on Precision@recall and AUC.

Relation: `country.capital`	
1-hop	... the golden gate bridge and the petronas towers in **kuala_lumpur**, **malaysia**, was experienced ...
2-hop	a friend from **cardiff** , the capital city of **wales** , lives for complex ...

Table 6: An example for case study, where the sentence with the highest attention weight is selected respectively from 1-hop and 2-hop sentence bag.

tity pair with nonempty S^T, the size of S^T is usually tens of times the size of S. From Figure 4 we can see BASE+MERGE performs much worse compared with PCNN+ATT when recall is smaller than 0.2. This is because 2-hop DS bag tends to be much larger than 1-hop DS bag, and the model has a larger chance to attend to the noisy sentences obtained from 2-hop DS. While ignoring the information in its directly associated sentences. We alleviate this problem by introducing hierarchical structure to first aggregate the two sets separately and then weight and sum them together. The proposed `REDS2` model has a comparable precision with PCNN+ATT in the beginning and gradually outperform it.

4.4.3 Effect of Sentence Number

Number of sentences from 1-hop DS. In the originally testing set, there are 79176 entity pairs that are associated with only one sentence, out of which 1149 actually have relations. We hope our model can improve performance on these long-tail entities. Following Lin et al. (2016), we design the following test settings to evaluate the effect of sentence number: the "SINGLE" test setting contains all entity pairs that correspond to only one sentence; the "MULTIPLE" test setting contains the rest of entity pairs that have at least two sentences associated. We further construct the "ONE" testing setting where we randomly select one sentence for each entity pair; the "TWO" setting where we randomly select two sentences for each entity pair and the "ALL" setting where we use all the associated sentences from MULTIPLE. We use all sentences in S^T for each entity pair if it is nonempty. Results are shown in Table 4, from which we can see that `REDS2` and BASE+MERGE have 25.0% and 18.7% improvements under AUC compared with PCNN+ATT in the SINGLE setting. Although the performance of all models generally improves as the sentence number increases in MULTIPLE setting, models leveraging 2-hop DS are more stable and have smaller changes. These observations indicate that 2-hop DS is helpful when information obtained by 1-hop DS is insufficient.

Number of sentences from 2-hop DS. We also evaluate how the number of sentences obtained by 2-hop DS will affect the performance of our proposed model. In Table 5, we show the performance of `REDS2` with different numbers of sentences sampled from S^T. We observe that: (1) Performance of `REDS2` improves as the number of sentences sampled increases. This shows that the selective attention over S^T can effectively take advantage of the extra information from 2-hop DS while filtering out noisy sentences. (2) Even with 50 randomly sampled sentences, our model `REDS2` still has a higher AUC than all baselines in Table 3. This indicates information obtained by 2-hop DS is redundant, even a small portion can be beneficial to relation extraction. How to sample a representative set effectively is worth further exploring in future work.

4.5 RE for Entity Pairs with Empty 1-hop Sentence Bag

We observe that there are large amounts of entity pairs in the table corpus that have no associated sentences but have anchor entity pairs mentioned in the text corpus. By leveraging 2-hop distant supervision, we can do relation extraction for this set of entity pairs.

We extract a total number of 251917 entity pairs from the WikiTable dataset which do not exist in the NYT dataset but have at least one anchor entity pair that appear in the original NYT training data. We randomly sample 10000 examples and evaluate our trained model on them. Surprisingly, the relation extraction result is even better than the result on the NYT test data in Table 3, with an overall AUC of 54.7 and a P@0.3 of 71.1. This can be explained partly by two observations: (1) The table corpus generates higher-quality entity pairs, 18% of extracted entity pairs have non-NA relations, compared with only 1.8% in NYT test data. (2) The newly extracted entity pairs have 14 useful anchor entity pairs and 175 2-hop DS sentences on average, which give ample information for prediction. This study shows that for two entities that have no directly associated sentences, it is possible to utilize the 2-hop DS to predict their relations accurately.

4.6 Case Study and Error Analysis

In addition to the motivating example from the training set shown in Figure 1, we also demonstrate how 2-hop DS helped relation extraction using an example from the testing set in Table 6. As we can see, the sentence with the highest attention weight in 1-hop DS bag does not express the desired relation between the target entity pair whereas that in 2-hop DS bag clearly indicates the `country.capital` relation.

We also conduct an error analysis by analyzing examples where REDS2 gives worse predictions than BASE (e.g., assigns a lower score to a correct relation or a higher score to a wrong relation), and 50 examples with most disparity in the two methods' scores are selected. We find that 29 examples have wrong labels caused by KB incompleteness and our model in fact makes the right prediction. 11 examples are due to errors in column processing (e.g., errors in NE/subject column selection and entity linking), 9 are caused by anchor entity pairs with differet relations (e.g., **(Greece, Atlanta)** and **(Mexico, Xalapa)** are in the same table *"National Records in High Jump"* under columns **(Nation, Place)**, but only the latter has relation `location.contains`), and 1 is because of wrong information in the original table.

5 Conclusion and Future Work
