Abstract

Competitive debaters often find themselves facing a challenging task - how to debate a topic they know very little about, with only minutes to prepare, and without access to books or the Internet? What they often do is rely on "first principles", commonplace arguments which are relevant to many topics, and which they have refined in past debates. In this work we aim to explicitly define a taxonomy of such principled recurring arguments, and, given a controversial topic, to automatically identify which of these arguments are relevant to the topic. As far as we know, this is the first time that this approach to argument invention is formalized and made explicit in the context of NLP. The main goal of this work is to show that it is possible to define such a taxonomy. While the taxonomy suggested here should be thought of as a "first attempt" it is nonetheless coherent, covers well the relevant topics and coincides with what professional debaters actually argue in their speeches, and facilitates automatic argument invention for new topics.

1 Introduction

In his treatise *De Inventione* Cicero defines the five canons of classical rhetoric as: inventio (invention), dispositio (arrangement), elocutio (style), memoria (memory), and pronuntiatio (delivery). The first of these, *Inventio*, is defined as a systematic search for arguments (Glenn et al., 2008), with applicability to a wide variety of situations often seen as a desired property (Lauer, 2004). This problem has been referred to in the context of NLP as the task of *Argument Invention* (Walton and Gordon, 2012, 2017), but did not receive abundant attention.

One natural way people go through the process of *inventio* is to look for arguments in relevant texts, or, if they are familiar with the topic, rely on their knowledge and *memoria* for doing so. This is reminiscent of the way Argument Mining algorithms operate (see e.g. Lippi and Torroni, 2015, 2016). However, we often find ourselves in situations where that is not possible. For example, when arguing politics over lunch, we might find ourselves backed into a corner, facing a topic with which we are not very familiar, but somehow nonetheless need to justify or oppose. This often happens because we were initially arguing some *principle*, and now we need to apply it to an unfamiliar example.

Professional debaters often face this problem. Presented with an unfamiliar topic they need to quickly come up with relevant arguments. The main technique for doing so is called arguing from "first principles" – relying on a "bank" of principled arguments, which are relevant to a wide variety of topics¹.

A common example is the Black market argument: banning a product or a service may lead to the creation of a black market, which in turn makes products or services obtained therein less safe, leads to exploitation, attracts criminal elements, and so on. Hence, even if we agree that something should not be encouraged, it is advisable to have it legal and regulated.

This kind of argument can be made, *mutatis mutandis*, when debating quite different topics, such as legalizing organ trade, or banning pornography. However, it is not always relevant when debating whether to legalize or ban something; For example, when debating whether to legalize polygamy or ban breastfeeding in public, the black market argument seems less appropriate.

Here, we aim to create a knowledge base of such principled arguments, which, when given a topic for debate or a critical essay, would readily yield the relevant ones. We do this in a framework of

¹This is reminiscent of, yet different from, the Aristotelian use of this term, which refers to self-evident propositions.

certain types of *motions* (section 3). Specifically, we define several commonplace themes which are likely to be a point of contention – that is, where arguments of opposing stance can be made around this theme². We show that for most motions there exist relevant arguments within the suggested knowledge base, and that they can be identified automatically with reasonable precision and recall. Moreover, we show that professional human debaters often allude to such arguments when they debate.

2 Related work

Previous computational work on argument invention was mainly done within the field of argument mining, where – as the name implies – the focus is on identifying arguments within a given text. Most works (e.g. Stab and Gurevych, 2014; Palau and Moens, 2009; Eger et al., 2017) assume that a relevant text is provided, while some include the task of extracting such text from a large open-domain corpus (e.g. Levy et al., 2014; Rinott et al., 2015; Shnarch et al., 2018; Al-Khatib et al., 2016; Levy et al., 2018). The work here complements such techniques by providing a dataset of arguments whose manual construction facilitates automatic retrieval for topics of interest and ensures quality, validity, style and so on.

A somewhat similar approach is suggested in work of Walton and Gordon (2017, 2018), where arguments are constructed from a database (Reed and Rowe, 2004) of smaller argumentative building blocks. However, these building blocks are topic-specific and can not readily provide arguments for topics not in the database.

The attempt to categorize arguments by looking for commonalities dates back to ancient times, such as Aristotle's list of 28 topoi (Aristotle and Kennedy, 1991). Modern works, such as Perelman (1971); Walton et al. (2008); Walton (2013), expanded on these ideas, similarly focusing on how an argument's conclusion is inferred from its premises. Unlike these efforts, the taxonomy suggested here is of recurring principled semantic themes. That is, arguments which in this work would be categorized as belonging to a specific argument theme could be of various topoi and follow different argumentation schemes.

In modern competitive debating the notion of commonalities between topics is prevalent due to

the advantages they serve in overcoming knowledge barriers and in speeding up argument generation³. Armed with limited facts on the topic, the task of locating recurring patterns in order to argue the motion abstractly is composed of understanding what are the fundamental 'clashes' in the debate (cf. Sonnreich (2012), "debating from first principles"), similar to the taxonomy herein.

Our approach bears similarities to work in social sciences that attempts to describe different types of information *framing*, usually in the context of the news media (e.g. Semetko and Valkenburg, 2000). Recurring themes, like *Fairness and equality* or *Crime and punishment*, can be identified in the way the news media frames a certain policy issue or event (Card et al., 2015). de Vreese (2005) differentiates between specific and generic frames, characterizing the latter as those that can be applied to a wide range of events and contexts. Similarly, our work aims to categorize commonplace themes and identify their relevance (at a considerably larger scale), in the context of framing a topic that is subject to debate.

Our work also has some commonalities with psychological research on ideology (e.g. Altemeyer, 1981; Sidanius and Pratto, 2001; Jost et al., 2003). For example, Everett (2013) lists a 12-item scale to assess conservative ideology - of these, some map to our taxonomy (e.g. Welfare), while others are too specific. Moreover, conservatism in itself gives rise to one class of recurring arguments in our work.

3 Definitions

In the context of parliamentary debate, a *motion* is a proposal that is to be deliberated by two sides (government and opposition). Here we formally define a motion as a pair (*action, topic*), where *topic* is a Wikipedia title (or a redirect to one), and *action* is a term coming from a closed set of allowed actions (Appendix A), and describes the government's proposal w.r.t. *topic*. For example, the motion (*ban, smoking*) should be interpreted as the government suggesting to ban smoking, and can be explicitly phrased as "we should ban smoking"⁴. Note that not all combinations of *action* and *topic* make for a good motion – the implied pro-

²In the context of debates, these are called "clashes".

³E.g. https://debate.uvm.edu/dcpdf/WUDC% 20Malaysia_2014_Debating_and_Judging_ Manual.pdf

⁴In the context of competitive debate, the phrasing would usually be "This House would ban smoking".

posal should be worth deliberating; one for which reasonable arguments can be made by either side.

One often discerns between *policy motions* where the government proposes a concrete policy, and *analysis motions* in which the government declares its opinion on the *topic*. For the sake of simplicity and brevity (and with some abuse of notation) we will ignore this distinction. In particular, one of the allowed "actions" is *brings more harm than good*, which would usually be considered as indicating an analysis motion.

We define a *Class of Principled Arguments*, or *CoPA*, as a set of arguments revolving around a principled recurring theme (we define the name of the CoPA as this theme), alongside a set of motions to which this theme is relevant. Formally, a CoPA is a pair c = (A, M), where A is a set of arguments, and M is a set of motions, s.t. every $a \in A$ is an argument that can plausibly be made when deliberating any motion $m \in M$. For every $a \in A$ we say that a is an argument in c, and similarly that every $m \in M$ is a motion in c, and that m and c match.

In this work we focus on modelling debate *clashes*, and hence are interested in *A*'s which contain arguments of opposing stances towards the class's theme. For the sake of simplicity we consider only *A*'s of size 2, and only simple arguments, which are essentially just claims or premises (appendix B). Note that this is indeed a simplification, and that for many CoPAs several distinct arguments can be naturally included in *A* (cf. Section 7).

The pair of claims may directly contradict each other, denoting a disagreement about facts. But by and large we tried to select pairs of claims that people tend to agree with⁵, but would assign different valuation depending on their point of view (see Kock, 2009). For example, one of the CoPAs we define is *Clean energy*, with $A = {$ "Humanity must embrace clean energy in order to fight climate change", "Ecological concerns add further strain on the economy"}, and M including motions such as (subsidize, renewable energy) and (fight, global warming). Most people would agree that on the one hand climate change is a problem, and on the other that moving towards clean energy will be expensive. When debating motions where clean energy is a relevant theme the two sides are likely to agree that both claims have some merit, yet disagree on which supersedes the other. The valuation might very well depend on their subjective viewpoints, but also on the specific motion.

4 Data

4.1 Initial data

The definition above is a functional one, oriented towards facilitating labeling motion-class matches, so some care is required in CoPA construction. A pair of claims with one saying that the policy will not work, and the other that it will, defines a CoPA that essentially covers all policy motions. Conversely, very particular claims will yield a class for which relevant motions are hard to come by.

The set discussed in this work was defined based on the following guidelines:

- 1. One is able to define two concise claims of opposing stance towards the CoPA's theme.
- 2. One can think of at least three motions (not necessarily from the initial set) which would belong to the CoPA, and are not overly similar to one another.

Our motivation for requirement 1 was to model "clashes", the recurring themes in debates which are points of contention, since our main use-case is, given a motion, to suggest argumentative text with a clear stance towards the motion. Other use cases may relax this requirement, according to their goals. Requirement 2 ensures that the CoPA indeed captures a recurring theme, rather than a specific one.

Two annotators were presented with these guidelines and an initial list of 100 motions to make the task more concrete⁶. They authored a list of about 60 CoPAs which was manually curated by two of the authors to a more concise, final list of 37 CoPAs, to avoid redundancy and ease the following labeling task.

Appendix B lists these 37 CoPAs and the claims therein. They are quite varied – some revolve around public policy (e.g. *Environment, Public health*), others on basic rights and freedoms (e.g. *Right to privacy, Freedom of religion*), some on the effect of a policy (e.g. *Black market, Greater*

⁵This is somewhat similar to what Perelman (1971) call "Values" and also close to what Aristotle calls *Endoxa* (Aristotle and Kennedy, 1991).

⁶see supplementary materials in www.research. ibm.com/haifa/dept/vst/debating_data. shtml

good), while yet others are very general (*Fixable*, *Conservatism*, and *Framework*)⁷.

Next, the same two annotators annotated all 100 motions for membership in the suggested CoPAs. In total, 92 motions were matched to at least one CoPA, and on average each motion was matched to 2.03 CoPAs. In our dataset, the greatest number of CoPAs a motion is a member of is 5, with two motions achieving this number – (legalize, prostitution) and (ban, infant circumcision). The full annotation is provided in the supplementary materials.

In order to validate this annotation, a sample of motion-CoPA pairs was annotated via crowdsourcing platform Figure-Eight⁸. For each motion, argument pairs from 2 randomly chosen nonmatching CoPAs and (up to) 2 randomly chosen matching ones were annotated by 5 labelers. Average inter-annotator Cohen's kappa agreement was 0.63. Then, taking the majority vote for each pair as the crowd-sourced label, we computed agreement between it and our initial labeling, yielding a kappa score of 0.78. These indicate a rather high agreement, especially in the context of computational argumentation (Passonneau and Carpenter, 2014; Habernal and Gurevych, 2016).

4.2 Expanded data

The initial construction of CoPAs was done with the aim of identifying themes which are recurrent in general, not just in the initial 100 motions. To verify that they generalize to other motions, we collected 589 additional motions, and annotated them for CoPA membership (the same annotators who did the initial annotation). On this new dataset, we found that 503 motions were matched to at least one CoPA (85%), and on average each motion was matched to 1.94 CoPAs. Hence, while our modeling may be biased by the initial set of motions, it seems to generalize well to new ones.

As with the initial set of motions, we used crowd-sourced annotations of a similarly-sampled portion of the dataset to verify the full annotation, attaining an average inter-annotator kappa score of 0.60, and a kappa score of 0.76 when comparing the majority vote to the full annotation.

The full dataset can be found in the supplementary material.

4.3 CoPA claims in recorded speeches

It is natural to ask whether the claims authored for each CoPA are an artificial construct for facilitating motion assignment, or are actual claims, likely to be made by people deliberating these motions. To this end we considered the speeches we recorded in Mirkin et al. (2018). Each such speech is given in the context of a motion, all of which are included in our dataset. For each motion we extracted the CoPAs to which it belongs according to our annotation, yielding 184 speeches with at least one matching CoPA. 7 Figure-Eight annotators were presented with speeches in both audio and written form, alongside the claims from the matching CoPAs. They were asked whether each claim was (i) explicitly made by the speaker, was (ii) implicit in the speech or was (iii) not mentioned at all. A total of 800 (speech, claim) pairs were annotated, with one half of them being claims of a stance opposing that of the speaker.

In order to analyze agreement between annotators, we considered (i) and (ii) as a positive label and (iii) as negative. The average inter-annotator Cohen Kappa score was 0.54. Moreover, since we showed both CoPA claims to the annotators we checked whether claims whose stance opposed that of the speaker were ever marked positive. With only 5% of the annotations being so, we concluded that the annotation was of reasonable quality (cf. section 6.2).

5 Matching Methods

Having a sizable dataset of (motion, CoPA) pairs, we examined several classifiers over it. That is, given a motion and a CoPA, the classifier aims to determine whether they match. Since the CoPAs are quite varied, we examined various classifiers, some focused on a motion's action, some on its topic, and some on a combination of both.

Specifically, we examined the following classifiers:

By action (BA-k): Some actions are strongly indicative for (some of) the CoPAs a motion belongs to. To utilize this, this classifier trains by computing, for each allowed action a, and each CoPA c, the probability p(c, a) that a motion with action a will belong to c. Prediction for a new motion m = (a, t) is done by assigning each CoPA c the score p(c, a). In addition, if the number of (training-set) motions in c with action a is less than some parameter k, this method makes no predic-

⁷When analyzing our data, it will sometimes be interesting to omit these three classes, to ascertain they do not significantly skew the results.

⁸https://www.figure-eight.com/

tion.

By topic, nearest neighbors (KNN): Given a leftout motion, m = (a, t) the algorithm goes over the motions $m_i = (a_i, t_i)$ in the training set, looking for those such that t_i is most similar to t (using the similarity measure of Ein Dor et al., 2018). It keeps only those whose similarity is above a threshold of 0.5. If there are less than 3 such motions, no prediction is made. Otherwise it takes the (at most) top 5 motions. For each CoPA c, the assigned score is the fraction of these motions which belongs to c. This is then used to predict membership.

By topic, word2vec features (W2V): Each motion m = (a, t) is represented as the word2vec (Mikolov et al., 2013) embedding vector of t (if t is a multi-word expression the vectors are summed and normalized). This vector is then used as a feature vector for a logistic regression classifier. That is, each CoPA is assigned the classification score of the classifier so trained. As a safeguard mechanism, we also determine an actions blacklist, B_c , for each CoPA c. An action a is in B_c if in the training set no motion with action a is in c. During prediction, if the left-out motion's action is in B_c , it will not be predicted as belonging to c.

By topic, Naive Bayes (NB) and Recurrent Neural Network (RNN): Following the work of Rabinovich et al. (2018) each motion m = (a, t) is associated with a set of retrieved sentences containing the term t. For a given CoPA c, all the sentences associated with motions in c are considered as positive examples, and those of motions not in c as negative examples. For NB, A Naive Bayes classifier is then trained over the unigrams of these sentences, and uses its score for prediction. In addition, the same blacklist safeguard mechanism as for W2V above is used.

Similarly, these sentences were used to train an RNN to differentiate between positively-labeled sentences and negatively-labeled ones. See Rabinovich et al. (2018) for more details on these methods.

By topic and action (LR): We defined 17 features based on similarities between a motion and a CoPA, and on co-occurrence counts, similar to the one used in *BA-k*. A logistic regression classifier was trained and scored on the resulting feature vectors over pairs of (motion, CoPA). See appendix C for details.

Ensemble: For completeness, all 6 methods above

were aggregated by simply assigning each CoPA the highest score it attained among all of them. We note that this is a very naive approach; while all methods produce scores in [0, 1], it is not clear that they are comparable. In practice one would probably use an aggregation method that differentiates between the different classification methods, and between different CoPAs.

All classifiers (except one⁹) were evaluated in a leave-one-motion-out framework, over all motions and over relevant CoPAs. That is, each classifier was trained and tested 689 times – in each iteration it was trained over 688 motions and the relevant CoPAs, and then predicted whether the left-out motion matched these CoPAs. More precisely, each CoPA is assigned a score. We vary the score threshold, and determine membership by whether the assigned score exceeds the threshold.

6 Results

6.1 Complete dataset

All in all, our dataset describes the motion-CoPA relations of 689 motions and 37 CoPAs. Figure 1 shows a histogram of the CoPA sizes in this dataset. The two biggest CoPAs (*Fixable* and *Conservatism*) include nearly one third of the motions (207 motions and 211 motions respectively), while at the other end, the class *Self determination* contains only 3 motions. Most CoPAs (32 out of the 37) are of modest size, containing less than 10% of the motions.

Figure 1: Distribution of the number of motions per CoPA.

Importantly, the CoPAs capture different facets

⁹For technical reasons we trained and evaluated the RNN method using 3-fold cross-validation.

of a motion, rather than induce a partition of the motions set. On average, a CoPA has a non empty intersection with 11.95 other CoPAs, with the average intersection size being 21% of the CoPA size. Figure 2 shows the inter-connectivity graph among CoPAs. The aforementioned CoPA *Self determination* is an isolated vertex in this graph, but other than that the graph is connected. This is especially noteworthy, considering that many of the CoPAs are rather small. Figure 3 shows a heatmap of overlap sizes.

In the complete dataset, 87% of the motions belong to at least one CoPA, and on average each motion belongs to 1.95 CoPAs. That is, while this is certainly only a first step toward modeling principled recurring arguments, the suggested CoPAs are indeed a concise set that covers distinct argumentative themes and offers a good coverage w.r.t. the world of motions defined here.

6.2 CoPA claims in recorded speeches

Of the 184 annotated speeches of Mirkin et al. (2018), 87% had at least one CoPA-claim annotated as positive¹⁰, and in total, 66% of the 400 (speech, claim) pairs (where the stance of the claim and the speaker were aligned) were marked as positive. However, in the vast majority of cases the claim was marked as implicit in the speech – according to the annotation only 10% of the speeches contain a CoPA-claim explicitly, and only 5% of the pairs are labeled as an explicit mention.

One reason for this may be the three "general" CoPAs, since their claims are so general that they would usually be at least implicit in a speech. When removing these CoPAs from the analysis 62% of the speeches have at least one positive claim, and 39% of the pairs are positive. Hence, even without these classes, most speeches implicitly mention at least one claim from the dataset. This is probably due to the rather generic phrasing of the claims, which in the first place were constructed to be applicable "as-is" in multiple contexts. In other words, this annotation not only confirms that the CoPA claims convey arguments actually alluded to by humans, but that they do so at a rather high level, and so capture arguments that are not only plausible for a motion but also probable.

Conversely, for each CoPA, we also examined the speeches to which it matched, and computed the fraction of these speeches in which the CoPA's claim was annotated as positive. Of the 37 CoPAs, 29 match motions in Mirkin et al. (2018). For all but one (*Sexual morality*), in at least 25% of the relevant speeches, the CoPA's claim (of the correct stance) was labeled positive. For 24 CoPAs at least 50% were so labeled.

6.3 Motion-CoPA matching

As noted in section 5, we evaluated the proposed matching methods in a leave-one-out framework. For the action-based method, *BA-k*, we set k = 5 and consider only CoPAs which contains at least 5 motions with the same action. For the topic-based methods we considered only CoPAs which were manually marked as topic-based (see appendix B) and contain at least 10 motions. The *LR* method was naturally evaluated on all CoPAs.

Figure 4 describes the precision-recall trade-off for each of the 7 methods from section 5, which is computed over all (motion, CoPA) pairs: precision is the fraction of matching pairs whose score is above the threshold from among all pairs with such a score; recall is the ratio between the number of matching pairs with such a score, and the total number of matching pairs.

Note that for methods which look at only a subset of the CoPAs recall is bound to be low, since recall calculation takes into consideration all Co-PAs, not just this subset.

With the task of *Argument Invention* in mind, a use-case of interest is, given a motion, to provide (at least) one CoPA from which argumentative content can be extracted. Accordingly, Figure 5 evaluates the precision for the highest scoring CoPA of each motion – for a given threshold, the figure depicts the fraction of motions whose highest scoring CoPA is both a match and above the threshold, as a function of the fraction of motions for which at least one CoPA passes the threshold. As can be seen, for a threshold that yields CoPA prediction for half the motions, the ensemble method has 86% precision for its top prediction.

Finally, recall that the three "general" CoPAs (*Conservatism, Fixable, Framework*) might dominate the predictions analyzed above. Omitting them from the analysis does reduce precision somewhat, but nonetheless, the top prediction of

¹⁰A pair is considered positive if a majority of annotators chose option (i) or (ii); cf. section 4.3.

Figure 2: Graph of CoPAs, where edges indicate non-empty intersection and distance between vertices is indicative of intersection size. Not shown is "Self determination", an isolated vertex.

Figure 3: Fraction of overlapping motions among classes; the value of entry (i,j) is the fraction of motions in class i which also appear in class j. Green indicates high values, red low ones.

the ensemble method for a threshold yielding a prediction for half the motions attains a precision of 75% (Figure 6; For this analysis the "general" classes were not included in the recall computation).

A naive baseline would always (and only) predict the CoPA with the largest number of motions as a match. When considering all CoPAs, this attains a precision of 30% (for *Conservatism*), and when omitting the three general CoPAs, a precision of 12% (for *Coercion*).

Figure 4: Precision-Recall curve for the various motion-CoPA matching methods.

7 Discussion

The most basic argument model is probably Aristotle's *categorical syllogism*, which consists of a major premise, a minor premise and a conclusion (Aristotle and Kennedy, 1991); with the minor premise being a categorical proposition connecting between the major premise and the conclusion. The canonical example is:

All men are mortal. Socrates is a man. Therefore, Socrates is mortal.

It is interesting to consider the CoPAs and the claims they contain in this context. When aim-

Figure 5: P@1 vs. coverage of the various motion-CoPA matching methods.

Figure 6: Precision results when ignoring the three general classes, *Conservatism, Fixable, Framework*

ing to argue for a motion, and identify a CoPA to which it belongs, one can create a syllogistic-like argument as follows. The major premise would be the CoPA claim, the minor premise would explain why the motion is a member of the CoPA, and the conclusion would be that the motion should stand¹¹. For example, when deliberating the motion (further exploit, solar energy), and identifying that it belongs to the CoPA *Clean energy*, the resulting (heuristic) argument could be:

Humanity must embrace clean energy in order to fight climate change. Solar energy is a form of clean energy. Therefore, humanity must further exploit solar energy.

Similarly, a very basic model for describing deliberation is Hegelian dialectics: The deliberation or debate starts with a thesis, which is countered by an antithesis, and is then resolved with synthesis. The CoPA's claims can be seen as providing a thesis and an antithesis in the context of a member motion, with the synthesis dependent on the motion and on the valuation of the claims by the adjudicator.

A major challenge in constructing the CoPAs herein was finding an explicit phrasing for the arguments, one that would be suitable without further context. One example for this is the *backlash* argument – an argument stating that implementing the policy will be counter-productive, since it will create a backlash reaction. While this is a common argument, arguing why a backlash reaction will occur and how it will be counterproductive may well depend on context. Moreover, it is difficult to phrase an appropriate claim of the opposite stance without further context.

However, the CoPAs can actually provide us with an appropriate context needed for phrasing such arguments. Thus, one could phrase more specific backlash arguments for the CoPA *Subsidies* or *Coercion* (with different phrasings), and use them when the CoPA is matched to a motion. In other words, we can expand the set of CoPA arguments to include more than just 2 claims; it could include further instances of principled arguments, each perhaps tailored to the specific CoPA. Recall that our motivation is *Argument Invention* – when a CoPA is matched, the underlying system can present all arguments the CoPA contains.

Indeed, with the aim of assisting critical writing in mind, one need not limit CoPAs to claims or even to coherent arguments. CoPAs could very well be rhetorical *loci* for relevant anecdotes, proverbs, memes, quotes from famous people and

¹¹Since the major premise here is not a categorical proposition, the argument will not be true in the propositional, *modus*

ponens sense. But if the claim is indeed an *endoxa*, the argument should be one that most people consider plausible.

so on. They could also include text written in different styles to accommodate different types of presentations (*pronuntiatio*). In response to a topic, a system making use of the CoPAs knowledge base could present all these texts to the users, or filter them according to their preferences.

An interesting research direction in this respect is to include in a CoPA, for each claim it contains, a rebuttal argument that counters it. This can enable an argumentative dialog system (Rach et al., 2018), along the lines alluded to in Mirkin et al. (2018) - one can envision a system that performs listening comprehension, identifies the relevant CoPAs, checks whether any of the claims in the CoPA were mentioned in the audio, and, for those that do, responds with the rebuttal arguments matching this claim. This is similar to scripted dialog systems, with the important difference that the texts are not written for a specific scenario. They are principled arguments which can be used in many different contexts, allowing for an opendomain dialog system. We intend to describe such a system in future work.

Furthermore, a CoPA can include complex argumentative structures such as those in AraucariaDB (Reed and Rowe, 2004), from which multilayered arguments can be constructed, e.g. using the Carneades Argumentation System of Walton and Gordon (2012). That is, instead of having such data per topic, as is currently the case in AraucariaDB, having such data for commonplace principled arguments facilitates their use over a wide range of topics. Note that for this the stance of the argument w.r.t the CoPA and the motion is important. For the sake of simplicity and brevity we have ignored this issue in this manuscript, but the relevant stance labeling is available in the supplementary material.

In the field of computational argumentation, *de novo* argument synthesis has received relatively little attention. One naive attempt is that of Bilu and Slonim (2016), where claims are generated by pasting together a topic and short predicate. The framework suggested here may provide a richer and more stable basis for argumentative text generation. That is, a CoPA may include structured data which describes its principal theme. Then, when presented with a motion in this CoPA, the system would automatically generate, *de novo*, argumentative text based on this structured data *and the topic*. For example, this could be an NLG neu-

ral net trained on a large corpus of claims extracted using argument mining for motions in the CoPA.

Finally, let us reappraise the basic intuition of the corpus-wide argument-mining approach to argument invention - that an effective argumentation is one that draws on the widest possible array of proofs and arguments. Rhetoricians have characterized the art of convincing as starting from general and basic views, facts and opinions accepted by everyone (Perelman, 1971; Kock, 2009). In other words, an efficient argument starts not from the most original and unseen premises, but from what the audience takes as consensual, and only then progresses to what is controversial. Therefore, the need for principled arguments is not only a question of time and practicality, but also stems from the essential nature of rhetoric: it is the necessity to call on the general views and opinions shared by everyone and to show that they uphold the desired conclusion.

8 Conclusion

We presented a novel framework – 689 controversial motions with a variety of topics and actions – in which the *Argument Invention* task can be formalized and assessed. We formalized the notion of commonplace principled arguments, and suggested a concrete and diverse taxonomy for them. While this taxonomy can certainly be expanded and refined, it nonetheless has the basic desired properties: most motions in our framework belong to it, annotators tend to agree on CoPA-motion matching, this matching can be done automatically with reasonable success, and human debaters tend to allude to the ascribed arguments when debating these motions.

9 Acknowledgments

We thank Uri Zakai for insightful discussions which helped initiate this work. We thank Anatoly Polnarov and Noga Zaslawsky for their help in developing the taxonomy and data sets presented here.

B Classes of Principled Arguments

This appendix lists the 37 CoPAs. In each, the number of motions associated with it follows the class's name, and two opposing CoPA-claims are

listed in the entries below it. CoPAs marked with a superscript t are those deemed as topic-related.

Adolescent rig	ghts (9 motions)	
Many adolescents can not make responsible decisions	Adolescents are as ca- pable as adults	
Animal right	s ^t (21 motions)	
Animals should not be treated as property	There is nothing wrong with using animals to further human interests	
Big governme	ent (21 motions)	
Public utility is best served by actions coor- dinated by central gov- ernment	Public interest is best served and propelled by voluntary interactions, and not ones dictated by government	
Black marke	t^t (35 motions)	
Prohibiting products and activities makes them less visible and available, and thus less harmful	Prohibition is counter- productive and only leads to increased demand	
Clean energy	t^{t} (25 motions)	
Humanity must em- brace clean energy in order to fight climate change	Ecological concerns add further strain on the economy	
Coercion (81 motions)		
A decisive and enforced policy is the best way to deliver a message	Enforcement tends to be less effective than persuasion and educa- tion	
Conservatism	n (211 motions)	
The current system is working, and making such a change could have negative conse- quences	It is time to change the old ways and try some- thing new	
Criminal deterr	cence (8 motions)	
When people will have to pay for their actions there will be less crime	Strict punishment is not effective in preventing criminal behavior	
Discrimination ^{t} (19 motions)		
It is a fact that there are differences between people. Hence, there should sometimes be differences in the way people are treated.	All people should be treated equally	
Environment ^{t} (44 motions)		
People must protect na- ture and respect its bio- logical communities	Environmentalism stands in the way of technological progress and economic growth	

Fair trial ^{t} (17 motions)		
Upholding the rights of the accused and ensur- ing a fair process is the best way to maintain justice	The focus should not be on the rights of crimi- nals, but on protecting the law-abiding public from harm	
Fixable (2	07 motions)	
There are some issues here that need address- ing, but that doesn't mean it should all be eliminated	Due to the many problems associated with [TOPIC], the best course of action would be to put an end to it	
Framework	(102 motions)	
[TOPIC] works efficiently	[TOPIC] fails to achieve its goals	
Freedom of ch	Dice (35 motions)	
People have the right to make their own choices, including bad ones	It is the duty of society to protect people from their own bad choices	
Freedom of religion (10 motions)		
People should be free to practice their religion	Religions are outdated, irrational and harmful	
Gender equality ^{t} (5 motions)		
Banishing the mis- guided notions of gender roles in society is the way to achieve true equality for women	Gender roles reflect true biological dif- ferences between the sexes. It doesn't make sense to ignore them	
Greater goo	d (40 motions)	
The safety and well- being of the community is more important than individual freedom	Individual freedom is a sacred value. It cannot be subordinated to sub- jective opinions decid- ing what is best for so- ciety	
Immigration	n^t (5 motions)	
People who come in search of a safer and better life should not be turned away	Mass immigration threatens social cohesion	
Media's impa	ct ^t (15 motions)	
Media consumption has no significant social or behavioral effects	Stereotypes distributed in the media lead to a distorted view of soci- ety and of the other	
National security (19 motions)		
Some rights and free- doms need to be lim- ited in the interest of national security	Security does not justify brushing aside fundamental rights and freedoms	
Objectification (9 motions)		
Women should have the power to use and show their bodies as they would like to	Society cannot allow women to be treated as commodities	

Offensive encede (12 vi)		
Offensive speech (13 motions)		
Freedom of expression	The freedom of expres-	
not apply to troubling	offending people's val-	
and controversial ideas	ues and beliefs	
Playing god	l (20 motions)	
People can, and there-	Only God should de-	
fore should, interfere	termine how life comes	
with nature in order to	into being and how it	
Price interfere	nce (46 motions)	
Price regulation is use-	Market forces should	
ful for achieving social	determine the rates of	
and economic goals	prices and fees	
Privatization	1 (30 motions)	
Privatization often	The state is a better and	
leads to improved	a more natural provider	
enciency and quanty	vices	
Public health ^t (17 motions)		
It is the government's	The state should have	
duty to safeguard pub-	no role in encouraging	
healthy life choices	or discouraging partic-	
Religion ^t	(23 motions)	
Religion creates a sense	Religion has proven	
of community for peo-	over the years that it is	
ple, and organizes hu-	a harmful, destructive	
man life	force	
Right to priva	cy ^e (23 motions)	
The right to privacy is a fundamental right	Privacy is not abso-	
	stances when it must be	
	compromised in order	
~	to protect society	
Self-determina	ttion (3 motions)	
The political status of a	Self-determination can-	
be defined by its popu-	not be handed freely,	
oe denned of no popu	especially not as a prize

Tradition (66 motions)		
A society should re- spect its traditions and try to avoid changes for the sake of change	Society should move on with the times, in- stead of clinging to old and obsolete traditions which are no longer rel- evant	
Value of science ^{t} (9 motions)		
Theories which are not based on scientific methods should not be supported	Not everything can be explained by science	
Virtual life ^{t} (12 motions)		
The virtual world en- riches our lives in ways that other forms do not	In the virtual world, people lose touch with reality	
Wealth distribution (11 motions)		
Society has a duty to minimize inequality by allocating resources more evenly	The way to achieve a fair distribution of wealth is to let it be de- termined by the market forces	
Welfare state (30 motions)		
The state has a duty to provide for the social and economic security of its citizens	State-sponsored welfare is coun- terproductive and actually exacerbates the problem	

Note the special token [TOPIC] which, during labeling and application, is replaced by the topic of the relevant motion. For example, when labeling the motion (disband, NATO) for the CoPA *Framework*, the claims presented to the annotators were *NATO works efficiently* and *NATO fails to achieve its goals*.

C Features engineered for (motion, CoPA) pairs

For each CoPA c we manually listed a set c_m of Wikipedia titles as related to it. With this in hand, we define a set of 17 features (listed below) that aim to capture the similarity between the motion and the class. These include similarities between the motion's action and topic and the list of Wikipedia titles as well as similarities between the motion's topic and the topics of other motions in the class (as in *KNN* above). In addition to these similarity features, we also included counts-based features. Using this feature a logistic regression classifier was trained, and each CoPA was assigned the score computed by it.

C.1 Similarity features

We associate a motion m with two sets of texts. $m_t = action, topic$ is simply the set containing the text of the action and the text of the topic. The second set aims to identify Wikipedia titles related to the topic. Each Wikipedia title linked to in the topic's Wikipedia article is scored by the p-value computed for it for its appearance in the article compared to a set of random articles, using the hypergeometric distribution. m_w is the set of (at most) 10 titles with the lowest p-value.

We also associate each CoPA with two sets of texts. The first is the aforementioned manually-generated list, c_m . The second is the set of topics of motions in the CoPA, c_t (when doing leave-one-out analysis, we always ignore occurrences of the topic of the left-out motion).

Given some method to compute similarity between two terms, we define the similarity between two sets of terms as the average over all pairs of terms, one from each set. We employ three types of similarity scores: word2vec (Mikolov et al. (2013)), that of Ein Dor et al. (2018), and cosine similarity of Tf-Idf vectors. All in all this defines 12 similarity features.

In addition, we take all terms in c_m which also appear in the Wikipedia article of the *topic*, and take their average Idf score as a 13th similarity feature.

C.2 Counts-based features

For a motion m = (a, t), Let M_a be the set of all motions with action a. Let M_* be the set of all motions in our dataset. For m and CoPA $c = (A_c, M_c)$ we define the following four countsbased features:

- 1. $|M_a|/|M_*|$
- 2. $|M_a \cap M_c| / |M_a \cup M_c|$
- 3. $|M_a \cap M_c| / |M_a|$
- 4. $|M_a \cap M_c| / |M_c|$
