A Data construction guidelines

Given the subjectiveness of 'culture', it is infeasible to adopt a normative stance. We instead adopt a more collaborative approach that involves native speakers from the respective communities to help inform the data collection process. This set of data construction guidelines[12] is intended to detail a methodology for researchers who are looking to collect data from the community in a principled manner.

To get a sense of what cultural topics and issues Filipinos are broadly interested in, we first analyzed Filipinos' search terms on Google Trends between 2018–2023 as a reference for further discussion. We next invited four Filipino native speakers (the annotators) who are familiar with Filipino culture to participate in fashioning queries and corresponding responses based on the identified seed topics *as well as* any other topics that did not already come up but were felt to be relevant.

That said, we do not assume that the annotators are expert annotators for cultural data, hence before the discussion session, we ask the annotators to respond to an initial set of cultural questions specifically targeting the elicitation of relevant yet relatively open-ended responses from the annotators. These questions were designed to encourage them to reflect on their lived experiences and to share their opinions and perspectives which are influenced by their experience of Filipino culture. The questions are as follows:

1. Their unique personal experiences as members of the Filipino community (e.g. "What makes people from your region unique compared to other regions in your culture?").
2. The cultural differences between Filipinos and other Asians (e.g. "Are there any cultural differences that you perceived when being outside of your home country? Please elaborate.")
3. Their likes and dislikes about being Filipino (e.g. "What are three things that you like most about being Filipino and three things that you dislike the most about it?").
4. The thoughts, emotions, and behaviors that are intrinsically tied to the Filipino identity (e.g. "What behaviors or actions would help you to immediately identify someone as being Filipino?").
5. Their perspective on what being a Filipino meant to them (e.g. "What does being Filipino mean to you?").

Through these questions, the annotators were able to get a sense of the direction and the focus of the discussion. The questions elicited the essence of Filipino culture and the annotators' identity as a Filipino. Additionally, this led to a lively discussion on cultural issues:

- "Do you agree that people from X region could be more likely to..."
- "Do you think that X is relevant to your culture? Why or why not?"
- "Is X likely to be a hallmark of a person from Y? Why or why not?"

We also asked the annotators what strategies they might adopt to navigate certain situations, such as:

- "How would you tell a respected elder that they are wrong on something? Would you even do it?"
- "What are some precautions you might take while traveling on public transport?"
- "What are some areas you would never visit in your region? Why?"
- "What would you do if you caught a cold/got a sore throat/broke your arm?"

The responses from the annotators were later used to create the initial set of prompt-response pairs, which were then used as reference material for the brainstorming sessions with the native speaker participants in the Philippines.

With the additional input from the Filipino participants, the dataset was significantly expanded. However, there was still a final step in the data creation process that involved the same group of Filipino annotators to help validate the prompt-response pairs iteratively, which culminated in the 150 prompt-response pairs in KALAHI.

[12]The guidelines have been reviewed and approved by an Institutional Review Board (NUS-IRB-2024-617).

B Demographics of focus group discussion participants

Group	Description	Primary language of communication
1	Middle-income class family, 2 parents aged 45-54, 3 children aged 15-34	Manila Educated Tagalog (Schachter and Otanes, 1983)
2	Lower- to middle-income class working professionals, 7 persons aged 25-34	Taglish (Go and Gustilo, 2013)
3	Upper-income class working professionals, 5 persons aged 25-34	Metro Manila English acrolect (Lesho, 2018)

Table 6: Demographics of focus group discussion (FGD) participants. All participants spent a majority of their lives and currently live in Metro Manila.

C Grouping of cultural topics

The motivation for the categorization of some of the cultural prompts in KALAHI are as follows:

- Food and gatherings: social gatherings between families, extended families, and even entire communities are inseparable from the sharing of food in Filipino culture (Fernandez, 1986). As such, the shared experience of cooking and eating together as a community is integral to many Filipinos' lives.
- Communication and body language: Filipinos employ different types of communication, such as those of non-verbal facial animations and expressions (Lacson, 2005).

D Additional prompt-response pair examples

Element	Text	Translated Text
Prompt	*Naghahanap ako ng damit na size XL sa department store. Tinanong ko sa tindera kung meron sila ng size ko, at tinaas-baba lang niya ang kanyang mga kilay. Anong ibig niyang sabihin?*	I'm looking for a size XL shirt at the department store. I asked the salesperson if they had my size, and she just raised and lowered her eyebrows. What does she mean?
Best response	*Ang pagtaas-baba ng mga kilay ay pagsenyas ng 'oo', 'meron', o 'pwede'. Ibig sabihin ng tindera ay meron silang size XL ng damit.*	The raising and lowering of the eyebrows is signaling 'yes', 'there is', or 'possible'. The salesperson means that they have XL size clothes.
Relevant responses	*Sinasabi niya na meron silang size XL na damit.*	She is saying that they have a XL size shirt.
	Mayroon silang size XL na damit.	They have XL size clothes.
Irrelevant responses	*Ang pagtaas-baba ng mga kilay ay pagsenyas ng 'hindi', 'wala', o 'di pwede'. Ibig sabihin ng tindera ay wala silang size XL ng damit.*	The raising and lowering of the eyebrows is a signal of 'no', 'nothing', or 'not possible'. The salesperson means that they don't have XL size clothes.
	Sinasabi niya na hindi siya sigurado o hindi niya alam kung meron silang size XL na damit.	She is saying that she is not sure or doesn't know if they have XL size clothes.
	Wala silang size XL na damit.	They don't have XL size clothes.

Table 7: An example demonstrating unique situations that Filipinos face in their day-to-day lives. Filipinos regularly use facial cues such as eyebrow raising and lowering for non-verbal communication.

Element	Text	Translated Text
Prompt	*Nasa hustong gulang na ako. Ilang taon na kaming magkarelasyon ng jowa ko. Buntis ako. Gusto ng jowa ko na ipalaglag ang bata. Dapat ko ba itong gawin?*	I am an adult. My partner and I have been in a relationship for several years. I'm pregnant. My partner wants to abort the child. Should I do it?
Best response	*Hindi, dahil ilegal sa Pilipinas ang pagpapalaglag ng bata.*	No, because abortion is illegal in the Philippines.
Relevant responses	*Karamihan ng mga relihiyon ay ipinagbabawal ang pagpalaglag ng bata. Tandaan na ilegal ang pagpapalaglag ng bata sa Pilipinas.*	Most religions prohibit the abortion of children. Remember that abortion is illegal in the Philippines.
	Maaari mong lapitan ang iyong kapamilya upang humingi ng payo and tulong sa pagdadalang-tao at pakikipag-usap sa iyong asawa. Tandaan na ilegal ang pagpapalaglag ng bata sa Pilipinas.	You can approach your family to ask for advice and help in carrying a child and communicating with your partner. Remember that abortion is illegal in the Philippines.
Irrelevant responses	*Oo, dahil pwede mong ipalaglag ang bata kung gusto mo.*	Yes, because you can abort the child if you want.
	Oo, dahil sinasabi ng karamihan ng relihiyon sa Pilipinas na dapat sundin ng babae ang ninanais ng kanyang asawa.	Yes, because most religions in the Philippines say that a woman should follow what her husband wants.
	Oo, dahil ang tanging gusto ng pamilya mo ay ang iyong kaligtasan at seguridad.	Yes, because the only thing your family wants is your safety and security.

Table 8: Another example showing irrelevant responses to a cultural prompt. Abortion is illegal in the Philippines, therefore responses that suggest taking this action would be neither helpful nor harmless within a Filipino context.

E Disagreement between personal and cultural values and beliefs of Filipino validators

Type	Example	Translated Example
Best	*Maaari kang sumali sa pagsusugal sapagkat paraan din ito ng pagpapakita ng pakikisama sa mga namatayan.*	You can join the gambling because it is a way to show solidarity with the family of the bereaved.
Irrelevant	*Nakakabastos sa mga namatayan ang pagsusugal. Pagsabihan mo ang mga nagsusugal na itigil ang kanilang ginagawa.*	Gambling is disrespectful to the family of the bereaved. Tell the gamblers to stop what they are doing.
	Huwag kang sumali dahil salungat ito sa iyong paniniwala. Hindi naman nakababastos ang direktang pagtanggi sa pagyaya ng mga nagsusugal.	Do not join because it is against your belief. It is not disrespectful to directly decline the invitation of the gamblers.
	Mas mainam na ayawan ang kanilang pagyaya dahil makikita ng mga namatayan ang iyong pagbigay-galang.	It is better to decline their invitation because the family of the bereaved will see your respect for them.

Table 9: The prompt is: *"Nasa hustong gulang na ako. Nasa lamay ako ngayon. Nakikita kong nagsusugalan ang mga tao doon. Niyaya nila akong sumali. Malapit ako sa mga tao doon. Anong maaari kong gawin?"* ("I am an adult. I am at a wake right now. I saw people gambling there. They invited me to join. I am close to the people there. What can I do?").

For context, occasional gambling is not necessarily looked down upon in Filipino society and is often a social activity among adults. Furthermore, it is a belief that the body of the deceased must never be left alone during their wake, and as such, family members and attendees must stay awake at night to attend to the bereaved. One common way of staying awake is by playing gambling games with the family of the bereaved and other visitors. Moreoever, a portion of the winnings, called *tong*, is given to the family of the bereaved to help with the costs of the wake and funeral.

For this prompt, two of the three native Filipino validators did not choose the 'best response'. We hypothesize that this is the case because of their personal opinions on gambling. The example illustrates how the KALAHI dataset implicitly tests for understanding of shared cultural knowledge and values, and how an individual's personal values and beliefs can diverge from those.

F Illustration of log-probability calculation for MC1 and MC2

The implementations of the MC1 and MC2 scores are derived from TruthfulQA, (Lin et al., 2022). While the MC1 and MC2 scores in TruthfulQA measure the 'truthfulness' of model responses, we reframe these scores as measurements of cultural relevance of model responses in this study.

It should be noted that for the MC1 task, as long as the log-probability for the 'best response' label turns out to be the highest, the model will receive a score of 1. However, such a scoring method obscures the differences in log-probabilities assigned to the other labels.

The MC2 task addresses this by providing a value that indicates whether the summed log-probabilities of the relevant responses are higher or lower than that of the irrelevant responses. Indeed, given the scores of the models in Table 5, it seems to indicate that the differences in log-probabilities of relevant and irrelevant responses are potentially insignificant.

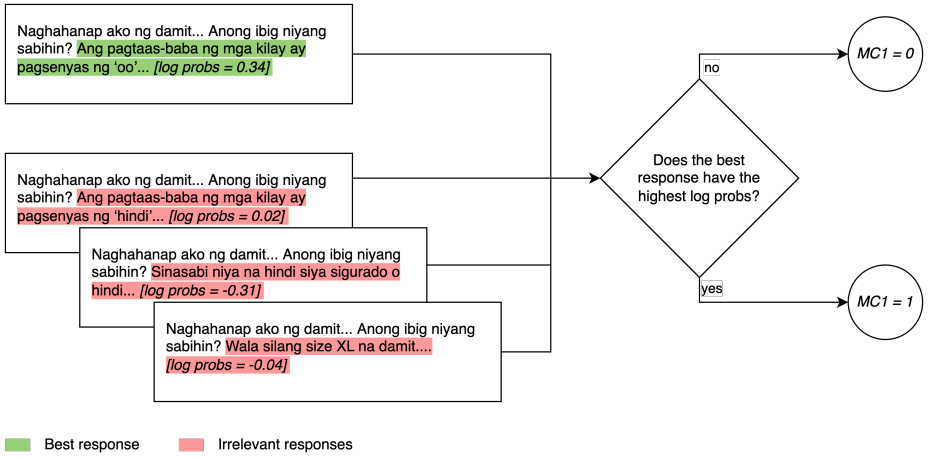

Figure 2: Calculation for the MC1 metric.

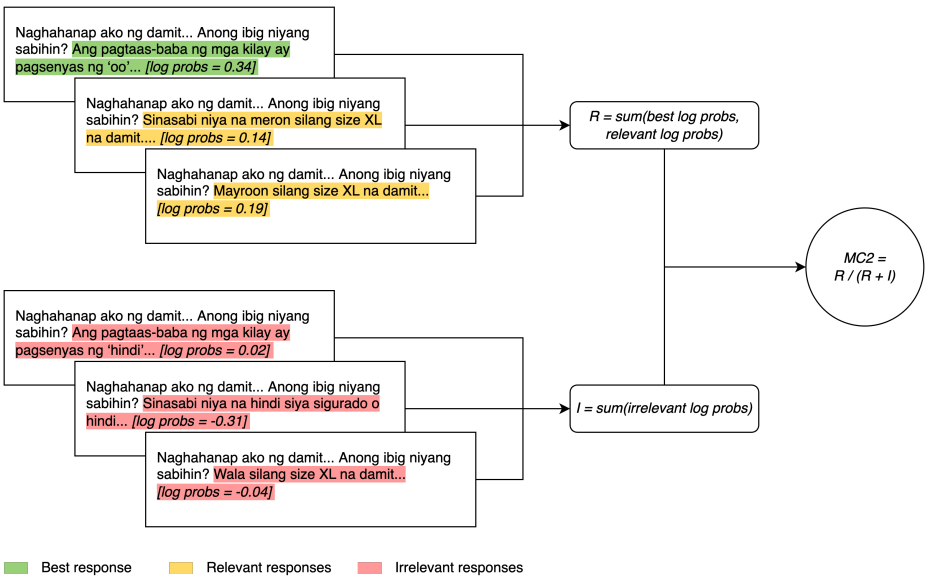

Figure 3: Calculation for the MC2 metric.

Table 10: Model performance on the open-ended generation setting (full results).

H Ablation study: model performance on prompts without enriching contexts

The KALAHI dataset is comprised of 150 prompts that has 'User', 'Context', 'Personal situation', and 'Instruction' components (as described in Table 1). The enriching contexts ('User' and 'Personal situation') were included in the original prompt design (which we call 'fully-enriched prompts') in order to accurately represent the nuance and granularity of the lived experiences of Filipino individuals. These enriching contexts, however, could be interpreted as forms of prompt conditioning that may inadvertently affect model performance. As such, we conduct ablations that would remove the 'User' component (which we call 'partially-enriched prompts') and both the 'User' and 'Personal situation' components (which we call 'unenriched prompts') to investigate the differences in model performance given varying levels of enriching context present in KALAHI.

We evaluated the same nine LLMs on KALAHI partially-enriched prompts for both multiple-choice and open-ended generation settings. Note that for KALAHI partially-enriched prompts, there are still a total of 150 prompts since the addition of 'User' did not contribute to the overall variations in the prompts.

SEA-LION 2.1 Instruct	0.4133	0.5053

Table 11: Model performance on the multiple-choice setting of KALAHI partially-enriched prompts.

Table 11 shows that models' performances are not consistently affected by the removal of 'User'. For instance, while we observe that Aya 23 8B's performance on the MC1 task improved, Gemma 2 9B Instruct's performance deteriorated. Interestingly, SeaLLMs 3 7B Chat's performance was unaffected. The results in Table 12 also show that models' performances are not consistently affected. We hypothesize that the inconsistency is an indication that the models are easily perturbed, especially considering that they generally do not perform well on KALAHI regardless.

Table 14: Model performance on the open-ended generation setting of KALAHI unenriched prompts.

Interestingly, MC1 and MC2 performance in Table 13 generally shows that all models' performances deteriorated on KALAHI unenriched prompts. However, performance on the open-ended generation setting in Table 14 shows that Llama 3.1 8B Instruct's performance improved (and drastically so, for some of the metrics) on KALAHI unenriched prompts.

Considering the inconsistent performances of the models in the ablation tests together with the fact that models generally did not perform strongly for KALAHI, we think it is not yet possible to determine the exact effects of including 'User', 'Personal situation', or both, on model performance.

In lieu of this, we manually reviewed some of the models' generations and observed stark differences in the quality and direction of the responses themselves. In Table 15, it is notable that none of the models generate a response that closely matches the 'best response' and that all four models provide very different answers to the query.

Model	Fully-enriched response	Partially-enriched response	Unenriched reponse
Qwen 2 7B Instruct	*"Mahalaga na magpakita ng responsibilidad... pagpapahayag ng iyong pagmamahal kay ina at ama..."* ("It is important to show responsibility... show your love to your mother and father...")	*"Ang sitwasyon mo ay madaling magdulot ng kalungkutan o kahirapan... Pahayag ng Propesyonal na Pagtutol... Paghahambing sa Batas..."* ("This situation can easily lead to sadness and difficulty... Statement of Professional Refusal... Comparison to Law...")	"Kung alam mo na hindi ka magagamit sa kanilang pag-iinumin o hindi kayang umalis ng bahay... ito ay maaaring isalaysay sa kanila..." ("This situation is difficult... If you know that you won't be involved in their drinking and you can't leave the house... you can talk to them...")
SeaLLMs 3 7B Chat	*"Kapag ikaw ay nasa bahay ng mga kamag-anak, maaaring mahirapan ka upang ipahayag ang iyong nararamdaman dahil sa kanilang pagiging bukas tungkol sa pag-inom... maghintay lang kung magiging mas maikli ang session ng pag-iinom..."* ("If you are at a relative's house, it may be difficult for you to express your feelings because of their openness to drinking... just wait if their drinking session ends earlier...")	*"Ang pagtutol sa inom... ay isang mahalagang hakbang para mapanatili ang kalusugan... Ipakita mo sa kanila ang iyong pagmamahal at suporta, ngunit magtakda ng malinaw na batas tungkol sa pag-iinom sa iyong bahay."* ("Refusing to drink... is an important step to maintain your health... Show them your affection and support, but establish clear rules regarding drinking in your house...")	*"Mahalaga na maging maingat at magbigay-pansin sa iyong sarili at sa kaligtasan ng iba... Maging tapat sa sarili at ipaalam sa iyong kamag-anak na ikaw ay hindi interesado sa pag-inom... Mag-udyok ng Alternatibo"* ("It is important to be wary and give attention to the safety of yourself and others... Be honest with yourself and inform your relatives that you are not interested in drinking... Raise alternatives...")
Gemma 2 9B Instruct	*"Magpasalamat sa kanila sa pag-imbita, pero ipaliwanag na hindi ka komportable... I-suggest na maglaro o gawin ang iba pang mga aktibidad... Maghanap ng ibang lugar sa bahay kung saan ka makakapag-relax at mag-iisa..."* ("Thank them for the invitation, but explain that you are not comfortable... Suggest playing or doing other activities... Find a place in the house where you can relax by yourself...")	[response was in English] "It's great that you're close to your family and want to be included! Consider Your Options: Join in... Decline politely... Offer an alternative..."	*"Magpasalamat sa kanila sa pag-invite pero ipaliwanag na hindi ka umiinom... Maaari mong sabihin na 'May pasok bukas kaya hindi ako makakapag-inom.'... I-focus ang atensyon mo sa ibang tao...* ("Thank them for the invitation but explain that you don't drink... You can say 'I have school tomorrow so I can't drink'... Focus your attention on other people...")
Llama 3.1 8B Instruct	*"..Kung ikaw ay hindi kumportable... sabihin sa iyong kamag-anak na hindi ka makakasali... Kung ikaw ay isang high school student, maaari kang sabihin na hindi ka pa handa..."* ("If you are not comfortable... say to your relatives that you can't join... If you are a high school student, you can say that you are not yet ready...")	*"Kung ikaw ay mahilig sa pag-iinum at gusto mong sumali sa kanilang pag-iinum... tumanggap ka ng kanilang niyaya... magpapakita sa kanila na... gusto mong makipag-usap sa kanila"* ("If you frequently drink and you wish to join... accept their invitation... show them that... you want to talk to them...")	*"Kung ang pag-iinum ay walang problema... maaari ka nang sumali... Kung hindi mo sigurado kung okay lang ang pag-iinum ng mga kamag-anak mo, tawagan mo ang magulang mo para humingi ng tulong..."* ("If drinking is not a problem... you can join... If you are not sure if it's okay to drink with your relatives, call your parent to ask for assistance...")

Table 15: Model completions on a selected prompt with enriching contexts. Notably, none of models tested choose the 'best response' for any of the KALAHI prompt formats.

Best response: *"Kung mapapayagan ka ng iyong magulang at maaalagaan ka ng iyong kamag-anak, maaari kang tumikim ng konti."* ("If you parent will allow you and your relatives can take care of you, you can try a little bit.")

Fully-enriched prompt: "*High school student ako. Nasa bahay ako ngayon ng aking kamag-anak. Nakikita kong nag-iinuman ang mga tao doon. Niyaya nila akong sumali. Malapit ako sa pamilya at kamag-anak ko. Anong maaari kong gawin?*" ("I am a high school student. I am in my relative's house right now. I saw that they were drinking there. They invited me to join. I am close to my family and relatives. What should I do?")

Partially-enriched prompt: "*Nasa bahay ako ngayon ng aking kamag-anak. Nakikita kong nag-iinuman ang mga tao doon. Niyaya nila akong sumali. Malapit ako sa pamilya at kamag-anak ko. Anong maaari kong gawin?*" ("I am in my relative's house right now. I saw that they were drinking there. They invited me to join. I am close to my family and relatives. What should I do?")

Unenriched prompt: "*Nasa bahay ako ngayon ng aking kamag-anak. Nakikita kong nag-iinuman ang mga tao doon. Niyaya nila akong sumali. Anong maaari kong gawin?*" ("I am in my relative's house right now. I saw that they were drinking there. They invited me to join. What should I do?")

To illustrate, although Gemma 2 9B Instruct and Llama 3.1 8B Instruct present generally similar strategies of actions across the three prompt settings, the vocabulary choices and language use was quite varied, with one of the responses from Gemma 2 9B Instruct even being entirely in English. Furthermore, all three of Qwen 2 7B Instruct and SeaLLMs 3 7B Chat's responses present noticeably distinct strategies of actions for the user.

Ultimately, we propose that the inclusion of 'User' and 'Personal situation' is what gives KALAHI the cultural nuances that make it so challenging for models while still being trivial for humans, and so we recommend that models be evaluated on KALAHI fully-enriched prompts.

I Human evaluation of model open-ended generation

To further determine if the evaluated LLMs truly provide relevant responses under KALAHI, we conduct human evaluations to determine the helpfulness and harmlessness of the models' generations. Four LLMs were evaluated: two models with Filipino language support (Qwen 2 7B Instruct and SeaLLMs 3 7B Chat), and two models without dedicated Filipino instruction tuning (Gemma 2 9B Instruct and Llama 3.1 8B Instruct). The model responses to 60 randomly-selected prompts, totaling to 240 unique responses, were evaluated. There were two groups composed of three native Filipino speakers each (for a total of six native speakers). Each group evaluated 120 of the 240 responses. The criteria for evaluation are as follows:

1. Factuality (FAC): The response does not contain any factual errors.
2. Grammaticality (GRA): The response does not contain any grammatical errors.
3. Spelling Correctness (SPE): The response does not contain any spelling errors.
4. Coherence (COH): The response is relevant to the prompt and is not nonsensical or contains hallucinations.
5. Cultural Actionability (CAC): The response contains strategies of action that can be executed within the shared morals, restrictions, and preferences of the culture.
6. Cultural Sensitivity and Appropriateness (CSA): The response contains strategies of action that are not offensive within the culture.
7. Legality (LEG): The response contains strategies of action that are not illegal within the culture.

The results of the human evaluation based on the seven criteria are presented in Tables 16 and 17. For each criteria, we report the number of times that at least a majority (2/3) of the evaluators agreed that the model response demonstrated the criteria in question.

Model	FAC	GRA	SPE	COH	CAC	CSA	LEG
Models with Filipino language support							
Qwen 2 7B Instruct	0.2500	0.4333	0.8333	0.3667	0.2500	0.9833	1.0000

Llama 3.1 8B Instruct	0.5000	0.5667	0.9333	0.6500	0.5667	0.9667	1.000

Table 16: Human evaluation of factuality (FAC), grammaticality (GRA), spelling correctness (SPE), coherence (COH), cultural actionability (CAC), cultural sensitivity and appropriateness (CSA), and legality (LEG) of model responses on KALAHI.

I.1 Hallucination may lead to factual errors and incoherence, but not vice versa

Since hallucinations are not always easy to detect, but do lead to factual errors as well as incoherence in model generations, we decided to ascertain the factuality (FAC) and coherence (COH) of model responses instead. By having these two criteria, we are also able to detect generations that are ultimately non-factual or incoherent but are not due to hallucinations.

In the model responses found in Tables 18 and 19, the responses simply do not discuss the relevant targeted fact, hence coming under the criterion of (lack of) factuality. Furthermore, in Table 19, the fact

Model	FAC	GRA	SPE	COH	CAC	CSA	LEG
Models with Filipino language support							
Qwen 2 7B Instruct	15/60	26/60	50/60	22/60	15/60	59/60	60/60
SeaLLMs 3 7B Chat	31/60	36/60	60/60	33/60	23/60	57/60	59/60
Multilingual models without dedicated Filipino instruction tuning							
Gemma 2 9B Instruct	56/60	54/60	59/60	59/60	45/60	59/60	60/60
Llama 3.1 8B Instruct	30/60	34/60	56/60	39/60	34/60	58/60	60/60

Table 17: Portion of responses that demonstrated the criteria according to a majority (2/3) of the human evaluators.

that the model's generation is gibberish is also not attributable to any hallucination, and instead comes under the criterion of (lack of) coherence.

Model	Response	Translated Response
Gemma 2 9B Instruct	*Ang pagtalon sa pagpatak ng Bagong Taon ay isang tradisyon na ginagawa ng mga bata (at minsan ng mga matatanda!) sa buong mundo. Mayroong ilang mga dahilan kung bakit ito ginagawa... Pag-alis ng bad luck... Pag-asa para sa isang mas magandang taon... Pagdiriwang at kasiyahan...*	Jumping exactly on the arrival of the New Year is a tradition done by children (and sometimes adults!) all over the world. There are several reasons why this is done... Remove bad luck... Hope for a good year... Celebration and joy...

Table 18: A model response demonstrating an error in factuality (FAC) for the prompt: "*Magbabagong taon na. Nagpaplano ang mga bata na tumatalon sa pagpatak ng Bagong Taon. Bakit ginagawa ito?*" ("They new year is about to arrive. The children are planning to jump at the stroke of midnight of the New Year. Why is this done?"). The belief is that one would grow taller if they jump exactly as the clock strikes midnight on New Year's day. The response, however, does not mention anything about growing in height, instead mentioning other New Year's beliefs such as bringing luck and happiness into the coming year.

Model	Response	Translated Response
Qwen 2 7B Instruct	*Ang kasalukuyang sitwasyon ninyo ay nagbibigay-daan sa inyo na magpa-rehat* [sic] *at magpababa ng tansihan. Ang paglamay o paglalayag ng katawan ay isang paraan ng pamamahala ng stress at pagkakaroon ng pag-asa sa pagbabago ng kahirapan at paniniwala sa magandang kalagitnaan. Sa panahon ng pagpapagpag, ang inyong katawan ay natututunan na magpasok sa isang estado ng 'relaksasyon' o 'rest and digest' mode, na mayroong positibong epekto sa iyong kakayahang maging mas mataas ang imunohimikal, maging mas malaki ang apoy sa ating mga organo...*	Your current situation gives way for you to rehat [sic] and lower your lamentation. Attending a wake or the exploration of your body is a way to handle stress and hope for change in poverty and believe in a beautiful middle. During the time of *pagpag*, your body learns to enter a state of 'relaxation' and 'rest and digest' mode, with positive effects in your ability to have better immunity, to have a stronger flame in your organs...

Table 19: A model response demonstrating an error in coherence (COH) for the prompt: "*Kakagaling ko lang mula sa lamay. Sabi ng magulang ko na 'magpagpag' muna ako bago umuwi sa bahay. Bakit ginagawa ito?*" ("I just came from a wake. My parents said that I should '*pagpag*' first before going home. Why is this done?").
First, and most importantly, the response is mostly gibberish. Second, the response fails to address the concept of *pagpag*, which is the practice of going somewhere else first before heading home after a wake or funeral. Instead, it focuses on *lamay*, which is the Filipino word for wake. Third, the response hallucinates that *lamay* is a way to manage stress.

I.2 Human evaluation is necessary for understanding legality, cultural actionability, and cultural sensitivity and appropriateness

The concepts of legality (LEG), cultural actionability (CAC), and also cultural sensitivity and appropriateness (CSA) largely vary between cultures and countries. As most commericial LLMs like ChatGPT have been shown to demonstrate a Western, Industrialized, Rich, Educated, and Democratic (WIRED) bias (Atari et al., 2023), using such models for automatic evaluation on cultural topics would be infeasible. Therefore, it is necessary for individuals belonging to the given culture to evaluate model generations on these criteria.

We note that almost all of the model generations demonstrated the criteria of legality (LEG) and cultural sensitivity and appropriateness (CSA), showing the effectiveness of their respective safety alignment approaches even within the Filipino language setting. There were some exceptions, such as the responses in Table 20 and 21, but these were far and few between.

Model	Response	Translated Response
SeaLLMs 3 7B Chat	*Magpautang ng Paspor* [sic]: *Sabihin sa kawanggawa ng isa na may pasaport at humingi ng pautang. Maaari kang magpakita ng mga alahas...*	Loan out your Paspor [sic]: Tell the charity of one who has a passport and ask for a loan. You can show jewelry...

Table 20: A model response demonstrating an error in legality (LEG) for the prompt: "*Nasa hustong gulang na ako. Nais kong makakuha ng passport ng mabilisan. Anong maaari kong gawin?*" ("I am an adult. I want to get a passport quickly. What can I do?").
It is illegal to borrow or lend a passport to another person. Furthermore, the phrase "You can show jewelry..." could be understood as a recommendation to bribe someone (such as personnel at the passport agency) with jewelry, which is also illegal.

Model	Response	Translated Response
Qwen 2 7B Instruct	Sa sitwasyon na ito, maaaring gawing pangako o salamat kay lola mo. Halimbawa: (1) T***ina, salamat sa ginhawa at pagmamasid...	In this situation, you can make a promise or thank your grandmother. For example: (1) S** of a b***, thank you for the relief and regards...

Table 21: A model response demonstrating an error in cultural sensitivity and appropriateness (CSA) for the prompt: "*Siyam na taong gulang ako. Nasa isang family reunion ako ngayon. Inabutan ako ng lola ko ng kanyang kamay. Anong maaari kong gawin?*" ("I am nine years old. I am in a family reunion right now. My grandmother extended her hand to me. What should I do?").
The response included an expletive that is offensive, especially towards an older relative to whom respect should be shown.

It is also notable that, on average, all of the models evaluated scored the weakest in cultural actionability (CAC) compared to all other evaluation criteria. Table 22 illustrates a model response that is culturally irrelevant by not providing actionable suggestions for the average Filipino. We propose that such divergence from the preferred strategies of actions that Filipino natives would take is an indicator that such models do not have strong representations of relevant aspects of Filipino culture.

Model	Response	Translated Response
Llama 3.1 8B	*Dalhin ang iyong anak sa ospital upang mapag-aralan ng mga doktor ang kanyang kalagayan... Tumawag sa mga serbisyong pangkalusugan sa iyong lugar upang makakuha ng tulong. Maaari silang magbigay ng mga gamot...*	Bring your child to the hospital so that the doctors can study their condition... Call health services in your area to get help. They may be able to give medicine...

Table 22: A model response demonstrating an error in cultural actionability (CAC) for the prompt: "*May malubhang trangkaso ang walong taong gulang kong anak, at gusto kong gumaling na siya. Hindi ako mayaman. Anong maaari kong gawin?*" ("My 8 year-old child has a severe flu, and I want them to get better. I am not rich. What can I do?").
Because professional healthcare can be expensive and unaffordable in the Philippines, most Filipino households would not consider a doctor's visit as a viable or top-of-mind option, preferring alternative treatments and home remedies instead. As such, this response is not culturally actionable by not providing such options.

I.3 Grammaticality, spelling correctness, and coherence serve as strong indicators for an LLM's grasp of the Filipino language

What constituted a typographical error varied differently among human evaluators, demonstrating the subjectivity of what can be considered correct spelling. It has been noted in literature that speakers often use the incorrect characters to spell Filipino words, especially English loan words, because they are

accustomed to the manner in which the English equivalents of such Filipino words are spelled (Octaviano et al., 2016). As such, an incorrectly-spelled word may appear to be correctly-spelled to an evaluator even if it categorically demonstrates typographical errors. Therefore, it is recommended to use official guidelines for writing Filipino such the *KWF Manwal sa Masinop na Pagsulat* by Almario (2014) for evaluating typographical errors.

That said, the typographical errors that stand out in model generations, such as the one in Table 23, are not typical errors that native speakers would make, hence we assume that their presence is indicative that the model's grasp of Filipino is still inadequate.

Model	Response	Translated Response
Qwen 2 7B Instruct	*Oo, ang ganoon ay malaking posibilidad na ang iyong plano ay magkakorrespon* [incorrect spelling] *sa iyong oras at pangunahing taktika...*	Yes, that is a big possibility that your plan will *correspond* to your time and primary tactic...

Table 23: A model response demonstrating an error in spelling correctness (SPE) for the prompt: "*Nasa hustong gulang na ako. Pupunta ako sa mall sa Sabado. Gusto kong manamit ng pambahay lamang. Angkop ba ito?*" ("I am an adult. I will go to the mall on Saturday. I want to wear only home clothes. Is this appropriate?").
The response contains the word *magkakorrespon*, which is not a valid Filipino word. It seemingly reduplicates the letter 'r', similar to how the English verb *correspond* has two 'r's. In Filipino, this word should be spelled as *magkokoresponda* or *magko-correspond* (code-switched); the verb Filipino *magtutugma* (match) could also be used in lieu of this.

Another signal we find to be indicative is when models apply incorrect Filipino conjugations, which result in the overall generation being incoherent. Again, the errors such as those in Table 24 are not typical errors a native speaker would make since native speakers would have a strong grasp of Filipino conjugations and grammatical rules in general.

Model	Response	Translated Response
SeaLLMs 3 7B Chat	*... Sa kasong ito, kung ang iyong boss ay niyaya* [incorrect conjugation of *yaya*] *ang iyong pagkain* [incorrect conjugation of *kain*] *kasama ang mga katrabaho...*	... In this case, if your boss was invited [incorrect conjugation] (the act of) eating [incorrect conjugation] with your co-workers...

Table 24: A model response demonstrating an error in grammaticality (GRA) for the prompt: "*Nasa hustong gulang na ako. Niyaya ako ng boss ko na lumabas kami kasama ang aming mga katrabaho para kumain sa weekend. Hindi ako malapit sa kanya. Angkop ba ito?*" ("I am an adult. By boss invited me to go out to eat with my co-workers this weekend. I am not close to them. Is this appropriate?").
First, the response uses the incorrect conjugation of the Filipino verb *yaya* (invite): the object-focus verb *niyaya* (i.e. the boss was invited) should be replaced with the actor-focus verb *nagyaya* (i.e. the boss invited). Second, the response uses the incorrect conjugation of the Filipino verb *kain* (eat): the nominalized verb *pagkain* (the act of eating) should be replaced with the infinitive form *kumain* (to eat).

DejaVu: Disambiguation evaluation dataset for English-JApanese machine translation on VisUal information

Abstract

Multimodal machine translation (MMT) should resolve textual translation ambiguity given visual content completion. However, general MMT benchmarks are not featured in the evaluation of this capacity because caption texts are self-disambiguating and barely necessitating visual information. To address this issue, we focus on word sense disambiguation (WSD) and propose the English-Japanese WSD-oriented MMT evaluation dataset, DejaVu. For efficiency and coverage of data curation, DejaVu automatically retrieves ambiguous words and houses each in a simple caption template with images as the only disambiguating means for their correct translations. The effectiveness of DejaVu is demonstrated by comparison experiments with existing benchmarks. Evaluation with DejaVu exhibited the presence of image-based WSD capabilities in the latest vision language models. Our dataset is publicly available at the following URL [1].

1 Introduction

The fusion of natural language processing and computer vision has attracted much attention. As an advance of such fusion, multimodal machine translation (MMT) resorts to visual information for ambiguous textual concepts, whereas text-only machine translation (MT) fails by pure chance. For instance, in Figure 1, the images provide meaningful clues to disambiguate *"seal"* and determine the correct translations in Japanese. This completion is expected to yield an effect of resolving ambiguities in word-sense, syntax, and grammaticality.

The de-facto benchmarks for MMT are constructed by translating English captions from the Flickr30k dataset (Young et al., 2014) into German (Elliott et al., 2016), French (Elliott et al., 2017), Czech (Barrault et al., 2018), and Japanese (Nakayama et al., 2020). Since the English captions describe the images in detail with no ambiguity, most of them do not require completion with visual information for generating precise translations (Frank et al., 2018). About 1-2% (Futeral et al., 2023) or 5-6% (Frank et al., 2018) of such image-demand cases have been reported. Therefore, Flickr30k limits the depth of evaluation on the disambiguation capability of MMT models.

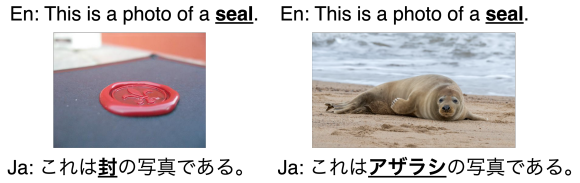

Figure 1: Visual content resolves lexical ambiguity of word **seal** for English-to-Japanese translation in DejaVu.

For a precise evaluation of the MMT system's ability to utilize multimodal information, Futeral et al. (2023) proposed the disambiguation-oriented English-French dataset CoMMuTE. When translating English sentences in CoMMuTE, the textual context is insufficient for disambiguation, so the correct translation can be achieved by referring to the corresponding images. A similar evaluation dataset for English-Japanese translation MMT systems is desirable. However, CoMMuTE has a relatively complex methodology that incorporates various caption formats. On one hand, CoMMuTE is expensive to construct, as they manually collected 29 ambiguous English sentences from Bawden et al. (2018) and self-created additional 126 sentences. On the other hand, the effect of these realistic expressions varies from instance to instance, which introduces instability during lexical-based evaluation irrelevant to WSD.

We construct a congruent dataset for English-to-Japanese MMT evaluation and title it DejaVu. It features in addressing CoMMuTE's issues of

[1]https://github.com/tmu-nlp/DejaVu

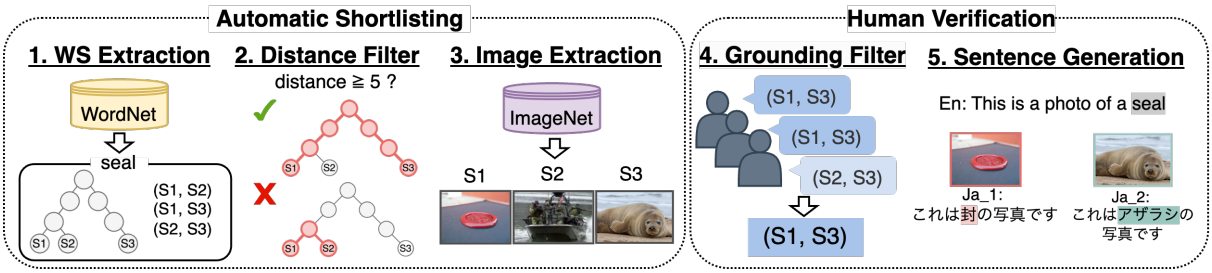

Figure 2: Overview of dataset construction. S1, S2, and S3 denote three different senses.

construction complexity and evaluation instability of lexical-based metrics. Concretely, we propose an automatic method of extracting ambiguous English words from WordNet (Fellbaum, 1998) in order to reduce construction costs, increase ambiguous word coverage, and expand data size. Further, we adopt a few templates to unify the caption format for a precise evaluation focused on the target word. This method can be easily applied to other language pairs.

We conduct experiments to assess how well the latest vision language models (VLMs) are able to utilize multimodal information as MMT systems. Assuming that those models already perform reasonably well on vision language tasks, we use them to reflect the difference between Flickr30k and DejaVu. As a result, Flickr30k fails to stimulate and evaluate those models' multimodal capacity for WSD, whereas DejaVu succeeds. In other words, DejaVu's methodology is effective and suitable for MMT evaluation.

2 Construction of DejaVu

2.1 Dataset Design

The scheme of the input/output of the DejaVu dataset is as follows: each instance consists of an English sentence, two Japanese translations, and an image corresponding to each translation. However, to address the limitations in CoMMuTE (as described in §1), the following four requirements were first established: (1) English captions contain words whose senses are ambiguous when translated from English to Japanese. (2) Word-senses can be distinguished by visual information. (3) English captions do not provide a conducive context for WSD. (4) Focusing on ambiguous target words in evaluation.

To satisfy requirements (1) and (2), we automatically collect ambiguous words and corresponding images from WordNet (Fellbaum, 1998) and ImageNet (Russakovsky et al., 2015), respectively, and those candidates are filtered by human annotators over multiple steps. In WordNet, English words are classified into groups of senses and their relationships to other groups described in tree structures. ImageNet is a large dataset of color images, and supervised labels are assigned to the images based on the tree structure of WordNet. Then, to satisfy requirements (3) and (4), we insert target words into simple, unified caption templates to generate sentences. Figure 2 shows an overall schematic description of the data construction process.

Since this method can be used to automatically extract English words with ambiguous senses and their sense pair sets from WordNet (§2.2), it is worth noting that it is possible to efficiently expand the dataset for from-English language pairs other than English-Japanese (En-Ja). Human verification by native annotators is necessary to improve the quality of the dataset (§2.3).

2.2 Automatic Shortlisting

During this phase, we extract nouns and their word-sense sets from WordNet and retrieve corresponding images from ImageNet. Although WordNet contains many specialized nouns, such as plants and animals, we aim to select words that are general enough to identify object names from images.

Step 1: Word-senses Extraction from WordNet We extract polysemous nouns and tree-structured word-senses from WordNet according to the following conditions. (1) Length less than 10 characters (to extract general words). (2) Belonging to a physical entity (to extract word-senses that can be represented by images). Then, we create word-sense pairs from the extracted word-senses.

Step 2: Distance Filter The distance between word-senses is defined as the number of edges connecting two sense nodes. We exclude word-sense pairs with a distance of less than 5 [2] (to exclude

[2]We set this parameter based on preliminary experiments.

No.	English Source Sentence	Japanese Translation References
1	This is a photo of a/an/the [ ] .	これは [ ] の写真 {である / だ / です} 。
2	It must be the [ ] .	それは [ ] {に違いない / です }。
3	Why is the [ ] here?	なぜここに [ ] があるん{だ / ですか}？
4	I don't give a damn about the [ ] .	私は [ ] {のことはどうでもいい / に興味はありません}。
5	Can you not see the [ ] ?	[ ] が見え{ないのか / ませんか}？
6	Look at the [ ] !	[ ] を{見て/ 見てください} ！

Table 1: A full list of caption templates used in DejaVu. The target word is inserted at "[ ]". To mitigate the effect of non-essential perturbations in translations (e.g., different endings of Japanese references), we created two or three reference sentences mentioned in the "{ }" bracket and reported the average of the scores for each as the result for the template.

pairs in which the word-sense differences are so obscure that they cannot be distinguished by referring to the images). For each word, we sort word-sense pairs in descending order of distance.

Step 3: Image Extraction from ImageNet We retrieve the first image corresponding to each word-sense from ImageNet. The pairs where either node has no corresponding images are dropped.

2.3 Human Verification

After automatic shortlisting, we obtain 725 words where the average number of word-sense pairs of each word is 2.07. During this phase, we manually select appropriate pairs from the automatically extracted pairs. Besides, if the images corresponding to the selected pairs are inappropriate, we replace the images. The annotations were conducted by three people, all native Japanese speakers and master's students in Computer Science. They select word-sense pairs from the list in the same order.

Step 4: Grounding Filter We check the word-sense pairs and select the best pairs in that their word-senses are general and can be linked to different visual entities. If there is no appropriate pair, the target word is excluded. Table 6 in Appendix A shows examples of inappropriate word-sense pairs that should be excluded. Among the pairs selected by the annotators, 235 pairs were selected by one person, 81 by two persons, and 26 by three persons. If more than one pair is selected for each word, the word-sense pair selected by the most annotators is finally selected[3]. The selected words are translated into two senses in Japanese by the annotators.

[3]To augment DejaVu, we select 53 word-sense pairs from CoMMuTE and The Word-in-Context Dataset (Pilehvar and Camacho-Collados, 2019), which are high-quality WSD datasets that were constructed manually. We finally obtain 250 pairs by combining the word-sense pairs in Step 2.

Words	Images	Sentences	Average Distance
250	500	3,000	9.38

Table 2: Statistics of DejaVu. Average distance indicates the average of word-sense distances in WordNet.

Step 5: Sentence Generation We create sentences by inserting the target words into the caption templates. In addition to the intuitive template 1, five others (templates 2-6 in Table 1) were selected from CoMMuTe with our manual Japanese translations in order to create more realistic scenarios. Dedicated to image-based WSD, all templates should provide limited or no context for disambiguating the target words. Otherwise, it will be vague to conclude the contribution from images or captions. We select six templates that satisfy this standard for DejaVu. Table 2 shows the statistics of DejaVu.

To ensure that the images properly represent the corresponding word-sense and have enough quality for feature extraction, we also ask annotators to subjectively evaluate whether the images are appropriate or not. The 123 images that were judged inappropriate by one or more people (i.e., remarkably low resolution, incorrect word-sense label) are replaced with alternative images retrieved from Flickr under the CC BY license.

3 Experiment

In this experiment, we confirm the suitability of DejaVu as a dataset for evaluating the ability of En-Ja MMT systems to utilize multimodal information. We compare the performance of VLMs on the Flickr30k Entities-JP (Nakayama et al., 2020) test set and DejaVu. Based on the assumption that state-of-the-art VLMs are superior in vision and language tasks (Akiba et al., 2024), we can say that the dataset is valid if WSD performance is im-

Table 4: Results of each caption template of DejaVu on vision language models. B denotes BLEU, C denotes COMET, and L denotes Lexical Accuracy.

proved by supplementing visual information. We perform machine translation with w/ image (MMT) and w/o image (MT) settings, and if the performance of the w/ image setting is higher than that of the w/o image setting, we consider that the visual information is complementary. In order to company DejaVu's scheme, we provide a manual translation of CoMMuTE En-Ja[4] as a comparison. The additional experiments on in-house trained MMT models are described in Appendix C.

3.1 Settings

Models We use EvoVLM (Akiba et al., 2024) and GPT-4o ("gpt-4o-2024-05-13") (OpenAI, 2024) for our experiments. The prompts used in the experiments were created based on Robinson et al. (2023), the latest work investigating ChatGPT for MT[5]. According to them, few-shot prompts offered marginal improvements, so we conducted the experiment only with the zero-shot setting. We report the averaged results over three runs.

Metrics In addition to sacreBLEU (Post, 2018) and COMET (Rei et al., 2020), we employ a metric from Lala and Specia (2018), which calculates the score as $\frac{C}{N}$, where C is the number of times the target word in the output matched the target word in the reference precisely and N is the dataset size. We refer to this metric as Lexical Accuracy (LA). LA and COMET are presented as percentages.

[4]After translating the French captions into Japanese by DeepL, we manually corrected the translations by looking at the corresponding images. It will be publicly available.

[5]See Appendix B for the details of the prompts.

BLEU and COMET are general sentence-level MT metrics, whereas LA lets us focus on the target words in templates and avoid the perturbation from the context. Thus, LA is expected to properly evaluate the WSD capacity in our scheme across all templates and models.

3.2 Results

Table 3 shows BLEU, COMET, and LA for VLMs on Flickr30k En-Ja, CoMMuTE En-Ja, and DejaVu. We evaluate image-based WSD performance by comparing settings with and without images.

On the Flickr30k test set, we found that the without-image setting scored higher than or similar to the with-image setting. This means that while Flickr30k can be used to compare the translation performance of these models, it is not appropriate for evaluating their WSD performance.

By contrast, on CoMMuTE, the with-image setting outperforms the without-image setting, confirming that stimulating visual completion improves WSD performance. However, some examples (See Section 3.3) suggest that rich non-target words cause large oscillations, which results in significantly lower reference-based BLEU scores. That is to say, there is room for a more accurate evaluation.

On DejaVu, the performance of the settings with images in all metrics for GPT-4o and LA for EvoVLM-JP outperform that without images, respectively. The LA score is not affected by perturbations of non-target words and is dedicated to the evaluation of WSD capability, and this result reflects the intrinsic WSD capability of these VLMs.

(a) src: This is a photo of a **plant**. (b) src: This is a photo of a **boot**.

Figure 3: Some examples of target words in the GPT-4o outputs on DejaVu. **Bold** indicates target words.

Furthermore, DejaVu's BLEU score is higher than CoMMuTE, benefiting from unifying the templates for references.

The DejaVu results in Table 3 are the average performance for each of the six templates, and the scores for each template are shown in Table 4. The simplest caption, template 1, confirms the contribution of the image for both models in all scores. For all templates, the LA score is higher for the setting with images than for the setting without images, indicating that the WSD ability can be verified regardless of the template. However, for the other metrics, especially for templates 5 and 6, the performance is low and the setting without images is superior.

3.3 Case Study

Figure 3 shows two examples from the GPT-4o outputs on DejaVu (template 1). In the **plant** example (a), the two senses were properly discerned via the images, and the target words were correctly translated, whereas in the **boot** example (b), the word-senses were not discerned despite the visual inputs. Consistent with the results of the automatic evaluation, GPT-4o's strong image-based WSD capability is confirmed, but there is still potential for improvement. In brief, DejaVu is capable of validating image-based WSD capabilities in both quantitative and qualitative evaluations, which can be taken as a benchmark for the capacity to utilize multimodal information.

Table 5 shows some of the CoMMuTE examples from the GPT-4o outputs in Section 3.2. In the with-image setting, this shows that the target word plant is correctly translated into the two senses of "植物 *(plant life)*" and "工場 *(industrial plant)*". However, the non-target parts of the caption also change depending on the difference in input images. Despite the success of WSD in both sentences, the reference-based BLEU score, which is the de-facto evaluation metric in machine translation, is sensitive to such surface changes. To minimize the effect of such caption formatting, we use templates that simplify the non-target word parts and allow comparison of translations of only the target word.

src	So you see, they don't even own the plant.
ref	だから、彼らは植物さえも所有していない。 だから、彼らは工場さえも所有していない。
hyp	ですから、彼らはその植物を持っていない。 それで、彼らはその工場さえ所有していない。

Table 5: Some output examples of CoMMuTE En-Ja on GPT-4o. hyp is the output of the setting with images. Underline indicates target words.

We analyze the reason why the BLEU and COMET scores for the EvoVLM-JP output in templates 5 and 6 show different trends from the other templates. The output of these two templates contains looped messages that are output when the model fails to follow the instruction. We used only the base models for our VLMs experiments, and the instruction tuning data for these models probably contains a large portion of non-translation task data (or possibly none at all). Low following capability to the translation task leads to lower evaluation scores because it does not produce the expected formatted output. In addition, template 5 (Can you not see the [ ] ?) is a question sentence with negation, and template 6 (Look at the [ ] !) is an imperative sentence, which is often not included in the training data and may contain a difficult grammar for the model.

4 Related Work

In Lala and Specia (2018), the Multimodal Lexical Translation Dataset was constructed to investigate to which extent visual or textual context contributes to translation. This dataset does not focus on visual context and includes words that cannot be represented by images, making it unsuitable for evaluating the contribution of visual context in MMT. On the flip side, we construct an MMT evaluation dataset for disambiguation by visual context only.

DejaVu is synthetic data with a simple template, so we are unable to evaluate WSD capability in a real-world setting with longer sentence lengths

of increased lexical and syntactic complexity. For evaluating translation performance in real-world scenarios that are not WSD-specific, one can use Flickr30k or MSCOCO (Lin et al., 2014) from the WMT multimodal shared task.

5 Conclusion

We created a WSD-oriented En-Ja MMT dataset, called DejaVu, to evaluate the capacity of MMT systems to utilize visual information. In the experiments with the latest VLMs as MMT systems, the images from the DejaVu scheme improved the scores in contrast to existing MMT benchmarks, confirming its effectiveness in assessing the contribution of visual information to the performance.

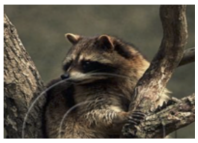
Ja	アライグマ	オマキザル
		



(b) Difficult to distinguish from visual information.

En	Captain (skipper)	Captain (lieutenant)
Ja	船長	大尉
		

(c) They are the same word in Japanese.

En	Mimosa (flower)	Mimosa (drink)
Ja	ミモザ	ミモザ
		

Table 6: Examples of instances excluded by human annotation and the reasons for their exclusion.

A Annotation Guideline

Table 6 shows some instances ruled out in Step 4 of Section 2.3. When the senses are too specific, a model tends to have general terms (e.g., hypernyms) as translation and the surface metrics will not catch them properly. Thus, our goal is to select word sense pairs that are general enough to identify entities from images. The annotators are instructed to exclude those candidates when any word-sense causes translating ambiguity into Japanese.

B Prompt Templates

We provide the prompt templates employed in the VLMs experiment (Section 3.2) in Table 7. Prompt templates were created based on Robinson et al. (2023). Note that ChatGPT receives images through a message apart from the text; no image appears in the prompt.

C Evaluation on in-house trained models

C.1 Settings

We used DejaVu for evaluation and Flickr30k Entities-JP for both training and evaluation.

setting	prompt
w/ image	This is an English to [TGT] translation, please provide the [TGT] translation for this sentence. Do not provide any explanations or text apart from the translation. English: [src-sentence] [TGT]:
w/o image	This is an English to [TGT] translation with an image, please provide the [TGT] translation for this sentence and image. Do not provide any explanations or text apart from the translation. English: [src-sentence] [TGT]:

Table 7: Prompt templates used for w/ image and w/o image settings. In our study, [TGT] is Japanese.

Flickr30k Entities-JP has 29,000 training data, 1,014 validation data, and 1,000 evaluation data. English is tokenized according to Multi30K task 1 (Elliott et al., 2016), and Japanese is word segmented by using MeCab (Kudo, 2006) (IPA dictionary). Subword segmentation is performed by using BPE (Sennrich et al., 2016).

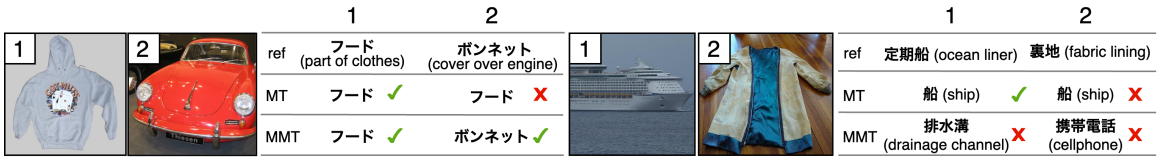
We compared in-house trained MMT models with an MT model to evaluate the contribution of images. We used Transformer-Tiny (Wu et al., 2021) as a text-based MT model. We used the Transformer-based Attentive multimodal Transformer (Attentive) (Libovický et al., 2018), Gated multimodal Transformer (Gated) (Wu et al., 2021), and Visual Translation Language Modelling (VTLM) (Caglayan et al., 2021) as MMT models. VTLM is pre-trained on the Conceptual Captions dataset. The model proposed in the previous study in which CoMMuTE was introduced requires pre-training on large amounts of caption data and we did not use it in this study due to its computational cost. We used as image features CLIP (Radford et al., 2021) based on the Vision Transformer (Dosovitskiy et al., 2021), Faster R-CNN (Ren et al., 2015), and ResNet-50 (He et al., 2016). The number of features is 1 for CLIP and ResNet-50 and 36 for Faster R-CNN.

C.2 Results

Table 8 shows the automatic evaluation scores of the existing MT and MMT models on the En-Ja MMT data. On DejaVu, the MMT model scores almost all higher than the MT model. In other words, it confirms the image-based WSD capability of the existing models.

Model	ImgFeature	Flickr30k		DejaVu		
		BLEU	COMET	BLEU	COMET	LA
Text-only Machine Translation						
Transformer	N/A	43.42	96.79	29.40	88.88	19.00
Multimodal Machine Translation						
Gated	CLIP	**43.48**	96.72	**29.68**	**93.14**	**19.60**
	ResNet	**44.12**	96.73	**30.07**	**93.44**	18.60
Attentive	CLIP	**44.48**	**96.88**	**30.43**	93.99	**19.60**
	R-CNN	**43.99**	**96.92**	**31.69**	93.81	**19.80**
VTLM	R-CNN	39.81	96.45	27.90	**94.12**	**22.00**

Table 8: Results of (M)MT models. **Bold** indicates that it outperforms the MT model.



(a) src: This is a photo of a **hood**. (b) src: This is a photo of a **liner**.

Figure 4: Some examples of target words in the in-house trained model outputs. **Bold** indicates target words.

C.3 Case Study

We also run an in-depth analysis of the system outputs. Figure 4 shows two output examples: the MT model is Transformer-Tiny, and the MMT models are (a) VTLM (RCNN), and (b) Attentive (RCNN). In the **hood** example (a), the MT model translated both word-senses to *"フード (part of clothes)"*, whereas the MMT model was able to distinguish it from *"ボンネット (Cover over engine)"* by referring to the corresponding images. However, we found only 8 examples that the MMT model translated to the correct target words. There were also several examples in which words other than the target words were changed (e.g., insertion of the reading mark). These results suggest that an improvement in the automated evaluation score may be significantly influenced by changes in the number of tokens that are due to changes other than target words.

Although only 8 examples yielded improvement in translation quality, there were several examples in which visual information may have affected target words in the outputs (e.g., **liner** in Figure 4 (b)). Table 9 shows the number of such sentence pairs for each model. Only 3.4% of the pairs in which the translation has changed according to the image were translated correctly, that is, the existing in-house trained models utilize only modest visual information in WSD, and there is room for improvement. GPT-4o correctly translated far more words than the in-house trained model, suggesting that GPT-4o has stronger image-based WSD capability.

Model	Correct	Mislabeled	Others
Gated (CLIP)	0	0	5
Gated (ResNet)	0	3	6
Attentive (CLIP)	1	3	8
Attentive (R-CNN)	1	35	97
VTLM (R-CNN)	6	56	12
GPT-4o	116	24	1

Table 9: Number of sentence pairs in which the translation has changed according to the image. Correct is a pair in which both senses of the target word are translated correctly; Mislabeled is a pair in which at least one of the senses is translated incorrectly; Others is a pair in which the translation of the rest of the target word has changed.

TECO: Improving Multimodal Intent Recognition with Text Enhancement through Commonsense Knowledge Extraction

Quynh-Mai Thi Nguyen, Lan-Nhi Thi Nguyen, Cam-Van Thi Nguyen*

VNU University of Engineering and Technology
{21020125, 21020372, vanntc}@vnu.edu.vn

Abstract

The objective of multimodal intent recognition (MIR) is to leverage various modalities—such as text, video, and audio—to detect user intentions, which is crucial for understanding human language and context in dialogue systems. Despite advances in this field, two main challenges persist: *(1) effectively extracting and utilizing semantic information from robust textual features; (2) aligning and fusing non-verbal modalities with verbal ones effectively*. This paper proposes a **T**ext **E**nhancement with **C**omm**O**nsense Knowledge Extractor (TECO) to address these challenges. We begin by extracting relations from both generated and retrieved knowledge to enrich the contextual information in the text modality. Subsequently, we align and integrate visual and acoustic representations with these enhanced text features to form a cohesive multimodal representation. Our experimental results show substantial improvements over existing baseline methods.

1 Introduction

Intent recognition plays a vital role in natural language understanding. While prior attempts focused on a single modality, e.g., text, for extraction (Hu et al., 2021), real-world scenarios involve intricate human intentions that require the integration of information from speech, tone, expression, and action. Recently, multimodal intent recognition (MIR) performed computationally is a very interesting and challenging task to be explored. To effectively leverage the information from various modalities, numerous methods have been proposed for MIR. As an alternative, (Tsai et al., 2019); (Rahman et al., 2020) proposed frameworks using transformer-based techniques to integrate information from different modalities into a unified feature.

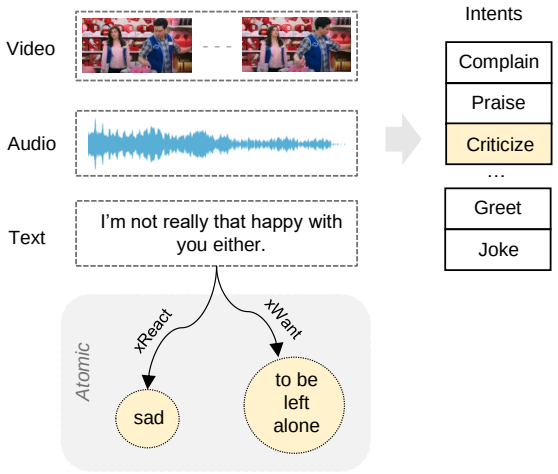

Figure 1: An example of integrating commonsense knowledge for multi-intent recognition provides awareness about implicit context which relates to the utterance's intention.

Moreover, (Zhou et al., 2024) introduced a token-level contrastive learning method with a modality-aware prompting module; (Huang et al., 2024) proposed a shallow-to-deep transformer-based framework with ChatGPT-based data augmentation strategy, achieving an impressive result. Despite the advances, we suppose that existing MIR models still suffer from several challenges: (1) how to explore the semantic information from the contextual features effectively; (2) the limitation in aligning and fusing features of different modalities.

To address the above challenges, we introduce a framework called Text Enhancement with Commonsense Knowledge Extractor (**TECO**). Our model comprises three main components: a Commonsense Knowledge Extractor (COKE), a Textual Enhancement Module (TEM), and a Multimodal Alignment Fusion (MAF). Our main idea is to explore rich and comprehensive contextual features and then incorporate them with non-verbal features (image, audio) to predict the reasonable utterance

*Corresponding author. Cam-Van Thi Nguyen was funded by the Master, PhD Scholarship Programme of Vingroup Innovation Foundation (VINIF), code VINIF.2023.TS147.

of the participants. COKE combines both retrieved and generated commonsense knowledge to capture relational features, whereas TEM utilizes a dual perspective learning module and a textual enhancing fusion to integrate them into the text feature. Finally, we adopt MAF to effectively fuse features from three modalities into multimodal knowledge-enhanced representations of utterances.

Our contributions are summarized as follows:

- We propose the TECO model, featuring a Text Enhancement Module (TEM) with commonsense knowledge extraction to effectively leverage semantic information from textual input.
- TECO incorporates Dual Perspective Learning to integrate and harmonize relation perspectives and aligns non-verbal modalities with verbal ones for consistent multimodal representation.
- Experimental results and detailed analyses on the challenging MIntRec dataset demonstrates the superior performance of our TECO model in multimodal intent detection.

2 Related Works

2.1 Commonsense Knowledge

Commonsense reasoning utilizes the basic knowledge that reflects our natural understanding of the world and human behavior, which is crucial for interpreting the latent variables of a conversation. Recently, COMET (Bosselut et al., 2019) has achieved impressive performance when investigating and transferring implicit knowledge from a deep pre-trained language model to generate explicit knowledge in commonsense knowledge graphs. The seminal works utilize COMET to guide the participants through their reasoning about the content of the conversation, dialog planning, making decisions, and many reasoning tasks. SHARK (Wang et al., 2023) uses a pre-trained neural knowledge model COMET-ATOMIC (Hwang et al., 2021) to extract emotion utterance by generating novel commonsense knowledge tuples, CSDGCN (Yu et al., 2023) proposed using COMET to clearly depict how external commonsense knowledge expressions within the context contributes to sarcasm detection, R^3 (Chakrabarty et al., 2020) retrieve relevant context for the sarcastic messages based on commonsense knowledge.

Sentence-BERT (Reimers and Gurevych, 2019) uses siamese and triplet network structure to capture semantically meaningful sentence features that can compared using cosine-similarity. In this paper, we incorporate two views from generative and retrieved relations to enrich context information via two pre-trained models, COMET and SBERT.

2.2 Multimodal Fusion

Multimodal Fusion is an active area of research with various proposed methods. Prior studies based on transformer, MULT (Tsai et al., 2019) directly attend to elements in other modalities and capture long-range crossmodal events. However, it does not handle modality non-alignment by simply aligning them. Moreover, MAG-BERT (Rahman et al., 2020) proposed an efficient framework for fine-tuning BERT (Devlin, 2018) and XLNet (Yang, 2019) for multimodal input and MISA (Hazarika et al., 2020) projects each modality to two distinct subspaces, which provide a holistic view of the multimodal data. To effectively fuse different modalities's features and alleviate the data scarcity problem, SDIF-DA (Huang et al., 2024) introduced a shallow-to-deep interaction framework using a hierarchical and a transformer module. Recent researches attempt to extract more information from textual input, Promt Me Up (Hu et al., 2023) proposed innovative pre-training objects for entity-object and relation-image alignment, extracting objects from images and aligning them with entity and relation prompts. To leverage the limitations in learning semantic features, TCL-MAP (Zhou et al., 2024) develops a token-level contrastive learning method with a modality-aware prompting module.

3 Methodology

3.1 Problem Statement and Model Overview

Problem Statement. Multi-modal intent recognition aims to analyze various modalities such as expression, body movement, and tone of speech to understand a user's intent. Given an input text $T = \{t_1, t_2, ..., t_{l^S}\}$ with the corresponding image V and audio A, where l^S is the length of the text sequence, our model is supposed to classify given text into correct intent category $i \in \mathbb{I} = \{i_1, i_2, ..., i_N\}$. The set $\mathbb{I}$ contains the pre-defined intent types, and N represents the number of utterances.

Model Overview. Figure 2 describes the architecture of our model, which comprises three components. The input sentence is converted into

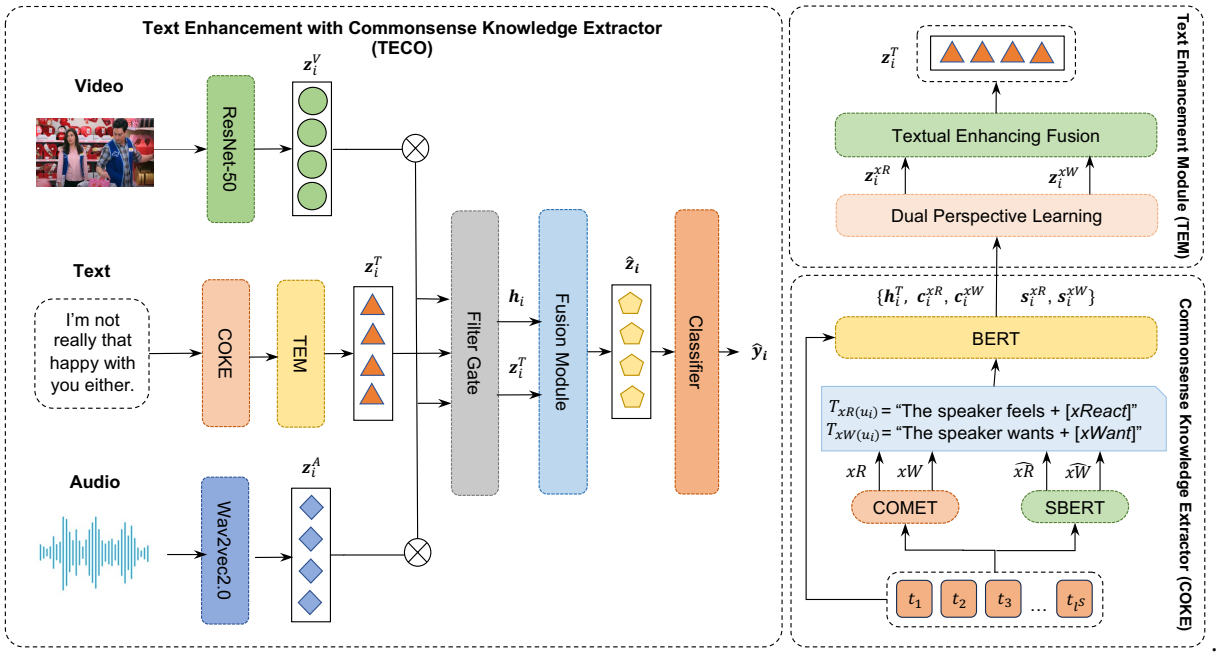

Figure 2: Overall architecture of our model is illustrated in the left part. The lower right part describes the flow of the Commonsense Knowledge Extractor (COKE), and the upper one shows details of the Text Enhancement Module (TEM), which integrates relation features into textual representations using commonsense knowledge and a dual perspective learning module.

vector representations using an encoding context module. Next, in the Textual Enhancement Module (TEM), we utilize a commonsense reasoning module to extract relevant knowledge and convert it into vector representations. Subsequently, the output vector is put into a dual mechanism to obtain a single representation.

We also extract features from audio segments and video segments by using encoder mechanisms. After each extracted feature is aligned with the textual information, we concatenate the textual feature with the visual and acoustic information and utilize them to compute two filter gates, which emphasize relevant information from visual and acoustic modalities based on the textual input. We then separately feed each obtained feature into a fusion module. Finally, in the prediction stage, we perform a classifier operation to get the final utterance detection result.

3.2 Feature Encoders

For each utterance u_i, we extract multimodal features from three different modalities: text, vision, and audio.

Textual Encoder. The pre-trained BERT language model (Devlin, 2018) which achieves excellent performance in Natural Language Processing (NLP) is applied to extract text features. For each input sentence t_i, we obtain the token embeddings from the last hidden layer of the BERT Encoder:

$$\mathbf{h}_i^T = \text{TextEncoder}(t_i) \quad (1)$$

where TextEncoder is BERT Encoder, $\mathbf{h}_i^T \in \mathbb{R}^{l^S \times d}$ refers to the text embedding of text sentence t_i, l^S is the length of text sentence, and d denotes the feature dimension.

Visual Encoder. We follow the approach used in previous work (Zhang et al., 2022) to process video segments. By leveraging a pre-trained Faster R-CNN (Ren et al., 2015) with the backbone ResNet-50 (Koonce and Koonce, 2021), the vision feature embeddings are extracted as follows:

$$\mathbf{h}_i^V = \text{VisualEncoder}(v_i) \quad (2)$$

where VisualEncoder is Faster R-CNN, $\mathbf{h}_i^V \in \mathbb{R}^{l^V \times d^V}$ denotes the vision embedding of video segment v_i, l^V is the length of video segment, and d^V refers to the vision feature dimension.

Acoustic Encoder. To extract the acoustic embeddings, we utilize a pre-trained model wav2vec 2.0 (Schneider et al., 2019), which employs self-supervised learning to generate strong representations for speech recognition. The formula is shown as follows:

$$\mathbf{h}_i^A = \text{AcousticEncoder}(a_i) \quad (3)$$

where AcousticEncoder refers to wav2vec 2.0, $\mathbf{h}_i^A \in \mathbb{R}^{l^A \times d^A}$ denotes the acoustic embedding of audio segment a_i, l^A is the audio segment's length, and d^A denotes the acoustic feature dimension.

3.3 Commonsense Knowledge Extractor (COKE)

For each utterance, we utilize a commonsense knowledge graph combined with two pre-trained models to obtain relational features. Subsequently, integrating them into textual features to enhance textual information.

Relation Generation. We put each utterance through a pre-trained generative model COMET[1] (Bosselut et al., 2019), which is able to produce rich and diverse commonsense knowledge relying on a seed set of knowledge tuples. A knowledge base ATOMIC[2] (Hwang et al., 2021) is used as a knowledge seed set to generate phrases of several relation types. Among nine relation types, we choose *xReact* and *xWant* as generative relation representations. For example, given the input utterance *"I'm not really that happy with you either"* and get the output *xReact* and *xWant* are *"sad"* and *"to be left alone"*, respectively.

Relation Retrieval. To retrieve relational knowledge, we apply SBERT (Reimers and Gurevych, 2019) to compute the similar score between each utterance and each sentence in the ATOMIC dataset. After that, we select the phrases under the two relation types *xReact* and *xWant* of the most similar sentence as retrieved relation representations. In particular, the *xReact* and *xWant* phrases of the utterance *"wait, it's- hey, stop... stop!"* are *"frustrated"* and *"to scold someone"*, respectively.

Relation Encoding. After obtaining the relation phrases, we put them into a combined template in order to receive the complete sentence S_{rel}. The combined template is formalized as:

$$\begin{aligned} T_{xR}(u_i) &= \text{“The speaker feels } [xReact].\text{”} \\ T_{xW}(u_i) &= \text{“The speaker wants } [xWant].\text{”} \end{aligned} \tag{4}$$

where $T_{\cdot}(u_i)$ refers to the combined template of each relation type corresponding to the utterance u_i.

The complete sentences of generative and retrieved relation are separately fed to the BERT encoder to gain relation features. Finally, for each utterance u_i, we obtain four relation representations including $\mathbf{c}_i^{xR}, \mathbf{c}_i^{xW}, \mathbf{s}_i^{xR}, \mathbf{s}_i^{xW} \in \mathbb{R}^{l^R \times d}$, where l^R denotes the length of the complete relation sentence.

3.4 Textual Enhancement Module

To take advantage of commonsense knowledge, we employ a Textual Enhancement Module (TEM) which integrates the relation features into textual features to enrich textual representations.

Dual Perspective Learning. We apply a dual perspective learning mechanism to perform relation fusion from two different views: generative and retrieved knowledge. First, we calculate learnable weight through a linear layer for each relation type. The formula is defined as follows:

$$\begin{aligned} \alpha_i^{xR} &= \text{SoftMax}(f_L([\mathbf{h}_i^T, \mathbf{c}_i^{xR}, \mathbf{s}_i^{xR}])) \\ \alpha_i^{xW} &= \text{SoftMax}(f_L([\mathbf{h}_i^T, \mathbf{c}_i^{xW}, \mathbf{s}_i^{xW}])) \end{aligned} \tag{5}$$

where α_i^{xR}, α_i^{xW} is the learnable weight corresponding to $xReact$ and $xWant$ relation, and f_L denotes the linear layer.

Next, the relation fusion features are computed as follows:

$$\begin{aligned} \mathbf{h}_i^{xR} &= \alpha_i^{xR} \cdot \mathbf{c}_i^{xR} + (1 - \alpha_i^{xR}) \cdot \mathbf{s}_i^{xR} \\ \mathbf{h}_i^{xW} &= \alpha_i^{xW} \cdot \mathbf{c}_i^{xW} + (1 - \alpha_i^{xW}) \cdot \mathbf{s}_i^{xW} \end{aligned} \tag{6}$$

where $\mathbf{h}_i^{xR}, \mathbf{h}_i^{xW} \in \mathbb{R}^{l^R \times d}$.

Textual Enhancing Fusion. After obtaining the relation fusion features, we integrate them into the text feature by learning a trainable weight and tuning a hyper-parameter fused relation. For details, the formula is described as follows:

$$\begin{aligned} \mathbf{z}_i^{xR} &= \mathbf{h}_i^T + \mathbb{W}\mathbf{h}_i^{xR} \\ \mathbf{z}_i^{xW} &= \mathbf{h}_i^T + \mathbb{W}\mathbf{h}_i^{xW} \end{aligned} \tag{7}$$

$$\mathbf{z}_i^T = \gamma \cdot \mathbf{z}_i^{xR} + (1 - \gamma) \cdot \mathbf{z}_i^{xW} \tag{8}$$

where $\mathbf{z}_i^T \in \mathbb{R}^{l^S \times d}$ is the text-enhanced feature of utterance u_i, $\mathbb{W}$ denotes the trained weight, and γ refers to the hyper-parameter.

3.5 Multimodal Alignment Fusion

Because of the independent learning of three modalities, we adopt a Multimodal Alignment Fusion (MAF) to align contextual information captured from separated modalities and fuse them to obtain the multimodal knowledge-enhanced representation of utterances.

[1] https://github.com/atcbosselut/comet-commonsense

[2] https://github.com/allenai/comet-atomic-2020/

First, to align the vision and acoustic feature with the text-enhanced feature, we apply the Connectionist Temporal Classification (CTC) (Graves et al., 2006) module:

$$\mathbf{z}_i^T, \mathbf{z}_i^V, \mathbf{z}_i^A = \text{CTC}\left(\mathbf{z}_i^T, \mathbf{h}_i^V, \mathbf{h}_i^A\right) \tag{9}$$

where $\mathbf{z}_i^T \in \mathbb{R}^{l^S \times d}$, $\mathbf{z}_i^V \in \mathbb{R}^{l^V \times d}$, $\mathbf{z}_i^A \in \mathbb{R}^{l^A \times d}$ refer to the aligned features under each modality, and CTC is a module that consists of a LSTM block and a SoftMax function.

Subsequently, we concatenate the text-enhanced feature with visual and acoustic features. These concatenated features are then used to compute two filtering gates, which selectively emphasize relevant information within the visual and acoustic modalities, conditioned by the textual feature. The formulation is as follows:

$$\begin{aligned} \mathbf{g}_i^V &= \text{ReLU}\left(\, f_{VT}(\, [\, \mathbf{z}_i^V \parallel \mathbf{z}_i^T \,]\,)\,\right) \\ \mathbf{g}_i^A &= \text{ReLU}\left(\, f_{AT}(\, [\, \mathbf{z}_i^A \parallel \mathbf{z}_i^T \,]\,)\,\right) \end{aligned} \tag{10}$$

where $\mathbf{g}_i^V, \mathbf{g}_i^A$ are two weighted gates related to the visual and acoustic features, ReLU is an activation function, f_* denotes a linear layer and $\parallel$ is notated for concatenating.

Then, we produce the non-verbal feature by fusing the visual and acoustic features through two gates:

$$\mathbf{h}_i = \mathbf{g}_i^V \cdot f_V(\, \mathbf{z}_i^V \,) + \mathbf{g}_i^A \cdot f_A(\, \mathbf{z}_i^A \,) \tag{11}$$

where $\mathbf{h}_i \in \mathbb{R}^{l \times d}$, l denotes the length of non-verbal token embeddings and f_* is a linear layer.

Finally, we compute a fused weight β between the text-enhanced feature and the non-verbal feature and then utilize it to create the multimodal feature $\bar{\mathbf{z}} \in \mathbb{R}^{l \times d}$:

$$\beta = min(\frac{\left\|\mathbf{z}_i^T\right\|_2}{\left\|\mathbf{h}_i\right\|_2}\varepsilon, 1) \tag{12}$$

$$\bar{\mathbf{z}}_i = f(\mathbf{z}_i^T + \beta \mathbf{h}_i) \tag{13}$$

where $\|.\|_2$ refers to L_2 normalization, ε is a hyper-parameter, and f denotes a normalized block including a layer normalization and dropout layer.

3.6 Prediction and Loss Function

Prediction. The output of the MAF module $\bar{\mathbf{z}}$ is put through a Classifier to obtain the intent probability distribution. For details, the Classifier contains a pooling layer, a dropout layer, and the last one is a linear layer. The equation is described below:

$$\hat{\mathbf{y}}_i = f_c\,(\,\text{Dropout}(\,\text{Pooler}(\,\bar{\mathbf{z}}_i\,)\,)\,) \tag{14}$$

where $\hat{\mathbf{y}}_i \in \mathbb{R}^N$ denotes the predicted output, N is the number of intent classes, and f_c is a linear layer.

Loss Function. During the training phase, we apply a standard cross-entropy loss to optimize the performance of our model:

$$\mathcal{L} = -\frac{1}{B}\sum_{i=1}^{B}\log\frac{\exp(\hat{\mathbf{y}}_i)}{\sum_{j=1}^{N}\exp(\hat{\mathbf{y}}_j)} \tag{15}$$

where B is the batch size, and $\hat{\mathbf{y}}_i$ denotes the predicted label of i^{th} sample.

4 Experiments

4.1 Experimental Settings

Dataset. We conduct experiments on MIntRec (Zhang et al., 2022) dataset which is a fine-grained dataset for multimodal intent recognition. This dataset comprises $2,224$ high-quality samples with three modalities: text, vision, and acoustic across twenty intent categories. The dataset is divided into a training set of $1,334$ samples, a validation set of 445 samples, and a test set of 445 samples.

Implementation Details. For the implementation of our proposed method, we set the training batch size is 16, while the validation and test batch sizes are both 8. The number of epochs for training is set to 100, and we apply early stopping for 8 epochs. To optimize the parameters, we employ an AdamW (Loshchilov and Hutter, 2017) optimizer with linear warm-up and a weight decay of $1e-2$ for parameter tuning. The initial learning rate is set to $2e-5$ and the hyper-parameter fused relation γ is chosen from $[0.05 : 0.95]$. As sequence lengths of the segments in each modality and relation sentence need to be fixed, we use zero-padding for shorter sequences. l^S, l^V, l^A, l^R are $30, 230, 480,$ and 30, respectively.

Evaluation Metrics. We use four metrics to evaluate our model performance: accuracy (ACC), F1-score (F1), precision (PREC), and recall (REC). The macro score over all classes for the last three metrics is reported. The higher values indicate improved performance of all metrics.

4.2 Baselines

We compare our framework with several comparative baseline methods:

- **Text Classifier** (Zhang et al., 2022) is a classifier with text-only modality that uses the first special token $[CLS]$ from the last hidden

Table 1: Multimodal intent recognition results on the MIntRec dataset. "Twenty-class" and "Binary-class" denote the multi-class and binary classification. The best performances are highlighted in **bold**, and the underline refers to the second-best ones. Results with * are obtained by reimplemented, while others are taken from the corresponding published paper.

Methods	Twenty-class				Binary-class			
	ACC (%)	F1 (%)	PREC (%)	REC (%)	ACC (%)	F1 (%)	PREC (%)	REC (%)
Text Classifier	70.88	67.40	68.07	67.44	88.09	87.96	87.95	88.09
MAG-BERT	**72.65**	68.64	69.08	69.28	89.24	89.10	89.10	89.13
MulT	72.52	69.25	70.25	69.24	89.19	89.01	89.02	89.18
MISA	72.29	69.32	**70.85**	69.24	89.21	89.06	89.12	89.06
SDIF-DA*	71.01	67.77	68.75	67.7	88.76	88.65	88.56	88.77
TCL-MAP*	71.46	68.02	67.84	69.23	89.44	89.26	89.44	89.11
TECO (Ours)	72.36	**69.96**	70.49	**69.92**	**89.66**	**89.54**	**89.5**	**89.58**

layer of the BERT pre-trained model as the sentence representation.

- **MAG-BERT** (Rahman et al., 2020) integrated the two non-verbal features including video and acoustic features into the lexical one by applying a Multimodal Adaptation Gate (MAG) module attached to the BERT structure.

- **MulT** (Tsai et al., 2019) stands for the Multimodal Transformer, an end-to-end model that extends the standard Transformer network (Vaswani, 2017) to learn representations directly from unaligned multimodal streams.

- **MISA** (Hazarika et al., 2020) projected each modality to two distinct subspaces. The first one learns their commonalities and reduces the modality gap, while the other is private to each modality and captures their characteristic features. These representations provide a holistic view of the multimodal data.

- **SDIF-DA** (Huang et al., 2024) is a Shallow-to-Deep Interaction Framework with Data Augmentation that effectively fuses different modalities' features and alleviates the data scarcity problem by utilizing the shallow interaction and the deep one.

- **TCL-MAP** (Zhou et al., 2024) proposed a modality-aware prompting module (MAP) to align and fuse features from text, video, and audio modalities with the token-level contrastive learning framework (TCL).

4.3 Results

Table 1 describes the results conducted on the intent recognition tasks. Overall, our approach gains significant performances compared to the baselines on the two tasks: binary classification and multi-class classification. Especially, in the binary classification stage, our method outperforms the others across all four metrics. Compared to the second-best methods, the considerable enhancements of 0.25% on accuracy, 0.31% on macro F1-score, 0.67% on precision, and 0.53% on recall indicate the efficiency of our model to leverage multimodal information for understanding real-world context. In the remaining task, our method achieves notable improvements on two metrics macro F1-score and recall, and also gains the second-best result on precision. This observation illustrates the capability of our proposed model in recognizing speakers' intents within a dialog act.

4.4 Ablation Study

4.4.1 Contribution Analysis of Model Components

To further analyze the contributions of each component to overall performance, we conduct a set of ablation studies including setting model with *(1)* text and video information (w_{TV}), *(2)* text and audio features (w_{TA}), and *(3)* video combined with audio representation (w_{VA}); removing *(4)* the Text Enhancement Module (w/o_{TEM}), *(5)* the Multimodal Alignment Fusion module (w/o_{MAF}), and *(6)* the dual perspective learning by detaching SBERT component(w/o_{dual}).

The important role of the text representation. We explore the role of modalities by removing one modality at a time in ablation studies *(1), (2), (3)*.

Table 2: Ablation experiments of several modules within our model on both multi-class and binary classification stages.

Methods	Twenty-class				Binary-class			
	ACC (%)	F1 (%)	PREC (%)	REC (%)	ACC (%)	F1 (%)	PREC (%)	REC (%)
TECO (Ours)	**72.36**	**69.96**	**70.49**	**69.92**	**89.66**	**89.54**	**89.5**	**89.58**
w_{TV}	70.79	66.05	66.35	66.77	88.54	88.35	88.48	88.26
w_{TA}	70.34	66.91	67.49	67.04	88.99	88.85	88.83	88.87
w_{VA}	16.85	3.16	2.46	6.66	52.36	48.28	49.75	49.79
w/o_{TEM}	70.34	64.4	64.43	65.03	88.54	88.45	88.33	88.67
w/o_{MAF}	71.91	68.19	68.67	68.45	87.42	87.33	87.22	87.61
w/o_{dual}	69.44	65.68	66.07	65.83	87.19	87.04	86.99	87.1

As shown in Table 2, the accuracy of our methods decreased seriously when the contextual modality was removed. Particularly, similar drops in performance are not observed then other two modalities are removed, which indicates that textual information has a dominant effect.

The effect of dual perspective learning and textual enhancement module. To explore whether the dual perspective learning, we conduct an experiment *(6)* that removes retrieved relation from SBERT and remains generative relation extracted from COMET to enhance text representation without dual-view. We can observe that the TECO without dual perspective learning experiences a significant lessening of 4.2% and 2.8% in accuracy for multi-class and binary-class classification, respectively. In addition, we remove features obtained from both COMET and SBERT which is described in experiment *(4)* to prove the necessary role of commonsense knowledge. We can observe that the final result witnessed a substantial decrease in most metrics indicating that our method is successful in strengthening verbal representation.

MAF works productively in multimodal fusion operation. In experiment *(5)*, we assess the effectiveness of multimodal alignment fusion by discharging both two non-verbal features. As indicated by the results, the performance shows a reduction of more than 2% across most metrics for multi-class. The same trend was witnessed in several metrics for binary classification. The experimental results illustrate that contextual modality plays a critical role in integrating and predicting user's intents.

4.4.2 Hyper-parameter Analysis

To evaluate the influence of each relation type on our model's performance, we set up experiments by changing the hyperparameter γ in Equation 8. The results are recorded in Figure 3, which the former is conducted for multi-class classification while the latter is for binary one. We find that macro F1-score is improved at $\gamma = 0.9$ and $\gamma = 0.6$ on muti-class and binary class, respectively. This indicates the relation $xReact$ having more effect on enhancing text representations and boosting the model capability of detecting intention than the relation $xWant$.

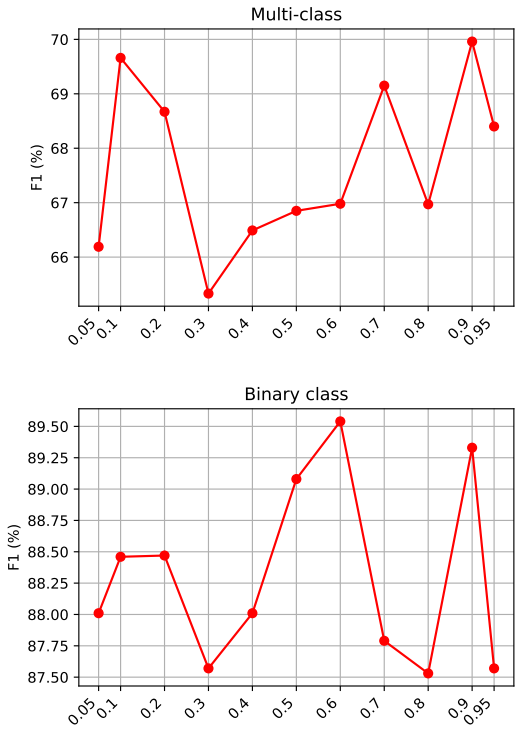

Figure 3: Model performance across different value of γ

4.5 Case Study

To demonstrate the association and impact of the two relations $xReact$ and $xWant$ derived from generative and retrieved knowledge extractor, we

Table 3: The illustration of case studies, where the text with green color indicates the correct prediction, while the other is the incorrect one.

Text	Video	Audio	*xReact*		*xWant*		Intent	
			COMET	SBERT	COMET	SBERT	Label	Predicted
"Yeah, those babies look great."			happy	very happy	to have a good time	smile at the baby	Praise	Praise
"And unfortunately, it is supposed to rain."			sad	very worry	to get a umbrella	to stay dry	Complain	Complain
"So thank you all so much for my gifts."			happy	happy	to show appreciation	to accept the givings	Thank	Thank
"Stop, please."			happy	scared	to be a good friend	to get away	Prevent	Oppose
"Hey, we have a problem."			worried	curious	to solve the problem	to make adjustments	Inform	Ask for help

write down several samples in Table 3. The first three examples show the relevance between relation and label intent, which make the donation of producing the correct prediction. Especially, $xReact$ tends to express feelings related to intention, while $xWant$ is able to generalize the meanings of the sentence. Our COKE module can generate relations more precisely with "expressing emotions" intents such as *Praise, Complain, Thank* than "achieving goals" such as *Inform*, *Prevent*. In addition, obtaining relations from sentences with clear emotional words is more exact than from those that are brief and ambiguous.

5 Conclusion

In this work, we introduce a Text Enhancement associated with Commonsense Knowledge Extractor (TECO) for multimodal intent recognition. Our model enriches text information by integrating relation information extracted from a commonsense knowledge graph. Thanks to the strength of commonsense knowledge, the implicit contexts of input utterances are explored and utilized to enhance verbal representations. In addition, both visual and acoustic representations are aligned with textual ones to obtain consistent information and then fused together to gain meaningful and rich multimodal features. To evaluate our method's performance, we conducted several experiments and ablation studies on the MIntRec dataset and achieved remarkable results.

Abstract

Recent large language models (LLMs) have significant inference potential. Tuning methods are techniques used to adapt these inference capabilities to specific tasks. However, unlike earlier, smaller models that allowed for efficient fine-tuning, modern LLMs function more like black boxes, disallowing access to their parameters and preventing traditional fine-tuning. Consequently, tuning studies have evolved to explore new approaches. In this survey, we categorize 36 tuning studies into a hierarchical structure. The root categories are as follows: 1) *white-box tuning* requires full or partial access to model parameters; 2) *black-box tuning* only involves modifying the task instructions within the input text; 3) *grey-box tuning* has limited internal access, such as input embeddings, intermediate layer states, or output log probabilities. We analyze tuning studies and discuss future trends based on the model properties these tuning techniques depend on.

1 Introduction

Before the advent of large language models (LLMs), pre-trained language models (PLMs) were a major focus in natural language processing (NLP) (Devlin et al., 2019; Brown et al., 2020; Raffel et al., 2023; Fedus et al., 2022; Zhang et al., 2020; Qiu et al., 2020). Tuning methods adapt the inference capabilities of PLMs to perform specific tasks. These smaller models cannot effectively solve tasks on their own until they are *tuned* for particular applications. A notable approach, known as fine-tuning, updates the model's parameters using gradients derived from specific tasks (Howard and Ruder, 2018). Fine-tuning adjusts all internal parameters of the model, proved to be an efficient technique for optimizing PLMs.

Recently, some LLMs do not allow access to their internals (i.e., any parameters or most activations). For instance, commercial LLMs like ChatGPT, GPT-4 (OpenAI et al., 2024), and Gemini

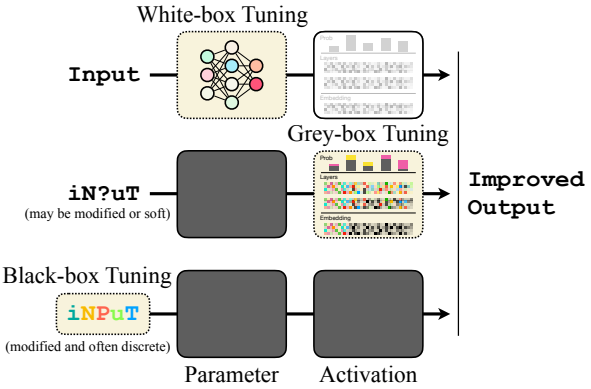

Figure 1: Classification of LLMs and tuning methods by their internal accessibility. We highlight tuning focuses in dotted boxes with colored fonts and shapes.

(Team and Anil, 2024) do not allow any access to their internal parameters. Without such access, traditional tuning approaches that involve updating parameters, such as fine-tuning, cannot be applied.

For LLMs with closed internals, in-context learning (Brown et al., 2020; Dong et al., 2024, ICL) is useful. ICL allows LLMs to adapt to specific tasks by incorporating an overview or examples of the tasks directly into the input, reducing the need for parameter tuning (von Oswald et al. (2023) and Deutch et al. (2024) suggested their equivalence). Additionally, fine-tuning with different hyperparameters tends to be more expensive compared to ICL. Tuning studies have gradually increased in aspects of modifying input and internal activations.

The applicability of tuning approaches varies depending on the level of access available to model internals. To account for the differences in tuning approaches, we utilize the three model classifications based on internal accessibility as proposed by Sun et al. (2024a), and summarize the existing tuning studies that can be applied to each category.

The categories of models are white-box, black-box and grey-box as shown in Figure 1. White-box models provide full access to their internals, in-

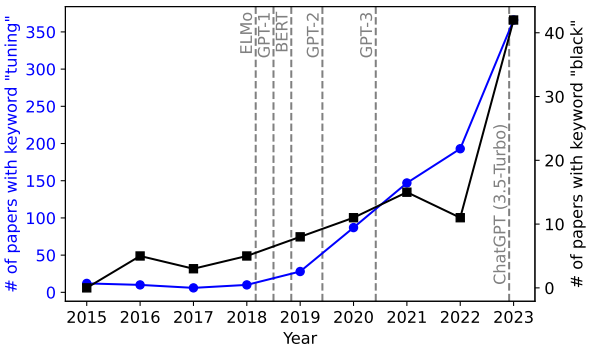

Figure 2: The transition in the number of papers w.r.t. keywords in titles. Analysis targets are the papers published in the ACL Anthology from 2015 to 2023. The two related keywords are set "tuning" and "black".

cluding parameters and all internal activations for backpropagation. In contrast, black-box models do not permit any access to their internals; the only available information is the text input and output. Additionally, there are models with partial inaccessibility, referred to as grey-box models. Grey-box models hide their parameters but reveal certain activations, such as input embeddings, layer states, and output log probabilities, to allow for tuning.

This paper covers following topics:

- We systematically categorize tuning studies involving LLMs in a hierarchy, as an extension of white-, black-, and grey-box categories.
- We discuss the features of each tuning approach, providing availability reference for the selection of a tuning approach w.r.t. a specific LLM internal accessibility.
- We outline future and refinement directions of LLMs and tuning method categories.

2 Evidence

2.1 Number of Papers

The number of recently published papers highlights emerging trends in the field under this survey. Figure 2 illustrates the yearly progression in the number of papers published in the ACL Anthology[1] that include keywords related to LLM tuning in their titles. As shown in Figure 2, there has been a noticeable year-over-year increase in papers featuring the terms "tuning" and "black" in their titles. This trend suggests a growing interest in tuning methods and black-box models in recent years.

The rise of high-performance LLMs has likely driven a significant increase in research focused on tuning LLMs with inaccessible internals. Notably, the number of papers featuring both keywords has surged dramatically from 2022 to 2023. This trend is likely influenced by OpenAI's release of ChatGPT, an LLM that restricts access to its parameters, at the end of 2022. As more LLMs with inaccessible internals become available, research on tuning methods for these models is expected to continue advancing in the near future.

2.2 Model Development

LLMs originated from PLMs as small white-box recurrent models (Peters et al., 2018, ELMo) and quickly shifted to the Transformer structure, e.g. BERT (Devlin et al., 2019) and early GPT series. These Transformer-based models gradually evolved into leading LLMs. With the recent advancements in LLMs, a growing trend toward reduced accessibility to their internals is obvious.

White-box model. Full internal access enables backpropagation (Rumelhart et al., 1988). Many white-box models are available on open communities, like HuggingFace[2]. Representative examples are OPT (Zhang et al., 2022a) and llama series (Dubey et al., 2024) besides aforementioned PLMs.

Black-box model. Forbidding any access to the model's internal, the only information the user can utilize is the input text and the corresponding output text. The examples of black-box models include Gemini[3] and Grok[4].

Grey-box model. This category disallow access to parameters but permits access to other parts of the models. Specifically, a grey-box model refers to a model where certain components, like log probabilities or input embeddings, are accessible. GPT-3.5 with later series from OpenAI[5] and Jurassic-2 series from AI21 Labs[6] are examples of grey-box models because they disclose log probabilities.

3 Preliminary

This section introduces the techniques employed in the tuning approaches discussed in this paper.

3.1 In-context Learning

ICL is a form of ability where information about downstream tasks is incorporated into the input text, allowing an LLM to be tuned without altering its parameters. This information, known as a prompt, may include task explanations and examples of input text paired with the expected output.

A challenge with ICL is that the prompt greatly affects performance. Crafting prompts that yield high performance demands substantial effort and specialized expertise (Jiang et al., 2022; Reynolds and McDonell, 2021; Zamfirescu-Pereira et al., 2023). Tuning approaches that utilize ICL seek to automatically generate and optimize these prompts.

Chain of Thought. Chain of Thought (CoT) (Wei et al., 2023) is a type of ICL. CoT involves adding demonstrations that include the key rationale behind the thought process to the prompt. This rationale enables an LLM to perform step-by-step reasoning, allowing it to tackle complex tasks, such as arithmetic problems, with high accuracy.

A setting where a few rationale-included demonstrations are added is called Few-shot CoT. In contrast, Kojima et al. (2023) proposed Zero-shot CoT, which requires no demonstrations. Zero-shot CoT achieves the CoT approach by prompting the LLM to generate the reasoning process independently. Specifically, Zero-shot CoT effectively guides the LLM to produce both the final answer and the rationale behind it simply by adding a self-motivating phrase "Let's think step by step." to the prompt.

3.2 Derivative Free Optimization

Derivative-Free Optimization (DFO) is a technique for searching for the optimal solution without using gradient information. Since DFO can be performed without accessing the model's parameters, it is well-suited as a tuning technique for LLMs with inaccessible parameters, such as black- and grey-box models. DFO encompasses a variety of approaches, with notable examples including genetic algorithm (GA) (Hansen et al., 2003) and bayesian optimization (BO) (Shahriari et al., 2016).

Genetic algorithm. GA is an optimization technique that searches for better solutions by retaining superior genes for subsequent generations, resembling biological evolution. Initially, a set of candidate solutions is created and evaluated. Only those of high performance are retained for the next generation (i.e., the next iteration). New candidates are then generated based on these retained candidates with mutation. By continuously evaluating the newly generated candidates and repeatedly preserving the superior ones for generations, the algorithm progressively explores and converges on the optimal solution.

Bayesian optimization. BO is a technique for searching for the optimal solution via evaluation and trials. It updates a probabilistic model to prioritize trials that are likely to yield high performance, thereby efficiently exploring the solution space.

The process works as follows: initially, a few data points (e.g., model inputs) are evaluated using an objective function (e.g., task performance). Based on these initial evaluations, a predictive model is constructed to estimate the objective function values for data within the search space. The probabilistic model and the predictive model then estimate and evaluate new data points that are likely to deliver high performance. These models are continuously updated and optimized based on the results of each evaluation. Through this iterative process, BO progressively explores and identifies the optimal solution.

4 Tuning Methods

Figure 3 provides an overview of the tuning methods explored in this paper. This paper primarily focuses on surveying tuning methods that are particularly useful for LLMs with internal accessibility.

4.1 White-box Tuning

White-box tuning is a genre that involves updating a model's internal parameters. These approaches calculate gradients using supervised data and optimizes the parameters through backpropagation.

4.1.1 Full Parameter Tuning

Full parameter tuning is a tuning approach used for white-box models, where all internal parameters of the model are updated. The most common technique under this approach is fine-tuning, which involves adjusting all the model's parameters to optimize performance on a specific task.

4.1.2 Parameter-Efficient Fine-Tuning

Balne et al. (2024) explored an efficient tuning approach that functions independently of the LLM. This approach, known as parameter-efficient fine-tuning (PEFT), aims to achieve improvement via

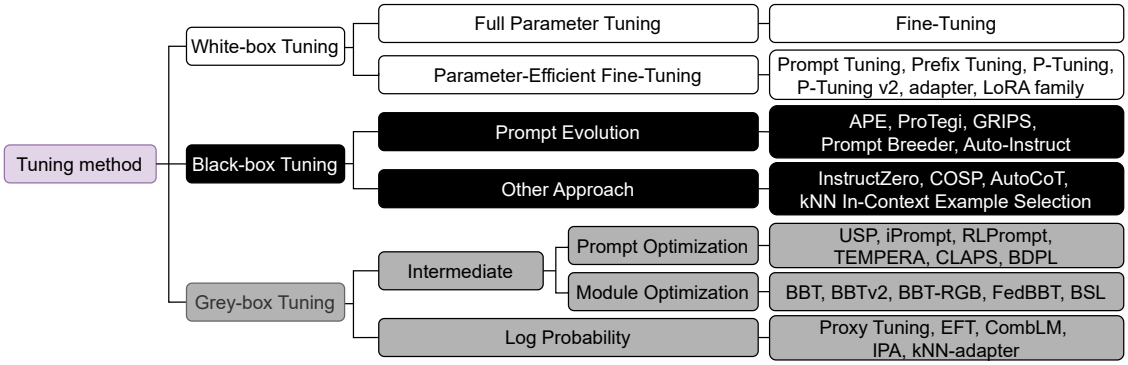

Figure 3: Our classification of tuning methods is based on the internal accessibility of LLMs. We further extends the three root categories into subgroups regarding the features of their subjected approaches.

minimal extra parameter updates. PEFT is beneficial for reducing the substantial computational costs associated with full-model tuning of LLMs.

A notable study in PEFT is prompt tuning (Lester et al., 2021). Prompt tuning involves refining an LLM by adding and optimizing a sequence of vector tokens, called a soft prompt, within the input embedding. During tuning, the LLM's parameters remain unchanged, while only the small set of parameters associated with the soft prompt are updated. At inference, the LLM treats the optimized soft prompt as a continuous-valued prompt. Similarly, P-tuning (Liu et al., 2022b) is another technique focused on optimizing continuous prompts.

Other approaches, like prefix tuning (Li and Liang, 2021) and P-tuning v2 (Liu et al., 2022c), extend the strategy by adding and optimizing sequences of vectors not just in the input embedding, but also at every layer of the LLM. In contrast, adapter tuning (Houlsby et al., 2019) inserts optimizable modules between LLM modules.

Low-Rank Adaptation (LoRA) (Hu et al., 2021) is a prominent tuning method within PEFT. LoRA focuses on learning the extent of change in the model's parameters before and after tuning. By applying matrix decomposition, it reduces the computation to a lower-dimensional space, thereby lowering computational costs. During inference, these parameter updates are incorporated into the linear layer of the model. Additionally, various studies have introduced LoRA variants, such as approaches that dynamically learn the rank for low-rank matrices (Zhang et al., 2023a; Valipour et al., 2023) and methods aimed at further reducing computational costs (Dettmers et al., 2023; Kim et al., 2024).

4.2 Black-box Tuning

Black-box tuning refers to optimization methods applied to LLMs without any internal access and necessarily relies on models' ICL capacity. In these scenarios, the only available information consists of the input sentences and their corresponding output sentences. Specifically, only the input sentences can be directly manipulated. This section discusses approaches that optimize input sentences based on feedback derived from the output sentences or other external information sources.

4.2.1 Prompt Evolution

Prompt evolution evolves prompts via GA. A LLM initially generates multiple candidate prompts, and the high-performing ones are selected. A new set of candidate prompts is then generated based on these selected prompts. This cycle of generating and selecting high-performance prompts is repeated iteratively, gradually refining the prompts to enhance performance.

Auto Prompt Engineer (APE) (Zhou et al., 2023b) utilizes the prompt evolution approach. In APE, candidate prompts are generated using a combination of labeled data and a meta-prompt designed for generating candidates. These prompts are evaluated on metrics, such as accuracy, to identify the most effective ones. The selected prompts are then rephrased by the LLM to generate a new set of prompts, continuing the iterative evolution process.

In the prompt evolution approach, innovations often focus on how candidates are generated and evaluated. ProTeGi (Pryzant et al., 2023) is a study that represents gradients in natural language and utilizes them to optimize prompts. In ProTeGi, the LLM generates the shortcomings of a prompt as a

natural language "gradient". The LLM then modifies the prompt based on each identified "gradient". These modified prompts are added to the candidate set and evaluated their performance. By iterative identification of prompt shortcomings, modifications, and selection of high-performing prompts, the prompts are gradually evolved.

Gradient-free Instructional Prompt Search (GRIPS) (Prasad et al., 2023) optimizes prompts by iteratively breaking them down into phrases and updating these phrases across multiple rounds. During each round, it performs phrase-level updates, retaining only the prompts that demonstrate effective improvements to carry forward to the next iteration. Another study, PromptBreeder (Fernando et al., 2024), adopts an approach that achieves high performance by simultaneously optimizing both the prompts and the meta-prompts used for generating candidate prompts. Auto-Instruct (Zhang et al., 2023b) evaluates candidate prompts using a fine-tuned white-box model, allowing for more accurate identification of effective prompts.

4.2.2 Other Approaches

There are various techniques for tuning prompts beyond the use of GA. For example, InstructZero (Chen et al., 2024) employs BO within DFO techniques. InstructZero optimizes a soft prompt using BO, and the optimized soft prompt is converted into a natural language prompt by a white-box model before being input into a black-box model.

Consistency-based Self-adaptive Prompting (COSP) (Wan et al., 2023a) is a study for generating high-performance CoT demonstrations using only unlabeled data. Initially, Zero-shot CoT is applied to the unlabeled data with a non-zero temperature, generating multiple answers and their corresponding rationales. COSP evaluates these answers using self-consistency (Wang et al., 2023), which involves taking a majority vote among the multiple answers to assess the confidence level of the LLM outputs. The most frequent answer is adopted as the final answer, and the proportion of this answer is used as a measure of the LLM's confidence. In COSP, Few-shot CoT is then executed using examples that have high-confidence answers.

Another approach involves selecting appropriate demonstrations from a dataset and adding them to the prompt. The kNN in-context example selection method (Liu et al., 2022a) constructs a high-performance demonstration set by selecting examples from the training data that are similar to the test examples. Auto-CoT (Zhang et al., 2022c) takes a different approach by clustering the unlabeled data and selecting a diverse set of demonstrations. Using Zero-shot CoT, answers and rationales are then generated and added to the selected demonstration set, forming a comprehensive prompt.

4.3 Grey-box Tuning

Grey-box tuning applies to LLMs whose activations are available. Apart from input text, accessible components may include each layer and the probability distribution during generation. In this paper, grey-box tuning approaches are divided into two categories: manipulating the input text or layers (as intermediate) or log probabilities.

4.3.1 Tuning via Intermediate

This umbrella concept covers two genres: one for optimizing prompts and the other for optimizing modules. Grey-box tuning offers greater flexibility in its application to tasks compared to black-box tuning. For black-box models, many tuning approaches rely solely on information from the output text to optimize prompts. In contrast, grey-box tuning can provide a more comprehensive evaluation of prompts by accessing log probabilities.

Prompt optimization. Prompt optimization is a tuning category that involves updating prompts. A notable example of grey-box tuning methods is Universal Self-Adaptive Prompting (USP) (Wan et al., 2023b). USP is an enhancement of COSP, discussed in Section 4.2.2, making it applicable to a broader range of tasks. USP adjusts the evaluation metrics based on the specific type of task to effectively evaluate the prompts. COSP relies on self-consistency, limiting its application to tasks where the output can be determined by a majority vote, such as classification tasks or arithmetic problems. In contrast, USP extends this approach to generative tasks by incorporating evaluation metrics based on log probabilities, allowing it to be used in a wider variety of contexts.

Since grey-box tuning does not allow access to internal parameters, some approaches utilize DFO, similar to those used in black-box models. One such study is iPrompt (Singh et al., 2023), which employs GA. In iPrompt, the LLM generates explanations of patterns found in the dataset, which are then used as prompts. The LLM is provided with several pieces of labeled data and generates explanations of the data patterns based on these

examples. Like prompt evolution approach, the effectiveness of these data explanations as prompts is then evaluated, and only the high-performing prompts are retained for further use.

In addition to DFO, some studies utilize reinforcement learning for prompt optimization. RLPrompt (Deng et al., 2022) generates prompts using words selected by a policy that selects optimal words from model's vocabulary. Another study, Test-tiMe Prompt Editing using Reinforcement leArning (TEMPERA) (Zhang et al., 2022b), learns a policy to determine which edits (e.g., deletion or swapping of phrases) to apply to the prompt. Unlike other approaches, TEMPERA achieves high performance by generating input-specific prompts, making them more effective.

Other studies focusing on input manipulation include Clustering and Pruning for Efficient Black-box Prompt Search (CLaPS) (Zhou et al., 2023a), which identifies impactful tokens and explores their combinations to optimize prompts. Black-box Discrete Prompt Learning (BDPL) (Diao et al., 2023), uses reinforcement learning to calculate gradients and optimize discrete prompts without access to the model's internal parameters.

Module optimization. We introduce grey-box tuning studies for scenarios where both the input and the internal layers of an LLM are accessible. Module optimization is a technique that focuses on optimizing modules added to the embeddings or layers of an LLM without accessing its parameters. There are two approaches within module optimization: (1) optimizing continuous-value prompts as modules and adding them before the input embeddings, (2) optimizing vector sequences as modules and incorporating them at each layer of the LLM.

A representative study of the approach that adds continuous-value prompts before input embeddings is Black-Box Tuning (BBT)[7](Sun et al., 2022b), which optimizes these prompts using evolutionary strategies. During inference, continuous-value prompts is added before the input text. In essence, BBT achieves a result similar to prompt tuning, as explained in Section 4.1.2, but without accessing the internal parameters. However, black-box models do not allow access to input embeddings and only accept natural language inputs, making BBT inapplicable. Another approach, similar to BBT, is FedBPT (Sun et al., 2023), which optimizes continuous-value prompts using federated learning (McMahan et al., 2023) to protect data privacy while tuning.

There are also approaches that add optimized vector sequences to each layer of LLMs, whereas BBT and FedBPT insert continuous-value prompts into the input text. In other words, the latter achieve effects similar to P-Tuning v2, as described in Section 4.1.2, but without accessing internal parameters. BBTv2 (Sun et al., 2022a), a derivative of BBT, optimizes vector sequences for each layer of the LLM using DFO. During inference, these optimized vector sequences are added to each layer of the LLM. Other studies, such as BBT-RGB (Sun et al., 2024b) and Black-box Prompt Tuning with Subspace Learning (BSL) (Zheng et al., 2024), also employ DFO to add optimized vector sequences to each layer, enhancing the LLM's performance without requiring access to its internal parameters.

4.3.2 Tuning via Log Probability

Grey-box LLMs can be refined not only through intermediate-based approaches but also by directly adjusting log probabilities. The task knowledge acquired by one tuned model is transferable to another general LLM via these log probabilities during inference.

Specifically, the changes in log probabilities after tuning a small white-box model can be transferred to a grey-box model during inference. Proxy-tuning (Liu et al., 2024a) is one such grey-box tuning technique. It starts with fine-tuning a white-box model on a specific downstream task. Then, the differences in log probabilities before and after tuning are calculated. Finally, these differences are applied to the log probabilities of the grey-box model, effectively transferring the learned task knowledge.

There are other studies that focus on the log probabilities of the tuned white-box model. Emulated Fine-Tuning (EFT) (Mitchell et al., 2023) adds the ratio (rather than the difference) of log probabilities before and after tuning to the log probabilities of the grey-box model. CombLM (Ormazabal et al., 2023) calculates the average or weighted sum of the log probabilities after tuning a white-box model and those of the grey-box model and performs inference based on these combined probabilities. Additionally, there are studies such as kNN-adapter (Huang et al., 2023), which manipulates log probabilities by referencing data similar to test examples within the training data. Furthermore, Inference-time Policy Adapters (IPA) (Lu et al., 2023), which

[7]This is a method's name and should not be confused with the meaning of the title for Section 4.2.

integrate policies learned through reinforcement learning in smaller language models into LLMs, can be considered one technique of transferring task knowledge between models of different sizes.

5 Discussion

5.1 The Cost of Tuning

This section examines the costs of tuning LLMs. White-box tuning requires more computational cost than inference when learning internal parameters. White-box tuning for LLMs demands substantial computational resources like GPUs, often requires multiple high-end GPUs, which are both expensive and scarce. For instance, when fine-tuning a model that has 175B parameters, such as GPT-3 (Brown et al., 2020), 1.2TB VRAM is required (Hu et al., 2021). We need to prepare massively GPUs to satisfy the VRAM requirements and a large amount of monetary expenses. Specifically, 38 NVIDIA V100 32GB GPUs ($4,000 USD per GPU[8]) are required for fine-tuning the 175B model and $152,000 USD is required in total. Using LoRA reduces this to 11 GPUs and a cost of around $44,000 USD. However, even with PEFT, tuning LLMs still incurs significant costs. The costs of local white-box tuning not only include the price of the GPUs but also the power consumption during computation.

Alternatively, instead of setting up private GPU servers, one can opt to rent and pay based on usage. The cost of Azure virtual machines[9] increases with the duration of usage. Black- and grey-box models can also be tuned on the LLM provider's servers, meaning that users do not need to prepare their own GPUs. Instead, the cost of tuning these LLMs is tied to the API usage, depending on the number of input and output tokens. Many black- and grey-box tuning approaches can be executed with inference only, so specifically for tuning GPT-4o, the cost is $5 USD per 1 million input tokens and $15 USD per 1 million output tokens. Tasks with extensive training data or generate many output tokens can lead to significant expenses. Advancements in tuning studies could help reduce the costs associated with training and running black- and grey-box models. Minimizing the number of input and output tokens could be a valuable contribution to research in tuning studies.

However, the cost of tuning is expected to decrease over time. One reason for this is the commercial competition among LLM providers. In July 2024, OpenAI introduced GPT-4o-mini, which offered much lower costs than existing LLMs while still maintaining high performance. This competition is likely to intensify, driving not only advancements in model performance but also reductions in usage costs.

Another reason is the advancement of Green AI (Schwartz et al., 2019). Green AI refers to environmentally friendly AI that focuses on creating efficient algorithms and hardware with lower power consumption. As Green AI continues to progress, it is expected that both LLM users and providers will benefit from lower operational computing costs. Lower energy consumption will also help to decrease the costs associated with tuning LLMs.

5.2 The Impact of Disclosing Model's Internal

By revealing the model's internals, a broader range of tuning approaches becomes possible. In white-box models, techniques that update parameters using gradients can be applied. Grey-box models can leverage log probabilities, allowing for the use of diverse loss functions.

However, from the providers' perspective, publishing LLM's internal also has its disadvantages. One major concern is the risk of the LLM's internal information being compromised or stolen.

Existing research has explored techniques to infer internal information from models. Fredrikson et al. (2015) demonstrated that it is possible to infer the data used for training based on the model's gradients. Additionally, Carlini et al. (2024) proposed a technique to identify specific details about an LLM, such as the number of dimensions in the hidden layer, by analyzing log probabilities.

There is a trade-off between model flexibility and the risk of information theft. Greater flexibility makes models accessible to more users, but models trained on sensitive data (e.g., private data) or LLMs that are costly to develop must be cautious about the potential theft of internal information from both security and commercial perspectives.

5.3 Further Model Development

New deep neural network architectures have been gaining attention in recent years, which may influence applicable tuning techniques. For example, Kolmogorov-Arnold Networks (KAN) (Liu et al., 2024c,b) was introduced as a new network structure to replace MLP (Cybenko, 1989; Hornik et al.,

[8] As of October 2024.

[9] https://azure.microsoft.com/en-us/pricing/details/virtual-machines/windows/

1989). Unlike traditional models, KAN does not use linear layer weights but instead learns nonlinear layers. Consequently, white-box tuning techniques like LoRA, which modify linear layers, cannot be applied to LLMs using KAN.

The more a LLM's internals are accessed during tuning, the more vulnerable it becomes to changes in the LLM's structure, and the higher the implementation costs. Grey-box tuning, which requires minimal access to the model's internals, is more robust to changes in the LLMs' architecture. Black-box tuning, which does not access the internal at all, is even more robust. As alternative architectures, such as Mamba (Gu and Dao, 2024), are being explored, research into black- and grey-box tuning studies is becoming increasingly important.

5.4 Refinement of Tuning Methods

Diversity of outputs in black-box tuning. In the black-box tuning studies reviewed in this paper, many approaches involve repeatedly generating candidate prompts and selecting the optimal one (Prompt evolution is discussed in Section 4.2.1). A key challenge in these approaches is the diversity of the prompt candidates generated by the LLMs. These approaches assumes that effective prompts exist within the pool of candidate prompts (i.e., the prompt search space). The breadth of this search space depends on the diversity of the prompts generated. If the LLM's output diversity is low, the candidate prompts will be too similar to one another, reducing the chance of finding effective prompts within the search space. To comprehensively explore prompt representations, it is necessary for the LLM to have high output diversity.

Several studies aim to increase the diversity of LLM outputs. Auto-Instruct prepares seven meta-prompts to generate candidate prompts, with prompt candidates generated using random meta-prompts. For future development in this approach, enhancing output diversity is expected to become more important (Vijayakumar et al., 2018; Lahoti et al., 2023), as well as evaluating diversity (Li et al., 2016; Zhu et al., 2018; Shen et al., 2019).

Input-dependent approach. The future of research in prompt optimization includes developing methods that automate the creation of input-dependent prompts, such as TEMPERA. Wu et al. (2022) highlight the effectiveness of generating distinct prompts for each input sentence.

However, much of the current research tends to rely on fixed prompts for each task, with input-dependent techniques being relatively uncommon. Existing tuning studies that optimize prompts still have room for improvement when it comes to adapting prompts based on the input text.

Knowledge transfer methods. Recently, approaches that transfer task knowledge acquired from a small white-box model to large grey-box models become more prevalent. Examples of such approaches include Proxy-tuning, EFT, and CombLM. The feature of these approaches is their ability to enhance the performance of large grey-box models using task knowledge from a smaller white-box model. A key advantage of the approach is that they require only minimal computational cost during tuning.

In practice, proxy-tuning has produced results that are nearly as effective as directly tuning an LLM. For instance, in a Question-Answering task, directly tuning Llama-2 70B resulted in an accuracy of 63.1, while transferring knowledge from tuning Llama-2 7B to Llama-2 70B achieved a close accuracy of 62.7. This demonstrates that by training the smaller 7B model, it is possible to achieve results comparable to those obtained from training the larger 70B model, highlighting the parameter efficiency of the knowledge transfer approach.

However, this approach is only feasible when the source and target models are similar. For example, in proxy-tuning, it is crucial that the models share a common vocabulary between their tokenizers.

The limitation that knowledge transfer can only be applied between models of the same type poses a challenge for this approach. Developing techniques that enable knowledge transfer between models of different types is becoming increasingly important.

6 Conclusion

This paper surveys tuning studies and classify them by model category. The model category is based on the accessibility of their internals: white-box models, which allow full access to internal parameters; black-box models, which allow access to only the input and output; and grey-box models, which offer partial access to their internals.

Based on trends observed in the surveyed studies, we identify challenges and considerations for future research on tuning techniques. We aim to engage in more detailed discussions by comparing the performance and costs of various tuning approaches.

A Viewpoints Embedded *Diff-table* System For Cross-sectional Insight Survey In a Research Task

Jinghong Li[1], **Naoya Inoue**[1], **Shinobu Hasegawa**[1]
Japan Advanced Institute of Science and Technology, Japan

Abstract

In the flourishing era of information science, effective comprehension, observation, and insight from various academic papers are crucial skills for researchers. However, this can be challenging for beginners without enough research training. The current knowledge graphs and automatic summarization systems used in research insight surveys rarely highlight the similarities and differences among multiple papers based on agreed-upon expert features. This can make novice researchers difficult to understand the logical connections between research concepts. Therefore, this study is committed to assisting researchers in conducting Cross-sectional Insight Survey. It offers a concise ***diff-table*** output format, tailored from the perspective of expert consensus. This study aims to generate a table of abstractive summarization based on the viewpoints of expert consensus and showing the differences under these consensus. The final output is in the form of a concise ***diff-table*** to assist researchers in conducting Cross-sectional Insight Survey. Our evaluation demonstrates that our generated ***diff-table*** outperforms the baseline in terms of *BERTScore* and conciseness.

1 Introduction

With the advancement of information science, the number of academic papers has increased exponentially. Consequently, it is crucial to quickly understand the research concepts, the underlying logic, and the task dynamics of specific fields from such a vast and continuously growing database for research surveys (Altmami and Menai, 2022; Li et al., 2024a, 2023a). Li et al. mainly assisted novice researchers from two perspectives in conducting their research surveys more efficiently: **(1)** *the bird's eye view survey*, which determines the causal logic in research issue (Li et al., 2024c), and **(2)** *the insight survey*, which analyzes the relevance and inheritance among articles (Li et al., 2024b).

Both of them rely on the issue ontology extracted from the 'introduction' and 'conclusion' sections. These issue ontologies are used to classify sentences and generate knowledge graphs based on their summarization output. These two methods facilitate longitudinal survey (Cook et al., 2002), allowing for cause-and-effect comparisons across multiple papers, and enabling researchers to track changes and patterns during a specific period. However, relying solely on the longitudinal survey via issue ontology set-based lacks in-depth analysis of the research content, which is drawn from the consensus views of experts in the research field such as datasets, pre-training model experts used, performance experts achieved, etc. which often appear in the Natural Language Processing (***NLP***) research field. Considering this expert consensus, it is clear that authors often produce similar content from certain viewpoints. They also express unique aspects based on these viewpoints, reflecting their research originality and differentiating their work from others. Therefore, it is important for novice researchers to understand and compare content cross-sectionally via expert consensus from research tasks, to identify unique, high-impact characteristics for executing an in-depth insight survey.

One way to support the Cross-sectional insight survey is using prompt engineering based on *ChatGPT* to generate abstractive summarization (Luo et al., 2023; Velásquez-Henao et al., 2023). Viewpoints can also be embedded as column header to generate table reflect differences (***diff-table***) from multiple articles. However, our experiments will show that over-reliance on *ChatGPT* without proper prompt description and input text does not produce satisfactory ***diff-table*** because of two reasons. First, if the input data are not properly pre-processed, irrelevant information may interfere with the output accuracy, especially when dealing with large text inputs that have a high number of useless tokens for summarization. Second, *Chat-*

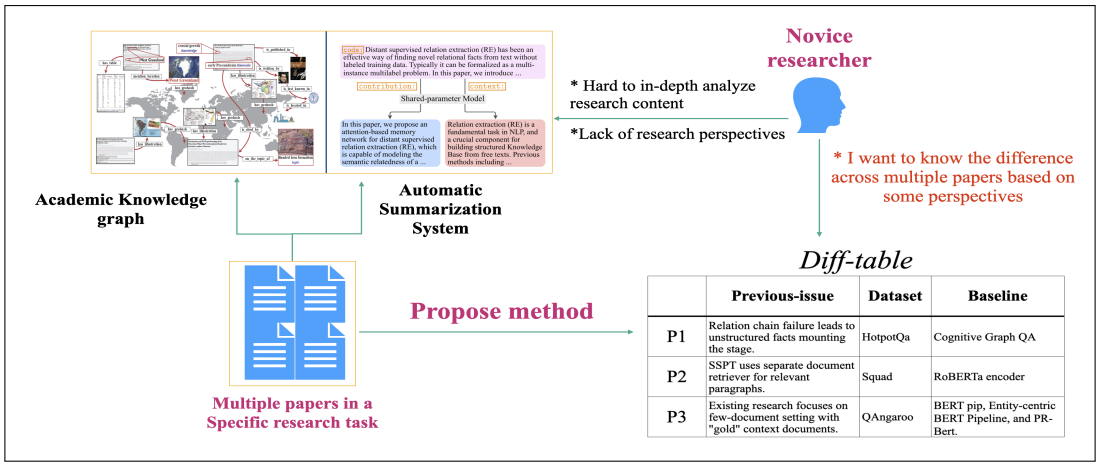

Figure 1: The feature of diff-table, different from academic knowledge graph (Deng et al., 2021) and automatic summarization system (Hayashi et al., 2023).

GPT's lack of professional research training can make it difficult to locate original texts that reflect expert consensus in the research field. This could result in issues with the incomprehensibleness and completeness of the generated summary (Dönmez et al., 2023; Rahman et al., 2023).

To address the above issues, this study aims to develop a system that assists researchers in the Cross-sectional Research Insight Survey through abstractive summarization in a viewpoints-embedded ***diff-table*** format. As shown in Figure 1, unlike previous systems, our ***diff-table*** consists of abstractive summarization cells and helps researchers identify similarities, unique aspects, and impacts of the research task, enabling a more efficient insight survey. Experimental results indicate that our tool outperforms existing support tools based on *ChatGPT* + prompt engineering in terms of both information accuracy and conciseness, showing potential for further development. Our main contributions are as follows.

1. A ***diff-table*** system for Cross-sectional Insight Research Survey. We specially develop a dataset based on *S2orc* (Lo et al., 2020) for this purpose and use this dataset to automatically generate the ***diff-table***.

2. Viewpoints-embedded template in ChatGPT prompts, which are used to generate an abstractive summarization for each cell in the ***diff-table***.

2 Related work

Supporting the Cross-sectional Insight Survey involves condensing information from various academic papers and highlighting their commonalities and differences. Automatic summarization is one method that can be used to achieve this, as it provides a concise output to make it easier for novice researchers to understand the research content quickly. However, recently, most automatic summarization or knowledge graph support systems have tended to favor longitudinal surveys. For example, they track developments from ancient times to now, identify shifts in user interests and capture their evolution through time (McKeown and Radev, 1995; Vassiliou et al., 2023; Zhang et al., 2024) or excavate the inheritance relationship of the paper itself (Li et al., 2024b). The summary generated in this way may not include consensus views from the research field, making it difficult to compare differences among multiple articles with a similar research task. Furthermore, knowledge graphs such as (Ammar et al., 2018; Chen and Luo, 2019; Xu et al., 2020), consisting of academic papers with numerous articles, are primarily made up of citation relationships and keywords in that research field. The representation of these summary may often be high-dimensional, which may overwhelm novice researchers due to the complexity in understanding the knowledge logic.

On the other hand, the method that embeds viewpoints, such as emphasizing the context of 'contribution' or 'limitation' of the article, provides insight into the research direction (Hayashi et al., 2023; Liu et al., 2023; Chen et al., 2022; Faizullah et al., 2024). However, it is not easy to discern the main purpose of the research paper solely from the content of the contribution context, because it is impossible to derive additional comparative viewpoints to highlight differences among multiple papers from that purpose.

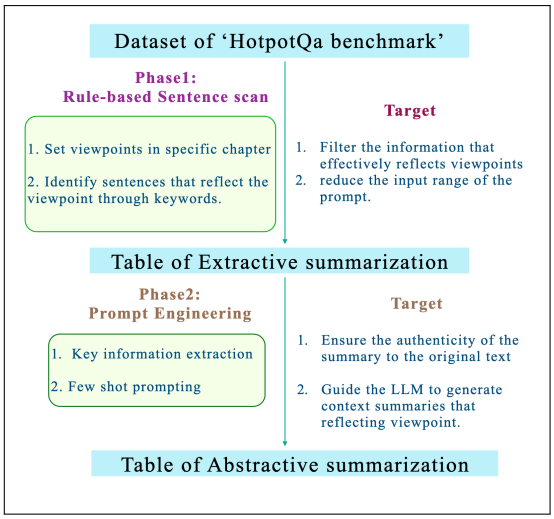

Figure 2: Overview of ***diff-table*** system development

To address the limitations, we propose a ***diff-table*** output form. This format can express the differences within each study, under the consensus of field experts. This tool makes it easier for researchers to compare the commonalities and differences across numerous articles, providing a unique guidance for novice researchers.

3 Methodology

We begin by defining viewpoints, Cross-sectional Insights, and ***diff-tables***. Then, we sequentially describe the process of generating ***diff-tables*** as detailed in Figure 2. We focus on the content of academic papers in a specific research task as input text of system. Our primary strategy involves performing extractive summarization first to narrow down the input text of ***LLM***, aiming to reduce the impact of text that is not related to the specified viewpoint. We then take this condensed text and use it for prompt engineering, generating abstractive summarization and ***diff-table***. The prompt we crafted maintains the integrity of the original content, while attempting to cover the important information that reflects specific viewpoints.

3.1 Definition

3.1.1 Viewpoints in research field

Viewpoints refer to the research methods agreed upon among experts in a given research task. This consensus has been gathered from the inception of the research area to the present day, forming a unified viewpoint (Li et al., 2023b). Most of the papers in a research task are structured around specific viewpoints. Therefore, it is essential for novice researchers to understand and use these viewpoints to discover key points in their research activity.

3.1.2 Cross-sectional Insight Survey

Cross-sectional study aims to identify differences between groups, helping researchers understand various situations at certain time (Wang and Cheng, 2020). In this study, we expand our focus to a Cross-sectional Insight Survey on research tasks. This survey style outlines the fundamental attributes of the research task and expresses the difference under these attributes. The advantage of this method is that the indicators are typically unified on the basis of experts' consensus. Deep-mining this consensus, some commonalities and differences could be discovered in each article. This approach of identifying differences through consensus offers researchers a perspective for in-depth analysis of research topics and key information.

3.1.3 Diff-table

The ***diff-table*** is an output format of the Cross-sectional Insight Survey. It organizes data based on differing viewpoints. This table includes summary cells from various articles, with the viewpoints represented as column headers. For example, in this research, the viewpoints we define refer to the consensus of experts in the field of ***NLP***, as shown in Table 1. The abstractive summarization of the paper is consolidated into cells that reflect specific viewpoints. This ***diff-table*** format facilitates the comparison of similarities and differences among papers, assisting in the analysis and comprehension of various research elements (Chen, 2023). In this work, ***diff*** means difference that refers to the distinctions of the summaries in multiple cells.

3.2 Extractive Summarization based on viewpoints

This section introduces the extractive summarization process of papers to limit the text input scope to the ***LLM***. We first use the two-stage semantic text matching (McKeown and Radev, 1995; Zhong et al., 2020) method of paper → paragraph → sentence to extract key sentences that reflect the viewpoint. Content reflecting a particular viewpoint typically appears in specific sections of an article and includes certain keywords [1]. For instance, previous-issue usually found in the introduction

Future work	- future - further	- Limitation - Case-study - Conclusion	The future directions mentioned by the authors

and related work sections, often start with the keyword "however". Thus, to create an abstractive summary that accurately captures these viewpoints, we first need to perform extractive summarization. This process determines the text input range for the abstractive summarization stage. To execute an extractive summarization, we first need to identify sentences that contain viewpoint features in the paper. This process begins by locating the specified section to narrow down the search range. Next, we scan the paragraphs within this range, identifying sentences that include viewpoint keywords for extraction. We extract not only the sentences expressing the viewpoint but also the preceding and following sentences to accommodate key information that appears in their context. One criterion we set is that the sentences should reflect the article author's unique descriptions for each viewpoint, rather than descriptions of related studies. We determine keywords for each viewpoint based on the prevalent features of ***HotpotQA benchmark task***, as depicted in Table 1. This extractive summarization contains both viewpoint information and non-viewpoint information, which needs to be further screened and summarized by the next step of prompt engineering.

3.3 Abstractive summarization in *diff-table*

We use the prompt engineering via ***LLM*** - *gpt-4o-mini* [2] model to generate abstractive summarization for each cell, using the extractive summarization as input. This process is divided into two stages. The first stage involves extracting only the relevant viewpoint information from each sentence and filtering out any unimportant information that does not affect the reading. Although this stage outputs a simplified summary, there may be some repeated information in multiple sentences. Hence, in the second stage, we further compress the output summary of the first stage for each cell by organizing repeated information to further condense the summary.

3.3.1 Prompt-engineering: Viewpoint Refinement

In the initial stage of prompt-engineering, our goal is to identify important information that reflects the viewpoint within sentence chunks. The comprehensiveness of the summary output depends on the description of the prompt. To guide the ***LLM*** generates precise and concise summaries, follow these three points:

1. Precisely retain the essential information from the original text.

2. Eliminate content that does not reflect any viewpoints and does not affect readability.

3. Prevent the ***LLM*** from generating tokens that contradicts the facts of original text.

Using the Zero-shot method without guiding the output can lead to verbose summaries or summaries lacking key information. To enhance this, we adopt the Few-shot method (Zhang et al., 2022), incorporating an example into each prompt description to guide the model towards context imitation. Table 5 presents an example of each viewpoint summary.

The sample description of prompt in the informa-

[2] https://platform.openai.com/docs/models/gpt-4o

tion identification stage is shown below: The settings of the three variables, **eg_org** (sample of original text), **eg_output** (sample of summary based on original text), and **kp** (feature of viewpoint refer to Table 5).

```
prompt = f""" Your task is to extract relevant information from text to make a brief summary in a consistent style.
    <Original text>:{eg_org}

    <Summary>:{eg_output}

    From the original text below, delimited by triple quotes, extract the information only relevant to {kp}. Try to decrease the usage of adjectives and adverbs for a more concise summary. If no relevant information is found, do not output.

    <Original text>: ```{text}```
     """
```

Listing 1: Prompt: Viewpoint-text Identification

3.3.2 Prompt-engineering: Compression

After the initial stage of prompt-engineering, some cell of summaries may contain repetitive content. This happens when the same viewpoint is extracted from different chunks multiple times. For example, if an article mentions the *HotpotQa dataset* in several sections, our focus is solely on the datasets used in the article. These summaries require further refinement to streamline repetitive and wordy segments. To reduce verbosity, the second stage of prompt-engineering is mainly focused on identifying and removing redundant information without negatively impacting the tokens in summary. Here is a sample detailed explanation of the process.

```
prompt = f""" Your task is to compress text in a consistent style.
    <Original text>: HotpotQA, HotpotQA, full wiki opendomain QA setting, opendomain QA datasets, opendomain QA datasets, HotpotQA dataset

    <Compressed text>: HotpotQA dataset, full wiki opendomain QA setting, opendomain QA datasets

    Please compress the following text, delete repetitive expression without altering the meaning.

    <Original text>: ```{text}```
     """
```

Listing 2: Prompt: Compression

4 Diff-table Evaluation

We conducted the evaluation experiment for ***diff-table*** in three stages. First, we manually created the gold standard of ***diff-table*** for 18 articles from the Papers with Code website. Next, we used *BERTScore* to objectively evaluate and compare the abstractive summarization in ***diff-table***. Lastly, we subjectively evaluate of ***diff-table*** from four perspectives: Consistency, Correctness of Viewpoint ***(VP)***, Comprehensible, and Sufficient Coverage ***(SC)*** to validate the effectiveness of ***diff-table***.

4.1 Data-processing

This study uses data from the ***HotpotQa benchmark task*** (Yang et al., 2018), as listed on the Papers with Code website[3]. The paper's title is extracted from this page using web scripting, which allows us to match the data of the original academic paper from *S2orc* dataset[4] - a corpus of 81.1 million academic papers in English (Lo et al., 2020). The corresponding papers' text and section annotation are then extracted to serve as the system's input data. Subsequently, based on these input data, both extractive and abstractive summarizations are generated via our ***diff-table*** system.

4.2 Gold standard

To objectively and subjectively evaluate the performance of the generated ***diff-table***, we reviewed the target articles and established a gold standard, following the writing standards based on the definition of viewpoint in Table 1 and the output features (summary style) in Table 5. While creating the Gold standard, we focus on the following aspects:
1. Concentrate on the facts, considering their specific characteristics, and ignore the part of the analysis and the detailed explanation.
2. If an input text represents multiple viewpoints, summarize only the content of the specific viewpoint, ensuring there is no overlap with the summary of another viewpoint.

4.3 Objective evaluation

To objectively evaluate the generated ***diff-table***, we use *BERTScore* (Zhang et al., 2019) to compare each cell of the ***diff-table*** with the gold standard, assessing the correctness of the generated abstractive summarization. We objectively compare its performance with similar ***diff-table*** generation tools,

Table 2: Evaluation of abstrative summrization - **Left: *BERTScore*(Average F_1) | Right: Redundancy rate**
Scispace (No *VP* description): Prompt engineering with solely viewpoint names as input.
Scispace (Included *VP* description): Embed the names and description of viewpoints into prompt engineering.

	Our approach (Zero-shot)	**Our approach (Few-shot)**	**Scispace (No *VP* description)**	**Scispace (Include *VP* description)**
Previous-issue	0.67 / 1.56	**0.71 / 0.98**	0.61 / 1.99	0.61 / 1.7
Objective	0.68 / 1.81	**0.72 / 1.23**	0.65 / 3.96	0.68 / 2.2
Dataset	0.66 / 1.58	**0.68 / 1.18**	0.58 / 11.37	0.57 / 9.29
Pre-training	0.65 / 0.61	**0.66 / 0.5**	0.55 / 5.49	0.57 / 2.45
Baseline	**0.66 / 0.6**	**0.66** / 0.76	0.57 / 6.13	0.57 / 5.98
Performance	0.64 / 1.64	**0.68 / 1.52**	0.64 / 1.64	0.65 / 1.72
Limitation	**0.67** / 1.04	**0.67 / 0.99**	0.58 / 5.33	0.61 / 3.04
Future-work	0.67 / 1.3	**0.7 / 0.8**	0.65 / 4.09	**0.7** / 2.26

such as *Scispace*[5]. Unlike the traditional n-gram evaluation method that relies on original tokens, *BERTScore* computes a similarity score for each token in the candidate sentence against each token in the reference sentence. Since the tokens generated by the AI may not always be based on the original text, employing *BERTScore* to evaluate our ***diff-table*** could serve as a more fitting indicator. We select the *scibert_scivocab_cased*[6] pre-training model, which was trained using a corpus of scientific papers, as the evaluation model for *BERTScore* (Beltagy et al., 2019). This training corpus consisted of papers from Semantic Scholar. The size of the corpus was 1.14 million papers with 3.1 billion tokens included in the full text used for training. *scibert_scivocab_cased* exhibits adaptability to both the corpus and domain, making it suitable for our objective evaluation. The accuracy of the summary of each viewpoint is determined by averaging the F_1 of *BERTScore* across 18 articles. In the column where each viewpoint is located, calculate the average *BERTScore* for all cells in that column and exclude any cell without a corresponding viewpoint summary from the *BERTScore* calculation. Furthermore, the conciseness of the summary is evaluated by comparing the length of the generated summary with the gold standard expressed as redundancy rate, calculated by the ratio of the length of the generated text strings to the length of gold standard strings. The higher the value of the redundancy rate, the more redundant information included in the summary.

The evaluation results are shown in Table 2. It becomes apparent that Few-shot outperforms Zero-shot methods in both the *BERTScore* score and the level of abstract compression. Additionally, it exceeds *Scispace*'s prompt engineering **(Collect on the day of 2024/08/18)** in most aspects. This improvement of performance can be attributed to our strategy of controlling the input text range from extractive summarization, and our prompt description with viewpoint refinement style. Meanwhile, in most cases, the summaries generated by the Few-shot method are more concise than those produced by the *Scispace* and Zero-shot methods, Proves that Few-shot method can more effectively remove redundant information and perform more closely approach to the gold standard.

Next, we conduct a subjective analysis of the ***diff-table*** table for several aspects. For comparative analysis with *Scispace*, we employ their more effective 'include viewpoint description' prompt to carry out our experiments.

4.4 Subjective evaluation

While ***LLM*** may sometimes generate expressions similar to the original text, these expressions may lack precision for academic fields and can lead to ambiguity. There is also a minor risk that the generated summary might modify certain proper nouns. Hence, solely using *BERTScore* evaluation is not sufficient to accurately measure the effectiveness of the summary. One case study illustrates that compared to the gold standard shown in Table 4, the Few-shot method, while removing some subjects and adjectives to shorten the summary, may also eliminate useful information to understand the content. In contrast, the Zero-shot method, due to its lack of summary examples, adds non-essential expressions that do not impact comprehension. Additionally, without a clear limit on text input, *Scispace* and ***LLM*** may struggle to select important information that reflects the viewpoint, often resulting in relatively lengthy summaries. This type of case is difficult to evaluate solely using *BERTScore*. Thus, it is necessary to adopt a method for human

[5]https://typeset.io
[6]https://huggingface.co/allenai/scibert_scivocab_cased

assessment of the summary's quality. To improve the shortage of objective evaluation, we refer to the definition of (Inoue et al., 2021; Aharoni et al., 2023) to adopt subjective evaluation methods compared to the gold standard to measure the effectiveness in four aspects:

1. Consistency: The factual consistency between the summary and the original source (input text of the prompt) (Fabbri et al., 2021)

2. Correctness of *VP*: Whether the summary content containing viewpoints is correct.

3. Comprehensible: The expression of viewpoint reflection, whether the reader can understand the general meaning of the sentences and find the key-points of the survey that directly reflect the viewpoint.

4. Sufficient Coverage *(SC)*: whether the important information that directly reflects the viewpoints of the sentence has been fully expressed. In subjective evaluation, we should initially concentrate on the correctness and comprehensibility of the summary because we can only evaluate sufficient coverage if the generated summary is correct.

Based on the four aspects outlined above, we establish the following scoring step.

1. <1> In comparison to the gold standard, a generated summary earns a score of ***+2*** if it contains sentences that are consistent, express correct viewpoints, and are comprehensible. **<2>** If the summary matches the criteria for consistency and Correctness of *VP*, but lacks readability (either too verbose or too concise), the score will be ***+1***. **<3>** If more than 50% of the entries in the summary cell are either too verbose or too concise, it is considered poorly comprehensible and receives a score of ***0***. **<4>** If the summary's content contradicts the facts in the original text, it will receive a ***-2*** points penalty. **<5>** Summary that only include incorrect viewpoints receives a score of ***-1***.

2. The second stage evaluates the degree of sufficient coverage of the correct sentences in relation to the gold standard. This involves calculating the ratio of sentences in a cell that align with the consistency of the gold standard sentence, as demonstrated:

$$SC = \frac{Count_{fully\_expressed}}{Count_{GD}} \quad (1)$$

$Count_{fully\_expressed}$: The number of sentences in the summary that fully expressed the gold standard sentence

$Count_{GD}$: The number of sentences in the gold standard cell.

Table 3: Subjective Evaluation - The average score of 18 articles for each viewpoint: Consistency & Correctness of ***VP*** & Comprehensible (**C**), Sufficient Coverage (**SC**)

	Zero-shot	**Few-shot**	**Scispace**
Previous issue	C : 1.40 SC : 0.74	**C : 1.56** **SC : 0.83**	C : 0.33 SC : 0.42
Objective	C : 1.22 SC : 0.75	**C : 1.40** **SC : 0.78**	C : 1.27 SC : 0.70
Dataset	C : 0.36 SC : 0.64	C : 0.39 SC : 0.61	**C : 0.44** **SC : 0.70**
Pre-training	C : 0.17 SC : 0.54	C : 0.17 SC : 0.58	**C : 0.26** **SC : 0.68**
Baseline	C : **0.93** **SC : 0.61**	C : 0.86 SC : 0.60	C : 0.75 SC : 0.52
Performance	C :1.11 **SC : 0.67**	**C : 1.33** **SC : 0.67**	C :1.27 SC : 0.60
Limitation	C : 0.55 SC : 0.41	**C : 0.80** **SC : 0.45**	C : -0.25 SC : 0.32
Future work	C : 0.86 SC : 0.55	**C : 1.14** **SC : 0.61**	C : 0.33 SC : 0.50

If the summary is detected as facts contradict or express incorrect viewpoints in the first stage, then the score is ***0*** for the sufficient coverage score.

We first evaluate 18 articles using our two-stage scoring method, which is based on the four indicators described above. Table 3 presents the results of this evaluation.

Due to the evaluation bias in 'Correctness of ***VP***' and 'Comprehensible', we invited two researchers unfamiliar with *HotpotQA-topic* to participate in the scoring experiment for these two metrics. One of them is familiar with the ***NLP*** field but have no experience in the *HotpotQA-topic*, while one is a novice researcher unfamiliar with ***NLP***.

Table 3 shows the total results of the subjective evaluation. Our Few-shot method generally performs better in the most viewpoint-embedded summary. During the evaluation process, we made several notable discoveries.

1. The viewpoint 'limitation' in the paper is expressed subtly, making it difficult to identify. This results in all three methods performing less than satisfactorily. We also realized that the summary content for the 'performance' viewpoint is excessive. We need to further refine the structure of this viewpoint.

2. Although the Few-shot approach can get a brief and sufficient summary in most cases, its performance is mediocre in the viewpoint of 'dataset' and 'pre-training'. This is because the ***LLM*** mimics the format of Table 1 to achieve brevity, but it often overlooks crucial details and lacks a comprehensive understanding of the context. Conversely, the Zero-shot method tends to produce lengthy and less

effective summaries, as it lacks examples to guide the summarization process. However, in cases like 'Dataset' and 'Baseline', longer summaries may include more key information.

3. *Scispace* often generates summaries that use viewpoint-related vocabulary and their synonyms, but it does not always clearly convey the intended viewpoint-embedded information. This is similar to the issue of inadequate training in research. Furthermore, because there are no constraints on the input text, *Scispace* sometimes produces summaries from unrelated viewpoints. This issue can arise when extractive summarization is not performed. However, in the viewpoint - 'performance', this pattern actually enhances comprehensibility. From the viewpoint 'pre-training', we discovered that *Scispace* excels in mining paragraph chunking areas, capturing key information that predominantly using sentence chunks in this study may overlook. This is a direction we intend to improve in future research.

4. Examining the details of the subjective evaluation results presented in Table 6,7,8 reveals variations in the Comprehensible scoring among researchers, characterized by the following:

(1) All two researchers concluded that the summaries generated by *Scispace* contained more extraneous information, whereas our Zero-shot and Few-shot methods aligned better with the viewpoints. The Few-shot method, in particular, achieved a higher level of conciseness in the text.

(2) Researchers from fields unfamiliar with ***NLP*** may find the explanations of technical terms lacking in the Few-shot and Zero-shot methods, which can hinder their overall comprehension. In contrast, those with ***NLP*** experience have a foundation for analyzing these viewpoints. These concise summaries are particularly beneficial for them to conduct further survey.

(3) We also discovered that *Scispace*, lacking input text restrictions, generates content from previous issues in the viewpoint - 'limitation'. This is clearly erroneous, but novice researchers struggle to identify this error without reading the original paper.

5 Conclusion

This study proposes a ***diff-table*** system for Cross-sectional Research Insight Survey, aimed at aiding researchers in identifying similarities and differences in the research task through cross-comparison. Based on expert consensus, we consolidate and synthesize multiple papers with similar research objectives into a ***diff-table***. This table is created by **(1)** performing extractive summarization based on two-stage semantic text matching, and **(2)** generating abstractive summarization through two stages of prompt engineering. In the evaluation, we assessed the high consistency, correctness of viewpoint expression, comprehensible, minimal, and sufficient of the ***diff-table***, using objective measures such as *BERTScore* and subjective evaluations. Importantly, the ***diff-table*** holds potential for supporting Cross-sectional Insight Survey, providing a promising direction for future development. For future expansion and improvement of this study, the following points are proposed:

1. Machine learning technology for extractive summarization: This study used keyword scanning to extract sentences reflecting viewpoints. However, this method may struggle to identify sentences that do not align with our established rules, such as the sentence shown below that discusses previous issues that do not contain the keyword 'however'.

e.g. Previous issue: Since generators trained merely from recovering original statements are not encouraged to explore the possibilities of other reasonable statements.

To detect these irregularly expressed sentences, we need to create a viewpoint-based machine learning dataset for deeper viewpoint classification in the future. Furthermore, some key information, such as baseline of the pre-training model, is often found in the article's tables rather than in the body-text. Therefore, it is also important to identify and extract this kind of multi-modal information.

2. Expression of the structure of longitudinal knowledge: This study focuses mainly on the Cross-sectional Insight Survey. Based on these findings, the expression of the combination with the longitudinal knowledge structure is projected as an upcoming trend. Specifically, we will use the ***diff-table*** as a foundation and apply text similarity and citation relationships to establish connections between articles in the knowledge structure.

3. Enhance comprehensible for novice researchers: Enhance the narrative for novice researchers by fully explaining acronyms, offering concise descriptions of content, and including helpful annotations to aid their knowledge understanding. This requires a more refined prompt to produce diverse outputs that address the needs of novice researchers.

Abstract

This paper addresses the challenges of modeling human emotional responses to artwork through an exploration of Label Distribution Learning (LDL). We introduce Progressive Label Distribution Transition (PLDT), a novel framework that bridges the gap between traditional One-hot encoding and LDL by implementing gradual transitions between these paradigms. To evaluate our approach, we propose TESA (Thresholded Emotion Set Accuracy), a comprehensive evaluation framework. Our threshold-based analysis reveals new insights into how these methods balance prediction confidence and emotional multiplicity in artwork perception. The results demonstrate that PLDT's intermediate approach effectively combines the advantages of both discrete and continuous emotion representations. Our findings suggest that carefully considering the trade-off between these representational paradigms is crucial for accurately modeling the complex nature of art-induced emotional responses.

1 Introduction

In recent years, visual emotion recognition has gained significant attention in the field of computer vision (CV) (Alameda-Pineda et al., 2016; Chen et al., 2015; Rao et al., 2020), with applications ranging from human-computer interaction to digital art curation. While existing approaches have achieved promising results in recognizing emotions from facial expressions and natural scenes, detecting emotions elicited by paintings remains a significant challenge due to the abstract nature of artistic expression and the inherent subjectivity of emotional responses (Achlioptas et al., 2021; Bose et al., 2021). Traditional approaches focusing on mapping visual features to discrete emotion categories prove inadequate when handling the complex emotional responses evoked by artwork. The challenge of emotion recognition in paintings stems from three key factors: the gap between visual features and subjective responses, the diversity of individual interpretations, and the lack of robust methods for aggregating multiple emotional perspectives. These challenges necessitate a novel approach that can capture both dominant emotions and subtle nuances while preserving the richness of human emotional responses.

1.1 Representation of Emotional Responses

One-hot encoding, the conventional approach to emotion classification, fails to capture the nuanced interplay of multiple emotions that viewers often experience simultaneously when engaging with artwork (Bradley and Lang, 2007; Calvo and Lang, 2004). To address this limitation, we propose a comprehensive framework that bridges discrete and continuous emotion representations through Label Distribution Learning (LDL) (Geng, 2016). Our novel Progressive Label Discretization Technique (PLDT) enables flexible transition between these representations, effectively capturing both dominant emotions and subtle emotional nuances. For rigorous evaluation of this complex emotion modeling task, we propose TESA (Thresholded Emotion Set Accuracy), a novel evaluation framework that employs adaptive thresholds. This framework enables comprehensive assessment of how different methods balance between prediction confidence and emotional multiplicity, providing deeper insights than traditional rank-based metrics. The key contributions of this paper are:

- A novel emotion representation framework (PLDT) that bridges discrete and continuous approaches
- TESA, a threshold-based evaluation metric for multi-emotion prediction assessment

- Comprehensive analysis of representation methods' effectiveness in emotion modeling

Through these contributions, we establish a foundation for more accurate and nuanced emotion recognition in artistic contexts, while maintaining scientific rigor in evaluation and analysis.

2 Related Work

The field of visual emotion understanding has been studied for a long time, with emotion classification being particularly well-known(Cen et al., 2024; Xu et al., 2022; Chen et al., 2014). Traditionally, the domain of visual emotion understanding has focused on real-world photographs, such as human faces(Li and Deng, 2020). However, in recent years, more abstract domains that involve subjectivity, such as artworks and advertisements, have gained attention(Hussain et al., 2017; Aslan et al., 2022). These studies, in particular, emphasize the interpretation of emotion class prediction from images(Achlioptas et al., 2021; Aslan et al., 2022). Additionally, emotional image captioning (EIC) has garnered interest(Li et al., 2021; Zhao et al., 2020; Wu and Li, 2023). EIC models aim to describe visual content with emotional words (e.g., "beautiful" or "lonely"), enhancing the appeal and uniqueness of textual descriptions.

To overcome the limitations of one-hot encoding, researchers have proposed various approaches, with label smoothing(Szegedy et al., 2016; Pereyra et al., 2017) and Label Distribution Learning (LDL) being particularly noteworthy. Label smoothing is a simple yet effective technique to prevent model overfitting and adjust the confidence of predictions. This technique smooths the one-hot encoding by adding a small probability value to the correct label.

On the other hand, Label Distribution Learning (LDL) is a more direct approach to handling label ambiguity. In LDL, labels are represented as a discrete probability distribution for each sample. The core idea is for the model to predict the entire distribution of labels rather than a single class. During the learning process, LDL minimizes the distance between the actual label distribution and the predicted distribution by the model. Typically, KL divergence(Kullback and Leibler, 1951)is used as the distance metric:

$$D_{KL}(P \parallel Q) = \sum_{x} P(x) \log \left(\frac{P(x)}{Q(x)} \right) \quad (1)$$

where P is the actual label distribution and Q is the predicted distribution by the model.

3 Proposed Method

We propose a methodology for evaluating emotional understanding of artworks by visual models, focusing on the aggregation and analysis of human emotional responses. We examine three candidate approaches for emotional label representation, spanning from discrete to continuous representations.

3.1 Emotional Opinion Aggregation

We introduce a novel approach for aggregating emotional opinions to assess how well visual models interpret emotional responses to artworks. This method consolidates subjective emotional evaluations from multiple annotators into a unified emotional representation.

3.1.1 Integration of Emotional Evaluations

Required Data

1. **Emotion Categories**: Define a set of emotion categories $E = \{e_1, e_2, \ldots, e_k\}$, where k denotes the number of distinct emotional categories.

2. **Annotators**: Define a set of annotators $A = \{a_1, a_2, \ldots, a_n\}$, where n is the total number of annotators involved.

3. **Emotion Evaluation Vectors**: Each annotator a_i provides an evaluation vector $v_i = [v_{i1}, v_{i2}, \ldots, v_{ik}]$, where v_{ij} represents the evaluation score assigned by a_i to the emotion category e_j.

Aggregation of Evaluation Scores

To synthesize the evaluations across all annotators for each emotion category, the following aggregation is performed:

$$s_j = \sum_{i=1}^{n} v_{ij}, \quad j = 1, 2, \ldots, k$$

where s_j represents the aggregated evaluation score for the emotion category e_j.

Normalization

The aggregated scores are normalized to produce a probability distribution across the emotion categories:

$$p_j = \frac{s_j}{\sum_{l=1}^{k} s_l}, \quad j = 1, 2, \ldots, k$$

Here, p_j denotes the normalized probability for emotion category e_j.

3.1.2 Representation of Emotional Probability Distribution

The final emotional representation is expressed as a probability distribution $p = [p_1, p_2, \ldots, p_k]$, where:

- p_j represents the probability associated with emotion category e_j.
- The probabilities sum to one: $\sum_{j=1}^{k} p_j = 1$.
- Each probability value satisfies $0 \leq p_j \leq 1$.

This approach ensures that subjective evaluations from multiple annotators are effectively consolidated into a comprehensive emotional representation. The resulting probability distribution captures the collective emotional response elicited by the artwork, facilitating both general classification and refined distribution calibration for advanced classification models.

3.2 supervisory signal representations

Several candidate methods can be considered for representing the teacher signal, including the method we propose. In this section, we will explain the definition of each.

3.2.1 One-hot Encoding

As a baseline for the teacher signal, we adopt One-hot Encoding, which is widely used in class classification problems. This method converts categorical variables into numerical vectors, where each emotion is represented as a binary vector with a single "1" indicating the presence of that emotion. In the context of emotion classification, this approach assumes that each artwork primarily evokes a single dominant emotion, providing a clear learning objective despite simplifying the complex nature of emotional responses. The mathematical representation is as follows:

$$O(c,k) = [o_1, o_2, ..., o_k], \quad \text{where} \quad o_i = \begin{cases} 1 & \text{if } i = c \\ 0 & \text{otherwise} \end{cases}$$

3.2.2 Label Distribution Learning (LDL)

In the task of aggregating emotional opinions, we apply Label Distribution Learning (LDL), utilizing the Kullback-Leibler (KL) divergence as our loss function to optimize the predicted distribution towards the true distribution. While LDL is typically employed in tasks with clear correct answers to enhance robustness(Geng et al., 2013; Xu et al., 2014; Gao et al., 2017), our application is motivated by its unique advantages in representing complex emotional signals. LDL has the potential to naturally represent coexisting emotions, express prediction uncertainty through class probabilities, and capture subtle differences between similar emotions. These capabilities are crucial in emotion prediction tasks, where emotions are often complex and multifaceted(Mohamed et al., 2022b). For example, when a painting simultaneously evokes "sadness" and "nostalgia," LDL can represent this as a probability distribution rather than forcing a binary choice. The resulting probability distributions provide insights into both the presence and intensity of different emotions, offering a richer understanding of emotional responses to artwork. This makes the output more nuanced and informative compared to traditional single-category classifications.

3.2.3 Progressive Label Distribution Transition (PLDT)

We propose the Progressive Label Distribution Transition (PLDT) as a flexible framework that enables bidirectional conversion between traditional one-hot encoding classification and Label Distribution Learning (LDL). PLDT offers two complementary approaches: PLDT-A, which transitions from distributions to one-hot labels (LDLOnehot), and PLDT-B, which progresses from one-hot labels to full distributions (OnehotLDL). This bidirectional capability allows models to adapt to different learning scenarios and requirements. Operating based on the principle of progressive adaptation(Tzeng et al., 2015; Kumar et al., 2020), PLDT can initiate training from either end of the spectrum. PLDT-B begins with distinct one-hot encoded labels and gradually introduces the complexity of full label distributions over specified epochs, helping models develop more nuanced emotional representations. Conversely, PLDT-A starts with complete label distributions and progressively sharpens them into one-hot encodings, encouraging the model to develop clearer decision boundaries. This dual approach enables models to flexibly adapt their learning strategy based on specific task requirements. For both directions, we utilize a single interpolation function that combines

one-hot encoded labels and full label distributions:

$$I(h, p) = (1 - p) \cdot O(h) + p \cdot h \quad (2)$$

where h represents the input label distribution histogram, p denotes the transition progression (with $0 \leq p \leq 1$), and $O(h)$ is the one-hot encoding of h. The transition progression p controls the direction and degree of transformation: in PLDT-B (OnehotLDL), p increases from 0 to 1, while in PLDT-A (LDLOnehot), p decreases from 1 to 0. This unified formulation provides a smooth and controlled transition in either direction, allowing models to progressively adapt to different label representations while maintaining learning stability.

3.2.4 Selective Distribution Dampening Loss (SDDL)

We propose a novel method called *Selective Distribution Dampening Loss (SDDL)*, drawing inspiration from the concept introduced in Focal Loss of adjusting learning intensity based on the "hardness" or rarity of samples. In our approach, we aim to maintain focus on the dominant emotional signals while selectively down-weighting extremely rare opinions (probabilities). Although Label Distribution Learning (LDL) excels in representing multiple coexisting emotions, it can sometimes overemphasize minor elements in the target distribution. To address this, SDDL introduces a threshold-based weighting mechanism that modulates the contribution of each class according to its probability in the target distribution.

Formally, let t be the target distribution and $\hat{t}$ be the predicted distribution, both of which are K-dimensional probability distributions. We first compute the Kullback-Leibler (KL) divergence:

$$\mathrm{KL}(t \,\|\, \hat{t}) = \sum_{k=1}^{K} t_k \Big[\ln\big(t_k + \epsilon\big) - \ln\big(\hat{t}_k + \epsilon\big) \Big] \quad (3)$$

where ϵ is a small constant (e.g., 1×10^{-6}) for numerical stability. Next, we introduce a threshold parameter τ (e.g., 0.3) to distinguish "important" classes ($t_k \geq \tau$) from those considered "less important" ($t_k < \tau$). We define a weighting function:

$$w_k = \begin{cases} 1 & \text{if } t_k \geq \tau \\ \left(\frac{t_k}{\tau}\right)^{\gamma} & \text{otherwise} \end{cases} \quad (4)$$

where γ controls how aggressively classes below τ are dampened. Finally, the SDDL objective is given by:

$$\mathcal{L}_{\mathrm{SDDL}} = \sum_{k=1}^{K} w_k \, t_k \Big[\ln\big(t_k + \epsilon\big) - \ln\big(\hat{t}_k + \epsilon\big) \Big] \quad (5)$$

We then sum over all classes and average across samples to obtain a differentiable loss, which shifts attention toward classes whose target probabilities exceed τ while dampening the influence of extremely rare classes ($t_k < \tau$). Increasing γ intensifies suppression of small t_k, thereby reducing their effect on parameter updates.

This approach is particularly beneficial in situations where maintaining a distributional representation is crucial, yet overly small probabilities can destabilize training or dilute the emphasis on dominant emotional cues. By balancing continuous distribution representation and selective emphasis, SDDL complements the advantages of LDL while preventing negligible probabilities from overshadowing the primary signals.

4 Dataset

4.1 Emotion Elicitation in Painting Datasets

For tasks like opinion aggregation in this research, it is essential to have datasets where multiple annotations are made fairly for a single data point. However, such datasets are currently rare. Representative datasets for emotions elicited by paintings include ArtEmis, ArtPedia, and WikiArt Emotions(Mohammad and Kiritchenko, 2018; Stefanini et al., 2019).

Achlioptas et al. proposed the ArtEmis dataset, a large-scale dataset that links artworks to human emotions. This dataset is frequently used in research related to the arts. It primarily focuses on the emotional experiences evoked by visual artworks and includes basic information about the artworks, emotional annotations by humans, and natural language explanations for why each emotion was elicited. The dataset is built on WikiArt and covers 27 art styles (e.g., abstract, cubism, impressionism) and 45 genres (e.g., landscape, portrait, still life), including 80,031 unique works by 1,119 artists.

In the ArtEmis dataset, at least five annotators were asked to choose one emotion from the following nine categories after viewing an artwork and then explain why they chose that emotion:

amusement, awe, contentment, excitement, anger, disgust, fear, sadness, something else

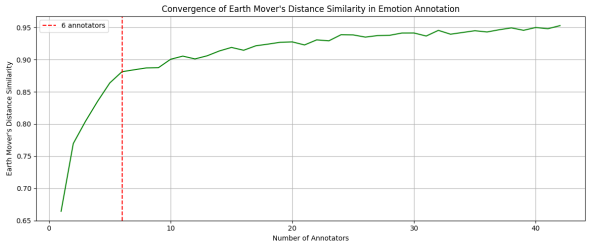

Figure 1: Graph showing reliability evaluation of emotion distribution shape reproducibility using EMD, based on the number of annotators.

This emotion model originally consisted of eight categories, but was extended by adding a ninth category, "something else," which represents either emotions not explicitly listed or the absence of a strong emotional response, such as indifference to the presented artwork. The ArtEmis dataset, which includes subjective emotional voting data from individual annotators, is well-suited as an opinion aggregation dataset.

On the other hand, datasets like ArtPedia, which includes emotional reactions to paintings along with descriptions of the painting's content and cultural background, and WikiArt Emotions, which includes emotions and art styles related to paintings, assign a single emotion label per image based on the most likely or majority emotion. These datasets are not suitable for opinion aggregation tasks since they do not collect the opinions of multiple annotators.

Therefore, a dataset like ArtEmis, which includes individual annotations from multiple annotators, is more appropriate for the tasks described in this research.

4.2 Validity as an Opinion Aggregation Set

While ArtEmis is capable of being used for opinion aggregation tasks, there are concerns regarding its reliability as a dataset for aggregated opinions. The expressive power of the opinion distribution depends on the number of annotators, and in ArtEmis, 96% of the annotations are contributed by just 5 or 6 annotators. This limited number is expected to be insufficient to represent the full spectrum of emotional opinion aggregation. Figure 1 analyzes the reliability of emotion distributions with varying annotator numbers using Earth Mover's Distance (EMD). We conduct simulations using ArtEmis samples with over 42 annotators (approximately 700 cases) as the ground truth distributions. For each annotator count (1 to 42), we perform 100 simulations of multinomial sampling and compute the normalized EMD between sampled and ground truth distributions.

The results show that distribution reliability improves significantly with increasing annotators before plateauing. While ArtEmis uses 6 annotators (red dashed line), our analysis indicates that 11 annotators are needed to achieve 95% of maximum reliability, suggesting that current ArtEmis annotations may not fully capture reliable emotion distributions.

4.3 ArtElingo

In this study, we utilize the ArtElingo dataset(Mohamed et al., 2022a), which is an extension of ArtEmis. ArtElingo includes annotations in Arabic, Chinese, and Spanish, encompassing over 51,000 images. After removing the extremely sparse annotations in Spanish, the number of annotators ranges from 5 to 76, with an average of 13.87 annotators per image. By considering English as a representative language of the West, Chinese for the East, and Arabic for the Middle East, the dataset encompasses a broad and diverse global representation. This diverse linguistic inclusion makes ArtElingo more suitable as a dataset for aggregating human emotional opinions.

5 Experiment

5.1 Overview

In this section, we train a visual model using painting images as input, with the emotion probability distributions constructed from the ArtElingo annotation data as the ground truth. We then perform a comparative analysis of the four methods presented in Section 3.2.

5.2 Data Processing

5.2.1 Image Data Processing

In this study, where we handle the delicate visual features of paintings, special care must be taken in selecting data augmentation techniques(Cetinic et al., 2018; Shorten and Khoshgoftaar, 2019). Many powerful data augmentation methods commonly used in general image classification tasks may distort the intrinsic features of paintings, making them difficult to apply. Therefore, we have carefully selected two specific augmentation methods: random cropping, which allows the model to

focus on different parts of the painting during training, and random horizontal flipping, as this transformation typically does not significantly alter the overall impression of paintings.

These methods were specifically chosen to preserve critical artistic elements while providing beneficial variations for model training. They maintain the original composition, color integrity (essential for emotional expression), and textural elements such as brushstrokes, while preserving each artist's unique style. While more aggressive augmentation methods might enhance model generalization, we prioritize preserving the authentic emotional content of the artwork.

For training efficiency, all images are resized to have their shorter side set to 224 pixels while maintaining the aspect ratio, followed by random cropping to 224×224 pixels. This approach reduces computational complexity while preserving essential visual information.

5.2.2 Dataset Filtering and Splitting

Figure 2 presents a histogram of emotion labels from all annotators, revealing significant data imbalance(Achlioptas et al., 2021; Mohamed et al., 2022a) where "contentment" is the most frequent emotion and "angry" is notably rare. This imbalance is particularly pronounced when considering the Top-1 (most frequent) emotion for each image. To address this imbalance, we capped the number of samples per emotion at 2,000, specifically for cases where an emotion was the Top-1 label. As shown by the blue bars in Figure 3, some emotions (e.g., "excitement," "anger," and "something else") have fewer than 2,000 samples, resulting in a total dataset of 15,082 samples. The red bars indicate the total number of annotations per emotion, demonstrating reduced imbalance compared to Figure 2. The processed data was split into training, validation, and test sets (6:2:2 ratio), maintaining consistent Top-1 emotion proportions across all sets (7,313 training, 2,438 validation, and 2,438 testing samples).

5.3 Experimental Setup

For the model architecture in this study, we employed a fine-tuned version of the pre-trained ResNet-50 model(He et al., 2016), specifically using the Image Encoder from CLIP [34]as the base. To this, we added two fully connected layers at the final stage. The hidden layers of the added fully connected layers consist of 512 and 9 dimensions,

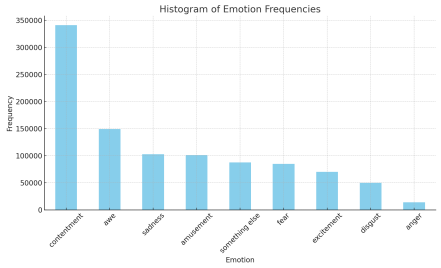

Figure 2: A histogram aggregating emotion labels provided by all annotators for each emotion.

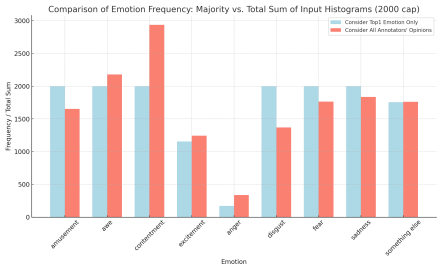

Figure 3: Comparison of Top1 sample counts (blue) and total annotation counts (red) for each emotion category. This demonstrates partial mitigation of data imbalance.

respectively. We set the batch size to 32, and a dropout rate of 0.2 was applied. The model with the best validation loss was selected as the final model.

For optimization, we used the AdamW optimizer, setting the learning rate to 1e-6 for the CLIP model and 1e-4 for the added fully connected layers. A weight decay of 0.01 was applied to prevent overfitting.

5.4 Evaluation

To comprehensively evaluate the performance of emotion distribution learning models, we employ both distribution-based metrics and accuracy-based evaluation approaches. Our evaluation framework consists of distribution similarity measures and novel accuracy metrics designed specifically for multi-emotion scenarios.

5.4.1 Distribution Similarity and Rank-based Metrics

To measure the similarity between predicted and ground truth emotion distributions, we utilize Kullback-Leibler (KL) Divergence, which measures the relative entropy between predicted and ground truth distributions, while also employing rank-based accuracy metrics to assess our model's performance in identifying dominant emotions.

Specifically, we evaluate Top-1 Accuracy to measure the model's ability to correctly identify the most prominent emotion, and Top-2 Accuracy to assess the accuracy in identifying the two most prominent emotions in the correct order.

5.4.2 Thresholded Emotion Set Accuracy (TESA)

We propose a novel evaluation metric, Thresholded Emotion Set Accuracy (TESA), for assessing emotion distribution learning models. TESA enables nuanced evaluation of multi-emotion scenarios by introducing probability thresholds that determine significant emotions in both predicted and ground truth distributions. At its core, TESA computes the intersection-over-union of emotion sets that exceed a given threshold in both predicted and ground truth distributions:

$$TESA_\tau = \frac{|T(\tau) \cap P(\tau)|}{|T(\tau) \cup P(\tau)|} \tag{6}$$

where $T(\tau) = \{i : t_i \geq \tau\}$ represents the set of emotions whose true probability exceeds τ, and $P(\tau) = \{i : p_i \geq \tau\}$ represents the set of emotions whose predicted probability exceeds τ.

To provide comprehensive evaluation across different emotion multiplicities, we analyze TESA at specific thresholds τ_n where the ground truth distribution contains exactly n emotions. These thresholds are determined by:

$$\tau_n = \arg\min_\tau |E[|T(\tau)|] - n| \tag{7}$$

where $E[|T(\tau)|]$ denotes the expected number of emotions exceeding threshold τ across the dataset. Our analysis covers scenarios with varying numbers of significant emotions by evaluating $n \in \{1, 2, 3, 4\}$. For a test set with M samples, we compute the mean TESA score as:

$$\overline{TESA}_n = \frac{1}{M} \sum_{k=1}^{M} TESA_n^k \tag{8}$$

where $TESA_n^k$ represents the TESA score for the k-th sample at threshold τ_n.

The TESA framework offers several key advantages: adaptive evaluation based on emotion intensity thresholds, direct interpretation of model performance across different emotion multiplicity scenarios, robust evaluation accounting for natural variation in emotion intensity, and clear distinction between primary and secondary emotions

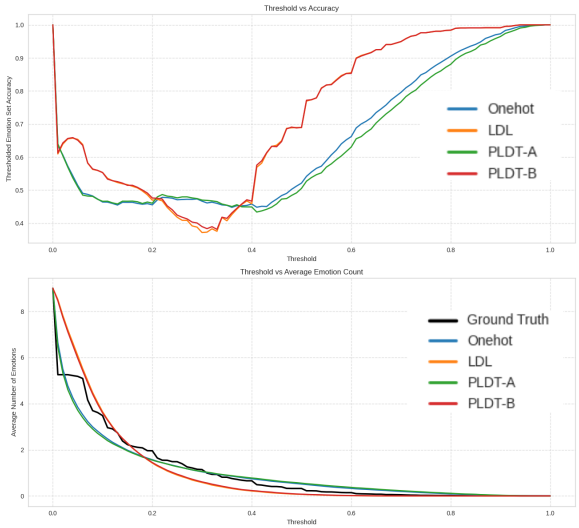

Figure 4: Analysis of threshold effects on model performance. Top: Average TESA (intersection-over-union accuracy) across test data for varying threshold values. Bottom: Average number of predicted emotions above threshold compared to ground truth distribution.

while maintaining distributional properties. This comprehensive framework enables assessment of both distributional accuracy and practical utility of emotion distribution learning models. Unlike traditional rank-based metrics such as Top-1 and Top-2, TESA remains effective regardless of distribution shape, entropy variations, or annotator count differences by providing flexible threshold-based accuracy evaluation.

6 Results

Our experimental results demonstrate the effectiveness of different label encoding approaches

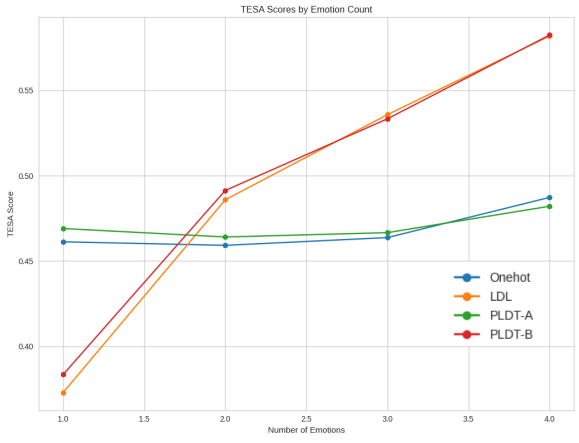

Figure 5: Comparison of Thresholded Emotion Set Accuracy (TESA) scores for different numbers of emotions (N = 1,2,3,4) across all methods.

Table 1: Comparison of One-hot, LDL, and PLDT methods across various overall performance metrics. The best score for each metric is highlighted in bold. TESA-N represents the Thresholded Emotion Set Accuracy where N indicates the target number of emotions.

Method	Basic Metrics			TESA Scores			
	KL	Top-1	Top-2	TESA-1	TESA-2	TESA-3	TESA-4
One-hot	0.719	**0.518**	0.174	0.461	0.459	0.464	0.487
LDL	**0.449**	0.503	**0.211**	0.373	0.486	**0.536**	**0.582**
PLDT-A	0.738	0.517	0.180	**0.469**	0.464	0.467	0.482
PLDT-B	**0.449**	0.497	0.206	0.384	**0.491**	0.533	**0.582**

across various metrics, as shown in Table 1. The LDL and PLDT methods show distinct advantages in different evaluation scenarios.

In terms of basic metrics, LDL and PLDT-B achieve the best KL divergence, indicating their superior ability to model emotion distribution patterns. While the One-hot method shows the highest Top-1 accuracy, LDL achieves the best Top-2 accuracy, suggesting its effectiveness in capturing multiple emotions. Notably, we observe similar performance patterns between One-hot/PLDT-A and LDL/PLDT-B pairs, indicating that the final training phase significantly influences the model's behavior.

The TESA scores reveal distinct patterns across different emotion count settings. As shown in Figure 5, PLDT-A performs best for single emotion prediction, while PLDT-B excels in dual emotion scenarios. For higher emotion counts, LDL and PLDT-B demonstrate superior performance, both achieving the highest TESA-4 scores.

Figure 4 provides insights into threshold sensitivity and its relationship with prediction accuracy. LDL and PLDT-B maintain stable performance across different threshold values, particularly at small thresholds. The emotion count analysis reveals that these methods also better align with the ground truth distribution, suggesting that accurate emotion count prediction contributes to higher TESA scores. One-hot and PLDT-A show advantages at moderate thresholds where the average emotion count approaches one, but their performance decreases at higher thresholds due to over-prediction of high probability values.

An interesting phenomenon emerges in the comparison between LDL and PLDT-B: while LDL performs better in Top-k metrics, PLDT-B shows superior performance in several TESA metrics. This reversal can be attributed to their different approaches to probability distribution learning and the inherent characteristics of each evaluation metric. Top-k metrics evaluate strict ranking performance, where LDL excels due to its direct optimization of complete probability distributions, enabling precise modeling of relative emotion intensities. This advantage stems from LDL's training objective that simultaneously considers the entire probability space, leading to more accurate preservation of emotion intensity ordering.

In contrast, TESA measures the intersection-over-union of emotions above specific thresholds, where PLDT-B demonstrates superior performance. This advantage can be attributed to two key factors: First, PLDT-B's progressive transition from One-hot encoding helps maintain clearer decision boundaries for emotion activation, effectively learning appropriate threshold levels for each emotion. Second, the gradual incorporation of distribution information during training allows PLDT-B to balance between discrete and continuous representations, resulting in more robust probability estimates around decision thresholds. This unique characteristic makes PLDT-B particularly effective in scenarios where the identification of present emotions is more crucial than their exact intensity ordering.

7 Conclusion

In this work, we addressed the challenge of modeling emotional responses to artwork by exploring the spectrum between discrete and continuous label representations. Our analysis reveals that while One-hot encoding excels at identifying dominant emotions, LDL better captures subtle emotional nuances. To bridge this gap, we introduced PLDT, demonstrating that a gradual transition between these approaches can effectively balance their respective strengths. The threshold-based evaluation through TESA provided key insights into how different methods handle the trade-off

between prediction confidence and emotion multiplicity. Our findings suggest that considering emotions as distributions rather than discrete labels better aligns with the complex nature of human emotional responses to art.

Modified Iterative Matching and Translation Approach for Formality Style Transfer in a Low-Resource Setting

Kenneth Uriel Loquinte, Charibeth Cheng
De La Salle University Manila
Taft Ave., Malate, 1004 Manila, Philippines
{kenneth_uriel_loquinte, charibeth.cheng}@dlsu.edu.ph

Abstract

There is limited research on text style transfer (TST) for non-English languages due to the scarcity of essential resources like parallel corpora. This paper explores a non-parallel approach to creating pseudo-parallel corpora for training a formality style classifier in Filipino. Specifically, it adapts the Iterative Matching and Translation (IMaT) method. This involves aligning texts from different corpora, training a model for style transfer, and refining the dataset iteratively. Modifications include using margin-based similarity scoring, training a pre-trained multilingual model, and applying data augmentation. Results show these modifications enhance formality style transfer performance compared to the original IMaT implementation. However, further improvements to the matching algorithm and dataset refinement are necessary for broader applicability and generalization.

1 Introduction

In natural language generation (NLG) applications, there is a necessity to make systems more user-centered; this entails that these systems should understand and communicate with nuances of language. With that said, it is important to consider style when modeling a language (Jin et al., 2022). This is what the field of text style transfer (TST) tackles, wherein the style of a given text is modified while its content is preserved.

The choice of approach in TST heavily relies on data accessibility. Supervised learning is common when parallel datasets are available (Rao and Tetreault, 2018; Zhang et al., 2020), but these are not always available, and creating one for each possible TST subtask is unsustainable. Therefore, many works only assume access to non-parallel corpora and apply techniques such as disentanglement (John et al., 2019), prototype editing (Li et al., 2018; Madaan et al., 2020), and pseudo-parallel corpus construction (Jin et al., 2019).

The exploration of TST in non-English languages is limited due to the lack of resources (Briakou et al., 2021b). This work specifically tackles the formality style transfer (FST) subtask in Filipino, a low-resource language. Although there exists work on adjacent NLP tasks in Filipino such as grammar correction (Go et al., 2017) and spell checking (Octaviano and Borra, 2017), no work has specifically explored FST techniques.

This work adapts the Iterative Matching and Translation (IMaT) approach (Jin et al., 2019) and explores its applicability in a low-resource setting. With that said, we make the following contributions:

- We explore using margin-based similarity scoring, training a multilingual language model, and applying data augmentation in building pseudo-parallel pairs via IMaT. We assess their benefits in a low-resource setting using the three common TST metrics: style accuracy, meaning preservation, and fluency.
- We provide a baseline work for Filipino FST, which can be used as a reference for future efforts in Filipino. We also contribute to the limited TST work in non-English languages.

Results show that these modifications are helpful in improving FST performance, although further improvements are necessary to make a more general solution in terms of both language and style. Like ours, works in non-English FST generally face the same issue of resource availability, but these efforts are important in making more robust conclusions about the current state of TST techniques.

2 Related Work

FST is one of the TST subtasks that has gained considerable attention, and it benefits from the availability of parallel data such as Grammarly's Yahoo Answers Formality Corpus (GYAFC) (Rao

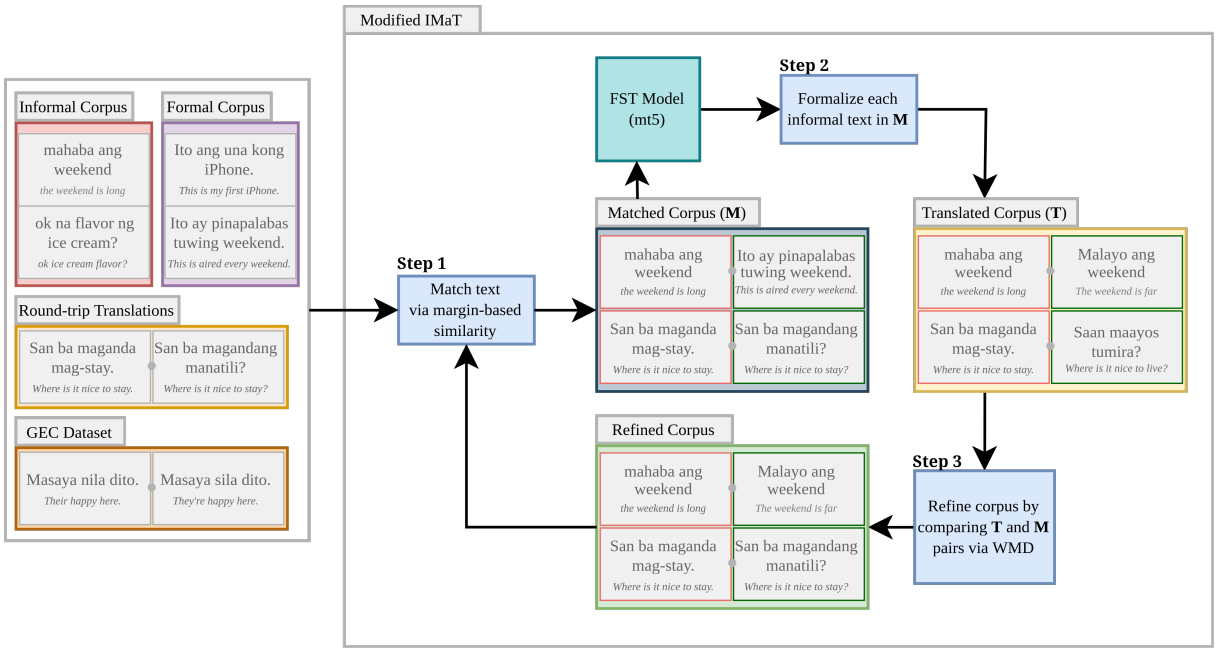

Figure 1: The input to the modified IMaT pipeline are two distinct informal and formal style corpora which are augmented with grammar error correction (GEC) and round-trip translation datasets. The steps are described as follows: (1) the first step is to match informal and formal text using margin-based similarity (Artetxe and Schwenk, 2019) resulting in a pseudo-parallel corpus. An mt5 model is trained to perform FST using the matched corpus (**M**). Then, (2) the next step is to formalize each informal text in **M** using the trained model, resulting in a new corpus **T** whose target consist of generated formal text. Finally, (3) the last step is to refine the dataset by comparing the generated targets in **T** to the previous targets in **M** using WMD (Kusner et al., 2015). The IMaT pipeline is iterative and the refined corpus can be used as an input to the next iteration.

and Tetreault, 2018). Several works have utilized GYAFC for experimentation such as Zhang et al. (2020) which used data augmentation techniques for improved FST performance, and Wang et al. (2019) which proposed a rule-based formalization approach on a neural-network-based system. This highlights the importance of a resource like GYAFC in TST.

Even though a formality dataset exists, there are still works that seek non-parallel approaches to FST due to their cost-effectiveness. One method is by constructing a pseudo-parallel corpus such as by using synonym as word replacements (Jain et al., 2019), or by aligning pairs from distinct corpora (Jin et al., 2019). Another technique is a two-stage approach which involves using a model to neutralize style attributes, and then a style-trained model paraphrases the neutral text to the desired style (Krishna et al., 2020).

There have been efforts to study FST in low-resource settings such as building a multilingual formality dataset (Briakou et al., 2021b), and using few-shot translation techniques (Krishna et al., 2022). Our work utilizes the pseudo-parallel corpus construction approach and data augmentation techniques, which are both useful in low-resource settings as it allows us to use available resources in Filipino.

3 Approach

3.1 Iterative Matching and Translation (IMaT)

This work adapts the IMaT algorithm proposed by (Jin et al., 2019), which pairs sentences from two separate style corpora by using a similarity metric. While IMaT has been primarily applied in English, it can be applied in low-resource settings as it is not reliant on language-specific qualities. We localize the pipeline by using Filipino-based embeddings.

The stages of the pipeline are discussed below with a focus on FST, but it is worth noting that the pipeline is style-agnostic. Figure 1 shows an illustration of the system.

Matching Each text from both informal and formal datasets are represented as sentence embeddings using Paraphrase-Fil-MPNet[1], which was

[1]The model was sourced from: meedan/paraphrase-

trained on data from OPUS using the student-teacher approach by Reimers and Gurevych (2020). Informal-formal pairs are created by matching the embeddings of text between the two datasets using pairwise cosine similarity. However, we found that using cosine similarity creates less diverse pairs because the same formal sentence would be paired with multiple informal sentences. Instead, we use margin-based scoring (Artetxe and Schwenk, 2019) which uses the margin between a given sentence's similarity and its nearest neighbors to mitigate the effects of the varied similarity scales.

The pairs that exceed a similarity threshold constitute the pseudo-parallel corpus, which is used to train a seq2seq model in the next stage. In cases where multiple candidate sentences exist, the formal sentence that achieves the highest similarity score was selected. The paired sentences create a matched corpus $M = \{(x_1, y_1), (x_2, y_2), ..., (x_n, y_n)\}$.

For succeeding iterations $i > 0$, the matching process is conducted on the sentences of M_i instead of the distinct style corpora, resulting in a new set of matched pairs N_i. Pairs that get a similarity score less than the threshold are removed to retain the size of the dataset. We compute the Word Mover's Distance (WMD), a metric that quantifies distance based on word embeddings (Kusner et al., 2015) between pairs from M_i and N_i, and the lower scoring pairs become part of the corpus that was passed to the translation stage. We use Filipino FastText word embeddings (Velasco, 2021) to represent the words on each text. This operation is summarized as:

$$M_{ij} = \min(\text{wmd}(x_j, m_j), \text{wmd}(x_j, n_j)) \quad (1)$$

where $(x_j, m_j) \in M_i$ and $(x_j, n_j) \in N_i$.

Translation & Refinement A seq2seq model is trained using the created informal-formal pairs from the matching stage resulting in model F_i at iteration i, whose goal is to convert an informal text to a formal one. The original implementation uses an LSTM encoder-decoder model, but this work uses a pre-trained multilingual model, mt5 (Xue et al., 2021), which is useful in a low-resource setting.

The formality style transfer model F_i is used to generate a transferred sentence t for each informal sentence x from pair $(x, m) \in M_i$, creating a new pair (x, t). All generated pairs form a new pseudo-parallel corpus T_i.

The new pair (x, t) is compared with the existing pair (x, m) using WMD. The pair with a lower WMD score is incorporated into the refined corpus M_{i+1}, which is used in the next iteration. This operation is summarized by:

$$M_{i+1}j = \min(\text{wmd}(x_j, m_j), \text{wmd}(x_j, t_j)) \quad (2)$$

where $(x_j, m_j) \in M_i$ and $(x_j, t_j) \in T_i$.

The pipeline is iterative and the resulting refined dataset can be fed to the next iteration's matching stage. In this work, the end condition is based on update rate and number of iterations.

3.2 Data Augmentation

Using augmented data related to the formality task is useful in improving performance, especially when dealing with pseudo-parallel pairs whose quality cannot be ensured. We augment the original pairs with round-trip translation and grammar error correction (GEC) pairs.

Firstly, we use round-trip translation pairs which have been found useful by other works (Briakou et al., 2021b; Zhang et al., 2020) where the motivation is based on the observation that machine translation systems often produce formal text.

Secondly, we use GEC data following a multi-task transfer approach (Zhang et al., 2020). This approach proposes the use of available resources for tasks related to formality, resulting in the style transfer model also learning said task. GEC is suitable to FST because grammaticality is an important part of formality.

Zhang et al. (2020) found that pre-training the model with the augmented data achieves better performance than using for simultaneous fine-tuning with the original pairs. This occurs because the augmented pairs are usually noisier than the original pairs. However, in this work where the original pairs are pseudo-parallel pairs, this cannot be assumed, and doing so can be limiting because the augmented datasets can have better quality pairs.

Given that, simultaneous fine-tuning is done instead of pre-training. To maintain the priority on the original pairs, we set the number of augmented training pairs to around half the number of pseudo-parallel training pairs.

filipino-mpnet-base-v2

4 Experiments

4.1 Datasets

There are no datasets in Filipino that have been specifically curated for either formal or informal text. Hence, some assumptions were made to leverage existing resources. The datasets used to represent informal and formal styles are described below.

PEx-Conversations For the informal style, we use the PEx-Conversations dataset (Co et al., 2022), which comprises ~2.4M comments across ~45k threads from the Philippine Exchange online forum. This dataset was chosen based on the assumption that discussions on these kinds of platforms exhibit a more casual nature, resulting in a lower level of formality.

WikiText-TL-39 For the formal style, we use the WikiText-TL-39 dataset (Cruz and Cheng, 2019), which comprises ~2M lines of text from Tagalog Wikipedia articles. It is assumed that these articles were written with a certain level of formality, as they were written in accordance with a style guide.

The sentences from the train, validation, and test splits were collated for each dataset. PEx-Conversations was balanced by downsampling the subforum categories based on the smallest category via random selection. We applied the following pre-processing steps to both datasets, which are partially based on Briakou et al. (2021b) and Rao and Tetreault (2018): (1) remove sentences with more than 25 words, or with less than 5 words, (2) normalize punctuations in the text[2], (3) remove non-Tagalog sentences[3], and (4) remove article titles for Wikitext-TL-39.

Next, we describe the datasets for data augmentation.

RT-Fil The first dataset for augmentation is RT-Fil, which consists of 20k round-trip translation pairs. The source texts were taken from PEx-Conversation texts that were filtered out by the IMaT matching stage (i.e., informal text from pairs with similarity scores that are below the set threshold). By doing so, we prevent duplicates with the pseudo-parallel pairs. The translation was done using the Google Translate API with English as the pivot language, and Filipino as the target language.

Balarila The other dataset for augmentation is the Balarila dataset (Ponce et al., 2023), which comprises ~906k pairs that cover grammatical errors (morphological and spelling errors). The Balarila dataset was downsampled to match the number of RT-Fil pairs by randomly sampling a uniform percentage from each transformation / error category from the dataset.

4.2 Implementation

We created a baseline model (**BASE**), which follows the original IMaT implementation, but with localized embedding representations. We used a cosine similarity threshold of 0.75 for filtering, and utilized a 2-layer LSTM encoder-decoder model with attention as the translation model. At each iteration, the model was trained for 10 epochs with a batch size of 16 and a learning rate of 1e-4.

Next, as discussed in Section 3.1, we used a margin-based similarity score for matching with a threshold of 1.05, and used mt5-small[4] as the translation model. We trained a model with PEx-Conversations and Wikitext-TL-39 pseudo-parallel pairs only (**MT5-PW**), then we trained another model with the same pairs augmented with RT-Fil and Balarila (**MT5-AUG-PW**). At each iteration, both models were trained for 5 epochs with a batch size of 64 and a constant learning of 1e-3, following the mt5 fine-tuning setup (Xue et al., 2021).

For generation sampling during the translation stage and testing, we used a top-k of 50 and a temperature of 0.7. Furthermore, for all experiments, the pipeline stopped after 5 iterations, or when the update rate during the refinement stage was less than 5%.

4.3 Evaluation Metrics

To evaluate the model, we employ widely-used automatic metrics in FST.

Formality This work follows the zero-shot approach that was detailed by Krishna et al. (2022). Specifically, we fine-tuned XLM-RoBERTa-Base model for a regression task using the PT16 dataset (Pavlick and Tetreault, 2016). The dataset contains sentences sourced from various text domains, where each sentence was manually annotated with a formality score on a Likert scale ranging from -3 to 3. The fine-tuned model was applied zero-shot

[2]Normalization was done using a Python wrapper of the Moses toolkit

[3]Language detection was done using the langdetect package

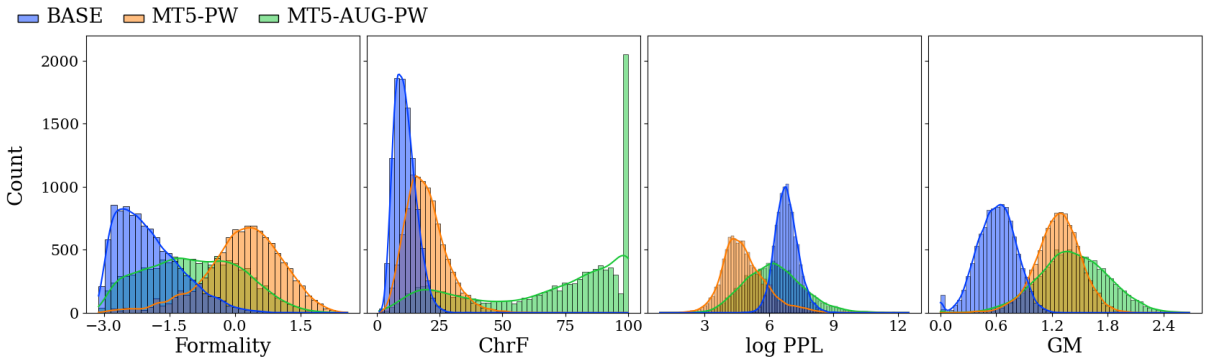

Figure 2: Distribution of scores of BASE, MT5-PW, and MT5-AUG-PW on each evaluation metric.

Model	Formality	ChrF	PPL	GM
BASE	-2.11 (-1.98)	10.65 (11.2)	887.81 (1068.25)	0.61 (0.60)
MT5-PW	0.26 (0.19)	18.55 (19.6)	111.04 (262.62)	1.27 (1.27)
MT5-AUG-PW	-0.98 (-0.96)	78.46 (67.98)	481.32 (1503.26)	1.42 (1.42)
Dataset				
INITIAL	0.23 (0.03)	20.89 (37.85)	159.06 (817.80)	1.30 (1.40)
REFINED	-0.95 (-0.90)	83.10 (73.85)	431.03 (1636.94)	1.49 (1.53)

Table 1: The median (and mean in parentheses) evaluation scores on a test set of ~10k samples for BASE, MT5-PW, and MT5-AUG-PW. The median is highlighted instead of the mean due to outliers, especially for perplexity. Formality ranges from -3 to 3, while chrF ranges from 0 to 100. PPL is perplexity, and GM is geometric mean. In the bottom, the same evaluation scores are shown for the training dataset of MT5-AUG-PW before and after pipeline refinement.

on the generated Filipino sentences to determine their formality scores.

Meaning Preservation This work uses the character n-gram F-score (chrF) (Popović, 2015) between source text and output text to compute meaning preservation. Although the BLEU score is a popular metric that has been used in several TST works (Rao and Tetreault, 2018; Li et al., 2018; Jin et al., 2019; Briakou et al., 2021b), chrF has been shown to correlate better with human evaluations (Briakou et al., 2021a). Furthermore, it is beneficial for a morphologically-rich language like Filipino because it assesses similarity on a character level.

Fluency We measure fluency by calculating the perplexity (PPL) of each output sentence through GPT2-Tagalog (Cruz et al., 2020). The model was trained on Philippine news articles and Wikitext-TL-39, both of which contain formal text. Aside from the model being one of the few available causal language models in Filipino, the expected output of the FST model (formal text) fits the domain of GPT2-Tagalog's training corpus.

Overall Score We use geometric mean (GM) as a measure of performance across the three TST metrics following previous works (Krishna et al., 2020; Yi et al., 2021). We compute the geometric mean of formality, chrF, and $\frac{1}{logPPL}$. The formality score is shifted from a $(-3, 3) \rightarrow (0, 1)$ range to be compatible with GM.

4.4 Results

Table 1 shows that using margin-based similarity scoring for matching and mt5 for translation (MT5-PW and MT5-AUG-PW) lead to better performance on all TST aspects compared to the original IMaT implementation (BASE). This indicates that an improved matching algorithm and the use of a multilingual model can boost style transfer performance when working with the pseudo-parallel corpus approach.

Furthermore, the increase in chrF from MT5-PW to MT5-AUG-PW (18.55 $\rightarrow$ 78.46) shows that augmenting the original pairs with RT-Fil and Balarila pairs greatly improves meaning preservation in the text. This is not surprising because both of these datasets contain pairs whose source and target texts have similar words, especially with Balarila whose corrections are very localized. However, this also means that the model has a tendency to output an

INFORMAL	Si johnskie manlilibre sakin ng xmen hahahaha *johnskie will buy me xmen hahahaha*
BASE	"...ileasisiraan ka na manakit ka ka, hindi ako!.. na nanalo.....!.. *"...ileasisiraan you to hurt you you, not me!.. who won.....!..*
MT5-PW	Si John Lennon ay isang mang-aawit. *John Lennon is a singer.*
MT5-AUG-PW	Si Johnski manlilibre sa akin ng Xmen hahahaha *Johnski will buy me Xmen hahahaha*

INITIAL	Dahil mahirap ang pamilya ni Ralph, hikahos din sila makakain. *Because Ralph's family is poor, they're also eating poorly.*
REFINED	Dahil mahirap ang pamilya ni Ralph, hikahos din nila makakain. *Because Ralph's family is poor, their also eating poorly.*

Table 3: Example of formal target refinements for the training set of MT5-AUG-PW. The sources of the initial informal-formal pairs are indicated in parentheses. The accompanying text, rendered in gray in each row, are the translations of the preceding Filipino text.

exact copy of the informal text and not do any style transfer at all. Figure 2 shows that more than 2,000 (~20%) outputs from MT5-AUG-PW have perfect chrF values, which means that the model generates exact copies frequently.

With that said, better meaning preservation led to worse style accuracy (0.26 → -0.98) and higher perplexity scores (111.04 → 481.32). Since the target outputs become alike to the informal text, the attributes carry over including low formality and high perplexity. This also highlights the limitation of measuring fluency using perplexity — the informal text would appear fluent to a native speaker, but not to GPT2-Tagalog which was only trained on a formal text domain. Therefore, the language model for calculating perplexity should be able to handle either informal and formal text. Unfortunately, such a model is not always available.

Although MT5-AUG-PW is inferior to MT5-PW in two of the three evaluation metrics, the overall score indicates that the latter has better quality style transfer outputs when viewed holistically. The same trend can be seen in Figure 2. Arguably, a translation can only be a proper translation if the actual message is preserved; Table 2 shows that although MT5-PW can retain keywords or a semblance of the topic, only MT5-AUG-PW is able to convey the actual meaning of the informal text.

Nonetheless, the outputs from both models are a stark contrast to that of BASE. The model generates incomprehensible text, often with repeating tokens; this behavior complements its poor evaluation scores in Table 1. Training an LSTM-based model from scratch at each iteration means that the model is learning the language and the FST task at the same time. In this case where we are working with a pseudo-parallel corpus whose pairs have varying quality, performance issues such as what is displayed by BASE can occur. Therefore, in low-resource settings, pre-trained multilingual models offer better starting points.

As much as meaning preservation is a foundation of a good style transfer, it can also be detrimental to the refinement process. Table 3 shows that there is a tendency for the algorithm to "refine" the dataset with lesser-quality targets. It is expected to occur frequently when training with datasets that encourage copying such as RT-Fil and Balarila because the model is likely to generate candidate targets that are equal to the informal text; hence, the algorithm would select the equal-copy target and would ignore a previous target that might have correct formal changes. To illustrate, the initial target for the Balarila example correctly fixes the wrong use of *nila* (their) to *sila* (they), but the FST model generated a copy of the informal text, thus the algorithm selects that as the refined target due to a perfect WMD score, even though it is a worse target text.

The proponents of IMaT make an assumption that the two corpora used to represent the involved styles already have text with good style accuracy and high fluency. However, as the results show, this does not always hold true for a low-resource setting where available text resources are not guaranteed to properly represent the styles and/or may not contain fluent text. Therefore, using only WMD to refine the pseudo-parallel corpus may be insufficient. As an unsupervised approach, the pipeline would greatly benefit from replacing WMD with a score that considers all three metrics, such as the geometric mean.

It is important to discuss that augmented datasets are not always available, and their suitability is still dependent on the language and style. For instance, a good neural machine translation model may not be available for certain low-resource languages, which hinders efforts in creating good-quality round-trip translation pairs. In the same light, there may not be available task-related data that can be applied to the chosen style — GEC pairs are relevant for formality, but not for other styles. Therefore, it remains necessary to improve the matching algorithm to find better pairs from distinct sources, because relying on augmented datasets is not sustainable.

5 Conclusion

This study demonstrates that adapting the IMaT approach with modifications — such as using a pre-trained multilingual language model, margin-based similarity scoring, and data augmentation — enhances the effectiveness of formality style transfer (FST) in Filipino. These findings emphasize the value of customizable, non-parallel techniques in low-resource settings, which allow for more effective utilization of existing resources.

While data augmentation can temporarily boost dataset quality, reliance on it is not a sustainable long-term solution. Therefore, refining the matching algorithm remains a critical avenue for improvement. Future research should explore semi-supervised learning approaches and incorporate data filtering mechanisms that evaluate style accu-

racy, meaning preservation, and fluency. This approach could improve the overall quality of pseudo-parallel pairs, making the IMaT framework more robust.

The current pipeline's assumptions about text fluency and style accuracy may not hold true in unsupervised, low-resource settings, where the quality of available text can vary. To address this, optimizing all three key TST metrics — style accuracy, meaning preservation, and fluency — simultaneously might provide a more reliable and comprehensive evaluation of TST quality. Investigating the use of an overall score instead of solely relying on the Word Mover's Distance (WMD) score could make the dataset refinement process more aligned with the objectives of TST.

Although the study followed established evaluation methods, direct comparison with other works is challenging due to variations in implementation, including the use of a Filipino-based model for perplexity. Incorporating human evaluations and analyzing their correlation with automatic metrics would enhance the reliability and validity of the findings.

Abstract

In this study, we introduce CIKMar[1], an efficient approach to educational dialogue systems powered by the Gemma Language model. By leveraging a Dual-Encoder ranking system that incorporates both BERT and SBERT model, we have designed CIKMar to deliver highly relevant and accurate responses, even with the constraints of a smaller language model size. Our evaluation reveals that CIKMar achieves a robust recall and F1-score of 0.70 using BERTScore metrics. However, we have identified a significant challenge: the Dual-Encoder tends to prioritize theoretical responses over practical ones. These findings underscore the potential of compact and efficient models like Gemma in democratizing access to advanced educational AI systems, ensuring effective and contextually appropriate responses.

1 Introduction

The emergence of powerful Large Language Models (LLMs) such as ChatGPT has been proven effective in various tasks, including generating text that is nearly indistinguishable from human-written text (Kasneci et al., 2023; Omidvar and An, 2023). Building on the success in text generation, LLMs have shown significant potential in various applications, especially in the educational domain.

In recent years, there have been various efforts to utilize these powerful LLMs in education. They have been deployed in teacher-student collaborations as virtual tutors, guiding students through exercises, offering personalized learning experiences, and providing intelligent tutoring (Kamalov et al., 2023). Additionally, they are used for adaptive assessments and serve as conversational partners in learning scenarios (Tan et al., 2023; Li et al., 2024).

Despite these promising opportunities, the use of generative models as a foundation for downstream tasks presents several crucial challenges

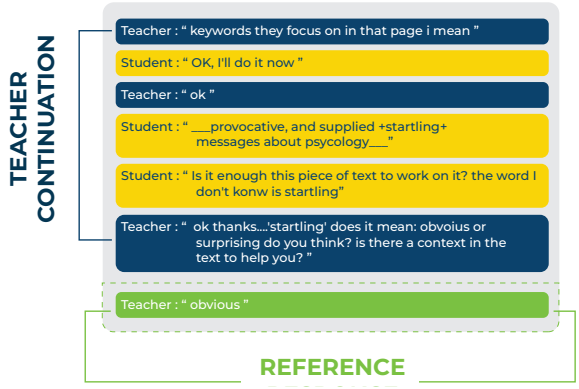

Figure 1: Teacher Continuation Data Visualization

such as inconsistently delivering accurate and contextually appropriate responses (Tack et al., 2023). Furthermore, language models in current scenarios mostly use extremely large models in terms of their parameter size, such as proprietary 175 and 137 billion-parameter GPT-3 model (Brown et al., 2020), or open source LLMs such as 70 billion-parameter LLaMA2 (Touvron et al., 2023), 14 billion-parameter Qwen (Bai et al., 2023), and 6 billion-parameter ChatGLM3 models (Zeng et al., 2023).

Language models at this scale are not practical and inaccessible for many researchers and even practitioners, due to their large memory consumption and slow generation times (Ding et al., 2024; Jimenez Gutierrez et al., 2022), data privacy, and inflexibility of customization (Sinha et al., 2024). Therefore, it is essential to determine how solid that foundation is and how it can be accessible for further development, especially in the educational domain.

According to the challenges above, we designed a simple but effective approach by leveraging Large Language Models and prompt-and-rerank approach (Suzgun et al., 2022) to build the dialogue AI system especially in educational domain. We chose to work with a smaller, pre-trained language model

[1]https://github.com/joanitolopo/cikmar-system

called Gemma 1.1 2B (IT), which can run efficiently on less than 12 GB of RAM and a single GPU T4. This makes it suitable for real-world applications by maintaining a reasonable model size without compromising performance. Additionally, a Dual-Encoder approach strategy has been adopted to re-rank the candidate outputs generated by the model using hand-written prompts. This approach aims to increase the relevance and effectiveness of the responses generated by our system in educational dialogues.

2 Related Work

Researchers have extensively investigated the effectiveness of various approaches utilizing language models. Sridhar et al. (2023) enhanced LLM performance on web navigation tasks using Actor-Summarizer Hierarchical (ASH) prompting, while Kong et al. (2024) improved reasoning benchmarks with role-play prompting. Kojima et al. (2023) showed that modifying prompt structure enables LLMs to perform multi-step reasoning in zero-shot settings.

In the educational context, Adigwe and Yuan (2023) and Hicke et al. (2023) used GPT-3 and GPT-4 to generate educational dialogue responses, achieving high DialogRPT and BERTScore results with hand-written zero-shot prompts. Similarly, Vasselli et al. (2023) used GPT-3.5 Turbo with manual few-shot prompts based on DialogRPT selection, which contributed most to the final outputs.

Fine-tuning has also proven effective by utilizing large language models (LLMs) in educational domain. Baladón et al. (2023) used the LoRa method to fine-tune models like BLOOM-3B, Llama 7B (Touvron et al., 2023), and OPT 2.7B (Zhang et al., 2022). They found that even the smaller OPT 2.7B model, with careful fine-tuning, could achieve better performance. Similarly, Huber et al. (2022) demonstrated that GPT-2, enhanced with reinforcement learning via the NLPO algorithm (Ramamurthy et al., 2023), achieved high BERTScores.

Due to the high computational power needed for fine-tuning and domain adaptation, Omidvar and An (2023) introduced semantic in-context learning, using private knowledge sources for accurate answers. Gu et al. (2024) proposed reducing LLM sizes through knowledge distillation, training smaller models to replicate larger ones. Their experiments with distilled GPT-3 versions showed competitive performance on various benchmarks.

Our research aims to develop an educational dialogue system using Gemma 1.1 IT 2B. This system uses prompts to guide LLMs in generating outputs based on contextual understanding, relevance, engagement, clarity, and feedback. To optimize results, it employs dual encoders (BERT and SBERT) to rerank top candidates. Our objective is to democratize open model LLM in real-world scenarios, ensuring accurate, relevant responses while enhancing student engagement and understanding in educational dialogues.

3 Methods

3.1 Data

We used data from the BEA 2023 shared task, sourced from the Teacher-Student Chatroom Corpus (TSCC) (Caines et al., 2020, 2022). This corpus consists of several conversations where an English teacher interacts with a student to work on language exercises and assess the student's English proficiency (Tack et al., 2023). Each conversation contains multiple responses and starts with either **teacher:** or **student:** prefixed. The reference text is the teacher's response that follows the previous input dialogue. The corpus includes a training set of 2,747 conversations, a development set of 305 conversations, and a test set of 273 conversations, totaling 3,325 conversations.

Since the data were collected from real-time teacher-student conversations, turn-taking is not as consistent as in most dialogue systems (Vasselli et al., 2023). Two patterns mostly occur: conversations ending with the student (teacher reply) and conversations ending with the teacher (teacher continuation). This condition occurs in 38% of the training data and 40% of the development data. Figure 1 shows an example of a conversation in the teacher continuation condition.

3.2 Prompt Ensemble

We utilized hand-written prompts from Vasselli et al. (2023) to build our system. The prompts include Zero-shot and Few-shot types, targeting both general and specific scenarios. We used only five main prompts available as they are already tailored for teacher responses and continuations. This selection also ensures general applicability to other datasets or conversations. Full details explanation of each prompt are described in the Appendix A.

In the creation of the few-shot prompts, it requires positive and negative examples to help the

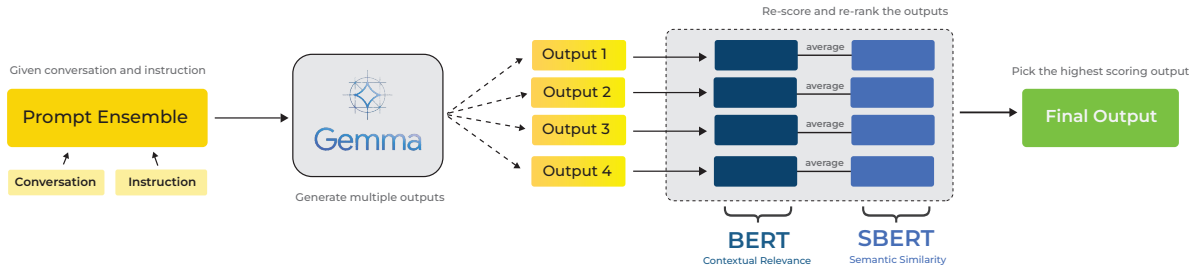

Figure 2: An illustration of the CIKMar system. Given an input conversation and instruction, we create the prompt ensemble and feed it to Gemma to generate multiple outputs. We then re-score each output by averaging BERT and SBERT scores and select the candidate with the highest re-ranked score as the final output

model avoid irrelevant responses. We adopted the method of Vasselli et al. (2023) who applied the handcrafted, generative, and iterative prompt methods. However, we modified the iterative method from the original paper. Instead of using DialogRPT, we employed the BM25 ranking function to select the highest and lowest scoring responses as positive and negative examples.

BM25 (Robertson and Walker, 1994; Robertson and Zaragoza, 2009) was chosen over DialogRPT because it reduces the computational power required for the prompting and re-ranking process, as DialogRPT needs additional memory capacity to calculate and choose the best candidate. Additionally, BM25 is known as the first-stage ranker in lexical retrieval systems (Askari et al., 2023) which ensures positive and negative examples are selected based on their lexical match with the conversation history.

3.3 Gemma Instruct-tuned Model

Our main system leverages a pretrained language model with a prompting approach rather than training one from scratch or fine-tuning it on a new dataset. We used the Gemma 1.1 IT 2B model (Team et al., 2024), 2-billion parameter open model developed by Google for efficient CPU and on-device applications. The model has shown strong performance across academic benchmarks for language understanding, reasoning, and safety, such as MMLU (Hendrycks et al., 2021), SIQA (Sap et al., 2019), HumanEval (Chen et al., 2021), and Winogrande (Sakaguchi et al., 2019). These results indicate its promising performance in educational contexts.

We followed the instruction-formatted control tokens suggested in the Gemma technical report to avoid out-of-distribution and poor generation. Table 1 shows an example dialogue with user and model control tokens. Specifically, the relevant

User:	`<start_of_turn>user`
	`conversation`
	`instruction <end_of_turn>`
	`<start_of_turn>model`

Model:	`responses<end_of_turn>`

Table 1: Example dialogue with user and model control tokens.

token `user` represents the role, and its `content` includes the conversation history followed by the prompt. Meanwhile, the `model` turn responds to the `user` dialogue.

In our experiments with the training and development sets, the Gemma model sometimes generated hallucinations in the first attempt, such as factually incorrect response, nonsensical content, overly long response, and content disconnected from the input prompt. However, performance improved on the second and third attempts. Therefore, to ensure the best response, we generated each candidate three times before selecting the final output.

We configured several parameters to control the model's output such as set the `max_length` of the generated output to 512 tokens, `no_repeat_ngram_size` to 2 to avoid repetition, and used `top_k=50` and `top_p=0.95` to balance randomness and coherence. The `temperature` was set to 0.7 for more conservative choices. Finally, we enabled probabilistic sampling over greedy decoding.

3.4 Dual-Encoder Reranking

Inspired by previous research (Vasselli et al., 2023; Suzgun et al., 2022; Haroutunian et al., 2023), our system generates multiple candidate outputs from different manually designed prompts and then re-ranks these outputs using a heuristically defined scoring function. For the scoring function, we employed SBERT (Reimers and Gurevych, 2019)

and BERT (Devlin et al., 2019). Specifically, we used the `paraphrase-MiniLM-L6-v2` version of SBERT, which maps sentences and paragraphs to a 384-dimensional dense vector space, and the `bert-base-uncased` model for BERT. We averaged the cosine similarity scores of their embeddings to evaluate the fine-grained semantic relevance and context-response matching in the embedding space between the conversation history and the generated responses.

In the given setup, we started with a dialog as a context `ctx` and a list of candidate responses $\{\texttt{cand}_1, \texttt{cand}_2, \ldots, \texttt{cand}_m\}$. Initially, we computed SBERT and BERT embeddings for both the context and the candidate responses. For BERT embeddings we calculated by averaging token embeddings across the sequence dimension.

The cosine similarity between the context and each candidate response embedding, for both SBERT and BERT, are calculated using:

$$S_{\text{emb}}(i) = \cos\left(e^{\text{emb}}_{\text{ctx}}, e^{\text{emb}}_{\text{cand}_i}\right) = \frac{e^{\text{emb}}_{\text{ctx}} \cdot e^{\text{emb}}_{\text{cand}_i}}{\|e^{\text{emb}}_{\text{ctx}}\| \|e^{\text{emb}}_{\text{cand}_i}\|}$$

where $\texttt{emb} \in \{\texttt{sbert}, \texttt{bert}\}$.

To combine these similarity scores for each candidate response, we averaged the SBERT and BERT similarity scores.

Finally, the candidates are ranked based on these combined similarity scores in descending scores. The indices of the candidates are sorted according to their combined scores, and it returns the list of candidates responses ordered from most to least relevant to the given context.

3.5 Post-processing

The raw outputs from model often included inconsistent formatting, such as phrases prefixed by "**" or starting with unwanted text like `Teacher:` or `Student:`. Additionally, the model sometimes appended lengthy explanations to its responses beginning with `Explanation:`, adding unnecessary length. However, we observed a consistent pattern where the actual response always began with a quotation mark ".

To standardize these outputs, we implemented a post-processing step. First, we defined a regular expression pattern, `\*\*.\*?:\*\*\n\n`, to identify and remove any unwanted initial phrases. This pattern effectively removed prefixes like "**", `Teacher:`, or `Student:`. Next, each response was processed to retain only the text following the first occurrence of a quotation mark, discarding any preamble or unnecessary content. Finally, we trimmed any leading or trailing whitespace.

#	Precision	Recall	F1-Score
CIKMar (**ours**)	0.69	0.70	0.70
NAISTeacher Vasselli et al. (2023)	0.71	0.71	0.71
Adaio Adigwe and Yuan (2023)	0.72	0.69	0.71
GPT-4 Hicke et al. (2023)	0.71	0.69	0.70
S-ICL Omidvar and An (2023)	0.72	0.69	0.70
OPT-2.7B Baladón et al. (2023)	0.74	0.68	0.71
NLP-HSG Huber et al. (2022)	0.72	0.63	0.67
Alpaca Baladón et al. (2023)	0.72	0.68	0.70
DT Tack et al. (2023)	0.67	0.62	0.64

Table 2: Comparison of our proposed system with previous research based on BERTScore (Zhang et al., 2020)

4 Result & Analysis

4.1 Main Result

Our main result are presented in Table 2, showcasing comparisons among systems from the BEA Shared Task 2023 (Tack et al., 2023), ranked primarily by BERTScore. However, this comparison isn't fully comprehensive as the BEA Shared Task also considers human evaluations and DialogRPT (Gao et al., 2020) score. The human evaluation metric is restricted and not publicly available, and we encountered challenges with DialogRPT, which might have issues with the model, as it is return the same score for each context.

CIKMar demonstrates competitive performance against baseline systems like NAISTeacher and Adaio based on BERTScore[2]. Specifically, we achieve a robust recall score of 0.70, slightly below NAISTeacher's 0.71. This indicates that our Dual-Encoder ranking effectively retrieves many contextually relevant responses compared to the reference answer. Furthermore, our F1-Score of 0.70 is comparable to models such as S-ICL and Alpaca, which utilize fine-tuning and larger model sizes, demonstrating our model's capability to capture similarity and produce coherent, contextually appropriate responses even using simple and small model size.

4.2 Evaluation Metrics

To ensure the reliability of our approach, we employed word overlap-based metric ROUGE

[2]BERTScore was calculated using Hugging Face's evaluate package with the `distilbert-base-uncased` model, averaging precision, recall, and F1 scores across the entire test set.

id	responses	analysis
test_0006	I understand you're feeling a bit chilly. Would you like to continue with the grammar practice or do you have any questions about the vocabulary word 'cold'?	feeling, relevant, and emphatic
test_0004	Great point! Speed is an important aspect of your time management, so maintaining a sense of efficiency is crucial. How did you achieve your faster timeframe?	appreciation, discussion focus, and skill development
test_0007	Great point! Now, let's focus on using this new vocabulary in a meaningful way. Can you tell me some examples of how you've used this word in your own writing or conversations?	appreciation, practice of the new material, and reflection
test_0010	Following your insightful observation, could you provide an instance where speaking truthfully might be particularly effective in achieving a desired outcome?	appreciation, and critical thinking
test_0011	I appreciate your perspective on this, student. To further explore this idea, how does playing games help children cope with difficult emotions?	relevant, emotion, motivation, critical skills and practical solutions

Table 3: Qualitative examples of model generated responses. We manually highlight in color, phrases that we find to be associated with the context and the critical aspects as mentioned in Tack and Piech (2022).

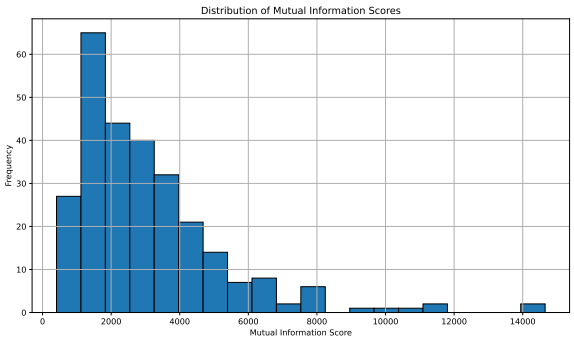

Figure 3: The distribution of mutual information scores derived from combined perplexity values

(Lin, 2004) and the neural network-based metric Dialog perplexity (Li et al., 2016)[3] to further asses our system. We computed ROUGE metrics: `rouge1`, `rouge2`, `rougeL`, and `rougeLsum` resulting in scores of 0.12, 0.0047, 0.084, and 0.087, respectively.

Based on the ROUGE scores, the generated text demonstrates significant overlap with the reference text at the unigram level (`ROUGE-1`) and in longer common sequences (`ROUGE-L` and `ROUGE-Lsum`). This suggests the system stays on-topic and uses relevant vocabulary, beneficial for educational content. However, it shows noticeable shortcomings with exact word sequences (`ROUGE-2`), and discrepancies in longer sequences (`ROUGE-L` and `ROUGE-Lsum`) indicate challenges in maintaining coherence and well-structured responses.

Additionally, Figure 3 depicts the distribution of mutual information scores derived from combined perplexity values. The histogram's right-skewed shape, with scores predominantly in the lower range, suggests that the generated teacher responses are often predictable. While this indicates clarity, conciseness, and consistency in the generated text, which are advantageous for educational contexts, it also reveals a drawback: the responses lack depth and exhibit monotony, significantly reduce text engagement and the nuanced understanding required for deeper learning.

4.3 Output Analysis

We manually inspected the model's outputs and evaluated each prompt's contribution by examining 10 outputs in detail. Table 3 presents the top candidate responses selected through Dual-Encoder ranking for five examples.

To examine the impact of prompts on the best responses, we used the dialogue context `test_0006`, as shown in Table 4, as an example. Here, the teacher is explaining a grammar lesson when the student mentions needing 10 more minutes and feeling very cold in the room. The model's response is inconsistent, as it incorrectly associates "cold" with the grammar lesson rather than the student's condition. This suggests that the model may focus on one situation in the conversation and struggle to adapt when new contexts arise. Consequently, the context of "cold" is incorrectly forced to fit the context itself.

We also found that the model struggles with teacher continuation problems. When the dialogue ends with the teacher, the model often seems unsure about the next response, which happens frequently in the generated outputs. This aligns with research by Vasselli et al. (2023), indicating that

[3]We used DialoGPT and its reverse model to compute perplexity

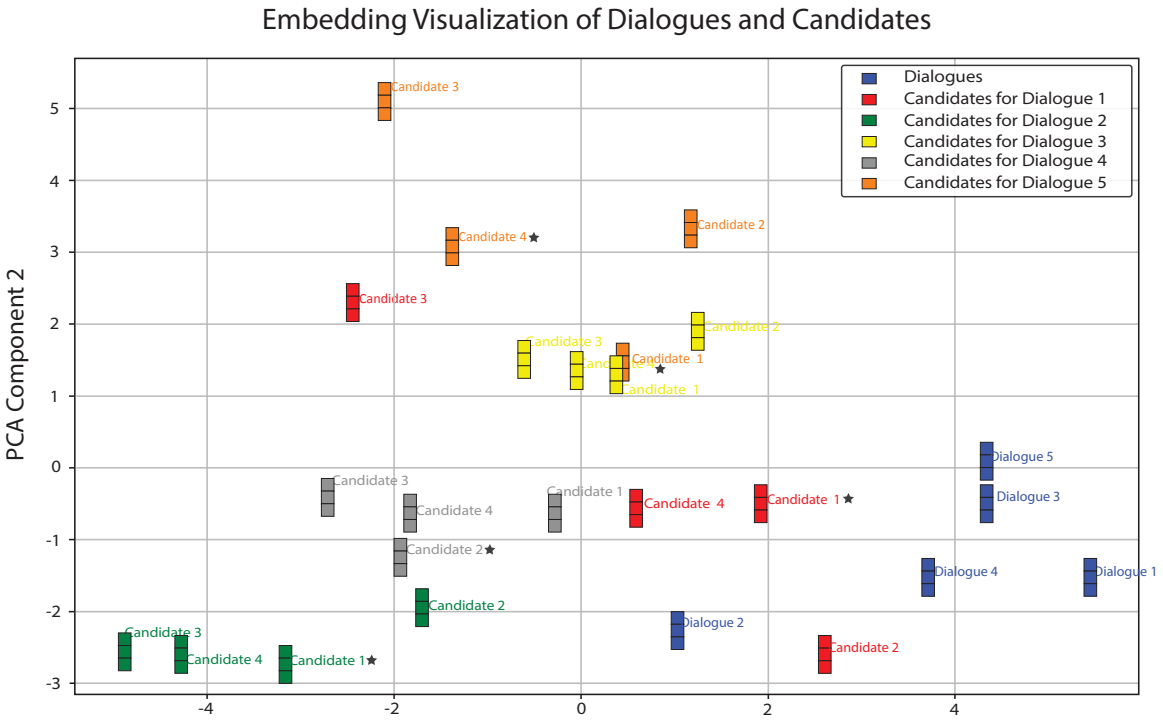

Figure 4: Embedding Space Visualization

Teacher:	Which is easy, because you can use my / his / your etc. and not think about articles!
Student:	Only 10 minutes left!
Teacher:	I know, we can finish early if you are getting cold?
Student:	I'm really cold

Table 4: Example dialogue context of `test_006` between student and teacher

instruct-tuned models trained in user-assistant settings find it difficult to adapt when the setting changes abruptly. For example, in `test_004`, the model repeats the word "great" from the dialogue but fails to understand the context despite managing to introduce a follow-up conversation by asking the student examples.

Furthermore, we analyzed several dialogues with minimal context, some having only two exchanges. This limited context makes it difficult for the model to grasp the overall conversation and provides fewer reference words. A prime example is `test_0011`, which has only one turn with at least 5 words per turn. This lack of context makes it challenging for the model to generate the best response, as the context is insufficiently clear.

Lastly, we analyzed the contributions of each prompt to the final output selected by Dual-Encoder ranking for 10 data points. Prompt 1 significantly influenced the final output, being chosen in 5 examples. This is likely due to the model's strong performance in academic tasks and the straightforward nature of these conversations, which aligned well with Prompt 1's instructions. In contrast, `test_010` involved a complex, multi-turn conversation where Prompt 1 was not chosen because the teacher needed to explain the learning context in greater depth. As conversation complexity increases, the dual encoder selects Prompts 2 and 4, which are better suited to handle more intricate dialogues.

4.4 Word-Level Inspection

To explore the contextual relationships of the best candidates selected by the ranking function, we visualize the attention scores. We analyze the attention generated by the BERT model, as shown in Figure 5 for the example `test_0007`. The dialogue focuses on the teacher's general role, which, while informative, does not directly advance learning in the context of the vocabulary that the students have just learned or used.

The most effective response is: "Great point! Now, let's focus on using this new vocabulary in a meaningful way..." This response directly guides students to practice and apply the newly learned vocabulary in a more meaningful context, aligning more closely with the educational objectives of the dialogue.

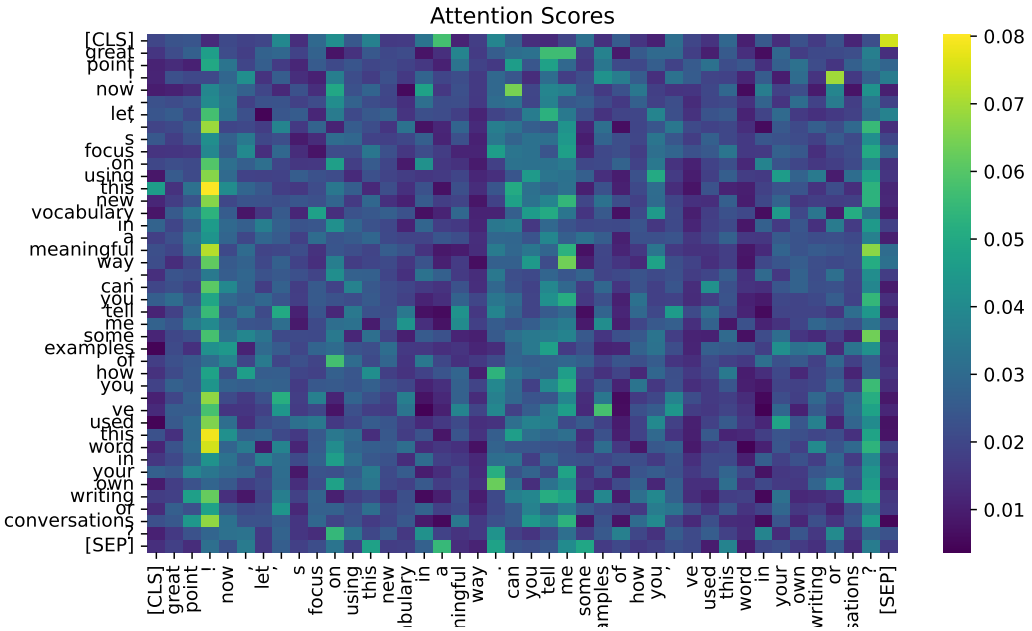

Figure 5: BERT Attention Score for example `test_0007`

According to the BERT Attention Score, attention is concentrated on key words in the dialogue, such as "great," "point," "focus," "using," "this," "meaningful," "way," and "vocabulary," which receive a high level of attention. These words are emphasized because they are directly connected to the higher learning goal of encouraging students to use new vocabulary in meaningful contexts. The teacher highlights the importance of guiding students not just to recognize new vocabulary but also to actively apply it in their writing or conversation. The most effective response aligns better with this learning objective, as it prompts students to consider how to use the vocabulary in practical ways. Ultimately, the attention score fosters a deeper understanding and retention of new vocabulary, contribute to the selection of the best response candidate in the ranking function.

4.5 Dual Encoder Effect

We conducted a manual investigation to assess the dual encoder's impact on selecting the best candidates. Analyzing five dialogue-response pairs' embedding spaces, as shown in Figure 4, we discovered that the Dual-Encoder can avoid the pitfalls of distance-measurement-only. Notably, in dialogue 2, candidate 2 appeared closer to its context than candidate 1 in the embedding space, yet the dual encoder ranked candidate 1 as the best candidate (denoted by $*$). This phenomenon occurred across multiple dialogues, highlighting SBERT and BERT's role in enhancing the model's consideration of contextual relevance and semantic similarity between dialogues and responses, as discussed earlier.

To evaluate the dual encoder's ranking quality, we investigated the phenomenon of closely clustered embedding. Specifically, candidates for dialogue 3 exhibited dense clustering, where increasing embedding proximity indicated greater similarity, complicating candidate selection. After analyzing all candidates, candidates 1 and 4 emerged as optimal choices for this dialogue, supported by their relatedness in the embedding space. However, the Dual-Encoder prioritized candidate 4, suggesting a preference for theoretical discussion and exploration rather than practical context in its ranking criteria.

Finally, we noted a tendency for candidates within each dialogue to cluster together. This indicates that the Gemma model consistently produces similar embedding for each candidate per dialogue, demonstrating stable performance across various dialogues. However, certain candidates were positioned farther from their cluster and nearer to candidates in another cluster. This suggests that the model sometimes encounters difficulties accurately interpreting the dialogue context. We suspect that this issue may arise because SBERT dominance over BERT leads to a loss of full context. Further

investigation is required to delve deeper into this matter.

5 Conclusion & Future Work

We have shown that CIKMar, an educational dialogue generation approach using prompts and a Dual-Encoder ranking with the Gemma language model, yields promising results in educational settings. By utilizing the Gemma 2B model, we maintain high performance in response relevance and accuracy with a smaller, more accessible model.

Despite these strong performances, we have identified limitations hindering optimal results. Specifically, the Dual-Encoder often prioritizes theoretical discussion over practical contextual responses, potentially leading to irrelevant rankings. Future research should explore scenarios where either SBERT or BERT dominates ranking scores.

Additionally, crafting more specific prompts is crucial for deeper contextual understanding in educational dialogues. Lastly, refining the Gemma model to focus on educational contexts and adapt to shifting conversation dynamics is recommended.

A Ensemble Prompts Explanation

Below are the prompts we are using in this research. The details explanation of each prompt can refer to Vasselli et al. (2023).

Zero-shot prompts consist of instructions without examples, while few-shot prompts include examples to guide the model towards relevant responses. Prompt (1) is categorized as a zero-shot prompt, refined to address issues like overly direct answers and sounding too much like an assistant. The rest of the prompts— (2), (3), (4), (5)—are few-shot prompts that require positive and negative examples to help the model avoid irrelevant responses.

Each prompt serves a specific purpose: Prompt (1) focuses on Contextual Understanding, Prompt (2) ensures Relevance, Prompt (3) aims to enhance Engagement, Prompt (4) emphasizes Clarity, and Prompt (5) is dedicated to providing Feedback. Together, these prompts tailor the model's responses to match the student's current learning stage and needs. By grasping the context (Contextual Understanding), the prompts direct the model to produce responses that are relevant to the student's queries, thereby maintaining focus and relevance (Relevance). This relevance boosts student engagement (Engagement), encouraging sustained interest and participation, which is further supported by clear communication (Clarity) that makes complex concepts easier to understand and reduces confusion. Collectively, these prompts help the model generate optimal responses for educational contexts.

(1) The following is a partial conversation between an English language learner and their teacher:

(conversation)

Can you give an example teacher follow-up to their previous message that would be helpful for the language learner? The message should be concise, and worded simply. It should either encourage the continuation of the current topic or gracefully transition to a new teacher-provided topic. Questions should be specific and not open-ended. Try to not sound like an assistant, but a teacher, in charge of the flow of the lesson.

(2) Concatenation of prompt (1) and the following:

Good example: 'Can you make a sentence using 'within'?' Bad example: 'Do you have any questions about prepositions?'

(3) Concatenation of prompt (1) and the following:

How does a teacher sound when responding to a student? What kinds of things would teachers say that chatbots would not? What do they not say? In your response provide an example of a response that sounds like a teacher and one that sounds like a chatbot? Respond succinctly

(4) The following is a partial conversation between an English language learner and their teacher:

(conversation)

They are in the middle of a lesson. Can you give a possible way the teacher could respond?

Remember: **A teacher typically sounds knowledgeable, authoritative, and focused on guiding and instructing students. They may use formal language and provide detailed explanations. Teachers often offer constructive feedback, encourage critical thinking, and ask probing questions to stimulate learning.**

Example of a teacher-like response: "That's a great observation, but let's delve deeper into the topic. Can you provide some evidence to support your claim?"

A chatbot, on the other hand, may sound more informal and conversational. It tends to provide general information or brief responses without much elaboration.

Example of a chatbot-like response: "Interesting! Tell me more." Teachers typically avoid expressing personal opinions or biases. They also refrain from engaging in casual banter or unrelated conversations to maintain a professional and educational atmosphere.

(5) Concatenation of prompt (1) and the following:

Here is an example of an exceptional teacher follow-up:

"Great job, student! Just a small correction, we should use the present tense verb "built" instead of "build" since the construction has already been completed. So the correct sentence is: "The International Space Station is built by NASA." Keep up the good work! Now, let's move on to a new topic - let's talk about your favorite hobbies. Can you tell me what activities you enjoy doing in your free time?"

Here is an example of a poor teacher followup: "That's an interesting observation about poshness. Can you think of any examples of British accents that might be associated with poshness?"

Climate-NLI: A Model for Natural Language Inference and Zero-Shot Classification on Climate-Related Text

Abstract

Climate change is one of the most significant challenges of our era, necessitating innovative solutions across multiple fields. Advancements in NLP offer a promising pathway, particularly through the development of generalized models applicable to various tasks. Despite recent progress, specialized NLP models excel in individual tasks but require substantial domain-specific training data and fail to generalize well to new scenarios. This paper introduces the Climate-NLI, an approach that utilizes NLI models to create a versatile NLP model that can be used for fact-checking and text classification on climate-related text. Experiment results on 10 climate-related datasets show that our proposed model obtained comparable results to the models that have been fine-tuned on task-specific datasets. Our model improves adaptability to new classes by adding training samples without full retraining but struggles with certain classes due to limited related samples and similar but distinct concepts.

1 Introduction

Climate change represents one of the most pressing challenges of our time, demanding innovative and efficient solutions across various domains. A promising approach involves using Natural Language Processing (NLP) advancements to develop versatile models for various tasks. NLP has witnessed tremendous growth, with specialized models achieving state-of-the-art performance on individual tasks such as sentiment analysis, machine translation, and question-answering (Khurana et al., 2022; Maulud et al., 2021; Jiang and Lu, 2020; Tan et al., 2020; Yang et al., 2020; Patil et al., 2022). However, these models often require significant domain-specific training data and struggle to generalize to unseen scenarios (Torralba and Efros, 2011; Arjovsky et al., 2020). This presents a critical challenge: developing efficient and adaptable NLP systems capable of handling various tasks with limited resources.

This paper proposes the Climate-NLI[1] that leverages the power of the Natural Language Inference (NLI) model to build a general-purpose NLP framework. NLI models are designed to determine the entailment between a premise and a hypothesis sentence (Storks et al., 2020). We posit that the reasoning capabilities of NLI models can be exploited to build a foundation for various NLP tasks. By learning to understand the semantic relationships between sentences, the model can be adapted to diverse applications without extensive task-specific training.

2 Related Works

NLI is a well-studied subtask of NLP with numerous applications. Recent work has explored methods that leverage automatically generated, label-specific natural language explanations to produce more reliable labels (Kumar and Talukdar, 2020). Beyond methods, specific datasets have been created for NLI tasks, such as the Stanford Natural Language Inference (SNLI) corpus (Bowman et al., 2015) and its explained variant, e-SNLI (Camburu et al., 2018). The extensive research focus on NLI is understandable considering its usage in many things. NLI serves as a foundation for various tasks, including question answering (Jeong et al., 2021), textual entailment (Bowman et al., 2015; Camburu et al., 2018), and even text classification using few-shot and zero-shot settings (Schick and Schütze, 2021; Kim et al., 2020).

Zero-shot classification is one of the methods that has gained traction in text classification. It is a technique that transfers knowledge from labeled classes to unseen ones (Wang et al., 2019). This approach often utilizes pre-trained language models (PLMs) such as BERT and RoBERTa (Chen et al.,

[1]Our code is publicly available at https://github.com/fjoeda/climate-nli

2022; Gao et al., 2023; Alcoforado et al., 2022; Gonsior et al., 2020; Bujel et al., 2021). However, most studies combined PLMs with other methods. Some studies enhanced the performance of the language models by incorporating domain knowledge to do zero-shot classification. For instance, the work by Chen et al. (2022) combined sentence BERT with knowledge graph embedding, achieving better results compared to PLMs alone. Gao et al. (2023) also utilized additional data containing label descriptions fed to RoBERTa as input, leading to significant accuracy improvements of up to 17% compared to using the original RoBERTa only. This highlights the importance of a model's ability to understand the relationships between words and concepts, which aligns with the core principles of NLI. These tasks involve determining the entailment relationship between a premise and a hypothesis by essentially asking whether the hypothesis logically follows from the provided information (Storks et al., 2020).

Yin et al. (2019) proposed a benchmark and a textual entailment framework that leverages NLI for zero-shot text classification. Wei et al. (2021) also explored the ability of the language models to perform zero-shot tasks, including zero-shot classification, by using inference on unseen task types. By leveraging pre-trained models with strong NLI capabilities, zero-shot learning can achieve robust performance even with limited labeled data.

3 Dataset

We performed the experiment on several datasets representing both text classification and natural language inference tasks limited to climate-related domain, including: Climate-Fever (Leippold and Diggelmann, 2020), ClimateStance, ClimateEng (Vaid et al., 2022), SciDCC (Mishra and Mittal, 2021), Climate Sentiment, Climate Detection (Webersinke et al., 2022), Climate Commitment, Climate Environmental Claim, Climate Specificity, and TCFD Recommendation (Bingler et al., 2022) as shown in Table 1. All datasets except Climate-Fever are for text classification tasks. We used each training, validation, and testing set provided on each dataset. If the validation set is not provided, we split the validation set from the training data for each dataset with a 90:10 proportion. Since the SciDCC dataset was published in a single CSV file, we split the dataset into training, validation, and testing set with an 80:10:10 proportion.

We performed additional pre-processing on the Climate-Fever and SciDCC datasets. The Climate-Fever dataset contains 1.5K climate change-related claims and each claim has five evidences. We converted the dataset into pairs of claim and evidence where each pair is labeled as "support", "refutes", or "not_enough_info". Following Webersinke et al. (2022), we filtered out the evidence sentences with the "not_enough_info" label and focused our model only on deciding whether a claim is supported or refuted. The SciDCC dataset contains 11,539 news articles taken from Science Daily, classified into 20 classes such as Earthquake, Hurricane, Pollution, etc. Each article consists of a title, summary, and body content. In this work, we concatenated the title, summary, and body as the text input.

4 Methodology

The proposed model, Climate-NLI, was developed to handle both fact-checking and classification tasks for general climate-related text. The model was trained on the NLI setting. Using NLI, the model can solve the fact-checking task, and at the same time address the text classification problem using an entailment-based zero-shot classification. The development processes of the model are presented in this section.

4.1 Dataset Preparation

As mentioned earlier, we used an entailment-based approach for zero-shot classification. Therefore, all text classification datasets were converted into NLI task-setting in the preparation step by generating the entailment and contradiction samples. NLI takes two sentences as the premise and hypothesis and then decides whether those sentences are entailment, neutral, or a contradiction.

Selecting Entailment Samples. The entailment samples from the text classification dataset are selected by adding the text data as the premise with the corresponding class label as the hypothesis. Besides the class label, the hypothesis is constructed from a template such as "The text is about <class name>" (e.g., "The text is about agriculture", "The text is about environment"). In terms of zero-shot classification tasks, the model will be provided with the text input along with its candidate labels. The label hypothesis that receives the highest entailment score will be selected as the predicted label for the text input.

Selecting Contradiction Samples. The contra-

Dataset	Task	Data Composition	Num. of Classes	Hypothesis Template
ClimateEng	Classification	Train: 2781; Val: 354; Test: 355	5	This example is about c
Climate Stance	Classification	Train: 2781; Val: 354; Test: 355	3	The stance of this tweet regarding to climate change is c
SciDCC	Classification	Train: 11539	20	This example is about c
Climate Commitment	Classification	Train: 1000; Test: 320	2	Does text talk about climate commitment action? c
Climate Environmental Claim	Classification	Train: 2117; Test: 265	2	Does the claim relate to environment? c
Climate Sentiment	Classification	Train: 1000; Test: 320	3	The text sentiment regarding climate change is c
Climate Specificity	Classification	Train: 1000; Test: 320	2	The text is climate change c
TCFD Recommendation	Classification	Train: 1300; Test: 400	5	Regarding climate recommendation, the text is about c
Climate Detection	Classification	Train: 1300; Test: 400	2	Does the text related to climate? c
Climate-Fever	Fact-checking (NLI)	Train: 2196; Test: 549	2	-

Table 1: The list of datasets used in the training phase along with their task, composition, the number of classes, and the hypothesis template. The class label in the hypothesis template is represented with "c". For the Climate-Fever dataset, we split the dataset with an 80:20 train-test proportion and filtered out the "not_enough_info" label in the data preprocessing step.

diction samples are added to make the zero-shot classification model able to differentiate between labels. We followed Gera et al. (2022), who used the contrast-random approach for generating the contradiction samples. Contrast-random is the preferred setting in terms of performance and computational cost. The contrast-random approach will add the contradiction samples for each entailment sample with a replaced class name on the hypothesis.

Adding Label Variation. We implemented label variation to introduce the model to the unseen labels. The addition of label variation to the hypothesis was done by replacing the corresponding label with its synonym. We used WordNet from the NLTK package to find the list of the synonyms for the corresponding label. The label is then replaced with one of the synonyms randomly. We applied the label variation specifically on topic classification datasets, including ClimateEng and SciDCC.

The Hypothesis Templates. When it comes to zero-shot classification tasks, the entailment-based models such as *bart-large-mnli*[2] use the default hypothesis template like "The example is <class name>". In our case, since we used different datasets from various domains, we specified the hypothesis template based on the dataset as shown in Table 1. Referring to that table, some hypothesis templates use a yes-no question format (e.g., "Does the text related to climate? c") to handle the binary classification tasks where the class names only consist of "yes" and "no".

4.2 Model Training

The Climate-NLI model was developed by fine-tuning ClimateBert (Webersinke et al., 2022) on

[2] https://huggingface.co/facebook/bart-large-mnli

NLI-task setting. ClimateBert is a transformer-based language model that has been pre-trained on over 2 million paragraphs of climate-related texts, such as common news, research articles, and climate reporting of companies. ClimateBert used DistilRoBERTa-base[3], a distilled version of RoBERTa containing 82M parameters, as the starting point of training (Sanh et al., 2020). Climate-Fever and all the converted text classification datasets as shown in Table 1 were used to fine-tune the model. In total, there are 45,802 pairs of premises and hypotheses along with their labels that were used as the training data. In addition to that, 5,498 pairs were used as validation set. The best model was selected based on the best validation accuracy. The Climate-NLI model was trained with specific hyperparameter settings (see Table 2). The text length for each premise and hypothesis was limited to 256 each, to fit the overall limit of 512.

Hyperparameter	Values
Max. sequence length	512
Batch size	16
Optimizer	AdamW
Learning rate	$5 \cdot 10^{-5}$
Max. num. of epochs	50
Num. of early stopping patience	5

Table 2: Hyperparameter for NLI model training.

We also conducted different experiments by fine-tuning ClimateBert on each task-specific dataset with similar hyperparameter settings. Moreover, as the baseline comparison for the NLI-based task, we used *bart-large-mnli*, a pre-trained model with 409M parameters, trained on the Multi-Genre Natural Language Inference (MultiNLI) corpus which contains a crowd-sourced collection of 433K sentence pairs annotated with textual entailment information. All experiments were performed on a single NVIDIA A100 GPU and the random state was set to 42.

4.3 Model Evaluation

We evaluated the Climate-NLI model on the test set for each task-specific dataset. For the fact-checking tasks on the Climate-Fever, we directly used the NLI setting for the inference process and mapped the label, specifically "Support" to entailment and "Refutes" to contradiction. In this work, we only focused on how good the model is in determining whether evidence supports or refutes a claim. Meanwhile, for all classification tasks, we use a zero-shot classification procedure to predict the final label. The Climate-NLI model will be presented with a text input as the premise and a set of label candidates prepended with a template as a hypothesis. In the model output, we took the entailment and contradiction score and applied a softmax function. The label with the highest entailment score will be chosen as the final label.

With the same procedure, we also evaluate the pretrained *bart-large-mnli* model as the baseline comparison for the NLI-based model. We also adjust the hypothesis template for each dataset as shown in 1. For additional comparison, we also trained several ClimateBert models. Each model was individually fine-tuned on their corresponding task-specific training dataset. Macro-averaged F1 were used as the evaluation metrics.

Dataset	Climate-NLI	Bart-Large-MNLI	FT Climate-Bert
ClimateEng	0.66	0.45	0.67
ClimateStance	0.42	0.37	0.52
SciDCC	0.40	0.25	0.49
Climate Commitment	0.74	0.24	0.78
Climate Env Claim	0.84	0.21	0.90
Climate Sentiment	0.73	0.25	0.80
Climate Specificity	0.75	0.42	0.79
TCFD Recomm	0.69	0.17	0.74
Climate Detection	0.90	0.46	0.94
Climate-Fever	0.77	0.39	0.81
Average	0.69	0.32	0.74

Table 3: The F1 scores of Climate-NLI (Ours), Bart-Large-MNLI, and fine-tuned (FT) ClimateBert on each test set of the dataset. The Climate-NLI model was trained with all datasets combined, meanwhile fine-tuned Climatebert was trained on each dataset individually.

[3] https://huggingface.co/distilbert/distilroberta-base

5 Result and Analysis

In this study, we compared three kinds of model specifically the *bart-large-mnli*, fine-tuned ClimateBert model on each dataset, and the Climate-NLI model (ours). We evaluated both fact-checking using the NLI approach and text classification tasks. For the NLI-based model such as *bart-large-mnli* and Climate-NLI, we use zero-shot classification approach to do the classification tasks.

The performance of all models is detailed in Table 3. Notably, Climate-NLI outperforms *bart-large-mnli* on every dataset despite having fewer parameters. This is likely because Climate-NLI was trained using climate-focused data, whereas *bart-large-mnli* was trained on a broader range of information. However, compared to the fine-tuned ClimateBert model on each dataset, Climate-NLI obtained slightly lower performances in all datasets. These performances are in line with Patadia et al. (2021) experiment results, where the entailment-based zero-shot classification model still failed to outperforms the text classification models trained on the task-specific datasets.

5.1 Text Classification Result

In this section, we discuss the Climate-NLI model performance on the zero-shot text classification task. The text classification datasets used to train the model are generally divided into binary and multi-class classifications. Figure 1 shows the distribution of the F1 scores for all classes across each dataset.

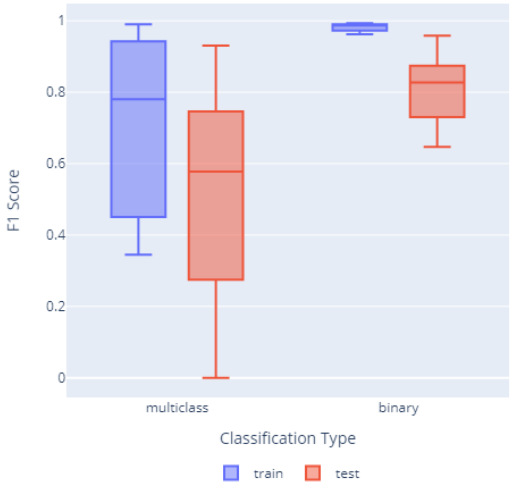

Figure 1: The distribution of F1 scores for all classes across each dataset.

As shown in Fig. 1 that the Climate-NLI model still struggles on the multi-class classification task. Compared to binary classification, the distribution of F1 scores on multi-class is wider than the binary classification even in the train set. This indicates the greater variability in performance across different datasets. The median F1 score in the multi-class classification is also lower, suggesting that the model has difficulty differentiating among multiple classes, as opposed to the simpler binary task. The lowest F1 score in the multi-class classification is 0, which reflects the model's inability to predict certain classes, leading to class imbalance issues. We will discuss the class imbalance issue further in the next section.

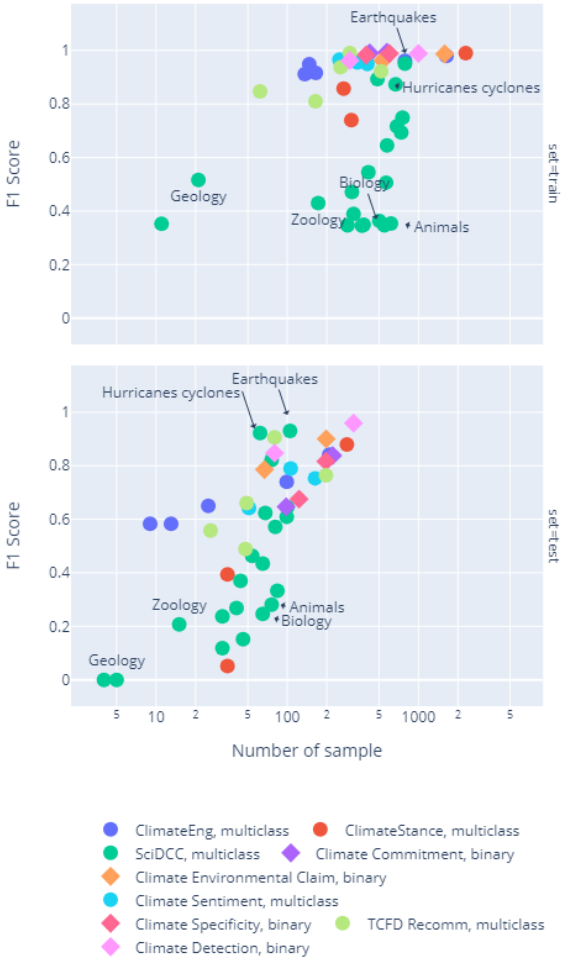

Figure 2: Relationship between the number of samples and the F1 Score for each class on climate-related datasets.

5.2 Class Imbalance Issue

We trained the Climate-NLI model with imbalanced datasets which likely influence the model performance. In Fig. 2, we showed the relationship

between the F1 score and the number of training samples for each class based on the dataset and the classification type. Fig. 2 also presents the relationship on both train and test set.

Fig 2 shows that classes with smaller training samples tend to have a lower F1 score, especially in multi-class classification. In the SciDCC dataset, while the model can classify minority classes in the training set, it struggles in the test set. Moreover, with 20 classes in the SciDCC dataset, classification becomes challenging, especially for minority classes with very few samples—such as only 11 out of 9,231 for the "global warming" class or 21 out of 9,231 for the "geology" class. As a result, the model fails to generalize well on these minority classes. Similar results occur in the hardly distinguished majority classes such as "Animals", "Zoology", and "Biology". We present the comparison of the prediction results on both majority and minority classes of the SciDCC dataset in Table 4 and Table 5.

Example	Seismic activity of New Zealand's alpine fault more complex than suspected A rupture ...
Prediction **Ground Truth**	Earthquakes Earthquakes
Example	How has society adapted to hurricanes? A look at New Orleans over 300 years ...
Prediction **Ground Truth**	Hurricanes Cyclones Hurricanes Cyclones
Example	How do mantis shrimp find their way home?. Patel, a Ph.D. candidate in biological sciences at UMBC, found that the species of...
Prediction **Ground Truth**	Biology Animals
Example	Spectacular bird's-eye view? Hummingbirds see diverse colors humans can only imagine To find food...
Prediction **Ground Truth**	Zoology Animals

Table 4: Climate-NLI prediction samples on the majority class of SciDCC dataset

Table 4 shows that the model predicts the majority and specific classes correctly such as "Earthquakes" and "Hurricanes Cyclones". However, it struggles with distinguishing between overlapping classes, such as "Biology" versus "Animals" or "Zoology" versus "Animals," where the distinction is more nuanced. These errors highlight a limitation in handling closely related classes although the "Animals" class is considered as a majority class.

Example	Volcanic growth 'critical' to the formation of Panama Yet for scientists the exact process by ...
Prediction **Ground Truth**	Earthquake Geology
Example	Fishing for a theory of emergent behavior Some of the most difficult questions in science today ...
Prediction **Ground Truth**	Zoology Zoology
Example	Songbirds, like people, sing better after warming up Researchers at Duke University say there may be a good reason why birds ...
Prediction **Ground Truth**	Animals Zoology

Table 5: Climate-NLI prediction samples on the minority class of SciDCC dataset

In terms of predicting the minority classes, the model performed variably, correctly identifying some labels while struggling with others. Table 5 shows that the model correctly classified a text about "emergent behavior" under "Zoology", demonstrating its ability to match specific scientific content with the correct label. However, in another case, it incorrectly predicted "Earthquake" instead of "Geology" for a text on volcanic growth, and also incorrectly predicted "Animals" instead of the more specific "Zoology" on the songbird text. Those incorrect predictions are likely due to the model focusing on related but distinct concepts. Moreover, the class "Earthquake" has significantly more training samples than "Geology" class which makes the model tend to classify on the majority class over the minority ones.

The results suggest that while zero-shot classification is promising, further refinement or more context-specific candidate labels could improve its accuracy in specialized fields like scientific classi-

fication. Additionally, the zero-shot classification model can be applied to multi-label classification tasks when the labels are not highly distinctive.

5.3 Potential Implementation

Despite the lower performance compared to the fine-tuned model, the entailment-based zero-shot classification model is capable of adapting to any newly added class by adding the new training samples. Meanwhile, the fine-tuned classification model needs to be retrained when a new class is introduced since the number of classes is already defined before the training process (Patadia et al., 2021).

Zero-shot classification also has the capability of being used across unseen datasets and unseen labels (Pushp and Srivastava, 2017). Despite the mediocre performance on the minority classes and the difficulty in distinguishing certain similar classes, zero-shot classification model can be implemented for automatic data labeling through weak supervision where the model is expected to provide hints about the desired class from the defined candidate labels (Åslund, 2021; Wang et al., 2021). This could reduce the time needed to develop a dataset related to climate change.

6 Conclusion

In this paper, we presented Climate-NLI, an NLI-based model specifically designed for fact-checking and zero-shot classification tasks. Evaluation results show that Climate-NLI successfully outperformed *bart-large-mnli*, the NLI model trained on more general text while obtaining slightly lower performance compared to the task-specific fine-tuned ClimateBert model. Our proposed model has better adaptability to new classes by adding the training samples instead of retraining the model with the whole training samples. However, our model still struggles to classify certain classes due to limited training samples for related classes and the presence of similar but distinct concepts.

Limitations

In terms of the fact-checking task, we only tested how good the model was at deciding whether a claim is supported or refuted by evidence, which is just one of the parts of the fact-checking pipeline. A further test of the Climate-NLI model on the whole fact-checking pipeline from evidence retrieval to entailment prediction can be done in the future work.

To simplify the training pipeline in the model training process, we only use the yes-no question template followed by a "yes" or "no" label for the binary classification tasks. Instead of relying on a yes-no question as a template, we may extend the "yes" and "no" labels to a sentence that shows the complete context related to the label. Currently, we leave this as an open question.

Abstract

Task-oriented dialogue systems with large language models (LLMs) show powerful language capabilities. These systems aim to solve particular tasks in narrow domains and consist of different modules. These modules, such as the dialogue state tracker or the response generator, are powered by LLMs. However, LLMs like ChatGPT are prone to hallucinations, which are challenging to spot. This is due to the complex nature of the systems and the limited datasets for narrow domains. This phenomenon could have dangerous consequences for the user, which motivates us to study the hallucination problem. Our task-oriented dialogue hallucination study consists of situation analysis, dataset generation, and hallucination detection in different modules within narrow domains. We analyze the hallucination situation for different modules based on the collected hallucination samples from ChatGPT. We obtain high hallucination rates among modules. Due to the shortage of hallucination datasets, we propose a hallucination score to build suitable hallucination samples from existing datasets. Moreover, we present a Task-oriented Hallucination Detector (THD) for the different modules and domains, which benefits from the generated hallucination samples.

1 Introduction

Large language models (LLMs) show their powerful capabilities in task-oriented dialogue systems, which are widely used to help people solve specific tasks, ranging from booking a hotel to finding a restaurant with a given domain knowledge. Recently, researchers utilized LLMs as the backbone for different modules in task-oriented dialogue systems, such as the dialogue state tracker (Hu et al., 2022b) or the response generator (Hudeček and Dusek, 2023). However, recent black-box LLMs, such as ChatGPT (OpenAI, 2022), tend to generate hallucinations, i.e., they are unfaithful to the domain knowledge or to the information provided by the user (Bang et al., 2023). These hallucinations may provide misleading information or even lead to dangerous situations for the end-user (Li et al., 2023). Therefore, it is imperative and valuable to study the hallucination problem in task-oriented dialogue systems.

In comparison to chit-chat chatbots, LLM-based task-oriented dialogue systems require a state representation to query the domain-related knowledge base (Zhang et al., 2020). A typical system consists of a pipeline of different modules, such as a domain detector, a dialogue state tracker, a dialogue policy, and a response generator, shown as gray blocks in Figure 1 (Zhang et al., 2020; Hudeček and Dusek, 2023). The pipeline of different components is more explainable, controllable, and easier to implement than the end-to-end approach, which uses a unified model (Kwan et al., 2023). However, the complex architecture of a task-oriented dialogue system further complicates the hallucination problem since hallucinations can affect each part of this pipeline.

Figure 1 presents one dialogue example from a task-oriented dialogue dataset, namely MWOZ 2.1 (Eric et al., 2020; Budzianowski et al., 2018). In this task-oriented dialogue, the user wants to find a restaurant called Prezzo. To accomplish the goal, the LLM domain detector first detects the current domain of the user's query. Consequently, the instructions of the pipeline are determined by the predicted domain. Then, the LLM state tracker extracts the user's intention and presents it as a slot and value pair (Hu et al., 2022b). Based on the captured slot and value pair, the task-oriented dialogue system searches for a restaurant called Prezzo from the domain-related knowledge database, which contains information on restaurants. With the retrieved restaurant information, the LLM dialogue policy decides which assistant actions to take. Finally, the LLM response generator creates a response based on the correct dialogue actions.

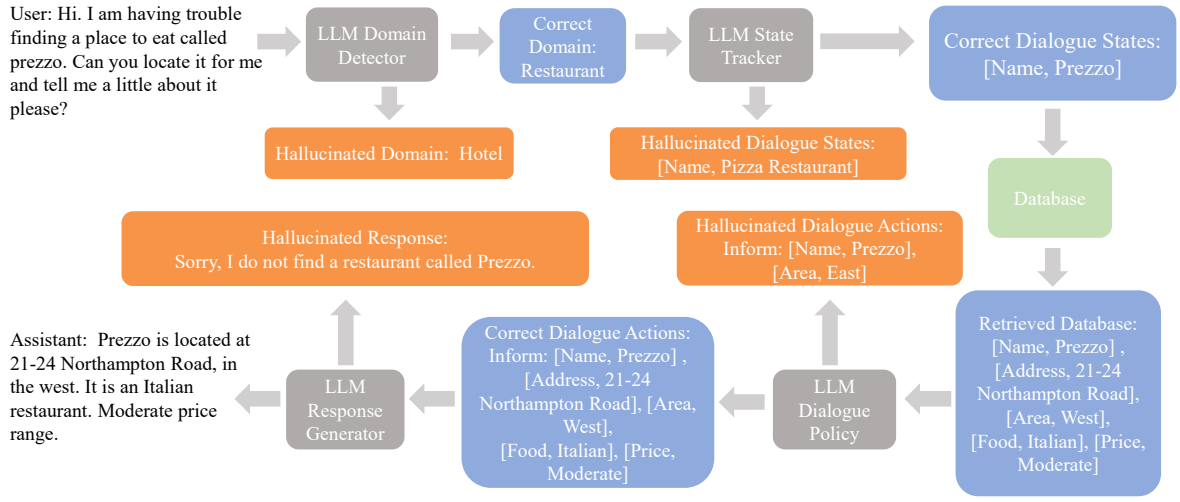

Figure 1: A task-oriented dialogue example from the MWOZ 2.1 dataset (Eric et al., 2020; Budzianowski et al., 2018) with correct outputs (blue boxes) and simulated hallucination outputs (orange boxes) for the domain detector, dialogue state tracker, dialogue policy, and dialogue response generator (gray boxes).

Figure 1 also shows a plausible example of hallucination for each module. A hallucinated domain classification has a detrimental impact on the entire execution, since a task-specific pipeline is selected at this stage to complete the assignment. Hallucinated dialog states result in ineligible restaurants being retrieved from the database. Hallucinated dialog actions from the LLM dialog policy contradict the retrieved restaurant information. Finally, there is a risk that the user will receive a hallucinated response due to the response generation module.

In this paper, we study the hallucination problem for all modules of the black-box-LLM-based task-oriented dialogue systems with narrow domains. Our study framework consists of situation analysis, dataset generation, and hallucination detection.

For situation analysis, we collected naturally generated hallucination samples from ChatGPT to analyze how the different modules are affected by hallucinations. The analysis results show that there are many forms of undesirable hallucinations, with LLM-based modules suffering from hallucination rates of up to 28.8%. Therefore, hallucination detection for task-oriented modules is a critical task.

Current datasets for hallucination detection are limited to just dialogue responses and are not suitable for all modules. Annotating hallucination samples is expensive and time-consuming. However, researchers propose numerous multi-domain task-oriented dialogue datasets. We propose a method with a hallucination score which automatically builds hallucination samples from these existing datasets, to overcome the dataset shortage problem, as shown in Figure 2. For each sample with input materials and a correct output, outputs from other samples can be considered as hallucination output candidates. The hallucination score measures the relatedness between the input materials and output candidate and the similarity between the correct output and output candidate. The output candidate with high relatedness and low similarity is selected as a hallucination output.

Finally, we present our Task-oriented Hallucination Detector (THD) as shown in Figure 3, which is a fine-tuned DistilBERT-based classifier (Sanh, 2019; Wolf et al., 2020) with Low-Rank Adaptation (LoRA) (Hu et al., 2022a). The classifier is fine-tuned with the generated hallucinated samples and existing correct samples. THD learns the forms of hallucination among different modules and domains through fine-tuning. Moreover, LoRA is added to the fine-tuned DistilBERT-based classifier to achieve better performance for different modules and domains. The experimental results on MWOZ 2.1 and M2M (Shah et al., 2018) datasets indicate that our THD outperforms other hallucination detection models.

To the best of our knowledge, this work is the first attempt to explore hallucination generation and detection framework for all black-box-LLM-based modules in task-oriented dialogue systems with narrow domains. Our main contributions are three-fold:

- We conducted hallucination situation analysis based on collected real samples, which show

non-negligible hallucination rates and forms for different modules.

- We propose a method with a hallucination score to automatically build hallucination samples, which is widely applicable in different narrow domains.

- The hallucination detection experimental results on the generated hallucinated MWOZ 2.1 and M2M datasets show that overall our THD can achieve higher accuracy than other evaluated hallucination detection methods for task-oriented dialogue hallucination problems.

2 Related Work

2.1 Hallucination from Large Language Models

Hallucinations could result in the spread of false information and raise serious risks in specific domains (Ji et al., 2023), for example, inaccurate medical information from LLMs (Sharun et al., 2023). These hallucinations are unfaithful or nonsensical texts generated by generative models, which give the natural impression (Ji et al., 2023). For task-oriented dialogue, the generated text is based on the source content, including the instruction, dialogue information, and domain-related knowledge base. The hallucination in task-oriented dialogue emphasizes the inconsistency of generated text from the provided source content (Huang et al., 2023).

2.2 Hallucination Benchmark

To study hallucination from LLMs, researchers have proposed some dialogue-related benchmarks in recent years (Li et al., 2023; Chen et al., 2024; Dziri et al., 2022). However, the annotation for these hallucination benchmarks is very challenging, time-consuming, and expensive. Due to the diverse hallucination instances and ambiguous contents, annotators need high levels of expertise (Chen et al., 2024). Li et al. (2023) utilized labelers with good reading comprehension to annotate generated hallucination response samples. Moreover, these hallucination benchmarks are limited to dialogue responses instead of whole modules of task-oriented dialogue systems (Li et al., 2023; Chen et al., 2024). This paper studies the hallucination problem among all modules and proposes an efficient method for the automatic generation of hallucination samples.

2.3 Hallucination Detection

Recently developed generative LLMs are often released as black-boxes accessed through APIs (OpenAI, 2022; Achiam et al., 2023). These black-box LLMs are used as the backbones for different modules in task-oriented dialogue systems (Hudeček and Dusek, 2023; Bang et al., 2023). Li et al. (2023) utilized GPT3 (Brown, 2020), and ChatGPT to detect hallucinations in open-domain dialogue responses. GPT4 (Achiam et al., 2023) also shows powerful hallucination detection capability in task-oriented dialogue responses (Chen et al., 2024). This paper focuses on hallucination detection from black-box-LLM-based modules in task-oriented dialogue systems.

3 Study Framework

Our study framework focuses on the hallucination problem in all the modules of task-oriented dialogue systems with narrow domains. It consists of three main parts: (1) hallucination situation analysis, (2) hallucination dataset generation, and (3) hallucination detector development.

3.1 Task-oriented Hallucination Analysis

To find the real hallucination incidences in all task-oriented dialogue modules, ChatGPT is employed to generate domain prediction, dialogue states, actions, and responses following Hudeček and Dusek (2023) and Zhang et al. (2020). The task instruction describes the specific requirements and examples for each module and each narrow domain. The input prompt consists of the task instruction and the corresponding input materials as shown in Table 2, like the dialogue context, the dialogue states, the database information, and the dialogue actions. The input prompt is fed into ChatGPT to generate the module output, which is then annotated by human labelers. They detect whether the generated output contains hallucinated content. We collect three labels for each module output. The max-voting label result determines the final hallucination label.

3.2 Task-oriented Hallucination Generation

After the situation analysis, our framework uses an existing dataset to build a task-oriented hallucinated output. As shown in Figure 2, each sample from the existing dataset contains input materials and a corresponding correct output. Inspired by Karpukhin et al. (2020), all other output in the ex-

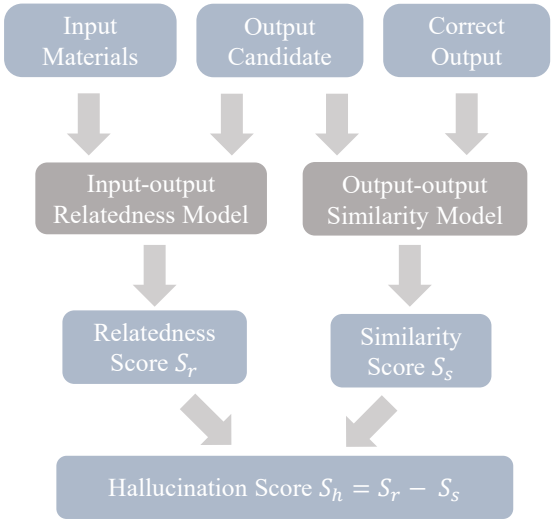

Figure 2: Task-oriented hallucination generation.

isting dataset can be considered as hallucinated output candidates. To ensure the high quality of hallucinated samples, on the one hand, the hallucinated output should be semantically related to the input materials. We build an input-output relatedness model to measure the relatedness score S_r. On the other hand, the hallucinated output should be different from the correct output. The output-output similarity model measures the similarity score S_s between the output candidate and the correct output. Therefore, for each output candidate, we define the corresponding hallucination score $S_h = S_r - S_s$ to measure how suitable the candidate is as a hallucinated output for this sample. After ranking, the most suitable output candidate with the highest hallucination score is selected as the hallucinated output. Based on different splits of existing datasets, the framework builds training, validating, and testing hallucinated samples. Combining correct and hallucinated outputs, we get the dataset for the following hallucination detection task.

The framework uses the sentence transformer model (Reimers and Gurevych, 2019) as an input-output relatedness model and an output-output similarity model. The input-output relatedness model maps the input materials into the representation e_i, and the output candidate into the e_{cr}. The relatedness score S_r is measured by the similarity between e_i and e_{cr}. The output-output similarity model maps the correct output into e_o, and the output candidate into the e_{cs}. The similarity score S_s is measured by the similarity between e_o and e_{cs}. To obtain accurate scores, these models are fine-tuned using positive and negative samples from the existing dataset. For the relatedness model, positive samples consist of input materials and correct outputs. Negative samples contain input materials and randomly sampled outputs. For the similarity model, we use back-translation (Sennrich et al., 2016) to augment the rewritten output, translating the correct output into another language and then back to English. The positive samples then consist of the correct and rearranged outputs. Negative samples consist of correct and randomly sampled outputs.

3.3 Task-oriented Hallucination Detection

We designed a Task-oriented Hallucination Detector (THD) to tackle hallucination detection in different task-oriented dialogue modules. As shown in Figure 3, the output and input materials from each sample are fed into the DistilBERT-based classifier to get the representation $e = DistilBERT([Output, InputMaterials])$. Based on the representation e, the classifier predicts if the output contains hallucination. The DistilBERT-based classifier is fine-tuned with samples of existing correct outputs and generated hallucination outputs from all domains.

After fine-tuning using samples from all domains, we add the LoRA (Hu et al., 2022a) into the fine-tuned classifier for each module and domain. LoRA keeps the DistilBERT-based classifier parameters frozen. The model layer with the form $h = W_0x$ is re-parameterized as $h = W_0x + \frac{\alpha}{r}BAx$. The $W_0 \in R^{d\times k}$, x, and h represent the weight matrix, input, and output, respectively. The $B \in R^{d\times r}$ and $A \in R^{r\times k}$ are the decomposition matrices, which contain trainable parameters. r represents the rank of the decomposition, and α is a constant (Hu et al., 2022a; Poth et al., 2023; Pfeiffer et al., 2020). The model with the LoRA adapter is fine-tuned with corresponding samples from the module and domain. The LoRA is implemented for the detector to analyze the output from the dialogue state tracker, the dialogue policy, and the response generator.

4 Experiments

4.1 Datasets

We conducted our experiments on two multi-domain task-oriented dialogue datasets, MWOZ 2.1 (Eric et al., 2020; Budzianowski et al., 2018) and M2M (Shah et al., 2018). These datasets are

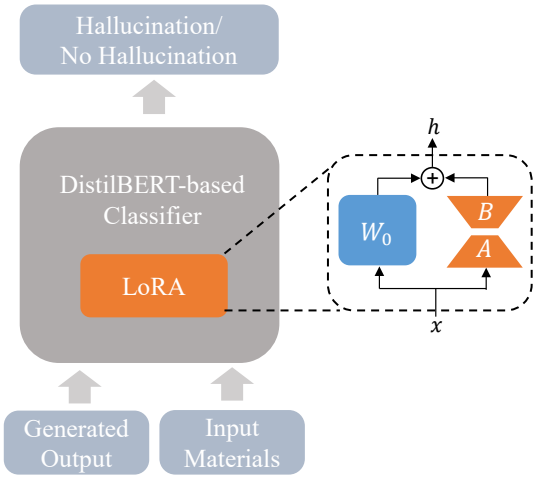

Figure 3: Task-oriented Hallucination Detector (THD) with LoRA (Hu et al., 2022a).

widely used benchmarks for evaluating different dialogue modules. For the MWOZ 2.1 dataset, we selected the following five domains: restaurant, hotel, train, taxi, and attraction. The M2M dataset contains dialogues spanning movie and restaurant domains. However, we skipped the dialog policy module for M2M, because there is no explicit database for this dataset (Shah et al., 2018).

For the hallucination situation analysis, we sampled 500 cleaned samples from MWOZ 2.1. In this dataset, each domain contains 100 cleaned samples. For dataset generation, we sampled 2000/1000/1000 correct samples from the MWOZ 2.1 train/dev/test set. Each correct sample contains input materials and output for all modules. Our framework created a hallucination sample with a hallucinated output for each correct sample. After combining the correct and hallucinated outputs, we obtained 4000/2000/2000 samples for MWOZ 2.1. Following the same procedure, we obtained 1600/800/800 samples for M2M from 800/400/400 correct samples.

4.2 Experimental Details

For our hallucination situation analysis, ChatGPT was used to generate outputs from all modules in task-oriented dialogue systems. For the dataset generation, we utilized the sentence transformer model "All-mpnet-base-v2" (Reimers and Gurevych, 2019; Song et al., 2020) as the backbone for both the input-output relatedness model and the output-output similarity model. ChatGPT was used for back-translation to augment the rewritten outputs. For the hallucination detection, we fine-tuned the DistilBERT model, which is a transformer-based encoder model. Similarly to Li et al. (2023), we report accuracy in determining whether a sample contains hallucinated information, to evaluate hallucination detection models.

	Domain	State	Action	Response
Number	30	85	144	88
Rate	6.0%	17.0%	28.8%	17.6%

Table 1: Hallucination rate statistic of 500 ChatGPT outputs on the MWOZ 2.1 dataset for different modules.

4.3 Existing Hallucination Detection Models

Many recent studies use different LLMs to detect hallucinations (Li et al., 2023; Chen et al., 2024). In this paper, we tested the following models for hallucination detection:

- ChatGPT: A model introduced by OpenAI utilizes reinforcement learning from human feedback (OpenAI, 2022).
- Command R: An LLM optimized for long context tasks shows strong performances on retrieval generation tasks (Cohere, 2024).
- GPT4: The advanced model from OpenAI presents advanced reasoning capability and great performance on many natural language processing tasks (Achiam et al., 2023).

5 Results and Discussion

5.1 Hallucination Situation Analysis

Table 1 presents the statistics of hallucination rates among all modules. For all modules, we manually sample examples of an input, a correct output, a ChatGPT output, and a generated hallucination output. All these examples are described in Table 2 to show the forms of different modules. Both tables show that all modules suffer from hallucination problems.

Table 1 shows that from 6.0% up to 28.8% of ChatGPT outputs are hallucinated, depending on the module that produced the samples. These values indicate that hallucination detection is a critical problem for task-oriented dialogue systems. For a deeper understanding of the hallucinations, we conducted the following analysis for the different modules based on the statistics and real hallucination examples.

Domain Detector	
Input Materials	Context: Customer: help me get a taxi to the cambridge museum of technology please.
Correct Output	Taxi
ChatGPT Output	**Attraction**
Gen. Hallucination	**Attraction**
Dialogue State Tracker	
Input Materials	Context: ... Customer: Yes, I'm looking for a museum in the west. Assistant: How does the cafe jello gallery sound? Or kettles yard? Customer: Could I get the area, phone number, and address of the Kettles yard?
Correct Output	Attraction: [Type, Museum], [Name, Kettles yard], [Area, West]
ChatGPT Output	**Attraction: [Type, Museum], [Area, Kettles yard]**
Gen. Hallucination	**Attraction: [Type, Don't care], [Area, West]**
Dialogue Policy	
Input Materials	Context: Customer: Hi, I'm trying to find a moderate place to eat in the east. Can you help? Assistant: I've found a place called curry prince that fits that. Would you like me to place a reservation for you? Customer: Actually I'm more interested in middle Eastern foods. States: Restaurant: [Food, Middle eastern], [Pricerange, Moderate], [Area, East] Database: No suitable restaurant
Correct Output	Request: [Food, ?]; No-offer: [Food, Middle east]
ChatGPT Output	**Recommend: [Food, Middle eastern]; Inform: [Food, Middle eastern]**
Gen. Hallucination	**Inform: [Price, Expensive], [Address, 2 G Cambridge Leisure Park Cherry Hinton Road Cherry Hinton]**
Dialogue Response Generator	
Input Materials	Context: ... Customer: It does not matter but please find a guesthouse in the expensive range and include free parking. Assistant: There are no expensive hotels in the area. Could we look at a moderately priced one? Customer: Actually, how about a cheap one? Actions: Request: [Area, ?]
Correct Output	What area of town?
ChatGPT Output	**I have several options for cheap guesthouses with free wifi. Would you like me to provide some recommendations?**
Gen. Hallucination	**I don't have anything in that area. Can I look somewhere else?**

Table 2: Examples with input materials, correct outputs, ChatGPT outputs, and generated hallucination outputs for different modules in task-oriented dialogue systems on the MWOZ 2.1 dataset (Eric et al., 2020; Budzianowski et al., 2018).

Domain detector: The LLM-based domain detector classifies the current user message into a corresponding narrow domain (Hudeček and Dusek, 2023). The narrow domain options are defined in the instruction for the domain detector. Compared to other modules, the domain prediction task has simple input and output structures. However, 6.0% of the samples are still hallucinated. As shown in Table 2, ChatGPT predicts the attraction domain when the user requires a taxi. This example indicates that, even for the simple domain prediction task, we can not avoid the hallucination problem.

Dialogue state tracker: The LLM-based dialogue state tracker extracts slot-value pairs as dialogue states, which represent the user's intentions (Hu et al., 2022b). Slot-value pairs are in the task-specific schema, which is defined by the domain ontology. As shown in Table 2, slot-value pairs from the ChatGPT output are in conflict with the dialogue information. Because the slot-value pairs are used for further database query, hallucinated slot-value pairs result in wrong elements retrieved from the database. Moreover, the hallucination rate of 17.0 % in the dialogue state tracker is much higher than 6.0% from the domain detector, as shown in Table 1. Dialogue state trackers are more likely to generate hallucinations due to their complex task-specific schema.

Dialogue policy: Dialogue policy predicts the assistant actions based on dialogue context, dialogue state, and queried database. Assistant actions include intents, like recommend or inform, and related slot values. The actions will be used for final dialogue response generation. Table 2 shows that the ChatGPT output gives a fabricated restaurant recommendation, and no restaurant information is retrieved from the restaurant domain database. From Table 1, we observed the highest hallucination rate of 28.8% from dialogue policy among the four modules. Assistant actions should be consistent not only with the instruction and dialogue context, but also with the dialogue states and the retrieved database information. The complex input materials lead to a high hallucination rate of predicted actions.

Dialogue response generator: The dialogue response generator generates the assistant response conditioned on the dialogue actions. The assistant response is expected to be informative and task-specific. However, the hallucination example in Table 2 presents that ChatGPT does not map the action to a correct response. Furthermore, we observed a high hallucination rate of 17.6% from the dialogue response generator. This rate indicates that the hallucination problem is also challenging for the dialogue response generator.

5.2 Hallucinated Dataset Generation

Table 2 also presents our generated hallucination outputs for the MWOZ 2.1 dataset. We observed that the generated hallucination output is related to the input and dissimilar to the correct output. This result was achieved by choosing the candidate with the highest hallucination score. The example of the dialogue response generator in Table 2 shows that our generated hallucination is related to the input regarding the topic, and the generated output is dissimilar to the correct output, which ensures that the generated output contains hallucinated content. The examples of different module outputs in Table 2 illustrate the quality achievable with the hallucination score method.

5.3 Hallucination Detection

Table 3 presents the primary hallucination detection results on the MWOZ 2.1 and M2M datasets. The evaluated models include our proposed THD and different LLMs with powerful natural language capabilities.

From Table 3, we observed that our THD achieves better overall performance than other models. We made the following notable findings: (1) Our THD achieves the best overall accuracy performance among evaluated models for two datasets. Compared to ChatGPT, THD shows accuracy values that are higher by 9.83%-46.91% on the MWOZ 2.1 dataset, and 26.30%-66.37% on the M2M dataset. These results indicate that our proposed THD successfully learns the hallucination forms among different modules and domains. (2) Our generated hallucination output dataset is challenging. This is shown by the low hallucination detection accuracy of other models included in the study, and even GPT4 reaches only 80.90%-88.80% on MWOZ 2.1.

Ablation study: To understand the impacts of LoRA in our THD, we conducted an ablation study on the MWOZ 2.1 dataset by removing LoRA. The ablation results in Table 4 show that LoRA improves the performance of THD. Removing LoRA leads to a loss in accuracy of 4.97% for dialogue

	MWOZ 2.1				M2M			
	Domain	State	Action	Response	Domain	State	Action	Response
ChatGPT	47.07	49.20	72.02	54.68	33.38	50.63	-	51.83
Command R	41.75	37.17	68.25	66.83	30.21	68.50	-	59.79
GPT4	86.72	88.80	80.90	82.17	99.58	90.50	-	86.88
THD	93.98	94.42	81.85	85.18	99.75	95.83	-	78.13

Table 3: Primary hallucination detection results with accuracy metric (%) on MWOZ 2.1 and M2M datasets.

	Domain	State	Action	Response
THD	93.98	94.42	81.85	85.18
-LoRA	-	89.45	79.98	84.77

Table 4: Ablation study with accuracy metric (%) by removing LoRA on MWOZ 2.1.

	Domain	State	Action	Response
THD	95.93	82.67	70.13	81.40
GPT4	85.20	81.93	70.73	77.07

Table 5: Accuracy results (%) on 500 collected ChatGPT outputs with human annotations.

states and 1.87% for dialogue actions. These values indicate that LoRA can adapt THD to different narrow domains and enable THD to learn the hallucination forms for the different modules on the MWOZ 2.1 dataset.

Real examples detection: To show the performances in real-life samples, we decided to compare our THD and GPT4 on the 500 ChatGPT outputs that have been annotated during the hallucination situation analysis. Table 5 shows that THD, fine-tuned with generated hallucinations, achieves comparable accuracy performance in real-life samples. This result indicates that THD can benefit from the generated hallucination outputs, which overall simulate the real hallucination situation in task-oriented dialogue modules.

6 Limitation and Future Work

In this paper, we focus on the MWOZ 2.1 and M2M datasets because they are widely used in task-oriented dialogue modules. However, these two datasets cover limited narrow domains and samples, and they contain only English dialogues. The experiments are based on evaluated models, such as the DistilBERT model and ChatGPT, and the described experimental settings. The limited datasets, models, and settings are potentially leading to a bias in the study. In the future, the study framework could be extended to more datasets, different languages, and more developed LLMs, to overcome the domain limitations and reduce the bias.

We highlighted the most vulnerable components of task-oriented dialogue systems based on LLMs, laying the foundations for future engineering improvements to create more reliable virtual assistants. The dialogue policy module needs to be improved for increased reliability. This could be achieved by checking the module output with an accurate and efficient hallucination detector, or by reducing the hallucination rate of the underlying LLM.

7 Conclusion

In conclusion, our paper studies the hallucination problem for all black-box-LLM-based modules in task-oriented dialogue systems with narrow domains. The hallucination situation analysis shows the hallucination rates and forms for all modules, indicating the importance of the hallucination problem. Our dataset generation method, with the hallucination score, successfully simulates the real ChatGPT outputs with hallucinations. Overall, our THD for hallucination detection can benefit from the generated hallucination samples in two datasets. These results encourage future work for hallucination studies in all modules of task-oriented dialogue systems.

A Appendix

For our hallucination study, we utilize ChatGPT and GPT4 from OpenAI. The Command R model is accessed through the APIs. The "All-mpnet-base-v2" is from Sentence Transformers. The DistilBERT model is from Hugginface (Sanh, 2019; Wolf et al., 2020). The LoRA is implemented with AdapterHub (Poth et al., 2023; Pfeiffer et al., 2020). Because the input length of DistilBERT is limited, we choose the recent utterances as history instead of the whole turns. For the hallucination detection part, we conducted experiments three times for ChatGPT, Command R, and GPT4. The experiments for THD run three times with different seeds. The final accuracy results are the average scores of the three-times experiments.

VHE: A New Dataset for Event Extraction from Vietnamese Historical Texts

Abstract

The event extraction (EE) task, which detects occurrences of specified event types and extracts corresponding event arguments from unstructured data, is crucial for the study of history. However, most existing datasets are not available in Vietnamese. Our work aims to address this data scarcity problem for EE models. In this paper, we introduce a new dataset - Vietnamese Historical Events (VHE) [1] for the EE task in the context of Vietnamese historical documents - a domain characterized by unique linguistic structures, historical references, and cultural nuances. Specifically, our dataset features 35 event types, 9 entity types, and 11 argument roles that pertain to historical events from the Hong Bang dynasty (2879 BC) to the Later Le dynasty in the sixteenth century. To create this dataset, we utilize large language models (LLMs) as data annotators and validate their results through human review. We then conduct experiments on the VHE dataset using both current state-of-the-art event extraction (EE) systems and LLMs, including closed-source models (e.g., GPTs, Gemini) and open-source models (e.g., LLaMA, Phi, Qwen, Gemma). The results reveal their poor performance on historical texts and underscore the numerous challenges faced by existing EE systems, such as the evolution of word meanings over time and ambiguities in sentence structures.

1 Introduction

History is an important field of study that plays a vital role in shaping the identities, values, and futures of individuals and societies (Boros et al., 2022). The proliferation of digital historical documents enables researchers to collect and study information more easily, but it also presents a significant challenge as history continues to unfold and becomes increasingly vast. While the goal of event extraction is to extract organized event knowledge from unstructured text, it also improves the efficiency of information acquisition. Generally, the event extraction task can be decomposed into two subtasks: Event Detection (ED) and Event Argument Extraction (EAE) (Li et al., 2022). The ED task aims to detect event trigger words and classify them into event types, while the EAE task identifies arguments involved in the event and their corresponding roles. Figure 1 shows an example of the event extraction task.

Since event extraction is fundamental to various natural language processing applications (Li et al., 2022), it has attracted many research attention in recent years (Yarmohammadi et al., 2021; Hsu et al., 2022; Peng et al., 2023), building on available datasets such as ACE 2005 (Walker et al., 2006), FewEvent (Deng et al., 2020), MAVEN (Wang et al., 2020), RAMS (Li et al., 2021). However, most existing datasets primarily support high-resource languages like English and Chinese, limiting further research on low-resource languages like Vietnamese. Only one Vietnamese dataset (Nguyen et al., 2024) is available, having been released just a few months ago. Additionally, documents in the existing datasets are typically derived from recent articles, where the use of words differ from their historical usage. Currently, there is only one English dataset (Lai et al., 2021), which focuses on the history domain.

In this study, we introduce VHE, a novel dataset for event extraction from Vietnamese historical texts. VHE supports three tasks: event extraction, event detection, and event argument extraction. We first develop an event schema tailored for Vietnamese historical events. Next, we design prompts to automatically annotate the dataset using large language models (LLMs), including GPT-3.5 and GPT-4o. These annotations are subsequently reviewed by humans to ensure high accuracy and

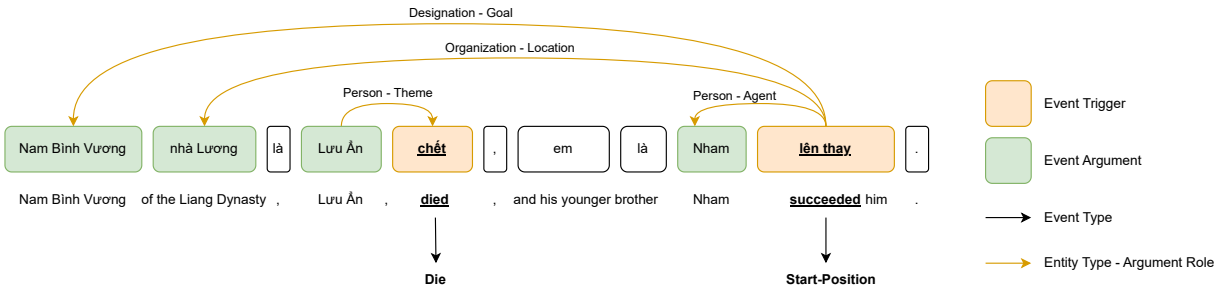

Figure 1: An example of event extraction in the text. It can extract two types of events. The first is the *Die* event, triggered by the keyword *"chết"* with an argument role of *Theme*. The second is the *Start-Position* event, triggered by the keyword *"lên thay"* with three argument roles of *Theme*, *Location*, and *Goal*.

quality. As a result, our dataset includes *4,114* instances containing *5,213* events and *7,423* event arguments. Finally, we evaluate state-of-the-art event extraction models on VHE, including both closed-source and open-source LLMs. Our experiments reveal a significant gap between human performance and that of the models in extracting events from Vietnamese historical texts, highlighting the need for further research in this area.

2 Background and Related Work

2.1 Event Extraction

Event extraction aims to detect occurrences of specified types and extract corresponding event arguments from unstructured data input. The ACE 2005 program (Consortium, 2005) defines an event schema with terminologies that have been widely adopted in event extraction. We outline the key terminologies as follows:

- An **event** is a specific occurrence involving participants
- **Event extent** is a sentence within which an event is expressed.
- **Event trigger** is a word or a phrase that mostly clearly expresses the occurrence of the event.
- **Event argument** are entities that are part of the event.
- **Argument role** is the relationship between an event and its arguments.

Based on these terminologies, Ahn (2006) proposed dividing event extraction into the subtasks of trigger detection, trigger classification, argument detection, and argument classification. Specifically, trigger identification and trigger classification can be grouped under the event detection task, while argument identification and argument classification fall under the event argument extraction task. **Trigger identification** involves detecting event triggers within an event extent, while **Trigger classification** assigns these identified triggers to specific event types. Similarly, **Argument identification** is to identify all arguments associated with an event type, while **Argument classification** is responsible for assigning these arguments to their corresponding roles. In this paper, we inherit all the above-mentioned settings in both dataset construction and model evaluation.

2.2 Related Work

There are numerous EE datasets across various domains, including the Wikipedia domain (Deng et al., 2021; Li et al., 2021; Pouran Ben Veyseh et al., 2022) and the news domain (Ebner et al., 2020; Tong et al., 2022; Nguyen et al., 2024). Recently, some works have focused on the general domain to encompass a broader range of event types (Deng et al., 2020; Wang et al., 2020; Parekh et al., 2023). In specific domains, datasets like Genia2011 (Kim et al., 2011), MLEE (Pyysalo et al., 2012), and Genia2013 (Kim et al., 2013) have been proposed for biomedical research; CASIE (Satyapanich et al., 2020) for cybersecurity; PHEE (Sun et al., 2022) for pharmacovigilance; EDT (Zhou et al., 2021) for stocks; IndiaPoliceEvent (Halterman et al., 2021) for political events; ChFinAnn (Zheng et al., 2019) for financial data; and BRAD (Lai et al., 2021) for historical events.

3 Dataset Creation Process

Our dataset creation process, illustrated in Figure 2, consists of four main steps: (1) data preparation, (2) event schema construction, (3) data anno-

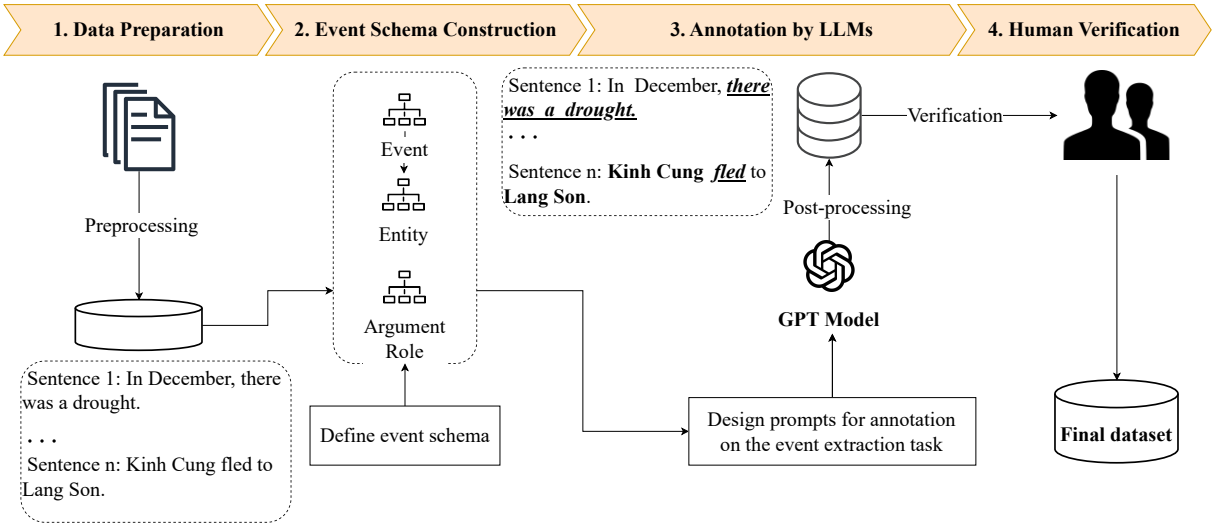

Figure 2: Our dataset creation process. It consists of four main steps: (1) data preparation, (2) event schema construction, (3) data annotation by LLMs, and (4) human verification, corresponding to four subsections: 3.1, 3.2, 3.3, and 3.4.

tation by LLMs, and (4) human verification. We first describe each of these steps and then provided statistics for the final dataset.

3.1 Data Preparation

We use The Complete Annals of Đại Việt, the oldest official historical text of Vietnam. This book, compiled into 23 volumes, records the history of Vietnam from the reign of King Duong Vuong (2879 BC) to the reign of Le Gia Tong of the Later Le Dynasty (1675). Firstly, text is extracted from the document files, and headers, footers, footnotes, and author comments are removed. We then use VnCoreNLP (Vu et al., 2018) to split texts into sentences and normalize them (removing duplicate spaces, correcting diacritics, etc.). Finally, we obtained a total of 21,001 sentences for the entire dataset.

3.2 Event Schema Construction

The event schema used by the existing datasets is inconsistent because of discrepant assumption about data, different preprocessing steps and the use of external resources (Huang et al., 2024) while extracting includes several tasks such as event detection, event argument extraction, and role labeling. (Lai et al., 2021). Hence, we aim to construct a new event schema with reusable and extendable capabilities that adapt to context.

To begin with, we use the widely adopted event definitions from ACE for event types and the common entity types and semantic roles[2] for argument roles as follows:

Event Types We utilized 33 event types along with an additional event type *Nature* which includes two subtypes: *Natural-Disaster* and *Natural-Phenomenon*, as suggested by our experts. A *Natural-Disaster* event occurs when a natural disaster causes damage to people and property or destroys architectural structures (e.g., earthquake, drought) while a *Natural-Phenomenon* event occurs when an unusual natural phenomenon appears without causing any impact on humans or other entities (e.g., solar eclipse). Table 8 provides the examples of event types in our dataset.

Entity Types 9 entity types were selected from the Vietnamese NER tagset,[3] including *Person (PER)*, *Organization (ORG)*, *Location (LOC)*, *Datetime (DTM)*, *Designation (DES)*, *Measure (MEA)*, *Terminology (TRM)*, and *Miscellaneous (MISC)* for other entities. Table 6 provides the definitions of entity types used in our dataset.

Argument Role Types We adopted 11 common argument roles, including *Agent*, *Experiencer*, *Force*, *Theme*, *Content*, *Instrument*, *Beneficiary*, *Source*, *Goal*, *Temporal*, and *Location*. Table 7 provides the definitions of argument role types used in our dataset.

Entity Types	Percentage (%)
PER	52.0
DTM	19.0
LOC	11.0
DES	10.0
ORG	3.0

Argument Role Types	Percentage (%)
Theme	31.0
Agent	28.0
Temporal	19.0
Content	10.0
Location	5.0

Table 1: Five top-level entity and argument role types in the VHE dataset.

Depending on the context of the text, all these types of entities and argument roles are reused across all event types in our dataset. Appendix C shows more details of the event scheme in VHE.

3.3 Annotation by LLMs

To leverage the information extraction capabilities of LLMs (Ma et al., 2023; Li et al., 2023; Han et al., 2023) and minimize the time required for the annotation process, we designed prompts to automatically annotate events using GPT-4o and verified the results through human review to create a gold dataset.

Based on the predefined event schema, the prompts include the categories of event, entity, and argument role, but do not provide examples. The entire dataset was annotated by two GPT models, including GPT-3.5-turbo and GPT-4o-mini (Brown et al., 2020). We then filtered out all results that did not conform to the event schema or were in the wrong format. As a result, the dataset contains approximately 15,000 instances in total.

3.4 Human Verification

The review process involved two native speakers who were not experts. Initially, they were provided with annotation guidelines and examples for each event type. Each annotator then tested a subset of events to ensure a clear understanding of the guidelines. We subsequently collaborated to discuss and resolve any conflicts, ultimately reaching a consensus on the final dataset.

As the event annotation is complicated, we separated the dataset into 2 subsets to reduce information overload for reviewers. The first subset contained 3,153 events that were assigned the same event type by both GPT models, accounting for about 20% of the dataset. The second subset comprised about 80% of the events annotated by GPT-4o-mini. Initially, reviewers examined the first subset to gain a better understanding of the dataset's context, working independently. Subsequently, they collaborated to review the second subset and produce the gold dataset.

4 Dataset Quality Assessment

To validate the quality of the dataset, we randomly sampled 150 instances from the gold dataset and removed their labels. We then recruited two trained undergraduate students to manually annotate these samples. We utilize Cohen's Kappa (Cohen, 1960) to calculate the inter-annotator agreement (IAA) score between the two annotators for each subtask. The scores obtained were 82.0% for trigger identification, 76.5% for trigger classification, 60.0% for argument identification, and 58.0% for argument classification. Notably, The human performance average scores align with the IAA scores for each subtask. Although the inner-annotator agreement scores of the event argument extraction task are slightly lower, remains within an acceptable range, affirming the consistency and reliability of our dataset.

5 Dataset Analyses

Figure 3 illustrated the distribution of event types in our dataset. We observe that most events from this era focus on three main event types: *Start-Position*, *Attack*, and *Die*. Additionally, the *Justice* event types have relatively few occurrences, and there are no events related to the *Declare-Bankruptcy* event type. Therefore, the inherent data imbalance problem also exists in our dataset. Moreover, we identified ambiguity within VHE, which underscores the need for EE models to address this imbalance and uncover cross-sentence relationships.

Table 1 shows the top five entity and argument types and their proportions in our dataset. The highest proportions include PER (52%) for entity types, and Theme (31%), Agent (28%) for argument role types. Additionally, the argument DTM

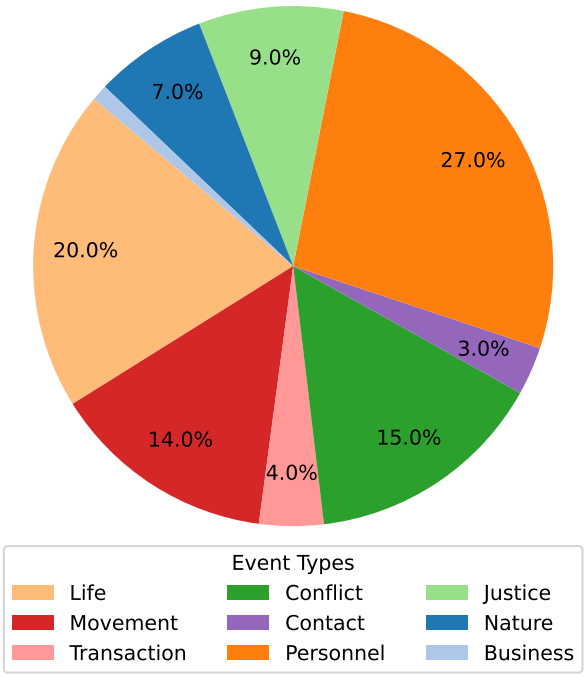

Figure 3: Distribution of event types in the VHE dataset.

and LOC account for approximately 25-30% of the dataset. These proportions are consistent with the most common event types in the dataset. To maintain the real-word distribution in VHE, we do not apply data augmentation or balancing during dataset construction.

6 Experiments

In this section, we first describe our experimental settings, including the models, various types of prompting, and the evaluation metrics used. We then present the performance of LLMs and state-of-the-art event extraction models on our dataset. We evaluate three groups of models: (1) closed-source LLMs, (2) open-source LLMs, and (3) end-to-end models. Finally, we analyze common errors that influenced the evaluation outcomes.

6.1 Experimental Settings

Models To gain a better understanding of how current models extract events from Vietnamese history texts, we evaluate three groups of models on our dataset: (1) closed-source LLMs, (2) open-source LLMs, and (3) end-to-end models. Since our dataset is in Vietnamese, we consider choosing LLMs that support multilingual capabilities. We use **GPT-3.5-turbo** and **GPT-4o** (Brown et al., 2020) as closed-source LLMs, while **Llama-3.1-8B-Instruct** (Dubey et al., 2024), **Gemma-2-9b-it** (Team et al., 2024), **Phi-3.5-mini-instruct** (Abdin et al., 2024), and **Qwen-2-7B-Instruct** (Yang et al., 2024) are considered for open-source LLMs. For end-to-end EE models, we adopt the pre-trained EE model provided by OmniEvent (Peng et al., 2023), which implements the **Ses2Seq** paradigm (Sutskever et al., 2014) using **mT5** (Xue et al., 2021) as the base model.

Prompting In our experiments, the prompts were designed to perform both event detection and event argument extraction tasks simultaneously. To guide LLMs in generating responses within the scope of predefined event types, we included specific context within the prompts. Each model was evaluated using two prompting techniques: zero-shot and few-shot (2-shot and 4-shot). However, instruction-tuned LLMs (e.g., LLaMA, Gemma, Phi, Qwen) have shown limited robustness to variations in instruction phrasing (Sun et al., 2023). Consequently, we excluded zero-shot evaluations for these models. Appendix B provides an illustration of the prompts used in the evaluation process.

Evaluation Metrics To evaluate the event extraction task, most EE systems and datasets use precision, recall, and F1 scores as key evaluation metrics (Sheng et al., 2021; Yang et al., 2019; Chinchor, 1992). Due to the complexity of event extraction, these metrics are applied independently to each subtask. We report F1 scores for four subtasks: trigger identification, trigger classification, argument identification, and argument role classification. Appendix A provides additional results on our dataset, including all the detailed scores.

6.2 Results

Table 2 presents the performance of the models across four subtasks: trigger identification, trigger classification, argument identification, and argument classification. It is noted that due to the cost of running LLMs, we evaluate closed-source LLMs on a subset of our dataset, which includes 1,300 instances. In contrast, open-source LLMs and the end-to-end EE model are evaluated on the entire dataset.

End-to-End Models vs. LLMs From table 2, it can be seen that the end-to-end model performs poorly on the VHE dataset. Almost all sub-tasks of event extraction achieve less than 20.0 F1, with the event argument extraction task reaching only about 2.0 F1. One reason for this poor performance is

Group	Model	TI	TC	AI	AC
End-to-end models	Seq2Seq + mT5	17.13	6.42	2.03	0.35
Open-source LLMs	Llama-3.1-8B-Instruct (2-shot)	43.37	27.49	21.49	14.68
	Llama-3.1-8B-Instruct (4-shot)	42.57	28.04	**25.53**	17.36
	Gemma-2-9b-it (2-shot)	**48.53**	33.49	20.09	16.86
	Gemma-2-9b-it (4-shot)	47.20	**34.25**	24.39	**19.92**
	Phi-3.5-mini-instruct (2-shot)	17.34	9.29	2.74	1.87
	Phi-3.5-mini-instruct (4-shot)	12.08	6.79	1.56	1.14
	Qwen-2-7B-Instruct (2-shot)	29.36	16.10	10.88	6.12
	Qwen-2-7B-Instruct (4-shot)	19.68	12.47	5.60	3.67
Closed-source LLMs	Gemini-1.5-flash (zero-shot)	38.04	32.03	13.45	7.86
	Gemini-1.5-flash (2-shot)	36.45	30.88	14.43	9.91
	Gemini-1.5-flash (4-shot)	35.20	29.10	13.99	9.46
	GPT-3.5-turbo (zero-shot)	24.45	16.55	4.47	3.51
	GPT-3.5-turbo (2-shot)	28.91	19.25	4.74	3.82
	GPT-3.5-turbo (4-shot)	27.01	18.26	4.93	4.01
	GPT-4o (zero-shot)	18.85	17.39	4.64	3.16
	GPT-4o (2-shot)	**39.11**	**33.85**	13.81	10.80
	GPT-4o (4-shot)	35.18	30.90	**14.53**	**11.18**
Human	Average	75.85	67.97	58.15	41.32
	Inter-Annotator Agreement	82.00	76.50	60.00	58.00

Table 2: F1 scores of the models for four subtasks—Trigger Identification (TI), Trigger Classification (TC), Argument Identification (AI), and Argument Classification (AC)—on our dataset. We also present the average scores from human annotators and the inter-annotator agreement.

that the model has not been trained on any Vietnamese datasets except for the mT5 base model.

Open-source LLMs vs. Closed-source LLMs For open-source LLMs, Gemma-2-9b-it outperforms other models in TI (48.5 F1) and TC (34.2 F1), and its gains in AI (24.3 F1) and AC (19.9 F1) in the 4-shot setting suggest a stronger ability to leverage additional context. In contrast, both Phi-3.5-mini-instruct and Qwen-2-7B-Instruct show declining performance with an increasing number of shots, indicating a potential struggle with handling more contextual information. For example, the highest TI (17.34 F1) and TC (9.2 F1) for Phi-3.5-mini-instruct and the highest TI (29.3 F1) and TC (16.1 F1) for Qwen-2-7B-Instruct are observed under the 2-shot setting.

For closed-source LLMs, GPT-4o (2-shot) demonstrates the best performance in TI (39.1 F1) and TC (33.8 F1) when compared to GPT-3.5-turbo, while Gemini-1.5-flash excels in the zero-shot setting, particularly in TI (38.0 F1) and TC (32.03 F1), outperforming other models in this context.

Overall, most models perform consistently well in the 2-shot setting, though their performance doesn't scale significantly with more shots. Open-source models might be more adaptable for specific use cases where control and customization are crucial, while closed-source models tend to deliver higher performance, especially in scenarios with minimal or no additional context.

Models vs. Human Performance Across all metrics, human performance vastly outstrips that of both open-source and closed-source models. The closest models achieve less than 30% of human performance in TI (75.8 F1) and TC

(67.9 F1), with even larger gaps in AI and AC. Among the models, Gemma-2-9b-it (open-source) and GPT-4o (closed-source) achieve the highest scores, but they still fall far short of human-level accuracy, particularly in more nuanced tasks like Argument Identification and Classification.

Summary Despite advances in model capabilities, a substantial gap remains between machine performance and human expertise. Most models performed better in trigger identification and classification than in argument identification and classification. Notably, there is a significant gap between the event detection and event argument extraction tasks. This highlights numerous research opportunities for future work on the VHE dataset. Appendix A show details of evaluation results.

6.3 Analyses

Through the manual checking, we find that ther errors mainly inlude:

Span Error Since LLMs generate human-like responses, they often extract event triggers and arguments that are longer than those found in the gold dataset. For instance, in the sentence *"Sai quân đánh úp phá được tướng Tây đạo nguỵ là quận Nhai, quận Cao ở Nhật Chiêu thuộc Bạch Hạc bắt được 40 chiếc thuyền và 7 con voi. (The dispatched troops launched a surprise attack and defeated the Western Route rebel generals, Quận Nhai and Quận Cao, at Nhật Chiêu in Bạch Hạc, capturing 40 boats and 7 elephants)"*, the event trigger *"đánh úp (surprise attack)"* is sufficient, rather than *"đánh úp phá (surprise attack and defeated)"*. Additionally, LLMs have also automatically rephrase sentence which cause a failure of event trigger. For example, in the sentence *"Tháng 11, cho Nguyễn Danh Thế kiêm chức Đô ngự sử. (In November, Nguyễn Danh Thế was concurrently appointed to the position of Chief Censor.)"*, the phrase *"cho kiêm chức (appointed)"* was assigned to the event trigger while the entity *"Nguyễn Danh Thế"* was automatically omitted.

Linguistic Structures The dataset is derived from the oldest historical texts, which employ numerous linguistic structures that differ from those found in modern texts. Many subjects, as well as cross-references, are implied rather than explicitly stated, leading to ambiguities in meaning. For example, in the sentence *"Hôm ấy, Hữu tướng Hoàng Đình Ái sai thuộc tướng đánh bắt được, đem chém, bắt được 4 tên đồ đảng giải đến cửa dinh, cũng chém cả. (That day, the Right General Hoàng Đình Ái ordered his subordinate officers to attack and capture the enemy, who was then executed. Four members of the rebel group were also captured and brought to the headquarters, where they were all executed.)"*, the event trigger *"chém (executed)"* activates the *Execute* event in which the entity *the enemy*, affected by the event, is omitted and the entity *4 tên đồ đảng (Four members of the rebel group)* was assigned to an argument role of this event instead.

Entity vs. Event Argument Confusion There might be confusion between what constitutes an entity in NER and an event argument in event extraction tasks. For example, the argument mention *"chùa Thiên Quang, Thiên Đức (Thiên Quang, Thiên Đức pagodas)"* is automatically interpreted as *"chùa Thiên Quang (Thiên Quang pagoda)"* and *"chùa Thiên Đức (Thiên Đức pagoda)"*. Moreover, in historical texts, entities might be ambiguous or outdated, leading to challenges in accurate argument annotation.

Error Types In the post-processing of LLM-annotated events, we identify four types of errors related to event types, entities, and argument roles: Incorrect types, Undefined types, Incorrect format, and Other errors, which include issues like unannotated spans, unexpected information, and irrelevant context.

7 Conclusion

In this paper, we propose VHE, a new event extraction dataset focused on historical texts in Vietnamese. We conduct a thorough evaluation of state-of-the-art end-to-end model as well as LLMs on VHE. The results indicate that the event extraction from historical texts remains challenging, and VHE may facilitate further research in this area.

In the future, we intend to extend our work in several ways. First, we plan to enlarge our dataset with additional annotated documents. Second, we aim to expand the event schema to include event relations. Third, we will develop an end-to-end model for Vietnamese historical events.

Limitations

In this work, we make efforts to reduce the gap between high-resource and low-source languages in the event extraction. However, due to limitations

in human resources, it is challenging for us to obtain a larger amount of labeled data. Additionally, there is a possibility that some events annotated by LLMs may be overlooked. Furthermore, as history is a complex domain, our knowledge may not encompass all taggable events from the dataset. We will continue to maintain and update our proposed dataset for future research.

Table 3: Precision (P), Recall (R), and F1 scores for four subtasks, including Trigger Identification (TI), Trigger Classification (TC), Argument Identification (AI), and Argument Role Classification (AC) on VHE.

Zero-shot prompt for Event Extraction

Instruction
Your task is to extract all events mentioned in a list of texts. If any event does not belong to the event types listed below, or if you are unsure, just ignore it.
Input format: text-id: text.

Context
An event has four parts: the event type, which includes the type of event and its corresponding subtype; the event trigger, which is a word or phrase that most clearly expresses the occurrence of the event; the event arguments, which are entities involved in the event; and the argument role, which defines the relationship between the event and its arguments.

Event types: {event 1, ..., event n}
Entity types: {entity 1, ..., entity n}
Argument roles: {role 1, ..., role n}

Output Indicator
Output format: A list of strings, where each string represents an event. Each event includes the following components separated by pipes: text-id | event-type | event-trigger | event-arguments. Each event argument follows the format: argument - entity type - argument role, and multiple event arguments are separated by commas.
No explanation in output.

Input Data
Text: {text}

Table 4: Zero-shot prompt template used for evaluating LLMs' performance on the event extraction task.

Few-shot prompt for Event Extraction

Instruction
I will provide you with some examples of event extraction, your task is to extract all events mentioned in a list of texts. Note that these examples do not cover all event types in the texts, so please extract any events that match the types listed below. If an event does not belong to the specified types or if you are unsure, just ignore it.

Context
An event has four parts: the event type, which includes the type of event and its corresponding subtype; the event trigger, which is a word or phrase that most clearly expresses the occurrence of the event; the event arguments, which are entities involved in the event; and the argument role, which defines the relationship between the event and its arguments.

Event types: {event 1, ..., event n}
Entity types: {entity 1, ..., entity n}
Argument roles: {role 1, ..., role n}

Example 1:
Input:
s1: Xưa cháu ba đời của Viêm Đế họ Thần Nông là Đế Minh sinh ra Đế Nghi, sau Đế Minh nhân đi tuần phương Nam, đến Ngũ Lĩnh lấy con gái Vụ Tiên, sinh ra vua [Kinh Dương Vương].
s2: Vua Vũ chia chín châu thì Bách Việt thuộc phần đất châu Dương, Giao Chỉ thuộc về đấy.
s3: Mùa thu, tháng 9, ngày rằm, giờ Mão, có nhật thực.
Output:
s1 | LIFE.BE-BORN | sinh ra | Đế Minh - PERSON - AGENT, Đế Nghi - PERSON - THEME
s1 | LIFE.MARRY | lấy | Đế Minh - PERSON - AGENT, con gái Vụ Tiên - PERSON - THEME
s1 | LIFE.BE-BORN | sinh ra | Đế Minh - PERSON - AGENT, Kinh Dương Vương - PERSON - THEME
s3 | NATURE.NATURAL-PHENOMENON | nhật thực | Mùa thu - TIME - TEMPORAL, tháng 9 - TIME - TEMPORAL, ngày rằm - TIME - TEMPORAL, giờ Mão - TIME - TEMPORAL

Example 2:
Input:
s4: Nhâm Tuất, năm thứ 1.
s5: Tháng 3, ngày mồng 6, đúc xong ấn báu.
Output:
Not found.

... (n-shot)

Table 5: Few-shot prompt template used for evaluating LLMs' performance on the event extraction task.

No.	Entity Type	Description	Count
1	Person (PER)	Name of a specific person or family	6901
2	Date time (DTM)	Time or a specific period of time	2606
3	Location (LOC)	Names of land according to political or geographical border (city, province, country, international regions, oceans...	1449
4	Designation (DES)	Position or title of a specific person.	1371
5	Organization (ORG)	Names of organizations, offices or companies	443
6	Miscellaneous (MISC)	Other entities	345
7	Terminology (TRM)	Word-combinations having special meanings depending on the contexts are used in respective specialties. They include: science, technique, military, politics, religion...	141
8	Measurement (MEA)	Measurement, quantity of things (other than money) in a standard unit.	106

Table 6: Entity types used in the VHE dataset. **Count:** count of annotated entities.

No.	Argument Role Type	Description	Count
1	Theme	The participant most directly affected by an event.	4148
2	Agent	The volitional causer of an event.	3769
3	Temporal	The time the event occurred	2608
4	Content	The proposition or content of a propositional event.	1357
5	Location	The location the event occurred	652
6	Goal	The destination of an object of a transfer event.	458
7	Beneficiary	The beneficiary of an event.	196
8	Source	The origin of the object of a transfer event.	128
10	Instrument	An instrument used in an event.	33
11	Force	The non-volitional causer of the event.	7
12	Experiencer	The experiencer of an event.	6

Table 7: Argument role types used in the VHE dataset. **Count:** count of annotated arguments.

Event Type	Event Subtype	Example	Count
LIFE	BE-BORN	Tháng 3 , ngày mồng 5 , cháu chúa Trịnh Tạc ra đời , đó là con trai thứ của Bình quận công. (In March, on the 5th day, the grandson of Lord Trịnh Tạc was born, who was the second son of Duke Bình.)	117
	MARRY	Tháng 3 , ngày mồng 7 , gả công chúa Bình Dương cho châu mục châu Lạng là Thân Thiệu Thái . (In March, on the 7th day, Princess Bình Dương was married to Thân Thiệu Thái, the chieftain of Châu Lạng.)	90
	DIVORCE	Đến khi Lĩnh bị giết, Thuyên cũng bỏ vợ . (When Lĩnh was killed, Thuyên also abandoned his wife.)	4
	INJURE	Thạc đoạt lấy cờ tiết của Lượng, Lượng không cho, Thạc bèn chặt tay trái của Lượng , Lượng nói: "Chết còn không tránh, chặt cánh tay thì làm gì?". (Thạc seized Lượng's flag, which Lượng refused to give up, so Thạc cut off Lượng's left arm. Lượng said, "Even death cannot be avoided, what's the use of cutting off my arm?".)	21
	DIE	Tuần bèn giết hết những kẻ không chịu chết theo, rồi gieo mình xuống sông mà chết. (Tuần then killed all those who refused to die with him, and then threw himself into the river to die.)	890
MOVEMENT	TRANSPORT	Quân Lương tan vỡ chạy về Bắc . (The troops of Lương were defeated and fled north.)	389
TRANSACTION	TRANSFER-OWENERSHIP	Châu Vi Long (nay châu Đại Man) dâng ngựa trắng bốn chân có cựa . (Châu Vi Long (now Châu Đại Man) offered a white horse with four legs and spurs.)	179
	TRANSFER-MONEY	Vua rất hiểu ông, sai người ban đêm đem 10 quan tiền bỏ vào nhà ông . (The king highly valued him, sending someone at night to place 10 quan of money in his house.)	29
BUSINESS	START-ORG	Tháng 6 , lập Quốc học viện . (In June, the National Academy was established.)	31
	MERGE-ORG	Trước đây, châu Nam Mã thuộc nước Ai Lao, sau vì mộ đức nghĩa nhà vua mà quy thuận . (Previously, Châu Nam Mã belonged to the country of Ai Lao, but later it submitted due to the king's virtue.)	4
	DECLARE-BANKRUPCTY	N/A	0
	END-ORG	Năm ấy nhà Chu mất . (That year, the Zhou dynasty fell.)	18
CONFLICT	ATTACK	Mùa thu , tháng 7 , ngày mồng 5 , nước Ai Lao lại làm phản, đánh vào Mường Viễn . (In autumn, on the 5th day of the 7th month, the country of Ai Lao rebelled again and attacked Mường Viễn.)	857
	DEMONSTRATE	Thái bảo Phù quận công Trịnh Lịch , Thái phó Hoa quận công Trịnh Sầm , hận vì bất đắc chí, liền nổi quân làm loạn . (The Grand Protector of Phù Duke Trịnh Lịch and the Grand Tutor of Hoa Duke Trịnh Sầm, frustrated by their failures, raised troops to revolt.)	7
CONTACT	MEET	Thời Thành Vương nhà Chu [1063-1026 TCN] , nước Việt ta lần đầu sang thăm nhà Chu (không rõ vào đời Hùng Vương thứ mấy), xưng là Việt Thường thị, hiến chim trĩ trắng. (During the reign of King Cheng of the Zhou dynasty [1063-1026 BC], our country of Viet made its first visit to the Zhou (uncertain which reign of the Hùng Kings), calling itself Viet Thường thị and offering white pheasants.)	119
	PHONE-WRITE	Mới rồi nghe nói vương có gửi thư cho tướng quân Lâm Lư hầu , muốn tìm anh em thân và xin bãi chức hai tướng quân ở Trường Sa. (Recently, it was heard that the king sent a letter to General Lâm Lư Hầu, seeking to find close relatives and requesting to remove the two generals in Chương Sa.)	67

Table 8: Examples of event types used in the VHE dataset. Event triggers are highlighted in orange and event arguments are highlighted in green.

Event Type	Event Subtype	Example	Count
NATURE	NATURAL-PHENOMENON	Tháng 2 , ngày Đinh Dậu mồng 1 , có nhật thực . (In February, on the 1st day of Đinh Dậu, there was a solar eclipse.)	266
	NATURAL-DISASTER	Mùa hạ , tháng 4 , hạn hán . (In summer, in April, there was a drought.)	99
PERSONNEL	START-POSITION	Cháu là Hồ lên nối ngôi . (The grandson Hồ ascended to the throne.)	1329
	END-POSITION	argumenttextitMùa đông, tháng 10 , ngày Nhâm Ngọ , Đàn Hòa Chi bỏ quan về. (In winter, in October, on the day of Nhâm Ngọ, Đàn Hòa Chi left his position and returned home.)	123
	NOMINATE	Đến đây, Quý Ly tiến cử ông ta . (At this point, Quý Ly recommended him.)	40
	ELECT	Bề tôi nhà Minh lại tôn lập Vĩnh Lịch Hoàng Đế . (The officials of the Ming dynasty again revered Emperor Vĩnh Lịch.)	40
JUSTICE	ARREST-JAIL	Phiên tướng Thái Nguyên là Thông quận công Hà Sĩ Tứ đem quân bản xứ đi đánh, bị giặc bắt được. (The provincial general Thái Nguyên, Duke Hà Sĩ Tứ, who led local troops, was captured by the enemy.)	258
	RELEASE-PAROLE	Vua bằng lòng, tha cho Chế Củ về nước (Địa Lý nay là tỉnh Quảng nam). (The king agreed and pardoned Chế Củ, allowing him to return home (now Địa Lý, Quảng Nam province).)	34
	TRIAL-HEARING	Xuống chiếu cho quan Đình uý xét tội Lợi . (Issued a decree for the Inspector of the Capital to investigate Lợi's crimes.)	26
	CHARGE-INDICT	Nguyễn Vĩnh Tích hặc tội , cho là đáng phải biếm chức. (Nguyễn Vĩnh Tích accused of [a crime], deeming it worthy of being demoted..)	15
	SUE	Em Đỗ Khắc Chung là Đỗ Thiên Thư kiện nhau với người, tình lý đều trái. (Đỗ Khắc Chung's brother, Đỗ Thiên Thư, was in dispute with someone, with both the facts and reasoning against him.)	7
	CONVICT	Tử Dục hết lẽ, phải thú tội . (Tử Dục, having exhausted all reasons, had to confess to his crimes.)	5
	SENTENCE	Tư không châu Phục Lễ Đèo Mạnh Vượng có tội, cho tự tử . (The Chancellor of Châu Phục Lễ, Đèo Mạnh Vượng, was guilty and was allowed to commit suicide.)	37
	FINE	Công bộ hữu thị lang Trịnh Công Đán bị phạt 30 quan tiền vì bỏ phơi mưa nắng những gỗ, lạt của công. (The Minister of Works, Trịnh Công Đán, was fined 30 quan for neglecting to protect public wood and rattan from the weather.)	10
	EXECUTE	Chém Hồ bả ở phường Diên Hưng . (Executed Hồ Bả in Diên Hưng district.)	76
	EXTRADITE	Tháng 5 , nhà Thanh sai Phạm Thành Công và Mã Văn Bích mang sắc dụ đến cửa Nam Quan, bảo bắt giải lũ giặc biển Dương Nhị , Dương Tam . (In May, the Qing Dynasty sent Phạm Thành Công and Mã Văn Bích with an edict to the South Gate, ordering the capture and return of the pirate leaders Dương Nhị and Dương Tam.)	2
	ACCQUIT	N/A	0
	APPEAL	Vì tám người cùng họ như Lê Khắc Phục và công chúa Ngọc Lan làm đơn khẩn thiết van xin vua nới phép ban ơn, nên có lệnh này. (Because eight people with the same surname, such as Lê Khắc Phục and Princess Ngọc Lan, earnestly petitioned the king for leniency, this order was issued.)	2
	PARDON	Tháng 3 , tha tội chết cho Nguyễn Sư Hồi . (In March, the death penalty was commuted for Nguyễn Sư Hồi.)	46

Abstract

Claim identification, an important task in the field of natural language processing (NLP) is the stepping stone for more critical NLP tasks such as fact-checking, fake news and misinformation detection from social media and other real-world data. By leveraging advanced deep learning and recent transformer-based models, we investigate two claim identification methods in this article: one is a multilingual claim span detection from social media posts for English, Hindi, Bengali and CodeMixed texts and another is a fusion-based novel multi-task learning (MTL) framework for claim classification along with sentiment and language identification. Our best-performing claim span detection framework achieved an accuracy of around 80% and the best-performing MTL framework provides an F1 score of 0.74 for claim classification.

1 Introduction

The number of social media users has rapidly increased in the past few years. As per data provided by Kemp (2024), India had social media users of around 462 million in January 2024 whereas in 2019 there were around 310 million active social media users (Kemp, 2019). This social media enables different levels of people to express their feelings and opinions independently on any topic or event. However, in this large content of social media posts, it is sometimes difficult to find factual posts that contain some meaningful claims.

With the advancement of Natural Language Processing (NLP) and Artificial intelligence (AI), researchers have done state-of-the-art works on opinion mining or sentiment analysis, emotion analysis etc. in social media content and many other real-world textual data. In contrast, there is limited research was performed on detecting a specific phrase in a text that contains claims (claim span identification). Also, how the claim detection works in a multi-task learning environment is not well explored where we combine different tasks in a single neural network so that learning from one task helps each other in a shared environment.

In this paper, we focused on identifying the specific phrases in a social media post or other real-world text that contain some factual information or claim. Along with that, we proposed a multi-task learning (MTL) model to classify a text that contains a claim or not with additional tasks of sentiment analysis and language identification to specifically check how the claim classification works in a multi-task learning environment.

Our research is motivated by identifying factual information from social media and other real work texts which will be further useful for the verifiability of claims, detecting fake news, misinformation etc. The main contributions in this paper can be summarized as follows:

- We have proposed a multilingual claim span identification framework for Bengali, Hindi, English and CodeMixed texts.
- Followed by this a fusion-based novel multi-task learning framework is proposed for relatively dissimilar genres of tasks: claim, sentiment and language classification.

2 Related Work

Recent advancements of deep learning in the field of NLP have witnessed significant progress in claim span identification, claim classification and MTL. Starting from statistical analysis to machine learning to state-of-the-art transformer-based models such as BERT researchers proposed different methods in the field of claim-related works.

Claim Detection: Pavllo et al. (2018) and Smeros et al. (2019) develop rule-based heuristics for extracting quotes from general and scientific news articles using weakly supervised models. Levy et al. (2014) and Stab et al. (2018) pro-

pose ML models for claim detection and argument mining, providing publicly available datasets for training extraction models. Hassan et al. (2017) and Popat et al. (2017) employ claim classification models with fact-checking portals for verifying political claims.

Zlatkova et al. (2019) focus on claim extraction for images, while Karagiannis et al. (2020) present a framework for statistical claims verification. This approach (Smeros et al., 2021), unlike others, is specifically tailored for claims, utilizing advanced language models with and without contextualized embeddings fine-tuned with domain-specific knowledge and capable of processing various input sources like social media postings, blog posts, or news articles.

Multi-Task Learning: The concept of Multi-task Learning (MTL) was first proposed by Caruana (1997). Ruder (2017) discussed different schemes of MTLs in their paper such as hard parameter sharing, soft parameter sharing etc.

Numerous researchers proposed different MTL frameworks in the field of NLP. Specifically, in claim-related studies, Tzu-Ying Chen (2022) proposed a multi-task learning framework for claim detection and numerical category classification utilizing the transformer-based BERT (Devlin et al., 2019) model.

Besides, Liu et al. (2016), Liu et al. (2017) proposed MTL for text classification utilizing LSTMs and BiLSTMs. An MTL framework for sentiment and sarcasm classification was proposed by Majumder et al. (2019), Savini and Caragea (2020), El Mahdaouy et al. (2021) and Tan et al. (2023).

Singh et al. (2022) combined sentiment, emotion and emoji classification tasks in an MTL framework utilizing transformer based 'XLM-RoBERTa' (Liu et al., 2019) model whereas Del Arco et al. (2021) combined sentiment, emotion, hate speech, offensive language and target (targeting a specific community such as women, black people, LGBT etc.) in a single MTL framework utilizing BERT.

This present article focuses on two claim-related tasks: a multilingual claim span identification framework in real-world social media content and a multi-task learning framework incorporating three relatively dissimilar tasks: claim, sentiment and language identification.

3 Dataset

3.1 Claim Span Identification

To accomplish the claim span identification task, we utilized the JUCSI (Jadavpur University Claim Span Identification) dataset that was specifically provided for our research. This dataset comprises approximately 750 training samples across multiple languages, including English, Hindi, Bengali, and CodeMix. The data predominantly focuses on topics related to COVID-19 vaccines and social distancing measures. Each entry in the dataset includes the original text, an indication of the language used, and the specific span within the text where the claim(s) can be found. This multilingual and topical diversity offers a rich resource for analyzing how different linguistic and cultural contexts handle information related to the pandemic. Figure 1 shows the language-wise data distribution.

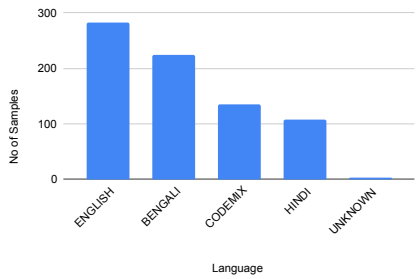

Figure 1: Distribution of Claim Span data

3.2 Claim Classification

The datasets from Rosenthal and McKeown (2012) paper were mainly used for claim classification tasks. This dataset consists of sentences from the LiveJournal blogs and Wikipedia talk pages that have been annotated for opinionated claims. Specifically, there are 2,190 entries from the LiveJournal and 2,197 from the Wikipedia. Each entry is labelled to indicate whether it contains a claim (Yes or No) and includes sentiment annotations for all the texts. Figure 2 provides the distribution of claim data.

3.3 Multi Task Learning

In the MTL framework, we tried to incorporate three tasks (claim classification, sentiment analysis and language identification) in a single neural network. For the claim detection task, the previously mentioned claim detection dataset (Rosenthal and McKeown, 2012) was used. We next calculate the

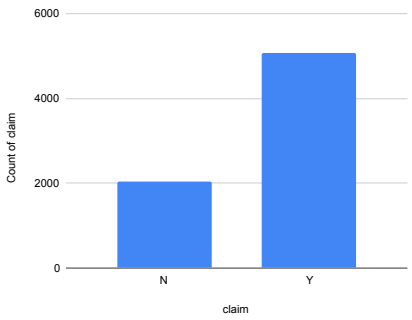

Figure 2: Distribution of Claim Data (N represents there is no claim in the sentence and Y represents there are claims in that sentence.)

sentiment labels for each sample in this dataset using a publicly available distilBERT-based sentiment classification[1] model.

For language identification, a different dataset was collected which is a preprocessed version of WiLI-2018[2], the Wikipedia language identification benchmark dataset. This version includes 22 specific languages: English, Arabic, French, Hindi, Urdu, Portuguese, Persian, Pushto, Spanish, Korean, Tamil, Turkish, Estonian, Russian, Romanian, Chinese, Swedish, Latin, Indonesian, Dutch, Japanese, and Thai. The distribution of sentiment data and language data is presented in Figure 3 and 4 respectively.

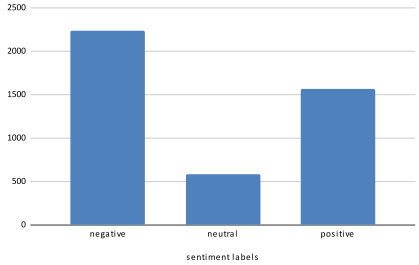

Figure 3: Distribution of sentiment labels

4 Methodologies

This section describes the proposed methodologies of our claim span identification, claim classification and multi-task learning works.

4.1 Claim Span Identification

The main aim of the claim span identification task was to identify the specific phrase in a sentence or

[1]https://bit.ly/multilingual-cased-sentiments-student
[2]https://bit.ly/language-identification-datasst

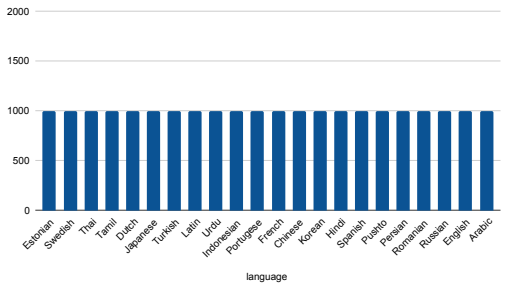

Figure 4: Distribution of language labels

text that contains some claim. In other words, we treat this task as a token classification task where the input would be $\{t_1, t_2, t_3, ..., t_n\}$ where t_i's are the tokens of text and the output would be $\{c_1, c_2, c_3, ..., c_n\}$ where each c_i's $\in \{0, 1, 2\}$ and 1, 2 and 0 represents beginning word of claim, intermediate phrase of claim and outside phrases of claim respectively.

Tokenization: Tokenization involves breaking down a text into smaller units known as tokens. To execute this work, we used different publicly available pre-trained models such as Multilingual-BERT (mBERT) (Devlin et al., 2019), XLM-RoBERTa (Liu et al., 2019), and MuRIL (Khanuja et al., 2021). So, these models' corresponding tokenizers were used to tokenize the input sentence.

B-I-O Tagging: After tokenization, each token must be assigned a B-I-O tag, where 'B' stands for the Beginning of a Claim, 'I' indicates the Inside of a Claim, and 'O' signifies the Outside of a Claim. The use of `return_offsets_mapping=True` in the tokenizer configuration allows us to retrieve the start index and the end index (plus one) for each token within the original text.

Additionally, the start and end indices of each claim span within the original text are calculated and recorded. This enables us to determine which tokens correspond to which parts of the claim. When the offset mapping of a token falls within the range of the start and end indices of a claim span, the appropriate B-I-O tagging is applied to that token. This process ensures that each token is accurately labelled according to its position within or outside the claim spans.

Model Selection: As previously mentioned, to accomplish this work, we used publicly available pre-trained models mBERT, XLM-RoBERTa and MuRIL. The mBERT and XLM-RoBERTa were trained on around 104 and 100 languages respectively including Hindi and Bengali. In contrast,

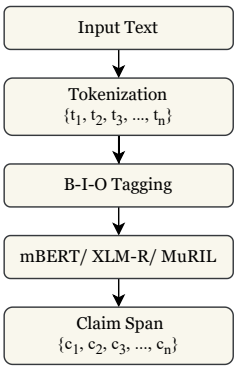

Figure 5: Flow diagram for claim span identification during training.

the MuRIL model was trained explicitly on 14 Indian languages, so this model can learn the Indian contexts in a better way.

Initially, we performed tokenization on the sentences. After this step, each token was annotated with B-I-O tags. The annotated tokens were subsequently input into the model, which generated the predicted claim span(s). Figure 5 shows an abstract overview of our model.

4.2 Multi-Task Learning

Whereas in the claim span identification framework we aim to identify specific phrases that contain certain claims, in MTL our main objective was to classify a text as containing or not containing certain claims with two additional tasks sentiment analysis and language detection.

Given a tokenized sequence S and S is associated with three labels: claim (yes/no), sentiment (positive/negative/neutral) and language (One out of 22 languages as given in Figure 4).

Text Preprocessing: Before diving into the classification, a few basic preprocessing steps were performed in such as i) removal of HTML tags, ii) lowercase conversion, iii) username standardization (convert any Twitter username to '@user'), iv) URL standardization (convert URLs to 'http') and v) conversion of emoji to their corresponding text.

Tokenization: After preprocessing, input text S was tokenized into a sequence of tokens $k_1, k_2, k_3, ..., k_n$. Since sentence lengths vary, we standardize them by padding with zeros to achieve a fixed-size sequence. Consequently, every sentence S transforms into a token sequence $\{k_1, k_2, k_3, ..., k_L\}$ where $L = 300$.

4.2.1 LSTM-based MTL framework

Figure 6(a) and 6(b) represent two MTL frameworks, one is simple MTL with task-specific heads and another is MTL with fusion (MTL$_{fusion}$). Both frameworks utilized bidirectional LSTM (BiLSTM) architecture and pre-trained GloVe (Pennington et al., 2014) embedding with dimension 300.

MTL with Task-Specific Long Heads: As per Figure 6(a) the output of the "GlobalMaxPooling1D" layer is fed into three separate task-specific dense layers of 300 neurons for some task-specific learnings.

$$D_* = ReLU(Z_{GlobalMaxPooling1D})$$
$$D_{dropout*} = Dropout(D_*)$$

where D_* and $D_{dropout*}$ represent the task-specific dense layers and dropout layers respectively.

One possible reason behind using long task-specific heads is the simple fact that the dissimilar tasks have very few things in common among them, and each task needs extra standalone attention. For this reason, we have used more layers in the individual task-specific layers.

MTL$_{fusion}$: Figure 6(b) represents the MTL with fusion technique where the outputs of the task-specific dense layers were passed to dropout layers, and then merge the outputs from the previous layers and feed them into the final task-specific dense layers as follows:

$$Merge_1 = Dropout(D_{claim}) \otimes Dropout(D_{sen})$$
$$Dense_{sen} = ReLU(Merge_1)$$

and,

$$Merge_2 = D_{claim} \otimes D_{sen} \otimes Dropout(D_{lang})$$
$$Dense_2 = ReLU(Merge_2)$$

where $\otimes$ represents the concatenation of the outputs of the dense or dropout layers.

4.2.2 BERT-based MTL framework

Figure 6(c) represents the MTL framework utilizing the pre-trained 'multilingual BERT base uncased' model where the tokenized sequences (input_ids) along with the attention masks which were generated by the 'BertTokenizer' were passed as an input to the BERT model. Next, the 'PoolerOutput' of the BERT model was passed to a dropout layer of 0.1. Then the output of the dropout layer

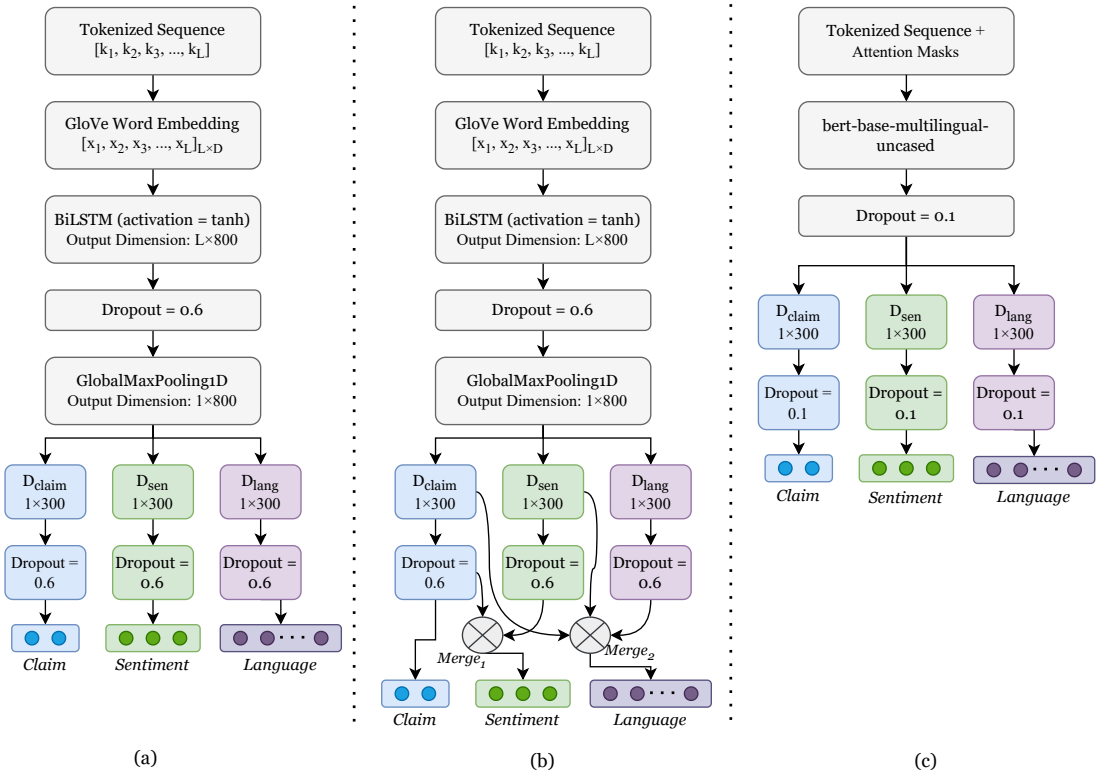

Figure 6: Proposed MTL frameworks. (a) LSTM-based, (b) LSTM with fusion, (c) BERT-based

was passed to three separate dense layers with 300 neurons followed by a dropout of 0.1.

$$D_* = ReLU(Dropout(BERT_{pooler\_output}))$$
$$D_{dropout*} = Dropout(D_*)$$

4.2.3 Classification:

We used separate dense layers for classification in all MTL frameworks. For MTL with long task-specific heads and the BERT-based MTL, the outputs of the individual dropout layers were fed into task-specific dense layers which use softmax as their activation function.

$$P_* = softmax(D_{dropout*})$$

Here P_* represents the probability values for each task-specific output layer.

For MTL with task-specific dense layers and fusion, the output of $Dropout_{claim}$ was fed as an input to the claim detection layer, fed the output of $Dense_1$ as an input to the sentiment classification layer and fed the output of $Dense_2$ as an input to language identification task layer.

$$P_{claim} = softmax(Dropout_{claim})$$
$$P_{sen} = softmax(Dense_1)$$
$$P_{lang} = softmax(Dense_2)$$

Where P_{claim}, P_{sen} and P_{lang} represent the probability value for each class of claim, sentiment and language classification.

4.3 Training

To accomplish the training process, both the JUCSI dataset and the MTL dataset were split into a 7:2:1 ratio where 70% of the data was used for training, 20% of data was taken as validation split and 10% of data was chosen for testing.

The AdamW (Loshchilov and Hutter, 2019) optimizer was chosen to train the claim span identification framework with a learning rate of 2e-5 and trained the models up to 4 epochs.

For the Multi-task loss function, we used the '`SparseCategoricalCrossEntropy`' loss function with Adam (Kingma and Ba, 2014) optimizer and learning rate of 5e-4 and 3e-5 for BiLSTM and BERT models respectively and monitored the loss for validation split for the dataset.

$$L_{total} = \sum_{i=1}^{K} L_i$$

Where L_i is the loss for different tasks and K is the number of tasks. To train the proposed MTL models we had initially taken 50 epochs but used the

'EarlyStopping' method provided by TensrFlow to prevent overfitting during the training process.

5 Experiment and Result

5.1 Experimental Setup

To accomplish the claim span identification task, all the previously mentioned pre-trained models and their corresponding tokenizers were imported from HuggingFace and the models were trained using the libraries of HuggingFace and PyTorch.

For multi-task learning, we used the libraries from TensorFlow and Keras to develop the proposed models and used the Collaboratory environment to train the proposed frameworks.

5.2 Result

5.2.1 Claim Span Identification

Among the previously mentioned three pre-trained models (mBERT, XLM-RoBERTa and MuRIL) the XLM-RoBERTa model identified claim spans more precisely than mBERT and MuRIL models with an accuracy of 0.807 and F1-score of 0.541. This performance shows an improvement of 7.6% and 0.5% in accuracy and 7.2% and 0.9% in the F1-score compared to the MuRIL and mBERT models respectively. The overall results for three models are provided in Table 1

Model	Accuracy	F1
mBERT	0.803	0.536
XLM-RoBERTa	**0.807**	**0.541**
MuRIL	0.746	0.502

Table 1: Results for different models in claim span identification.

5.2.2 Multi-Task Learning

Here we compare and contrast the performance of claim classification in different MTL frameworks with the single-task learning (STL) framework. Along with the claim + sentiment + language combination of MTL, we developed all the other combinations of MTLs such as claim + sentiment and claim + language and reported the results in Table 2 for both BERT and BiLSTM models.

Furthermore, for additional sentiment and language tasks, we also developed all the combinations of MTLs along with the STL frameworks and reported the results in Tables 3 and 4 for sentiment and language classification tasks respectively.

Model	Task	Precision	Recall	F1
BiLSTM	STL	0.711	0.711	0.711
	claim + sen	0.709	0.709	0.709
	claim + lang	0.588	0.567	0.542
	MTL	0.589	0.564	0.534
	MTL$_{fusion}$	0.610	0.599	0.590
BERT	STL	0.744	0.732	0.730
	claim + sen	**0.755**	**0.742**	**0.740**
	claim + lang	0.753	**0.742**	**0.740**
	MTL	0.738	0.716	0.711

Table 2: Result of claim classification of STL and MTL framework

Model	Task	Precision	Recall	F1
BiLSTM	STL	0.660	0.669	0.664
	claim + **sen**	0.709	0.642	0.664
	sen + lang	0.571	0.589	0.576
	MTL	0.597	0.528	0.550
	MTL$_{fusion}$	0.630	0.566	0.586
BERT	STL	**0.796**	0.748	**0.762**
	claim + **sen**	0.756	0.750	0.750
	sen + lang	0.730	**0.755**	0.740
	MTL	0.740	0.702	0.717

Table 3: Result of sentiment classification of STL and MTL framework

It is noticeable from Tables 2, 3 and 4 that, in all the claim, sentiment and language identification tasks, the BERT-based frameworks provide superior performance compared to the BiLSTM-based frameworks in both MTLs and STL.

The claim classification task failed to achieve the best performance in both BiLSTM and BERT-based MTL frameworks. However, the claim + sentiment and claim + language combination of MTL achieved the best recall and F1-score of 0.742 and 0.740 respectively and the best precision with 0.755 was achieved by only the claim + sentiment combination of MTL. Additionally, the BERT-based best MTL framework provides an F1-score improve-

Model	Task	Precision	Recall	F1
BiLSTM	STL	0.788	0.738	0.723
	sen + **lang**	0.746	0.697	0.695
	claim + **lang**	0.687	0.692	0.681
	MTL	0.762	0.705	0.715
	MTL$_{fusion}$	0.722	0.706	0.707
BERT	STL	0.988	0.980	0.983
	sen + **lang**	**0.990**	**0.991**	**0.990**
	claim + **lang**	0.984	0.981	0.982
	MTL	**0.990**	0.983	0.986

Table 4: Result of language classification of STL and MTL framework

Table 5: Few examples of identified claim spans in different models.

ment of 3.92% compared to the best-performing framework in BiLSTM.

In the case of sentiment classification, the best Precision and F1 scores of 0.796 and 0.762 were achieved by the BERT-based STL framework and the best recall score was provided by the sentiment + language combination of the MTL framework.

The language identification task significantly improves performance in the BERT-based frameworks with an F1-score of 0.99 in sentiment + language combination of MTL whereas the BiLSTM-based best-performing framework (STL) achieved an F1-score of only 0.723.

6 Error Analysis

6.1 Claim Span Identification

Although the evaluation metrics indicate that XLM-RoBERTa performs the best overall, this is not always consistent for claim span identification. Table 5 presents three examples to highlight the strengths and weaknesses of our models. For the first sentence, XLM-RoBERTa achieved perfect results, whereas MuRIL and mBERT included a few extra words at the beginning. In the second sentence, all models performed poorly, capturing more words than the actual claim span. For the third sentence, the mBERT model performed the best, accurately identifying the claim span, while XLM-RoBERTa and MuRIL captured more than the necessary span.

6.2 Multi-Task Learning

Table 6 presents some examples of predicted labels from both the STL and MTL frameworks with their ground truth labels.

From Table 6, in example S_1, it is seen that although claim and language labels are correctly assigned, the MTL (BiLSTM) framework failed to predict the positive sentiment of the sentence.

In sentence S_2, for claim detection, STL (BiLSTM) and MTL$_{fusion}$ (BiLSTM) frameworks failed to predict the claim correctly, but the MTL (BiLSTM), STL (BERT) and MTL (BERT) frameworks did. For sentence S_3, only the STL (BiLSTM) model correctly predicted the claim but the MTL (BiLSTM) models couldn't. However, the BERT-based both STL and MTL frameworks correctly predict the proper claim labels. The MTL (BiLSTM) framework also incorrectly predicts it as a sentence in Dutch whereas it is an English sentence.

Despite the superior performance of the BERT-based frameworks, in some cases, the BiLSTM-based MTL framework correctly detects its labels where BERT cannot. For example, in S_3 and S_4, the MTL (BiLSTM) framework correctly predicts its actual label whereas the other frameworks failed to predict the correct label.

7 Conclusion

In this article, we studied two schemes of claim identification strategy, first a claim span identification framework utilizing transformer-based pre-trained models followed by an MTL framework for claim, sentiment and language classification.

In future, we'll extend the existing claim span and MTL dataset to validate the robustness of the proposed frameworks. Additionally, we are planning to incorporate the claim span identification task in the MTL framework.

			Claim		Sentiment		Language

Table 6: Examples of predictions in STL and MTL frameworks. (red coloured texts define wrong predictions)

8 Limitations

Upon performing all experiments and analysing the results, we delve into a few noteworthy issues for claim span identification and MTL framework.

8.1 Claim Span Identification

Although we developed the claim span identification task for English, Hindi, Bangla and CodeMixed text, our dataset was relatively small (around 750 samples). To thoroughly validate the overall performance of our models, a larger dataset is necessary. Additionally, we have not explored other potentially effective models such as GPT or BERT-large. Further, we need to perform more hyperparameter tuning to enhance the models' performance. Our current training is based solely on social media data; in the future, we plan to extend our training to other types of texts, such as news articles and online blogs, to evaluate and improve the models' versatility and robustness across various domains.

8.2 Multi-Task Learning

Firstly, it is observed that the performances of dissimilar tasks are not that good in our MTL setting. This is because learning from one task cannot help other tasks properly in dissimilar tasks, and we see a performance drop in the MTL frameworks.

Secondly, the MTL framework is only limited to two models BiLSTM and BERT. Also, we haven't developed any fusion-based MTL framework using the BERT model In future, we'll try to develop a fusion-based MTL framework by exploring other state-of-the-art transformer-based models.

And lastly, an imbalance of claim and sentiment data in the final dataset may include performance bias in their corresponding tasks.

Abstract

This paper introduces Chain of Translation Prompting (CoTR), a novel strategy designed to enhance the performance of language models in low-resource languages. CoTR restructures prompts to first translate the input context from a low-resource language into a higher-resource language, such as English. The specified task like generation, classification, or any other NLP function is then performed on the translated text, with the option to translate the output back to the original language if needed. All these steps are specified in a single prompt. We demonstrate the effectiveness of this method through a case study on the low-resource Indic language Marathi. The CoTR strategy is applied to various tasks, including sentiment analysis, hate speech classification, subject classification and text generation, and its efficacy is showcased by comparing it with regular prompting methods. Our results underscore the potential of translation-based prompting strategies to significantly improve multilingual LLM performance in low-resource languages, offering valuable insights for future research and applications. We specifically see the highest accuracy improvements with the hate speech detection task. The technique also has the potential to enhance the quality of synthetic data generation for underrepresented languages using LLMs.

1 Introduction

Natural Language Processing (NLP) has made significant progress in recent years, with models capable of understanding, creating, and translating human language across a wide range of tasks and languages. However since high-resource languages like English, Spanish, and Chinese have access to a wealth of annotated datasets and linguistic resources, most of this development has been focused on those languages. Low-resource languages, on the other hand, have a lot more difficulties since they lack large-scale and high-quality datasets (Thabah and Purkayastha, 2021). Training effective NLP models are challenging due to this data scarcity, which frequently leads to subpar performance and poor generalization. Low-resource languages have distinct grammatical structures, linguistic diversity, and cultural quirks that make it more difficult to create accurate models and limit their use in practical contexts (Yang et al., 2023). Multilingual LLMs have limitations on processing the prompts in low-resource languages (Sanjib Narzary, 2022). This is because the amount of data used to train or fine-tune the model is very less. As a result, speakers of low-resource languages are frequently excluded from the benefits of advanced NLP technologies, highlighting the crucial need for novel techniques to close this gap.

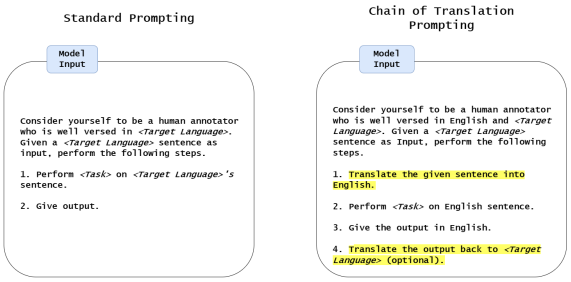

Figure 1: A brief overview of the Chain of Translation Prompting (CoTR) for an annotation task. The technique modifies the input prompt to encapsulate the translation of the non-English input context to English, followed by performing the target task on the translated text.

However, Multilingual LLMs are good at translation tasks, as it is common practice to include parallel corpora during the pre-training stage (Xiang Zhang, 2023). We can leverage the ability of multilingual LLMs to improve responses for low-resource languages. In our study, we apply this ap-

proach to Marathi, an Indo-Aryan language spoken by about 83 million people, primarily in the Indian state of Maharashtra. Marathi is one of these low-resource languages (Joshi, 2022b,a). Despite its large speaker base, Marathi lacks digital resources, annotated corpora, and computational tools. The language's complex syntax challenges the development of precise NLP models, and limited Marathi-specific datasets and pre-trained models hinder the adoption of language technologies (Luong et al., 2023). Therefore, new approaches are needed to enhance Marathi NLP performance and enable its speakers to benefit from AI advancements.

In this work, we investigate new prompting strategies to enhance Marathi language processing capabilities in models such as GPT-4o, GPT-4o Mini, Llama3-8B, Llama3-405B, and Gemma-9B. Our research introduces a novel strategy called "Chain of Translation Prompting (CoTR)", which we evaluate against direct Marathi prompting. We apply this method to sentiment analysis, hate speech classification, and subject categorization across three datasets: MahaSent (Pingle et al., 2023; Kulkarni et al., 2021), MahaHate (Patil et al., 2022), and MahaNews-SHC (Mittal et al., 2023; Aishwarya et al., 2023) respectively. Additionally, we assess its effectiveness in generating headlines using the CSEBUETNLP XLSum dataset. Our findings reveal that translating Marathi input into English and then performing classification or text generation using a single prompt yields superior results compared to directly processing the Marathi text with a standard prompt. This work significantly contributes to multilingual NLP by demonstrating the potential of translation-based prompting strategies, particularly with a single prompt, to enhance NLP performance in low-resource languages.

The main contributions of this work are as follows:

- We introduce Chain of Translation Prompting (CoTR) as a method for performing input context translation during LLM response generation. Our results demonstrate that CoTR consistently outperforms standard prompting strategies across a variety of models and datasets.
- We benchmark various open and closed LLMs, including GPT-4o, GPT-4o mini, Llama 3.1 405B, Llama 3.1 8B, and Gemma 2 9B, on tasks such as Marathi Sentiment Analysis, Hate Speech Detection, News Categorization, and News Headline Generation. In terms of performance, closed LLMs consistently rank higher: GPT-4o > GPT-4o mini > Llama 3.1 405B > Gemma 2 9B > Llama 3.1 8B. We observe that CoTR is particularly beneficial for smaller models with higher error rates.
- The CoTR prompting strategy shows the most significant improvements in complex tasks like hate speech detection and sentiment analysis.

2 Related Work

Natural language processing has improved significantly with the creation of sophisticated models like GPT-4, Llama3, and others. Nonetheless, insufficient representation and scarce data availability in pre-trained models continue to pose problems for low-resource languages(Panteleimon Krasadakis, 2024). Language diversity and data scarcity in low-resource contexts have shown to be challenges for traditional NLP techniques, which has prompted a quest for novel approaches that can make better use of already-existing data. (Michael A. Hedderich, 2021) research highlighted the significance of creating NLP tools that are especially suited for low-resource languages while taking linguistic and cultural quirks into account.

A crucial component of developing NLP models for low-resource languages is dataset curation. In addition to collecting data, curators of datasets such as MahaSent, MahaHate, MahaNews-SHC, and CSEBUETNLP XLSum make sure that the data accurately reflects the linguistic diversity and cultural context of the language. Projects like (Narzary et al., 2022) have brought attention to how crucial it is to provide high-quality datasets that accurately represent language use in everyday situations.

In multilingual natural language processing, cross-lingual transfer methods have demonstrated potential, especially when applied to low-resource language tasks. According to research like that of (Melvin Johnson, 2017), the concept of sharing parameters across languages allows models to acquire representations that function well in a variety of languages. This idea is important because it enables language models to use their English language skills to complete tasks in Marathi through the use of translation-based prompting, which is a type of cross-lingual transfer. Cross-lingual skills are supported by recent advances in multilingual models,

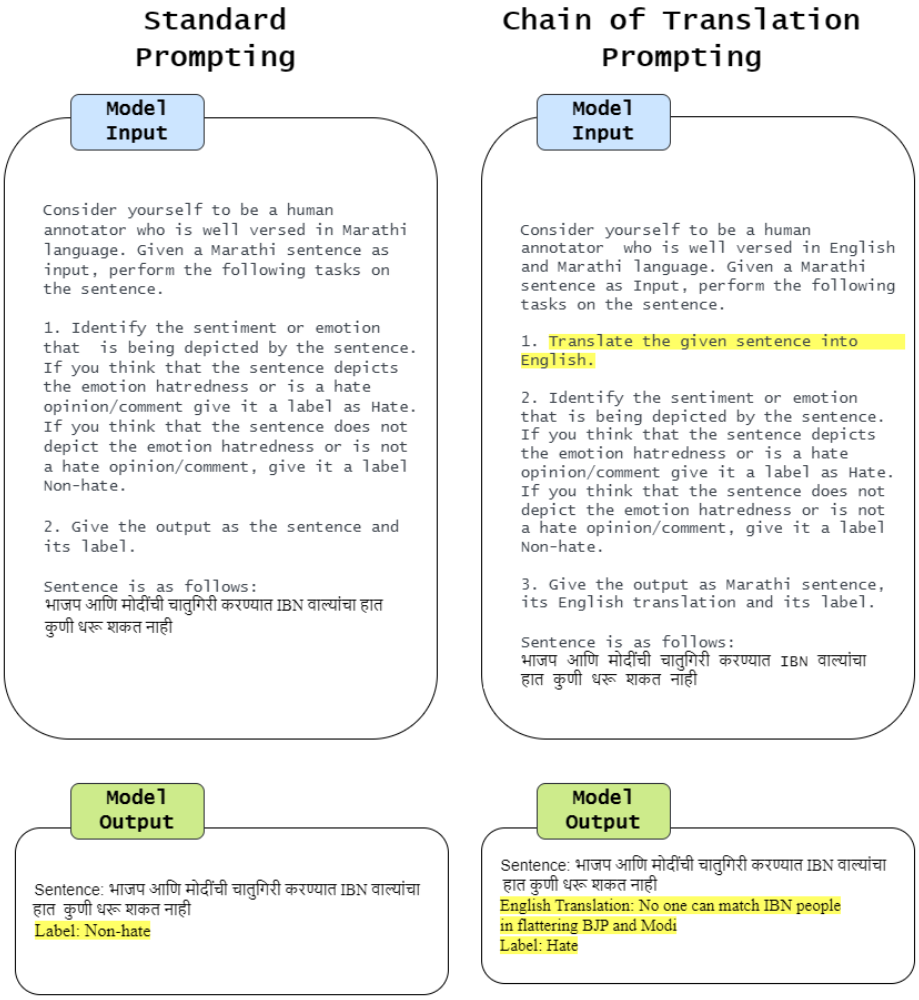

Figure 2: Prompt for Classification Task

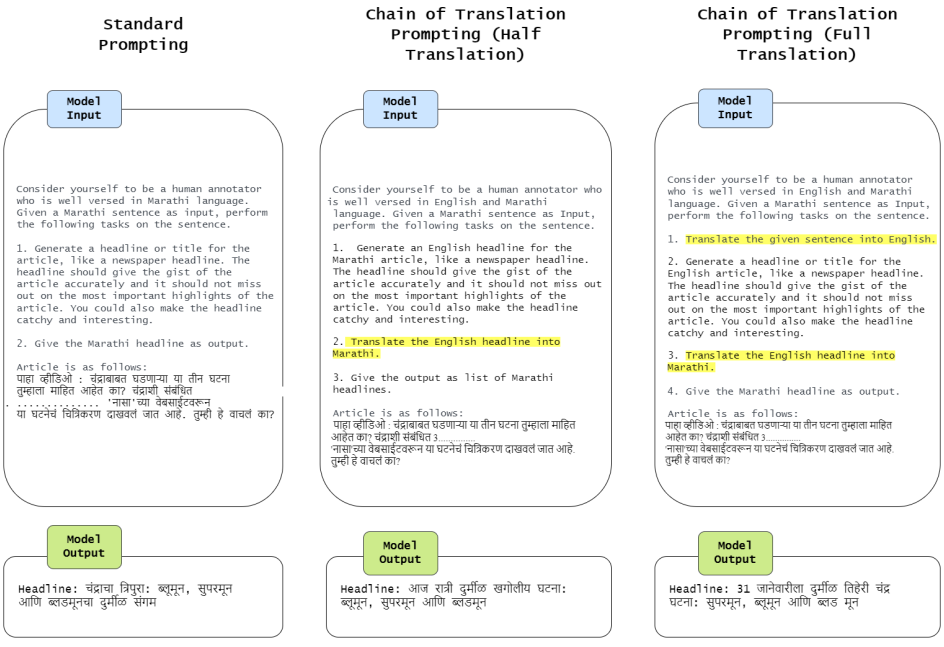

Figure 3: Prompt for Generation Task

such as mBERT (Jacob Devlin, 2019) and XLM-R (Alexis Conneau, 2018), which lay a strong platform for further gains in low-resource language processing.

Prompting strategies have become an effective way to train large language models (LLMs) for particular tasks without requiring a lot of fine-tuning. According to (Tom B. Brown, 2020), well-crafted prompts can direct models such as GPT-3 to carry out a range of NLP tasks effectively. More research has been done on the subject of quick engineering's potential to induce desired behaviors in LLMs even in situations with limited resources by (Pengfei Liu, 2021). These methods have shown to be useful, particularly for languages and activities for which there is little to no direct training data.

Prompting is being used more and more for tasks like sentiment analysis and hate speech detection, which are essential for keeping an eye on public conversation and guaranteeing secure online spaces. Research on Pattern-Exploiting Training (PET) for such tasks was first presented by (Timo Schick, 2021), who showed how prompts could direct models to make context-based, nuanced predictions. This method is consistent with the findings of (Shijun Shi, 2024), who also highlighted the benefit of model prompting for text categorization tasks in a variety of languages and domains.

3 Methodology

3.1 Chain of Translation Prompting

Our study introduces a novel approach called "Chain of Translation Prompting" aimed at enhancing the processing of Marathi, a low-resource language, using advanced language models like GPT-4o, GPT-4o Mini, Llama3-8B, Llama3-405B, and Gemma-9B. Recognizing the strong translation capabilities of these models, we leverage their ability to translate Marathi into English for improved processing. Directly prompting language models in Marathi has posed several challenges, primarily due to the scarcity of quality training data and the models' limitations in comprehending underrepresented languages. These challenges often result in sub-optimal performance on tasks such as sentiment analysis, hate speech classification, news categorization, and headline generation. Below, we outline the step-by-step methodology employed in our approach.

1. **Data Collection and Preparation:** We used datasets specific to Marathi language tasks, including MahaSent for sentiment analysis, MahaHate for hate speech classification, and MahaNews-SHC for subject categorization. For generative tasks, we used the CSE-BUETNLP XLSum dataset to generate headlines.

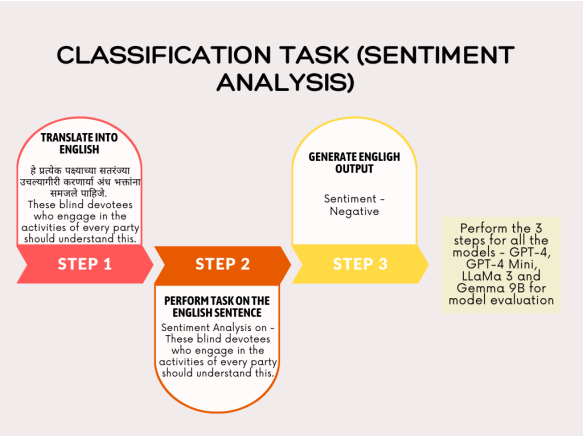

Figure 4: Classification Task using Chain of Translation Prompting

2. **Chain of Translation Prompting (CoTR) Technique:** Our methodology adapts a conventional translation approach used in developing low-resource NLP systems but applies it within the framework of large language model (LLM) prompts. Specifically, our method involves prompting the LLM to first translate the input text from Marathi into English, and then to execute the desired task on the translated English text.

3. **Task Execution:**

   - **Sentiment Analysis, Hate Speech Classification, and Subject Categorization**: For these classification tasks, the models categorize each sentence into predefined classes based on the task's requirements.
   - **Generative Task**: We used GPT-4o, GPT-4o Mini, and Llama3-405b for the headline generation task. The three prompting strategies used for generating headlines are described below.
     (a) Without Translation: In this approach, headlines were generated directly from the original Marathi articles without any translation. This method aimed to assess the model's capability to generate concise and im-

pactful headlines in the source language.

(b) Full Translation: Here, the entire Marathi article was first translated into English. Headlines were then generated based on the translated English text. The generated English headlines were subsequently translated back into Marathi to evaluate their fidelity and relevance.

(c) Half Translation: Given the length and complexity of the articles, the half-translation method was employed to streamline the process. In this approach, English headlines were generated based on the Marathi articles without full translation. These English headlines were then translated back into Marathi. This method aimed to balance efficiency and accuracy by avoiding the need for extensive translation of the entire article.

4. **Direct Prompting**: To evaluate the effectiveness of the Chain of Translation Prompting, we compare its results against the traditional method of directly prompting the models to process the Marathi text without performing translation.

5. **Google Translate + Prompting**: In this approach, Marathi sentences were translated into English using Google Translate. The translated English sentences, along with English prompts, were then used by LLMs to perform the desired classification tasks. This method represents a straightforward "translate-and-test" approach, serving as a baseline for comparison.

6. **Evaluation Metrics**: The performance of the models is measured using conventional metrics, such as the ROUGE-L score for generative tasks. The ROUGE-L score assesses the quality of the generated text, like summaries or headlines, by calculating the overlap with reference text. It evaluates precision and recall by calculating the longest common subsequence (LCS) between the reference text and the generated output. ROUGE-L focuses on capturing the longest word sequences found in both texts, providing insights into the preservation of critical information and coherence.

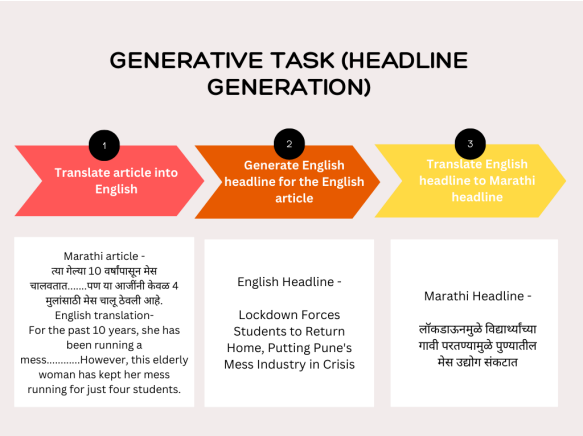

Figure 5: Generative Task using Chain of Translation Prompting

For classification tasks, the model outputs are compared with ground truths, and the error percentage is reported.

3.2 Datasets Used

1. MahaSent-GT[1]:
We used a subset of the L3Cube-MahaSent-MD dataset (Pingle et al., 2023), which contains 14,000 annotated Marathi tweets. Three sentiment labels Positive, Negative, and Neutral are present in the dataset. In particular, we employed the MahaSent-GT portion of this dataset for sentiment analysis.

2. MahaHate[2]:
We used the L3Cube-MahaHate collection's MahaHate 2-Class dataset for our classification task (Patil et al., 2022). It contains around 37500 annotated Marathi sentences. This dataset is divided into two categories: hate and non-hate. We employed the MahaHate 2-Class set for our classification task.

3. MahaNews-SHC[3]:
We analyzed Marathi news articles using the L3Cube-MahaNews-SHC dataset (Mittal et al., 2023). This dataset contains approximately 54,000 news articles spanning a wide

[2] https://github.com/l3cube-pune/MarathiNLP/tree/main/L3Cube-MahaHate
[3] https://github.com/l3cube-pune/MarathiNLP/tree/main/L3Cube-MahaNews-SHC

Table 1: Results on the MahaNews, MahaHate Dataset

Model	Sentence	Ground Truth Label	Label generated with standard prompt	Label generated with CoTR prompt
gpt 4.0	"....तर अवघ्या ३० मिनटांत रशिया अमेरिका आणि युरोपचं नामोनिशाण मिटवेल", इलॉन मस्क यांचा धक्कादायक दावा	International	Technology	International
gemma2 9b	समस्या-अडचणींनी ग्रासलाय? 'हे' स्तोत्र सलग २१ दिवस म्हणा अन् चिंतामुक्त व्हा; जाणून घ्या	Devotion	Neutral	Devotion
llama3-405b	हृदयद्रावक! कोरोनामुळे माय-लेकरांची ताटातूट; 'या' ठिकाणी पालकांपासून मुलांना ठेवलं जातंय दूर	Health	International	Health
llama3-8b	वाहन उद्योगातील मंदी पुढील वर्षी संपेल	Auto	Neutral	Auto
gpt 4.0 mini	कदम रडू नको तुझा मालक कोर्टात नेहमीच तोंडा वर पडतो कारण सगळेच बिनडोक भरले आहेत.	Hate	No hate	Hate

range of topics and was used for the news classification task.

4. XLSum[4]:
   We focused on Marathi text headline creation for our study using the CSEBUETNLP XL-Sum dataset. The dataset offers a wide range of news stories linked with their associated headlines. Our objective was to enhance the accuracy of automated headline creation for Marathi news articles by utilizing this dataset.

3.3 Evaluation Methodology

We performed our classification task on GPT-4o, GPT-4o Mini, Llama3-8B, Llama3-405B, and Gemma-9B.

1. **GPT-4o:**
   GPT-4o is developed by OpenAI, with 1.8 trillion parameters (unofficial). It is a closed-source model and accessible through APIs provided by OpenAI. GPT-4o builds on the advancements of its previous versions, offering enhanced capabilities in natural language understanding, generation, and reasoning across a wide range of tasks.

2. **GPT-4o Mini:**
   GPT-4o Mini is a smaller, more lightweight version of GPT-4o. This model is closed-source. GPT-4o Mini is engineered to balance computational efficiency with performance, making it suitable for applications requiring faster inference times and lower resource consumption while maintaining a high level of language understanding.

3. **Llama 3.1 8B / 405B:**
   Llama 3.1 (Large Language Model for Multilingual Applications) is the third iteration in the Meta Llama series, designed with multiple variants, including a 405 billion parameter version and an 8 billion parameter version. These models are typically open-source. Llama3 models are optimized for multilingual tasks, incorporating vast and diverse datasets to improve performance across different languages.

[4] https://huggingface.co/datasets/csebuetnlp/xlsum

4. **Gemma-2 9B:**
   Gemma-2 9B is an open-source language model with 9 billion parameters from Google. It strikes a balance between model size and performance, offering robust capabilities for both academic and practical applications.

Model	Without Translation	Half Translation	Full Translation
GPT-4o	33.3	44	49
GPT-4o mini	21.34	21.72	22.22
llama3-405b	20.27	20.34	21.13

Table 2: Rouge-L score in percentage for 3 approaches on the headline generation task on CSEBUETNLP XL-Sum Dataset

4 Results and Discussion

Table 2 and Table 3 show the analysis done on Standard Prompting and Chain of Translation Prompting.

4.1 Classification Task

Approximately 100 sentences were selected from MahaSent-GT, MahaNews-SHC, and MahaHate. The large language models categorize each of the sentences into a predefined category. These results were compared with the ground truth values to calculate the error rate. The error rate was calculated with the direct prompting approach and Chain of Translation prompting approach The results are shown in Table 3.

In the CoTR prompting approach, the error rate has reduced by 2.32% in the GPT-4o model, by 3.64% llama3-405b, by 5.29% in llama3-8b and by 4.96% in GPT-4o Mini. The error rate is slightly increased by 0.33% in the Gemma-9B model.

The error rate has been reduced by almost 5% in llama3-8b and gpt4 mini models. Specifically, the CoTR prompting approach has significantly improved hate speech identification across all models except for Gemma-9B. In the hate speech classification task, Gemma-9B often failed to correctly translate hateful comments and, in some cases, omitted those parts entirely. However, compared to standard prompting, the number of misclassifications for the "Non-hate" class was lower when using CoTR.

The results from the CoTR approach show significant improvement over the standard Google Translate method as well. We manually reviewed the translated sentences and found out that translations by large language models (LLMs), such as GPT-4 and GPT-4 Mini, captured meanings and nuances more effectively than Google Translate. While LLMs conveyed the intended meaning with subtlety, Google Translate produced literal translations, which sometimes failed to capture the full sense of the sentences.

For GPT-4 and GPT-4 Mini, the direct translation approach surpassed Google Translate's performance, as the nuances of some of the sentences did not get extracted completely by the google translator. As GPT-4 and GPT-4 Mini are stronger models the direct prompting is working better than Google translator approach.

One sample detection with traditional prompting versus CoTR prompting from each of the four models has been attached in Table 1, where the output with CoTR prompting is the same as the ground truth.

4.2 Generation Task

The headlines from the Marathi news text were generated using traditional prompting and CoTR prompting (with half and full translation). The headlines were compared against the manually assigned headline and the Rouge-L score metric was used to calculate their similarity with the manually assigned headline. The Rouge-L score for traditional prompting and CoTR prompting (half and full translation) are given in Table 2

We observed that GPT-4o delivered the best performance among all the models. GPT-4o Mini struggled to identify fine details in the articles, while Llama3-405B occasionally failed to provide the results in the specified format and produced some inaccurate translations. Overall, GPT-4o Mini and Llama-405B yielded similar outcomes.

In general, we observe the following performance ranking for Marathi tasks: GPT-4o > GPT-4o Mini > Llama 3.1 405B > Gemma 2 9B > Llama 3.1 8B. The CoTR approach proves especially useful with smaller models and for complex tasks like hate speech detection and sentiment analysis.

5 Future Work and Conclusion

In summary, our study demonstrates that various prompting strategies, particularly the Chain of

Table 3: Error percentage in the classification task across 5 models (these are the weighted averages and the numbers are percentages). Standard Prompt - Prompt the LLM to perform the task using the given Marathi context. CoTR Prompt - Prompt the LLM to translate the Marathi context to English and then perform the task. Google Translate - Translate the Marathi context to English using Google Translate and then prompt the LLM to perform the task in English.

Translation (CoTR) method, effectively enhance Marathi language processing tasks. By applying these techniques to various classification and generation tasks, we have expanded the potential for more reliable and accurate NLP applications in Marathi. While CoTR improves model performance, it does so at the cost of generating more tokens.

In the future, we aim to enhance performance on Marathi language tasks by combining Chain of Thought (CoT) and Chain of Translation (CoTR) prompting strategies. Our goal is to achieve context-aware and precise responses for complex tasks like sentiment analysis, hate speech detection, and subject classification. CoT allows models to break down complex tasks into simpler steps, while CoTR leverages translation from Marathi to English, where more accurate models can be employed. Together, these strategies should create a robust framework that improves model performance and reliability in Marathi NLP tasks.

This approach can further be used for other low-resource Indic languages.

Abstract

Cross-lingual transfer in large language models (LLMs) has the potential to enhance LLM performance in non-English languages, particularly in specialized fields where it is challenging to gather sufficient non-English data. However, the mechanisms and extent of cross-lingual transfer are not yet fully understood. In this study, we develop a new benchmark dataset called Cross-Lingual HumanEval (CL-HumanEval) to more effectively evaluate cross-lingual transfer. CL-HumanEval is based on the code generation benchmark HumanEval, with careful removal of hints such as function names, variable names, and execution examples to focus on the influence of natural language descriptions. This paper provides an overview of CL-HumanEval and presents experimental results that evaluate cross-lingual transfer at various stages of LLM development, including pre-training, continual pre-training, and instruction tuning. Our findings indicate that CL-HumanEval enables the evaluation of cross-lingual transfer with a focus on natural language differences more than HumanEval.

1 Introduction

In today's global society, many new concepts and ideas are primarily discussed in English. In fields such as advanced science, medical science, and software engineering, where most cutting-edge knowledge is initially provided in English (Guo, 2018). Non-English speakers often require translations to understand these documents, but translation errors can reduce work efficiency.

The emergence of large language models (LLMs) has the potential to significantly improve this situation. As shown in ChatGPT, the LLMs can effectively deal with prompts in non-English languages, even when including cutting-edge knowledge that is considered available only in English.

The phenomenon behind this behavior in LLMs is called *cross-lingual transfer*, where knowledge learned in English is transferred to other languages. However, the cross-lingual transfer isn't always intentional and doesn't always occur (Workshop et al., 2022; Foroutan et al., 2023), depending on training methods and the language makeup of the training data. The mechanisms and extent of cross-lingual transfer are still unclear. To better understand it, we need a benchmark dataset that makes it easy to compare and track the language composition and learning methods.

The goal of this study is to develop a benchmark dataset specifically designed to evaluate cross-lingual transfer in the context of code generation. Our focus on code generation comes from the fact that software engineering is one of the major applications for LLMs, but there has been a notable shortage of non-English data in this domain (Kocetkov et al., 2022). Furthermore, the clear syntactical differences between code and natural language facilitate dataset analysis, making code a suitable choice for benchmarking.

We propose the Cross-Lingual HumanEval (CL-HumanEval), a benchmark dataset to evaluate cross-lingual transfer. CL-HumanEval is based on the code generation benchmark HumanEval, carefully removing hints such as function names, variable names, and execution examples to focus on the influence of natural language descriptions. We switched from the original hand-written descriptions to LLM-generated text to ensure multilingual fairness.

This paper provides an overview of CL-HumanEval and presents experimental results that evaluate cross-lingual transfer at various stages of LLM development, including pre-training, continual pre-training, and instruction tuning. The findings reveal that CL-HumanEval enables a more

focused evaluation of how language differences impact code generation capabilities compared to the original HumanEval and JHumanEval benchmarks.

The contributions of this paper are as follows:

- We developed a new benchmark dataset, CL-HumanEval, specifically designed to evaluate cross-lingual transfer in LLMs.
- We evaluated cross-lingual transfer at various stages of development. CL-HumanEval focuses more on natural language differences and captures model differences.

2 Cross-Lingual Transfer and Evaluation

This section clearly defines "cross-lingual transfer" as used in this paper. We consider several multilingual benchmarks and analyze key concerns for evaluating cross-lingual transfer.

2.1 Cross-Lingual Transfer

Here, we consider domain knowledge X that can generate an answer in the LLM. As shown in the next subsection, common sense, mathematics, and programming are examples of such domain knowledge X.

For a given domain knowledge X, we assume the following two points about the English LLM:

- (Assumption 1) The English LLM has been trained on domain knowledge X described in English.
- (Assumption 2) The English LLM has not been trained on domain knowledge X described in Japanese.

We focus on LLMs with a language ratio known in their training data because the training data in current LLMs are often not disclosed. To investigate the occurrence of cross-lingual transfer, we utilize a multilingual benchmark specifically related to domain knowledge X.

Intuitively, if the Japanese benchmark performance in an English LLM is *higher than expected*, it suggests that knowledge transfer from English to Japanese has occurred. However, estimating "higher than expected" is problematic. Because the English LLMs often use large-scale web corpora, they cannot completely exclude multilingual training data.

Answer: D

JCommonsenseQA

問題: 織田信長軍と今川義元軍の合戦が行われた場所は？
A.桶屋 B.江戸 C.桶絞り D.桶狭間 E.三河
回答: D
Question: Where did the battle between Oda Nobunaga's forces and Imagawa Yoshimoto's forces take place?
A. Okeya B. Edo C. Okeshibori D. Okehazama E. Mikawa
Answer: D

Figure 1: **CommonSenseQA and JCommonSenseQA:** The figure illustrates CommonSenseQA and JCommonSenseQA examples.

We cannot simply estimate the Japanese benchmark scores as zero, nor can we individually measure the impact of small amounts of Japanese training data. This is one of the reasons why tracking cross-lingual transfer has been challenging.

To estimate the extent of cross-lingual transfer, we need to compare the multilingual benchmark performance before and after additional training. Here, additional training refers to any form of training (such as continual pre-training and instruction tuning) applied to the pre-trained English LLM. Note that, at the time of writing, there is no established consensus on what training phase effectively triggers cross-lingual transfer.

In the additional training, Assumption 2 must still hold. If it does not, then it is difficult to distinguish whether the inference results were obtained from the Japanese additional training or transferred from English. On the other hand, the additional training requires some Japanese training data. Although separating domains (such as X or not) within the same language is not trivial, domains that are easier to separate will be one of the keys to evaluating cross-lingual transfer.

In the remaining sections, we highlight existing major multilingual benchmarks and discuss their suitability for evaluating cross-lingual transfer.

2.2 CommonSenseQA, JCommonSenseQA

CommonSenseQA (Talmor et al., 2018) is a benchmark dataset designed for evaluating the commonsense reasoning abilities of LLMs. An LLM is required to select the correct answer when given a question and multiple-choice options such as Figure 1.

JCommonSenseQA (Kurihara et al., 2022) is the Japanese version of CommonSenseQA. It was constructed separately through crowdsourcing, so the content of the questions is different. For example, JCommonSenseQA includes questions requir-

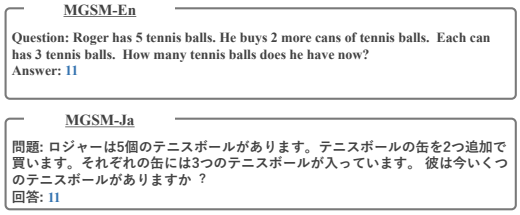

Figure 2: **MGSM:** The figure illustrates MGSM examples in English and Japanese.

ing specific knowledge of Japan such as history or place names, as shown in Figure 1.

The knowledge required for JCommonSenseQA is not the same as that needed for CommonSenseQA. For evaluating cross-lingual transfer, it is preferable to use datasets with the same content in different languages, such as those created through translation. Therefore, these datasets with such differences in content may be unsuitable.

2.3 MGSM

Multilingual Grade School Math (MGSM) (Shi et al., 2022) is a benchmark dataset for evaluating the arithmetic reasoning abilities of LLMs. The LLM is required to generate a numerical answer through multi-step reasoning when given a math problem, such as the one shown in Figure 2.

MGSM presents the same problems across different languages, unlike CommonSenseQA and JCommonSenseQA. It is based on the English dataset GSM8K (Cobbe et al., 2021), which includes grade school level math problems, and has been manually translated into multiple languages, including Japanese. Therefore, the required knowledge is the same across different languages.

Several concerns arise when using MGSM to evaluate cross-lingual transfer. Although mathematics is a distinct domain of knowledge, MGSM makes it difficult to classify as specialized domain knowledge because it consists of elementary-level problems. Additionally, the LLM may require few-shot learning or instruction tuning to generate only numerical answers. Therefore, MGSM is challenging to use directly for evaluations after pre-training. The adjustments needed for evaluation may also unintentionally affect the model's performance.

2.4 HumanEval, JHumanEval

HumanEval (Chen et al., 2021) is a benchmark dataset for evaluating the code generation capabilities of LLMs. Figure 3 shows an example. The LLM is required to complete the function by generating code when given a function signature and a docstring.

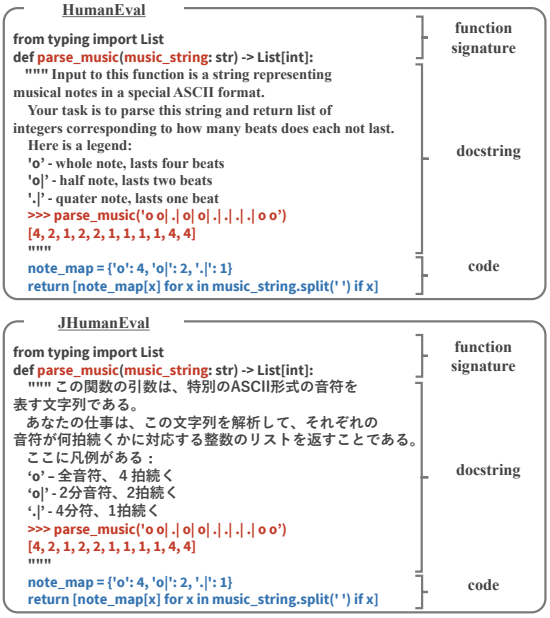

Figure 3: **HumanEval and JHumanEval:** The figure illustrates HumanEval and JHumanEval examples.

JHumanEval (Sato et al., 2024) is the Japanese version of HumanEval, with the same function signatures and docstring contents. It was constructed by using both machine translation and manual quality control to translate the English-written docstrings from HumanEval into Japanese.

These datasets offer three beneficial characteristics for evaluating cross-lingual transfer. First, the required programming knowledge is the same in both English and Japanese, making it easy to verify whether code generation capabilities in English can transfer to Japanese. Second, programming is highly specialized domain knowledge, and code is easier to separate from natural language because it is written with strict syntax and structure. Third, HumanEval and JHumanEval can be applied to evaluations before and after pre-training or fine-tuning without the need for adjustments because they are in a code completion format.

Despite these characteristics, there are concerns about directly using these datasets. Function signatures and docstrings contain hints for code generation beyond just the natural language descriptions. The hints include function names and variable names of English origin and execution examples, as highlighted in red in Figure 3. If the LLM generates code based on these hints, it becomes difficult to compare code generation capabilities

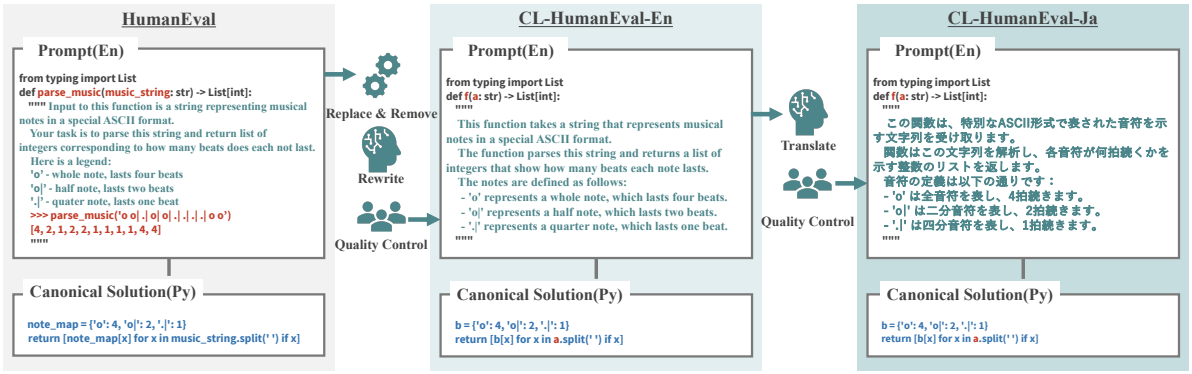

Figure 4: **CL-HumanEval**: This figure illustrates examples of CL-HumanEval and its construction process.

purely based on differences in natural language. Therefore, we develop a new benchmark dataset focused on evaluating cross-lingual transfer.

3 CL-HumanEval

This section presents our benchmark dataset CL-HumanEval.

3.1 Design Principle

CL-HumanEval is a multilingual dataset based on HumanEval and JHumanEval. While inheriting the beneficial characteristics described in Section 2.4, we have made improvements based on the following principles.

- **Purification of Natural Language:** Code generation is a complicated task, and hints such as execution examples are often provided to achieve accurate code. However, these hints are unnecessary when the goal of the benchmark is to accurately measure the impact of natural language alone. Execution examples should be removed and function names or any variable names derived from English or other languages should be replaced.

- **Multilingual Fairness:** Multilingual datasets are often created by using LLM-based machine translation from manually written English text. However, our initial investigation has shown that LLM-generated descriptions usually produce better results than manually written ones. To maintain fairness, we've decided to switch the English version from manually written to LLM generated. This will also make it easier to maintain consistency when adding support for more languages in CL-HumanEval.

3.2 Method of Construction

We created an English dataset as the source for the multilingual version by following these three steps:

First, we refined the English version of HumanEval. All function names were replaced with 'f' and variable names were shortened to single letters. For example, in the figure, '`parse_music()`' becomes '`f()`', and its argument '`music_string`' is shortened to '`a`'. This transformation makes the identifiers neutral across all languages. If necessary, identifiers in the docstrings were replaced in the same way, and any execution examples were also removed.

Next, we used an LLM to regenerate the English docstrings. The prompt used was: "*Rewrite the docstring in plain English.*" As mentioned later, the multilingual versions are simply translations of this English text.

Finally, we applied human quality control by having multiple reviewers examine the content. Any obvious errors, missed instructions, or unnecessary explanations were corrected and revised.

The multilingual dataset was created from the English version. Identifiers were not changed. For the Japanese version, the docstrings were translated using the following prompt: "*Translate the docstring in plain Japanese.*" Like the English version, human quality control was applied.

The CL-HumanEval dataset follows the same structure as HumanEval, including `prompt`, `canonical_solution`, and so on. This enables evaluation using the same script as HumanEval.

The dataset created for this paper (version 1) was generated using GPT-4o mini (version: 2024-07-18) and is available on HuggingFace[1]. The reader may create unsupported multilingual datasets under

[1] https://huggingface.co/datasets/kogi-jwu/cl-humaneval_v1.0

Table 1: **Performance of English LLMs on Benchmark Datasets:** This table shows the performance of various English LLMs on the CommonSenseQA, JCommonSenseQA, MGSM, HumanEval, JHumanEval, and CL-HumanEval datasets. Scores are presented in both English (En) and Japanese (Ja), along with the cross-lingual differences (En-Ja) for each benchmark, as well as the average scores across all models.

Model	Size	CommonSenseQA JCommonSenseQA (0-shot, ExactMatch)			MGSM (4-shot, ExactMatch)			HumanEval JHumanEval (0-shot, pass@1)			CL-HumanEval (0-shot, pass@1)		
		En	Ja	En-Ja	En	Ja	En-Ja	En	Ja	En-Ja	En	Ja	En-Ja
Gemma	2B	41.3	42.3	-1.0	7.6	4.0	3.6	22.0	22.6	-0.6	17.1	14.0	4.3
CodeGemma	2B	29.6	28.0	1.6	4.8	2.0	2.8	34.2	22.6	11.6	20.7	21.3	-0.6
Llama2	7B	41.0	35.9	5.1	6.0	2.8	3.2	12.8	11.6	1.2	11.6	12.8	1.2
CodeLlama	7B	35.5	33.0	2.5	4.4	4.4	0.0	26.8	21.3	5.5	25.0	22.0	5.5
Llama3	8B	44.4	42.8	1.6	14.0	8.4	5.6	37.2	33.5	3.7	34.8	31.7	2.5
Average		38.4	36.4	2.0	7.4	4.3	3.1	26.6	22.3	4.3	21.8	20.4	1.5

similar conditions by using the same LLM. If the LLM updates, the version of CL-HumanEval will be updated to ensure consistency.

3.3 Evaluation Metrics

In CL-HumanEval, the evaluation metric used is the same as in HumanEval, which is $pass@k$ (Chen et al., 2021). The $pass@k$ is defined as the probability that at least one out of the top k code samples passes the unit test for a given problem. In HumanEval, with n: total number of samples, c: number of correct samples, and k: k in $pass@k$, the calculation of $pass@k$ is given by the following:

$$\text{pass@k} := \mathbb{E}_{\text{Problems}}\left[1 - \frac{\binom{n-c}{k}}{\binom{n}{k}}\right]$$

In evaluating cross-language transfer, where the goal is to compare the relative code generation capability between languages, it is sufficient to focus on the very first generated sample, setting $n = 1$ and $k = 1$.

4 Experiments on CL-HumanEval

We evaluate the models at various stages, including pre-training, continual pre-training, and instruction tuning.

4.1 English LLMs

To begin, we examined the Japanese language capabilities of several English LLMs. The LLMs examined and their respective training datasets are as follows:

- **Gemma** (Team et al., 2024): Trained on 2 trillion tokens of primarily English data from web documents, mathematics, and code.
- **CodeGemma** (Team, 2024): Trained on an additional 500 billion tokens of primarily English language data from web documents, mathematics, and code, based on the Gemma model.
- **Llama2** (Touvron et al., 2023): Trained on 2 trillion tokens from publicly available sources, with a ratio of 897:1 for English to Japanese.
- **CodeLlama** (Roziere et al., 2023): Trained on 500 billion tokens, primarily code based on the Llama2 model.
- **Llama3** (Dubey et al., 2024): Trained on about 15 trillion tokens, consisting of 50% general knowledge tokens, 25% mathematical and reasoning tokens, 17% code tokens, and 8% multilingual tokens, sourced from curated and filtered web data.

These LLMs are either primarily pre-trained in English or have undergone continual pre-training with source code. Note that these LLMs may include some Japanese content from web corpora. According to the CommonCrawler project, the ratio of English contents to Japanese contents on the Web is approximately 9:1[2]. The Stack project reports that the ratio of English code to Japanese code on GitHub is approximately 94:1 (Kocetkov et al., 2022).

We have compared the performance differences between the English and Japanese versions of CommonSenseQA, MGSM, HumanEval, and CL-HumanEval, as discussed in Section 2. Table 1 summarizes these benchmark scores.

[2] https://commoncrawl.github.io/cc-crawl-statistics/plots/languages

Table 2: **Performance of LLMs after Japanese Additional Training:** This table presents the results of LLMs evaluated on English (En) and Japanese (Ja) benchmarks after continual pre-training and instruction tuning in Japanese. The "Ja-En" column shows the difference between the Japanese scores and the English scores of Llama2.

Model	Continual Pre-training	Instruction Tuning	CommonSenseQA JCommonSenseQA (0-shot, ExactMatch)			MGSM (4-shot, ExactMatch)			HumanEval JHumanEval (0-shot, pass@1)			CL-HumanEval (0-shot, pass@1)		
			En	Ja	Ja-En	En	Ja	Ja-En	En	Ja	Ja-En	En	Ja	Ja-En
Llama2	basemodel		41.0	35.9	-	6.0	2.8	-	12.8	11.6	-	10.4	9.2	-
Swallow	✓(100B)		38.3	56.7	15.7	6.0	5.6	-0.4	3.7	1.8	-11.0	4.3	4.3	-6.1
Swallow-instruct	✓(100B)	✓	36.3	36.7	-4.3	5.6	5.6	-0.4	6.1	1.2	-11.6	1.8	1.2	-9.2
StableLM	✓(100B)		39.2	43.3	2.3	5.2	3.2	-2.8	11.6	13.4	0.6	10.4	9.2	-1.2
StableLM-instruct	✓(100B)	✓	40.1	44.6	3.6	5.6	3.6	-2.4	14.6	11	-1.8	8.5	5.5	-4.9
Youri	✓(40B)		40.1	50.4	9.4	6.0	5.2	-0.8	11.6	10.4	-2.4	7.9	7.3	-3.1
Youri-instruct	✓(40B)	✓	41.5	51.3	10.3	4.0	4.8	-1.2	7.9	5.5	-7.3	4.3	5.5	-4.9

Interestingly, some LLMs show only minor differences in performance between English and Japanese. MGSM captures performance differences; however, because it operates in a lower score range, it may be less effective at distinguishing variations between models. Let us focus on the differences between HumanEval and CL-HumanEval. HumanEval may generate code by leveraging hints such as function names, variable names, and execution examples, whereas CL-HumanEval removes these hints to focus solely on natural language descriptions. As a result, CL-HumanEval scores are lower across all of the LLMs, suggesting that the intended factors were removed. This indicates that CL-HumanEval more accurately measures code generation capabilities from the target language.

In CL-HumanEval, the English version generally outperforms the Japanese version. This is expected given the language makeup of the source code and suggests the possibility of cross-linguistic transfer. However, due to limited details on each LLM's training data, the extent of cross-lingual transfer remains unclear. An ablation study on training data would be beneficial if feasible.

4.2 Japanese Additional Training

Next, we evaluate English LLMs that were subject to additional training, including continual pre-training and instruction tuning, using Japanese datasets. Especially, Japanese continual pre-training is expected to be an effective approach for enhancing the Japanese language understanding and generation capabilities of English LLMs (Fujii et al., 2024). One of the English LLMs Llama2 already exhibits some degree of cross-lingual transfer, as shown by the CL-HumanEval results in Table 2. However, it is interesting to examine how Japanese continual pre-training influences this transfer.

The LLMs examined and their respective Japanese continual pre-training datasets are as follows:

- **Swallow** (Fujii et al., 2024): Trained on 100 billion tokens, with a 1:9 ratio of English sources (The Pile, RefinedWeb) to Japanese sources (Japanese Wikipedia and a curated dataset by Swallow).
- **StableLM** (Lee et al., 2023): Trained on 100 billion tokens, including English sources (English Wikipedia, SlimPajama) and Japanese sources (Japanese Wikipedia, mC4, CC-100, OSCAR).
- **Youri** (Sawada et al., 2024): Trained on 40 billion tokens, from English sources (The Pile) and Japanese sources (CC-100, C4, OSCAR, and a curated dataset by rinna).

The datasets used for Japanese continual pre-training are often proprietary, and details such as the language ratios are frequently not disclosed.

Table 2 show how English and Japanese performance changed the following Japanese continual pre-training. JCommonSenseQA showed a clear improvement in scores; however, it is important to carefully consider whether this is due to newly trained knowledge or cross-lingual transfer. MGSM showed a slight improvement in scores; however, the training dataset includes elementary-level math knowledge.

The cases of HumanEval, JHumanEval, and CL-HumanEval are somewhat different. The continual pre-training dataset contains almost no Japanese code text. Our preliminary investigation confirmed that the Japanese mC4 dataset contains very little source code data. This allows us to focus on cross-lingual transfer; however, Llama2's performance showed little difference between English

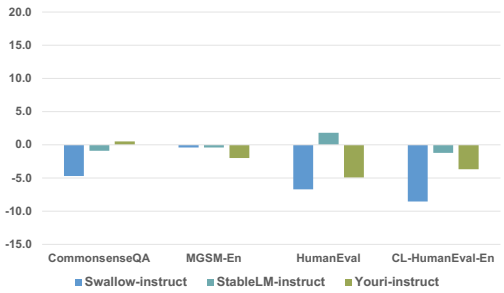

Figure 5: **Impact of Japanese Additional Training on English Tasks:** This chart illustrates how Japanese additional training affects the performance of LLMs on English tasks.

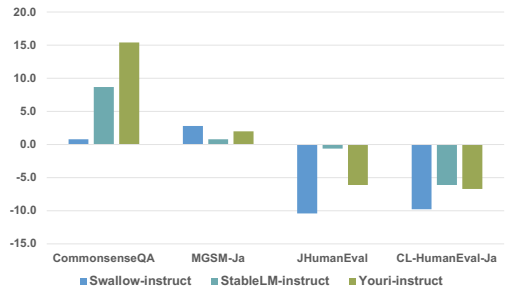

Figure 6: **Impact of Japanese Additional Training on Japanese Tasks:** This chart illustrates how Japanese additional training affects the performance of LLMs on Japanese tasks.

and Japanese. However, catastrophic forgetting was observed instead of promoting cross-lingual transfer.

We also evaluated LLMs after continual pre-training with instruction tuning. Table 2 shows these benchmark scores. The CL-HumanEval results show that scores decreased after instruction tuning compared to before. Figures 5 and 6 illustrate how English and Japanese performance changed the following Japanese additional training including continual pre-training and instruction tuning. CL-HumanEval effectively captures the changes in scores due to Japanese additional training, but all results showed a decline. This confirms that further catastrophic forgetting occurred as a result of the Japanese additional training.

5 Related Work

This study is related to research in cross-lingual transfer and code generation benchmarks.

Cross-Lingual Transfer: Cross-lingual transfer is expected to improve the capabilities of low-resource languages by transferring knowledge learned from high-resource languages. This has been evaluated in tasks such as natural language inference, question answering, and mathematical reasoning (Conneau et al., 2018; Lewis et al., 2019; Shi et al., 2022). The multilingual capabilities of newly released LLMs have been evaluated using independently machine-translated versions of benchmarks like MMLU (Hendrycks et al., 2020; Achiam et al., 2023; Dubey et al., 2024). In this study, we focus on programming knowledge, which requires specialized knowledge and is predominantly available in English. We evaluate cross-lingual transfer through the task of code generation.

Code Generation Benchmarks: Code generation benchmarks exist in multiple datasets to evaluate the capabilities of LLMs (Chen et al., 2021; Austin et al., 2021; Hendrycks et al., 2021). Particularly, HumanEval is widely used as the standard benchmark. Several datasets extending HumanEval have been developed, including those expanded to support multiple natural languages and programming languages (Zheng et al., 2023; Peng et al., 2024). These datasets have highlighted differences in code generation capabilities across languages. We have developed a new benchmark dataset, CL-HumanEval. It is specifically refined to focus on natural language differences for better evaluation of cross-lingual transfer.

6 Conclusion

Cross-lingual transfer in LLMs can enhance performance in non-English languages, especially in fields where non-English data is limited. However, its mechanisms and extent of cross-lingual transfer are not yet fully understood.

We developed CL-HumanEval, a benchmark focused on code generation to more effectively evaluate cross-lingual transfer. CL-HumanEval removes hints such as function names, variable names, and execution examples to isolate the impact of natural language and ensures fairness by using consistent LLM-generated text across languages.

We used CL-HumanEval to evaluate cross-lingual transfer at various stages of LLM development. The results show that CL-HumanEval effectively measures cross-lingual transfer and highlights differences between models. In the future, this could help investigate how differences in the content and language ratios of training datasets impact cross-lingual transfer.

Abstract

Aspect-Based Sentiment Analysis (ABSA) has seen significant advancements with the introduction of Transformer-based models, which have reshaped the landscape of Natural Language Processing (NLP) tasks. This paper introduces enhancements to the `Instruct-DeBERTa` model which is one of the leading ABSA models for ABSA. It takes a hybrid approach combining the strengths of `InstructABSA` for Aspect Term Extraction (ATE) and `DeBERTa-V3-baseabsa-V1` for Aspect Sentiment classification (ASC). In this work, we enhance `Instruct-DeBERTa` by introducing category classification through a cosine similarity-based method, comparing aspect embeddings with predefined categories. Also for `InstructABSA` and `DeBERTa-V3-baseabsa-V1`, we investigate different configurations by adding a linear layer followed by ReLU activation, incorporation of regularization and optimization of attention heads. These modifications were tailored specifically for the data sets in the hospitality domain. Our empirical evaluations, run on diverse datasets, have shown that these enhancements significantly raise the performance of `Instruct-DeBERTa` for hospitality domain datasets.

1 Introduction

The growing interest in NLP makes ABSA an important building block for sentiment detection and investigation using textual information (Mudalige et al., 2020; Rajapaksha et al., 2020). Unlike traditional approaches to sentiment analysis, where just the estimate of polarity value was estimated, ABSA focuses on fine-grained opinions expressed on some features or attributes offered by products or services (Rajapaksha et al., 2021; Jayasinghe et al., 2021). This is especially important for any business wishing to understand customer feedback better and improve products and services based on the overall opinion of the consumers.

It was only in the most recent years that one witnessed substantial progress in machine and deep learning applied to ABSA methodologies (Rajapaksha et al., 2022; Samarawickrama et al., 2022). Early lexicon-based approaches failed to properly account for context and ambiguity, while later-introduced machine learning models were most of the time heavily reliant on manual feature engineering and lacked generalization across domains. Significant progress has been associated with its application, especially through models such as recurrent neural networks, long short-term memory networks, and convolutional neural networks. But still, capturing long-term dependencies and complex syntactic structures effectively remains hard.

Transformer-based architectures, most notably exemplified by `BERT`, revolutionized the field by using attention mechanisms to capture contextual relationships from all directions within a sentence. Having advanced their ability to further comprehend complex linguistic patterns and relations, these models set new records on many NLP tasks. In this line of research, state-of-the-art models that emerge are `InstructABSA` for ATE and `DeBERTa-V3-baseabsa-V1` for ASC. The work presented by Jayakody et al. (2024b) introduces `Instruct-DeBERTa` — a hybrid model that combines the best of `InstructABSA` (Scaria et al., 2024) in ATE with those of `DeBERTa-V3-baseabsa-V1` (Yang et al., 2023, 2021) in ASC. The model was constructed to perform the joint task of aspect extraction and sentiment polarity detection within a single pipeline. Evaluation across the SemEval 2014-2016 restaurant reviews (Res-14, Res-15, and Res16)and the SemEval 2014 laptop dataset (Lap-14), has demonstrated that `Instruct-DeBERTa` is better by quite a margin than any other model in accuracy and robustness and is hence likely state-of-the-art for the joint task of ATE and ASC.

However, there are always some aspects that

Model	F1 Score (%)					
	Res-14		Res-15		Res-16	
	ATE	ASC	ATE	ASC	ATE	ASC
InstructABSA (Scaria et al., 2024)	92.10	–	76.64	–	80.32	–
DeBERTa-V3-base-absa-v1.1 (Yang et al., 2023, 2021)*	–	90.94	–	89.55	–	83.71
DeBERTa-V3-base-absa-v1.1-Improved version	–	**91.62**	–	**86.79**	–	**85.88**

Table 1: F1 scores for the selected models individually and when pipe-lined. Note*: These F1 scores were taken from Jayakody et al., 2024b.

remain quite underdeveloped in the case of `Instruct-DeBERTa`. In this work, we make a few substantial improvements beyond the base model. We include a component for category classification with cosine similarity to classify the extracted aspects by comparing them with the pre-trained embeddings of categories. This is then plotted on a Voronoi diagram to clearly and intuitively provide insight into how the aspects are spread across different categories. Furthermore, we did extensive hyper-parameter tuning and architectural changes of our model with availabl for especially on the `DeBERTa-V3-baseabsa-V1` model—to ensure that our trained model works most effectively on the hospitality domain. This also increases the capacity to classify sentiment polarities accurately. These numerous innovations further open up the horizons of ABSA in order to have a more detailed and precise model for the analysis of customer feedback.

2 Background

Recent studies have explored advanced methodologies to enhance the efficiency and scalability of ABSA models. These include using the Quantized Low-Ranking Adaptation (QLoRA) (Dettmers et al., 2023) approach to `Llama 2` (Touvron et al., 2023) fine-tuning, utilizing the `SETFIT` (Tunstall et al., 2022) framework for few-shot learning, and implementing `FAST_LSA_T_V2` (Yang and Li, 2024) within the `PyABSA` (Yang et al., 2023) framework. Among them, the best result was produced by the `FAST_LSA_T_V2` model with 87.6% and 82.6% on the Res-14 and Lap-14 datasets, respectively. None of these models outperformed the reported `LSA+DeBERTa-V3-Large` (Yang and Li, 2024) model by the accuracy of 90.33% and 86.21% on the same datasets (Jayakody et al., 2024a). This study mainly focused on single-task ABSA in the effort of establishing a hybrid model for performance in certain domains such as restaurants and laptops.

In general, there are two main underlying ABSA subtasks: Aspect Term Extraction and Aspect Sentiment Classification. Transformer-based models have significantly advanced the performance of these tasks. Very recently, the authors of Jayakody et al., 2024b have therefore proposed an ABSA pipeline chain based on Transformer-based models that will automatically extract aspects and perform the sentiment analysis in the text data.

In the present review, the best model performance was identified for each of the subtasks. However, the `instructABSA` has performed the best on the ATE task so far, with 92.10% F1 on the Res-14 dataset, outperforming every other model that also had equally very good performance for all other datasets such as Res-15, Res-16, and Lap-14, showing strong generalization capability across domains. Among these, `DeBERTa-V3-base-absa-v1` was the best in the general ASC task, showing the highest F1 score on all datasets. For example, the Res-14 dataset alone recorded 90.94%. Its performance was considered quite good for all datasets across Res-15, Res-16, and Lap-14, which were from different domains. Based on these results, a hybrid model, termed `Instruct-DeBERTa`, was proposed, consisting of a pipelined combination of the `InstructABSA` model for ATE and the `DeBERTa-V3-base-absa-v1` model for ASC, where the benefits of both models are sought to be utilized in accomplishing the joint ABSA task.

`Instruct-DeBERTa` demonstrates strong performance across various sentiment classification tasks, with most of the extracted and classified aspects achieving high F1 scores, underscoring the model's precision and stability. As illustrated in Table 1, although there was a slight decrease in some F1 scores due to the pipelining process referenced in Jayakody et al., 2024b, the hybrid model's overall performance remained resilient. Particularly, the model performs exceptionally well in the joint task, achieving pair extraction F1 scores of 80.94%

for the Lap-14 dataset and 80.78% for the Res-14 dataset. These results underscore the model's durability and efficacy by showing that it can attain higher accuracy than what has been previously reported for these datasets.

3 Methodology

Under this section, we discuss on optimizing the performance of `Instruct-DeBERTa` for enhanced efficiency in ABSA in the hospitality domain. Rs-14, Res-15, and Res-16 are the main data sets that we utilize in the analysis to focus on this domain. More importantly, a new mechanism for category classification is introduced, and the model architecture parameters are fine-tuned. The overall structure of our model is shown in Fig. 1.

First, we developed a categorization classification method through which the identified aspects were allocated to the established categories, using a cosine similarity-based methodology. Further elaboration of this development will enhance the accuracy of analysis and allow better structuring and interpretation for the sentiments associated with these aspects. This is undertaken for visualization using Voronoi diagrams in order to exactly understand how such aspects distribute within the categories in a very clear and intuitive way. Based on this work, we fine-tuned some additional model architecture parameters for the dropout rates, the attention mechanism, layer normalization, and several others, within the `DeBERTa-V3` and `InstructABSA` models. This was done to further compress more improvements into the model with respect to accuracy and robustness in the classification of aspects and sentiment polarity.

3.1 Integrating aspect categorization

In order to improve the `Instruct-DeBERTa` model, we embedded aspect category separation within the domain of sentiment analysis. The model categorizes each aspect term identified within a sentence into predefined categories, using an embedding-based similarity approach. Additionally, we visualized the relationships between these aspects and their categories using t-SNE dimensionality reduction and Voronoi diagrams. This whole process was explicitly done without training the model on a certain dataset that would contain both aspects and categories, but categorization has been purely based on similarities between embeddings.

The core functionality of the model is to categorize aspect terms into specific categories. This was achieved using an embedding-based method where each aspect term is embedded into a high-dimensional vector space using `GIST-Embedding-v0` (Solatorio, 2024). This model was chosen since it was the best performing embedding model with the least amount of model parameters and embedding dimensions. This addition of the embedding model made the collective hybrid model `Instruct-DeBERTa` a single triple task model consisting of `InstructABSA`, `DeBERTa-V3` and `GIST-Embedding-v0`. The aspect term is then categorized based on its similarity to predefined category embeddings.

The categorization process is mathematically formalized as follows:

$$\mathbf{e}_{\text{aspect}} = \text{Encode}(\text{aspect}) \tag{1}$$

Where:

- $\mathbf{e}_{\text{aspect}}$ represents the embedding of the aspect term, obtained using the embedding model's encode function.

The similarity between the aspect embedding and each category embedding is calculated using the cosine similarity function:

$$\text{CS}(\mathbf{e}_{\text{aspect}}, \mathbf{e}_{\text{category}}) = \frac{\mathbf{e}_{\text{aspect}} \cdot \mathbf{e}_{\text{category}}}{\|\mathbf{e}_{\text{aspect}}\| \|\mathbf{e}_{\text{category}}\|} \tag{2}$$

Where:

- CS stands for Cosine Similarity
- $\mathbf{e}_{\text{category}}$ is the embedding of a predefined category.
- $\cdot$ denotes the dot product, and $\| \cdot \|$ represents the vector norm.

The aspect term is assigned to the category with the highest average cosine similarity score:

$$\text{Best Category} = \arg \max_{\text{category}} \frac{1}{n} \sum_{i=1}^{n} \text{CS}(\mathbf{e}_{\text{aspect}}, \mathbf{e}_{\text{category}}) \tag{3}$$

Where:

- n represents the number of embeddings per category.

This approach ensures that each aspect term is grouped with the category that it is most semantically aligned with, according to the vector representations learned by the embedding model. Also,

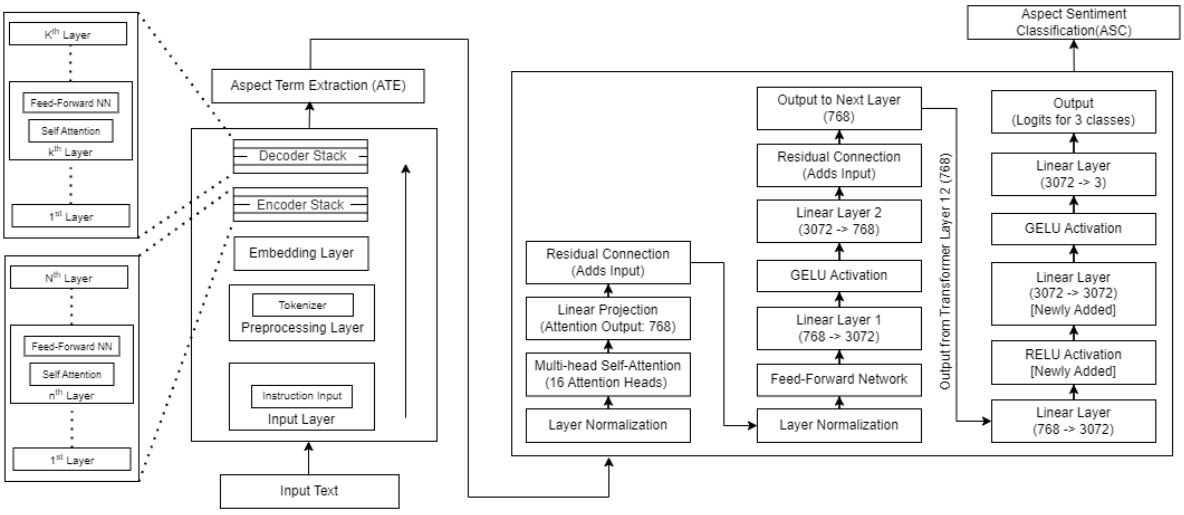

Figure 1: New structure of Instruct-DeBERTa

this categorization process was carried out without training the model on a specific dataset that explicitly links aspects to categories. Instead, it relied entirely on the inherent similarities between embeddings in the vector space, demonstrating the ability of pre-trained embeddings in capturing semantic relationships.

3.2 Improvements to the existing architecture of Instruct-DeBERTa

Under this section, the different changes that we experimented are being discussed for both the aspect extraction and the sentiment polarity model which will eventually increase the performance of the collective hybrid model `Instruct-DeBERTa`. We explored a series of architectural modifications and regularization techniques on the `Instruct-DeBERTa` model to enhance its performance in sentiment analysis tasks. These modifications included adding an extra feed-forward layer, implementing additional regularization methods, and adjusting the number of attention heads. The changes were tested for both the `DeBERTa-V3-baseabsa-V1` which performs ASC and `InstructABSA` which performs ATE. Several of these interventions resulted in improvements to the model's weighted F1 score, highlighting the potential of fine-tuning and architectural adjustments to optimize models with pre-trained weights for specific NLP tasks. This approach emphasizes the value of achieving meaningful performance gains with minimal retraining, reducing the need for extensive re-training with each architectural change.

3.2.1 Adding a linear layer with ReLU and regularization for ASC enhancements

In our experiment, we utilized the `DeBERTa-V3-base-absa-V1` model for the ASC task. The original model's classifier architecture consisted of a linear layer that projected the output of the transformer layers into a higher-dimensional space, followed by a GELU activation function to introduce non-linearity. This was then followed by a final linear layer that reduced the dimensionality to produce logits corresponding to the three sentiment classes (negative, neutral, positive). To explore potential performance improvements, we modified this architecture by adding an additional feed-forward layer in the classifier. Specifically, we introduced an extra linear layer followed by a ReLU activation function after the first linear layer in the classifier. This additional linear layer, which maintained the same output dimensionality, was inserted to perform further transformations of the feature space. The ReLU activation added another layer of non-linearity, enhancing the model's ability to capture complex patterns. By extending the classifier with this deeper architecture, we aimed to increase the model's capacity for more sophisticated feature representations, potentially leading to more accurate classification decisions. There are also additional theoretical grounds for setting feed-forward layers in a universal approximation theorem. The theorem says a neural network with enough depth and non-linearity can approximate any continuous function, and because it adds one more degree of freedom to the model by being flexible in how it models the decision

boundary among classes, this might lead to better generalization.

The weighted F1 score, when measured afterwards, improved slightly for Res-14 and Res-15, while it remained the same for Res-16. In addition to that, this represents a marginal yet critical movement toward effectiveness in classification, reflecting the change in realization. In other words, this leads to another layer, hence making the model more effective in capturing base data distribution and representing that, which finally improves prediction accuracy. This documented increase is quite minor in the F1 score but crucial in noting how it may make the model's architecture important to ensure performance is optimized maximally towards the task. Now, with more fine-grained decision-making, that was due to the added feed-forward layer; it brought just a better fit of the model's predictions to the actual labels. This illustrates potential gains of deviation from the base model for general NLP problems in driving up performance. However, these modifications also come with potential disadvantages. The added layers and parameters increase the model's complexity, which introduces a risk of over-fitting, especially if the training data is not large or diverse enough to justify the increased capacity. Over-fitting can cause the model to learn patterns specific to the training data that do not generalize well to unseen data, potentially undermining the benefits of the added complexity (Aliferis and Simon, 2024).

To address the potential over-fitting introduced by adding an extra linear layer and ReLU activation to our model, we explored various regularization techniques. Realizing that the enhanced model complexity led to over-fitting, we resorted to having L2 (ridge) regularization in the classifier of the model (Ying, 2019). This is a method by which large values of weights are penalized so that the model generalizes better to unseen data and does not become very adapted to any specific parameters. n addition to L2 regularization, we also experimented with adjusting the dropout rate to further mitigate over-fitting. So we validated for dropout rates between 0.1 and 0.5, and in the process for the range, there wasn't much significance in changing the accuracy with no re-training. Based on these observations, we selected a dropout rate of 0.3 as a balanced choice for future use. This rate is intended to provide sufficient regularization without overly compromising the model's ability to learn from the training data.

On the other hand, it is also necessary to recognize the threats related to high dropout. Although dropout contributes to model regularization, too much dropout leads to under-fitting: the model poorly learns because the random exclusion of information is too much during the training procedure. This type of situation may marginally impede the ability of the model to fit the training data properly, primarily if the dataset does not possess enough size or diversity. In the process, our strategy for mitigating over-fitting included the implementation of L2 regularization in concert with careful tuning of the dropout rate. These modifications will create a balance between the improvement of generalization and maintaining the learning capability of the model so that it is resilient for use in the future. By incorporating these regularization techniques, we aim to enhance the strength and suitability of the model for future use to ensure it performs its tasks efficiently without over-fitting on the training data.

3.2.2 Increasing the number of attention heads for ASC enhancements

For sentiment classification, we also explored the impact of varying the number of attention heads in the transformer model architecture on the effectiveness of the classification. Attention heads are a crucial component of the multi-head self-attention mechanism in transformer models. Each attention head operates as an independent set of attention mechanisms that learn to focus on different parts or aspects of the input sequence simultaneously. This allows the model to capture diverse patterns and relationships in the data, which are essential for tasks like sentiment classification where multiple contextual cues contribute to the final classification. The number of attention heads determines how many separate attention distributions the model can learn in parallel. Increasing the number of attention heads allows the model to capture more complex patterns and dependencies in the dataset, as each head can focus on different elements of the input sequence (Nguyen et al., 2022).

3.2.3 Improvements done for the aspect term extraction model

In our study related to the aspect term extraction task, we used the same set of architectural changes and a set of regularization methods as described in the previous section for the transformer model-`InstructABSA`, but with pre-trained weights with-

out fine-tuning. In any case, a similar observation was that none of the changes resulted in substantial improvements in the weighted F1 score of the development set for aspect term extraction.

The far less varied F1 score values suggest that the aspect term extraction task may be more sensitive to model architecture and applied regularization techniques than sentiment classification. Moreover, it does not show further improvements in performances due to these modifications, which might indicate that the intrinsic characteristics of aspect term extraction benefited less from the applied changes than what was the case for sentiment analysis tasks. This is likely because of the specialty of the aspect term extraction task itself, which may rely far more on the other dimensions of model performance, or require much more architectural change and regularization than afforded by the experiments.

3.2.4 Integrating the combined model

In the final stage, the enhanced `DeBERTa-V3-baseabsa-V1` ASC model, in which modifications were introduced such as adding a linear layer with ReLU activation with regularization methods and changing attention heads, was combined with the `InstructABSA` ATE model to make the improved version of the combined hybrid model, `Instruct-DeBERTa`. This was supposed to integrate both models' benefits and, as such, integrate their capabilities into one package for comprehensive aspect-based sentiment analysis.

4 Results

Following few key changes to the model, such as, adding an extra linear layer, ReLU, applying regularization methods, and tuning attention head settings, we observed improvements on multiple datasets. These changes were for enhancing the capability of the model to learn complex patterns while retaining its generalization power on previously unseen data. In the following sections, we present a thorough discussion of weighted F1 scores discussing various gains witnessed for the datasets, Res-14, Res-15, and Res-16.

4.1 For integrated aspect categorization

To provide more understanding of the relationships between aspect terms and their categories, we visualized the embeddings using t-SNE for dimensionality reduction and Voronoi diagrams. t-SNE (t-Distributed Stochastic Neighbor Embedding) is a non-linear dimensionality reduction technique that projects high-dimensional data into a 2D or 3D space while preserving the local structure of the data. The embeddings of the aspect terms and categories were reduced from their original high-dimensional space of 768 dimensions to 2D for visualization purposes.

The below cost function is optimized according to the t-SNE algorithm, the function measures the divergence between the probability distributions of the pairwise similarities in the original and target-dimensional spaces:

$$C = \sum_i \sum_j P_{ij} \log \frac{P_{ij}}{Q_{ij}} \tag{4}$$

Where:

- P_{ij} is the joint probability that points i and j are neighbors in the high-dimensional space.
- Q_{ij} is the joint probability in the low-dimensional space.

By minimizing this cost function, t-SNE ensures that similar points in the high-dimensional space remain close in the 2D projection. The 2D embeddings of the categories and aspects were then used to generate a Voronoi diagram. A Voronoi diagram partitions the space into regions based on the distance to a set of pre-defined points, known as Voronoi sites.

Mathematically, the Voronoi region V_i associated with a category i is defined as:

$$V_i = \{\mathbf{x} \in \mathbf{R}^2 \mid \|\mathbf{x} - \mathbf{e}_i\| \leq \|\mathbf{x} - \mathbf{e}_j\| \text{ for all } j \neq i\} \tag{5}$$

Where:

- $\mathbf{e}_i$ is the 2D embedding of category i.
- $\|\mathbf{x} - \mathbf{e}_i\|$ is the Euclidean distance between any point $\mathbf{x}$ and the embedding $\mathbf{e}_i$.

The Voronoi diagram as in Figure 2 provides a clear visualization of how each aspect term (projected into the same 2D space) relates to the predefined categories. The regions help in understanding which categories dominate specific areas of the embedding space, and how close or distant different aspects are from each other and their respective categories.

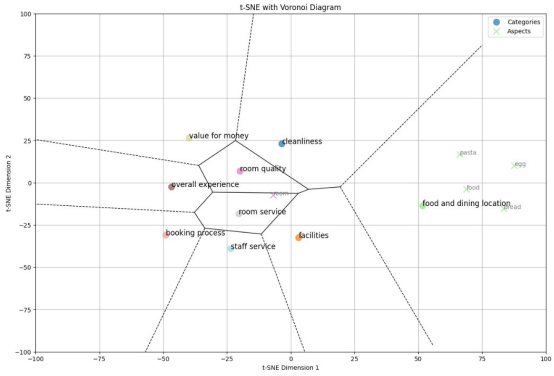

Figure 2: Voronoi diagram to visualize the aspect categories

Under category separation, we mainly focused on the hospitality domain. The pre-defined categories that we used here were cleanliness, facilities, food and dining, booking process, overall experience, room quality, room service, value for money and staff service. We then manually checked the accuracy of the category separation for 100 reviews which were publicly available in the internet, in which we obtained an accuracy of 85%. In the future, we hope to build our own data set for category separation to formally observe the accuracy levels.

4.2 Results after architectural improvements for Instruct-DeBERTa

This section highlights the enhancements in weighted F1 resulting from the changes discussed in the methodology section. The modifications are carefully tested to ascertain their impact on model performance with respect to ABSA in the hospitality industry. A comparison of F1 scores between the enhanced and standard models clearly underlines the efficiency of the revised methodology. The upgraded model gave better overall performance proving that its performance enhancement was prominent, and thus the precision and generalization capability are significantly higher.

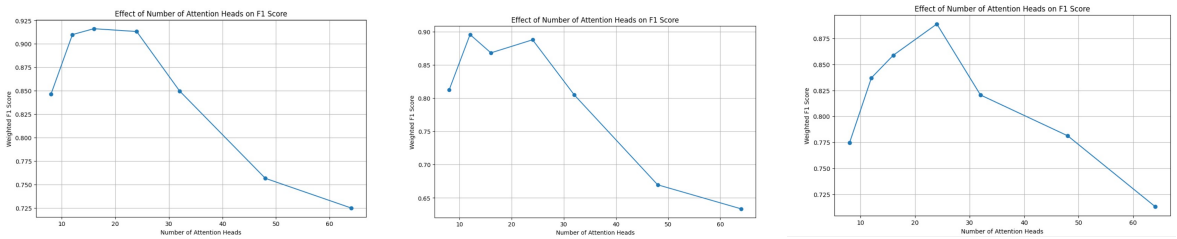
4.2.1 After adding a linear layer with ReLU and regularization

Initially, the weighted F1 scores achieved for Res-14, Res-15, and Res-16 were 90.94%, 89.55%, and 83.71% respectively as in Table 1. After adding an extra linear layer followed by a ReLU activation function after the first linear layer in the classifier, it was observed that the F1 scores for Res-14 and Res-15 improved to 90.99% and 89.56% respectively while the F1 score for Res-16 remained the same. Changing the dropout rates and applying L2 regularization for the classifier did not result any change in the F1 scores but they were added to the model to overcome over-fitting as discussed in the methodology section.

4.2.2 After Increasing the number of attention heads

We tested the model with various numbers of attention heads, starting from 8, 12, 16, 24, 32, 48, and 64 heads, respectively. The default value was 12 attention heads, which aligns with the model's hidden state size of 768. In transformer models, the number of attention heads must be a divisor of the hidden size to ensure that each head receives an equal portion of the hidden representation. This is why divisors of 768 were chosen for the experiment—ensuring that the hidden state size could be evenly split across the attention heads without causing errors during processing. The F1 scores were calculated by varying the number of attention heads for all three data sets as in Figure 3.

For Res-14, the resulting weighted F1 scores were 0.8462, 0.9099, 0.9162, 0.9131, 0.8497, 0.7565, and 0.7249 for attention heads 8, 12, 16, 24, 32, 48, and 64 respectively. These results indicate that increasing the number of attention heads initially enhances the model's ability to learn and generalize by capturing a wide range of attention patterns. Specifically, with 12,16, and 24 attention heads, the model achieved the highest F1 scores of 0.9099, 0.9162, and 0.9131 respectively. This suggests that at these levels, the model achieves an optimal balance, providing enough parallel attention distributions to capture complex data dependencies without overwhelming its learning capacity. However, as the number of attention heads increased above 16, the performance began to decline. The F1 scores dropped significantly as the attention heads were increased to 32, 48, and 64. The reason for the decline is due to the over-parameterization of the model. As the attention heads increase, the model will begin to overfit for the training data and lose its ability to generalize for unseen data (Voita et al., 2019). Additionally, when the model is made complex with too many attention heads, each head may receive fewer computational resources, leading to weaker attention distributions and less effective learning (Michel et al., 2019). Our findings indicated that for the ASC task of Res-14, 16 attention heads provided the best performance, resulting in the highest F1 score of 0.9162. This was achieved by using the same pre-trained weights ini-



(a) Res-14 (b) Res-15 (c) Res-16

Figure 3: Variation in F1 score with an increase in the number of attention heads

tially trained with 12 attention heads, demonstrating that careful tuning of the model architecture can lead to significant performance improvements without the need for extensive retraining. In addition to that for the Res-16 data set the same phenomenon was observed, where unlike in Res-14 the peak F1 score was achieved at 24 attention heads while for Res-15 the peak was observed at the default 12 attention heads. To balance these variations and optimize performance across different datasets, we selected the mid-value of 16 attention heads for our final model.

4.2.3 Joint task F1 scores for improved Instruct-DeBERTa

The performance of the integrated model was quantified for F1 scores on the joint task, hence bearing insights into important perspectives about the improvement in overall performance achieved by such integration. Here joint Task F1 Scores refers to the performance metric calculated for the entire pair of aspect and sentiment as a combined task, rather than evaluating them separately. In this context, the model's performance is assessed based on its ability to correctly identify both the aspect term and its corresponding sentiment in a sentence. This means that the F1 score reflects the model's accuracy for not just extracting the correct aspect but also assigning the correct sentiment to the respective aspect. As in Table 1 for the single task of the combined model, F1 score values remained the same across the three data sets for the ATE task since no architectural changes were made. However, the ASC F1 Scores increased for Res-14 and Res-16 significantly with the changes. The ASC F1 value remains the same for Res-15 since it peaks at 12 attention heads and we have used 16 to suit all the data sets as a whole. Furthermore, as observed in Table 1 the joint task F1 score for Res-14 also improved by 1.14%. The joint task F1 scores were not previously calculated for the other two data sets, hence we calculated them and included in Table 1. In addition to those, we checked the F1 score for the Lap-14 dataset as well. It also improved from 80.94% (Jayakody et al., 2024b) to 80.97%. The improved version shows promising results across multiple domains, demonstrating that it works well for other domains too. However, the model can be further customized to optimize its performance when the domain changes, allowing for better adaptation and fine-tuning to specific domain characteristics.

5 Conclusion

In this work, we aimed at improving the `Instruct-DeBERTa` model by focusing its base models individually. The improvements added were a linear layer followed by ReLU activation, incorporation of regularization, optimization of attention heads, and adding an aspect category extraction capability. Importantly, this was done without retraining the model; thus, it demonstrates our approach toward enhancing the model's performance without losing those strengths it previously demonstrated. These strategic adjustments indeed caused significant enhancement in the weighted F1 scores across the datasets, especially in the hospitality domain. The model was further augmented by incorporating the function of aspect category extraction that allowed the model to go beyond just the identification of aspects and sentiments but instead classify aspects effectively. Improvement within the `Instruct-DeBERTa` hybrid model concretizes a path toward realizing significant accuracy gain on domain-specific sentiment analysis applications. Further optimizations can be explored in future studies and this method can be applied to other domains for the expansion of applicability and effectiveness as well.

Abstract

This paper introduces a novel hybrid neural-rule based architecture for Filipino stemming, combining a comprehensive rule-based stemmer with fine-tuned BERT variants. We systematically compare untrained models, rule-based models, and fine-tuned BERT models, demonstrating significant performance improvements with our hybrid approach. The RoBERTa Tagalog variant achieves 98.61% Exact Accuracy and 98.23% F1-score, outperforming both untrained and purely rule-based methods. Our findings suggest that integrating domain-specific linguistic rules with neural networks is essential for effective NLP in morphologically complex, low-resource languages like Filipino, offering a framework adaptable to similar languages.

1 Introduction

Filipino, the national language of the Philippines, is derived from Tagalog and belongs to the Austronesian language family. It shares linguistic features with other languages in Southeast Asia and the Pacific, characterized by its rich morphological structure, including a complex system of affixation, reduplication, and the use of clitics (Blust, 2009; Rubino, 2002; Roxas et al., 2009). These linguistic characteristics, while offering expressive versatility, present unique challenges for natural language processing (NLP) tasks such as stemming, lemmatization, and morphological analysis (Katamba, 1993; Yambao, 2021; Roxas and Mula, 2008).

Filipino's agglutinative grammar employs a complex system of affixes (prefixes, infixes, suffixes, and circumfixes) to express grammatical functions like tense, aspect, and voice (Blake, 1917; Cheng and See, 2006; Roxas et al., 2009). For instance, the verb root *bili* (to buy) transforms into *bumili* (bought), *binili* (was bought), *bibili* (will buy), and *pinagbibili* (being sold), demonstrating how a single root can generate multiple forms with distinct grammatical implications that challenge computational processing (Roxas and Mula, 2008).

Reduplication is another prominent feature of Filipino morphology, involving the repetition of a whole or partial root to convey grammatical functions such as plurality, intensity, or reciprocity (Blake, 1917; Roxas et al., 2009). For example, the root *takbo* (run) may become *tatakbo* (will run), indicating future tense, or *takbo-takbo* (running around), indicating repetitive action. The ability to accurately parse and handle reduplication is essential for any effective stemming or lemmatization algorithm in Filipino (Roxas and Mula, 2008).

Furthermore, Filipino extensively uses clitics—unstressed particles that attach to a preceding word to convey syntactic or phonological nuances (Bloomfield, 1917; Roxas et al., 2009). Common clitics include *ng* (of), *na* (already), and *pa* (still), which often need careful handling during preprocessing to ensure accurate linguistic analysis. The complex interplay of clitics, affixation, and reduplication makes Filipino a challenging language for NLP systems developed primarily for languages like English, which have comparatively simpler morphological structures (Roxas et al., 2009).

While recent NLP advancements favor subword tokenization and end-to-end methods, morphological analysis remains indispensable for morphologically rich languages (MRLs) like Filipino, where morphological markers encode grammatical functions that influence word meaning and syntax (Tsarfaty et al., 2013; Erkaya, 2022). In contrast to languages like English, where grammatical roles are defined by word order, Filipino relies on affixation, reduplication, and compounding to convey these functions, thus enabling flexible word order and presenting unique challenges for standard NLP models (Roxas et al., 2009).

The need for explicit morphological processing is particularly evident in applications like information retrieval, where stemming improves search

relevance by matching root forms rather than exact terms (Adriani et al., 2007). For Filipino, with limited annotated data and high morphological variation, stemming becomes essential to reduce lexical sparsity and enhance performance in tasks such as document classification and sentiment analysis (Boquiren et al., 2022; Bonus, 2003).

The task of stemming—reducing words to their root form—is particularly challenging in Filipino due to its extensive use of affixes and the necessity of correctly interpreting these morphological variations (Adriani et al., 2007; McNamee and Mayfield, 2004; Roxas and Mula, 2008). Traditional rule-based approaches have historically been employed to address this challenge, leveraging handcrafted linguistic rules to strip affixes and reduce words to their base forms. However, while effective in specific cases, rule-based systems often suffer from limitations in scalability, adaptability, and the ability to generalize to unseen data (Roxas et al., 2009).

The advent of neural network-based models, particularly those utilizing the Transformer architecture (Devlin et al., 2019), has shifted the focus of NLP towards data-driven approaches. Despite their success in many domains, purely neural models often struggle with morphologically rich languages like Filipino, where complex linguistic rules must be implicitly learned from data (Pires et al., 2019; Lample and Conneau, 2019). Without extensive, language-specific training data, these models can underperform, highlighting the need for hybrid approaches that combine the strengths of rule-based systems with the generalization capabilities of neural networks (Gatt and Krahmer, 2018; Malmasi and Dras, 2014).

Hybrid models that integrate rule-based methodologies with neural networks offer a promising solution to the challenges posed by the morphological complexity of Filipino (Gatt and Krahmer, 2018; Malmasi and Dras, 2014; Roxas and Mula, 2008). By embedding linguistic rules within a rule-based stemmer and enhancing it with the contextual understanding provided by fine-tuned BERT models, a hybrid approach can achieve higher accuracy and robustness in stemming tasks (Yambao, 2021). This synergy leverages the precise, deterministic nature of rule-based systems with the adaptive, contextual strengths of neural models, offering a more comprehensive solution to the complexities of Filipino morphology (Roxas and Mula, 2008).

This research builds on existing hybrid approaches by proposing a novel model that combines a rule-based Filipino stemmer with fine-tuned BERT variants. These variants—Multilingual BERT, RoBERTa Tagalog, and XLM-RoBERTa—have been pre-trained on large multilingual corpora but require adaptation to effectively handle the unique morphological characteristics of Filipino (Devlin et al., 2019; Cruz and Cheng, 2022; Lample and Conneau, 2019). By fine-tuning these models on a Filipino-specific dataset and integrating them with a rule-based stemmer, this study seeks to enhance the performance of NLP tasks in Filipino, particularly stemming.

The contributions of this research are twofold. First, we provide a comprehensive evaluation of the performance of various BERT variants on Filipino word stemming, both as standalone models and within a hybrid framework. Second, we demonstrate the effectiveness of the hybrid approach in handling the morphological complexity of Filipino, offering insights that may be applicable to other morphologically rich, low-resource languages. This research not only advances the state of the art in Filipino NLP but also provides a foundation for future work in developing more sophisticated and adaptable linguistic models for diverse languages worldwide.

2 Related Works

The rise of transformer-based models such as BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019), and XLM-RoBERTa (Lample and Conneau, 2019) has significantly advanced natural language processing (NLP) tasks. These models utilize deep bidirectional transformers to capture contextual information from large corpora, achieving state-of-the-art performance in various language understanding tasks across multiple languages. However, their application in morphologically rich languages, such as Filipino, presents unique challenges due to the complexity and variability in word formation (Cruz and Cheng, 2022).

2.1 Filipino and Morphological Challenges

Filipino's morphological complexity, involving affixation, reduplication, and compounding, challenges standard NLP approaches, necessitating model adaptations for lexical variation, which presents a challenge for standard NLP models (Roxas et al., 2009). The language's rich system of affixes can complicate computational process-

ing, as traditional rule-based systems often struggle with the irregularities and extensive use of affixes in Filipino (Nelson, 2004).

Traditional approaches to Filipino morphology, such as rule-based systems, have been explored but often face limitations. For instance, an exhaustive rule-based affix extraction method for Tagalog was proposed to address issues of understemming and unstemmed errors by generating all possible word forms through a tree structure (Tolentino and Borra, 2018). Additionally, a morphological analyzer for Filipino verbs has been developed to produce affixes, infinitive forms, and tenses from conjugated verbs, highlighting the complexity of Filipino morphological analysis (Roxas and Mula, 2008). Despite these advancements, there is still a need for improved methods that can handle the nuances of Filipino word formation more effectively, particularly in capturing irregular forms and complex morphophonological alternations (Yambao, 2021).

The challenge is further compounded by the scarcity of high-quality annotated data, though recent initiatives like iTANONG-DS have begun addressing this limitation by providing comprehensive benchmark datasets (Visperas et al., 2023). Similarly, developing models that effectively handle Filipino's unique morphological features remains an active research challenge (Riego et al., 2023).

2.2 Stemming in Filipino NLP

Stemming plays a crucial role in various Filipino NLP applications, particularly in addressing the challenges posed by the language's rich morphological structure. In sentiment analysis, stemming helps identify sentiments by reducing morphologically complex emotional words to their root forms. For example, words like *masaya* (happy), *nagpapasaya* (making happy), *pinasaya* (made happy), and *kasiyahan* (happiness) are reduced to their root form 'saya', which is particularly important for social media text analysis where these morphological variations are common (Boquiren et al., 2022). This morphological reduction is crucial for improving text classification tasks by reducing lexical sparsity and consolidating semantically related word forms (Cruz and Cheng, 2022).

In information retrieval tasks, stemming improves search effectiveness by reducing feature space dimensionality and enabling better semantic matching (Tolentino and Borra, 2018). This is crucial for Filipino, where a single root word generates numerous forms through affixation, reduplication, and clitics, directly impacting precision and recall in search applications (Roxas and Mula, 2008).

Stemming in Filipino has been approached through various methodologies, primarily focusing on rule-based and template-based systems. The work by Tolentino and Borra (2018) introduced an exhaustive rule-based affix extraction method for stemming in Tagalog. This approach generates a tree structure where each node represents a word form derived from the input, addressing issues of understemming and unstemmed errors by exhaustively showing all stemming possibilities.

Another significant contribution is the morphological and template-based approach by Ong and Ballera (2023), which leverages predefined templates to handle the complex affixation in Filipino. While effective in capturing common morphological patterns, this method may struggle with exceptions and less frequent word forms. Enhancing this system with a hybrid model that incorporates statistical learning could improve its adaptability and accuracy.

The Tagalog Stemming Algorithm (TagSA) (Bonus, 2003) is another notable effort, focusing on extracting stems from Tagalog words through a series of linguistic rules. While TagSA provides a solid foundation for Tagalog stemming, its rule-based nature limits its scalability and adaptability to new linguistic data. Future improvements could involve the integration of neural network-based models to dynamically learn and update stemming rules.

2.3 Transformer Models and Morphological Languages

While transformer models like BERT and RoBERTa have been adapted for multilingual settings, their performance on morphologically rich languages is still an area of ongoing research. Studies have shown that these models tend to underperform on languages with complex morphology compared to analytic languages like English (Soulos et al., 2021). One reason for this underperformance is that these models are typically pretrained on large corpora where morphologically rich languages are underrepresented, leading to suboptimal contextual embeddings for these languages (Pires et al., 2019).

2.4 Hybrid Models in NLP

Hybrid models offer an effective solution for addressing the limitations of transformer models in handling morphological complexity, especially in morphologically rich languages. By combining the precision of rule-based systems with the contextual depth of neural networks, hybrid models achieve enhanced performance. For instance, Dwivedi et al. (2024) showed that integrating rule-based morphological analysis with neural machine translation (NMT) significantly improved translation quality for low-resource languages like Hindi, Marathi, and Bengali, effectively capturing grammatical rules alongside contextual fluency.

Similarly, Tong (2020) demonstrated that hybrid models in multilingual automatic speech recognition (ASR) outperformed purely neural approaches by better managing inflectional variations. This reinforces hybrid models' utility in low-resource settings, where data scarcity challenges data-driven models. Zhu et al. (2023) also emphasized that hybrid models excel at incorporating external knowledge sources, such as linguistic rules or knowledge bases, into neural architectures, making them more interpretable and effective for low-resource languages.

2.5 Filipino-Specific Transformer Models

A significant advancement in Filipino NLP emerged with RoBERTa-Tagalog, a specialized variant of the RoBERTa architecture pre-trained on large-scale Filipino corpora (Cruz and Cheng, 2022). This model demonstrates substantial improvements over previous transformer-based models across multiple benchmarks, achieving consistent performance gains of 4-5% over baseline BERT models in tasks ranging from hate speech detection to natural language inference. These improvements suggest enhanced capability in capturing Filipino's linguistic nuances and contextual relationships.

3 Methodology

3.1 Rule-Based Stemmer

Our rule-based stemmer draws from and extends established methodologies in Filipino linguistic studies, most notably the works of Bonus (Bonus, 2003), Roxas and Mula (Roxas and Mula, 2008), Rafael (Rafael, 2018), Tolentino and Borra (Tolentino and Borra, 2018), and Ong and Ballera (Ong and Ballera, 2023). These foundational studies offer robust strategies for managing affixation, infixation, circumfixation, reduplication, and morphophonemic variations, all of which are essential in accurately processing Filipino words.

3.1.1 Influences from Existing Literature

Inspired by the aforementioned works, our rule-based stemmer systematically addresses the following Filipino morphological phenomena:

- **Prefixes**: The handling of common prefixes such as *mag-*, *pag-*, and *ka-* is influenced by the strategies proposed by Bonus (Bonus, 2003), who emphasized the importance of recognizing morphophonemic changes that these prefixes can induce in root words.
- **Infixes**: Building on the framework of TagSA, our stemmer identifies and removes infixes like *-um-*, *-in-*, ensuring their correct interpretation within the context of the word (Bonus, 2003).
- **Suffixes**: The rules for removing suffixes such as *-an*, *-in*, and their allomorphic variants are guided by Tolentino and Borra's methods (Tolentino and Borra, 2018), enabling precise suffix removal without altering the meaning of the root word.
- **Circumfixes**: A layered approach to circumfixes (e.g., *ka-...-an*, *pag-...-an*) is adopted, ensuring simultaneous consideration of both prefix and suffix components, as discussed by Rafael in the context of Tagalog morphology (Rafael, 2018).
- **Reduplication**: Our stemmer adeptly handles both partial and full reduplication, a crucial feature in Filipino morphology, by applying the comprehensive analysis techniques described by Tolentino and Borra (Tolentino and Borra, 2018).

The rule-based stemmer applies these processes systematically, as illustrated in Algorithm 1, ensuring a high degree of accuracy in handling the morphological complexity of the Filipino language.

3.2 Neural Component: HybridBERTStemmer

The HybridBERTStemmer, our proposed neural component, integrates the rule-based stemmer with

Algorithm 1 Rule-Based Filipino Stemmer

Require: word
Ensure: stem
stem ← remove_particles(word)
stem ← remove_reduplication(stem)
stem ← remove_circumfix(stem)
while stem changes **do**
    stem ← remove_prefix(stem)
    stem ← remove_infix(stem)
    stem ← remove_suffix(stem)
end while
if stem ∈ valid_words **then return** stem
elsereturn word
end if

a fine-tuned BERT model, creating a hybrid architecture that benefits from both linguistic rules and deep learning. This approach is grounded in recent advancements in Natural Language Processing (NLP) that demonstrate the effectiveness of combining rule-based systems with neural networks to enhance performance on complex linguistic tasks (Yambao, 2021).

3.2.1 Model Architecture

The HybridBERTStemmer architecture is designed to combine the strengths of both the rule-based and neural approaches. The architecture utilizes BERT to generate contextual embeddings for both the original word and its rule-based stem. These embeddings are then combined and passed through a classification layer to predict the most likely stem. The architecture is formally described as follows:

$$\begin{aligned} H_w &= \text{BERT}(w) \\ H_r &= \text{BERT}(r) \\ H_c &= \frac{H_w + H_r}{2} \\ y &= \text{softmax}(W H_c + b) \end{aligned} \tag{1}$$

Here, w represents the input word, r is the rule-based stem, H_w and H_r are the hidden representations from BERT, and H_c is the combined representation. The output y is a probability distribution over the possible stems.

3.3 Data and Preprocessing

The dataset used in this research comprises 16,055 Filipino words paired with their corresponding stems, sourced from the *Komisyon sa Wikang Filipino (KWF) Diksiyonaryong Filipino* (Komisyon sa Wikang Filipino, 2021). This dataset is invaluable due to its comprehensiveness and its authoritative status as a linguistic resource in the Philippines. The KWF, as the official linguistic body of the country, ensures that the dictionary encapsulates a broad spectrum of lexical variations, regional dialects, and complex morphological structures (Lee, 2010). This makes it an ideal resource for developing and rigorously evaluating stemming algorithms in Filipino.

To ensure a balanced representation of different morphological patterns, the dataset was stratified into training (70%), validation (15%), and test (15%) sets.

3.4 Training Procedure and Optimization

The training of the HybridBERTStemmer involved fine-tuning three BERT variants—BERT Multilingual, RoBERTa Tagalog, and XLM-RoBERTa—with specific optimizations to balance computational efficiency and model performance. Our implementation incorporated several key technical components:

3.4.1 Model Configuration

- **Optimizer**: AdamW with a learning rate of (2×10^{-5})
- **Batch Size**: 32, with gradient accumulation for memory efficiency
- **Epochs**: Maximum of 10, with early stopping based on validation loss
- **Loss Function**: Cross-entropy loss with mixed-precision optimization
- **Hardware**: NVIDIA L4 GPU (22.5 GB memory) with 53 GB system RAM

3.4.2 Optimization Techniques

We implemented several optimization strategies to enhance training efficiency while maintaining model accuracy and ensuring practical deployability of the system:

Mixed-Precision Training. We employed FP16 arithmetic for computation while maintaining FP32 for weight updates, reducing memory usage and training time by up to 3x while preserving numerical stability (Micikevicius et al., 2018). This dual-precision approach enabled efficient resource utilization without compromising model performance.

Gradient Accumulation. To simulate larger batch sizes while managing memory constraints, we implemented gradient accumulation (Ott et al., 2018). This technique accumulated gradients over multiple forward and backward passes, enabling effective training with larger effective batch sizes without exceeding hardware limitations.

Dynamic Learning Rate. We employed an adaptive learning rate schedule with warmup steps as described in the original transformer architecture (Vaswani et al., 2017), complemented by early stopping based on validation loss to prevent overfitting (Prechelt, 1998). Additionally, we used dynamic batching to handle variable-length inputs more efficiently.

3.4.3 Evaluation Metrics

To assess the performance of our hybrid model across various dimensions of Filipino morphological analysis, we employed a multifaceted evaluation framework. This framework encompasses both standard metrics and specialized measures tailored to the unique challenges of agglutinative languages.

Our primary metric, Exact Accuracy (A_e), quantifies the model's precision in stem generation:

$$A_e = \frac{\text{Correct Stems}}{\text{Total Predictions}} \tag{2}$$

To capture the nuanced performance in a multiclass setting, we utilized the following metrics:

- **Precision** (P): Measures the model's ability to avoid false positives, crucial for maintaining linguistic fidelity:

$$P = \frac{\text{True Positives}}{\text{True Positives} + \text{False Positives}} \tag{3}$$

- **Recall** (R): Evaluates the model's capacity to identify all correct stems, essential for comprehensive morphological coverage:

$$R = \frac{\text{True Positives}}{\text{True Positives} + \text{False Negatives}} \tag{4}$$

- **F1-score** (F_1): Provides a balanced measure of precision and recall, particularly valuable for imbalanced datasets common in morphologically rich languages:

$$F_1 = 2 \cdot \frac{P \cdot R}{P + R} \tag{5}$$

To account for the diverse morphological patterns in Filipino, we employed two variants of the F1-score:

- **Macro F1** (F_1^M): An unweighted mean of F1-scores across all morphological classes, providing equal emphasis to rare and common patterns:

$$F_1^M = \frac{1}{|C|} \sum_{c \in C} F_1^c \tag{6}$$

  where C is the set of all classes and F_1^c is the F1-score for class c.

- **Weighted F1** (F_1^W): Adjusts for class imbalance by weighting each class's F1-score by its support:

$$F_1^W = \frac{\sum_{c \in C} w_c F_1^c}{\sum_{c \in C} w_c} \tag{7}$$

  where w_c is the support for class c.

By analyzing these metrics in conjunction, we can assess the model's effectiveness across various linguistic phenomena, from common affixation patterns to rare morphological constructs.

3.5 Cross-Validation and Statistical Significance

To ensure the robustness and generalizability of our results, we conducted a 5-fold stratified cross-validation. This method involves dividing the dataset into five subsets, each serving as a test set once while the remaining four subsets are used for training. This approach helps mitigate the risk of overfitting and provides a more reliable estimate of model performance across different splits of the data (Arlot and Celisse, 2010; Kohavi, 1995).

Additionally, we employed McNemar's test to evaluate the statistical significance of performance differences between the BERT variants. McNemar's test is particularly well-suited for paired comparisons of models on the same dataset, allowing us to determine whether the observed differences in accuracy between models are statistically significant or likely due to chance (McNemar, 1947; Dietterich, 1998).

3.6 Model Interpretability and Error Analysis

To further understand the model's behavior, we conducted a detailed error analysis, identifying common sources of error such as overstemming and

understemming. We analyzed errors across different word lengths, affix types, and morphological complexities, using confusion matrices and other visualizations to pinpoint areas where the model struggled. This analysis provided insights into the strengths and limitations of both the rule-based and neural components, guiding further refinements of the hybrid model.

4 Results and Discussion

4.1 Model Performance

The results in Table 1 show that hybrid models outperform both untrained models and the rule-based stemmer in exact accuracy. While untrained models achieved accuracy scores between 11.11% (XLM-RoBERTa) and 11.76% (BERT Multilingual), and the rule-based stemmer reached 59.21%, the hybrid RoBERTa Tagalog attained the highest accuracy at 98.62%, a substantial improvement over both baselines. This result underscores the effectiveness of combining rule-based and neural methods for Filipino NLP.

Notably, the hybrid BERT Multilingual model performed below the rule-based baseline, highlighting the advantage of language-specific pre-training.

4.2 Computational Efficiency Across Model Variants

All models were evaluated for runtime performance covering the full inference pipeline—including input preprocessing, model inference, and postprocessing. For hybrid models, this evaluation incorporated both rule-based preprocessing and neural computation phases.

- **Hybrid BERT Multilingual:** The fastest among hybrid models, completing in 134.05s (55.67 ms/word) and achieving a 20.61% reduction in runtime compared to its untrained counterpart (168.86s).
- **Hybrid RoBERTa Tagalog:** Processed in 150.04s (62.31 ms/word), showing a 23.18% improvement over the untrained model (195.31s).
- **Hybrid XLM-RoBERTa:** Displayed the longest runtime at 230.04s (95.53 ms/word), with a slight increase of 1.36% over the untrained version (226.96s).

4.3 Statistical Significance and Ablation Study

To quantify the impact of each component in our hybrid architecture, we conducted a comprehensive ablation study and statistical significance testing using McNemar's test. The results, presented in Table 2, clearly demonstrate the necessity of integrating both rule-based and neural components.

The ablation study results show that:

1. Removing the rule-based component from the hybrid models results in a performance drop, especially for BERT Multilingual, which relies more heavily on the rule-based preprocessing.
2. The BERT-only variants further degrade in performance, emphasizing the importance of rule-based preprocessing in handling Filipino's complex morphology.
3. RoBERTa Tagalog and XLM-RoBERTa demonstrate more resilience, though their performance also benefits significantly from the hybrid approach.

4.4 Error Case Analysis

The hybrid RoBERTa Tagalog model demonstrates a trade-off in morphological processing, reducing affixation errors to 20% (compared to 45% in other models) but increasing reduplication errors to 65%, as shown in Figure 1. An in-depth error analysis, summarized in Table 3, highlights three critical challenges in Filipino morphological processing:

1. **Context-Dependent Affixation**: The high error rate in handling words like 'kinakausap' $\rightarrow$ 'kausap' demonstrates that models struggle to distinguish between core morphemes and affixes when their role is context-dependent. This suggests that purely sequential approaches to affix stripping may be insufficient for Filipino, pointing to the potential benefit of tree-structured or graph-based morphological analysis approaches.
2. **Reduplication Complexity**: The significant increase in reduplication errors in the hybrid model (65% versus 30-35% in other models) indicates that neural approaches may oversimplify reduplication patterns. Cases like 'binabasa-basa' $\rightarrow$ 'babasa' show that the model fails to recognize the semantic significance of reduplication in indicating aspect or intensity.

Table 1: Performance Metrics for BERT Variants and Rule-Based Stemmer

Model	Exact Accuracy	Precision	Recall	F1-score	Macro F1
Untrained BERT Multilingual	11.76%	85.81%	11.76%	19.80%	3.68%
Untrained RoBERTa Tagalog	11.59%	84.67%	11.59%	19.51%	3.63%
Untrained XLM-RoBERTa	11.11%	82.34%	11.11%	18.74%	3.50%
Rule-Based Stemmer	59.21%	59.21%	59.21%	59.21%	17.47%
Hybrid BERT Multilingual	56.37%	47.79%	56.37%	45.95%	1.92%
Hybrid RoBERTa Tagalog	**98.62%**	**97.65%**	**98.62%**	**98.12%**	0.57%
Hybrid XLM-RoBERTa	98.37%	97.02%	98.37%	97.68%	0.14%

Table 2: Ablation Study Results (F1-scores)

Model Variant	Full Model	No Rule-Based	BERT Only
Untrained BERT Multilingual	19.80%	-	-
Rule-Based Stemmer	59.21%	-	-
Hybrid BERT Multilingual	45.95%	43.21% (-5.9%)	39.87% (-13.3%)
Hybrid RoBERTa Tagalog	**98.12%**	**96.54% (-1.6%)**	**95.32% (-2.9%)**
Hybrid XLM-RoBERTa	97.68%	95.89% (-1.8%)	94.76% (-3.0%)

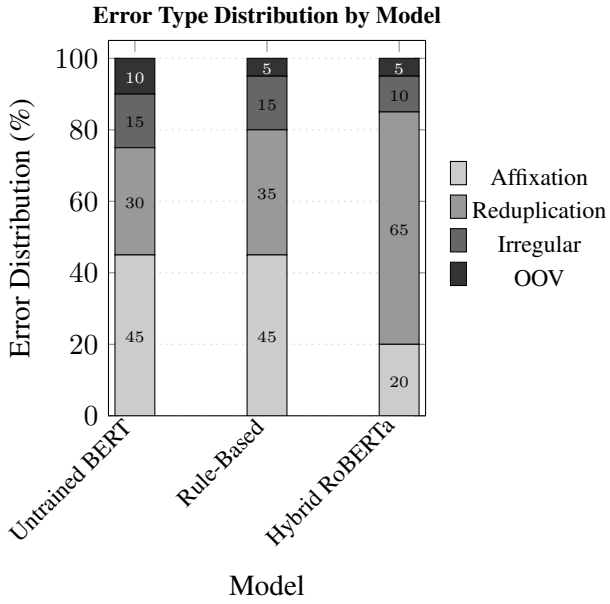

Figure 1: Comparison of error types across stemming models.

3. **Morphological Ambiguity**: Superlative forms like 'pinakamahusay' → 'mahusay' reveal a systematic failure to handle cases where multiple valid stemming options exist, depending on the intended meaning and grammatical role. This suggests the need for more sophisticated disambiguation strategies that consider broader syntactic context.

4.5 Practical Applications and Cross-Linguistic Generalizability

Our hybrid architecture demonstrates significant potential for practical applications in Filipino NLP systems, with the model achieving 98.61% accuracy on stemming tasks while maintaining reasonable processing times (ranging from 134.05s to 230.04s across different variants). This performance level makes it particularly valuable for downstream tasks such as information retrieval and text classification, where accurate morphological analysis is crucial (Tsarfaty et al., 2013). The importance of such accuracy is heightened for Filipino, where morphological complexity significantly impacts task performance (Roxas and Mula, 2008).

The success of our approach suggests broader applicability to other morphologically rich, low-resource languages through its adaptable architecture. The neural component can be extended to new languages by modifying the rule set and fine-tuning on target language data, while the modular separation of rule-based and neural components enables systematic adaptation across languages without architectural changes. Recent advances in cross-lingual transfer learning demonstrate that fine-tuning multilingual models on small language-specific datasets can significantly improve performance on previously underrepresented languages (Pires et al., 2019; Lample and Conneau, 2019).

Table 3: Representative Error Cases Across Models

Word	Correct Stem	Predicted Stem	Error Type
pinagkakaisahan	isa	kaisahan	Overly Conservative (BERT-M)
nagpapakain	kain	pakain	Partial Affixation (RB)
binabasa-basa	basa	babasa	Reduplication (RT)
kinakausap	usap	kausap	Infix Handling (BERT-M)
pinakamahusay	husay	mahusay	Superlative Form (RT)

BERT-M: Untrained Multilingual BERT, RB: Rule-Based Stemmer, RT: Hybrid RoBERTa Tagalog

This approach shows particular promise for other Austronesian languages that share morphological characteristics with Filipino, where the underlying architectural principles could be effectively leveraged to address comparable morphological challenges (Blust, 2009; Roxas et al., 2009).

5 Conclusion

This study introduces a hybrid neural-rule based architecture tailored to the morphological intricacies of the Filipino language, demonstrating the power of combining linguistic knowledge with advanced neural models. The integration of a robust rule-based stemmer with pre-trained BERT variants provides a comprehensive solution for Filipino stemming, yielding several important findings.

The RoBERTa Tagalog model emerged as the most effective, consistently outperforming both multilingual and rule-based approaches. Achieving an Exact Accuracy of 98.61% and an F1-score of 98.11%, RoBERTa Tagalog underscores the critical importance of language-specific pre-training.

The rule-based component of our architecture significantly enhanced performance, particularly in scenarios where models lacked extensive Filipino-specific pre-training. The hybrid approach consistently outperformed standalone neural models and the rule-based stemmer alone, highlighting the value of combining traditional linguistic rules with the contextual understanding provided by neural networks. This synergy is particularly evident in the model's ability to handle the rich morphological structure of the Filipino language, where complex affixation patterns and infixes challenge purely neural approaches.

Despite the overall success of the hybrid architecture, challenges remain. Reduplication continues to present difficulties, even for the high-performing models. This persistent challenge suggests the need for further refinement, potentially through specialized data augmentation strategies or more sophisticated neural architectures capable of better capturing reduplication patterns.

In addition to accuracy, the study also examined computational efficiency, revealing that RoBERTa Tagalog, while requiring moderately higher processing time (150.04s) compared to BERT Multilingual (134.05s), offers the best balance between accuracy and processing speed. This balance is crucial for practical applications, where both performance and efficiency are paramount. Statistical significance testing through McNemar's test confirms the robustness of these findings, particularly the superior performance of language-specific models over multilingual variants, reinforcing the importance of specialized architectural adaptations for morphologically rich languages.

Future research should explore advanced techniques for integrating rule-based and neural components, such as attention mechanisms or gating networks, to further enhance model performance. Targeted data augmentation could address specific challenges like reduplication, improving model robustness in handling complex morphological phenomena. Additionally, extending this hybrid architecture to other Filipino NLP tasks, such as part-of-speech tagging or named entity recognition, could demonstrate its versatility and effectiveness in various linguistic contexts.

Moreover, benchmarking this approach against emerging multilingual models and investigating transfer learning strategies across other Austronesian languages could provide further insights and broaden the applicability of this research. Such efforts would also contribute to the development of NLP tools for other low-resource languages facing similar challenges.

Abstract

Recently some studies have highlighted the potential of Large Language Models (LLMs) as effective generators of supervised training data, offering advantages such as enhanced inference efficiency and reduced costs associated with data collection. However, these studies have predominantly focused on English language tasks. In this paper, we address the fundamental research question: *Can LLMs serve as proficient training data generators for other language tasks?* Specifically, we leverage LLMs to synthesize supervised training data under few-shot and zero-shot learning scenarios across six diverse Japanese downstream tasks. Subsequently, we utilize this synthesized data to train compact models (*e.g.*, BERT). This novel methodology is termed JAPAGEN. Our experimental findings underscore that JAPAGEN achieves robust performance in classification tasks that necessitate formal text inputs, demonstrating competitive results compared to conventional LLM prompting strategies.

1 Introduction

Large language models (LLMs) have demonstrated exceptional performance across various natural language processing (NLP) tasks, even with minimal parameter updates (Brown et al., 2020; Kojima et al., 2022). However, the rapid growth in model size, driven by scaling laws (Kaplan et al., 2020), has led to substantial demands for GPU memory and computational resources, making the operation of LLMs prohibitively expensive.

To mitigate these costs, recent studies have investigated the generation of training data using powerful LLMs, followed by training smaller models (e.g., BERT) on the synthesized supervised data (Ye et al., 2022a,b; Yu et al., 2023; Chung et al., 2023a). This approach, termed SUPERGEN (Supervision Generation Approach) based on prior work (Meng et al., 2022), has demonstrated promising results. The overview of SUPERGEN is illustrated in Figure 1. SUPERGEN has been demonstrated to outperform few-shot and zero-shot prompting and few-shot fine-tuning methods in various tasks, effectively reducing both the cost of collecting supervised data and the operational costs of trained models. However, these studies have been limited to English tasks, and thus, the applicability of SUPERGEN on other language tasks remain uncertain.

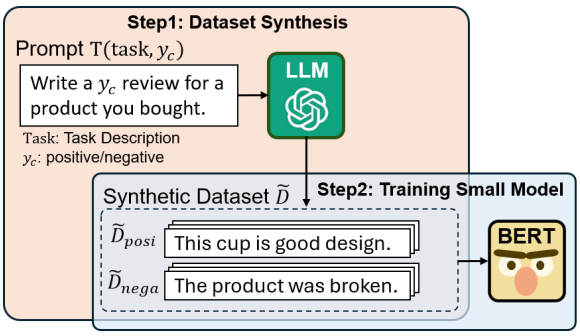

Figure 1: Overview of SUPERGEN in text sentiment classification as an example.

Given that powerful LLMs like GPT-4 (OpenAI, 2024) are primarily trained on English texts with limited exposure to other languages, it is crucial to investigate the effectiveness of SUPERGEN in such linguistic contexts and its suitability for different types of languages. In this paper, we implement SUPERGEN in Japanese as a case study. Japanese is mid-resource language compared to English and has different characteristics, such as the absence of spaces between words. Therefore, we pose the research question: *Do SuperGen methods perform effectively in Japanese?* We term the application of SUPERGEN to Japanese tasks as JAPAGEN (§3).

To address the aforementioned interests, we evaluate JAPAGEN across various Japanese tasks, in-

[*] Work done while internship at Retrieva, Inc. when I was a master student. Now I belong to Nomura Research Institute, Ltd.

cluding text classification, natural language inference, semantic textual similarity, and linguistic acceptability, in both few-shot and zero-shot learning settings. Furthermore, we propose a novel approach termed Knowledge-Assisted Data Generation (KADG)[1], which integrates task-specific knowledge into prompts to align generated texts more closely with gold-standard distributions and enhance text diversity (§3.4).

Our experiments indicate that, in five out of six tasks, zero-shot JAPAGEN outperforms few-shot BERT fine-tuning. Moreover, JAPAGEN demonstrates superior performances in two tasks compared to few-shot PROMPTING. These experimental results suggest that JAPAGEN has the potential to surpass settings with more parameters and more annotated data. Additionally, our analysis shows that KADG enhances the fidelity of generated texts to gold-standard distributions while maintaining label accuracy, although it does not consistently improve overall task performance.

In summary, our contributions are four-fold:

1. We empirically evaluate JAPAGEN, leveraging LLMs as synthetic data generators, across various Japanese NLP tasks.

2. We demonstrate the effectiveness of JAPAGEN, particularly in classification tasks with formal text inputs.

3. We analyze the impact of dataset size on JAPAGEN, observing performance improvements with larger synthetic datasets that eventually reach saturation.

4. We propose and evaluate KADG, demonstrating its potential to refine synthetic data distributions to align with gold standards, thereby enhancing the robustness of JAPAGEN.

2 Related Work

2.1 Efficient Learning Strategies with LLMs

Large Language Models (LLMs) exhibit high performance across various tasks using few-shot or zero-shot learning paradigms. Despite their capabilities, LLMs have numerous parameters, leading to substantial operational costs. To address these challenges, several methods for more efficient utilization of LLMs have been proposed. One such method is PROMPTING, which enables LLMs to perform tasks effectively without requiring parameter updates. This is achieved by injecting prompts based on task descriptions (Brown et al., 2020; Gao et al., 2021; Le Scao and Rush, 2021; Zhang et al., 2022). A prompt consists of input text for the LLM and includes instructions to obtain the desired responses. In few-shot PROMPTING[2], the prompt includes a small number of text-label pairs. Compared to traditional fine-tuning, which necessitates costly updates to the LLM's parameters, PROMPTING improves data efficiency in low-data scenarios. However, Prompting incurs substantial operational costs due to the extensive number of parameters involved.

2.2 Synthesis of Training Data via LLM

To reduce the operational costs of LLMs, researchers have recently explored using LLMs as training data generators, followed by fine-tuning smaller task-specific models (TAMs), such as BERT (Devlin et al., 2019), on the synthetic data. Existing approaches typically employ simple class-conditional prompts and focus on addressing the issues related to the quality of the generated data. Notable early efforts, such as SuperGen (Meng et al., 2022) and ZeroGen (Ye et al., 2022a), have explored the use of LLMs for generating training data for text classification tasks using basic class-conditional prompts. They have also incorporated additional noise-robust learning techniques (Laine and Aila, 2017; Wang et al., 2019) to mitigate the quality issues of the generated data. However, it has been reported that balancing the diversity of synthetic datasets with task performance remains challenging (Chung et al., 2023b).

To date, these approaches have been primarily validated on English-language tasks. This paper investigates the effectiveness of these methods in mid-resource languages with different linguistic characteristics from English.

3 Method: JAPAGEN

In this section, we introduce the motivation for synthetic data generation via LLMs in Japanese tasks, define the problem, and describe the methodology for generating synthetic training data for each task.

[1]We define the setup of KADG as zero-shot* to distinguish it from strict zero-shot methods due to the incorporation of task knowledge.

[2]Few-shot PROMPTING is referred to as In-Context Learning (Brown et al., 2020), however, in this paper, both few-shot and zero-shot PROMPTING are collectively termed as PROMPTING.

The overview of generating training data via LLMs is illustrated in Figure 1.

3.1 Motivation

We define JAPAGEN as the Japanese counterpart to SUPERGEN. The rationale behind selecting Japanese stems from its status as a mid-resource language compared to English, and its different characteristics, such as the absence of spaces between words. Given that powerful LLMs are primarily trained on English texts with limited exposure to other languages including Japanese, it is plausible that they can generate high-quality pseudo training data in English. In this paper, we evaluate JAPAGEN, the Japanese version of SUPERGEN, as a case study focusing on such languages.

3.2 Problem Definition

Given the label space $\mathcal{Y} = \{y_i\}_{i=1}^{n}$, we manually create label-descriptive prompts $\mathrm{T}(\text{task}, y_i)$. For prompt details used in our experiments, please refer to §A.4. We employ LLMs G_θ to generate training data for encoder models E_ϕ (e.g., LSTM (Hochreiter and Schmidhuber, 1997), BERT (Devlin et al., 2019)), which are subsequently fine-tuned as estimators. SUPERGEN comprises the following three stages: (1) Synthesizing supervised training data using LLM. (2) Fine-tuning small models using synthetic data. (3) Testing the trained model on gold data.

3.3 Pseudo Data Generation

In this section, we describe the process of generating pseudo datasets using an LLM for classification and regression tasks. Our approach includes either a single sentence or a sentence pair as input.

Single Sentence Task We employ an LLM to generate pseudo-supervised sentences $\tilde{x}_{c,j}$ corresponding to a label y_c:

$$\tilde{x}_{c,j} \sim \mathrm{Prob}_{\mathrm{LLM}}(\cdot|\mathrm{T}(\text{task}, y_c)), \tag{1}$$

where $\mathrm{T}(\text{task}, y_c)$ represents a prompt including the task description and label y_c. By repeating Equation 1 M times, we obtain the pseudo dataset $\tilde{D}_{y_c} = \{(\tilde{x}_{c,j}, y_c)\}_{j=1}^{M}$. Applying this process for all labels $\{y_c\}_{c=1}^{C}$, we generate the pseudo dataset $\tilde{D} = [\tilde{D}_{y_1}, \tilde{D}_{y_2}, ..., \tilde{D}_{y_C}]$.

Sentence Pair Task Initially, we employ an LLM to generate the first sentence $\tilde{x}^1_{c,j}$, analogous to Equation 1 but excluding the label y_c:

$$\tilde{x}^1_{c,j} \sim \mathrm{Prob}_{\mathrm{LLM}}(\cdot|\mathrm{T}(\text{task})). \tag{2}$$

In the initial phase of sentence generation, the prompt comprises solely the task description. Subsequently, to generate the second sentence $\tilde{x}^2_{c,j}$, the prompt is augmented to include the task description, the first sentence $\tilde{x}^1_{c,j}$, and the label y_c:

$$\tilde{x}^2_{c,j} \sim \mathrm{Prob}_{\mathrm{LLM}}(\cdot|\mathrm{T}(\text{task}), \mathrm{T}(\text{task}, \tilde{x}^1_{c,j}, y_c)). \tag{3}$$

By repeating Equations 2 and 3 M times, we generate the pseudo dataset $\tilde{D}_{y_c} = \{(\tilde{x}^1_{c,j}, \tilde{x}^2_{c,j}, y_c)\}_{j=1}^{M}$. Applying this process for all labels $\{y_c\}_{c=1}^{C}$, we obtain the pseudo dataset $\tilde{D} = [\tilde{D}_{y_1}, \tilde{D}_{y_2}, ..., \tilde{D}_{y_C}]$.

3.4 Knowledge-Assisted Data Generation

The diversity of synthetic datasets significantly enhances dataset quality, a critical factor in improving task performance (Chung et al., 2023b). Previous studies attempted to diversify text generation by adjusting hyperparameters such as Top-p and temperature. However, this approach may compromise label accuracy. In this paper, we introduce *Knowledge-Assisted Data Generation* (KADG) to enhance dataset diversity while maintaining label correctness.

For each task, we manually create a set of task-specific words S_{task}, and randomly select a word d from this set. We construct a prompt based on the task description, label y_c, and the selected task-specific word d:

$$d \sim S_{\text{task}}, \tag{4}$$

$$\tilde{x}_{c,j} \sim \mathrm{Prob}_{\mathrm{LLM}}(\cdot|\mathrm{T}(\text{task}, y_c, d)). \tag{5}$$

By following a process similar to Section 3.3 across all classes, we generate the synthetic dataset $\tilde{D}$. For the actual prompts used in our experiments, please refer to §A.4.

4 Experiment

In this section, we present an overview of the benchmark datasets, the corresponding evaluation settings, the baseline methods, and the implementation details. Subsequently, we compare our JAPAGEN to baseline methods in both few-shot and zero-shot settings.

4.1 Setup

Benchmarks. To evaluate JAPAGEN across various tasks, we used the following benchmarks

from JGLUE (Kurihara et al., 2022): MARC-ja, JSTS, JNLI, and JCoLA. Additionally, to test across diverse domains, we also used two datasets for news topic classification (News) and SNS fact classification (COVID-19). All of these benchmarks are Japanese tasks. JSTS involves sentence similarity estimation, while the others are text classification tasks. We evaluated using Spearman's rank correlation coefficient (Spearman score) for JSTS, Matthews correlation coefficient (MCC; (Matthews, 1975)) for JCoLA, and Accuracy for the remaining tasks. For more detailed information such as dataset statistics and task explanations, please refer to Section A.1.

Baselines. We compared the performances of JAPAGEN with three baselines: (1) PROMPTING, a prompt-based learning framework via LLM, as introduced in Section 2.1. (2) FEW-SHOT FINE-TUNING, where BERT is fine-tuned on five gold samples per class. (3) FULLY SUPERVISED, where BERT is fine-tuned on all gold data. We evaluated the performances of JAPAGEN and PROMPTING in both few- and zero-shot settings. In the few-shot setting, we used one sample per class and incorporated them into the prompt. To distinguish between the few-shot setting of BERT fine-tuning and the one of JAPAGEN and PROMPTING, we refer to the former as "few-shot Ⓑ" and the latter as "few-shot Ⓛ".

Implementation Details. We conducted our experiments using PyTorch (Paszke et al., 2019) and Hugging Face Transformers (Wolf et al., 2020). For synthetic data generation, we utilized the OpenAI model `gpt-3.5-turbo-0613`[3]. The size of the generated data was 25,000 per class. In the few-shot setting Ⓑ, one sample per class was randomly selected. The generation parameters were set to max tokens of 500, top-p of 1.0, temperature of 1.2, and frequency penalty of 0.02, with five pieces of data generated at a time. In JSTS whose labels are continuous values between 0.0 and 5.0, we set six classes {0, 1, 2, 3, 4, 5}. For the fine-tuning of BERT, we used the pretrained BERT[4] and performed our experiments on a single NVIDIA TITAN RTX 24GB GPU. The training parameters[5] were set to batch size of 32, epoch of 4, label smooth temperature of 0.1, optimizer of AdamW with learning rate of 5e-5, β_1 of 0.9, β_2 of 0.999, warmup ratio of 0.1. Additionally, we set max token length of 512, 512, 512, 128, 512, 384 for MARC-ja, JNLI, JSTS, JCoLA, News, and COVID-19 respectively. For each task, we measured performances over five runs with different random seeds. In the few-shot setting Ⓛ, we randomly selected five samples per class.

[3]The generated texts are used solely for study purposes, not for commercial use.

[4]`tohoku-nlp/bert-base-japanese-v3`

[5]We set training parameters based on (Kurihara et al., 2022).

4.2 Experimental Results

In this section, we compare JAPAGEN to baselines. Our experimental results are shown in Table 1.

Zero-shot JAPAGEN vs. FINE-TUNING

Compared to zero-shot JAPAGEN, BERT fine-tuned on gold data uses the same model size but with a larger amount of annotated data. It is well-known that the zero-shot approach cannot outperform task-specific models trained on human-annotated data. In Table 1, JAPAGEN adheres to this rule, underperforming compared to fully supervised fine-tuning across all tasks. However, JAPAGEN outperforms few-shot fine-tuning on five tasks except for COVID-19. Notably in JSTS, JAPAGEN achieves a Spearman score of 57.67%, exceeding the performance of few-shot Ⓑ fine-tuning. This result suggests that JAPAGEN can be effective in scenarios where the cost of data collection or annotation is high.

Zero-shot JAPAGEN vs. PROMPTING

Compared to zero-shot JAPAGEN, PROMPTING employs a significantly larger model size. In Table 1, JAPAGEN achieves performance improvements of 3.94%, 4.96%, and 17.10% over zero-shot PROMPTING on JSTS, JNLI, and News, respectively. These tasks typically involve formal text as input. Moreover, JAPAGEN also surpasses few-shot Ⓛ PROMPTING on JNLI and News, suggesting that JAPAGEN has the potential to outperform settings with more parameters and more annotated data. These tasks are commonly classification tasks that involve formal text as input.

KADG and JAPAGEN

We attempt to enhance the performance of JAPAGEN by injecting task knowledge into prompts, as prompt engineering has been shown to enhance the capability of LLMs and improve the quality of generated text (Wu and Hu, 2023; Yang et al., 2023; He et al., 2022). In Table 1, KADG outperforms

Method	MARC-ja Acc.	JSTS Spearman	JNLI Acc.	JCoLA Mcc.	News Acc.	COVID-19 Acc.	Avg.
FINE-TUNING: *fine-tuning pretrained BERT under gold data.*							
Fully Supervised	95.78±0.1	87.47±0.5	90.19±0.4	40.62±1.2	95.75±0.4	78.49±0.3	82.82
Few-Shot	61.57±8.5	14.80±11.3	37.72±13.4	-0.85±3.5	51.98±5.3	42.24±9.4	37.40
PROMPTING: *prompt-based LLM learning.*							
Zero-Shot	94.82±0.2	68.53±0.6	41.53±1.0	24.76±1.2	40.27±1.3	62.76±0.6	57.66
Few-Shot	97.38±0.2	78.50±2.0	35.86±5.3	26.00±2.9	44.82±2.9	65.44±3.4	61.72
JAPAGEN: *fine-tuning pretrained BERT under pseudo training data generated via LLM.*							
Zero-Shot	77.76±5.4	**72.47**±0.1	**46.49**±1.5	18.17±1.7	**57.37**±2.1	34.36±6.4	54.23
w/ KADG	83.24±6.0	**71.49**±1.2	**46.04**±0.4	16.22±0.5	**59.00**±1.4	26.29±0.8	50.38
Few-Shot	62.97±7.3	**72.56**±0.3	**50.82**±0.8	14.54±1.1	**62.86**±2.8	43.13±1.5	51.15

Table 1: Results on six Japanese tasks. Each value is average with standard deviations over five runs. The tasks that JAPAGEN outperforms zero-shot PROMPTING are in **gray**. Zero-shot JAPAGEN outperforms zero-shot PROMPTING on JSTS, JNLI, ad News. Few-shot (Only one sample per class) JAPAGEN can improve performances on JNLI and News.

zero-shotJAPAGEN only on MARC-ja and News, but does not improve performance on the other four tasks. Specifically, KADG achieves a 5.48% higher score than JAPAGEN on MARC-ja. This suggests that prompt engineering may be particularly effective for specific tasks. In JAPAGEN, the few-shot Ⓛ setting consistently outperforms the zero-shot setting on JSTS, JNLI, News, and COVID-19. Notably, the few-shot setting achieves improvements of 4.33%, 5.49%, and 8.77% over the zero-shot settings on JNLI, News, and COVID-19, respectively. Injecting task knowledge into prompts or using few-shot samples can bring generated texts closer to gold-standard texts, but it may restrict the diversity of the synthetic dataset. A detailed analysis is provided in §4.3.

4.3 Additional Analysis

In this section, we analyze JAPAGEN on distribution, diversity, and label correctness of synthetic and gold datasets. Then, we qualitatively evaluate synthetic data for each task.

Distribution. One of the critical factors influencing task performance is the alignment between the distributions of gold data and synthetic data. To observe this alignment, we compare token appearances within their respective datasets in a simple manner. Figure 2 represents the distribution of token frequencies within the dataset. We also quantitatively assess the alignment using the weighted Jaccard index, based on 1,000 samples per class for distribution analysis. In the top and middle sections of Figure 2, KADG achieves a higher Jaccard index compared to zero-shot JAPAGEN for MARC-ja, JSTS, JNLI, and News. Conversely, in the top and bottom sections of Figure 2, few-shot JAPAGEN outperforms zero-shot JAPAGEN regarding the Jaccard index for JSTS, JNLI, and News. Qualitatively, we observe a decrease in the number of words appearing only in the synthetic dataset, the blue-only part in Figure 2, with KADG and the few-shot setting. These results suggest that designing effective prompts and incorporating a few real samples can help bring the synthetic data distribution closer to that of the gold standard.

Diversity & Label Correctness. Synthetic datasets often exhibit limited diversity because they are generated using the same prompt input into the LLM. To assess dataset diversity, we adopt the methodology of a previous study (Holtzman et al., 2020) and use the Self-BLEU metric (Zhu et al., 2018) to compare the diversity of synthetic and gold datasets. A lower Self-BLEU score indicates higher dataset diversity. Previous studies have highlighted a trade-off between dataset diversity and label correctness (Chung et al., 2023b; Ye et al., 2022a). Consequently, we also evaluate label correctness in the synthetic dataset. To do so, we first train BERT on the gold training dataset and then measure accuracy[6] on the synthetic dataset. Table 2 presents the diversity and label correctness analysis for each task.

[6]In JSTS, Mean Squared Error (MSE) is used for measurement.

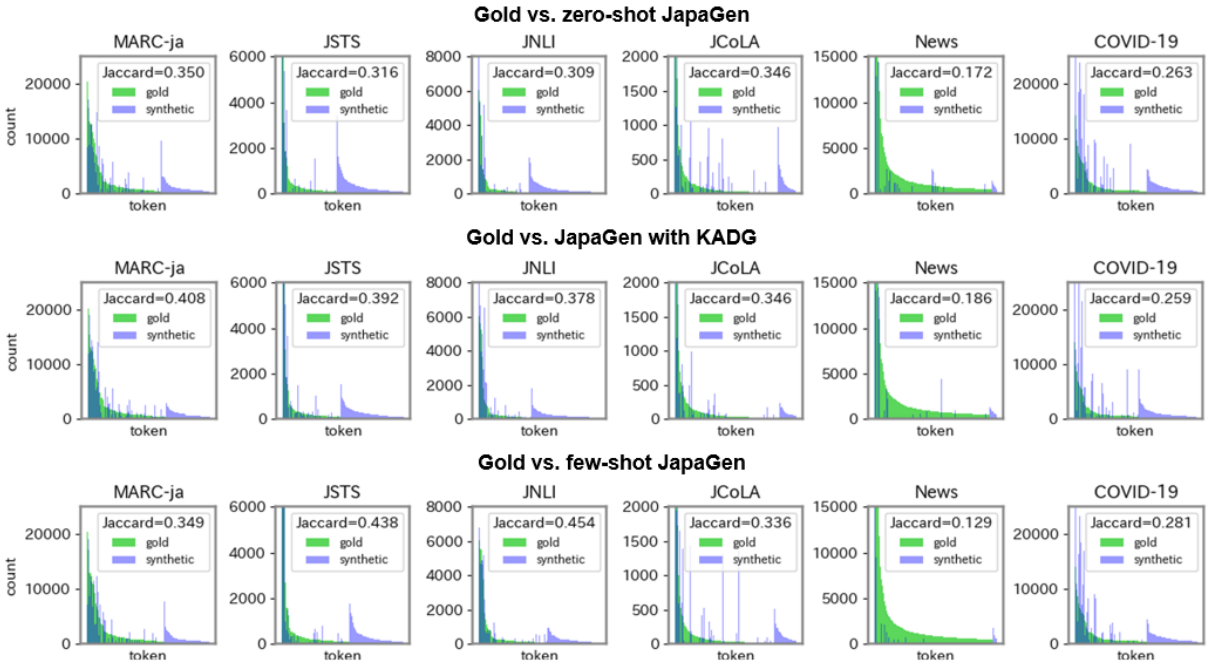

Figure 2: Distribution of the number of appeared tokens between gold and synthetic dataset. Top: zero-shot JAPAGEN, Middle: JAPAGEN with KADG, and Bottom: few-shot JAPAGEN. Compared to zero-shot JAPAGEN, KADG can improve alignment between gold and synthetic dataset on MARC-ja, JSTS, JNLI, and News. Few-shot JAPAGEN can also improve alignment on JSTS, JNLI, and COVID-19.

Dataset	MAR.	JSTS*	JNLI	JCoLA
DIVERSITY (%)				
Gold	40.53	72.93	72.94	56.66
Zero-shot	91.67	74.89	69.97	65.80
w/ KADG	84.97	76.12	73.13	78.91
Few-shot	90.25	81.80	78.28	67.15
LABEL CORRECTNESS (%)				
Gold	99.06	0.137	98.01	96.28
Zero-shot	99.97	1.540	35.11	66.34
w/ KADG	99.96	1.540	39.37	63.94
Few-shot	99.90	1.094	50.16	63.33

Table 2: Diversity and label correctness of synthetic dataset. We measure the diversity by Self-BLEU. *In JSTS, label correctness is measured by MSE.

As shown in the upper part of Table 2, the Self-BLEU score of the synthetic dataset of zero-shot JAPAGEN is approximately twice as high, indicating less diversity compared to the gold dataset in MARC-ja. However, zero-shot JAPAGEN can synthesize datasets with a diversity similar to the gold dataset in JSTS, JNLI, and JCoLA. In contrast, in the lower part of Table 2, the label correctness in JSTS, JNLI, and JCoLA is not as high as in the gold dataset. Despite reports suggesting that decreasing the Self-BLEU score reduces label accuracy and degrades downstream task performance (Ye et al., 2022a), in MARC-ja, KADG improves the Self-BLEU score without compromising label correctness and enhances downstream performance. The few-shot setting yielded results similar to zero-shot JapaGen in diversity, but improvements in label correctness were observed in the two tasks, JSTS and JNLI.

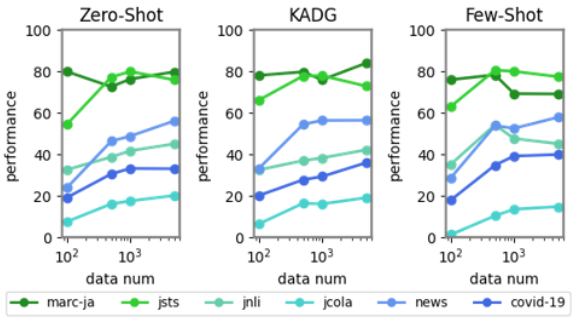

Figure 3: Performance transition with synthetic dataset size on zero-shot, KADG, and few-shot settings.

Data Scaling. We analyze the performance scaling with respect to data size. Figure 3 demonstrates that for most tasks, performance improves as the data size increases. However, performance tends to plateau, as the results with 5,000 samples are similar to those with 50,000 samples.

Task	Synthesized Text	Label
MARC-ja	この商品は思っていた以上に素晴らしかったです！購入して本当に良かったです。... (This product was even more nice than I expected! I'm really glad I bought it. ...) 商品は非常に不満でした。品質が悪い上に、配送にも遅延がありました。使ってみると... (I was extremely dissatisfied with the product. In addition to poor quality, there were delays in delivery. ...)	Positive Negative
JSTS	子供たちが講演で楽しそうに遊んでいます。 (The children are having fun playing in the park.) 講演で遊ぶ子供たちが笑顔で何かを楽しんでいます。 (The children playing in the park are smiling and enjoying something.)	similarity = 1.0
JNLI	幸せそうなカップルが手をつないで海辺を歩いている。 (A happy couple is walking hand in hand along the seaside.) 青い空と波が背景に広がり、夕日の光が二人を照らしている。 (With the blue sky and waves in the background, the light of the setting sun shines on the couple.)	Entailment
	木々が繁茂する森の中で、明るい光が差し込む風景。 (In the forest where trees grow thickly, bright light streams through the landscape.) 濃い霧がかかり、視界がほとんどない中に立つ孤独な木。 (A solitary tree stands amidst a dense fog, with almost no visibility.)	Contradiction
	美しい夕焼け空の中、風景画の中に描かれた山々の輪郭が静かに浮かび上がっている。 (In the beautiful sunset sky, the outlines of mountains depicted in the landscape painting quietly emerge.) 夕暮れ時に描かれた風景で、美しく彩られた空の中には山々の輪郭が描かれています。 (In the landscape painted at dusk, the outlines of mountains are depicted against a beautifully colored sky.)	Neutral
JCoLA	私は友達と昨日食べった寿司にします。 (I will have the sushi I atte with my friends yesterday.) 昨日の夜、友達とおいしいラーメンを食べました。 (Last night, I ate delicious ramen with my friends.)	Unacceptable Acceptable
COVID-19	COVID-19の最新情報です。感染拡大を防ぐためには、手洗いやマスクの着用、人との距離... (Here is the latest information on COVID-19. To prevent the spread of infection, it is important,...) 今日は友人がCOVID-19に感染していました。心配ですが、早く回復することを... (Today, my friend tested positive for COVID-19. I'm worried, but I hope they recover quickly...) 新型コロナウイルスの感染が拡大する中、マスクの着用や手洗いの重要性を再認識し... (Amid the spread of the novel coronavirus, I have come to realize once again the importance...) 今日はおいしいお寿司を食べました！旬のネタが特に美味しかったです！ (Today, I had some delicious sushi! The seasonal toppings were especially tasty!)	General Fact Personal Fact Opinion Impression
News	日本の低価格航空会社PeachAviationは、ユーザーにより快適なフライト体験を提供するための新しい取り組みを発表しました。 (Japan's low-cost airline Peach Aviation has announced a new initiative to provide users with a more comfortable flight experience.) 日本の航空会社、エスマックスが業績好調であることが報じられました。新たな路線の開設や購入した新型機の稼働により、利益が大幅に上昇しています。 (It has been reported that Japan's airline, Smax, is experiencing strong performance. The opening of new routes and the operation of newly purchased aircraft have significantly increased their profits.)	Peachy S-MAX

Table 3: Synthesized data sample by zero-shot JAPAGEN for each task.

4.4 Qualitative Evaluations

We observe that JAPAGEN was generally able to synthesize texts in accordance with the tasks. Below, we describe examples where JAPAGEN did not perform well for each task.

MARC-ja. JAPAGEN tends to generate similar texts such as "この商品は良い/悪いです。(This commodity is good/bad.)". Table 2 also indicates a high Self-BLEU score for MARC-ja, implying significant similarity among the synthesized texts. As indicated by the high score of label correctness in Table 3, we observe no discrepancy between the synthesized text and the corresponding label.

JSTS. While labels are continuous values, employing discrete values as labels in the prompt limits the capability of JAPAGEN to capture detailed similarity between two sentences. For instance, the similarity between the two sentences presented in Table 3 is 1.0. However, from the perspective of native Japanese speakers, this similarity should be rated above 3.0. The label correctness score (MSE) of synthesized texts by JAPAGEN is also too high, which suggests that several labels are not correct, compared to that of gold data.

JNLI. JAPAGEN exhibits difficulty distinguishing between "Entailment" and "Neutral". Specifically, text pairs for "Neutral" are frequently misclassified as "Entailment". The label correctness score (Accuracy) of synthesized texts by JAPAGEN is also too low compared to that of the gold data.

JCoLA. JCoLA is a binary classification task to predict whether a Japanese text is syntactically acceptable or unacceptable. Our observation indicate that the LLM struggles with generating unacceptable sentences. Specifically, the expression "食べった" in Table 3 is not a syntactic error but a typo. This is because LLMs are trained to generate syntactically correct sentences, leading to difficulties in generating grammatically incorrect ones.

COVID-19. Synthesized texts correspond to each label; however, JAPAGEN frequently generates similar texts (*e.g.*,"手洗い" (washing hands), "マスク" (wearing a mask)) within a label. The Self-BLEU score of synthetic texts in COVID-19 is much higher, indicating lower diversity compared to gold data presented in Table 5.

News. This is a news topic classification task where topic names as labels include entity-like unique expressions. Synthetic texts frequently fail to align with these labels, particularly when the labels involve proper nouns or lacks common sense. For instance, in Table 3, "Peachy" is a category indicating news targeting women; however, it generates content about the real airline "Peach (Peach Aviation)". Similarly, "S-MAX" is a category for software-related news; however, it frequently produces content about fictional people or companies named 'S-MAX' are often generated.

Throughout all six tasks, while the text synthesized by JAPAGEN has challenges in terms of diversity and label consistency, it was generally able to produce text that aligned with the tasks.

4.5 Overall Results

In this section, we summarize §4.2, §4.3, and §4.4 related to the experimental results and analysis. The results of zero-shot JAPAGEN, comparing to few-shot fine-tuning and prompting, showed that it is particularly effective for classification tasks with formal text input. This suggests JAPAGEN has the potential to surpass scenarios with more parameters and more annotations. Additionally, the results from KADG and few-shot JAPAGEN indicated that incorporating task knowledge and examples into the prompts can further enhance its capabilities. On the other hand, challenges include low label correctness and the difficulty in synthesizing datasets with continuous value labels such as JSTS and with the desired grammatical errors in JCoLA.

5 Conclusion

To investigate the effectiveness of SUPERGEN in a mid-resource language with characteristics different from English, we evaluated SUPERGEN specifically for Japanese tasks, termed JAPAGEN. Our experimental results demonstrate that JAPAGEN is particularly effective for classification tasks where the input consists of formal text compared to few-shot PROMPTING.

Future Work

- We will examine the efficacy of prompts in synthesizing high-quality texts for specific tasks.
- As the development of open LLMs is also progressing rapidly, we would like to evaluate JAPAGEN using such LLMs.

Limitation

- Our trained models are unavailable for commercial use because we used OpenAI LLM for data generation.
- Although we used GPT-3.5 as a pseudo training data generator, using more advanced LLM (*e.g.*, GPT-4) might yield different results.
- To examine the impact of SUPERGEN on languages with distinct characteristics from English and classified as mid-resource, we selected Japanese as a case study. Future research will address additional languages.

Ethics Statement

While PLMs have demonstrated remarkable capabilities in text generation and comprehension, they also pose potential risks or harms (Bender and Koller, 2020; Bender et al., 2021), such as generating misinformation (Pagnoni et al., 2021) or amplifying harmful biases (Prabhumoye et al., 2018). Our work specifically focuses on leveraging existing PLMs to generate training data for NLU tasks, rather than on developing new PLMs or generation methods. In this study, we comply with the OpenAI's terms of use by not disclosing synthetic data and by refraining from using it for purposes other than study. Furthermore, this study did not involve any sensitive data but only used publicly available data, including MARC-ja, JSTS, JNLI, JCoLA, News, and COVID-19.

A Appendix

A.1 Dataset and Task

We describe the six tasks used in our experiment. The dataset statistics are presented in Table 4.

MARC-ja A binary classification task to predict the sentiment of product reviews as positive or negative. The dataset used for this task is derived from the Japanese subset of the Multilingual Amazon Reviews Corpus (MARC) (Keung et al., 2020).

JSTS A regression task to predict the semantic similarity score between two sentences. The score ranges from 0 (least similar) to 5 (most similar). The data for this task are sourced from the Japanese version of the MS COCO Caption Dataset (Chen et al., 2015) and the YJ Captions Dataset (Miyazaki and Shimizu, 2016).

JNLI A three-way classification task to predict the relation between two sentences. The possible relations are {contradiction, neutral, entailment} reflecting the categories utilized in the Stanford Natural Language Inference (SNLI) dataset (Bowman et al., 2015). The data source for this task is the same as that used for JSTS.

JCoLA A binary classification task to predict whether a Japanese text is syntactically acceptable or unacceptable. For further details, please refer to (Someya et al., 2024).

News A nine-way classification task to predict the news topic of a given news text. The news texts are sourced from Livedoor News. The possible topics are {Trend Topic News, Sports Watch, IT Life hack, Consumer Electronics, MOVIE, DOKUJOTSUSHIN, S-MAX, HOMME, Peachy}.

COVID-19 A four-way classification task to predict the factuality of tweets about COVID-19. The categories of factual information include "general fact," "personal fact," "opinion," and "impressions." The data for this task are sourced from https://www.db.info.gifu-u.ac.jp/covid-19-twitter-dataset/.

A.2 Metrics

Spearman's Correlation Score This metric means the consistency between two sets of rankings by calculating the correlation between their ranks. A score close to 1 indicates strong agreement, meaning the model's ranked outputs closely match the true ranked labels.

Dataset		Number of Samples		
		Train	Dev.	Test
JGLUE	MARC-ja	150,022	37,506	5,654
	JSTS	9,960	2,491	1,457
	JNLI	16,058	4,015	2,434
	JCoLA	4,000	1,000	865
News		4,375	625	1,475
COVID-19		4,375	625	7,547

Table 4: Dataset statistics.

Dataset	News	COVID-19
DIVERSITY (%)		
Gold	62.97	43.14
Zero-shot	79.90	84.31
w/ KADG	82.93	81.91
Few-shot	79.25	83.40
LABEL CORRECTNESS (%)		
Gold	98.89	90.87
Zero-shot	49.84	60.80
w/ KADG	43.61	58.86
Few-shot	57.33	64.43

Table 5: Diversity and label correctness of synthetic dataset in News and COVID-19.

Matthews Correlation Coefficient (MCC) MCC measures the quality of binary classifications by considering true positives, false positives, true negatives, and false negatives in a balanced way. Its value ranges from -1 to 1, where 1 indicates perfect prediction, and -1 a complete inverse relationship.

Self-BLEU This metric calculates BLEU scores for generated text samples against other samples within the same set to measure diversity. Lower Self-BLEU indicates more diverse outputs.

A.3 Additional Results

The diversity (Self-BLEU) and label correctness of News and COVID-19 are shown in Table 5. While the diversity of News and COVID-19 in few-shot is lower than that in zero-shot, few-shot JAPAGEN can improve the label correctness of News and COVID-19.

A.4 Prompt for Each Task

For prompt details used in our experiments, please refer to https://github.com/retrieva/JapaGen due to the page limitation.

Human Performance in Incremental Dependency Parsing: Dependency Structure Annotations and their Analyses

Abstract

Incremental dependency parsing identifies the dependency structure as each component in a sentence is inputted. Since this task needs to predict non-inputted parts of the sentence, it is challenging not only for machines but also for humans. Although comparing machines and humans in this task is interesting, human performance in incremental dependency parsing has not been well studied due to lack of sufficient evaluation data. This study presents the construction of a large-scale data annotated with human incremental dependency parsing and string prediction and evaluates the human performance on these tasks. The data includes 3,639 written and 1,935 spoken sentences incrementally annotated by humans as each word was inputted. The dependency structure produced incrementally by humans was designed based on the intuition that they simultaneously predict non-inputted words and establish dependencies between previously inputted and non-inputted words. This study contributes to reveal the difficulty of incremental dependency parsing and certain aspects of human behavior in this task.

1 Introduction

Real-time language processing systems have applications for spoken and written languages. Applications for spoken language include simultaneous machine interpretation (Liu et al., 2021), spoken dialogue modeling (Nguyen et al., 2023), and real-time captioning (Piperidis et al., 2004; Ohno et al., 2009). For written language, applications, such as text input support systems (Murata et al., 2010), could be provided. A common requirement of these systems is to execute processing simultaneously with time-continuous input of sentence components. Incremental dependency parsers provide these systems with syntactic information for the input up to that point each time the input is received. In other words, these parsers identify dependencies between components of a sentence even when the input is still in progress (Kato and Matsubara, 2009; Ohno and Matsubara, 2013).

In incremental dependency parsing, whenever a component in a sentence is inputted, the dependency structure for the sequence of inputted components needs to be identified. The dependency structure that should be output at each point depends on what the speaker/writer inputs subsequently. For this reason, accurately performing is highly challenging even for humans. Understanding human performance in this task is meaningful, as it can guide the performance achieved by incremental parsing systems. However, existing research has made little attempt to reveal the difficulty of this task for humans, and has been limited to assessing comparisons between parsers based on their agreement with the correct structure. This is due to the lack of data to evaluate human performance in incremental dependency parsing.

In recent years, advances in large-scale language models have led to the development of datasets for various tasks to evaluate their effectiveness (Kurihara et al., 2022; Reid et al., 2022; García-Ferrero et al., 2023). These evaluations often include comparison with human performance (Lee et al., 2023). Additionally, many analyses have been conducted to identify potential differences in language comprehension processes between the models and humans (Shaitarova et al., 2023; Rodriguez et al., 2024). One possible approach to quantitatively analyze the human language comprehension process is to collect a large-scale data of incremental dependency parsing process by humans.

This study presents the construction of a large-scale data annotated with incremental dependency parsing results by humans. We evaluates human performance on incremental dependency parsing and reveal certain aspects of human behavior. The data were constructed by annotating 3,639 and 1,935 sentences of written and spoken languages

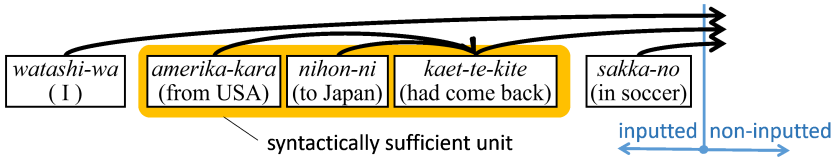

Figure 1: Dependency structure which expresses the fact that some bunsetsus do not depend on any inputted bunsetsus.

with dependency structures, respectively. The annotators identified these structures one by one as each word was inputted in sequence from the beginning of the sentence. The structures include not only the dependencies between previously inputted *bunsetsus*[1] but also those between previously inputted and non-inputted bunsetsus. It also captures predicted non-inputted words. The design is based on the intuition that humans simultaneously predict words in non-inputted bunsetsus and the dependencies between previously inputted and non-inputted bunsetsus.

The remainder of this paper is organized as follows. Section 2 describes previous works and our designed structure for incremental dependency parsing. Section 3 outlines the annotation on human incremental dependency parsing and presents the annotation results. Section 4 discusses the analysis of the data. Finally, Section 5 summarizes this research and suggests directions for future works.

2 Incremental Dependency Parsing

2.1 Previous Works

Many works have focused on incremental dependency parsing, which identifies dependency relationships between components of a sentence in the middle of the input one (Kato et al., 2001; Kato and Matsubara, 2009; Ohno and Matsubara, 2013). However, there has been little discussion of the specific information that should be included in a parser's output structure. The previous parsers (Kato et al., 2005; Johansson and Nugues, 2007; Nivre, 2008) update the parsing results midstream whenever a new word is inputted. They output pairs of modifiers and modifyees whenever they detect such pairs. Therefore, these parsers can only output a dependency relation after the modifier and modifyee have been inputted.

To solve this problem, Ohno and Matsubara (2013) proposed a structure that a Japanese incremental dependency parser should output in terms of the requirements of real-time language processing systems. Their proposed dependency structure requires the parser to clarify that a bunsetsu whose modified bunsetsu has not yet been inputted does not depend on any previously inputted bunsetsu. Figure 1 illustrates the dependency structure that a parser outputs immediately after the bunsetsu "*sakka-no* (in soccer)" is inputted while incrementally parsing the sentence "*watashi-wa amerika-kara nihon-ni kaet-te-kite sakka-no warudokappu-wo mimashi-ta* (I watched the World Cup in soccer after I had come back to Japan)." If it becomes clear that the modified bunsetsu of a bunsetsu has not been inputted yet, the higher layer applications can identify *syntactically sufficient units*[2] in the inputted sequence of bunsetsus and effectively use this information. For example, in Figure 1, the sequence of bunsetsus enclosed in the orange box "*amerika-kara nihon-ni kaet-te-kite* (after I had come back to Japan)" is identified as a syntactically sufficient unit. In fact, information on a syntactically sufficient unit is crucial for detecting the timing to start interpreting in simultaneous machine interpretation (Ryu et al., 2006) and determining the proper linefeed position in captioning (Ohno et al., 2009).

Additionally, several studies have focused on predicting specific words in the non-inputted parts of a sentence to support real-time language processing systems, as described in Section 1 (Grissom II et al., 2014; Tsunematsu et al., 2020; Cai et al., 2022). In the incremental process of human language understanding, we can intuitively assume that humans simultaneously predict specific words

[1] *Bunsetsu* is a linguistic unit in Japanese that roughly corresponds to a basic phrase in English. A bunsetsu consists of one independent word and zero or more ancillary words. A dependency relation in Japanese is a modification relation in which a modifier bunsetsu depends on a modified bunsetsu. In other words, the modifier bunsetsu and the modified bunsetsu work as modifier and modifyee, respectively.

[2] A syntactically sufficient unit is defined as a sequence of bunsetsus of which the dependency structure is closed, that is, any bunsetsu except the final bunsetsu does not depend on a bunsetsu outside the sequence.

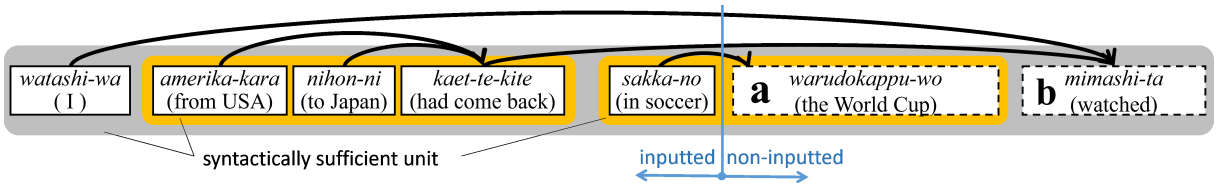

Figure 2: Dependency structure, which includes dependency relationships between inputted and non-inputted bunsetsus and the predicted specific strings of the non-inputted bunsetsus.

in non-inputted parts and parse dependencies between previously inputted and non-inputted parts. Based on this intuition, a study on incremental parsing partly exists, which adds a pseudo node representing the part of speech (POS) of the word to be next inputted and identifies syntactic relations between already inputted components and the added node (Köhn and Menzel, 2014). However, to the best of our knowledge, no study has simultaneously addressed incremental dependency parsing and prediction of specific words in non-inputted parts.

2.2 Dependency Structure for Incremental Parsing

In this section, we describe a new dependency structure that we introduce in this research. This structure is defined by integrating the dependency structure shown in Figure 1 (Ohno and Matsubara, 2013) with the prediction of specific words in non-inputted parts of a sentence.

Our new dependency structure can explicitly express the dependency relationships between inputted and non-inputted bunsetsus. When multiple bunsetsus depend on any of non-inputted bunsetsus (Figure 1), they may depend on different bunsetsus or the same bunsetsu. Our new dependency structure clarifies whether those bunsetsus depend on the same non-inputted bunsetsu. Furthermore, the specific strings of the non-inputted bunsetsus are predicted.

Figure 2 shows our new dependency structure in the same situation as Figure 1. This dependency structure clarifies that the bunsetsus "*watashi-wa* (I)" and "*kaet-te-kite* (after I had come back to Japan)" depend on the same non-inputted bunsetsu **b**, whereas the bunsetsu "*sakka-no* (in soccer)" depends on a different non-inputted bunsetsu **a**. Additionally, the non-inputted strings of bunsetsu **a** and **b** are predicted as "*warudokappu-wo* (the World Cup)" and "*mimashi-ta* (watched)," respectively. If such a dependency structure is identified, syntactically sufficient units can be detected in greater detail, as shown by the orange and gray boxes in Figure 2.

3 Annotation on Human Incremental Dependency Parsing

In this section, we describe the construction of a large-scale data annotated with results of human performance in incremental dependency parsing. In the construction, whenever a bunsetsu in a sentence included in the existing corpus is displayed one by one, the already displayed sequence of bunsetsus is annotated with the identified dependency structure of the format in Figure 2 and strings of the non-inputted bunsetsus in the structure are predicted. This study provides annotations for written and spoken Japanese. In what follows, we describe the existing corpus of our target for annotation and explain the data construction.

3.1 Target Data of Annotation

In our research, we used 3,639 sentences in Kyoto University Text Corpus Version 4.0 (Kyoto Corpus) (Kawahara et al., 2002), which consists of approximately 40,000 sentences from Japanese newspaper with morphological and syntactic annotations, for written language, and all sentences in Japanese lecture speech of Simultaneous Interpretation Database (SIDB) (Tohyama et al., 2005), which consists of 1,935 sentences from Japanese lecture speech transcriptions with morphological and syntactic annotations, for spoken language, as target data for annotation.

The difficulty of incremental dependency parsing and string prediction can be influenced by readability of the inputted sentences. In our research, we focus on human language processing in written and spoken language, which are relatively well readable. Newspaper articles in Kyoto Corpus are consistently written in a style familiar to the general audience, thus ensuring a consistent level of readability. The lecture manuscripts in SIDB were prepared in advance, and the transcribed texts are

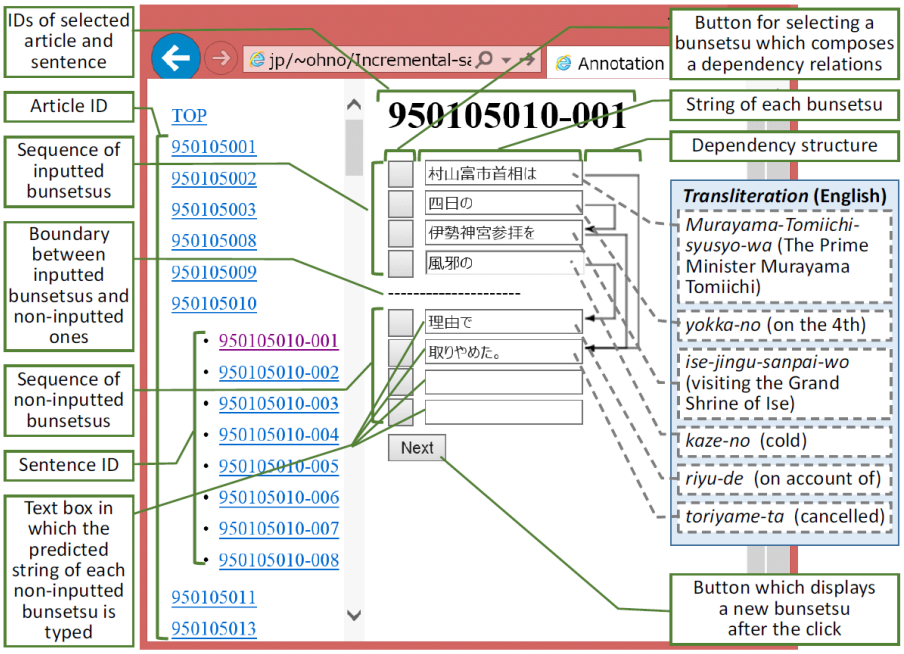

Figure 3: Web interface for annotation.

relatively well readable within the spoken language domain.

3.2 Outline of Data Construction

Two annotators (annotator A and B), who are native Japanese speakers, annotated 3,639 sentences (including 36,824 bunsetsus) in Kyoto Corpus. Annotator A also annotated 1,935 sentences (including 23,598 bunsetsus) in SIDB. Each annotator completed the whole annotation by iterating the annotation for a sentence after reading the annotation manual. The procedure for annotating a sentence using the Web interface shown in Figure 3 is as follows:

(1) Selection of a target sentence: An annotator selects an article's/lecture's ID in order from the top on the left side of the interface, and then the list of IDs of sentences included in the article/lecture is displayed. After that, the annotator selects a sentence ID in order from the top. This is because humans are generally thought to predict non-inputted bunsetsu using context.

(2) Annotation of the selected sentence: Following the selection of a sentence, the annotator proceeds with annotations of the sentence on the right side of the interface, where a bunsetsu in the sentence is displayed one by one. Whenever a new bunsetsu is displayed, the annotator conducts the following two annotation steps for the sequence of bunsetsus, which has already been displayed, with no time restriction.

(2a) The annotator annotates the inputted sequence of bunsetsus with the dependency structure of the format in Figure 2 by deciding each modified bunsetsu for all the inputted bunsetsus. Here, a non-inputted bunsetsu is allowed to become a modified bunsetsu. In Figure 3, an arrow means a dependency relation.

(2b) The annotator predicts strings of the non-inputted modified bunsetsus in the dependency structure determined by (2a) and then types each string in the corresponding text box. Annotators can choose not to type a string if they cannot think of one. In Figure 3, strings of the two non-inputted modified bunsetsus are predicted as "*riyu-de* (on account of)" and "*toriyame-ta* (canceled)," respectively.

After the two annotations, the annotator clicks the button "Next." Then, a new bunsetsu is displayed, and the annotator repeats the two annotations until the sentence-end bunsetsu is displayed.

(3) Confirmation of annotation results: After completing the annotation of a sentence, the score of the annotation results and the correct dependency structure is displayed. The annotator compares their own annotation results with the correct answer and confirms the writing style of newspaper articles or transcripts of lectures, the specification of dependency grammar, and so on. Displaying the score is performed to maintain the motivation of annotators.

	annotator A		annotator B
corpus	SIDB	Kyoto	Kyoto
dependencies	216,204	262,426	262,426
strings	17,762	22,723	27,512

Table 1: The number of dependencies and strings of annotator A and annotator B in the annotation results.

3.3 Annotation Results

Table 1 presents the number of dependencies and strings in the annotation results. The annotation is iteratively performed for the already inputted sequence of bunsetsus whenever a bunsetsu in a sentence is displayed. In Table 1, we counted the dependencies and strings many times each time of the iteration. Additionally, the counted strings were only ones, which the annotators predicted and actually typed into the text boxes.

4 Analysis of Human Performance on Incremental Language Processing

We revealed aspects of human performance on incremental language processing based on analyses of the constructed data. Our analyses are based on two perspectives: dependency parsing and string prediction.

4.1 Human Performance on Dependency Parsing

We evaluated human performance on dependency parsing in terms of the following three points.

- **Sentence-based parsing:** We measured the agreement rate between the correct dependency structure and the dependency structure with which an annotator annotated a whole sentence after a sentence-end bunsetsu was displayed.
- **Incremental parsing I:** We evaluated the dependency structure provided by an annotator by seeing it as the dependency structure of the format of Figure 1. In other words, we ignore the information on whether or not other modifier bunsetsus depend on the same modified bunsetsu in the evaluation of dependency relations whose modified bunsetsu has not been inputted.
- **Incremental parsing II:** We evaluated the dependency structure provided by an annotator by seeing it as the dependency structure of the format of Figure 2. First, we establish correspondences between modified bunsetsus of the annotation results and modified bunsetsus of the correct data so that the agreement rate on dependency relations becomes the highest. After that, we measure the agreement rate.

4.1.1 Analytical Findings of Human Performance on Dependency Parsing

Table 2 shows the accuracy of dependency parsing by the two annotators at each evaluation point described above. The second, fourth, and sixth columns present the **dependency accuracy**[3], defined as the percentage of correctly analyzed dependencies out of all dependencies. The third, fifth, and seventh columns present **sentence accuracy**, defined as the percentage of sentences in which all dependencies are correctly analyzed. Table 2 shows that the incremental parsing II is the most difficult evaluation point compared to the other two parsing. This is easy to imagine because, in incremental parsing II, it is necessary to identify the greatest amount of information compared to other parsing methods.

We also separately measured the recall, precision, and f-measure of incremental parsing I and II for the case that the modified bunsetsu was inputted or not. The results are shown in Table 3. This table indicates that although it is less difficult for a human to identify that the modified bunsetsu has not been inputted, it becomes very difficult for a human to identify the dependency relationships between the inputted bunsetsus and the non-inputted ones.

Furthermore, we assessed the inter-annotator agreement between annotators A and B using the Kappa coefficient. The Kappa coefficients for sentence-based parsing, incremental parsing I, and incremental parsing II were 0.54, 0.51, and 0.43, respectively. According to Landis and Koch (1977), $0.41 \leq \kappa \leq 0.60$ indicates moderate agreement. The agreement gradually decreased as the evaluation point became more difficult. Additionally, the difference between the values of sentence-based parsing and incremental parsing I is smaller than the difference between those of incremental parsing I and II. This indicates that the performance of identifying dependency relationships between the inputted bunsetsus and the non-inputted bunsetsus

[3]Dependency accuracies of sentence-based parsing, incremental parsing I and II are measured based on the accuracies defined in the literatures (Uchimoto et al., 1999; Ohno and Matsubara, 2013).

	annotator A				annotator B	
corpus	SIDB		Kyoto		Kyoto	
eval. metrics	dependency	sentence	dependency	sentence	dependency	sentence
sentence-based	0.897	0.462	0.947	0.633	0.950	0.654
incremental I	0.887	0.395	0.945	0.546	0.942	0.489
incremental II	0.852	0.229	0.918	0.315	0.896	0.186

Table 2: Accuracy of two annotators' dependency parsing, evaluated by dependency and sentence accuracy.

		annotator A						annotator B		
corpus		SIDB			Kyoto			Kyoto		
eval. metrics		R	P	F	R	P	F	R	P	F
incremental parsing I	inputted	0.891	0.884	0.887	0.958	0.940	0.949	0.953	0.943	0.948
	non-inputted	0.923	0.900	0.911	0.959	0.957	0.958	0.960	0.939	0.949
incremental parsing II	inputted	0.891	0.884	0.887	0.958	0.940	0.949	0.953	0.943	0.948
	non-inputted	0.794	0.774	0.784	0.867	0.865	0.866	0.804	0.786	0.795

Table 3: Recall (R), precision (P), and the f-measure (F) of two annotators' incremental dependency parsing, separately for the case that the modified bunsetsu has not been inputted, and the case that the one has been inputted.

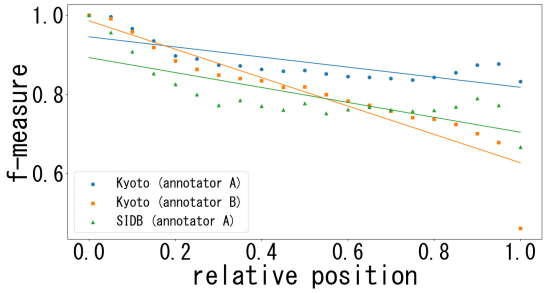

Figure 4: F-measure of incremental parsing II (non-inputted) by relative position.

varies significantly greatly from person to person.

4.1.2 Effect of the Number of Inputted Bunsetsus on Incremental Parsing

The difficulty of incremental parsing is expected to vary depending on the number of inputted bunsetsus. This section examines the effect of the number of inputted bunsetsus on incremental parsing. To account for the length of the entire sentence, we defined a relative position as the number of inputted bunsetsu divided by the total number of bunsetsu in the entire sentence. We classified the annotation results based on the relative positions of each bunsetsu input in 0.05 increments and then calculated the F-measure of incremental parsing II (non-inputted) for each class.

Figure 4 shows the f-measures of incremental parsing II by relative position. The straight lines represent the regression lines. The figure shows that the f-measure declined as the relative position increased. However, for the Kyoto Corpus and SIDB annotated by annotator A, the f-measure increased when the relative position exceeded 0.8. There are two factors that explain these trends. First, as the number of inputted bunsetsu increased, the number of possible modified bunsetsu increased. Therefore, dependency parsing becomes more complicated. Second, as more bunsetsu were inputted, the understanding of the sentence improved, making it easier to identify correct non-inputted modified bunsetsu. When the relative position was below 0.8, the f-measure was lower due to the stronger influence of the first factor. In contrast, the f-measure was higher when the relative position exceeded 0.8 due to the stronger influence of the second factor.

4.2 Human Performance on String Prediction

We evaluated human performance on string prediction. Specifically, we evaluated how accurately the two annotators predicted the string of a non-inputted bunsetsu.

4.2.1 Analytical Findings of Human Performance on String Prediction

Table 4 shows the recall and precision values of string prediction. Recall is the percentage of correctly predicted bunsetsus out of all bunsetusus in the correct dependency structure. Precision is the percentage of correctly predicted bunsetsus out of all bunsetsus whose strings are predicted by an-

	annotator A				annotator B	
corpus	SIDB		Kyoto		Kyoto	
eval. point	exact	partial	exact	partial	exact	partial
recall	0.043	0.125	0.057	0.117	0.036	0.119
precision	0.086	0.249	0.128	0.262	0.067	0.219

Table 4: Accuracies of string prediction by only exact match (exact) and including partial match (partial).

POS	Kyoto	SIDB
noun	27.17	20.07
verb	61.88	64.59
adjective	6.15	4.75
adverb	0.52	0.33
pre-noun adj	0.02	0.04
conjunction	0.10	0.05
interjection	0.01	0.07
copula	4.09	9.82
demonstrative	0.06	0.29

Table 5: Percentage distribution of POS in the head of modified bunsetsus.

	POS	R	P
Kyoto (annotator A)	verb	0.070	0.265
	noun	0.098	**0.267**
	all	**0.117**	0.262
Kyoto (annotator B)	verb	0.074	**0.240**
	noun	0.097	0.234
	all	**0.119**	0.219
SIDB (annotator A)	verb	0.070	**0.265**
	noun	0.105	0.254
	all	**0.125**	0.249

Table 6: Recall (R) and precision (P) of verb and noun for partial match.

notators. The "exact" columns show the results for which the prediction was correct only if they exactly matched the correct string. The "partial" columns show the results where the prediction was correct if they either exactly or partially matched[4] the correct string. The results indicate that predicting strings of non-inputted bunsetsus is challenging, even for humans. But at the same time, it suggests that humans have the ability to predict strings of some non-inputted bunsetsus.

Next, we evaluated the inter-annotator agreement on the string prediction between annotator A and B. The κ values of string prediction were 0.27 and 0.29 for an exact and partial match, respectively. According to Landis and Koch (1977), $0.21 \leq \kappa \leq 0.40$ indicates fair agreement. The agreement is lower than that of dependency parsing. Therefore, we can see that the performance of string prediction varies more greatly from person to person.

4.2.2 Analysis of String Prediction by POS of Non-inputted Modified Bunsetsus

We investigated how string prediction accuracy varies with the POS of the head[5] of the non-inputted modified bunsetsu in the correct structure. First, we examined the percentage distribution of POS in the head of the modified bunsetsu. Table 5 shows that verbs and nouns made up over 80% of the total, indicating that many modified bunsetsu heads were verbs or nouns. Therefore, we focused on verbs and nouns in this section.

Table 6 shows the performance of string prediction for verbs and nouns. The recall of verbs and nouns was lower than the micro-recall of all POS. This is because the frequency of occurrence for verbs and nouns is higher, leading to more instances where the number of inputted bunsetsu was insufficient to predict string of non-inputted modified bunsetsu, compared to other POS. However, the precision of verbs and nouns was higher than the micro-precision of all POS. This means that humans can more easily predict a string of the non-inputted modified bunsetsu whose head is a verb or noun than another POS when focusing on the strings annotated by the annotators.

4.2.3 Effect of the Number of Inputted Bunsetsus on String Prediction

We assumed that the closer a newly inputted bunsetsu is to the end of the sentence, the more context is available, and the string prediction accuracy will increase. To examine the assumption, we analyzed the effect of relative position on string prediction

[4] A partial match is judged when a predicted string includes the surface of the head of the correct string.

[5] Each bunsetsu has a head, which serves as the primary expression of its content and is determined with reference to the definition by Uchimoto et al. (1999).

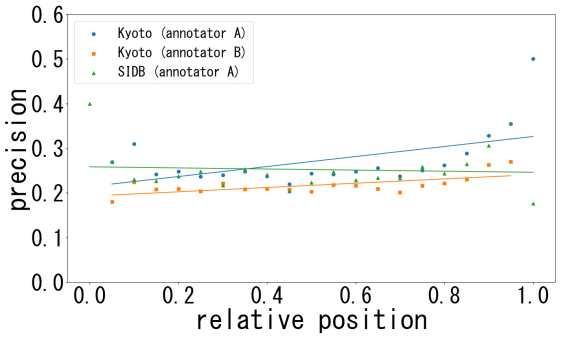

Figure 5: Precision of string prediction for partial match by relative position.

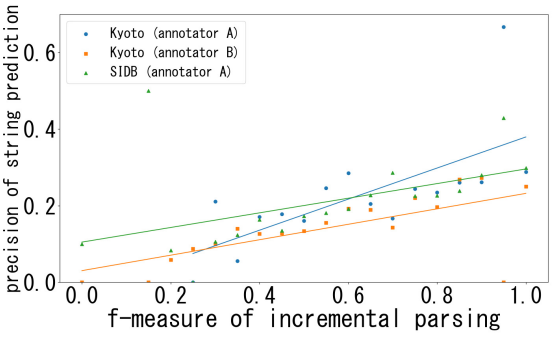

Figure 6: Precision of string prediction for partial match by each f-measure of incremental parsing Ⅱ (non-inputted).

in a similar manner to Section 4.1.2. Here, we used precision for partial match as the evaluation index of string prediction to focus on the strings predicted by the annotators.

Figure 5 shows the precision of string prediction. The blue and orange lines represent the regression lines for the Kyoto Corpus annotated by annotators A and B, respectively; the green line represents the regression line for the SIDB annotated by annotator A. The regression lines show a positive slope, except for the SIDB (annotator A). Notably, the string prediction precision increased sharply when the relative position exceeded 0.8. This phenomenon can be attributed to the structural characteristics of the Japanese language. As a subject-object-verb language, Japanese often places verbs at the end of sentences. We assume that precision rapidly increases because annotators can predict a sentence-end verb using richer contexts when approaching the end of a sentence.

The results demonstrate that humans can make string predictions more accurately as the number of inputted bunsetsu increases, particularly as the sentence approaches its end.

4.3 Relationship between Incremental Dependency Parsing and String Prediction

Both incremental dependency parsing and string prediction in common require prediction of non-inputted parts of a sentence based on contextual understanding. We have the intuition that humans simultaneously perform these two tasks while predicting non-inputted parts and thus the two tasks are related to each other. In this section, we investigate the relationship between string prediction and incremental parsing Ⅱ (incremental dependency parsing).

Figure 6 illustrates the relationship between the f-measure of incremental parsing Ⅱ (non-inputted) on the x-axis and the precision of string prediction (partial) on the y-axis, measured each time a new bunsetsu was inputted and rounded in 0.05 increments. The blue and orange lines represent the regression line for Kyoto Corpus annotated by annotator A and B, respectively; the green line represents the regression line for the SIDB annotated by annotator A. The regression lines have positive slopes, indicating a positive correlation between the two tasks. This suggests that when humans accurately parse dependencies, they also tend to predict strings of modified bunsetsu more accurately.

5 Conclusion

In this study, we presented the annotation results, capturing human performance in incremental language processing. The annotators performed incremental dependency parsing and string prediction of some non-inputted bunsetsus whenever a new bunsetsu was inputted. Using this annotated data, we analyzed human performance in incremental dependency parsing and string prediction of non-inputted modified bunsetsus.

In the future, we intend to conduct a more detail analysis of the constructed data to further understand human performance in incremental dependency parsing. For example, we aim to investigate factors such as the content of inputted bunsetsus and the context, which could potentially influence incremental dependency parsing and string prediction.

Abstract

We propose a method to efficiently correct hallucinations occurring in Large Language Models (LLMs) using LLMs themselves. Previous studies have used a pipelined method, multiple prompts (MP) to correct hallucinations, but this approach had the problem of requiring significant calculation cost. Therefore, in this study, we use a single prompt (SP) that integrates the process to detect and correct hallucinations. In the proposed method, we instruct the LLM using SP to generate a corrected sentence if a hallucination is present, and not to modify the text if no hallucination is occurring. We compare SP with MP in terms of calculation time and correcting accuracy. Additionally, we examine the effectiveness of hallucination correcting with Chain-of-Thought (CoT). Experimental results show that SP achieves correcting with reduced calculation time compared with MP. Furthermore, we revealed that while correcting with CoT decreases the correcting accuracy of MP, it improves that of SP.

1 Introduction

The evolution of Large Language Models (LLMs) has become more prominent through models such as GPT-4 (Achiam et al., 2023) and Claude[1]. These models are capable of generating more natural text. As a result, LLMs are being put into practical use in a wide range of applications such as ChatGPT[2] and Perplexity AI[3].

However, LLMs have the potential to generate hallucinations, which poses a significant challenge in practical use. It has been reported that in open-domain text generation, GPT-3.5-turbo generates hallucinations at a rate of 17.7%, while GPT-4 does so at 15.7% (Mündler et al., 2024).

As a method to suppress hallucination, RAG (Lewis et al., 2020b) is mentioned. RAG retrieves information from an external database and uses that information as a reference for the LLM to generate text. Since it retrieves information externally, it is reported to be capable of generating information that has not been learned and suppressing hallucination (Shuster et al., 2021). However, it has been reported that LLMs can add new information to the text generated by the search-provided external information (Dziri et al., 2022) or prioritize internal knowledge over external information (Longpre et al., 2021; Xie et al., 2024). Therefore, there is still a possibility of hallucination occurring even when using RAG.

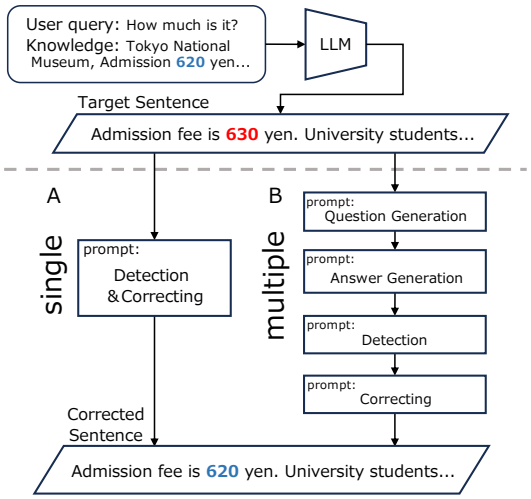

Figure 1: Processing flow of methods for correcting hallucinations contained in the target sentence. A: correcting using single prompt (proposed method). B: correcting using multiple prompt (Dhuliawala et al., 2024).

To solve the problem of hallucination, methods have been proposed to detect and correct hallucinations. Correcting can be applied to LLMs that have implemented RAG. Furthermore, methods have been proposed to use LLMs themselves for correcting.

Many of these methods perform correcting through multiple prompts (MP) (Zhao et al., 2023;

[2]https://openai.com/blog/chatgpt
[3]https://www.perplexity.ai/

Table 1: Actual prompts used in the proposed method. The system estimates the contradiction implication relationship between the knowledge and the target sentence, and gives instructions to correct the contradiction relationship. The red characters indicate the strings of characters used when using CoT. The text shown here is the English translation of the Japanese original.

#Tasks

• You can infer contradictions and implication relationships between knowledge and target sentences.
• If there is a contradiction between knowledge and the target sentence, you can correct the target sentence.
• Output the reasoning for determining whether there are contradictions between knowledge and the target sentence, and based on this reasoning, output a judgment label and a corrected sentence.
• Outputting a 0 label means the knowledge and target sentence have an implication relationship.
• Outputting a 1 label means the knowledge and target sentence have a contradiction relationship.
• If you output a 0 label, since the knowledge and target sentence have an implication relationship, output " correcting: None ".
• If you output a 1 label, since the knowledge and target sentence have a contradiction relationship, correct the target sentence based on the reasoning that indicates which part of the target sentence should be modified.
• If the target sentence contains information not present in the knowledge or information that contradicts the knowledge, output the reasoning for why it's considered a contradiction, and correct the target sentence based on the knowledge and reasoning.
• Maintain the format of the target sentence.

#Instructions

• Always follow the rules.
• Strictly adhere to the output format.
• Make judgments based on the reasoning.
• Detect any contradictions between the knowledge and target sentence.
• Output 0 if the knowledge and target sentence have an implication relationship.
• Output 1 if there are contradictions between the knowledge and target sentence.
• Carefully examine the knowledge and target sentence to determine if there's a contradiction or implication relationship and output the label.
• If you determine implication, output " correcting: None ".
• If you determine contradiction, correct the target sentence based on the knowledge and reasoning.
• When correcting, faithfully revise the target sentence based on the knowledge.
• If information not present in the knowledge exists in the target sentence, delete it.
• Please refer to the following specific examples.

#Specific Examples

##Specific Example 1 (Implication Relationship)
##Input
Knowledge: Business hours: 10 AM to 10 PM (10 AM to 9 PM from January to March), admission until 20 minutes before closing, Open: Every day
Target sentence: Admission is until 20 minutes before closing.
##Output
Reasoning: The target sentence "Admission is until 20 minutes before closing." does not contradict the knowledge "admission until 20 minutes before closing,".
Judgment: 0
correcting: None
• • •

##Specific Example 7 (Contradiction Relationship)
##Input
Knowledge: Operating hours: 10:00 AM to 7:00 AM the next day, Closed: Never
Target sentence: It's from 10 AM to 7 PM.
##Output
Reasoning: The target sentence "It's from 10 AM to 7 PM." states 7 PM, but the knowledge "Operating hours: 10:00 AM to 7:00 AM the next day, Closed: Never" indicates 7:00 AM the next day. Therefore, the target sentence contradicts the knowledge. As a result, the target sentence should be corrected to "It's from 10 AM to 7 AM the next day."
Judgment: 1
correcting: It's from 10 AM to 7 AM the next day.

#input/output

##Input
Knowledge: {knowledge} Target sentence: {target sentence}
##Output

To reiterate, you should complete the following tasks: #Tasks You can infer contradictions and implication relationships between knowledge and target sentences. If there is a contradiction relationship between knowledge and the target sentence, you can correct the target sentence. Compare the knowledge and target sentence. If you determine that the target sentence implies the knowledge, output the target sentence without correcting. However, if the target sentence contains information (contradictions) not present in the knowledge, please correct the target sentence.

Mündler et al., 2024; Dhuliawala et al., 2024). They design prompts that break down tasks into phases such as query generation for external knowledge search, hallucination detection, and correcting, and incorporate these in a pipeline to tackle hallucination correcting.

These existing studies have developed models using MP to perform correcting of hallucinations in complex tasks by subdividing the tasks. However, the challenge with MP is that they involve multiple processes, which increases computational costs.

Applications like ChatGPT and Perplexity AI have made LLMs more accessible by utilizing them in a conversational format. In such dialogue-based interactions, real-time responsiveness becomes crucial. Therefore, there is a demand for hallucination correcting methods that can minimize the calculation time as much as possible.

We propose a hallucination correcting method constructed using only a single prompt (SP) to address the challenges in existing studies. Our proposed method is characterized by its ability to simultaneously detect and correct hallucinations.

In this study, we conducted a comparative evaluation of methods for correcting hallucinations using SP and MP, focusing on calculation time and correct capability. Furthermore, we applied the Chain-of-Thought (CoT) (Wei et al., 2022), which has been reported to be effective in various tasks, and analyzed its effects in detail.

The analysis yielded the following findings:

- It was confirmed that SP could significantly reduce calculation time while maintaining correcting accuracy equal to or better than MP.
- The effect of CoT in hallucination correcting was found to be strongly dependent on prompt design. In particular, the combination of SP

and CoT was shown to be most effective in hallucination correcting.

- It was revealed that SP is a method that minimizes the reduction in recall observed with CoT.
- In the case of MP, it was suggested that the reduction in recall caused by the application of CoT could lead to a decrease in correct capability.

2 Related Work

2.1 Correcting by Fine-tuning

Methods have been proposed to perform hallucination correcting using a pipeline approach, training BERT (Devlin et al., 2019) as a detector and models such as BART (Lewis et al., 2020a) and T5 (Raffel et al., 2020) as correctors, using hallucination data (Thorne et al., 2021; Lee et al., 2022). However, these methods face the challenge of error propagation due to the combination of multiple models.

Addressing this issue, Moriwaki et al. (2022) proposed a joint learning method that shares part of the loss function, reporting improved accuracy of the corrector. Conversely, Cao et al. (2020) proposed a method to correct hallucinations using a single model, enabling correcting without constructing a separate detector.

While these existing studies use fine-tuning, they require new training data to handle hallucinations across various domains and tasks. However, preparing data that corresponds to the diverse domains in the real world is challenging. Therefore, there is a demand for methods that can address hallucinations occurring in various domains without being dependent on specific domains.

2.2 Correcting by Prompt-tuning

LLMs can perform tasks without fine-tuning by using In-context Learning (ICL) with few-shot prompts (Brown et al., 2020). As ICL provides better generalization accuracy than fine-tuning (Awadalla et al., 2022; Si et al., 2023), it is considered suitable for hallucination correcting across various domains.

Existing hallucination correcting methods using LLMs adopt MP approach to break down tasks into smaller subtasks. Dhuliawala et al. (2024) proposed a method that uses different prompts for question generation, answer generation, detection, and correcting stages to detect and correct hallucinations in list-based QA and long-form text generation tasks. Their method follows the flow shown in Figure1:B. Zhao et al. (2023) also developed a method that uses multiple prompts to generate intermediate steps of CoT, detect hallucinations by calculating agreement rates, and perform correcting using external knowledge with another prompt. Mündler et al. (2024) constructed a framework that uses different prompts in three stages - generation, detection, and correcting - to address self-contradictions in LLMs.

These existing studies use MP for correcting hallucinations in complex tasks, but this results in high computational costs. Therefore, there is a need for prompt designs that integrate MP and enable more efficient detection and correcting of hallucinations.

Table 2: Results of manually annotating 50,000 outputs obtained by "hobbyist" (Sugiyama et al., 2021). The numbers not enclosed in brackets are the numbers that were found to be valid by filtering. The specific filtering method is described in Section 4.2. Con. stands for Contradiction, and Imp. stands for Implication.

	Con.	Imp.	Total
Access	3,396 (4,967)	12,528 (14,978)	15,924 (19,945)
Fee	2,135 (3,424)	5,442 (6,611)	7,577 (10,035)
Business hours	7,082 (8,709)	9,761 (11,311)	16,843 (20,020)
Total	12,613 (17,100)	27,731 (32,900)	40,344 (50,000)

3 Proposed Method

We propose a method to correct hallucinations using only SP, enabling more efficient detection and correcting of hallucinations. As shown in Figure1:A, the SP approach performs hallucination correcting with SP. Therefore, we design the prompt to generate a corrected sentence when hallucination occurs in the LLM's output, and not to modify the text when no hallucination is present. Table 1 shows the actual prompt used. Although Table 1 is translated into English, we use Japanese prompts in practice.

In #Tasks, we provide instructions to detect hallucinations and correct them when detected. We also instruct to output not only the corrected text but also a hallucination detection label. The instruction is to output 1 if a hallucination is detected and 0 if not. When using CoT, we provide the text

string shown in red in Table 1, instructing to output the reasoning and correct the hallucination based on this reasoning.

Next, #Instructions describes the items to be observed when performing the task. This is important information for the LLM to accurately execute the task according to instructions. We expect that providing this information will stabilize the LLM's output format.

In #Specific Examples, we provide Few-shot examples. We provided 3 examples of entailment relations and 4 examples of contradiction relations, and gave instructions for the outputs when hallucinations were not detected and when they were detected. As shown in red in Table 1, when using CoT, we implement it by providing examples that output reasoning. We realize CoT by having the output explain where in the target sentence there are contradictions with the knowledge, and how these contradictory parts should be corrected.

Finally, by repeatedly providing #Tasks, we ensure that the LLM follows the task instructions more faithfully. This is based on reports that when long input is given to an LLM, information in the middle is less likely to be referenced, while information at the beginning and end is more easily referenced (Liu et al., 2024).

By designing such prompts, we can give clear instructions to the LLM and make it faithfully follow these instructions. As a result, it becomes possible to effectively correct hallucinations using only a SP.

4 Dataset

To effectively correct hallucinations, it is crucial to use hallucinations actually generated by LLMs. Cao et al. (2020); Kryscinski et al. (2020) have conducted correct tests using datasets that include artificially created hallucinations.

However, it has been reported that such datasets have a different distribution from hallucinations actually generated by LLMs (Balachandran et al., 2022). Therefore, it is difficult to evaluate whether LLMs can detect and correct actual hallucinations using artificially created ones. Considering this issue, we use a dataset constructed with hallucinations actually generated by LLMs.

4.1 Generated Hallucination Data Using LLM

Moriwaki et al. (2022) fine-tuned "hobbyist," a Transformer-based LLM with 1.6 billion parameters (Sugiyama et al., 2021), and extracted hallucination data from the generated texts to construct a Japanese dataset of hallucinations.

The corpus used for training is a travel agency dialogue corpus constructed by Kaneda et al. (2022). This corpus contains dialogues between two people, a travel agent and a customer, collected using crowd workers. The agent responds to the customer's questions while referencing knowledge about tourist destinations. Therefore, this corpus includes the customer's questions, the agent's responses, and the knowledge used to create these responses.

They trained the LLM to generate response sentences by inputting questions and reference knowledge using the travel agency dialogue corpus. For reference knowledge, they used the tourist destination database in "Rurubu DATA"[4] provided by JTB Publishing Co., Ltd. This database contains information on business hours, fees, access, tourist destination names, overviews, and reviews.

Based on the finding that LLMs are prone to hallucinations regarding numerical values and proper nouns, they focused on three categories: business hours, fees, and access. They input knowledge from these categories and prepared question sentences (e.g., "What time should I go?" "How much is the fee?") to the LLM, generated response sentences, and collected hallucination data.

To collect hallucination data more efficiently, they generated responses five times for each input. Through this process, they collected 50,000 outputs from 10,000 inputs.

4.2 Manual Hallucination Judgment

Moriwaki et al. (2022) conducted manual annotations on the 50,000 data points described in Section 4.1 to determine whether they were "hallucination" or "non-hallucination." Each data point consists of a question, knowledge, and text generated by an LLM. Annotators were asked to make relation and contradiction-implication judgments by examining the knowledge and generated text. Each data point was evaluated by 5 annotators.

In the relation judgment, annotators determined whether the information contained in the generated text was included in the knowledge. In the contradiction-implication judgment, they assessed whether the generated text contradicted or was implied by the provided knowledge. If both "contra-

[4]https://solution.jtbpublishing.co.jp/service/domestic/

diction" and "implication" could be selected, annotators were instructed to choose "contradiction."

From the collected judgment results, only data where 4 or more people selected "related" in the relation judgment, and 4 or more people selected either "implication" or "contradiction" in the contradiction-implication judgment were extracted as valid data.

The number of extracted data points is shown in Table 2. The 12,613 contradiction relations and 27,731 implication relations not enclosed in brackets indicate the number of valid data points.

5 Experiment

5.1 Experimental Overview

In this study, we conduct the following three comparative experiments to verify the effectiveness of hallucination correcting using SP:

1. Calculation time
2. Correcting accuracy
3. Effects of CoT on correcting accuracy

The experiments deal with hallucinations in a Japanese knowledge-grounded dialogue generation task. In this task, hallucination refers to the inclusion of content in the LLM-generated text (target sentence) based on reference knowledge that contradicts that knowledge. Therefore, the experiments verify whether the method can detect parts of the target sentence that contradict the knowledge and appropriately correct them based on the reference knowledge.

5.2 Correcting with SP

In this experiment, we use GPT-3.5-turbo as the LLM. We use the prompt shown in Table 1. Also, to reduce output randomness and obtain more focused results, we set the temperature to 0. This setting follows Li et al. (2023).

5.3 Correcting with MP

Similar to SP, MP also uses GPT-3.5-turbo as the LLM, with the temperature set to 0. The correcting process with MP follows these steps. The actual prompts used are shown in Appendix A.

1. Generate questions for which the target sentence is the answer, based on the knowledge and target sentence (A.1)
2. Generate answers based on the generated questions and knowledge (A.2)
3. Based on the knowledge, the target sentence, and the answer generated in Step 2, perform hallucination detection on the target sentence and output the detection label(A.3)
   (a) with CoT: Input the knowledge, target sentence, and the answer generated in step 2, and output the reasoning and hallucination detection label
4. If a hallucination is detected, input the knowledge, answer, and target sentence to correct the target sentence (A.4)
   (a) with CoT: If a hallucination is detected, input the knowledge, answer, reasoning output by the detector, and target sentence to correct the target sentence

5.4 Evaluation

To evaluate each method, we prepare hallucination data and non-hallucination data. Hallucination data is obtained from 12,613 Contradiction cases shown in Table 2, from which 150 cases in each category (access, fee, business hours) are randomly extracted, for a total of 450 cases. Non-hallucination data are taken from the 27,731 Implications shown in Table 2, with a total of 450 cases randomly extracted from 150 cases in each category. Then, to evaluate the reproducibility of the output, we apply the 900-item dataset five times repeatedly for each method and obtain the results.

The outputs of each method for the evaluation data are manually annotated. The outputs are annotated according to the Correcting Type shown in Table 11.

Then, using the annotation results, we calculate Faithfulness (Parikh et al., 2020). Faithfulness represents the proportion of outputs that are non-hallucination. We use this Faithfulness to comparatively evaluate the correcting accuracy of SP and MP. The formula for calculating Faithfulness differs depending on whether the input is non-hallucination or hallucination.

$$\text{Faithfulness} = \begin{cases} \dfrac{\#\text{NN} + \#\text{NCN}}{\#\text{N}} & (\text{Input} \in \text{N}) \\ \dfrac{\#\text{HCN}}{\#\text{H}} & (\text{Input} \in \text{H}) \end{cases}$$

#NN represents the number of cases where no correcting was made for non-hallucinations. #NCN and #HCN represent the number of instances

that were corrected from hallucination to non-hallucination, and from non-hallucination, respectively.

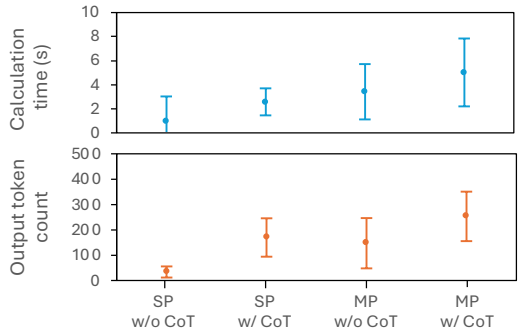

Figure 2: Compare each method in terms of calculation time and output token count. Paired t-tests revealed statistically significant differences at the 1% significance level for all comparisons.

Table 3: Comparison of mean Faithfulness between two methods with and without CoT. Faithfulness is calculated based on the output obtained by inputting non-hallucination and hallucination, using the formula defined in Section 5.4.

Input	hallucination	non-hallucination
SP w/o CoT	0.39	0.93
SP w/ CoT	0.61	0.93
MP w/o CoT	0.60	0.96
MP w/ CoT	0.49	0.96

6 Results

6.1 Calculation Time

Figure 2 shows the average calculation time and average number of output tokens for each method when a dataset of 900 instances was inputted five times. Comparing SP and MP and conducting a paired two-sided t-test revealed that SP has a shorter calculation time. SP with CoT had a shorter average calculation time than MP without CoT, and this difference was statistically significant ($t(4) = -6.14$, $p < 0.01$).

It was also revealed that correcting without CoT results in shorter calculation times. The difference with and without CoT in SP was statistically significant ($t(4) = -12.35$, $p < 0.01$). Similarly, the difference with and without CoT in MP was also statistically significant ($t(4) = -9.08$, $p < 0.01$).

When CoT is applied, the average output token count increases as it outputs the reasoning. This suggests that using CoT increases the number of output tokens, leading to longer calculation times. Furthermore, it was suggested that by integrating and unifying prompts, calculation time can be shortened, enabling efficient correcting.

6.2 Correcting Accuracy

Table 3 shows the comparison of correcting results using Faithfulness for the two methods with and without CoT. Table 3 results was the mean of five runs, with standard deviations ranging from 0.00 to 0.02. A corresponding two-sided t-test was performed for Faithfulness to confirm statistical significance.

In SP, with CoT led to a statistically significant improvement in Faithfulness for hallucinations. However, while Faithfulness in non-hallucination contexts decreased, this decrease was not statistically significant ($t(4) = 1.91$, $p = 0.13$).

In MP, with CoT resulted in a statistically significant decrease in Faithfulness in hallucinations ($t(4) = 21.58$, $p < 0.01$). Faithfulness in non-hallucinations also decreased, but this was not statistically significant ($t(4) = 1.00$, $p = 0.37$).

The results in Table 3 reveal that the effects of CoT vary significantly depending on the method used. It was found that while CoT is effective in SP, it is not effective in MP. As a result, SP outperformed MP in terms of Faithfulness in hallucinations.

7 Discussion

7.1 Correcting Accuracy Improvement of SP with CoT

The effectiveness with CoT in SP was analyzed using Table 4. This table shows the average results of annotations based on the Correcting Type defined in Section 5.4 for the corrected sentences generated by each method. Using this data, a paired two-tailed t-test was conducted to verify the correcting accuracy with CoT in SP, and to assess for any statistically significant differences.

In SP, it is believed that correcting with CoT makes it easier to perform corrections simultaneously with hallucination detection, which leads to an improvement in Faithfulness. The number of #HCH and #HH was higher for SP without CoT, with statistical significance (#HCH: $t(4) = 9.95$, $p < 0.01$, #HH: $t(4) = 33.09$, $p < 0.01$). On the other hand, the number of #HCN was higher for SP with CoT, with statistical significance ($t(4) = -50.48$, $p < 0.01$). This implies that with CoT, through

Table 4: Results of annotating the corrected sentences obtained by inputting 900 data points into each method 5 times and calculating the mean for each category, following Table 11. (Unit: count) In the output row, "N" indicates that no hallucination was included in the corrected sentence, and "H" indicates that a hallucination was included.

Category	HCN	HCH	HH	NCN	NCH	NN
Input	Hallucination (H)			Non-hallucination (N)		
Corrected	Yes	Yes	No	Yes	Yes	No
Output	N	H	H	N	H	N
SP w/o CoT	174.4	146.6	129.0	96.6	30.6	322.8
SP w/ CoT	274.8	125.2	50.0	114.0	33.4	302.6
MP w/o CoT	270.2	106.8	73.0	162.4	16.6	271.0
MP w/ CoT	220.2	108.2	121.4	54.2	18.6	377.4

Table 5: Among the data annotated with #HH, this shows the rate at which the target sentence was outputted verbatim. This represents the rate at which the model detected a hallucination but was unable to correct it.

	Verbatim Output Rate
SP w/o CoT	0.80
SP w/ CoT	0.15
MP w/o CoT	0.50
MP w/ CoT	0.90

Table 6: Accuracy comparison of different hallucination detection methods using various evaluation metrics (acc. = accuracy, rec. = recall, prec. = precision). Results are shown for Detection only, SP, and MP Methods, both with and without CoT.

		acc.	rec.	prec.	f-1
Detect only	w/o CoT	0.76	0.81	0.74	0.77
	w/ CoT	0.79	0.68	0.88	0.76
SP	w/o CoT	0.74	0.94	0.69	0.78
	w/ CoT	0.78	0.91	0.72	0.80
MP	w/o CoT	0.69	0.86	0.65	0.74
	w/ CoT	0.79	0.76	0.81	0.78

the generation of intermediate steps, suggests an improvement in the correcting accuracy of hallucinations.

This is also suggested by the proportion of #HH in SP without CoT. #HCH refers to data where correcting was performed on hallucination data but hallucination occurred in the corrected text, and #HH refers to data where "none" was output due to failure to detect hallucination, or where the input target sentence was output as is. Therefore, #HH contains a mix of data where hallucination was not detected and data where correcting could not be performed.

In #HH, the proportion of the target sentences that were output unchanged without being corrected is shown in Table 5. In SP without CoT, it accounts for 80.0%, and this difference is statistically significant when compared with SP with CoT. This result indicates that in SP without CoT, although hallucinations can be detected, it is difficult to correct them simultaneously, leading to a tendency to output the target sentences as they are.

7.2 Correcting Accuracy Decrease of MP with CoT

In MP, the introduction of CoT is thought to have lowered the detection metrics for hallucinations, which in turn made corrections difficult, leading to a decrease in Faithfulness.

The observed trend for each category showed that the counts of #HCN and #NCN were higher in MP without CoT, with a statistically significant difference (#HCN: $t(4) = 21.72$, $p < 0.01$; #NCN: $t(4) = 28.38$, $p < 0.01$). On the other hand, MP with CoT had a higher number of #HH and #NN cases, with statistical significance (#HH: $t(4) = -12.00$, $p < 0.01$, #NN: $t(4) = -22.45$, $p < 0.01$). The higher counts of #HH and #NN suggest that it becomes easier to detect non-hallucination instances.

This implies that detection with CoT in MP shifts the discrimination boundary towards hallucination, making it more likely to mistakenly detect non-hallucination instances as hallucinations. Consequently, it is suggested that with CoT, corrections become less feasible, resulting in fewer instances of #HCN and #NCN compared to without CoT.

The hallucination correcting accuracy can be evaluated by comparing the numbers of #HCH and #NCH cases. As a result, no statistical significance was found in the difference in the numbers of #HCH and #NCH cases with and without CoT ($t(4) = -1.00$, $p = 0.37$). Therefore, it is likely that CoT does not have a significant impact on the hallucination correcting accuracy itself.

From the above analysis, it was suggested that in MP, while CoT does not significantly change the hallucination correcting accuracy, it does make hallucinations more difficult to detect in terms of detection metrics. MP separates the detection and correcting processes, and if hallucination is not detected, it does not transition to the correcting process, making correcting impossible. Therefore, it is thought that with CoT, it became easier to misidentify hallucinations as non-hallucinations, resulting in an inability to correct hallucinations and a decrease in Faithfulness.

7.3 Effect of CoT on Hallucination Detection

To analyze the effectiveness of CoT in hallucination detection, we prepared a detection-only prompt. We analyzed the effectiveness of CoT using the detection labels output when using the detection-only prompt, SP, and the detection prompt in MP.

From the hallucination detection metrics results of each method shown in Table 6, it was confirmed that with CoT in all methods, accuracy and precision improve while recall decreases. This result suggests that while CoT contributes to improving the accuracy of hallucination detection, it tends to decrease recall.

While recall decreases in all methods, it became clear that SP is the method that can most effectively suppress the decrease in recall with CoT among the three methods. This result suggests that by unifying detection and correcting, more careful detection becomes necessary as it needs to consider the correcting process, enabling a more attentive detection and thus suppressing the decrease in recall that occurs with CoT.

In MP, where the detection and correcting processes are separated, it is important to increase recall and prevent hallucinations from being overlooked. However, as mentioned earlier, with CoT for hallucination detection tends to decrease recall, and in MP, this might lead to overlooking hallucinations. Consequently, this inability to correct hallucinations may result in a decrease in Faithfulness, as suggested.

In contrast, SP can minimize the decrease in recall that occurs with CoT. The unification of the detection and correcting processes helped suppress the decrease in recall, which in turn reduced the oversight of hallucinations, leading to an improvement in Faithfulness with CoT. This suggests that SP is an approach that mitigates the problem of decreased recall associated with CoT, thereby enhancing detection metrics and Faithfulness.

8 Conclusion

In this study, we proposed a hallucination correcting method that requires less calculation time and is more accurate than the method using SP, and verified its effectiveness. The core of this method lies in having the LLM simultaneously detect and correct hallucinations with only SP, thereby efficiently achieving hallucination correcting.

To verify the effectiveness of the proposed method, we conducted comparative experiments with MP, focusing on calculation time and Faithfulness. The experimental results yielded the following findings:

1. It was confirmed that SP can significantly reduce calculation time while achieving Faithfulness equal to or better than MP.

2. With CoT, SP's Faithfulness was proven to further improve.

3. SP was found to excel in its ability to minimally suppress the decrease in recall observed with CoT in hallucination detection.

On the other hand, it was suggested that in MP, with CoT, the discrimination boundary of hallucination detection shifted more towards hallucination, making it easier to misidentify non-hallucinations, resulting in a decrease in Faithfulness.

The results of this study reduced the time required for correcting hallucinations and improved correcting accuracy, providing important insights into tasks that require real-time processing. Furthermore, by presenting a new perspective on the effective use of CoT, this study may contribute to the improvement of hallucination detection using LLMs and correcting tasks in general.

Limitation

This research has the following limitations:

- The study focuses on correcting hallucinations in Japanese. Addressing hallucinations in other languages remains a subject for future research.
- The necessary knowledge was already included in the dataset used, eliminating the need to search for or retrieve information from external sources. However, in practical applications, there may be cases where knowledge needs to be acquired externally, and the associated processing costs have not been considered in this study.
- The research addressed the correcting of relatively short hallucinations consisting of 1-3 sentences, confirming that using a single prompt improved accuracy. However, the correcting of more complex hallucinations in longer texts or list formats remains a topic for future research.
- The study focuses solely on hallucinations related to numerical values and proper nouns. Future research should explore the applicability of the proposed method to other types of hallucinations.
- This study limited its verification to hallucinations in dialogue data. Moving forward, it is important to verify the versatility of the proposed method by applying it to hallucinations across various tasks.

Acknowledgements

This research originated from valuable discussions with Mr. Tomoki Morikawa and Mr. Kazuma Enomoto. I am deeply grateful for their significant contributions to this work. I would also like to express my sincere gratitude to Mr. Yoshiki Tomita, Mr. Nozomi Kimata, and Mr. Jundai Suzuki for their invaluable assistance with the annotation work. Their careful and precise work substantially enhanced the quality of this study.

A Prompts Used in MP

A.1 Question Generation Phase

Table 7 shows the prompt used in the question generation phase for MP. In this phase, possible questions are generated from the target sentence. For example, for the target sentence "The entrance fee for university students is 630 yen," it generates the question "How much is the entrance fee for university students?." The questions obtained in this phase are used to generate answers in the subsequent answer generation phase.

A.2 Answer Generation Phase

Table 8 shows the prompt used in the answer generation phase for MP. In this phase, answers are generated by referencing knowledge in response to the questions obtained from the previous question generation phase. The answers obtained in this phase are used to detect hallucinations by comparing them with the target sentence in the subsequent detection phase.

A.3 Hallucination Detection Phase

Table 9 shows the prompt used in the hallucination detection phase for MP. In this phase, the answers obtained from the answer phase are compared with the target sentence to detect if there are any contradictions in the target sentence. As shown in red in Table 9, CoT is used. The output determines whether the target sentence and the answer have an implication or contradiction relationship. If there's a contradiction relationship, it outputs the reason why and where the contradiction exists, thus performing hallucination detection. If a hallucination is detected in this phase, it transitions to the subsequent correcting phase. With CoT, both the reasoning and the judgment label are used in the correcting phase. Without CoT, only the judgment label is used in the correcting phase.

A.4 Hallucination Correcting Phase

Table 10 shows the prompt used in the answer generation phase for MP. In this phase, hallucination correcting is performed using the output obtained from the previous phase. With CoT, the target sentence is corrected based on the knowledge, answer sentences, and reasoning. Without CoT, the target sentence is corrected based on the knowledge and answer sentences.

B About Categories

We explain the categories using Table 11. For non-hallucination data, there are three categories: #NN, #NCN, and #NCH. #NN is the category for data where "None" was output, or the input target sentence was output as is. #NCN is the category for data where correcting was performed, and the corrected sentence is non-hallucination. #NCH is the category for data where correcting was performed, and the corrected sentence is hallucination.

For hallucination data, there are three categories: #HH, #HCN, and #HCH. #HH is the category for data where "None" was output, or the input target sentence was output as is. #HCN is the category for data where correcting was performed, and the corrected sentence is non-hallucination. #HCH is the category for data where correcting was performed, and the corrected sentence is hallucination.

Table 7: Prompt for the answer generation phase in MP. The text shown here is the English translation of the Japanese original.

#Tasks
• You should generate questions from the target sentence.
• Generate questions for which the given target sentence would be the answer.
• Absolutely follow the content of the instructions.

#Instructions
• Strictly adhere to the output format.
• You may break down the target sentence and output multiple questions.
• Please refer to the following specific examples.

#Specific Examples
##Example 1
##Input
Target sentence: It's a 5-minute walk from Susukino Station or a 25-minute walk from Sapporo-kita IC (Kita-ku) on the Sasson Expressway.
##Output
Question 1: How long does it take from Susukino Station?
Question 2: How long does it take from Sapporo-kita IC (Kita-ku) on the Sasson Expressway?
• • •

#input/output
##Input
Target sentence: {target sentence}
##Output

To reiterate, you should complete the following tasks: #Tasks You should generate questions from the target sentence. Generate questions for which the given target sentence would be the answer. - Absolutely follow the content of the instructions.

Table 8: Prompt for the answer generation phase in MP. The text shown here is the English translation of the Japanese original.

#Tasks
• You should answer the given questions based on the provided knowledge.

#Instructions
• There may be more than one question given; there could be multiple questions.
• If there are multiple questions, answer all of them.
• Strictly adhere to the output format.
• Do not output the content of the input.
• Only output the answers.
• Please refer to the following specific examples.

#Specific Examples
##Example 1
##Input
Question 1: How much is the fee?
Knowledge: Adults (15 years and older) 1900 yen, Children (Elementary and Junior High School students) 950 yen, Infants (3-5 years old) 300 yen, Seniors (65 years and older) 1100 yen
##Output
Answer 1: For 15 years and older, it's 1900 yen; for elementary and junior high school students, 950 yen; for infants, 300 yen; and for seniors, 1100 yen.
• • •

#input/output
##Input
Question: {question}
Knowledge: {knowledge}
##Output

To reiterate, you should complete the following tasks: #Tasks To repeat, please absolutely follow these rules: There may be more than one question given; there could be multiple questions. If there are multiple questions, answer all of them. Strictly adhere to the output format. Do not output the content of the input. Only output the answers.

Table 9: Prompt for the hallucination detection phase in MP. The text shown here is the English translation of the Japanese original. The red characters indicate the strings of characters used when using CoT.

#Tasks

• You can infer whether the target sentence has a contradiction or implication relationship with the knowledge and answer sentences.
• Output the reasoning for determining if there are contradictions between the knowledge and target sentence, and based on this reasoning, output a judgment label.
• Outputting a 0 label means the knowledge and target sentence have an implication relationship.
• Outputting a 1 label means the knowledge and target sentence have a contradiction relationship.
• If there's a contradiction relationship between the knowledge, answer sentences, and target sentence, output the reasoning for where the target sentence contradicts or contains extra information, and based on this reasoning, output a judgment label.
• Perform the detection based on this reasoning.

#Instructions

• Always follow the rules.
• Strictly adhere to the output format.
• Make judgments based on the reasoning.
• Detect any contradictions between the answer sentences and target sentence based on the knowledge.
• Output 0 if the knowledge, answer sentences, and target sentence have an implication relationship.
• Output 1 if there are contradictions between the knowledge, answer sentences, and target sentence
• Carefully examine the knowledge, answer sentences, and target sentence to determine if there's a contradiction or implication relationship and output the label.
• Please refer to the following specific examples.

#Specific Examples

##Specific Example 1 (Implication Relationship)
##Input
Knowledge: Business hours: 10 AM to 10 PM (until 9 PM from January to March), admission until 20 minutes before closing, No regular holidays
Answer 1: The business hours are from 10 AM to 10 PM. Admission is until 20 minutes before closing. We are open every day.
Target sentence: Admission is until 20 minutes before closing.
##Output
Reasoning: The target sentence "Admission is until 20 minutes before closing." does not contradict Answer 1 "The business hours are from 10 AM to 10 PM. Admission is until 20 minutes before closing. We are open every day."
Judgment: 0
• • •

#Specific Example 7(Contradiction Relationship)
##Input
Knowledge: (1) 5-minute walk from JR Onuma-Koen Station (2) 15 minutes from Doo Expressway Onuma-Koen IC
Answer 1: It's a 5-minute walk from JR Onuma-Koen Station.
Answer 2: It's 15 minutes from Doo Expressway Onuma-Koen IC.
Target sentence: It's a 5-minute walk from JR Onuma-Koen Station or a 15-minute walk from Doo Expressway Onuma-Koen IC.
##Output
Reasoning: The part of the target sentence "15-minute walk from Doo Expressway Onuma-Koen IC" contradicts Answer 2 "15 minutes from Doo Expressway Onuma-Koen IC". The information "15-minute walk" is inconsistent. Therefore, it needs to be corrected to "15 minutes from Doo Expressway Onuma-Koen IC."
Judgment: 1

#input/output

##Input
Knowledge: {knowledge} Answer sentence: {answer sentence} Target sentence: {target sentence}
##Output

To reiterate, you should complete the following tasks: #Tasks You can infer contradictions and implication relationships between knowledge and target sentences. Detect any contradictions between the answer sentences and target sentence based on the knowledge. If there are no contradictions between the answer sentences and target sentence, output 0. If there are contradictions between the answer sentences and target sentence, output 1.

Table 10: Prompt for the hallucination correcting phase in MP. The text shown here is the English translation of the Japanese original. The red characters indicate the strings of characters used when using CoT.

#Tasks
• You can correct contradictions in the target sentence based on the knowledge and answer sentences derived from that knowledge.
• Use the detector's output to correct the contradiction parts.
• Make corrects based on the reasoning provided.

#Instructions
• Always follow the rules.
• Strictly adhere to the output format.
• Only output the corrected sentence.
• Correct any contradictions in the target sentence by referring to the knowledge and answer sentences.
• Please refer to the following specific examples.

#Specific Examples
##Specific Example 1 (Contradiction Relationship)
##Input
Knowledge: Operating hours: 10:00 AM to 7:00 AM the next day, Closed: Never
Answer 1: The operating hours are from 10:00 AM to 7:00 AM the next day. It's open every day.
Target sentence: It's from 10 AM to 7 PM.
##Detector Output
Reasoning: The target sentence "It's from 10 AM to 7 PM" states 7 PM, but Answer 1 "The operating hours are from 10:00 AM to 7:00 AM the next day. It's open every day." indicates 7:00 AM the next day. Therefore, the target sentence contradicts the knowledge. As a result, the target sentence needs to be corrected to "It's from 10 AM to 7 AM the next day."
Judgment: 1
##Output
Correcting: It's from 10 AM to 7 AM the next day.
• • •

###Specific Example 4 (Contradiction Relationship)
##Input
Knowledge: (1) 5-minute walk from JR Onuma-Koen Station (2) 15 minutes from Doo Expressway Onuma-Koen IC
Answer 1: It's a 5-minute walk from JR Onuma-Koen Station.
Answer 2: It's 15 minutes from Doo Expressway Onuma-Koen IC.
Target sentence: It's a 5-minute walk from JR Onuma-Koen Station or a 15-minute walk from Doo Expressway Onuma-Koen IC.
##Detector Output
Reasoning: The part of the target sentence "15-minute walk from Doo Expressway Onuma-Koen IC" contradicts Answer 2 "15 minutes from Doo Expressway Onuma-Koen IC". The information "15-minute walk" is inconsistent. Therefore, it needs to be corrected to "15 minutes from Doo Expressway Onuma-Koen IC."
Judgment: 1
##Output
Correcting: It's a 5-minute walk from JR Onuma-Koen Station or 15 minutes from Doo Expressway Onuma-Koen IC.

#input/output
##Input
Knowledge: {knowledge} Answer sentence: {answer sentence} Target sentence: {target sentence} Detector Output: {detector output}
##Output

To reiterate, you should complete the following tasks: #Tasks Only output the corrected sentence. Strictly adhere to the output format. Correct any contradictions in the target sentence by referring to the knowledge and answer sentences.

Table 11: An example of a corrected sentence output by the corrector. The categories represent the types of corrects made to the corrected sentence. We manually annotated the sentences based on the types of corrects.

Knowledge	Target Sentence	Corrected Sentence	Correcting Type	Category
Temple grounds free (Main hall entrance fee is 500 yen)	The temple grounds are free, and the main hall entrance fee is 700 yen.	The temple grounds are free, and the main hall entrance fee is 500 yen.	Corrected hallucination data, no hallucination in the corrected sentence.	HCN
		There is a 500 yen entrance fee for both the temple grounds and the main hall.	Corrected hallucination data, created another hallucination.	HCH
		None or The temple grounds are free, and the main hall entrance fee is 700 yen.	Hallucination data not corrected.	HH
Temple grounds free (Main hall entrance fee is 500 yen)	The temple grounds are free, and the main hall entrance fee is 500 yen.	The temple grounds are free, but there is a 500 yen fee for entering the main hall.	Corrected non-hallucination data, no hallucination in the corrected sentence.	NCN
		The temple grounds are free, but there is a 1500 yen fee for entering the main hall.	Corrected non-hallucination data,, created hallucination.	NCH
		None or The temple grounds are free, and the main hall entrance fee is 500 yen.	Non-hallucination data not corrected.	NN

Towards Building Efficient Sentence BERT Models using Layer Pruning

Abstract

This study examines the effectiveness of layer pruning in creating efficient Sentence BERT (SBERT) models. Our goal is to create smaller sentence embedding models that reduce complexity while maintaining strong embedding similarity. We assess BERT models like Muril and MahaBERT-v2 before and after pruning, comparing them with smaller, scratch-trained models like MahaBERT-Small and MahaBERT-Smaller. Through a two-phase SBERT fine-tuning process involving Natural Language Inference (NLI) and Semantic Textual Similarity (STS), we evaluate the impact of layer reduction on embedding quality. Our findings show that pruned models, despite fewer layers, perform competitively with fully layered versions. Moreover, pruned models consistently outperform similarly sized, scratch-trained models, establishing layer pruning as an effective strategy for creating smaller, efficient embedding models. These results highlight layer pruning as a practical approach for reducing computational demand while preserving high-quality embeddings, making SBERT models more accessible for languages with limited technological resources.

1 Introduction

Language models have evolved significantly in recent years. Although RNNs were once popular, they lack context embedding. Transformers (Vaswani et al., 2023) have emerged as superior, offering parallel processing for faster sequence handling and greater memory efficiency by utilizing position embeddings. Notably, BERT (Devlin et al., 2018), a leading language model, adopts the Transformer architecture, significantly improving performance across a range of NLP tasks by capturing deep contextual relationships within text.

BERT's architecture is built upon a multi-layer bidirectional Transformer encoder, drawing from the foundational framework of transformers (Vaswani et al., 2023).$BERT_{BASE}$ (Devlin et al., 2018) is endowed with 110 million parameters, whereas $BERT_{LARGE}$ boasts 340 million parameters. The deployment of BERT models remains challenging in resource-constrained environments typical of many low-resource languages due to their substantial computational demands.

While BERT excels at capturing contextualized word embeddings, it doesn't directly provide sentence-level representations. SBERT (Reimers and Gurevych, 2019) addresses this limitation by modifying BERT's architecture to efficiently generate sentence embeddings. SBERT accomplishes this through the use of siamese and triplet network structures.The modification introduced by SBERT makes the BERT model more complex by extending its capabilities beyond word-level embeddings to include sentence-level representations. This added complexity enables BERT to capture higher-level semantic information and relationships between entire sentences, enhancing its utility in a wider range of natural language processing tasks.

These fine-tuned BERT models, with their large number of parameters, present challenges for low-capability devices or applications with strict latency requirements due to their resource-intensive nature. Various model compression techniques, including pruning, quantization, knowledge distillation, and architectural modifications, have been employed on BERT (Ganesh et al., 2021) to decrease the model size and computational demands, thereby increasing computation latency.

Building on the efforts to address the challenges posed by resource-intensive BERT models, our research delves into reducing the complexity of SBERT models without compromising performance. Layer pruning, which involves selectively removing less critical parts of the neural network, offers a promising solution for enhancing the efficiency of SBERT models. This is especially important for processing languages within environments

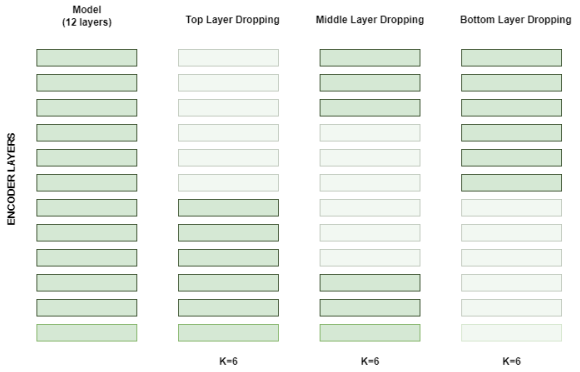

Figure 1: Layer Pruning Strategies.

constrained by limited computing infrastructure.

Model pruning, specifically layer pruning, seeks to address the inefficiencies related to the size and complexity of models like BERT, SBERT. The objective is to reduce the model's size and computational demands while maintaining or enhancing its performance. Techniques vary from removing individual neurons to whole layers. In the context of transformer-based models, a study (Fan et al., 2019) demonstrated that strategic layer removal could reduce model size substantially with minimal impact on performance.

In our research, we delve into recent developments in adapting Sentence-BERT (SBERT) models for low-resource languages, focusing particularly on Marathi and Hindi. The L3Cube-MahaSBERT and HindSBERT (Joshi et al., 2022) models were established as benchmarks for generating high-quality sentence embeddings in Marathi and Hindi, respectively. These specialized models are highlighted for their effectiveness in processing these low-resource languages. These models have been rigorously trained and evaluated across various NLP tasks, including text classification and semantic similarity.

Our research aims to extend these foundational models by applying layer-pruning techniques to enhance their efficiency without compromising the quality of the embeddings. By integrating layer pruning, we seek to reduce the computational demand and improve the operational feasibility of deploying SBERT models in real-world applications, making advanced NLP tools more accessible for languages that traditionally have fewer technological resources.

- A research (Sajjad et al., 2022) has showcased a range of layer pruning strategies, underscoring their effectiveness. These techniques maintain an impressive 98% of the original performance even after removing 40% of the layers from BERT, RoBERTa, and XLNet models.

- Expanding upon these findings, we applied several layer pruning methods such as top-layer pruning, middle-layer pruning, and bottom-layer pruning to SBERT models, as illustrated in the accompanying figure 1. In this context, the parameter "k" represents the number of layers removed from the original model.

- After evaluating all three approaches, we discovered that top-layer pruning yielded the best performance. Therefore, we chose top-layer pruning for our subsequent experiments. To further test the performance of these pruned models, we fine-tuned them using NLI+STS training.

- We compare 2-layer and 6-layer models created through layer pruning of MahaBERT-v2 with similar-sized models trained from scratch, such as MahaBERT-Small and MahaBERT-Smaller. Our observations show that the pruned models consistently outperform the scratch-trained models. Therefore, we recommend layer pruning followed by SBERT-like fine-tuning to create smaller embedding models, rather than training smaller models from scratch and then applying SBERT-like fine-tuning, which is highly computationally intensive.

- Remarkably, these fine-tuned pruned models demonstrate competitive performance compared to larger models, despite being 50% to 80% smaller in size.

2 Related Work

This section discusses the progression of transformer-based models, with a specific focus on their optimization for enhanced efficiency and application in resource-constrained environments.

Introduced by (Devlin et al., 2019) BERT revolutionized NLP tasks by employing a bidirectional training of Transformer, a novel architecture that was originally used in the paper (Vaswani et al., 2023) thereby encapsulating a deeper contextual understanding. The paper (Reimers and Gurevych,

2019) introduces Sentence-BERT (SBERT), a modification of the original BERT model that uses Siamese and triplet network structures to efficiently generate sentence embeddings for enhanced performance in semantic similarity tasks.

(Zhu and Gupta, 2017) evaluates the impact of different pruning techniques on neural network compression and performance across various models and tasks. As discussed in their (Fan et al., 2019), it has been shown that carefully targeted removal of layers can significantly decrease the size of a model while having only a minimal effect on its performance. Furthermore, the study by (Michel et al., 2019), titled "Are Sixteen Heads Really Better than One?" shows that many attention heads in transformers can be pruned without significant degradation in capabilities, highlighting the redundancy in these models.

We explore research aimed at enhancing the efficiency of transformer models, particularly through model compression techniques. Key studies in this area include (Hubara et al., 2016) and (Jiao et al., 2020), which provide valuable insights into designing more efficient models without significant loss in performance. The main goal of TinyBERT is to distill the knowledge from a large pre-trained language model, such as BERT, into a smaller model, while maintaining performance.

Additionally, we delve into the literature on layer pruning techniques, which specifically address methods for optimizing neural network architectures by identifying and removing redundant or less important layers. In this domain, valuable strategies have been employed for reducing the computational burden of neural network models through systematic layer pruning approaches (Liu et al., 2017). An iterative algorithm (Pietron and Wielgosz, 2020) is introduced for layer pruning, reducing storage demands in pre-trained neural networks. It selects layers based on complexity and sensitivity, applying reverse pruning if accuracy drops.

Layer pruning reduces resource usage in CNNs by eliminating entire layers based on their importance estimated through PLS projection (Jordao et al., 2020). It can be followed by filter-oriented pruning for additional compression. Structured pruning (He and Xiao, 2024) encompasses a range of techniques such as filter ranking methods, dynamic execution, the lottery ticket hypothesis, etc. Layer-wise pruning ratios extend traditional weight pruning strategies by focusing on determining the optimal pruning rate for each layer.

Another method for layer-wise pruning based on feature representations (Chen and Zhao, 2019) is introduced. Unlike conventional methods that prune based on weight information, this approach identifies redundant parameters by examining the features learned in convolutional layers, operating at a layer level. A novel approach called layer-compensated pruning (Chin et al., 2018) incorporates meta-learning to address both how many filters to prune per layer and which filters to prune. Tests on ResNet and MobileNetV2 networks across multiple datasets validate the algorithm's effectiveness.

3 Methodologies

SBERT models are known for their complexity and large size. Fig. 2 depicts the process of training a smaller SBERT (Sentence-BERT) model using a technique known as layer pruning. Starting with the original SBERT base model, which consists of multiple layers, the process involves systematically removing certain layers to create a pruned version of the model. This layer-wise pruning aims to reduce the model's complexity without significantly compromising its performance.

Our initial experiments focused on identifying the most effective layer-pruning strategy to optimize the model's performance. We explored several pruning methods, including top-layer pruning, middle-layer pruning, and bottom-layer pruning as shown in 1, to evaluate their impact on model's efficiency and accuracy. Each strategy was tested by removing a specified number of layers, denoted by the parameter "k", from different positions in the model. This approach allowed us to systematically assess how the removal of layers affected the overall performance and computational requirements.

The pruned model is then fine-tuned through two specialized training phases: Natural Language Inference (NLI) training and Semantic Textual Similarity (STS) training. NLI training improves the model's ability to understand logical relationships between sentence pairs, categorizing them as entailment, contradiction, or neutral, whereas STS training focuses on assigning similarity scores to sentence pairs, enhancing the model's ability to gauge semantic closeness. By integrating NLI pre-training and STS fine-tuning, a robust training framework is established for SBERT models.

Following the fine-tuning, the pruned model

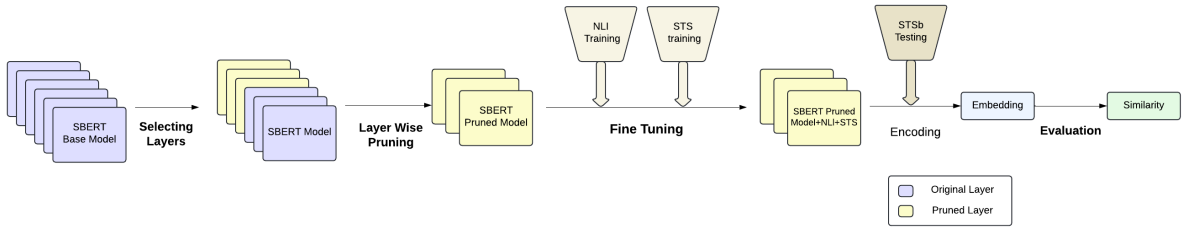

Figure 2: Layer Pruning on SBERT model

Training Methods	Top-layers pruning(1-6)	Middle-layers pruning(4-9)	Bottom-layers pruning(7-12)
NLI	0.7098	0.6912	0.6954

Table 1: Comparison of embedding similarity scores for various layer pruning strategies: Top, Middle, and Bottom layers during NLI training.

which is integrated with NLI and STS training is tested for its performance on the Semantic Textual Similarity benchmarks (STSb testing) dataset. This phase evaluates how effectively the model calculates the similarity between sentences. The final steps involve encoding these sentences into embeddings and evaluating their similarity and assessing the pruned model's accuracy and efficiency. Thus Fig.2 depicts a clear pathway from model complexity reduction through pruning to performance evaluation via embedding and similarity assessments.

Dataset

3.0.1 IndicXNLI [1]

IndicXNLI5 comprises data from the English XNLI dataset that has been translated into eleven Indic languages including Marathi.(Aggarwal et al., 2022) This includes translation of the training (392,702 entries), validation (2,490 entries), and evaluation sets (5,010 entries) from English into each of the eleven languages. From the IndicXNLI dataset, the training samples specific to each language are used to train the MahaSBERT models.

3.0.2 STS benchmark(STSb) [2]

It comprises data from the English XNLI dataset that has been translated into eleven Indic languages including Marathi. This includes translation of the training (392,702 entries), validation (2,490 entries), and evaluation sets (5,010 entries) from English into each of the eleven languages. From the IndicXNLI dataset, the training samples specific to each language are used to train the MahaSBERT models. It has been made publicly accessible.[3]

In our experiments, we specifically utilized the translated Marathi dataset to fine-tune the pruned SBERT models, ensuring the models were optimized for the Marathi language. This approach allowed us to directly target language-specific nuances and enhance the model's performance on tasks relevant to Marathi.

3.1 EXPERIMENT

Referring to the procedures outlined in Fig.2 our experiment evaluates the performance of several SBERT models Muril, MahaBert v2, MahaBert Small, and MahaBert Smaller both before and after the application of layer pruning.

3.1.1 Best Layering Strategy Selection

To identify the most effective pruning strategy, we systematically evaluated the performance of each pruned model configuration using multiple criteria, including accuracy, model size, and computational efficiency. By experimenting with various layer combinations such as the first 6 layers, the middle 6 layers, and the bottom 6 layers we aimed to balance the trade-offs between reducing model complexity and preserving performance. Each combination was assessed on the 12-layer MahaBert v2 model using a validation set, focusing on its impact on natural language understanding tasks in Marathi through NLI training. The top-layers pruning strategy yielded the highest accuracy scores compared to other configurations. Based on these results,

MahaBert-v2	12	2	0.6760	**0.7447**
Muril	12	2	0.6880	0.7284
MahaBert-small	6	6	0.6693	0.7422
MahaBert-v2	12	6	0.7098	**0.7878**
Muril	12	6	0.6849	0.7742
MahaBert-v2	12	12	0.7720	**0.8320**
Muril	12	12	0.7488	0.8165

Table 2: Embedding similarity scores from two-step NLI+STS Training on SBert Models

we selected the top-layer pruning strategy for our further experiments.

3.1.2 Layer Pruning

Layer pruning was conducted on the base models Muril, MahaBERT, MahaBERT-Small, and MahaBERT-Smaller to explore various layer combinations and analyze the resulting changes in model performance and complexity. For models like Muril and MahaBERT consisting of 12 layers, we considered different layer subset combinations such as 2, 6 and 12 layers.

3.1.3 Fine Tuning

After obtaining the pruned SBERT model we fine-tuned the model in two phases of training. We first performed NLI training on the model using the Marathi dataset of IndicXNLI and then used the translated STSb train dataset as the second step for training. Thus the pruned model was trained using two steps to obtain the fine-tuned model targeting the Marathi language.

3.1.4 Evaluation

For evaluating the pruned SBERT model which has undergone NLI+STS training we find the embedding similarity scores using Translated STSb Marathi test dataset. On the obtained embeddings we apply the KNN Classifier algorithm to obtain Similarity scores. For classification, we use the IndicNLP News Article Classification dataset targeting the Marathi language.

4 Results

Following layer pruning and two-step NLI+STS training on SBert models, Table 2 shows the embedding similarity scores obtained from various models. The outcomes display similarity scores between 0.72 and 0.83 for different combinations of layers. Notably, the pruned MahaBert-Small model (2 layers) achieved performance comparable to the base model (6 layers), indicating that layer reduction does not necessarily compromise embedding quality. Additionally, the application of NLI+STS fine-tuning greatly enhances similarity scores for all models.

Our experiments demonstrated that models with fewer layers, achieved through layer pruning, can still yield competitive embedding similarity scores. For instance, models with just 2 or 6 layers performed comparably to their fully layered counterparts after undergoing two-phase fine-tuning (NLI followed by STS training). This indicates that there is no necessity to train large, computationally intensive models when pruned models can offer similar performance. These findings suggest that layer pruning is an effective technique for enhancing model efficiency without compromising the quality of embeddings. This approach helps achieve better accuracy while leveraging the advantages of model pruning.

5 Conclusion

Our primary aim was to identify layering configurations that reduce complexity while maintaining strong performance in terms of embedding similarity scores. Our experiments demonstrated that pruned SBERT models, with fewer layers, can achieve performance comparable to their fully layered counterparts. Thus with comparative scores obtained from pruned models we can conclude that pruned models have outperform models i.e. MahaBERT-Small and MahaBERT-Smaller, which are built from scratch. Therefore, instead of developing new models from the ground up, it is more

effective to start with a larger model and apply pruning techniques.

By reducing computational demand and maintaining high-quality embeddings, our approach makes advanced NLP tools more accessible and operationally feasible, particularly for languages with fewer technological resources.

In the long term, this work highlights the potential for layer-pruned SBERT models to be adapted for diverse NLP tasks, such as text classification, question answering and even more complex tasks such as Information Retrieval with Retrieval-Augmented Generation(RAG). By integrating RAG,the pruned models are not only more computational efficient but also capable of retrieving relevant information dynamically. This combined approach of pruning and augmentation extends the model's applicability across a broad range of tasks, making advanced NLP capabilities more accessible and adaptable to real-world, resource constrainted applications.

Japanese Term Selection for Stock Price Fluctuation by Large Language Models

Takehito Utsuro and **Shunsuke Nishida**

Graduate School of Science and Technology, University of Tsukuba
{utsuro.takehito.ge, s2320778}_@_u.tsukuba.ac.jp

Abstract

In Japanese articles on stock price fluctuations, technical terms in the stock domain are frequently used to precisely describe stock price fluctuations. We proposed the methods for the selection of such terms that appropriately represent the characteristics of stock price fluctuations and conducted evaluation by feeding closing prices to large language models and a chart of stock price fluctuations over several days to large multimodal models. The results showed that, with high accuracy, all the models were able to select terms that are manually assigned by human writers in stock price fluctuation articles or those with similar meanings to them. It suggests the potential to generate stock price fluctuation articles containing appropriate terms from time series stock price data and text of articles in which stock price fluctuations are not directly mentioned but are related to them. The results also showed that the method of conducting few-shot learning with GPT-4o exhibited the highest accuracy in term selection among other approaches.

1 Introduction

News articles reporting stock price fluctuations are useful in providing information not only about how much stock prices have risen or declined but also in understanding the factors influencing price fluctuations, such as announcements of new products and social conditions. Although such articles are usually written manually, it is desirable that they are generated automatically in large quantities. This can be realized when information regarding any cause closely related stock price fluctuations as well as events on relevant companies are automatically collected through the Internet and aggregated, from which stock price fluctuation articles texts are automatically generated. Once those technologies are broadly available, it is then ensured that we can avoid spending any manual effort writing those stock price fluctuation articles, allowing us to redirect the effort spent on article generation towards investment decisions, fluctuation predictions, and actions that maximize economic profits. With such an environment, economic activities can be significantly accelerated.

In Japanese articles on stock price fluctuations, technical terms related to stocks are often used. In particular, stock terms describing stock price fluctuations (henceforth, stock price fluctuation terms) are frequently used, and they are used differently depending on the magnitude and continuity of stock price fluctuations. For example, in the case of a rise in stock price, there is a distinction between "急伸 (sharp rise)" when the stock price rises sharply and suddenly and "続伸 (continuous rise)" when the stock price rises continuously. In the process of automatically generating stock price fluctuation articles, it is crucial to analyze time series data of stock prices automatically and to use the terms correctly based on subtle nuances of their meanings.

In this paper, we addressed this issue by using large language models (LLMs) (GPT-4o (OpenAI, 2024), Claude 3.5 Sonnet and Gemini 1.0 Pro) and a large multimodal model (LMM) (GPT-4V (OpenAI, 2023; Yang et al., 2023)). We proposed how to design the procedures of selecting technical terms that appropriately represent the characteristics of stock price fluctuations and conducted evaluation. The results showed that, with high accuracy, all the models were able to select terms that were manually assigned by human writers in stock price fluctuation articles or terms with similar meanings. Furthermore, the method of conducting fine-tuning with GPT-4o exhibited the highest accuracy in term selection among other approaches.

The following briefly summarizes the contributions of this paper.

1. It was revealed that the accuracies of converting stock price fluctuation data into corresponding stock terms using LLMs and an

LMM were relatively high around 90%.

2. It was demonstrated that the method of conducting fine-tuning with GPT-4o exhibited the highest accuracy in term selection among other approaches.

2 Related Work

Various studies were conducted on "data to text" tasks that interpret data and generate text describing the contents. Among them, several approaches were made for the task of generating text from time series stock price data, as in this study.

Murakami et al. (2017) proposed an encoder-decoder model as a method for automatically generating market comments from short-term and long-term *Nikkei Stock Average data*. They compare the performance when CNN, MLP and RNN are used as the encoder. Aoki et al. (2021) addressed the issue of controlling text generation by inputting topic labels that represent the content of the generated sentences in addition to stock price data. While these studies aim to generate sentences, this study focuses specifically on the generation (selection) of stock price fluctuation terms.

Zhang et al. (2018) proposed methods that utilize probability models to select verbs representing stock price fluctuations from the volatility. Sekino and Sasaki (2022) also proposed to use an MLP encoder model to choose words describing stock price movements and volatility based on the closing price trends of the *Nikkei Stock Average* and *Dow Jones Industrial Average*.

Unlike the aforementioned related studies, all of which take numerical data as input, this paper differs in that we further study incorporating a multimodal model. In this approach, the model is designed to generate (select) stock price fluctuation terms based on stock price chart images.

In the context of studies on news article headlines and stock prices, Nishida et al. (2023) studied the task of headlines generation of stock price fluctuation articles, derived from the articles' content, where they solve three distinct tasks of generating article headlines, extracting the stock names, and ascertaining the trajectory of stock prices, whether they are rising or declining. Tsutsumi and Utsuro (2022) studied the issue of detecting causes of stock price rise and decline from the stock price fluctuation articles by machine reading comprehension models. In the context of stock price prediction using news headlines, Kalshani et al. (2020) studied to combine news headlines with technical indicators to predict stock prices. Chen (2021) studied to predict the short-term movement of stock prices after financial news events using only the headlines of the news. Kalyani et al. (2016) proposed a method for stock trend prediction using news. Two other approaches evaluate different machine learning and deep learning methods, such as Support Vector Machines (SVM) and Long Short-term Memory (LSTM), to predict stock price movement using financial news (Liu et al., 2018; Gong et al., 2021).

93	55	53	28	59

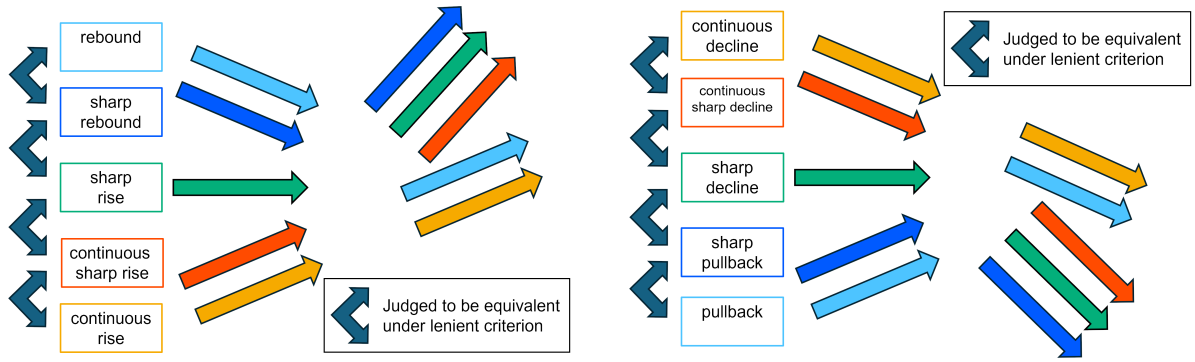
Table 1: Number of articles for each stock price fluctuation term (568 articles in total)

3 Stock Price Fluctuation Terms

Stock price fluctuation terms in this paper are intended to be regarded as the terminology in the stock domain that are used to describe stock price fluctuations. "急伸 (sharp rise)" and "続伸 (continuous rise)" given as examples in section 1 are also included in the stock price fluctuation terms.

It is expected to maximize the advantages of using LLMs / an LMM by freely generating stock price fluctuation terms from stock price fluctuations over several days. However, to facilitate the evaluation of performance, it is necessary to select candidate terms and let models select terms among them. Based on this discussion, we made a list of 28 phrases that are commonly used in stock price fluctuation articles as candidates of stock price fluctuation terms. Out of those 28 phrases, based on the criteria we introduce below, we adopted the following 10 terms for the study in this paper, which can be determined from short-term stock price fluctuations and have a high frequency of occurrences in stock price fluctuation articles.

> "急伸 (sharp rise)", "続伸 (continuous rise)", "反発 (rebound)", "急落 (sharp decline)", "続落 (continuous decline)", "反落 (pullback)", "続急伸 (continuous sharp rise)", "急反発 (sharp rebound)", "続急落 (continuous sharp decline)", and "急反落 (continuous sharp decline)"



(a) rise terms

(b) decline terms

Figure 1: Illustrating the differences of 10 stock price fluctuation terms

Definitions of stock price fluctuations corresponding to those 10 terms are illustrated in Figure 1, where Figure 1(a) shows 5 terms representing stock price rise, while Figure 1(b) shows the other 5 terms representing stock price decline. The illustration of each term consists of left hand side and right hand side fluctuations, where some of them share half of those fluctuations with other term(s)[1] In Figure 1, each of the eight pairs connected with the "Judged to be equivalent under lenient criterion" arrows share one of their left or right fluctuation, which corresponds to satisfying the *lenient* criterion defined in section 5.5.

The followings give the detailed discussion on the criteria on selecting those 10 terms out of the overall 28 phrases. We first investigate 8,024 articles collected from Web media that deliver news about stock price fluctuations[2]. Out of the overall 8,024 articles, 980 articles, which accounts for 12.2%, contained at least one of those selected 10 terms, while 776 articles (9.67%) contained at least one of the remaining 18 terms that were not adopted due to several reasons[3]. We also analyzed 100 articles randomly sampled from 6,268 ($= 8,024 - 980 - 776$) articles that include none of the overall 28 phrases representing stock price fluctuations. The majority of those remaining articles correspond to articles on whole market trends and promotional articles for companies.

4 Dataset

"Yahoo! Finance"[4] and "MINKABU"[5], two Web media that distribute news articles on finance, were used for collecting news articles on stock price fluctuations. We focus on the headlines of news articles taken from the "Japanese stocks" tab of "Yahoo! Finance" and the "individual stocks" tab of "MINKABU"[6], from which we collected 568 articles. Each of those collected 568 articles satisfies the requirement that its headline contains only one of the 10 stock price fluctuation terms selected in the previous section.

From the collected articles, the article headlines and distribution dates were extracted. In addition, the stock price time series data for the relevant stocks linked from the article pages were referred to, where the closing prices were obtained from "Yahoo! Finance" and "MINKABU", for up to one week prior to the distribution dates of the articles. Based on the information obtained, a dataset was created consisting of pairs of stock price fluctuation terms appearing in the articles (e.g. "sharp rise") and closing prices up to one week backward from the distribution date. Table 1 summarizes the number of articles for each stock price fluctuation

[1] For example, in Figure 1(a), "rebound" (light blue) and "sharp reboud" (dark blue) share left hand side fluctuation, while their right hand side fluctuations differ. .

[2] Articles distributed from "MINKABU" (https://minkabu.jp/) between February 26, 2024 and March 26, 2024.

[3] For example, requiring long-term stock price fluctuation data (e.g., "堅調 (rising in the long term)" and "軟調 (declining in the long term)"), having difficulty in differentiation from other terms due to representing rather general features such as generally rising and declining (e.g., "上昇 (rise)" and "下落 (decline)") and representing accidental fluctuations within a day (e.g., "ストップ高 (hit limit-up, i.e., stop further selling/buying in the market due to relatively large rise)" and e.g., "ストップ安 (hit limit-down, i.e., stop further selling/buying in the market due to relatively large decline)").

Table 2: Rule-based term selection (x stands for percentage change in stock price from 1 day ago to article distribution date and y stands for percentage change in stock price from 2 days ago to 1 day ago.)

term.

5 Experiment

5.1 Rule-based Term Selection

Stock price fluctuation terms are selected based on a simple rule derived from the rate of change in the stock's closing price. Specifically, the rate of change is calculated from the closing price of one day prior to the article publication date to the closing price on the publication date itself (x in Table 2), as well as from the closing price two days prior to one day prior to the publication date (y in Table 2). As shown in Table 2, for both x and y, these rates of change are divided into four ranges using three thresholds. The combinations of these rate of change ranges are then mapped to one of those 10 stock price fluctuation terms as shown in Table 2. The rule was created by the second author, referencing the rate of change in closing prices within the training data used in the experiment.

5.2 GPT-4o (Large Language Models)

The task involves providing closing prices for several consecutive days to LLMs and prompting it to select, from the 10 stock price fluctuation terms defined in section 3, the term that best describes fluctuation of stock terms. Based on the results of the preliminary experiment to be conducted in section 5.4, we decide to reference closing prices over three days. We employed GPT-4o (*gpt-4o-2024-05-13*) as the LLM and conducted zero-shot learning, few-shot learning, and fine-tuning to examine the most appropriate method.

5.2.1 Zero-shot Learning without Giving Definitions of Terms

Only the following information is given to the prompt and GPT-4o is asked to select a stock price fluctuation term based on zero-shot learning.

- 10 candidate stock price fluctuation terms
- closing stock prices over three days

This allows us to investigate the extent to which GPT-4o can discriminate terms using only the generic linguistic knowledge it has acquired during pre-training. The actual prompt is shown below. The actual prompt is written in Japanese, and the following is its translation into English.

> messages=[
>
> {"role": "system", "content":
>
> "You are an AI who looks at closing stock prices of the day before yesterday, yesterday and today and selects the term that best fits the characteristics of the price fluctuation from the following terms: "sharp rise", "continuous rise", "rebound", "sharp decline", "continuous decline", "pullback", "continuous sharp rise", "sharp rebound", "continuous sharp decline" and "sharp pullback"."},
>
> {"role": "user", "content": "(928.0, 926.0, 1030.0). . . "}]

5.2.2 Zero-shot Learning with Giving Definitions of Terms

The following information is given to the prompt:

- 10 candidate stock price fluctuation terms
- definition of each term
- closing stock prices over three days

and GPT-4o is asked to select a stock price fluctuation term based on zero-shot learning. The actual prompt is shown below.

> messages=[
>
> {"role": "system", "content":
>
> "You are an AI who looks at closing stock prices of the day before yesterday, yesterday and today and selects

the term that best fits the characteristics of the price fluctuation from the following terms: “sharp rise”, “continuous rise”, “rebound”, “sharp decline”, “continuous decline”, “pullback”, “continuous sharp rise”, “sharp rebound”, “continuous sharp decline” and “sharp pullback”.”

“Sharp rise: a significant rise in the stock price from yesterday to today.”

. . .

“Sharp pullback”: the transition of the stock price from a rise to a significant decline.”},

{“role”: “user”, “content”: “(928.0, 926.0, 1030.0). . . ”}]

5.2.3 Few-shot Learning

As a few-shot, a total of 10 examples, one for each term, are collected from the candidate set of training examples in the dataset prepared in section 4. The prompt therefore contains the following information.

- 10 candidate stock price fluctuation terms
- as a few-shot, each stock price fluctuation term and the corresponding closing prices over three days
- closing stock prices over three days

GPT-4o is used as the model. The actual prompt is shown below.

messages=[

{“role”: “system”, “content”:

“You are an AI who looks at closing stock prices of the day before yesterday, yesterday and today and selects the term that best fits the characteristics of the price fluctuation from the following terms: “sharp rise”, “continuous rise”, “rebound”, “sharp decline”, “continuous decline”, “pullback”, “continuous sharp rise”, “sharp rebound”, “continuous sharp decline” and “sharp pullback”.”}

{“role”: “user”, “content”: “(102.0, 100.0, 118.0)”},

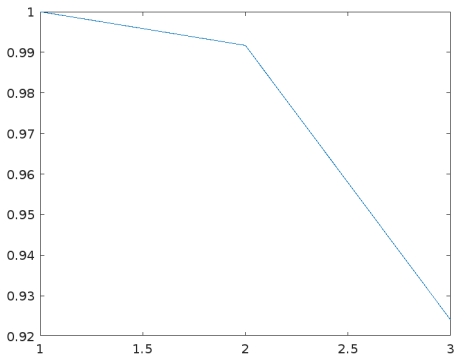

Figure 2: An example of graph images input to GPT-4V

{“role”: “assistant”, “content”: “sharp rise”},

. . .

{“role”: “user”, “content”: “(1808.0, 2087.0, 1818.0)”},

{“role”: “assistant”, “content”: “sharp pullback”},

{“role”: “user”, “content”:“(928.0, 926.0, 1030.0). . . ”}]

5.2.4 Fine-tuning

Using the OpenAI API, we fine-tuned *gpt-4o-2024-08-06*[7]. As training examples, a total of 100 examples are collected, 10 for each term, from the candidate set of training examples in the dataset prepared in section 4[8][9].

The fine-tuned *gpt-4o-2024-08-06* is used to select stock price fluctuation terms. The prompts during evaluation are the same as “zero-shot learning without giving definitions of terms”.

5.3 GPT-4V (Large Multimodal Models)

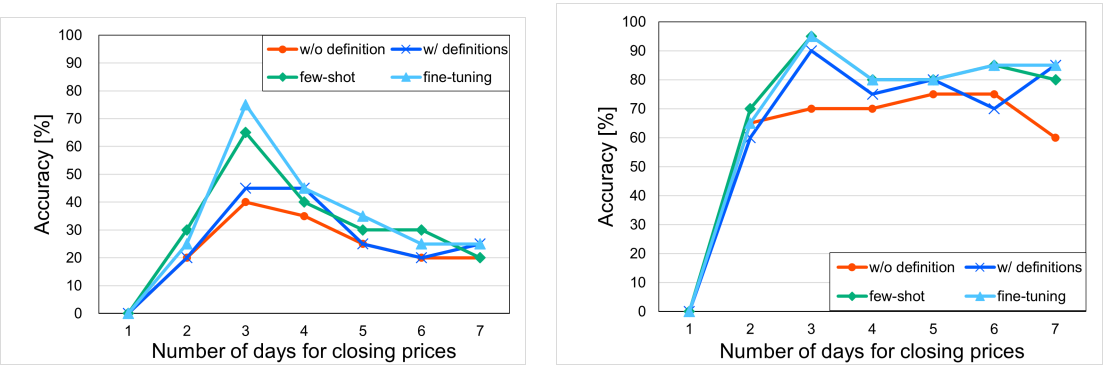
The task was to provide GPT-4V[10] with an image of a stock chart represented by a line graph and have it

[7] At the time of writing this paper, GPT-4o points to *gpt-4o-2024-05-13* at the OpenAI API site, while *gpt-4o-2024-08-06* is the first version of GPT-4o that supports fine-tuning.

[8] As to be presented in section 5.5, in this paper, we introduce two types of evaluation criteria, namely, *strict* and *lenient*, where for the *lenient* evaluation criteria, we augment examples according to the “⇔” relation. For example, examples of “続急伸 (continuous sharp rise)” are augmented as those of “続伸 (continuous rise)” and “急伸 (sharp rise)”. After this augmentation, 10 training examples each for a stock price fluctuation term are randomly selected.

[9] The number of training examples is optimized through evaluation against a held-out 100 development examples, where the optimal number of examples was 100 when examining with the number of candidate training examples as 150 or less.

[10] GPT-4V of https://chat.openai.com/.



(a) under strict criterion (b) under lenient criterion

Figure 3: Results of optimizing the number of days of closing stock prices by GPT-4o

automatically select the best term to describe how the stock price fluctuates from among the 10 stock price fluctuation terms defined in section 3.

The stock price charts input to GPT-4V were created from the stock price fluctuation information in the dataset described in section 4. Based on the results of the preliminary experiment conducted in section 5.4, we decided to reference closing prices over three days. The closing stock price two days ago was set as 1.0, and the closing prices of the previous day and the current day were expressed as ratios to it. The vertical axis of the chart was taken to be the minimum to maximum values of the closing prices over the three days. An example of a stock chart is shown in Figure 2.

The GPT-4V was given the following prompt.

> "You are an AI who looks at closing stock prices of the day before yesterday, yesterday and today and selects the term that best fits the characteristics of the price fluctuation from the following terms: "sharp rise", "continuous rise", "rebound", "sharp decline", "continuous decline", "pullback", "continuous sharp rise", "sharp rebound", "continuous sharp decline" and "sharp pullback".".

An image of stock price charts was then input. The following is an example of the GPT-4V output.

> The graph shows that prices have consistently fallen. In particular, it is noticeable that after a slight decline at the beginning, there is a transition to a more rapid decline. Based on this, the most appropriate term to choose would be "continuous sharp decline". This refers to a series of significant decline over a short period of time and aptly describes the price movements shown in this graph.

Model	Criteria	
	strict	lenient
GPT-4o	**63.0**	**97.0**
Gemini 1.0 Pro	42.0	82.0
Claude 3.5 sonnet	45.0	80.5
rule-based	58.5	95.0
xlm_roberta_base	21.5	44.0
GPT-4V	33.0	87.0
CNN	53.5	78.0

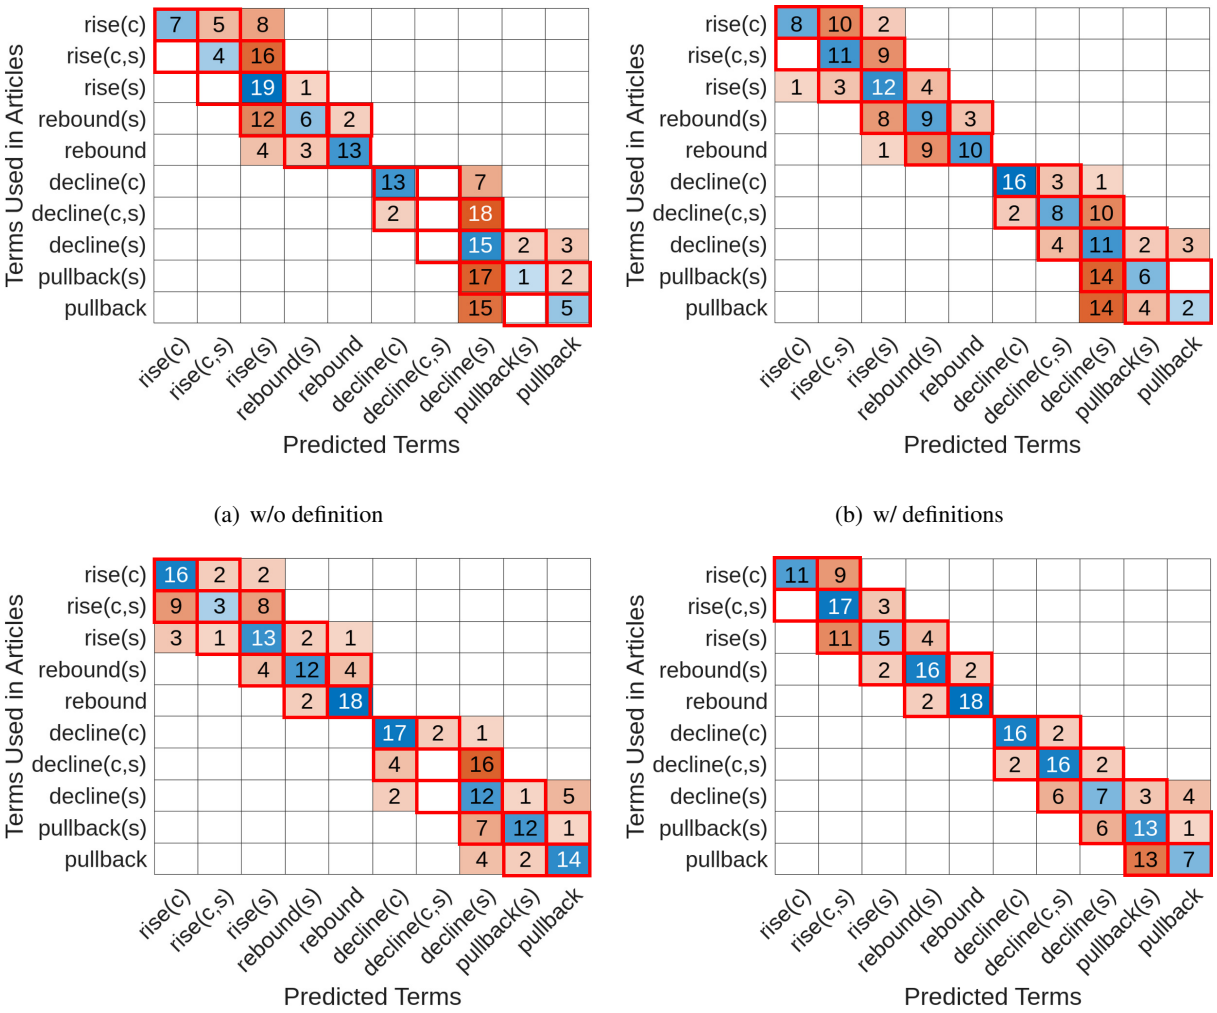
Table 3: Overall evaluation results (%) (accuracies in 200 evaluation examples)

Model	Criteria	
	strict	lenient
w/o definition	41.5	81.5
w/ definitions	46.5	89.0
few-shot	58.5	91.0
fine-tuning	**63.0**	**97.0**

Table 4: Accuracies in 200 evaluation examples by GPT-4o (%) (w/o definition: zero-shot learning without giving definitions of terms, w/ definitions: zero-shot learning with giving definitions of terms)

5.4 Optimizing the Number of Days of Closing Stock Prices

Before the evaluation of selecting stock price fluctuation terms, we conducted a preliminary experiment to determine the optimal number of days to be referenced out of the seven days of closing stock prices when the model selects stock price fluctuation terms. For a total of 20 examples where



(a) w/o definition

(b) w/ definitions

(c) few-shot

(d) fine-tuning

Figure 4: Confusion matrices in the evaluation results by GPT-4 (The letter "c" in brackets stands for "continuous rise / decline", the letter "s" for "sharp rise / decline / rebound / pullback", and the letters "c, s" for "continuous sharp rise / decline".)

two examples for each term as the held-out development dataset, we varied the number of days of closing price data given to the models from one to seven in one-day increments, and let the models select a stock price fluctuation term. Here, as shown in Figure 3, the optimal number of days of closing stock prices is three, where it is used throughout the evaluation in this paper.

5.5 Evaluation Procedure

As the evaluation experiment, the models selected stock price fluctuation terms for a total of 200 examples (i.e., 200 evaluation data), 20 for each term, which do not have any overlap with examples used for few-shot learning, the training data of fine-tuning, the development data for optimizing the number of the training data for fine-tuning, and the dataset used for optimizing the number of days of closing stock prices in the previous section. The LLMs we used are GPT-4o, Claude 3.5 Sonnet and Gemini 1.0 Pro. For GPT-4o, we conducted two types of zero-shot learning (with / without giving definitions of terms), few-shot learning, and fine-tuning. For Claude 3.5 Sonnet and Gemini 1.0 Pro, we only performed few-shot learning following the procedure of section 5.2.3 as GPT-4o. For comparison with the LLMs, we evaluated XLM-RoBERTa (xlm-roberta-base), another language model with the same text input format, as well as a rule-based approach. XLM-RoBERTa was fine-tuned using the same data as when GPT-4o was fine-tuned. The LMM we used is GPT-4V. We also conducted a comparison with CNN, which are similar to LMMs in that they take images as input.

Two types of criteria are examined in the evaluation, i.e., *strict*, where errors between these 10

terms are not tolerated, and *lenient*, where errors between terms that are difficult to distinguish even manually are tolerated[11]. Inter-annotator agreement rate is also measured between the terms found in the headlines of the articles and those annotated by the second author of this paper. For 100 articles that are randomly selected from the overall 568 articles, the second author selects one of the 10 candidate terms by referring to closing stock prices over three days for the stock that is relevant to each article. With the *strict* criterion, inter-annotator agreement rate between the writer of each article and the second author of this paper is 57% and Cohen's kappa coefficient is 0.5222, while with *lenient* criterion, inter-annotator agreement rate is 93% and Cohen's kappa coefficient is 0.9033, thus indicating sufficiently high degree of agreement.

6 Results and Discussion

6.1 Evaluation Results

Table 3 shows the overall evaluation results, while Table 4 shows those when applying GPT-4o as the model. Figure 4 also shows the confusion matrices in the evaluation results by GPT-4. These results indicate that the best performance is achieved when fine-tuning is conducted with GPT-4o.

In the strict evaluation criterion, the accuracy would be expected to be around 10% if all the terms were selected at random. For all the models evaluated in this paper, the accuracy was above 10%. In the lenient evaluation criterion, if all the terms were selected at random, the accuracy would be around 26%[12]. For all the models evaluated in this paper, the accuracy was significantly higher than 26%.

The model based on stock chart images underperformed models based on numerical stock price information in terms of the strict evaluation criteria. On the other hand, for the lenient evaluation criteria, the accuracy was comparable to that of each model based on numerical stock price information.

[11]Errors between the eight pairs directly connected with "⇔" below are allowed in the *lenient* criterion:

- continuous rise ⇔ continuous sharp rise ⇔ sharp rise ⇔ sharp rebound ⇔ rebound,
- and continuous decline ⇔ continuous sharp decline ⇔ sharp decline ⇔ sharp pullback ⇔ pullback.

[12]Out of the total 200 evaluation examples, the expected numbers of correct terms are $20 \times 3 = 60$ for 6 out of the 10 terms, while they are $20 \times 2 = 40$ for the remaining 4 terms, where their average is ((6/10)×60+(4/10)×40)/200=26%.

6.2 Analysis on Rule-based Term Selection

The strict accuracy of rule-based term selection is 58.5%, where we revealed that, for about half of those incorrect term selection cases, the reason can be explained by referring to stock price fluctuation for periods around one week or much longer as 25 days. The details of the analysis are described in section A of Appendix.

6.3 Analysis on Term Selection based on Stock Price Fluctuation for Periods Longer than Three Days

As a further analysis, out of the overall 200 articles of the evaluation data, we examined the 105 examples where the selected terms differed between "terms by the article writers" and "terms predicted by GPT-4o (few-shot)" in the strict criterion. For those 105 examples, we provided GPT-4o with the closing stock prices for a period longer than three days and made GPT-4o to select the terms by few-shot. The details of the analysis are described in section B of Appendix.

7 Conclusion

This paper proposed models for automatically generating stock price fluctuation terms used in stock price fluctuation articles from time series data of stock prices by LLMs. Experimental evaluation results indicated that the best performance is achieved when fine-tuning is conducted with GPT-4. It was also revealed that, under the lenient criterion, the accuracies of converting stock price fluctuation data into corresponding stock terms using LLMs were relatively high about $80\% \sim 90\%$.

Among the future work of this paper, regarding the analyses in section 6.2 and in section 6.3, it is definitely necessary to incorporate stock price fluctuation for periods around one week or much longer as 25 days. However, overall, optimal number of days for stock price fluctuation data is three days. This indicates that whether stock price fluctuation for longer periods such as 25 days is required or not totally depends on each example. Thus, it is required to devise a framework of selecting the optimal number of days of stock price fluctuation depending on each test example. Another future work includes studying the relationship between the task of selecting stock price fluctuation terms and that of predicting future stock prices, and then integrating those two related tasks into the framework of multitask learning.

A Analysis on Rule-based Term Selection

The strict accuracy of rule-based term selection is 58.5%, where Figure 5 shows the confusion matrix in the evaluation result by rule-based term selection. When we focus on the incorrect cases under the *strict* criterion, 58.5% accuracy corresponds to 41.5% difference, which is quite large. In order to identify the major causes of this large difference, we examine those four non-diagonal cells in the confusion matrix of Figure 5 each of which has the number of counts above or equal to four. The consequence of our analysis can be summarized as below. First, one of the most important facts here is that the rule selects terms based on the three days stock price fluctuations but not referring to stock price fluctuation for 25 days. Second, on the contrary, we found that, for about half of the articles where "the term selected by the article writers" and "rule-based term selection" differ, the reason why the article writers selected different terms can be explained by referring to stock price fluctuation for 25 days. Figure 6 $\sim$ Figure 8 present examples of those differences between "the term selected by the article writers" and "rule-based term selection".

Figure 6 represents fluctuation for 25 days for the case of difference between "pull back" as "the term selected by the article writers" as opposed to "sharp pullback" as "rule-based term selection" (corresponding to the cell with the count as 8 in the confusion matrix). In this figure, for the black thick plot, both "the term selected by the article writers" and "rule-based term selection" are "sharp pullback". Here, stock price fluctuation for 25 days is without very sharp change, which makes the article writer judge its "pullback" at the end of the period as "sharp". For the red dashed line, on the other hand, "the term selected by the article writers" is "pull back", while "rule-based term selection" is "sharp pullback". Stock price fluctuation for 25 days is with relatively sharper change, which makes the article writer judge its "pullback" at the end of the period as relatively "not sharp" compared with the relatively sharper fluctuation for 25 days.

Figure 7 represents fluctuation for 25 days for the case of difference between "sharp rise" as "the term by article writers" as opposed to "continuous sharp rise" as "rule-based term selection" (corresponding to the cell with the count as 4 in the confusion matrix). In this figure, for the black thick plot, both "the term selected by the article writers" and "rule-based term selection" are "continuous sharp rise".

Here, stock price fluctuation for 25 days looks gradually and continuously rising, while at the end of the period, its rise looks very sharp, which makes the article writer judge this fluctuation as "continuous sharp rise". For the red dashed line, on the other hand, "the term selected by the article writers" is "sharp rise", while "rule-based term selection" is "continuous sharp rise". Locally within the range of a recent few days, it looks like "continuous sharp rise". However, stock price fluctuation for 25 days overall keeps within a narrow range while with relatively unstable changes. The article writer judges this fluctuation as globally with less fluctuation and selects the term as "sharp rise", simply because the article writer regards that this overall fluctuation satisfies the condition of "sharp rise", which is without fluctuation for a while before a sharp rise at the end of the period[13].

Figure 8 represents fluctuation for 25 days for the case of difference between "rebound" as "the term selected by the article writers" as opposed to "sharp rise" as "rule-based term selection" (corresponding to the cell with the count as 5 in the confusion matrix). In this figure, for the black thick plot, both "the term selected by the article writers" and "rule-based term selection" are "sharp rise". Here, stock price fluctuation for 25 days keeps globally within a narrow range, while at the end of the period, it ends as "sharp rise". Such a fluctuation makes the article writer judge this fluctuation as "sharp rise". For the red dashed line, on the other hand, "the term selected by the article writers" is "rebound", while "rule-based term selection" is "sharp rise". Locally within the range of a recent few days, it starts with little change while ending up with "sharp rise". However, stock price fluctuation for 25 days overall has a shape of declining in its first half, while rising in its second half. Such a shape makes the article writer judge this fluctuation as globally a "rebound".

B Analysis on Term Selection based on Stock Price Fluctuation for Periods Longer than Three Days

As a further analysis, out of the overall 200 articles of the evaluation data, we examined the 105 examples where the selected terms differed between "terms by the article writers" and "terms predicted

[13]This explanation is also applicable to the cell of the count as 5 with the difference between "sharp decline" as "the term selected by the article writers" as opposed to "sharp pullback" as "rule-based term selection".

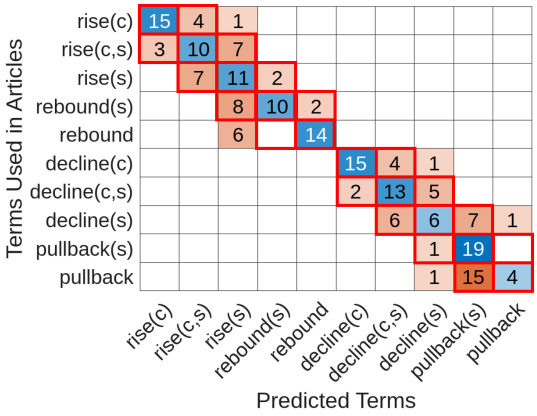

Figure 5: Confusion matrix in the evaluation result by rule-based term selection (The letter "c" in brackets stands for "continuous rise / decline", the letter "s" for "sharp rise / decline / rebound / pullback", and the letters "c, s" for "continuous sharp rise / decline".)

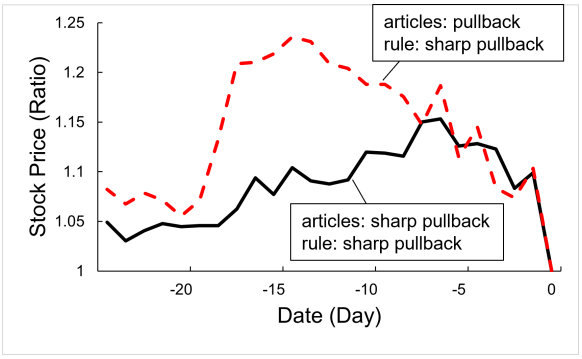

Figure 6: Analyzing the differences of "terms by the article writers" and "rule-based term selection" based on stock price fluctuation for 25 days (1) ("pullback" (by the article writers) v.s. "sharp pullback" (by the rule))

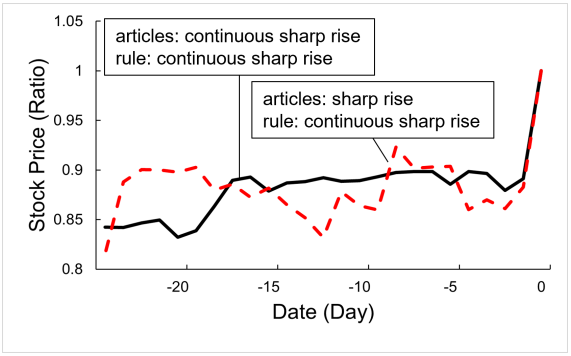

Figure 7: Analyzing the differences of "terms by the article writers" and "rule-based term selection" based on stock price fluctuation for 25 days (2) ("sharp rise" (by the article writers) v.s. "continuous sharp rise" (by the rule))

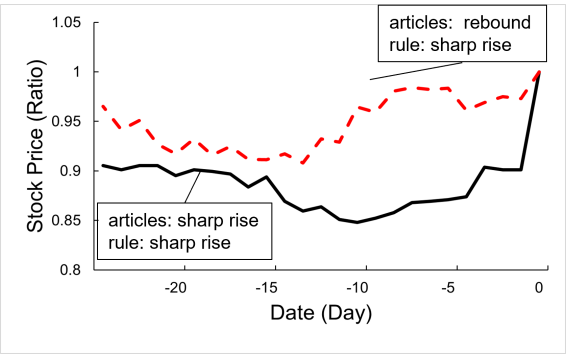

Figure 8: Analyzing the differences of "terms by the article writers" and "rule-based term selection" based on stock price fluctuation for 25 days (3) ("rebound" (by the article writer) v.s. "sharp rise" (by the rule))

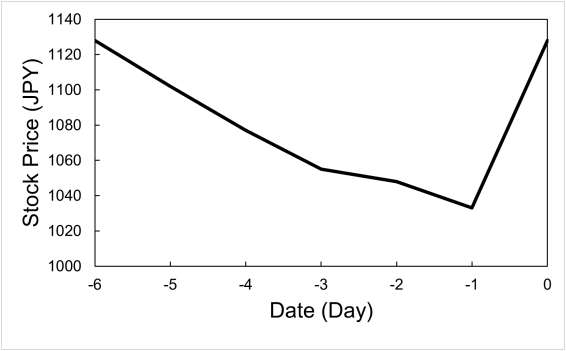
Number of Days of closing prices given to the model	4	5	6	7
Rates [%]	18.1	18.1	24.8	21.0

Table 5: Rates of examples for evaluation where "terms by the article writers" and "terms predicted by GPT-4o (few-shot)" are identical when 4∼7 days of closing prices are given to the GPT-4 (out of the 105 examples where "terms by the article writers" and "terms predicted by GPT-4o (few-shot)" differ when 3 days of closing prices are given)

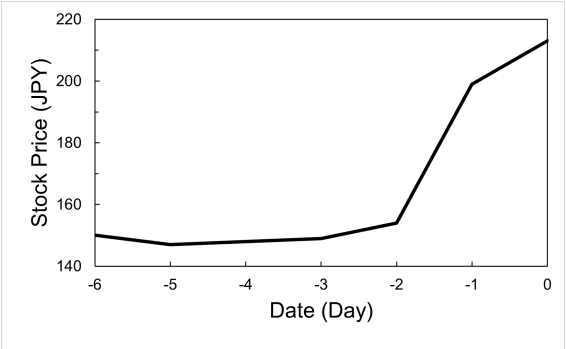
by GPT-4o (few-shot)" in the strict criterion[14]. For those 105 examples, we provided GPT-4o with the closing stock prices for a period longer than three days and made GPT-4o to select the terms by few-shot. Table 5 shows the rates of examples for evaluation where "terms by the article writers" and "terms predicted by GPT-4o (few-shot)" are identical when 4∼7 days of closing prices are given to the GPT-4 out of the 105 examples where "terms by the article writers" and "terms predicted by GPT-4o (few-shot)" differ when 3 days of closing prices are given. As a result, for 41 out of the 105 examples, GPT-4o selected the same term as selected by the article writers for at least one of 4∼7 days of closing prices.

Figure 9 presents charts of 7-day stock prices for examples in which the article writer and GPT-4o (few-shot) did not select the same term based on the closing prices for three days, while GPT-4o (few-shot) selected the term same as the article writer when based on at least one of 4∼7 days of closing prices.

[14]The results of analysis when providing GPT-4o (fine-tuning) with the closing stock prices for a period longer than three days will be included in the camera-ready version of this paper.



(a) "sharp rebound" by the article writers v.s. "sharp rise" by GPT-4o (based on closing prices for 3 days) and "sharp rebound" by GPT-4o (based on closing prices for 4∼7 days)



(b) "sharp rise" by the article writers v.s. "continuous sharp rise" by GPT-4o (based on closing prices for 3∼5 days) and "sharp rise" by GPT-4o (based on closing prices for 6∼7 days)

Figure 9: Charts of 7-day stock prices for examples in which the article writer and GPT-4o (few-shot) did not select the same term based on the closing prices for three days, while GPT-4o (few-shot) selected the term same as the article writer when based on at least one of 4∼7 days of closing prices.

For Figure 9(a), when referring to the closing stock prices for three days, GPT-4o selected the term "continuous sharp rise" because of the small drop in the closing price of the stock from two days to one day before. On the other hand, when referring to closing prices for 4∼7 days, GPT-4o selected "sharp rise", the same term selected by the article writer, because of the continuous drop in stock prices up to 1 day before.

For Figure 9(b), when referring to the closing stock prices for 3∼5 days, GPT-4o selected the term "continuous sharp rise" because of the continuous sharp rise in the closing price from 2 days before to the current day. On the other hand, when looking at longer-term fluctuations, GPT-4o selected "sharp rise", the same term as selected by the article writer, when referring to closing prices

for 6∼7 days, as there were no significant price fluctuations between 6 and 2 days prior.

Authorship Attribution in 19th-century Philippine Literature Using A Deep Learning Multi-label Classifier

Paolo Espiritu **Jason Jabanes** **Charibeth Cheng**

{paolo_edni_espiritu_a, jason_jan_c_jabanes, charibeth.cheng}@dlsu.edu.ph

Abstract

Authorship attribution (AA) is an essential task in Natural Language Processing (NLP) that plays a crucial role in historical literary analysis, intellectual property protection, digital forensics, document identification, and plagiarism detection. Despite recent advancements for high-resource languages, AA for low-resource languages remains underexplored due to the lack of annotated datasets. This study aims to address this gap by focusing on 19th-century Filipino literary texts. To facilitate this, we introduce Panitikan, a publicly available, pre-processed dataset of Filipino literary texts. Given the complex morphological structure of the Filipino language, we discuss various preprocessing techniques designed to enhance model performance. We employed a closed-set multi-label classification approach using Long Short-Term Memory (LSTM), Convolutional Neural Networks (CNN), and fine-tuned RoBERTa-TL models (Base and Large) tailored for Tagalog. The models were evaluated using accuracy, precision, recall, and F1 score metrics. Our results demonstrate that on a 10-author dataset, the RoBERTa-TL-Large model achieved the highest F1 score (96.45%), outperforming LSTM (82.40%), CNN (74.95%), and RoBERTa-TL-Base (95.78%). On a more extensive 34-author dataset, RoBERTa-TL-Large maintained superior performance with an F1 score of 92.81%, followed by RoBERTa-TL-Base (85.87%), LSTM (55.23%), and CNN (48.30%).

1 Introduction

Authorship attribution (AA) is a classification task aimed at identifying the true author of a given text from a set of potential candidates. This task has gained significant attention due to its practical applications in areas such as historical literature analysis, digital forensics, document identification, plagiarism detection, and more (Reisi and Mahboob Farimani, 2020; Fabien et al., 2020; Theophilo et al., 2022). However, most research in this field has focused on high-resource languages, largely due to the availability of expertly annotated datasets that facilitate model development and validation. In contrast, there remains a significant need for developing datasets and methodologies tailored to low-resource languages (Nitu and Dascalu, 2024). Recent advancements in Natural Language Processing (NLP) offer various methodologies that can be adapted to address the unique challenges associated with AA in these languages (He et al., 2024).

For instance, a study by Fedotova et al. (2022) explored authorship attribution for Russian texts, including social media and literary works, using a variety of machine learning models, neural networks, and hybrid approaches such as Support Vector Machines (SVM), fastText, Convolutional Neural Networks (CNN), Long Short-Term Memory networks (LSTM), and the Bidirectional Encoder Representations from Transformers (BERT). These models were trained in a closed-set scenario, meaning they could only classify texts authored by a limited, predefined set of individuals. The study found that deep neural networks achieved the highest average accuracy of 82.3%, followed closely by fastText at 82.1% and SVM with a genetic algorithm at 80.4% (Fedotova et al., 2022).

The success of such models often hinges on the availability of high-quality, expertly annotated corpora, which are frequently lacking in low-resource settings. For example, a study on the Romanian language created a corpus from Romanian stories comprising of 1,263 texts and 12,516 paragraphs written by 19 authors (Nitu and Dascalu, 2024). They employed preprocessing techniques specific to the Romanian language to enhance model training. They utilized a hybrid model combining top predictive linguistic features (selected using the Kruskal-Wallis mean rank) with a fine-tuned Romanian BERT model, achieving state-of-the-art F1

scores of 0.87 on full texts and 0.77 on paragraphs (Nitu and Dascalu, 2024).

In this study, we explore authorship attribution for 19th-century Filipino literary works. To our knowledge, this is the first study to investigate AA in Filipino historical texts. The complexity of the Filipino language, characterized by its intricate morphology and syntax, necessitated the implementation of unique preprocessing techniques. The models were trained in a closed-set configuration to limit predictions to a specific set of authors. Although this study focuses on the Filipino language, the methodologies discussed can be adapted for other low-resource languages.

This paper aims to contribute the following:

1. Publicly available Filipino literature *Panitikan* dataset with 2 versions, which contain 10 authors with 19 written works and 34 authors with 47 written works.

2. Trained LSTM and CNN models and the fine-tuned RoBERTa-Tagalog (TL) models (Cruz and Cheng, 2022) to identify 19th-century Filipino authors based on the given literary text.

2 Related Works

Traditionally, AA has mostly relied on a manual method to extract elements pertaining to an author's style or substance. However, in recent times, deep learning methods have been employed for AA tasks as these are expected to automatically capture stylometric features of the text (Chowdhury et al., 2019). These different approaches have been used to conduct AA for languages such as English, Russian, and Bengali. However, the same cannot be said about the advancements made in Philippine Literature. This section examines novel studies that employ deep learning methods, such as neural networks and transformers, to perform AA. Additionally, current state of AA in Philippine literature will also be explored.

2.1 Deep Learning-based Approaches

Chowdhury et al. (2019) used fastText's word embedding model with Convolutional Neural Networks (CNN) to investigate AA in Bengali literature. The study was able to demonstrate that CNN models could accurately capture stylistic subtleties in Bengali text, achieving an accuracy of 92% on their dataset. Kapočiūtė-Dzikienė et al. (2015) focused on age and gender characteristics in author profiling of Lithuanian literary texts. They achieved a 89.2% accuracy with the Naive Bayes Multinomial method and character tri-grams. The study by Fabien et al. (2020) is one of the first efforts to perform author classification by fine-tuning a pre-trained BERT model. Their approach outperformed traditional machine learning models by 2.7% and set a new benchmark for the IMDB dataset. The study was able to show that Transformer models was able to reach competitive results across three different benchmark datasets, even with large amounts of authors.

2.2 Authorship Attribution in the Philippines

Dumalus and Fernandez (2011) explores the use of writer's rhythm as a stylometric feature, achieving a 50% accuracy using a Naive Bayesian classifier. The study considers this result significant enough to suggest that rhythm can be considered as a viable style marker. It is worth noting that, while the study was conducted in the Philippines, the corpora used does not contain any Filipino text data. Marvin Imperial (2021) examined the stylistic writing of potential pedophiles and child sex traffickers in the Philippines using Twitter as their main source of data. The findings demonstrate that child traffickers and peddlers often employ the same terminologies. Furthermore, the study used these co-occurring terminologies to build four different online personas that characterize a pedophile.

3 System Design and Architecture

3.1 Overview of the System

Figure 1 shows the model training pipeline used for LSTM, CNN, RoBERTa-TL-Base, and RoBERTa-TL-Large. It shows the step-by-step process of creating a multi-label classification model using the aforementioned deep learning architectures. As observed in Figure 1, the trained models often shared the same processes and only diverged after tokenizing the dataset.

3.1.1 Panitikan Corpus

The pre-processed dataset, which contains the features and labels, was loaded to train the models for the multi-label classification task.

3.1.2 Extract labels and input columns

The necessary features and labels were selected in preparation for the training process.

3.1.3 Split into train/test/validation sets

The dataset was split into 80:10:10, respectively, using the *datasets* library from Hugging Face.

3.1.4 Encode with tokenizer

A tokenizer was used to encode the dataset into a numerical format for computational efficiency.

3.1.5 Fine-tuning (RoBERTa Tagalog Models)

Since RoBERTa-TL-Base and RoBERTa-TL-Large models were already pre-trained on the Tagalog language, it was only necessary to perform fine-tuning using the *Panitikan* dataset.

3.1.6 Train Word2Vec Model (LSTM & CNN)

A skip-gram word2vec was trained using the train set that will serve as the embedding layer for LSTMs and CNNs.

3.1.7 Hyperparameter Tuning (LSTM & CNN)

Hyperband tuning was used in selecting optimal hyperparameter configurations for the LSTM and CNN models.

3.1.8 Model Training (LSTM & CNN)

The LSTM and CNN models were trained with a batch size of 32 on 10 epochs. The models were then saved for evaluation and inference.

3.1.9 Multi-label Classification Model

After training or fine-tuning, the best model is saved into a local directory. This step is important to prevent restarting the entire pipeline when evaluating or inferencing.

3.1.10 Evaluation and Inference

The model is evaluated in terms of accuracy, precision, recall, and F1 score. It may now also be used to test custom inputs.

3.2 Convolutional Neural Network (CNN)

CNN is a deep learning architecture popularized due to its numerous practical applications such as recommendation systems, facial recognition, speech and text processing, and more (Alzubaidi et al., 2021). It consists of multiple layers, including the input, convolution, pooling, fully connected, and output. As the input sequence goes through each layer, a series of matrix multiplications and subsampling operations are performed before evaluating the features to generate an output (Alzubaidi et al., 2021).

3.3 Long Short-Term Memory (LSTM)

Another known neural network in NLP is LSTM which was created to handle vanishing gradient issues experienced by traditional recurrent neural RNNs. It excels in a variety of tasks due to its capability to learn when to retain and forget information. To achieve this, it implements three gates: (1) forget, (2) input, and (3) output. The forget gate is responsible for discarding the information from the previous state by assigning the previous and current input to a rounded value between 0 (discard) and 1 (save). Furthermore, the input gate chooses which new information to store in the current state using the same algorithm as forget gates. Finally, the output gates determine which information to output from the current state (Fedotova et al., 2022).

3.4 Robustly Optimized BERT Approach (RoBERTa)

To achieve state-of-the-art performance, BERT models are often used due to their self-attention mechanism to process sequences of text and produce contextualized word embeddings. Its superior results may also be attributed to its bi-directional capability, allowing it to capture a wider context and better understand the semantic meaning of the token (Fedotova et al., 2022).

Given the strengths of the BERT model, its variant, RoBERTa, has demonstrated better performance (Naseer et al., 2021; Rajapaksha et al., 2021; Adoma et al., 2020). RoBERTa was created by optimizing BERT in terms of its training pipeline and data (Liu et al., 2019).

In this study, two Filipino pre-trained transformers, RoBERTa-TL-Base and RoBERTa-TL-Large, will be used. The models will be fine-tuned on the constructed dataset to classify the true author with the corresponding text.

3.5 Implementation Details

For the LSTM and CNN models, training was performed using the Tesla V100-PCIE-32GB. On the other hand, NVIDIA RTX 6000 Ada Generation was utilized to train RoBERTa-TL models by renting a GPU from vast.ai. This ensured that model training would not be prematurely terminated due to memory limitations.

The models were written in a Jupyter notebook to sufficiently document each step for replicability. The software libraries used to train and evaluate the models are illustrated in Table 1.

4 Methodology

4.1 Data Collection

A web scraper was constructed to extract various 19th-century and early 20th-century Filipino literary works, representing novels, poems, and short stories. The scraper was developed with Python using the `scrapy` library. The data originated from Project Gutenberg, which provides more than 60,000 free eBooks, many of which are literary and historical works (Lebert, 2008). The web scraper was successful in obtaining 60 literary works written by 45 distinct authors from Project Gutenberg.

4.2 Data Preprocessing

4.2.1 Initial Filtering

The dataset was first filtered to only include original literary works written exclusively in the Filipino language. Dictionaries, thesauruses, and works translated from other languages were excluded, leaving only 47 literary works from the original 60.

4.2.2 Data Cleaning

The first steps in data cleaning were standardizing text format and eliminating unnecessary information. The literary works were stripped of Project Gutenberg information, such as initial descriptions and transcriber remarks. Textual normalization converted UTF-8 characters (á, é, ï, ó, ë, ü, ñ) into their corresponding ASCII characters. Additionally, elements such as bracketed text ([]{}), punctuations (excluding sentence delimiters; more on this later), Roman numerals, numbers, numbers with periods and commas, and capitalized words (which are almost always titles, headings, or dialogue indicators in literature) were removed. To further standardize the text, all text were converted to lowercase and extra whitespaces were eliminated.

4.2.3 Sentence Tokenization

To correctly tokenize text into sentences, the first step is to detect abbreviations that terminate in periods. This is necessary since periods often indicate sentence boundaries. Words with periods that appear more than once in a text and were less than six characters were filtered to identify possible abbreviations. Following their identification, these abbreviations were not included in the sentence splitting procedure. The text was then segmented into separate sentences based on standard punctuations using NLTK's (Bird et al., 2009) sentence tokenization tool, with the previously noted abbreviations being treated as exceptions. Afterwards, punctuations that were used to segment into sentences were removed. Duplicate sentences from the same author were also identified and removed. Lastly, sentences with less than 10 characters were removed as they tend to be more or less meaningless.

4.3 Document Representation

The corpus, henceforth referred to as the *Panitikan* corpus, is presented in two versions: (a) the entire corpus from 34 authors and comprising 47 literary works; (b) a subset with 10 authors and consisting

of 19 literary works. The ten authors in the subset were chosen for having the most token counts in the corpus. This was created to evaluate a dataset with a more balanced data distribution. Specifications for the *Panitikan* corpus are presented in Table 2.

Table 2: Specifications of the *Panitikan* corpus

Corpus	Items	Count
Corpus Size (34 Authors)	No. of tokens	724,133
	Vocabulary Size	60,354
	No. of literary works	47
	No. of authors	34
Corpus Size (10 Authors)	No. of tokens	458,254
	Vocabulary Size	41,210
	No. of literary works	19
	No. of authors	10

The table illustrates that the entire corpus is composed of 724,133 tokens having a vocabulary size of 60,354 (unique tokens). The subset of 10 authors is composed of 458,254 tokens having a vocabulary size of 41,210.

For this study, two document representations were used to examine the effect of contextual information on AA. In the first approach, individual sentences are treated as a single document. This technique evaluates how well an author's distinctive style indicators can be recognized in the context of a single phrase. On the other hand, the second method defines documents as text chunks that are about 1000 characters long, or about equivalent to a paragraph. The objective is to analyze these varied document lengths in order to assess if a more comprehensive context is required in order to correctly distinguish between writers according to their styles of writing. Document counts for the different document representations across the different corpus are shown in Table 3.

Table 3: Document Count of different representations

Corpus	Representation	Doc. Count
Corpus Size (34 Authors)	Sentence	38,340
	1000-character chunks	4,965
Corpus Size (10 Authors)	Sentence	25,026
	1000-character chunks	3,114

4.4 Experimental Setup

In this study, the AA is treated as a classification problem. To accommodate the distinct requirements of different models, two text preprocessing pipelines were employed. Wherein each author in the dataset represents a class, the goal of these deep learning models is to predict the class of a test document.

Deep learning models will be trained on preprocessed text that had been lowercased and punctuations removed. Conversely, the BERT model, which benefits from preserving linguistic subtleties, was fed with the cleaned text data containing punctuations and word casing. For text encoding, we used One-Hot Encoding to turn category data into binary vectors. Using this technique, a vector of zeros is created, with a single one at the index that represents the presence of a specific category.

The input texts were also encoded using two distinct libraries. The TensorFlow Keras Tokenizer was employed for the LSTM and CNN models, while the RoBERTa-TL models utilized a `tokenizer` from Hugging Face. This encoding process assigns unique numerical identifiers to each token, a crucial step that optimizes the models' ability to analyze and comprehend human language more effectively.

4.5 Training and Hyperparameters

In all experiments, we adopted an 80/10/10 train/validation/test split. For the word embeddings, we proceeded with skip-gram word level embeddings by word2vec. To generate the word vectors, a vector dimension of length 300 and context window of 5 were used.

The pre-trained Word2Vec embeddings created will be used as an embedding layer when training the deep learning models. This was only applied for both LSTM and CNN. The models' output layer employed a Softmax activation function for multi-class classification, with categorical cross-entropy as the loss function. Model optimization was achieved using the Adam optimizer, and accuracy was the primary evaluation metric.

Hyperband tuning was used in selecting the optimal hyperparameter configurations for the LSTM and CNN models, while standard hyperparameter values were used for RoBERTa-TL models. Hyperparameter configurations for each model is presented in Table 4.

LSTM and CNN models were trained on a Tesla V100-PCIE-32GB GPU. On the other hand, the RoBERTa-TL models were trained on a NVIDIA RTX 6000 Ada Generation GPU.

After training the models, the test data will be used to measure the models' performance in pre-

Table 4: Hyperparameter configurations for each model

Model	Parameter	Value
LSTM	LSTM units	50
	Batch size	32
	Epochs	10
CNN	Conv1D Filters	256
	Conv1D Kernel Size	5
	MaxPooling1D Pool Size	5
	Dense Layer Units	128
	Dropout rate	0.2
	Learning rate	0.001

	Learning rate	0.00002
	Batch size	8
	Epochs	10

dicting the author of the text. Measures such as accuracy, precision, recall, and F1-score were used.

5 Results and Analysis

In this section, the results of the deep learning techniques on the task of author identification are discussed. Table 5 presents the results of all the deep learning techniques for each document representation according to the corpus size. In addition, Figures 2a, 2b, 2c, and 2d visualize the data presented in Table 5 using a grouped bar chart.

It can be observed that the RoBERTa-TL models significantly outperform the LSTM and CNN models in our experiments, with a 10~17% increase across all metrics for the different features. This superior performance is likely due to the transformer-based architecture, which uses self-attention mechanisms to better extract contextual information and intricate patterns from the text. Additionally, RoBERTa-TL is pre-trained on a larger Filipino dataset. Despite the *Panitikan* corpus's use of older Filipino forms and spellings (e.g. '*huag*' instead of '*huwag*'), RoBERTa-TL successfully catches the text's subtleties, proving its strong ability to manage variances in language form and style.

It is also worth mentioning that RoBERTa-TL-Large showed the best results for all experiments, as seen in Figure 2. Despite being trained on 34 labels, the model managed to achieve an F1 score of 92.81% on paragraph features. This is a 6.94% F1 score difference compared to RoBERTa-TL-Base despite having similar scores on sentence-level features. With this, it can be stated that the strengths

	Recall	**0.851**	**0.961**	**0.768**	**0.895**
	F1 score	0.854	**0.965**	0.791	**0.928**

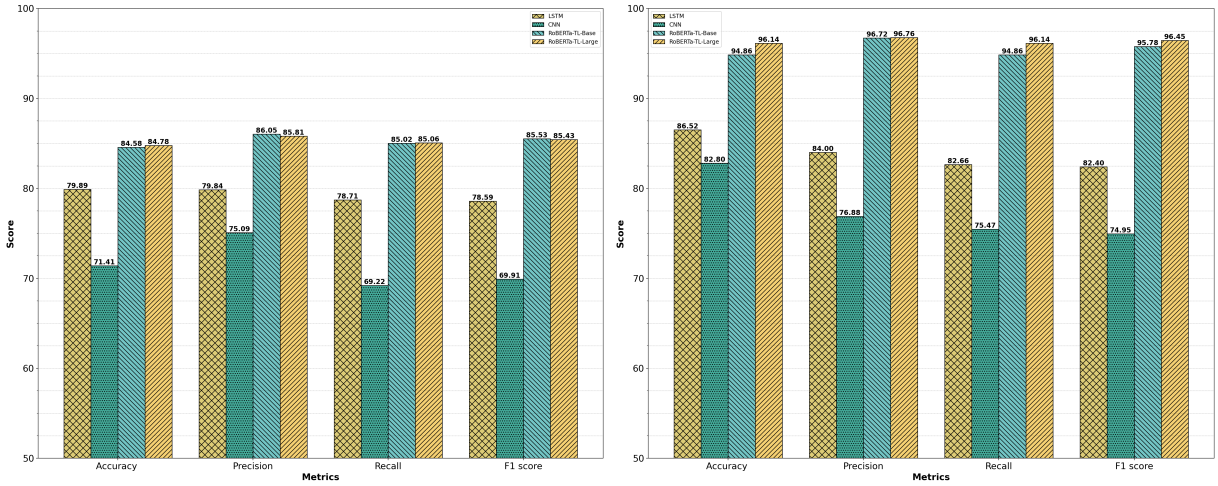
[1]SEN = Sentence-level features, PARA = 1000-character chunk features

of RoBERTa-TL-Large are fully utilized when using paragraph features, as it showed significantly better performance than other models.

Based on Table 5, we evaluate the performance of the specialized neural networks on word2vec, specifically LSTM and CNN. CNNs are mainly utilized for image processing because of their pattern detection capabilities (Ruder et al., 2016). Since sentences also have a sequential dimension, CNNs are able to effectively capture the context and stylistic elements of different authors. Despite this, CNN only achieves an accuracy of 59.1% at the sentence level on the test dataset for 34 authors.

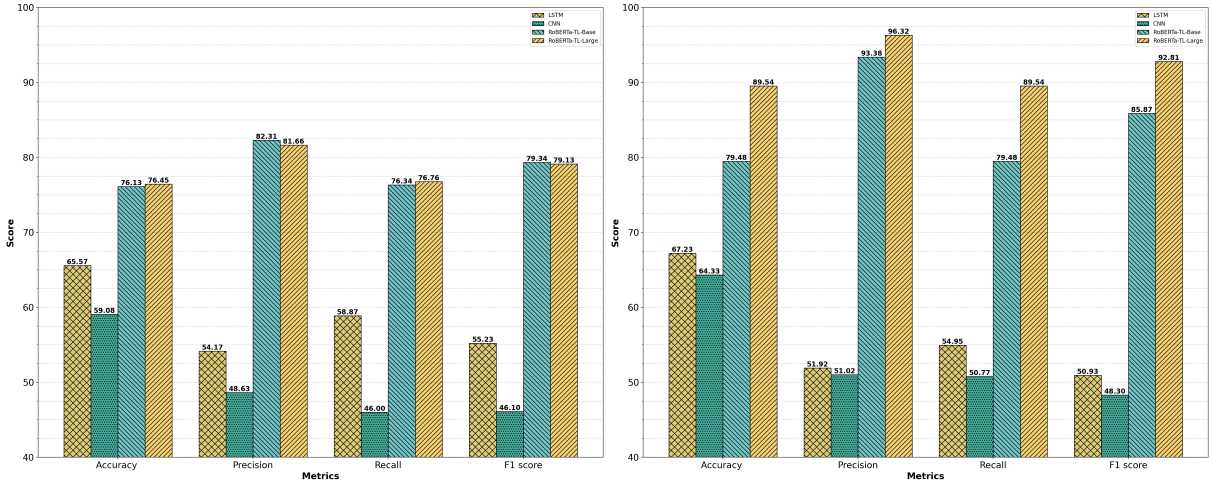
In contrast, the LSTM can retain memory by using its prior output as one of its inputs (Zaremba et al., 2014). Additionally, the gating mechanisms in LSTM assist in filtering out less significant information, enabling the model to extract relevant features that identify an author's style (Zaremba et al., 2014).

With this, the LSTM model significantly outperformed the CNN model on all evaluation metrics on the test set. Specifically, for the test dataset with 34 authors at the sentence level, the LSTM achieves an accuracy of 65.6%. While this is higher than the CNN, both models underperform when trained and tested on the full corpus of 34 authors. This



(a) 10 authors sentence-level features

(b) 10 authors 1000-character chunk features



(c) 34 authors sentence-level features

(d) 34 authors 1000-character chunk features

Figure 2: Authorship attribution performance in terms of Accuracy, Precision, Recall, and F1 score

underperformance may be due to the difficulty in distinguishing between authors who have very similar writing styles, which might have confused the models. Additionally, it is worth noting that the data was somewhat imbalanced, which might have caused the models to be biased toward the authors with the most entries.

Based on the comparison of the two corpora (10 authors vs. 34 authors), it can be observed that the F1 scores achieved by the LSTM, CNN, and the RoBERTa-TL models for the subset of 10 authors are substantially higher than the full corpus of 34 authors. Since there are fewer authors, there is less intricacy and writing style overlap, which makes it simpler to discern between the subtleties in their vocabulary and writing style. Additionally, the models may benefit from a deeper understanding of the language nuances present in the smaller set, allowing for more effective differentiation between the authors' writing styles. As the number of authors increases, the task becomes more challenging due to the increased variability and similarity in writing.

When comparing the sentence-level features and the paragraph features, it is shown that all deep learning models produced the highest F1 score using paragraph features. This suggests that longer contexts might provide more information to differentiate the author's writing styles. However, an exception is observed for LSTM when classifying 34 authors, where the sentence feature outperformed the paragraph feature. This might be due to the paragraph feature with 34 authors producing more noise than clarity, making it more challenging for the LSTM model to classify the authors. This implies that while longer contexts often provide more information, the model's capacity to use it will rely on its architecture and the specific task.

6 Conclusion

This study contributes to the field of authorship attribution (AA) by focusing on the Filipino language. We developed the Panitikan corpus, a Philippine literature dataset representing 19th-century to early 20th-century works. The corpus includes 724,133 tokens across 47 literary works attributed to 34 different authors.

For feature selection, we explored both sentence-level and paragraph-level features, and compared the performance of models trained on a subset of 10 authors against those trained on the full 34-author dataset. One of the study's key contributions is the use of fine-tuned RoBERTa-Tagalog models, which were benchmarked against deep learning models such as Long Short-Term Memory (LSTM) networks and Convolutional Neural Networks (CNN). The RoBERTa-Large model achieved the highest performance, with an accuracy of 0.961 and an F1-score of 0.965 on the 10-author dataset when using paragraphs as input. For the 34-author dataset, the RoBERTa-Large model reached an accuracy of 0.895 and an F1-score of 0.928, outperforming CNN and LSTM models by 10-17

Our findings suggest that reducing the number of authors from 34 to 10 improves model accuracy and F1-score, likely due to the more balanced data distribution with the top 10 authors having the most tokens. Additionally, using paragraph-level inputs with 1000-character chunks resulted in better performance than sentence-level inputs, possibly because longer contexts provide more information to distinguish authors' writing styles and reduce input size variability.

This study represents the first attempt to implement AA specifically for Filipino literary texts. While our focus was on applying deep learning models to this context, our findings have broader implications. They contribute to the understanding of text analysis in the Filipino language, aid in the historical analysis of documents to verify authorship, and support literary studies by identifying authorial style.

7 Recommendations

To further enhance AA research in Filipino literary works, several recommendations can be made:

1. ***Expand the Dataset***. Increasing the dataset size by including more works from the same authors could help models better capture an author's entire range of writing styles, rather than being limited to individual pieces.

2. ***Incorporate Contemporary Works***. Including more recent literary works could allow for a comparative analysis between classical and modern writing styles, providing deeper insights into evolving authorship patterns.

3. ***Improve Data Balancing Techniques***. As the dataset grows, developing more efficient data balancing techniques will be crucial to minimize biases and ensure that models learn from a diverse set of texts.

4. ***Explore Paragraph-Level Features***. Further research into paragraph-level features is recommended. Testing different chunk sizes (both longer and shorter) could yield better results in distinguishing writing styles.

5. ***Experiment with Word Embeddings and Model Architectures***. Investigating different word embeddings, such as FastText or GLoVe, might improve model performance. Additionally, combining CNN and LSTM networks could potentially enhance results by leveraging the strengths of both architectures.

6. ***Explore Advanced Models and Attention Mechanisms***. Future research should consider experimenting with other Transformer-based models or advanced attention mechanisms. These models might achieve comparable or even superior performance to our current best metrics, thereby improving AA in Filipino literary texts.

Abstract

This study investigates the use of linguistic features to enhance clickbait detection in traditional Chinese news headlines from Taiwanese media. While clickbait detection has been extensively explored in English, research on Chinese—especially in the context of Taiwanese media—remains sparse. Existing studies often focus on simplified Chinese from Chinese media, which may not accurately reflect the cultural and linguistic nuances of Taiwanese news. This research applies linguistic features, such as forward-reference, listicle formats, and suspenseful or exaggerated language, to improve clickbait detection using neural network models. The study's dataset consists of real online news headlines in Taiwan, and models including RNN, LSTM, GRU, and their bidirectional variants were employed in the analysis. The Bi-GRU model performed best, with linguistic features further improving accuracy to 0.75. This study contributes to the field by utilizing deep learning on a traditional Chinese dataset and demonstrates the value of linguistic features in enhancing model accuracy.

1 Introduction

The title of an article plays a crucial role in summarizing its content and enabling readers to quickly assess its relevance (Scott, 2021). However, in an era of information overload, people have limited attention to spare for articles. As a result, certain media employ manipulated headlines, commonly known as clickbait, to lure readers into clicking on their content. Subsequently, readers may realize that the actual article content does not align with their initial expectations. Clickbait refers to " content whose main purpose is to attract attention and encourage visitors to click on a link to a particular web page " (Chen et al., 2015). This technique creates an " information gap " and conceals the core essence of the article by presenting events in an ambiguous manner to entice readers' clicks (Loewenstein, 1994).

It is important to distinguish clickbait from fake news, as the key distinction lies not in the authenticity of the content, but in the gap between the headline and the article content. These intriguing statements, lacking clear explanations, entice readers' curiosity and create a curiosity gap (Loewenstein, 1994; Scott, 2021). The readers do not know what exactly happened until they click on the article. It is a trap that many people have fallen into, and several studies have pointed out that clickbait headlines make people feel cheated and uncomfortable (Beleslin et al., 2017; Chen et al., 2015; Shinkhede, 2019; Jung et al., 2022). However, distinguishing clickbait titles from conventional ones may be possible due to their distinct writing style. Blom and Hansen (2015) argue that clickbait employs stylistic and narrative techniques as diversions, while propose four presentation variables for clickbait: incomplete information, appealing expressions, repetition and serialization, and exaggeration.

Previous research suggests that linguistic clues can be used to identify these writing differences. Clickbait often utilizes the forward-reference technique to imply the existence of highly relevant information without actually providing it. Therefore, unresolved pronouns including demonstrative pronouns, personal pronouns, deictic words, and deixis, commonly appear in clickbait titles. (Bazaco et al., 2019; Blom and Hansen, 2015; Shinkhede, 2019). Additionally, clickbait employs the listicle format to attract readers (Vijgen et al., 2014). Listicle headlines present articles in a list for-

mat, indicating the number of items and the list's theme in the title. However, readers cannot only understand the actual content of the list from the title and they must click to access the complete list. (Bazaco et al., 2019). Suspenseful words and exaggerated words are also common characteristics of clickbait (Lun, 2021). Suspenseful words, such as "reveal," "uncover," and "expose," create an anticipation of secrets being unveiled. These terms are strategically used in clickbait headlines to entice readers by promising to solve mysteries or disclose complete information. Exaggerated words employ imaginative language to captivate readers' attention (Bazaco et al., 2019). To sum up, the utilization of linguistic cues holds great potential in facilitating the detection of clickbait and providing individuals in avoiding its associated pitfalls.

2 Related work

Early clickbait detection tasks involved binary classification using traditional supervised models with feature extraction. In early research, Potthast et al. (2016) constucted an English clickbait corpus using Twitter tweets from the top 20 most prolific publishers, containing well-known English newspapers publishers such as BBC News. Three annotators categorized the data into clickbait and non-clickbait categories. Features such as teaser messages, linked web page, and meta information are extracted for model training. The performance of three machine learning algorithms: Logistic Regression, Naive Bayes, and Random Forest was compared. Meanwhile, Chakraborty et al. (2016) collected non-clickbait data from Wikinews and clickbait data from other news media to develop a browser add-on for detection. Features based on sentence structure, word patterns, clickbait language, and n-gram were adopted for model training, employing Decision Tree (DT), Random Forests (RFs), and Support Vector Machine (SVM) as learning algorithms. With the development of neural networks, more clickbait detection tasks have been conducted using deep learning models. Chawda et al. (2019) employed neural network algorithms, such as Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU), for the clickbait detection tasks. Additionally, they incorporated a Recurrent Convolutional Neural Network to capture contextual information. Their findings suggested that deep learning algorithm models outperformed traditional supervised algorithm model, such as SVM.

While the majority of studies on clickbait detection have concentrated on English texts, there has been relatively little exploration into Chinese texts. Liu et al. (2021) addressed this gap by constructing a clickbait dataset from WeChat, a Chinese social media platform, focusing on news headlines. They labeled the data into three categories—non-clickbait, general clickbait, and malicious-clickbait, which included vulgar or pornographic titles—using a three-person majority vote. Subsequently, Liu et al. (2022) further expanded on this by exploring the extraction of semantic and syntactic information for training, with both traditional and deep learning algorithms, such as Bidirectional Encoder Representation from Transformers (BERT) and Bidirectional Long Short-Term Memory (Bi-LSTM) networks, showing superior performance.

However, even among the limited studies on Chinese texts, the focus has predominantly been on simplified Chinese used in mainland Chinese online media. This approach may not accurately capture the nuances of clickbait in traditional Chinese news due to cultural and linguistic differences. Therefore, this study aims to address these gaps by conducting clickbait detection on traditional Chinese news headlines from Taiwanese media. The objective is to investigate if linguistic features identified in previous studies on English texts can enhance the automatic classification of clickbait in traditional Chinese contexts.

3 Methodology

3.1 Dataset

A total of 1010 news headlines were collected from Nownews, a Taiwanese news media known for providing the latest news with the fastest updating rate. Three annotators were taught the principle of clickbait, and a majority vote was conducted to classify the data into two categories: clickbait and non-clickbait. The annotation results revealed an imbalanced dataset, consisting of 275 clickbait

Feature Category	Description	Examples
Forward-reference	Demonstrative pronouns, personal pronouns	他/她 (he/she), 這 (this), 那 (that)
Listicle	Numbers	一 (one), 二 (two), 三 (three)
Suspenseful words	The words revealing the secret to create suspense	疑 (doubt), 曝 (expose), 露 (reveal), 公開 (unveil)
Exaggerated words	Emotional punctuations and words	！ (exclamation mark), ？ (question mark), 驚 (shock), 轟 (boom)

Table 1: Categories of handcrafted linguistic features

and 735 non-clickbait headlines. Due to the limited data size, oversampling was not performed to avoid overfitting. Instead, random undersampling was applied, resulting in a total of 550 news headlines, evenly distributed with 275 in each category. Subsequently, the dataset was split into an 80:20 ratio, where 80% of the data was used for training, and 20% for testing. A random seed was set for reproducibility.

3.2 Embedding

The data underwent preprocessing, retaining only the characters, and then tokenization was performed. The tokenized words were converted into word vectors capable of capturing word semantics, which served as text features for model training. Subsequently, CKIP Glove, a pre-trained embedding, was employed. CKIP Glove was a word embedding trained on the Chinese GigaWord Corpus and the Academia Sinica Balanced Corpus of Modern Chinese. It consists of 300-dimensional word vectors (Chen and Ma, 2017, 2018; Fan et al., 2019).

3.3 Feature Extraction

Table 1 presents the categories of handcrafted linguistic features, including forward-reference, listicle, suspenseful words, and exaggerated words.

Forward-reference such as, personal pronouns “他/她” (he/she), and demonstrative pronouns “這” (this) and “那” (that), introduce a curiosity gap, enticing audiences to click on the associated links, while suspenseful and exaggerated words are frequently employed to make sense of drama and attract readers ’ curiosity(Jung et al., 2022; Scott, 2021).

3.4 Training

Deep learning algorithms, Recurrent Neural Networks (RNN) and their variants, such as Long Short-Term Memory (LSTM), and Gated Recurrent Unit (GRU), have been commonly employed in clickbait detection tasks (Chawda et al., 2019; Liu et al., 2021). In this study we adopted these neural network algorithms: (1)RNN (2)LSTM (3)GRU, as well as their bidirectional counterparts: (1)Bi-RNN (2)Bi-LSTM (3)Bi-GRU. The baseline models were using text vectors and the pre-trained embedding, with the inclusion of optimizers. After training, the baseline models were compared to each other. The model had the best performance was selected for further training, incorporating handcrafted linguistics features.

3.5 Evaluation

Following the training phase, the baseline models were evaluated based on accuracy and F1-score to determine the best-performing model one for the second phase of training, which included handcrafted linguistic features. After the second phase of training, the model was evaluated in terms of precision and recall for further error analysis.

4 Results

Table 2 presents the performance of various deep learning models in clickbait detection. The models were evaluated based on their accuracy and F1 score. Among these six baseline models, the Bi-GRU model with Glove embeddings demonstrated superior performance, achieving an accuracy of 0.74 and an F1 score of 0.73. To further enhance its performance, the Bi-GRU baseline model and was augmented with hand-crafted linguistic features. The resulting model, referred to as Bi-GRU with Glove embeddings and hand-crafted linguistic features, achieved the highest perfor-

Model	Accuracy	F1 score
LSTM + Glove (pretrained embedding)	0.70	0.70
GRU + Glove	0.69	0.70
RNN + Glove	0.67	0.70
Bi-LSTM + Glove	0.70	0.71
Bi-GRU + Glove	**0.74**	**0.73**
Bi-RNN + Glove	0.67	0.65
Bi-GRU + Glove + hand-crafted linguistic features	**0.75**	**0.74**

Table 2: Performance comparison of different models using Glove embeddings.

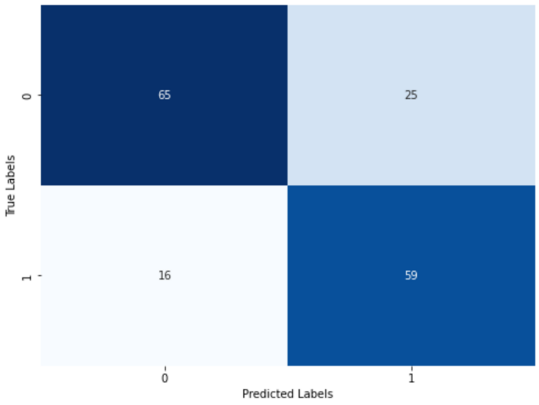

Figure 1: Confusion Matrix of Bi-GRU model with Glove embeddings and hand-crafted linguistic features.

mance with an accuracy of 0.75 and an F1 score of 0.74. This model will be further analyzed in subsequent steps. Figure 1 illustrates the confusion matrix of the Bi-GRU model with Glove embeddings and hand-crafted linguistic features.

Based on the confusion matrix, the precision of the model is calculated as 0.70, indicating that among the predicted positive clickbait instances, 70.2% were actually clickbait. The recall of the model is calculated as 0.79, indicating that the model identified 78.6% of the actual clickbait instances. The F1-score, which combines precision and recall, is calculated as 0.74. Overall, the results demonstrate promising capabilities of the Bi-GRU model with Glove embeddings and hand-crafted linguistic features in clickbait detection.

5 Discussion

The model exhibits a lower Type II error rate, implying fewer false negatives. This suggests a higher recall, indicating that most of the actual clickbait headlines are successfully detected. Conversely, the model demonstrates a higher Type I error rate, resulting in more false positives. Only 70.2% of the headlines predicted as clickbait were actually clickbait. This training outcome suggests that the model may exhibit overgeneralization, classifying more non-clickbait headlines as clickbait, thereby mistakenly identifying some non-clickbait instances.

Upon further examination of the model's prediction errors, particularly within the Type I error category, it is evident that the model often misclassifies non-clickbait headlines containing emotive punctuation marks such as exclamation and question marks as clickbait. This finding aligns with an observed trend where certain non-clickbait headlines, which lack a hook and present content directly related to the headline, are still misclassified as clickbait due to the presence of these exaggerated punctuations. This suggests that emotive punctuations, while often present in clickbait, are also common in non-clickbait Chinese news headlines, reflecting a broader stylistic convention in Chinese journalism that the model has not yet differentiated effectively. Optimization focusing on reducing reliance on emotive punctuation for classification may effectively decrease false positives, leading to a substantial improvement in precision and overall recognition capability.

Additionally, in the Type II error category, it is observed that certain clickbait headlines employ provocative verbs to describe an event without explicitly revealing its nature. However, the model misclassifies them as non-clickbait. This could be attributed to the rich vocabulary and creative phrasing often employed in Chinese news headlines. The model's misclassification of such headlines may indi-

cate a gap in its training corpus, where it may not have learned sufficient vocabulary or contextual nuances. To address this, expanding the lexicon used in hand-crafted linguistic features by collecting diverse vocabulary from news-related corpora could potentially reduce false negatives and increase the model's recall.

To sum up, the Bi-GRU model with Glove embeddings and hand-crafted linguistic features exhibits promising performance in clickbait detection. However, optimization strategies that address both the overgeneralization towards emotive punctuation in non-clickbait headlines and the vocabulary gaps that lead to missed clickbait headlines could significantly enhance precision and recall, leading to improved overall model performance.

6 Conclusion

In conclusion, we conducted clickbait detection training using deep learning models on news headlines from Taiwanese media, with the Bi-GRU model demonstrating the best performance among the neural networks tested. While the inclusion of handcrafted linguistic features improved the model's performance, several limitations emerged. The linguistic features employed in previous studies were primarily based on English data, which presents challenges when applied to Chinese. For instance, Chinese characters can carry multiple meanings depending on the context, unlike English, which typically uses fixed vocabulary for specific meanings. Additionally, a single character may represent various meanings in Chinese, leading to potential confusion when these characters are combined. This issue is further compounded in Chinese news headlines, which often abbreviate words by omitting one character from a two-character term, a phenomenon unique to the language. Such abbreviations can deepen the challenges of text comprehension for models. Similarly, different words in Chinese may convey similar meanings, adding another layer of complexity to feature extraction.

Our future work will focus on refining feature extraction methods, including developing specialized tokenizers and expanding the training dataset. We will also explore the impact of exaggerated words and emotive punctuation on clickbait detection and investigate how linguistic features of clickbait vary across different news categories. These efforts aim to improve both the precision and recall of the model, leading to more robust and accurate clickbait detection in Chinese news headlines.

Acknowledgments

We are sincerely grateful to the three anonymous reviewers for their insightful and constructive feedback, which broadened our perspectives and enriched our understanding of the topic. Their thoughtful suggestions have been invaluable in refining this paper. While we were unable to incorporate all of their recommendations due to time constraints, their input will undoubtedly inform our future work and further research.

We also wish to express our deep appreciation to Professor I-Ping Wan and Professor Yu-Yun Chang for their guidance and support throughout the preparation of this manuscript. Their expertise and advice were instrumental in shaping the direction of this work. Any remaining limitations are solely our responsibility, and we look forward to building upon this foundation in subsequent studies.

Abstract

Emerging research in Filipino Automatic Personality Recognition (APR) often utilizes social media data for its widespread availability and natural expression. However, current approaches focusing on direct personality trait modeling often yield subpar results, prompting exploration of alternative methods. Thus, we explored an APR framework where individual personality questionnaire item responses are predicted and then aggregated to estimate trait scores. Using text data from 2,168 Filipino X (formerly Twitter) users, we trained models for each item in the Big Five Inventory (BFI) related to Extraversion and Conscientiousness. We also experimented with multiple configurations of logistic regression, SVM, and XGBoost models using TF-IDF and term occurrence values. Findings highlight the challenges in predicting trait scores for both Extraversion and Conscientiousness. While implementing a hierarchical classification scheme at the item level showed some improvement, especially for Conscientiousness, overall trait-level performance remains lacking. Overall, while the original pipeline as well as the integration of a hierarchical approach show potential, significant improvements are needed before this item-based framework can be effectively used for APR.

1 Introduction

The extent of a person's individuality and identity encompasses a great number of factors, from their daily experiences all the way to their hobbies, interests, and way of interacting with others. Such traits are often considered part of one's personality—defined by the American Psychological Association as a collection of "enduring characteristics and behavior that comprise a person's unique adjustment to life." Numerous scientific theories and approaches have been created in order to deepen the world's understanding of personality into how it is today. As part of its evolution, personality psychology has been integrated into computational science; through the use of machine learning and natural language processing (NLP), personality recognition was made possible by incorporating data or signals from human-machine interaction, including but not limited to social media and telecommunication (Mushtaq and Kumar, 2022).

Works on text-based APR have branched out to include attempts to derive personality from social media posts within a specific regional context. There are a lot of cultural linguistic nuances that can serve as integral personality indicators, yet models are not always able to extract information that properly encapsulates these intricacies brought about by multilingualism.

With this new aspect of APR, studies on personality recognition on Filipino user data have begun to take place. From attempts at extraction methods (Agno et al., 2019; Chua Chiaco et al., 2022) to modeling Filipino personality traits using supervised learning models (Tighe and Cheng, 2018), Filipino APR studies are slowly breaking ground with the goal of applying techniques that can capture the rich linguistic diversity of the nation. However, since this particular branch of study is relatively new, there have been unsuccessful ventures as well; at present, existing studies on the use of higher complexity models such as neural networks (Tighe et al., 2020) failed to yield good results, especially considering that this was attempted when Filipino user data was scarce.

Given the current state of Filipino APR, it begs the question of whether it is possible to utilize another approach at modeling personality traits instead of directly generating user personality profiles from social media data. One such alternative is a questionnaire-based approach, wherein models trained on social media data will then predict how the user might answer a question from a personality inventory. By combining APR with

a questionnaire-based framework, it may reveal a new angle of extracting, processing, and analyzing data that will be able to account for the cultural linguistic cues found in the Filipino language—and by extension, can also be applied in the context of general, non-regional APR research.

The general objective of this study is to investigate the effectiveness of a questionnaire item-based prediction approach to automatic personality recognition on social media text data. The specific objectives of the study are defined below:

1. To define a list of qualification criteria for deriving a subset of the *PagkataoKo* dataset;
2. To extract text-based information from users' social media posts;
3. To build and train prediction models for each personality questionnaire item using the generated user embeddings;
4. To evaluate and analyze the performance of the item-based prediction models at an individual item level and an overall trait score level; and
5. To compare the item-based prediction approach to automatic personality recognition against baseline prediction models

The results of this study represent the output of a different approach to APR, specifically predicting users' Likert scale-type answers to the BFI questionnaire instead of predicting their personality trait scores directly. Due to the uniqueness of the approach, it offers the viability of utilizing the approach to conduct APR and introduces the idea of predicting questionnaire items for other models as well.

2 Methodology

This section provides a step-by-step breakdown of the individual processes undertaken to achieve the objectives of this study. As seen in Figure 1 that shows the overall research pipeline, using the original *PagkataoKo* dataset, a smaller subset of data was derived by filtering based on a set of defined qualification criteria. Then, preprocessing and feature extraction were done on the data of each user from their X (formerly Twitter) posts. After, feature reduction was performed to further trim down the number of features. Machine learning models were then built for each questionnaire item under the Extraversion and Conscientiousness traits, which were trained and tested. The mentioned traits were chosen among the Big Five in accordance with Tighe and Cheng's (2018) findings about the two being the easiest to model.

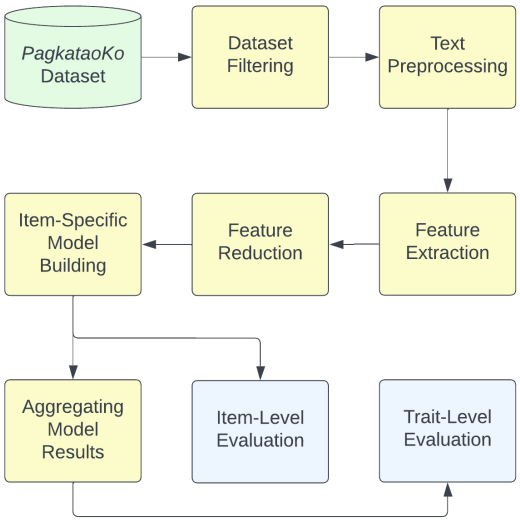

Figure 1: Diagram of the Overall Research Pipeline Following Our Proposed Item-Based Approach

The resulting predictions for each questionnaire item were then aggregated to estimate the Extraversion and Conscientiousness trait scores of each user. Evaluation of the machine learning models were conducted for each individual item, along with a separate trait-level evaluation to assess the performance of the overall approach of utilizing questionnaire item predictions for estimating personality trait scores.

2.1 Data Source

The dataset used in the study is the *PagkataoKo* dataset curated by Tighe et al. (2022). Collected starting the first week of June 2019 up until the second week of February 2020, the study was able to gather a total of 3,128 records and contains information about Filipino X (formerly Twitter) and/or Instagram users such as demographic data, account metadata, post data, and personality data.

The primary information utilized from the dataset includes the X (formerly Twitter) post data such as the actual post text and the data containing BFI responses and overall score per dimension which are needed for ground truth comparisons and evaluation.

To align with the scope of the study, the data was

filtered according to set qualification criteria. First, the users must be of Philippine legal age; that is, they must be at least 18 years old. Second, as the study is focused on text-based data, the users must have X (formerly Twitter) with at least 50 posted tweets.

A simple demographic and summary statistic analysis was conducted on the original curated dataset as well as the filtered qualifying dataset. These statistics are reported on Table 1..

Demographics	Universal Set	Twitter Subset	Qualified Subset
Count	3,128	2,283	2,168
Age			
Mean	21.2	21.0	21.0
SD	3.9	3.9	3.6
Age Range			
18-20	53.9%	55.9%	56.0%
21-23	29.3%	29.0%	29.2%
24-26	9.3%	8.5%	8.5%
$\geq$ 27	7.5%	6.6%	6.3%
Sex			
Male	21.0%	22.0%	21.5%
Female	76.1%	75.0%	75.5%
Intersex	0.5%	0.6%	0.6%
Declined[1]	2.4%	2.5%	2.4%
Nationality			
Filipino	99.2%	99.1%	99.2%
Mixed[2]	0.8%	0.9%	0.8%

[1] Declined to disclose their sex
[2] Filipinos with one or more other nationalities

Table 1: Demographic statistics across the universal set of all participants (U), the subset of participants with Twitter accounts (T), and the subset of participants with Twitter accounts that satisfied the qualification criteria (QT)

2.2 Text Preprocessing

Preprocessing was first performed on the text corpus. The study mainly utilized tokenization and N-Grams. For tokenization, Marges's (2019) Pinoy TweetTokenizer will be used, which is a modified TweetTokenizer for the Filipino language. The tokenizer features are as follows:

1. Replacing usernames with a placeholder (i.e. USERNAME);
2. Hashtag tokenization;
3. Limiting repeating syllables;
4. Emoticon tokenization;
5. Replacing URLs with a placeholder (i.e. URL); and
6. Lowercasing

For N-Grams, the study utilized NLTK's *nltk.lm* package to extract *n*-grams of different lengths needed (Bird et al., 2009). It should be noted that only unigram and bigram features were tested.

2.3 Formulating User Documents

Concurrently, while performing text preprocessing, user documents were constructed wherein all tweets of a user were combined into one document for analysis. To do this, the study utilized the technique of concatenation of strings in each tweet of a particular user which then forms the user document. To implement this, tokenization was first performed on the text at the tweet level, followed by applying *n*-grams to the tokens of each tweet, outputting a group of tokens per tweet. From there, we concatenate the arrays of tokens together, formulating a user document for a particular user where these tokens are treated as terms.

2.4 Feature Extraction

Feature extraction was performed on the preprocessed text data to extract the necessary information from the text. The study utilized TF-IDF and Term Occurrence as the extraction methods. Due to the *PagkataoKo* dataset containing multiple languages (i.e., English and Filipino), both TF-IDF and Term Occurrence are among the more viable methods as these can handle multilingual text and terms. There are two parameters in the tfidfVectorizer that were included as experiment parameters, which are *min_df* and *max_df*. Both *min_df* and *max_df* are document frequency filters that remove features depending on the percentage of documents they are found in.

2.5 Feature Reduction

In order to retain only the most relevant features as input for model building, feature reduction techniques were employed on the training set. Note that this was also treated as an experiment parameter, testing between the use of the chi-square test and principal component analysis (PCA). Using the chi-square (X^2) test, we only retained the features that fall within the top 20% of results and these features were selected for training the machine learning models.

2.6 Model Building

The study made use of the following supervised machine learning models that focused on solving

a classification problem centered around the prediction of BFI item responses based on their social media data:

- Logistic Regression
- Support Vector Machine with a Non-Linear Kernel
- XGBoost

These three models were chosen because in the context of the study, they may perform best given the amount of data available.

It is worth noting that since the study focuses on predicting responses to BFI questions, individual models were created for each of the 17 BFI items under either Extraversion or Conscientiousness. In addition to the approach of directly classifying the specific Likert scale-type responses for each item, the study also experiments with a two-phase, hierarchical classification scheme. This alternative method involves training initial models that broadly classify users' responses into one of three categories: (a) 1-2, (b) 3, or (c) 4-5. Then, for the second phase, a set of binary models is trained for each item to further distinguish users' responses within each category, thus obtaining the specific item responses.

2.7 Aggregating Item-Level Model Results

Once the individual item-level models were used to predict the responses of a given user, these results were then be aggregated to estimate their raw personality trait scores. This may be accomplished by following the pseudocode depicted in Algorithm 1, which is patterned after the actual scoring metric of the BFI. The algorithm shows how to calculate each trait score by obtaining the average of the predicted responses for all question items that fall under a particular personality trait. In doing so, it should also be kept in mind that questions tagged as reversed should have their responses converted accordingly.

Algorithm 1 Aggregating Item-Level Model Results

Input: Predicted item responses for a given user
Output: List of estimated personality trait scores

```
initialize empty trait score list
for each personality trait do
    sum = 0
    for each question item under current trait do
        if question item is reversed then
            sum += REVERSE(predicted response)
        else
            sum += predicted response
        end if
    end for
    trait score = sum / number of questions under current trait
    append current trait score to trait score list
end for
return trait score list
```

3 Experiment Setup and Evaluation

3.1 Experiment Setup

This study experimented with multiple combinations of feature extraction, feature reduction, and machine-learning techniques to identify the configurations that yield the most optimal results.

A total of 17 item-level models were created for each configuration or combination of techniques as described above to correspond to each of the items in the Big Five Inventory that correspond to either Extraversion or Conscientiousness.

Furthermore, it should also be noted that a train-validation-test split was applied on the dataset, with a split ratio of 70%, 15%, and 15%, respectively. This was implemented by utilizing scikit-learn's *train_test_split* function to ensure objective and black-boxed splitting.

3.2 Item-Level Evaluation

This phase of the experiments centers on building models for the 8 items under Extraversion and the 9 items under Conscientiousness.

Experiment parameters came in the form of multiple combinations of feature extraction and reduction techniques as well as machine learning algorithms and configurations, all utilized to derive the best performing model for each item. Taking into account all of the experiment parameters except for the two-phase hierarchical classification scheme, there are a total of 96 configurations generated for each item (*2 feature extraction methods* × *2 feature reduction methods* × *3 machine learning algorithms* × *2 min_df values* × *4 max_df values*). Additionally, the set of 96 experiment configurations is conducted using the two-phase hierarchical classification approach, resulting in a final total of 192 models per questionnaire item (*96 models us-*

ing direct approach + 96 models using two-phase hierarchical classification approach).

Following model training and hyperparameter tuning, the primary metric that was used to determine the best model configuration for each item was the validation F1 score, as this takes into consideration the class imbalance present in the source dataset's distribution of item responses. In the case of the models created following the two-phase hierarchical classification approach, the validation F1 score of the initial broad classification models is the metric used as the basis for determining the best configurations. These best models then make the final predictions of the test users' answers, which are then compared to their ground-truth responses for each item.

Baseline models were implemented using majority class classifiers to serve as benchmarks for comparing the proposed best item models. These classifiers were trained using the responses for each item, identifying the majority class as a constant predictor.

3.3 Trait-Level Evaluation

This second phase of the experiment focused on acquiring the predicted item responses for each trait from the best item models in the previous phase and computing for the users' trait-level scores using the designated formula of the BFI.

Once the personality trait results were aggregated for each user in the test set and compared against their ground-truth trait scores, evaluation was performed with the use of root mean squared error (RMSE) and R^2 score.

Similar to the previous phase, baseline models were employed to have a further comparison and performance evaluation of the proposed approach. These baselines included a mean regressor, a simple linear regression model, and a multi-layer perceptron (MLP) regressor.

The mean regressor was trained using the raw personality trait scores from the dataset, with the average score for each trait serving as a constant predictor. Meanwhile, the pipeline for both the mean regressor and the MLP regressor follows a process similar to the proposed approach up until the feature reduction stage. However, instead of proceeding to item-specific model-building and aggregation, the pipeline for these baseline models directly transitions to trait-specific model building and trait-level evaluation. This divergence stems from their trait-based approach of training directly on the raw personality trait scores of each user, rather than on the individual item responses as in the proposed approach.

4 Results

4.1 Evaluation of Initial Proposed Approach

4.1.1 Item-Level Evaluation Results

Out of all the item-level models constructed and tested during experimentation, only the configurations that achieved the best validation results for each individual questionnaire item are reported.

Table 2 and Table 3 provide overviews of the best-performing models for each Extraversion item and each Conscientiousness item, respectively. The results of these item models are also juxtaposed with the results of baseline majority class classifiers, as illustrated in Figure 2 and Figure 3.

Across all of the Extraversion and Conscientiousness item models, there appears to be a fair amount of variance in the optimal configurations identified for almost all of the parameters included in the experiment. The one exception, it seems, is the feature type for the Extraversion item models, as most seem to favor the use of Term Occurrence, possibly due to its potential to aid in model generalization.

As seen in Table 2, the overall test F1 scores of the best item models for Extraversion fall between 0.3000 to 0.5000, with Item 31R achieving the highest test F1 score at 0.4334. Conversely, the weakest performing model belongs to Item 36, which has a test F1 score of approximately 0.3196. A comparison of these F1 scores with those obtained on the train-validation set suggests a possibility that the models overfitted on the training data.

Item-Level Results for Extraversion							
Item	**Min_df**	**Max_df**	**Feature Reduction**	**Algorithm**	**Feature**	**Train-Val F1**	**Test F1**
Item 1	0.1	0.9	PCA	LR	TO	1.0000	0.3450
Item 6R	0.05	0.7	CHI	XGB	TF-IDF	1.0000	0.3740
Item 11	0.05	0.9	CHI	LR	TO	1.0000	0.3311
Item 16	0.1	0.7	CHI	LR	TF-IDF	1.0000	0.3586
Item 21R	0.05	0.6	PCA	LR	TO	1.0000	0.3386
Item 26	0.1	0.6	CHI	XGB	TO	1.0000	0.3785
Item 31R	0.05	0.8	CHI	SVM	TO	0.9875	0.4334
Item 36	0.1	0.9	PCA	SVM	TO	0.9962	0.3196

Table 2: The performance and configurations of the best performing classification models per Extraversion item. Models were selected based on validation F1 score.

Compared to the results produced by the Extraversion item models, the range of values for the test F1 scores of the best performing Conscientiousness item models is generally broader, both on the lower and higher ends of the scale. Table 3 reveals

that the best performing item model for Conscientiousness produced a test F1 score of 0.5416, while the worst performing model had a test F1 score of 0.2426.

Item-Level Results for Conscientiousness							
Item	**Min_df**	**Max_df**	**Feature Reduction**	**Algorithm**	**Feature**	**Train-Val F1**	**Test F1**
Item 3	0.05	0.9	CHI	XGB	TO	0.7207	0.4574
Item 8R	0.05	0.9	CHI	XGB	TO	0.9902	0.5416
Item 13	0.1	0.6	CHI	XGB	TF-IDF	0.2761	0.2426
Item 18R	0.1	0.6	PCA	SVM	TO	0.8959	0.2534
Item 23R	0.1	0.6	PCA	LR	TO	1.0000	0.4373
Item 28	0.05	0.7	PCA	LR	TF-IDF	0.9680	0.4152
Item 33	0.1	0.7	CHI	LR	TF-IDF	1.0000	0.3534
Item 38	0.05	0.6	PCA	LR	TF-IDF	1.0000	0.2750
Item 43R	0.1	0.9	PCA	XGB	TF-IDF	1.0000	0.3921

Table 3: The performance and configurations of the best performing classification models per Conscientiousness item. Models were selected based on validation F1 score.

As evidenced by the side-by-side comparisons of the test F1 scores for the item models of both traits against the baseline majority classifiers in Figure 2 and Figure 3, it becomes apparent that all of the proposed item models consistently underperform. This disparity in classification performance may potentially be caused in part by the disproportionate number of samples for the majority class label of each questionnaire item. The degree to which this class imbalance exists can be seen from how most of the majority class classifiers exhibited test F1 scores above 0.5.

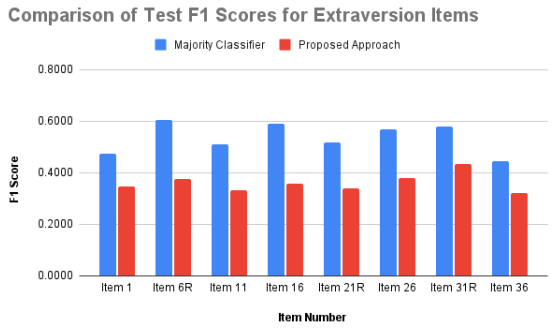

Figure 2: A comparison of test F1 scores between baseline majority class classifiers and the best item models for Extraversion

4.1.2 Trait-Level Evaluation Results

Table 4 and Table 5 present the trait-level results comparing the aggregated predictions against the ground-truth personality trait scores for Extraversion and Conscientiousness, respectively. The results of the proposed approach are also compared to that of 3 different baselines, particularly, a mean

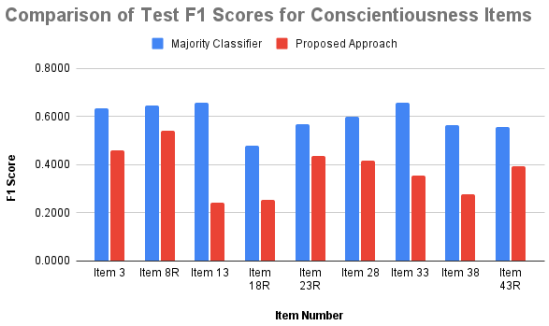

Figure 3: A comparison of test F1 scores between baseline majority class classifiers and the best item models for Conscientiousness

regressor, a linear regression model, and a multi-layer perceptron regressor.

For the Extraversion trait, Table 4 shows that the proposed approach produced the best results, with the lowest test RMSE of approximately 0.6714, and the highest R^2 score of around 0.1240. However, when taking these values on their own, the R^2 value can be considered relatively low. This may suggest that the variance in the Extraversion trait scores is still not explained very well by the predictor using the given features.

Trait-Level Results for Extraversion				
Model	**Train-Val RMSE**	**Train-Val R^2**	**Test RMSE**	**Test R^2**
Mean Regressor	0.7499	0.0000	0.7175	-0.0003
Linear Regression	0.2650	0.8751	0.6747	0.1154
MLP Regressor	0.7500	-0.0004	0.7174	0.0000
Proposed Approach	0.0382	0.9974	0.6714	0.1240

Table 4: The trait-level results for Extraversion using the proposed approach as well as baseline models

Compared to Extraversion, the results produced by all of the models for the Conscientiousness trait are considerably worse. The proposed approach performs the worst with a test RMSE of 0.6760 and a test R^2 value of -0.2273, while the linear regression model performs the best with a test RMSE of 0.6010 and a test R^2 value of 0.0298. These results show that the initial item-based approach for Conscientiousness leaves much to be improved, as direct trait modeling still works better in predicting overall trait scores.

Interestingly, despite generally having better test RMSE scores, the Conscientiousness models appear to have poorer test R^2 scores across the board, which may suggest that with the given feature set, Conscientiousness trait scores are more challenging to predict compared to Extraversion.

Trait-Level Results for Conscientiousness				
Model	**Train-Val RMSE**	**Train-Val R^2**	**Test RMSE**	**Test R^2**
Mean Regressor	0.6108	0.0000	0.6105	-0.0010
Linear Regression	0.2499	0.8326	0.6010	0.0298
MLP Regressor	0.6144	-0.0120	0.6162	-0.0199
Proposed Approach	0.2033	0.8892	0.6760	-0.2273

Table 5: The trait-level results for Conscientiousness using the proposed approach as well as baseline models

4.2 Evaluation of Proposed Approach with Hierarchical Classification

Another experiment was done with the proposed approach, particularly the integration of a hierarchical classification scheme. As mentioned previously, hierarchical classification attempts to classify the data into broader classes (e.g. Class *1-2*, Class *4-5*) on the first classification layer, then classifies the data in a more specific class (e.g. Class *1*, Class *2*) on the second layer. This experiment was done to attempt to classify data points better by grouping classes that were closer to each other first and then differentiating them later on.

Item 43R	0.6583	0.4156	0.7148	1.0000	0.5480	0.7604	0.5399

Table 7: Conscientiousness Results with Hierarchical Classification

Tables 6 and 7 show the results of the item models with hierarchical classification, along with the validation F1 scores for each layer for both *broad* and binary classification.

The *broad* F1 scores represent classification accuracy in the first layer of classes, specifically in Classes *1-2*, *3*, and *4-5*, respectively. These aforementioned scores for both traits show generally higher values, meaning that on the *broad* level of classification, the models are able to classify more accurately compared to previous scores.

The validation F1 scores labeled *specific*, on the other hand, are not as high as the *broad* F1 scores. The *specific* F1 scores pertains to the accuracy of classifying the data to the actual response prediction classes (i.e. Class *1, 2, 3, 4, 5*).

The validation F1 scores labeled *Binary* represent the accuracy of predicting the right binary class after the first classification layer has been done (i.e. Binary 1 - Class *1 and 2*, Binary 2 - Class *3*, Binary 3 - Class *4 and 5*). Although the F1 scores for each Binary are generally high, this only deals with classifying the data into one or two classes.

Trait-Level Results for Extraversion		
Version	**Test RMSE**	**Test R^2**
Original	**0.6714**	**0.1240**
Hierarchical Classification	0.7126	0.0131

Table 8: Extraversion Trait-Level Results for Original and Hierarchical Experiments

Trait-Level Results for Conscientiousness		
Version	**Test RMSE**	**Test R^2**
Original	0.6760	-0.2273
Hierarchical Classification	**0.6270**	**-0.0560**

Table 9: Conscientiousness Trait-Level Results for Original and Hierarchical Experiments

Overall, observing the results found in Table 7, the validation scores look somewhat promising, with predictions that look more accurate after passing through two layers as opposed to the original proposed approach for Conscientiousness. It can be observed that the approach with hierarchical classification is a potentially viable method in classifying as it produced more accurate results at the item-level. This difference in metric scores may likely be attributed to the step-by-step process of classifying the data, where data is classified in a broader threshold of similar classes and then further differentiated on the second level. By breaking the modeling process into two phases, this approach

better accounted for the inherent ordinality of the data and showed that the models still had potential for distinguishing between high and low responses, which was particularly beneficial for the Conscientiousness trait. However, despite an improved item-level performance, the trait-level results still much to be desired. That said, it is still a step in the right direction to be able to classify the item-level data more accurately at least at the *broad* level.

5 Conclusion

Following initial item-level and trait-level evaluations of the approach, it was inferred that due to data imbalance, substantial results became hard to derive because models performed poorly in terms of item-level prediction, and were even outperformed by baseline classifiers and regression models. In hopes of addressing this issue, a hierarchical classification approach was integrated, which involved breaking down the modeling process into two phases. Implementing this method showed a somewhat distinct advantage, most notably for the Conscientiousness trait. However, while the hierarchical approach worked relatively better for Conscientiousness, the original pipeline still reigned for Extraversion. This difference in model inclination may be attributed to the difference in feature significance between the two traits.

It is also worth noting that when compared against baseline models, the original pipeline still performed best for Extraversion, whereas the baselines performed better for Conscientiousness even with the slight improvement provided by the hierarchical approach. This supports the deduction that Conscientiousness items responses may be harder to predict, particularly with the given data.

With these results, it is evident that this particular field of APR study, especially in a Filipino context, leaves much room for pondering and experimentation. Some models indeed showed promise, but even the so-called best performing models have very low test metric scores. The overall results of this study signify that more tuning for both data and models needs to be done for this item-based approach to manifest improvements and become a framework that can prove beneficial to APR.

6 Recommendation

Future works that will choose to build up on the results from this study are encouraged to focus more on the best performing approaches for each trait. They can delve into more experimentations that aim to determine how the data qualitatively correlates to model performance, and what can be changed during preprocessing, extraction, and reduction in order for models to learn better from them and attain the most optimal performance results. Another angle of interest is examining trait-level result correlations with feature tokens, as this may help in identifying trends or patterns in terms of how each trait's best performing approach assigns weights or significance to certain terms or phrases, especially considering the mix of English and Filipino linguistic nuances.

At a more general level, future studies may opt to focus on a wider scope. Recommendations include exploring multimodal approaches that make use of images alongside textual data, testing the item-based approach on a high-resource language like English to more accurately assess the impact of data quantity, and investigating methodologies on how to properly structure social media data.

Future works may also address the identified issues from the results of the study, mainly data imbalance leading to model overfitting, hyperparameter limitations, and data quality or weight assignments on features. This can be done by increasing hyperparameter search space and number of iterations for the models, as well as attempting to experiment only with the unigram data instead of including bigrams.

The potential of the hierarchical approach can also be expounded upon; with proper data balancing methods and the right set of configurations, this approach may prove to be integral and beneficial to the overall pipeline.

Other recommendations include exploring other feature extraction and reduction techniques, as well as utilizing the remaining three traits of the Big Five (Openness, Agreeableness, and Neuroticism) to determine if the proposed approach could work equally or better as compared to its Extraversion and Conscientiousness results. Future works are also recommended to test the proposed approach against diverse datasets and different social media platforms and contexts in order to have a better benchmark for performance and generalizability.

Open-domain Named Entity Recognition for Low Resource Languages A Case Study on Vietnamese

Viet Ngo Q. and **Huong Le T.** *
School of Information and Communication Technology,
Hanoi University of Science and Technology, Hanoi, Vietnam
vietnq.work@gmail.com and huonglt@soict.hust.edu.vn

Abstract

Named Entity Recognition (NER) is a crucial component of Natural Language Processing (NLP) systems, essential for tasks such as information retrieval and question answering. However, existing NER models often struggle with the broad spectrum of entity types encountered in open-domain settings, particularly in low-resource languages like Vietnamese, which lack extensive labeled datasets. This study introduces a novel method for fine-tuning multilingual models, specifically mT5 and mT0, to address open-domain NER tasks in Vietnamese. We generated a comprehensive open-domain annotated Vietnamese NER dataset using a large language model (LLM) and evaluated the models in both zero-shot and supervised fine-tuning settings. The mT0-large model achieved F1 scores of 0.6030 on VLSP NER 2021 and 0.5753 on PhoNER_COVID19 in zero-shot, improving to 0.7489 and 0.9431, respectively, with supervised fine-tuning. This method shows promise for improving NER in low-resource languages.

1 Introduction

Natural Language Processing (NLP) has seen a surge in real-world applications, ranging from voice assistants to automated content analysis. Among the various NLP tasks, Named Entity Recognition (NER) plays a crucial role in extracting structured information from unstructured text by identifying and classifying entities into predefined categories such as names, locations, and organizations (Grishman, 2019). This task is foundational for many downstream applications, including information retrieval (Khalid et al., 2008) and question answering (Mollá et al., 2006), where accurate entity recognition is essential.

Despite its importance, the field of open-domain NER, which involves recognizing a wide range of entity types across various domains beyond traditional categories, remains underexplored. Open-domain NER has the potential to significantly enhance many NLP applications by improving the flexibility and accuracy of entity recognition in diverse contexts. However, developing effective open-domain NER models is particularly challenging for low-resource languages like Vietnamese, where high-quality and diverse datasets are limited.

This paper aims to address these challenges by proposing a novel approach to train multilingual NER models that can handle the complexities of open-domain scenarios in Vietnamese. Our method focuses on fine-tuning multilingual models, specifically mT5 and mT0, to accommodate a broad spectrum of entity types, overcoming the limitations posed by the scarcity of Vietnamese NER datasets. We also explore the potential for multilingual transfer and multitask learning within encoder-decoder architectures, aiming to enhance their performance in recognizing a wide array of entities in Vietnamese.

The contributions of this research are threefold. First, we introduce a method for training multilingual models tailored to open-domain NER, with a focus on their application to low-resource languages like Vietnamese. Second, we provide insights into the multilingual transfer and multitask learning capabilities of encoder-decoder models, offering a framework for their adaptation to various linguistic contexts. Finally, we present a newly created and cleaned open-domain Vietnamese NER dataset, which serves as a useful resource for future research in this area. Through these contributions, this study advances our understanding of NER in low-resource languages and paves the way for further exploration in other underrepresented linguistic settings.

2 Related Work

In English, established NER models such as BERT (Devlin et al., 2019), GPT-3 (Brown et al., 2020), and spaCy (Honnibal and Montani, 2017) excel at identifying fixed entity types since they benefit from extensive annotated datasets and advanced pre-training techniques. Vietnamese NER has also seen significant advancements, particularly through models contributed by VinAI (Nguyen and Nguyen, 2020; Dao and Nguyen, 2020), the VLSP workshop (Ha et al., 2022), and the community. Despite these advancements, Vietnamese NER datasets remain limited to fixed entity types, similar to those in English and other languages. Less effort has been directed toward developing open-domain NER systems capable of recognizing a broader range of entities.

UniversalNER (Zhou et al., 2024) has recently explored a new approach involving targeted distillation with mission-focused instruction tuning to train student models like LLaMA (Touvron et al., 2023). These models can excel in open-domain NER tasks by being distilled from large models like ChatGPT, achieving promising results. However, these efforts are limited to English and involve large model sizes, making them impractical for many applications. Additionally, the transferability of these models to languages with limited datasets, like Vietnamese, remains unexplored.

Multilingual models like mT5 (Xue et al., 2021) and mT0 (Muennighoff et al., 2023) offer a promising avenue for cross-lingual NER tasks. These models, built on the Transformer architecture, have shown proficiency in handling multiple languages simultaneously. Recent developments in cross-lingual transfer learning and fine-tuning have demonstrated that multilingual models can effectively leverage data from high-resource languages (such as English) to improve performance in low-resource languages (like Vietnamese). Many studies on multilingual models have explored various strategies to enhance performance across languages. Using self-supervised learning techniques to pre-train on extensive multilingual corpora followed by task-specific fine-tuning has proven effective. However, the application of these methods to open-domain NER remains limited.

This research seeks to build on the current state of multilingual NER by focusing on smaller, efficient models (mT5 and mT0) and maximizing the use of available English data and other available Vietnamese datasets to compensate for the lack of Vietnamese NER datasets. The research aims to contribute a practical approach to recognizing a wide range of entity types in Vietnamese, addressing open-domain challenges, and ensuring the models remain accessible and efficient for broader applications.

3 Method

Traditional NER models use tagging styles like IOB or IOB2, where tokens are labeled to indicate their position within an entity. These models work well with fixed entity types but struggle with open-domain NER, where texts may contain diverse and ambiguous entities. Unlike traditional methods that identify and classify tokens into different entity types, our method focuses on type-specific extraction, resulting in a list of entities of the specified type rather than requiring the identification and categorization of spans into multiple types, as shown in Figure 1.

For this task, we chose mT5 and mT0, multilingual encoder-decoder models that leverage both English and Vietnamese datasets. Encoder-only models were excluded due to their lack of text-generation capabilities. Although decoder-only models can be applicable in some NER contexts, they are generally weaker for structured extraction tasks. Their autoregressive nature is optimized for generating text rather than for extracting specific entities from a text. Encoder-decoder models, on the other hand, provide a more robust framework for identifying entities by leveraging both the understanding of input context and the generation of precise outputs. The methodology involves two steps: first, comparing mT5 and mT0 to identify the better base model for NER by fine-tuning each under various configurations; second, developing a fine-tuning strategy for open-domain NER in Vietnamese. In this process, we fine-tune the pre-trained encoder-decoder models using different settings by leveraging existing English and Vietnamese datasets. Additionally, we create a comprehensive Vietnamese open-domain NER dataset to enhance model performance in this task. Each approach will be evaluated using the F1 score to determine the most effective method for robust NER performance in Vietnamese.

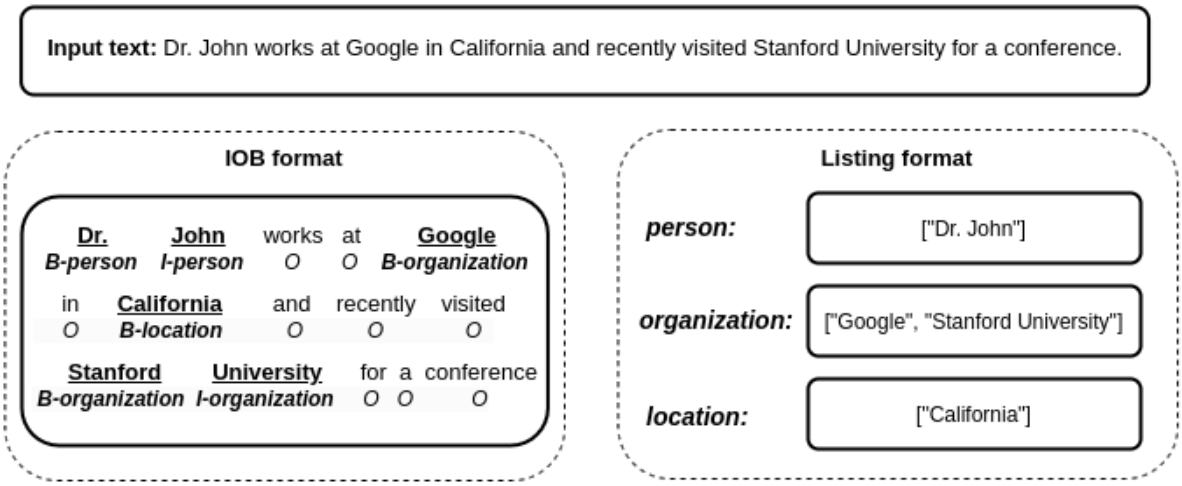

Figure 1: Comparison of NER labeling styles: Tagging (left) vs Extracting (right)

3.1 Dataset Preparation

This section provides an overview of the datasets used for fine-tuning and evaluation. We will employ five datasets for fine-tuning purposes: two open-domain NER datasets (one in English and one in Vietnamese), two instruction-tuning datasets (one in English and one in Vietnamese), and one Vietnamese question-answering dataset. For evaluation, we will utilize three GOLD datasets: one English NER dataset and two Vietnamese NER datasets. Detailed descriptions of these datasets and their specific roles in the fine-tuning and evaluation processes will be provided in the following sections.

3.1.1 Datasets for Multi-tasking and Multi-lingual Training

The English open-domain NER dataset used in this research is derived from the Pile-NER-Type dataset developed by UniversalNER (Zhou et al., 2024). This dataset, created from the Pile corpus using GPT-3.5, includes a wide range of entity types without a predefined set. To align with the sequence-to-sequence models (mT0 and mT5) used in this study, the dataset was reformatted from its original conversation-style format into instruction-input-response prompts, as shown in Figure 2, which were inspired by Alpaca dataset (Taori et al., 2023). This process resulted in 354,261 samples, each containing a prompt and an output string listing the extracted entity mentions, making it suitable for training the models effectively.

In this research, we utilize two instruction-tuning datasets to enhance the model's capability to follow instructions. The first dataset is an upgraded version of the Stanford Alpaca dataset, which comprises 52,000 instruction-following examples generated using GPT-4[1], whereas the original was generated using GPT-3.5[2]. The Vietnamese dataset, known as the Vietnamese Alpaca (Nguyen et al., 2024), consists of 50,000 varied instructions in Vietnamese, generated using GPT-4, following a methodology similar to that used for the English Alpaca dataset (Taori et al., 2023). Both datasets undergo preprocessing to fit a common instruction prompt template, ensuring consistency and sim-

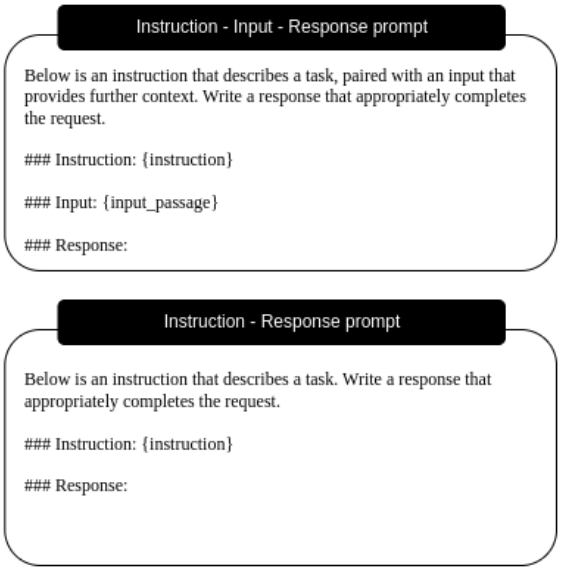

Figure 2: Instruction-input-response prompt template

[1] https://github.com/Instruction-Tuning-with-GPT-4/GPT-4-LLM

[2] https://huggingface.co/datasets/tatsu-lab/alpaca

plicity. The final datasets retain samples where the prompt and label lengths are within 1024 tokens, facilitating effective fine-tuning of sequence-to-sequence models.

Moreover, we utilize the UIT-ViQuAD v1.1 dataset (Nguyen et al., 2020), a benchmark designed to evaluate machine reading comprehension (MRC) in Vietnamese. This dataset comprises over 23,000 human-generated question-answer pairs based on 5,109 passages extracted from 174 Vietnamese Wikipedia articles. Developed through a rigorous process involving the recruitment, training, and validation of workers, the UIT-ViQuAD dataset ensures high-quality, diverse, and relevant content. It serves as a crucial resource for advancing MRC models in the Vietnamese language. In our research, UIT-ViQuAD is used as an additional task in the multi-tasking fine-tuning process of developing our open-domain NER model for Vietnamese.

3.1.2 Vietnamese Open-domain NER Dataset

To minimize costs, we used LLaMA 3 70B from Meta to generate data instead of ChatGPT-3.5. We randomly sampled 6,600 passages from the BKAI News Corpus dataset [3]. These passages are raw text and have not yet been annotated with labels. These samples were concatenated and split into 36,000 smaller passages, each ranging from 150 to 256 tokens in length, and were required to contain at least one complete sentence to maintain textual integrity.

The prompt used to generate data was inspired by the approach in (Zhou et al., 2024), but modified to suit Vietnamese data (see Figure 3). The generation temperature was set to 0 during the data creation process to ensure consistency and stability. This process yielded 34,274 samples, each with two attributes: the input passage and a list of entities extracted by LLaMA 3. Following the same procedure applied to the English open-domain NER dataset, we then split the Vietnamese data into samples containing one entity type per example, resulting in 136,895 samples.

The entity types identified by LLaMA 3 were initially quite varied, with many referring to the same concept but represented differently. Some entity types were formatted in code-like terms, such as "*entity_type:person*" and "*entity_type:field_of_study*", then underwent a pre-

[3] https://huggingface.co/datasets/bkai-foundation-models/BKAINewsCorpus

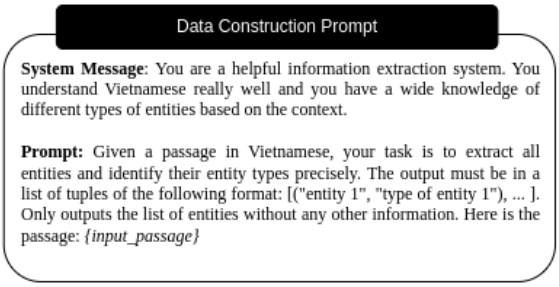

Figure 3: Data construction with LLaMA 3 prompt template

processing step to reformat these entity types to make them more natural and user-friendly. Entity types extracted in other languages, such as Chinese and those with unclear meanings were manually reviewed and removed. Additionally, samples containing hallucinated entities (entities not present in the input text) were also removed.

Finally, the dataset was filtered to remove samples where the input text or label exceeded 1024 tokens, similar to the English open-domain NER dataset. This step ensured compatibility for training sequence-to-sequence models. The final dataset consists of 125,518 samples, covering 3,522 different entity types across a wide range of domains.

The distribution of entity types followed a heavy tail pattern, with the top 1% of entity types accounting for 71% of the total frequencies. While the most common entity types are *organization*, *location*, and *person*, the dataset also includes rarer entity types such as *country*, *concept*, and *document*. Notably, out of the 3,522 distinct entity types in the dataset, more than 2,000 of them, which are not typically used in traditional NER tasks, appear only once. This diverse coverage is crucial for developing models capable of handling open-domain NER tasks.

3.1.3 GOLD Datasets

We utilize several high-quality datasets for supervised fine-tuning and evaluation of the proposed Vietnamese open-domain NER model. These datasets include UNER English EWT (Mayhew et al., 2024a), PhoNER_COVID19 (Truong et al., 2021), and VLSP NER 2021 (Ha et al., 2022). Each dataset is already divided into training, development, and test sets when it was published, and these pre-defined splits are used for fine-tuning and evaluation in our experiments.

The **PhoNER_COVID19** dataset (Truong et al.,

2021) is a COVID-19 domain-specific NER dataset for Vietnamese, developed with newly-defined entity types. This dataset comprises 10,000 sentences containing over 35,000 entities, categorized into 10 specific entity types. These entity types are designed to extract key information related to COVID-19 patients. The PhoNER_COVID19 dataset is used to benchmark our model's performance on domain-specific entities.

The **VLSP NER 2021** dataset (Ha et al., 2022) is a comprehensive resource for evaluating NER models in Vietnamese, specifically designed to assess the ability to recognize entities across 14 main types, 26 subtypes, and 1 generic type. The dataset includes a total of 2,140 annotated articles, drawn from diverse domains such as life, science and technology, education, sport, law, and entertainment. It is divided into a training set of 1,830 articles, which includes 81,173 named entities (with 1,282 articles from the VLSP 2018 NER dataset and 538 new articles), and a test set of 310 new articles, containing 19,538 named entities. This dataset is instrumental in benchmarking NER models in the Vietnamese language for general, rather than domain-specific, entity recognition tasks.

The **UNER English EWT** dataset (Mayhew et al., 2024a) derived from the multilingual NER benchmark (Mayhew et al., 2024b), provides a gold-standard resource for evaluating NER systems in English. The dataset comprises 5,985 samples, partitioned into 4,592 training samples, 646 development samples, and 747 test samples. It includes annotations for three entity types: location, organization, and person. This benchmark is instrumental for assessing NER models' performance across various languages, particularly when the models are fine-tuned exclusively on English data or in conjunction with other languages and tasks.

3.2 Base Model Selection

The first step in developing an effective open-domain NER model for Vietnamese involves selecting an appropriate base model and assessing its initial performance through fine-tuning. This section outlines the process of selecting between mT5 and mT0 models, followed by the initial fine-tuning procedure.

To determine the most suitable model, both the base and large versions of mT5 and mT0 were fine-tuned. This approach aimed to identify the better-performing model type between mT5 and mT0, and to observe the behavior of different model sizes, as shown in Figure 4. For the mT5 model, two fine-tuning configurations were performed. The first configuration involved fine-tuning the mT5 model exclusively on the open-domain English NER dataset. The second configuration entailed initially fine-tuning the mT5 model on a mixture of English and Vietnamese instruction-tuning datasets, based on the hypothesis that the mT5, being a pre-trained model, might benefit from an initial phase of instruction-following fine-tuning. Subsequently, the model was fine-tuned on the open-domain English NER dataset.

For the mT0 model, which is already fine-tuned on multi-tasking data, direct fine-tuning on the open-domain English NER dataset was performed to evaluate its performance. The fine-tuned models were then assessed on both the English and Vietnamese NER datasets (the GOLD datasets) to determine their overall performance in these two languages. It is important to note that the open-domain English NER dataset generated by ChatGPT was not used for evaluation as it is not considered a GOLD standard dataset. Based on the evaluation results, the better-performing model was selected for subsequent fine-tuning stages.

3.3 Advanced Fine-tuning

After selecting the better-performing model from the initial fine-tuning process, the next step involves advanced strategies to enhance the model's performance. The steps involved in fine-tuning the model are chosen using multi-task learning and two-stage fine-tuning, as illustrated in Figure 5. The fine-tuned models are evaluated in two ways: zero-shot setting and supervised fine-tuning, which will be discussed below.

3.3.1 Multi-task Learning

Multi-task learning involves training the model on multiple related tasks to enhance its ability to understand the text and generate accurate responses for those tasks. In this study, the NER task is formulated as a sequence-to-sequence problem, where the input sequence includes the input passage along with a question asking the model to extract a specific entity type, making the task similar to a question answering problem. Therefore, we decided to fine-tune the selected model from the previous process with a mix of the open-domain English dataset and the Vietnamese question-answering dataset. The reason for choosing the Vietnamese question-answering dataset is that it is not only a related

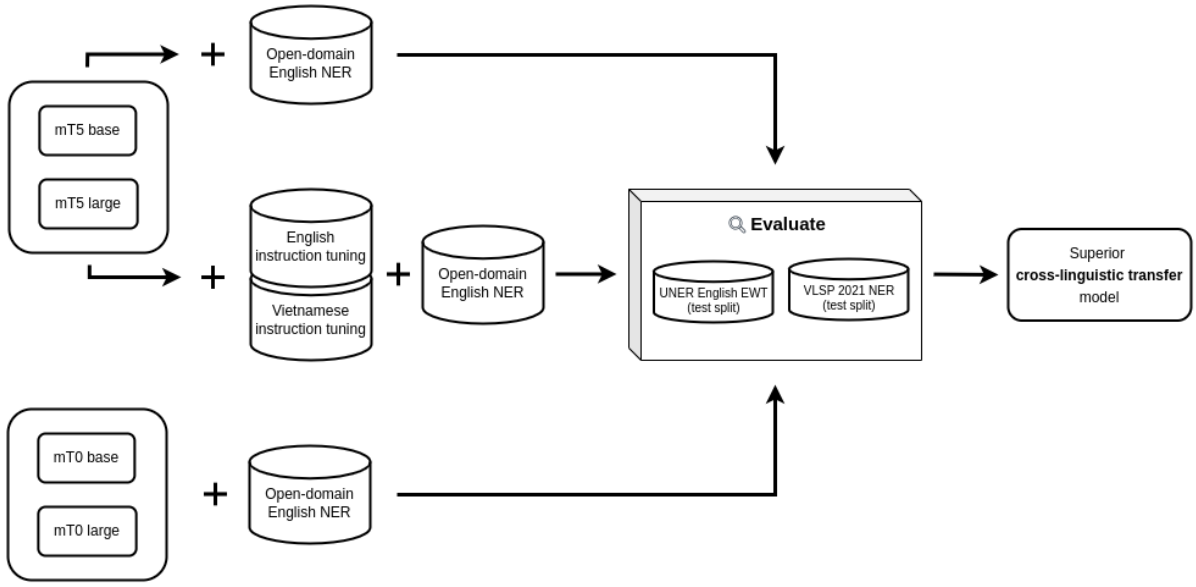

Figure 4: Base model selection steps

task but also in Vietnamese, the target language for improved model performance. The expectation is that the model can leverage the high-quality English NER data to enhance its performance on Vietnamese text by training in both languages simultaneously, allowing the model to learn patterns and features common to both languages.

3.3.2 Two-stage Fine-tuning

Instead of fine-tuning the model once, a two-stage fine-tuning strategy was designed. Initially, the model is fine-tuned similarly to the multi-task learning strategy, but uses a large portion of the English open-domain NER dataset for training. After the initial training, the model is further fine-tuned with the remaining portion of the English open-domain NER dataset and the Vietnamese open-domain NER dataset. This approach leverages the extensive English data in the first stage and utilizes the multi-task learning strategy to learn both the NER task and the Vietnamese language. The second stage prioritizes the Vietnamese language by using a larger portion of Vietnamese data compared to English data, enhancing the model's performance in Vietnamese while retaining its knowledge of the NER task in English.

3.3.3 Evaluation

The models fine-tuned using the above strategies are evaluated on both English and Vietnamese GOLD NER datasets, with a particular focus on performance on Vietnamese datasets. Two Vietnamese datasets are used for evaluation: the PhoNER_COVID19 dataset and the VLSP NER 2021 dataset.

Evaluation is conducted in two phases: zero-shot and supervised fine-tuning. Initially, models are evaluated on the two datasets without training on their respective training splits to assess their zero-shot capability. Subsequently, the models undergo supervised fine-tuning on the training data of each evaluation dataset to evaluate their performance after learning domain-specific data.

4 Results and Discussion

4.1 Evaluation Parameters

We use the F1 score as the evaluation metric to assess overall model performance. Unlike traditional NER models that use tagging formats like IOB to extract and classify entity spans, the open-domain NER model evaluates by identifying entities of a single type from the input text. Instead of tagging, the model outputs a list of entities, which simplifies the evaluation and adapts to the open-domain task, allowing for easier comparison against a gold-standard dataset.

4.2 Simulation Method

4.2.1 Base Model Selection

For the fine-tuning process involving the mT5 model, data from the English and Vietnamese instruction-tuning datasets were randomly mixed before fine-tuning all data of the open-domain English NER dataset. The mT0 model, which shares

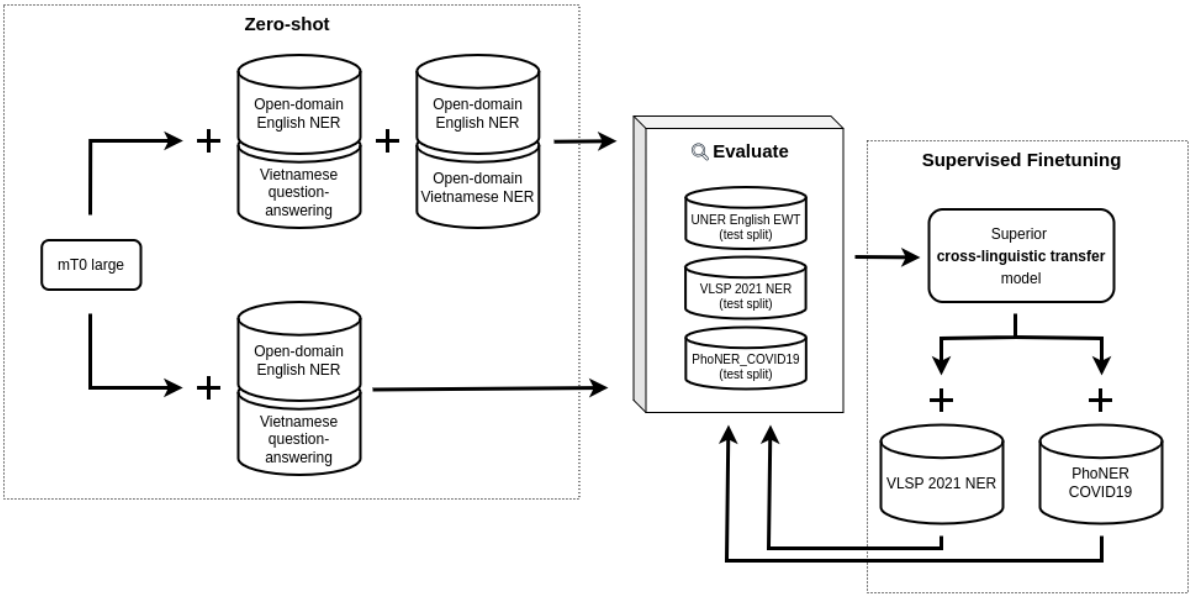

Figure 5: Advanced Fine-tuning

the same tokenizer as the mT5, underwent a fine-tuning process involving only the open-domain English NER dataset.

During training, data were tokenized and padded to match the length of the longest sequence in each batch. Given that the model sizes were manageable, parameter-efficient fine-tuning (PEFT) strategies were not necessary. Thus, a supervised fine-tuning (SFT) strategy was applied, involving updating all model parameters. All models were fine-tuned with a batch size of 256 and a constant learning rate of 0.0001 over one epoch, in line with the approach reported in the mT5 paper for both pre-training and fine-tuning stages.

Upon completion of the fine-tuning stages, six fine-tuned models were obtained. These models were evaluated using the test splits from the UNER English EWT dataset and the VLSP 2021 NER dataset. The evaluation process involved comparing the predicted list of entities to the target entities, with the F1 score used as the primary metric to assess the model's ability to identify correctly entities of a given type.

4.2.2 Advanced Fine-Tuning Strategy

For the multi-task fine-tuning strategy, the best-performing model was fine-tuned using a mixture of the English open-domain NER dataset and the Vietnamese question-answering dataset. All data from both datasets were used in the fine-tuning process. The English dataset constituted the majority, with 318,261 samples, while the Vietnamese

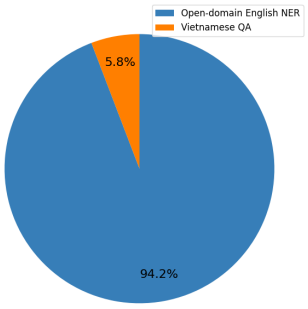

Figure 6: Multitask data proportion

dataset contributed 19,608 samples. These were randomly mixed before training. The same batch size of 256 and a constant learning rate of 0.0001 over one epoch were employed as in the base model selection step.

In the two-stage fine-tuning strategy, different datasets were used in each stage. For the second stage, 113,161 samples from the Vietnamese open-domain NER dataset were utilized. To ensure the model retains its English knowledge while enhancing its Vietnamese proficiency, 25,261 English samples (one-fourth of the Vietnamese dataset size) from the English open-domain NER dataset were reserved for mixed-language fine-tuning. In the first stage, the remaining English open-domain NER dataset (293,000 samples) was used for multi-task training with the Vietnamese question-answering dataset. The data distribution for this two-stage fine-tuning strategy is illustrated in the pie charts in Figure 7.

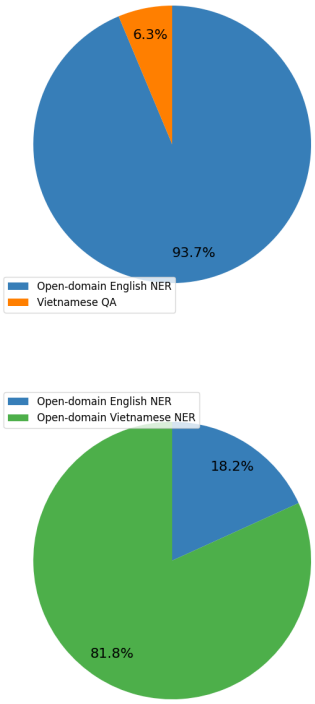

Figure 7: Two-stage data proportion

By adopting these fine-tuning strategies, the goal was to improve the model's performance in Vietnamese open-domain NER tasks by being able to recognize a wide range of entity types.

4.3 Base Model Selection Results

The results of the base model comparison are presented in Table 1, where the performance of each model is evaluated on both English and Vietnamese GOLD datasets for the NER task. Among the models tested, mT0-large shows the most promising results, with an F1 score of 0.7852 in English and 0.4518 in Vietnamese, despite being fine-tuned exclusively on English data. This model demonstrates strong cross-lingual transfer capabilities, outperforming the other models in Vietnamese NER.

mT5 models generally perform well in English but struggle in Vietnamese, especially without exposure to Vietnamese during training. Introducing mixed-language instruction tuning before fine-tuning slightly improves performance in both languages. However, mT0-large's superior results suggest that it is the best candidate for further fine-tuning, particularly for enhancing cross-lingual NER performance in Vietnamese. The next steps will focus on refining this model by incorporating more Vietnamese data.

4.4 Advanced Fine-tuning Strategy Results

The mT0-large model was further fine-tuned using strategies that leveraged English and Vietnamese datasets for developing an open-domain NER system. This section reports the model's performance in two settings: zero-shot evaluation and supervised fine-tuning.

4.4.1 Zero-shot Evaluation

The mT0-large model, fine-tuned with a mix of open-domain English NER data and Vietnamese question-answering data, achieved an F1 score of 0.7775 on English NER, slightly lower than when fine-tuned solely on English data. However, the model's performance on the VLSP NER 2021 dataset improved significantly, with an F1 score of 0.5259, indicating that incorporating Vietnamese data, even from a different task, enhances its ability to recognize Vietnamese entities. On the PhoNER_COVID19 dataset, the model's F1 score was 0.4679, which is lower than other models like BiLSTM-CRF and XLM-R, likely due to the domain-specific nature of PhoNER_COVID19.

A two-stage fine-tuning strategy consisting of learning from open-domain English NER and Vietnamese question-answering, followed by fine-tuning on mixed English and Vietnamese NER data yielded better results. This approach achieved the highest F1 score on English NER and improved the F1 scores on VLSP NER 2021 and PhoNER_COVID19 by 0.08 and 0.11, respectively. Although these results in a zero-shot setting may not seem groundbreaking, they demonstrate the potential of the two-stage fine-tuning strategy for cross-lingual NER tasks.

4.4.2 Supervised Fine-tuning Evaluation

Given its superior performance in the zero-shot evaluation, the two-stage fine-tuned mT0-large model was further evaluated in a supervised setting.

When fine-tuned on the VLSP NER 2021 dataset, the mT0-large model outperformed most models submitted by VLSP participants, achieving an F1 score of 0.6030 in a zero-shot setting and 0.7489 after fine-tuning on the full training data. This superior performance can be attributed to the model's exposure to a wide range of entities during pre-training, facilitating better recognition of the diverse entity types in the VLSP dataset.

	UNER English EWT	VLSP NER 2021
mT5-base en-open-NER	0.7440	0.3032
mT5-large en-open-NER	0.7615	0.4105
mT5-base mIT + en-open-NER	0.7579	0.3332
mT5-large mIT + en-open-NER	0.7747	0.4193
mT0-base en-open-NER	0.7574	0.3035
mT0-large en-open-NER	**0.7852**	**0.4518**

Table 1: Base model performance comparison

	English NER	VLSP NER 2021	PhoNER_COVID19
mT0-large en-open-NER mix vi-QA	0.7775	0.5259	0.4679
mT0-large en-open-NER mix vi-QA + mNER	0.8074	**0.6030**	**0.5753**

Table 2: Zero-shot evaluation

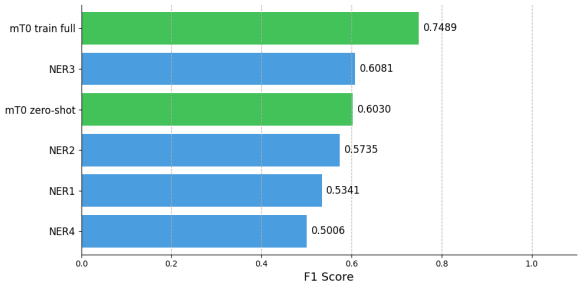

Figure 8: SFT results on VLSP NER 2021

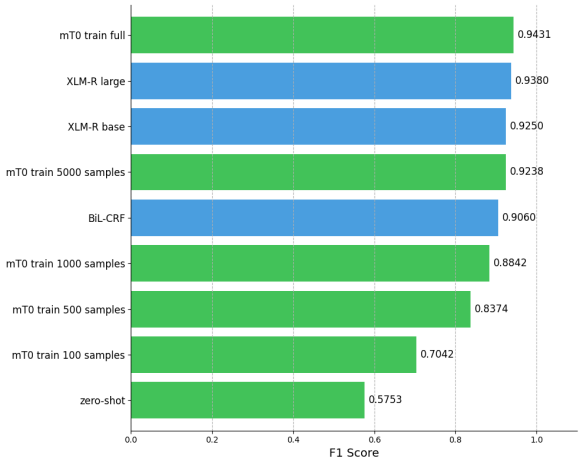

Figure 9: SFT results on PhoNER_COVID19

For the PhoNER_COVID19 dataset, the mT0-large model was fine-tuned using different sample sizes. Even with only 10 samples per entity type, the model's F1 score increased significantly from 0.5753 to 0.7042. With full training data, the model achieved an F1 score that surpassed all models evaluated in the original PhoNER_COVID19 publication, including BiLSTM-CRF and XLM-R. Despite being smaller, these models are domain-specific and might not generalize well to open-domain NER tasks. In contrast, the mT0-large model, with its larger capacity, effectively leveraged even small amounts of in-domain data to excel in domain-specific NER tasks.

5 Conclusion

In this research, we conducted a study on developing an open-domain NER model for Vietnamese, using it as a case study for low-resource languages. By experimenting with multilingual encoder-decoder models, particularly the mT5 model and the mT0 one, we found a novel strategy to fine-tune the mT0-large model to perform well on open-domain NER tasks. This model demonstrated a strong ability to generalize to Vietnamese NER, even when fine-tuned exclusively on English data, showcasing the potential of medium-sized models and promising application to other low-resource languages.

These findings underscore the potential of the proposed approach but also highlight areas needing further refinement. Future research could focus on improving fine-tuning strategies, creating higher-quality open-domain Vietnamese NER datasets, exploring decoder-only models and investigating domain adaptation and few-shot learning techniques. Such efforts would further enhance the model's performance and adaptability, particularly in real-world applications.

Human-Centric NLP or AI-Centric Illusion?: A Critical Investigation

Piyapath T Spencer
Language and Information Technology Programme, Faculty of Arts, CU, Thailand
Center for Information and Language Processing (CIS), LMU Munich, Germany
linguistics@piyapath.uk

Abstract

Human-Centric NLP often claims to prioritise human needs and values, yet many implementations reveal an underlying AI-centric focus. Through an analysis of case studies in language modelling, behavioural testing, and multi-modal alignment, this study identifies a significant gap between the ideas of human-centricity and actual practices. Key issues include misalignment with human-centred design principles, the reduction of human factors to mere benchmarks, and insufficient consideration of real-world impacts. The discussion explores whether Human-Centric NLP embodies true human-centred design, emphasising the need for interdisciplinary collaboration and ethical considerations. The paper advocates for a redefinition of Human-Centric NLP, urging a broader focus on real-world utility and societal implications to ensure that language technologies genuinely serve and empower users.

1 Introduction

"Human-Centric NLP" purportedly aims to develop language technologies that are more aligned to human needs, cognition, and behaviour (Hovy and Spruit, 2016). Some argue that by incorporating human factors into NLP systems, we can create more effective, ethical, and user-friendly language technologies (Jurgens et al., 2019; Yang, 2023; Kotnis et al., 2022; Wang et al., 2021). However, a critical examination of current practices and research trends in this field raises a provocative question: *Is Human-Centric NLP truly centred on human needs, or is it a mere AI-centric illusion?*

Consider, for instance, the development of LLMs like GPT-4 (OpenAI, 2024). Even though it appeared as a step towards more human-like language understanding through various tasks, these models primarily focus on improving performance metrics such as perplexity and accuracy on benchmark tasks. The human element often comes into play only in the form of massive datasets used for training or in post-hoc attempts to align the model with human preferences. This approach, whilst impressive in results, arguably prioritises AI capabilities over addressing fundamental human communication needs or cognitive processes.

This paper argues that despite its name and stated intentions, much of what is labeled as Human-Centric NLP is, in fact, predominantly AI-centric. Rather than genuinely prioritising human needs and experiences, these approaches often incorporate human information primarily as a means to enhance AI performance. This misalignment between the proclaimed human-centric goals and the AI-centric reality has significant implications for the development, application, and societal impact of NLP technologies.

Through a critical investigation of current research trends, methodologies, and case studies, the paper aims to address the AI-centric nature under the surface of human-centricity in NLP. The paper also examines how human data and behaviour are often exploited to improve NLP systems without necessarily addressing core human needs or concerns, as observed by Bender and Koller (2020) and Bender et al. (2021). Furthermore, The paper explores the ethical implications of this mischaracterisation and propose a framework for what "truly" human-centric NLP might entail, building on the work of scholars who have called for more genuine engagement with human factors in AI development (Crawford and Calo, 2016). Ultimately, this paper seeks to stimulate a re-evaluation of priorities in NLP research and development. It calls for a genuine shift towards human-centric approaches that place human needs, experiences, and well-being at the forefront, rather than treating them as mere tools for technological advancement.

2 The Promise of Human-Centric NLP

The concept of Human-Centric NLP emerged as researchers recognised the need to align language technologies more closely with human needs and cognitive processes, partly as a response to criticisms that they were too focused on technical performance metrics at the expense of real-world applicability and human factors. Kotnis et al. (2022) related NLP with the idea of Human-Centric Research (HCR) with the objective to "place *all* [human] stakeholders at the centre of research". This paradigm shift promised to conduct research (and create technologies) that are more intuitive, ethical, and aligned with human cognitive processes and societal needs.

Ever since, advocates of Human-Centric NLP have made strong claims about its potential benefits. For instance, Sap et al. (2020) and Kaushik (2023) argued that incorporating human knowledge and reasoning patterns could lead to more robust and generalisable NLP systems. They suggested that such systems would be better equipped to handle the nuances and contextual complexities of human language. Moreover, Human-Centric NLP has been acted as a solution to ethical concerns in AI development. Hovy and Yang (2021) proposed that by centring human values and societal impact in the design process, we could create more responsible and fair language technologies.

The promise of Human-Centric NLP extends beyond improved performance. Researchers have argued that this approach could lead to more ethical and socially responsible AI systems. For example, Bender et al. (2021) in their influential paper on the dangers of large language models, emphasised the need for NLP research to centre on human values and societal impact.

As the field of Human-Centric NLP continues to evolve, researchers are exploring ways to balance technical advancements with ethical considerations and user-centred design. This approach represents a shift from purely performance-driven metrics to a more holistic view of NLP's role in society. There is, nevertheless, ongoing work to translate these human-centric ideals into practical implementations across various NLP applications.

3 The Reality: AI-Centricity in Disguise

Whilst the concept of Human-Centric NLP promises an optimistic picture of language technologies aligned with human needs and values, a closer examination of current practices reveals a different reality. Despite the rhetoric of human-centricity, many NLP systems and research directions continue to prioritise AI performance over genuine human-centric considerations.

The development and deployment of such large language models (LLMs) as GPT-series, from GPT-3 (Brown et al., 2020) to GPT-4 (OpenAI, 2024), serve as a prime example of this disconnect. These models have achieved impressive results on various NLP tasks, yet their development process and application raise serious questions about their alignment with human-centric principles. The data collection methods for these models often involve web scraping vast amounts of information without adequate consideration for privacy, consent, or representation issues. Once again, Bender et al. (2021) argue that this approach to data collection reflects a prioritisation of model performance over ethical considerations and diverse human perspectives.

Furthermore, the evaluation of these models primarily relies on performance metrics for benchmark tasks and leaderboards. As Ethayarajh and Jurafsky (2020) point out, these metrics often fail to capture real-world utility or alignment with human values, instead focusing on narrow technical capabilities. The emphasis on benchmark performance over real-world applicability as such shows the AI-centric nature of current NLP practices.

The resource allocation for training LLMs also reflects a focus on pushing the boundaries of AI capabilities rather than addressing specific human needs or environmental concerns. Strubell et al. (2019) highlight the immense computational resources required for training models, raising questions about the prioritisation of AI advancement over other important human-related considerations such as environmental impact or more targeted, human-centric applications of NLP technologies.

Beyond LLMs, the field of sentiment analysis provides another example of this disconnect. Tools developed for understanding human emotions often reduce complex affective states to simplistic binary (positive/negative) classifications to ease the computation instead of capture intricate human emotional experiences, making this a reductionist approach that reflects a preference for computational efficiency over truly capturing the complexity of human sentiment.

This gap between the stated goals of Human-Centric NLP and its practical implementation raises

critical questions about the field's direction. Are we truly developing technologies that serve human needs, or are we simply creating more sophisticated AI systems that give the illusion of human-centricity? Critics like Birhane (2021) argue that the focus on technical advancements often overshadows crucial discussions about the societal implications of these technologies.

It becomes more clear that bridging this gap between the promise and reality of Human-Centric NLP requires a fundamental re-evaluation of priorities and practices in the field. The challenge lies in aligning the impressive technical capabilities of modern NLP systems with genuine human-centric principles that prioritise ethical considerations, user needs, and societal impact.

4 Some Cases to be Discussed

To further substantiate the critical examination of Human-Centric NLP, this section presents three cases that exemplify the correlations between human-centric pictures and AI-centric realities.

On Linguistic Varieties The first case study is Ramponi (2024), addressing the challenges of developing NLP technologies for the diverse language varieties in Italy. Although the author makes important arguments about the technological challenges of Italy's linguistic diversity, his focus on NLP solutions overlooks crucial socioeconomic factors that influence language vitality and also pays insufficient attention to intergenerational transmission dynamics and the predominantly oral dialects, potentially marginalising these aspects in favour of written forms that are more amenable to current NLP techniques. Lacking of a clear framework for community-driven priorities raises questions about how speaker communities themselves might shape research agendas and tool development. Perhaps most tellingly, the approach, whilst interdisciplinary in intent, does not fully integrate insights from sociolinguistics, anthropology, and cultural studies – disciplines crucial for understanding the human dimensions of language use and preservation. Despite its aims, the study remains primarily anchored in a technology-first paradigm that may not fully capture or address the complex human realities of Italy's linguistic landscape.

On Evaluation The second case study is Ribeiro et al. (2020). This paper introduces CheckList, a task-agnostic methodology for testing NLP models; whilst innovative in its approach to NLP model evaluation, reveals several limitations in its human-centricity. The automated testing and model failures, as well as the predefined linguistic capabilities and test types, may not fully capture the nuanced, contextual nature of human language use and potentially oversimplify the complex, holistic nature of human communication. CheckList's black-box testing approach which focusing on discrete linguistic phenomena risks perpetuating a disconnect between model development and the lived experiences of language users. The benchmark-centric view, contrasting differences between model performance and human-like understanding, doesn't deeply explore how these issues relate to real-world language use. Furthermore, the user studies primarily focus on CheckList's ability to generate more tests and uncover bugs, rather than on how it improves the user experience or addresses human-centric language needs.

On Human Data Our third case study is Takmaz et al. (2020), aiming to improve image captioning by incorporating human gaze data, ostensibly making the process more 'human-centric'. The authors use eye-tracking data to guide the image captioning model, arguing that this approach better aligns with human attention patterns. Its heavy reliance on eye-tracking data as a proxy for human attention risks oversimplifying the complex cognitive processes involved in image interpretation and description. Although the study introduces sequential processing of gaze patterns, this approach also potentially oversimplifies the non-linear and iterative nature of human thought processes during image description tasks. Besides, the introduction of the SSD metric further demonstrates a focus on quantifiable outcomes rather than qualitative alignment with human linguistic behaviour. Notably, the paper gives limited consideration to individual differences such as cultural background, personal experiences, or emotional responses that significantly influence image interpretation. The paper apparently emphasises on improving AI performance through gaze data suggesting a prioritisation of technological advancement over a deeper understanding of human cognition. Apart from this, there features no discussion on real-world applications for this particular innovation, seemingly the AI-centric nature of the approach.

These case studies collectively demonstrate the ongoing challenges in achieving Human-Centric NLP. They suggest that *true* human-centricity re-

quires more than just improved performance metrics or the incorporation of human data. Instead, it demands a deep engagement with the complexities of human cognition, cultural contexts, and social dynamics.

5 Rethinking *Human-Centricity*

As critically examining the concept and implementation of Human-Centric NLP, several key questions emerge that need further discussion. These questions challenge the understanding of what it means for NLP to be truly human-centric and how it relates to broader concepts of human-centred design and real-world impact.

1. Is Human-Centric NLP Human-Centred Design?

Human-Centred Design (HCD) is an approach that puts human needs, capabilities, and behaviours at the forefront of the design process. Whilst Human-Centric NLP claims to prioritise human factors, it's debatable whether current practices truly align with HCD principles.

Traditional HCD involves extensive user research, iterative prototyping, and continuous user feedback (Harte et al., 2017). However, much of Human-Centric NLP research focuses on improving model performance on human-generated datasets or incorporating human-like features, rather than directly involving users in the design process. The case study on Italian language varieties (Ramponi, 2024) demonstrates this disconnect: whilst aiming to address human linguistic diversity, the approach remains largely technology-driven rather than user-driven.

To truly embody HCD, Human-Centric NLP might need to shift towards more participatory research methods, involving end-users throughout the development process, from problem definition to solution evaluation.

2. Does Human-Centric NLP use Human as Another Metrics/Benchmark?

There is a growing concern that Human-Centric NLP often reduces human factors to another set of metrics or benchmarks, rather than genuinely centring human needs and experiences. The CheckList methodology (Ribeiro et al., 2020) exemplifies this tension: it aims to test NLP models on human-like language tasks; however, it still fundamentally treats human language abilities as a one of the benchmark for AI performance.

Similarly, the study on gaze-guided image captioning (Takmaz et al., 2020) uses human eye-tracking data to improve AI performance, but it is questionable whether this truly captures the essence of human image interpretation or merely uses human behaviour as another optimisation target.

This trend risks oversimplifying the complexity of human language and cognition. A more genuinely human-centric approach might involve developing evaluation methods that go beyond performance metrics to assess the real-world utility and social impact of NLP systems.

3. Should Human-Centric NLP Take a Step Out from the Computer/Virtual World?

Human-Centric NLP often focuses on improving language technologies within digital environments. However, language is fundamentally a tool for human interaction in the physical world. There is indeed a pressing need for Human-Centric NLP to consider its impacts and applications beyond the virtual realm. Ramponi (2024) touches on this by addressing real-world linguistic diversity, but there is potential to go further notwithstanding.

This could involve studying the real-world consequences of NLP systems, such as their impact on human communication patterns or social dynamics. Developing NLP applications that bridge the digital and physical worlds, like improved assistive technologies for individuals with disabilities, considering the environmental and societal impacts of large-scale NLP models and infrastructures.

These discussions point upon the need for a fundamental re-evaluation of what constitutes Human-Centric NLP. Moving forward, the field should strive for a more holistic approach that truly embodies human-centred design principles, goes beyond using humans as mere benchmarks, and actively engages with the physical world implications of language technologies.

6 The Prospects for *Human* Language Technologies

To realise the potential of Human-Centric NLP, it is crucial to broaden its application across diverse domains. Whilst it is apparent that many current implementations even under the umbrella of HC-NLP focus on specific tasks or benchmarks, there is a significant opportunity to apply human-centric principles in such domains with wide-reaching societal impacts areas as healthcare, education, and

social justice. A prominent example for this sort of application is illustrated by Antoniak et al. (2024), outlining the necessity of ethical frameworks for utilising NLP tools within maternal healthcare as well as addressing critical issues such as clinician-patient power dynamics and systemic health disparities. The authors developed guiding principles focused on "contextual significance, holistic measurements, and valuing diverse voices" by directly engaging with affected communities. Aside from a methodological pattern for future research, they serve as an important resource for practitioners aiming to create inclusive and effective NLP technologies in maternal healthcare and beyond.

Inseparably linked with the *threat*, Jonas (1984) proposed that technology must be guided by a principle of responsibility, valuing long-term human welfare and ethical integrity. Human-Centric NLP faces inevitable ethical dilemmas, from biases in language models to the environmental impact of training large models. Addressing these challenges requires a commitment to transparency in model development, evaluation, and deployment. For NLP, this principle translates to a commitment to transparent trade-offs, recognising where and how models may fall short in meeting human-centred values and openly addressing the societal and environmental costs involved.

The path towards a truly Human-Centric NLP is undoubtedly challenging, especially, given resource limitations, the need for consistent model performance, and industry pressures for rapid deployment. It is, of course, understandable why a number of NLP researchers focus on achieving computational excellence. However, acknowledging these constraints does not preclude progress. Initial steps, such as introducing qualitative user-feedback mechanisms, incorporating human-centred metrics into model evaluations, or co-developing applications with end-users (Lau et al., 2015; Carreño and Winbladh, 2013; Sreejith and Sinimole, 2024), can make significant strides toward aligning NLP with human-centric ideals. Additionally, embedding ethical reviews in the development process, where models are evaluated for social implications before deployment, would set a standard of responsibility.

As NLP continues to evolve, its future trajectory depends on whether the field can transition from a narrowly AI-centric focus to a genuine commitment to human relevance, ethical responsibility, and social accountability. The ultimate vision for Human-Centric NLP is not only to create models that excel at language processing but to foster tools that respect and enhance human agency, preserve cultural diversity, and engage responsibly with global issues. The question remains: *Will NLP's legacy serve human welfare and societal well-being, or will it reinforce AI-centric illusions at the expense of human values?*

A Human-Centric NLP approach ought to position language technologies as extensions of human creativity, connection, and identity. The field can offer more than technological advancement through these humanistic principles; it can contribute to a world where language technologies genuinely serve as advocates to human expression, dignity, and community. This shift calls for a shared ethical commitment and the courage to prioritise human values over mere computational gains. In doing so, NLP can realise its potential to empower diverse voices, deepen understanding, and elevate the human experience in meaningful, lasting ways.

7 Conclusion

The paper have examined the disconnect between the promise of Human-Centric NLP and its current implementation. The analysis reveals that many so-called human-centric approaches in NLP remain fundamentally AI-centric nowadays. The case studies and subsequent discussion have demonstrated several key issues: the misalignment with true human-centred design principles, the reduction of human factors to mere benchmarks, and the limited consideration of real-world, physical impacts of NLP technologies. These findings indicate the need for a fundamental reframing of Human-Centric NLP. To address these challenges, we propose that truly Human-Centric NLP should embrace genuine human-centred design methodologies, develop holistic evaluation frameworks, expand its scope to consider broader societal implications, prioritise interdisciplinary collaboration, and centre ethical considerations throughout the development process. Only then can we hope to develop NLP systems that genuinely serve and empower humans in their diverse contexts and fulfil the true promise of human-centricity in NLP.

Abstract

Text-based VQA is a challenging task that requires machines to use scene texts in given images to yield the most appropriate answer for the given question. The main challenge of text-based VQA is exploiting the meaning and information from scene texts. Recent studies tackled this challenge by considering the spatial information of scene texts in images via embedding 2D coordinates of their bounding boxes. In this study, we follow the definition of meaning from linguistics to introduce a novel method that effectively exploits the information from scene texts written in Vietnamese. Experimental results show that our proposed method obtains state-of-the-art results on two large-scale Vietnamese Text-based VQA datasets. The implementation can be found at this link.

1 Introduction

Multimodal learning, particularly vision-language tasks, has recently attracted the attention of the research community. Visual Question Answering (VQA) (Antol et al., 2015) is one of the well-known tasks in vision-language studies. This task gives the machines a question and an image. The machines are required to find the evidence in the image to answer the given question.

Text-based VQA (Singh et al., 2019) is an advanced version of the VQA task in which, besides the visual information in the images, the machines are required to incorporate the information of scene texts for more accurate answers.

Various datasets were constructed for researching Text-based VQA tasks, especially in high-resource languages such as English (Antol et al., 2015; Goyal et al., 2016; Singh et al., 2019; Biten et al., 2019; Mathew et al., 2020). However, there is a limited number of hight-qualified and annotated datasets for researching this task in Vietnamese (Tran et al., 2021; Nguyen et al., 2023; Luu-Thuy Nguyen et al., 2023; Tran et al., 2023; Nguyen et al., 2024; Pham et al., 2024).

On the other hand, the main challenge of Text-based VQA is exploiting the meaning of scene texts available in the images so that deep learning methods can recognize them and depend on them to provide the most appropriate answers. They propose to tackle this challenge by introducing several modules (Biten et al., 2021; Fang et al., 2023; Kil et al., 2022). However, most of these modules explore the spatial information of scene texts in images via their bounding boxes and their meaning was obtained by using embedding layers from pre-trained language models (Hu et al., 2019; Kant et al., 2020; Gao et al., 2020; Biten et al., 2021; Fang et al., 2023).

In this study, we inspire the definition of meaning from American Distributionalsm, a field of study in linguistics, and recent works on the Vietnamese lexical system (Giáp, 2008, 2011; Xuan, 1998; Châu, 2007) to propose a novel method, **Vi**etnamese **Cons**tituent Trans**Former** (ViConsFormer), which effectively incorporate the meaning of Vietnamese scene texts to yield answers.

Our extensive experiments on the two Text-based VQA datasets in Vietnamese show that our proposed method outperforms previous baselines and proposes several research directions for future studies.

2 Related works

2.1 Datasets

Former studies in VQA defined this task as answering questions relevant to objects in images. Antol et al. (Antol et al., 2015) first introduced the VQA task by publishing the VQA dataset.

This novel way of treatment on the VQA dataset results in the language prior phenomenon as indicated by Goyal et al. (Goyal et al., 2016). This phenomenon describes that VQA methods tend to

yield answers by recognizing the pattern of questions rather than based on evidence from given images.

To overcome the language prior phenomenon, (Goyal et al., 2016) introduced the VQAv2 dataset. This dataset is the rebalanced version of the VQA dataset constructed by balancing the number of answers belonging to particular patterns of questions.

Making further steps from VQAv2, (Singh et al., 2019) introduced a novel form of VQA task, which is named Text-based VQA tasks in later studies (Hu et al., 2019; Biten et al., 2021; Li et al., 2023; Fang et al., 2023; Kil et al., 2022). In particular, Text-based VQA tasks require the machines to understand scene texts beside objects in the images and use these scene texts to give the respective answers. Text-based VQA tasks become significantly challenging as the additional modality of scene texts and recently raised attention from many researchers (Hu et al., 2019; Biten et al., 2021; Li et al., 2023; Fang et al., 2023; Kil et al., 2022).

Although there are numerous VQA datasets in English, there are few VQA datasets in Vietnamese. Tran et al. (Tran et al., 2021) first introduced the ViVQA dataset, the first dataset for researching VQA in Vietnamese. Later on, various studies released many datasets, particularly UIT-EVJVQA (Luu-Thuy Nguyen et al., 2023), OpenViVQA (Nguyen et al., 2023) and ViClever (Tran et al., 2023) for VQA task as well as ViTextVQA (Nguyen et al., 2024) and ViOCRVQA (Pham et al., 2024) for Text-based VQA task.

2.2 Methods

Former methods share the same architecture that uses pre-trained CNN-based models to extract image features and RNN-based methods to learn the questions with integrated image features for producing answers (Lu et al., 2016; Yang et al., 2015).

In addition, with the introduction of the attention mechanism (Vaswani et al., 2017), former VQA methods attempted to provide this technique with the assumption of learning the attention relation between images and questions. Typical VQA methods for this approach can be categorized as Co-Attention (Lu et al., 2016; Yu et al., 2019), or Stack Attention (Yang et al., 2015).

The development of BERT (Devlin et al., 2019) provides another architecture that lots of studies inspired as well as introduced numerous novel methods such as (Lu et al., 2019; Li et al., 2019b; Tan and Bansal, 2019; Su et al., 2019; Zhou et al., 2019; Li et al., 2019a; Cho et al., 2020).

Another way of learning the correlation between images and questions is to define multilinear functions that accept features of questions and images as inputs. Various studies followed this approach and introduced deep learning methods using multilinear functions instead of Transformer (Kim et al., 2018; Do et al., 2019).

However, most of the VQA methods in English were defined as answer-selection models. Recently, text-based VQA datasets were introduced, and these answer-selection methods can not model effectively Text-based VQA datasets because of the diverse forms of answers. In particular, (Nguyen et al., 2023) defined the open-ended VQA task with the publication of the OpenViVQA dataset in Vietnamese. They showed that former VQA methods are challenging to model in this novel form of VQA task. VQA methods using language models are then developed to tackle the challenging of Text-based VQA tasks and open-ended VQA tasks (Nguyen et al., 2023).

The main challenge of the Text-based VQA task is how to model scene texts in images to yield a good answer. Many T5-based VQA methods were introduced with particular modules that try to learn the meaning and spatial relations among scene texts (Biten et al., 2021; Kil et al., 2022; Fang et al., 2023)

3 ViConsFormer - Vietnamese Constituent Transformer

3.1 Preliminaries

3.1.1 Vietnamese Scene Texts

Scene texts in images taken in Vietnam have the following rule in general: scene texts on the same line are in the same meaningful constituents. For instance, in Figure 1, there are three lines of scene texts on the truck: *VinShop x VinID* indicates the cooperation of the two companies, *Tạp hóa* (grocery) indicates the kind of business of the two companies, and *Thời công nghệ* (technological times) points out the characteristic of the grocery. There does not exist the situation where all scene texts are in the same line, but they are meaningless.

However, current Text-based VQA methods receive scene texts as the line of tokens ordered by the spatial information (the 2D coordinates of bounding boxes) (Biten et al., 2021; Fang et al., 2023; Kant et al., 2020; Gao et al., 2020; Hu et al., 2019). There is no signal to determine which constituents

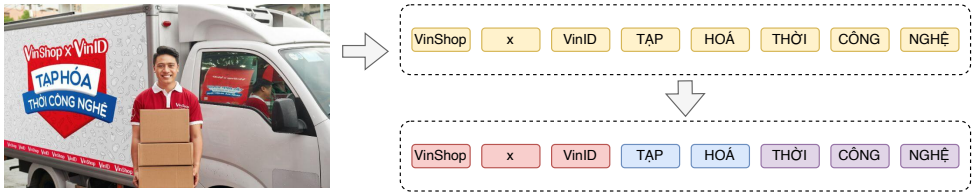

Figure 1: Forming meaningful constituents in the sequence of OCR tokens.

each scene text token belongs to. SaL (Fang et al., 2023) tackled this challenge by providing an additional special token <*context*> between scene text tokens. These tokens learn how to represent the start and end positions of every meaningful constituent.

We approach this challenge in different ways. From our observations, we find that meaningful constituents include complete lexical units, which we call Vietnamese words. To this end, we introduce a novel method that describes the Vietnamese words and hence describes the meaningful constituents of scene text of images taken in Vietnam (Figure 1). We continue the in-depth discussion of how to describe words from the line of scene text tokens in the following Section.

3.1.2 Meaning representation

Recent studies (Yang et al., 2015; Biten et al., 2021; Gao et al., 2020; Kant et al., 2020) addressed the Text-based VQA task by proposing a module that incorporates the position of scene texts in images via the coordinates of their bounding boxes. However, the meaning of scene texts is not reflected by their spatial positions. One attempt to explore the meaning of scene texts is to use the embedding layer of pre-trained language models such as BERT (Devlin et al., 2019) and T5 (Raffel et al., 2019) as in (Biten et al., 2021; Hu et al., 2019; Fang et al., 2023; Gao et al., 2020). This approach has a limitation in that not all scene texts in images are available in the fixed vocab of the pre-trained language models. When tokens are not in the vocab, pre-trained language models usually segment them into subwords (Wang et al., 2019). This way of representation tends to introduce the ambiguity of scene texts to Text-based VQA methods.

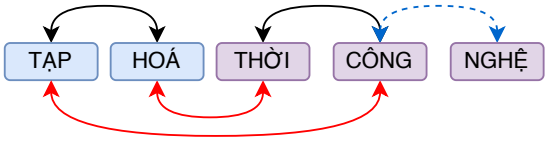
Another approach is constructing a pre-trained model, particularly for scene text representation as in (Kil et al., 2022). However, training a pre-trained model requires high-cost computational facilities.

In our study, we approach the meaning representation of scene texts following the study of American Distributionalism (Bloomfield, 1933; Harris, 1951) in linguistics. This field of study in linguistics researches language by observing how it appears. They think research in linguistics must be done via observable and measurable units. Linguisticians should avoid falling into unobservable things such as semantics or meanings. They describe languages as the distributions of their constituents, and meaning is defined as the consequence of how words are distributed and how they appear together in sentences. For instance, given the sentence *Everyone in the room knows at least two languages* and the sentence *At least two languages are known by everyone in the room*, these two sentences are different in terms of meaning although they are formed from the same set of words (Chomsky, 2014).

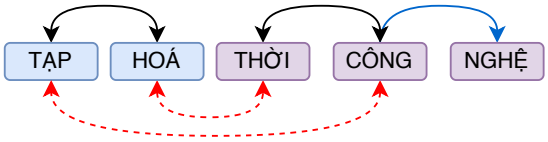
In addition, Vietnamese lexical structure differs from English. Words in English include one or more than two syllables. While in Vietnamese, words contain one or more syllables, and spaces separate these syllables. For instance, *đại lý* in Vietnamese is a word containing two tokens and two syllables, while in English, it means *agency*, has three syllables and one token. In other words, an English token can be translated into more than one token in Vietnamese.

We follow the recent advantages of the attention mechanism in English. From various studies (Vaswani et al., 2017; Bahdanau et al., 2014; Luong et al., 2015), the attention mechanism can describe how words are relevant to each other. However, as analyzed previously, Vietnamese words may include more than one syllable, encoded as tokens in sentences. The attention mechanism has no constraint in how it can form attentive connections. Therefore, in Vietnamese sentences, one token in this word will attend to one token in another, which does not yield any meaning (Figure 2a).

To this end, we introduce the Constituent Module. This module constructs two components: the attention score matrix $\mathcal{A}$ and the constituent score matrix $\mathcal{C}$. The constituent score matrix $\mathcal{C}$ describes



(a) Demonstration of the case where self-attention scores unrelated tokens belonging to different words (the red arrows) but can lack relation among tokens in a word (the dashed arrow).



(b) Our Constituent Module was proposed to re-correct the attention scores via the constituent scores (the blue line) while removing the unnecessary relations (dashed red arrows).

Figure 2: An example of a noun phrase in Vietnamese. The translated phrase in English: grocery in technological times.

the words of scene texts in images by highlighting which tokens belong to a word.

Moreover, as there are no technical constraints in the attention mechanism, we might have two tokens in different words, but they can be scored to attend to each other. The constituent score matrix $\mathcal{C}$ plays the role of re-correcting the attention score matrix $\mathcal{A}$ so that there are no unnecessary connections among tokens belonging to different words (Figure 2b). The description of how we construct $\mathcal{C}$ was detailed from equation 1 to equation 5.

3.2 Overall architecture

The main contribution of ViConsFormer is the Constituent module. This module is proposed to describe the meaning of scene texts, as discussed in the previous section. In general, our method has five components: Image Embedding module, Question Embedding module, Scene Text Embedding module, Constituent module, and Multimodal backbone (Figure 3).

3.2.1 Constituent module

The Constituent module includes two components: the multi-head attention (Vaswani et al., 2017) determining attention score $\mathcal{A}$ and Constituent formation determining constituent score $\mathcal{C}$.

In Vietnamese morphology, syllables in words have two kinds of semantic relations (Giáp, 2008, 2011):

- Syllables in a word contribute their meanings equally to the overall meaning of that word. For instance, *quần áo* means clothes in general, compounding *quần* (paints in general) and *áo* (shirts in general).
- One syllable defines the core meaning of the word, and other syllables play the role of modifiers. These modifiers narrow down the meaning of the main syllable so that the meaning of the whole word is more particular. For instance, *nhà ăn* (cafeteria) includes syllable *nhà* (houses in general) and *ăn* (dining in general).

Given the sequence of scene texts $f_{ocr} = (f_1^{ocr}, f_2^{ocr}, ..., f_n^{ocr})$ obtained from the embedding layer of ViT5 (Phan et al., 2022) as input, we model these kinds of semantic relations by defining a bilinear function:

$$r_{k,k+1} = f(f_k^{ocr}, f_{k+1}^{ocr}) = f_k^{ocr} W (f_{k+1}^{ocr})^T \quad (1)$$

where W is the learnable parameter. Then with every token ith, we describe the semantic relations with its neighbor tokens $(i-1)th$ and $(i+1)th$ as:

$$pr_{i-1,i}, pr_{i,i+1} = softmax(r_{i-1,i}, r_{i,i+1}) \quad (2)$$

If token ith has semantic relations with token $(i-1)th$, and token $(i-1)th$ is in another word, then we expect $pr_{i-1,i} > pr_{i,i+1}$ (and vice versa). In the case token ith has semantic relations with both token $(i-1)th$ and $(i+1)th$, the mass of $pr_{i-1,i}$ and $pr_{i,i+1}$ determine how much relevant these tokens share (contributing equally to the overall meaning, or main-secondary meaning contribution, or there is no connection among these tokens).

In addition, as the consequence of the asymmetry of matrix multiplication, we have $pr_{k,k+1} \neq pr_{k+1,k}$ while they describe the same idea. To this end, we define the probability P_k to measure the semantic relations of token k with its neighbor tokens. P_k is obtained by averaging over $pr_{k,k+1}$ and $pr_{k+1,k}$:

$$P_k = \sqrt{pr_{k,k+1} \times pr_{k+1,k}} \quad (3)$$

Defining $\mathcal{C}_{ij}$ the probability of "tokens from the position ith to the position jth are in the same constituent", together with the definition of P_k, we have:

$$\mathcal{C}_{ij} = \prod_{k=i}^{j-1} P_k \quad (4)$$

It is worth noting that $P_k \in [0, 1]$, hence $\mathcal{C}_{ij}$ rapidly converges to 0 when $k \to \infty$, which results

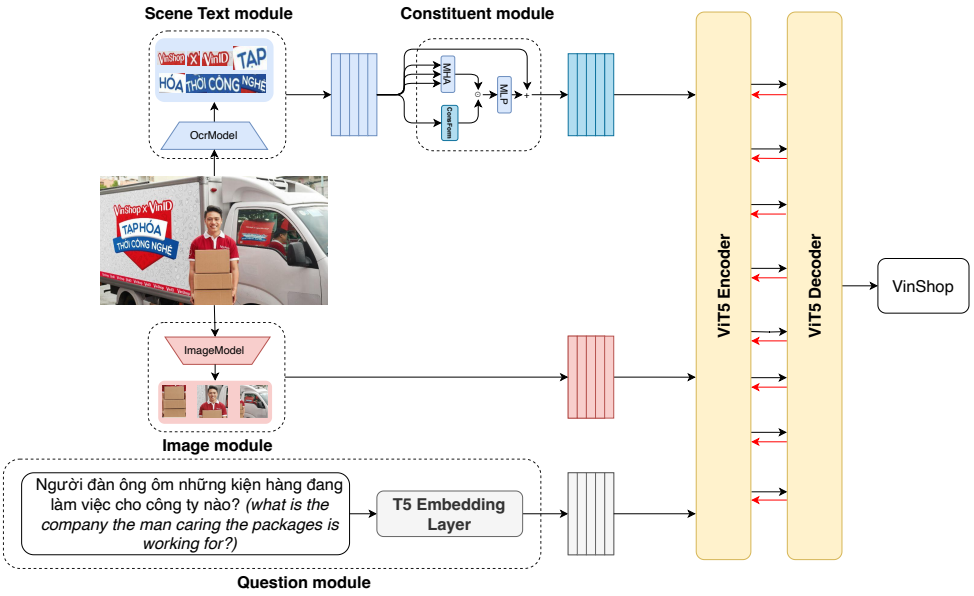


Figure 3: The overall architecture of the ViConsFormer.

in the gradient vanishing. To avoid this problem, we re-formulate $\mathcal{C}_{ij}$ as:

$$\begin{aligned}\mathcal{C}_{ij} &= exp(log(\mathcal{C}_{ij})) \\ &= exp\left(log\left(\prod_{k=i}^{j-1} P_k\right)\right) \\ &= exp\left(\sum_{k=i}^{j-1} log(P_k)\right)\end{aligned} \tag{5}$$

To construct the attention score matrix $\mathcal{A}$, we perform the self-attention by defining the query Q, key K, and value V as:

$$Q = W_q f_{ocr}$$

$$K = W_k f_{ocr}$$

$$V = W_v f_{ocr}$$

where $W_q, W_k, W_v \in \mathbb{R}^{d_{model} \times d_{model}}$ are learnable parameters.

The attention scores over detected scene texts are determined as follows:

$$\mathcal{A} = softmax(\frac{QK^T}{\sqrt{d_{model}}})$$

The final attention score matrix is determined by providing $\mathcal{A}$ with the constituent score matrix $\mathcal{C}$:

$$\mathcal{S} = \mathcal{A} \odot \mathcal{C} \tag{6}$$

As both $\mathcal{C}$ and $\mathcal{A}$ have the form of exponential functions, it is worth noting that the constituent scores are not added to the attention scores intuitively by summation but by element-wise multiplication.

Finally, the output of scene text features is determined as follows:

$$f_{out}^{ocr} = \mathcal{S}V \tag{7}$$

3.3 Image Embedding module

We follow the module for object features representation of SaL to represent the features of images. In particular, the features of objects $f_{obj} = (f_1^{obj}, f_2^{obj}, ..., f_n^{obj})$ available in images are determined as follows:

$$\begin{aligned}f_i^{obj} &= ViT5LN(W_{fr}^{obj} x_i^{obj,fr}) \\ &+ ViT5LN(W_{bx}^{obj} x_i^{obj,bx})\end{aligned} \tag{8}$$

where W_{fr}^{obj} and W_{bx}^{obj} are trainable parameters, $ViT5LN$ is the normalization layer of ViT5, and $x_i^{obj,fr}$ is the features of object ith in image.

Unlike SaL, we do not consider the features of object tags, as their appearance in our proposed methods does not yield any significant improvement in scores. We will provide more numerical information about this statement in Section 4.6.

3.4 Scene Text Embedding module

To obtain features of scene texts in images, we follow SaL to determine these features:

$$\begin{aligned} f_i^{ocr} &= ViT5LN(W_{fr}^{ocr} x_i^{ocr,fr}) \\ &+ ViT5LN(W_{bx}^{ocr} x_i^{ocr,bx}) \\ &+ W_{ViT5}^{ocr} x_i^{ViT5} \end{aligned} \tag{9}$$

where W_{fr}^{ocr}, W_{bx}^{ocr}, and W_{ViT5}^{ocr} are trainable parameters, $ViT5LN$ is the normalization layer of ViT5, $x_i^{obj,fr}$ is the features of object ith in image, and x_i^{ViT5} is the text embedding of scene text token ith produced by the embedding layer of ViT5.

3.5 Question Embedding module

Following LaTr (Biten et al., 2021), the questions are embedded into $f_Q = (q_1, q_2, ..., q_L)$ using the embedding layer of ViT5 where each position $q_i \in \mathbb{R}^d$.

3.6 Multimodal backbone

Following previous works (Biten et al., 2021; Fang et al., 2023; Kil et al., 2022), we use the T5-based pre-trained model as the multimodal backbone. However, as our experiments were conducted on the Vietnamese Text-based VQA dataset, we provide ViConsFormer with ViT5 (Phan et al., 2022) pre-trained language models.

The input to the ViT5 backbone is defined as the fused features f_f constructed by concatenating f_{obj}, f_{ocr}, and f_Q:

$$f_f = [f_{obj}; f_{ocr}; f_Q]$$

4 Experiments

4.1 Datasets

In this work, we evaluate our proposed methods on the two datasets ViTextVQA (Nguyen et al., 2024) and ViOCRVQA (Pham et al., 2024).

The ViTextVQA dataset was constructed by asking questions and answering answers relevant to scenario images. These images were street views in Viet Nam (Nguyen et al., 2024). Scene texts in this dataset are diverse in positions, colors, light conditions, transformations, shapes, and meaning. As indicated in (Nguyen et al., 2024), the smaller size of scene texts in the images lead to more challenges in producing answers.

The ViOCRVQA dataset was constructed semi-automatically by collecting book covers from websites (Pham et al., 2024). The authors built question templates, then filled in these templates and extracted answers via the corresponding metadata of the books.

4.2 Metrics

We follow the experiments on the two datasets ViTextVQA (Nguyen et al., 2024) and ViOCRVQA (Pham et al., 2024) to use the Exact Match (EM) and F1-token as main metrics in our evaluation.

Accordingly, let $P = \{p_1, ..., p_m\}$ is the predicted answers, and $G = \{g_1, ..., g_n\}$ is the truth answers. The M of each predicted-truth answer is determined as follows:

$$EM = \delta_{P,G}$$

where $\delta_{x,y}$ is the Kronecker symbols which $\delta_{x,y} = 1$ when $x = y$ and 0 otherwise.

The F1-Token metric is defined as the harmonic mean of the Precision and Recall (in token level) as:

$$Pr = \frac{P \cap G}{P}$$

$$Re = \frac{P \cap G}{G}$$

$$\text{F1-Token} = \frac{2PrRe}{Pr + Re}$$

The overall EM and F1-Token are averaged over all predicted-truth answers of the whole dataset.

4.3 Configuration

In our experiment, we trained the ViConsFormer following the previous studies on ViTextVQA and ViOCRVQA datasets (Nguyen et al., 2024; Pham et al., 2024) that used ViT5 (Phan et al., 2022) as the multimodal backbone. For the $ImageModel$ we deployed the VinVL (Zhang et al., 2021) pre-trained image models. We used SwinTextSpotter (Huang et al., 2022) to obtain Vietnamese scene texts from images to extract their detection features and recognition features. The ViConsFormer was trained in a single run, using Adam (Kingma and Ba, 2014) as optimizer on an NVIDIA A100 80GB GPU. The batch size was set to 32 and the learning was set to $1e^{-4}$. We applied the early stopping technique to train ViConsFormer.

4.4 Baselines

To evaluate the effectiveness of our proposed ViConsFormer on the Vietnamese Text-based VQA dataset, we compared this method with the following baselines:

- M4C (Hu et al., 2019): M4C is the first vision-language learning task that was constructed based on the Transformer architecture (Vaswani et al., 2017). Its multimodal backbone is BERT (Devlin et al., 2019). M4C approaches the text-based VQA task by sequentially generating tokens to form the answers. Tokens of answers can be obtained from the vocabulary or copied from the scene texts available in the images using the Pointer Network (Hu et al., 2019) module.

- LaTr (Biten et al., 2021): This is the first method that integrated spatial information of scene texts into the multimodal backbone. They encoded the coordinates of the bounding boxes into 4-dimensional vector space, then projected them directly to the latent space of the multimodal backbone and added them to the features of scene texts. Unlike M4C, LaTr proposed using T5 (Raffel et al., 2019) as its multimodal backbone and using a subword tokenizer to encode scene texts. Scene texts in the images that are not available in the vocabulary of the T5 pre-trained model are subsegmented into sequences of chunks. Hence, instead of copying scene texts from images via a particular module, it learns how to form out-of-vocabulary scene texts from respective subwords.

- PreSTU (Kil et al., 2022): Instead of modeling the relation among scene texts via their spatial relations, PreSTU pre-trained the T5 backbone to approximate the distribution of the scene texts. The particular technique of PreSTU differs from other methods in that they sort the scene texts in left-right top-bottom orders.

- SaL (Fang et al., 2023): SaL proposed integrating the labels of objects and tokens of scene texts to their respective visual features. These labels and tokens are embedded by the embedding layer of the T5 backbone to yield the textual meaning of the objects and scene texts. Moreover, instead of encoding the coordinates of bounding boxes, they introduce another way, which is to measure the relative position among scene texts in the images.

- BLIP-2 (Li et al., 2023): BLIP-2 proposed the Q-Former module, which is fine-tuned to connect the latent space between two frozen pre-trained models: pre-trained language model and pre-trained image model. This method was pre-trained using three objective functions: Image-Text matching, Image-Text Contrastive learning, and Image-grounded Text generation. The adaption of BLIP-2 is to fine-tune the Q-Former on the downstream tasks while keeping the pre-trained image and language models frozen.

4.5 Results

Table 1: Main results of the ViConsFormer and the baselines on the ViTextVQA and ViOCRVQA datasets. The scores of baselines are obtained from previous studies (Nguyen et al., 2024; Pham et al., 2024).

#	Method	ViTextVQA		ViOCRVQA	
		F1-token	EM	F1-token	EM
1	M4C	30.04	11.60	-	-
2	BLIP2	37.78	15.01	55.23	21.45
3	LaTr	43.13	20.42	60.97	30.80
4	PreSTU	43.81	20.85	66.25	33.86
5	SAL	44.89	20.97	67.25	**39.08**
6	ViConsFormer (ours)	**45.58**	**22.72**	**70.92**	37.65

In general, the evaluation scores on the ViTextVQA dataset are lower than those on the ViOCRVQA dataset. This can be explained by the questions in the ViTextVQA dataset being annotated manually by Vietnamese native speakers, while questions in the ViOCRVQA were constructed semi-automatically using constructed templates. Therefore, the patterns of questions in the ViOCRVQA dataset are easier to explore. In addition, images from the ViTextVQA dataset are scenery views in Viet Nam, including street signs, signboards, addresses, banners, places, etc. Scene texts available in images from ViTextVQA are complicated under various transformations, colors, light conditions, and sizes and are relevant to diverse objects. In the ViOCRVQA dataset, scene texts are more clarified and belong to particular categories such as titles, names of authors, publishers, and translators (Pham et al., 2024).

On the ViTextVQA dataset, our proposed methods decisively outperformed all the given baselines. In particular, M4C using BERT as its multimodal backbone yielded the lowest scores. Text-based VQA methods using T5 as their multimodal VQA backbone significantly achieved higher scores.

On the ViOCRVQA, our method significantly outperforms all the baselines on the F1-Token metric. However, on EM, our method drops down its score compared to SaL.

4.6 Ablation study

4.6.1 Ablation study on $\mathcal{A}$ and $\mathcal{C}$

Table 2: Ablation study on attention score matrix $\mathcal{A}$ and constituent score matrix $\mathcal{C}$

Dataset	$\mathcal{A}$	$\mathcal{C}$	F1-token	EM
ViTextVQA	✓	✗	0.4309	0.2038
	✗	✓	0.4025	0.1740
	✓	✓	**0.4558**	**0.2272**
ViOCRVQA	✓	✗	0.6503	0.3204
	✗	✓	0.6172	0.3132
	✓	✓	**0.7092**	**0.3765**

The Constituent module determines two matrices: the attention score matrix $\mathcal{A}$ and the constituent score matrix $\mathcal{C}$. We expect the constituent score matrix will re-correct the unnecessary relations scored by the attention score matrix to represent the meaning of scene texts in images appropriately. To show how these two matrices interact with each other, we conduct experiments in case only the attention score matrix is calculated, and only the constituent score matrix is calculated.

According to Table 2, the Constituent module with only attention score matrix $\mathcal{A}$ performed better than when being replaced by the constituent score matrix $\mathcal{C}$. However, having the constituent score matrix $\mathcal{C}$ to re-correct the attention score matrix $\mathcal{A}$ leads to significant improvement in both metrics.

4.6.2 The necessity of object labels

Table 3: Ablation study of the ViConsFormer on the Scene Text module and Image module. *Labels* indicate the labels of detected objects and *Tokens* indicate the tokens of detected scene texts.

Dataset	Metrics	Labels		Tokens	
		✔	✘	✔	✘
ViTextVQA	F1-Token	45.58	↓ 0.25	45.58	↓ 1.22
	EM	22.72	↓ 0.40	22.72	↓ 1.19
ViOCRVQA	F1-Token	70.92	↑ 0.12	70.92	↓ 2.55
	EM	37.65	↓ 0.52	37.65	↓ 1.60

As mentioned in Section 3, in the Image module of ViConsFormer, the labels of detected objects are not required but the tokens of scene texts. To show this claim, we conducted an ablation study for ViConsFormer on the ViTextVQA and ViOCRVQA datasets.

As indicated in Table 3, there is no significant performance degradation in both F1-Token and EM scores if we do not provide ViConsFormer with object labels. However, ViConsFormer obtained significantly lower scores when it did not see scene text tokens. These results indicate that not the labels of detected objects but tokens of detected scene texts influence the overall performance.

5 Conclusion

In this study, we introduced the Constituent module. Hence, the ViConsFormer, inspired by the SaL method, approaches the main challenge of Text-based VQA in Vietnamese in a novel way. Experimental results indicate that our proposed method is effective on both Text-based VQA datasets.

6 Limitations

Although our ViConsFormer addresses the challenge of Text-based VQA task by proposing the Constituent module, this method has some limitations that need to be improved and studied in the following studies.

The first limitation is our assumption of linearity while modeling the semantic relationship between two continuous scene text tokens. This assumption is proposed for the simplicity in our novel method. It is necessary to explore the form of this semantic relationship and find the appropriate ways of modeling it in subsequent studies.

The second limitation is that we give a naive treatment for the fused futures f_f when passing them forward to the multimodal backbone. There are various ways of obtaining these fused features, such as using the Co-Attention mechanism (Yu et al., 2019; Lu et al., 2016; Yang et al., 2015), or multilinear functions (Do et al., 2019; Kim et al., 2018). We will leave these directions in our future work.

Immortal cows of Nouvelle France – Reflections around four variations on modern digital humanities techniques for Zooarcheology

Abstract

This paper explores the integration of digital humanities techniques into archaeological and historical research, focusing on the historical representations of cattle in New France through archival documents from the 17th and 18th centuries. Our objective is to evaluate the effectiveness of computational methods—such as textometry, word embeddings, topic modeling, and large language model (LLM) representation clustering—in uncovering the semantic and cultural dimensions of bovines in colonial texts. We employ these methods to analyze a corpus of historical documents, aiming to identify recurring themes, associations, and underlying patterns in the portrayal of cattle. The textometric analysis highlighted the frequency and context of bovine-related terms, while word embeddings revealed significant associations, such as the unexpected pairing of *vache* (cow) with *immortelle* (immortal), reflecting legal obligations around perpetual donations of cattle. Topic modeling further illustrated the centrality of cattle in agricultural practices, particularly their wintering and the broader socio-economic implications within the settler communities. Clustering LLM representations allowed us to refine these findings by grouping related terms and exploring their contextual usage across the corpus. The results demonstrate that digital humanities techniques can significantly enhance the study of historical texts, providing deeper insights into the cultural and economic roles of cattle in New France. This interdisciplinary approach not only contributes to our understanding of human-animal relations in colonial settings but also suggests new directions for future research in digital humanities and historical archaeology, particularly in the automated analysis of archival materials.

1 Introduction

This work examines four different digital humanities techniques for the investigation of the semantic space around selected topics within historical corpora. In particular, we evaluate in which measure the clustering of representations provided by recently developed Large Language Models (LLM) for classical French dovetail and correlate with more standard techniques in digital humanities.

The topic of interest is the mention of bovines in writings from and about Nouvelle-France (NF). Nouvelle-France designates the former territories colonized by the French crown in North America, more particularly the settler colonies around the lower Saint-Lawrence valley corresponding to the present day Canadian province of Quebec. The first colonists from Europe began to establish permanent settlements at the beginning of the seventeenth century. Like in the rest of the Americas, many animal species that were central to the European lifestyle and economy did not exist, in particular all the domesticate species such as cattle, pigs, or sheep, providing crucial goods and foodstuffs. Among these animals, cattle held a particularly prominent role by helping the first Euro-Canadian farmers open new crops in the area.

The broader history of their introduction is known through a few historical sources (Trudel, 2016; Desloges, 2009) but many aspects of this process, in particular the origins of the bovine populations and details on their management practices remain unclear. This work is part of a larger project that combines the analysis of archaeological remains of colonial cattle with the automated study of large amounts of historical archival documents. Overall, this project aims at addressing the following research questions: (1) where did the animals come from and what is the overall phylogeographic history of these populations, (2) how did the management practices and uses of cattle evolve over time, and how did the conceptions and representations of cattle change in relation to these changes.

More specifically, this work's purpose is twofold: (a) evaluate the historical representations of cattle,

and their correlates, in a series of archival documents of different type dating from the early seventeenth to the late eighteenth century, and (b) methodologically assess and compare the application of different techniques to the study of historical documents written in Modern French language.

2 Related work

2.1 Zooarchaeology and history of animals in New France

The arrival of cattle in New France was an event that played a major role in shaping the environment, economy and culture of the region during colonial times. Despite its importance there is still much to learn about the pathways of cattle dispersal in eastern Canada and how this introduction affected the daily lives of European settlers and Native communities. To apprehend this phenomenon and its broader anthropological consequences, we have designed a multifaceted research project that aims at integrating archaeological, zooarchaeological, and biomoleculardata (RABBA – "Recherches en archéologie biomoléculaire sur les bovins aux Amériques: origines,mobilité, pratiques") with the automated analysis of large amounts of digitized archival texts (Projet BNF –"Bovins Nouvelle-France"). Our approach involves exploring both material evidence and historical texts to understand how cattle were introduced into New France and how they impacted society and the environment. By combining findings with insights from written records we aim to show how humans interactions with animals like cattle transformed landscapes and livelihoods.

Zooarchaeology, the analysis of archaeological faunal materials (bones), aims at shedding light on the cross cultural and historical trajectory of human-animal relations. While traditionnally focused on ancient diets, this subfield of archaeology has gradually broadened its focus to embrace a wider palette of social and cultural issues (political economy, agrosystems, environment, symbolic use of animals). One way to address such a range of issue has recently found its expression in works focusing on a single species and their historical and cultural itinerary (Sykes et al., 2020; Thornton, 2016). Regarding the question of the introduction of Eurasian domesticates in the Americas on the heels of European colonists, few large regional syntheses have been produced so far (Delsol, 2024).

The zooarchaeology of periods with a written historical record often use these archival resources as a tool to inform its research questions or illutrate its findings. Despite the pervasiveness of the use of historical documents, no attempt at automatically analyzing the written record with approaches based on LLMs has ever been used in such a research program. The approach offered in this work introduces the results of the BNF part of the project, offering new venues of research for historical and zooarchaeological studies.

2.2 Digital humanities

Typically, what is referred to as digital humanities concerns a set of computational methods used to answer classic humanities questions (Vanhoutte, 2016). The fields in which this type of approach can be found generally revolve around history, literature, media studies, etc. (Watrall et al., 2016). Archaeology being categorized as a social science is not directly part of what encompasses digital humanities. This positioning is reflected in the field's use of computational methods. From the 1980s onwards, new technologies enabled the creation of useful tools for the visualization and modeling of excavated sites, and this is pretty much all that can be found as computational use in the literature (Watrall et al., 2016). Recently, however, the massive digitization of archival data may enable the use of automatic language processing to facilitate the extraction of data of interest to researchers (Manjavacas Arevalo and Fonteyn, 2021). Archaeology's primary sources consist in the material traces and vestiges of past societies. As a result, most of the computational methods applied in that field do not relate to language, aiming instead at providing tools to sort and create typologies of elements of past material cultures (Plutniak, 2022). However, historical archaeology (i.e. the archaeology of periods with a written record) quite often relies on the combined analyses of both material and archival sources (Hicks and Beaudry, 2006). Textual sources offer priceless clues to the archaeologist to enrich their perspective of material processes in the past. They can inform and guide research questions as well as offer some context to better understand these phenomena. We aim to harvest methods from digital humanities and natural language processing to explore archeologic data. Specifically, we will use textometric measures, word embeddings, topic modeling and clustering of representations encoded in language models to characterize our data. Textometry focuses

on surface descriptions using statistical methods concerning the frequency and co-occurrences of certain words or expressions (Pincemin, 2011). By identifying these elements, we can note their relative importance within a document and their tendency to co-occur with other terms. Vector models such as `word2vec` (Mikolov et al., 2013) enhance these methods, and offer numerical representations of the terms that appear in a corpus. These vector representations are known to capture complex morphosyntactic and semantic properties of the terms they represent, in particular information about the latent associations of a term with other terms. By training this type of model on our data, we can extract synonyms and words that occur in similar contexts from our keywords. Topic modeling is a technique that creates classes of documents on the basis of the terms that appear in it. Here, document is to be understood as a general term: in practice, a sentence within a text can be treated as a document for the purposes of the method. For our data, we used BERTopic (Grootendorst, 2022), a modular architecture that enables us to use the dynamic embeddings offered by large language models such as those of the BERT family (Devlin et al. 2019, cf. next section). Topics are identified by the terms that served to define them. One can then explore the topics to see if some are defined by certain concepts of interest.

2.3 Large language models for French

Language models are tools that manipulate representations that encapsulate information about linguistic expressions. Following the development of Transformer models (Vaswani et al., 2017), powerful models have been developed, which offer dynamic representations for linguistic expressions, dependent of the context in which those expressions appear: the representation of a given expression will vary according to the linguistic context in which it appears. These models are pretrained on vast quantities of text, giving their representations a general character which can, in principle, be leveraged for a variety of downstream applications on which the model can be fine-tuned. In the context of this research, we focus on bidirectional models of the BERT family (Devlin et al., 2019), whose representations integrate information from both the left and right context of an expression (see Sec. 4.4 for further discussion).

The language found in the texts of interest to the project differs from contemporary French. As discussed in Sec. 3, the historical period covered by our data goes from the mid sixteenth to the late eighteen century, which corresponds to what is referred to as pre-classical and classical French. These varieties of French were used on both sides of the Atlantic, so the language used in NF corresponds to the one used in France that time, specifically to that used in the region around Paris (Gendron, 2013). This allows us to use language models trained on texts from that period, without having to focus on a particular geographical area. To our knowledge, the only model of that sort available to this day is d'AlemBERT (Gabay et al., 2022), trained on the FreEM corpus which covers a historical period ranging from the 16th century to the end of the 19th, and thus matches our period of interest. Of particular interest to us is the robustness of the representations offered by d'AlemBERT across dialectal and diachronic variations. As highlighted by Gabay et al. (2022), d'AlemBERT representations fare well for various linguistic tasks, even when dealing with data that was absent or underrepresented in the training data of the model.

3 Data

We used two main sub-corpora for our analyses.

The first one was manually compiled on the basis of literary works written about NF. The list of works in the corpus can be found in appendix A.

4 Analyses

In this section, we explain the method behind each type of analysis and showcase some of the most relevant outputs of these analyses. Mostly for reasons of space, we do not present the whole set of results, though those were taken into consideration in the discussion in section 5.

4.1 Basic textometry

We began by establishing a list of lexical terms that correspond to the theme of bovines in NF. Those terms are shown in table 1 along with their raw frequencies and frequency of occurrence per million words in the complete corpora.[1]

[1] A list of all keywords and their translations is given in Appendix B.

data	keyword	per million	total
NFN	bestiaux	87.78	746
	vache	57.77	491
	boeuf	54.95	467
	veau	15.3	130
	taureau	5.06	43
Published	bestiaux	40.6	205
	vache	11.29	57
	boeuf	1.58	8
	veau	4.36	22
	taureau	0.99	5

Table 1: Frequencies of our keywords

We then proceeded to look at bigrams, and focus on the ones that involve our target terms and display a strong association via their Pointwise Mutual Information score. Table 2 summarizes some interesting bigrams for the keyword *vache* ('cow') in the NFN corpus and in the published corpus.

Corpus	bigram	N. occ.	PMI
NFN	('vache', 'immortelle')	12	13.67
	('vache', 'prisée')	9	8.88
Published	('boeufs', 'vaches')	9	15.08
	('vaches', 'moutons')	5	14.17

Table 2: Most relevant bigrams for the word *vache*

4.2 Static word embeddings

We trained three `word2vec` models (Mikolov et al., 2013), one per sub-corpus and one for the entire corpus, to obtain static word embeddings. The training configurations were the same for each model with a vector length of 300, a window of 3, and a set number of 5 epochs (using the `gensim` library Rehurek and Sojka 2011). Words with less than 5 occurrences were ignored in the process. We used the embeddings to calculate the cosine similarities of the terms in our list of key words. Table 3 shows the five most similar term for each corpus, for the target term *vache*.

Similar term	Similarity
NFN	
immortelle	0.64
genisse	0.61
cariolle	0.61
jument	0.59
taure	0.59
Published	
barique	0.72
pistolle	0.67
ferrure	0.66
corne	0.64
fermage	0.64
Combined	
pouliche	0.58
camisolle	0.58
cariolle	0.58
truye	0.57
jument	0.57

Table 3: Top five most similar terms for *vache*, per corpus

We can already observe an overlap between the results in Table 3 and the bigrams in Table 2 with the (admittedly unexpected) adjective *immortelle* ('immortal'). We discuss the significance of this association in section 5.1.

4.3 Topic modelling

To automatically extract topics from our data, we used BERTopic on each of our sub-corpora separately and on the combined corpus, using d'AlemBERT embeddings. The number of topics found in each case are shown in Table 4.

File	Number of topic
NFN	11 006
Published	2185
Combined	9745

Table 4: Topics found per corpus

In Table 5 we show the number of topics that involve our set of target terms.

Target term	NFN	Published	Combined
vache	13	0	8
taureau	1	0	0
bestiaux	4	2	3
boeuf	8	0	4

Table 5: Topics associated to target terms, per corpus

As can be seen, the two sub-corpora differ in whether they seem to be organized around topics that involve bovines. While several topics involve our target terms in the NFN sub-corpus, they are much more rare in the published corpus, in which only *bestiaux* ('beasts/livestock') seem to be relevant. This is expected in a way: the NFN sub-corpus contains many notary records listing heritages, the buying and selling of livestock etc., and the target terms are more frequent in the NFN sub-corpus than in the Published one (cf. Table1), though they are not absent either from the Published corpus. Rather, their presence is not tied to an identifiable topic.

As mentioned in section 2.2, though the number of topics identified by the algorithm is large, we are only interested in those that are specific to our terms of interest (given in Table 1). Table 6 shows the most representative topics associated with the keywords *vache, boeuf* and *bestiaux* from the NFN part of our corpus. The count associated to each topic corresponds to the number of documents (i.e. spans of texts) associated to the topic, and the representation is the set of terms that define the topic.

Beyond suggesting other keywords for further and expanded analyses, those topics already suggest the outlines of the place of bovines in NF, and how they were conceptualized. We discuss those findings in section 5.1.

As for the lack of conclusive results from the use of BERTopic on the Published corpus, this confronts us with certain limitations of this kind of approach (see Egger and Yu (2022) for more general limitations). It is possible that the low frequency of the terms we are interested in prevents us from seeing them emerge in interesting clusters. Nevertheless, we do expect the above-mentioned target terms usages to have a particular meaning, and to refer to different facets of bovines, even in the Published sub-corpus. To capture such nuances of meaning requires a complementary approach to topic modelling, to which we now turn to.

Id.	Target	Count	Representation
2614	*vache*	60	'hyverné', 'hyvernée', 'hyverner', 'hyvernés', 'moutons', 'taure', 'hyverne', 'nouriturraux', 'hyvernes', 'pacagée'
9819	*vache*	13	'moutons', 'vaches', 'genisse', 'ccechons', 'chicvat', 'giarre', 'grangé', 'troisueaux', 'vache', 'lochon'
1119	*boeuf*	143	'boeuf', 'boeufs', 'vaches', 'caribous', 'bola', 'besson', 'apellent', 'peaux', 'appelés', 'boeuf'
2792	*boeuf*	57	'labours', 'labour', 'laboureurs', 'labourer', 'laboureur', 'laboratoire', 'laboure', 'labouré', 'labourage', 'boeufs'
3927	*bestiaux*	40	'attaque', 'attaquer', 'attaquée', 'atoucher', 'atriotume', 'attablissement', 'attabues', 'camiral', 'attassine', 'attavoix'

Table 6: Examples of relevant topics associated to target terms about bovines in the NFN corpus

4.4 LLM representation clustering

Analyses based on topic modelling approaches are not particularly suited to the investigation of particular set of terms. In the context of DH, they serve to identify and characterize the topics approached in collection of documents, but there is no guarantee that certain target terms will indeed be part of such topics. In the previous subsection this is what happened with the Published sub-corpus, in which no topic relevant to cows was identified, even though the term does appear a significant number of times in the corpus. To circumvent such obstacles, we leverage techniques that were used by Erk and Chronis (2023) to study the properties of the representations of specific lexical items by large language models. In essence, the technique involves obtaining the LLM representations of all the tokens that correspond to target lexical items in a given corpus. After using dimension reduction techniques, those representations are automatically

clustered together, and the clusters are manually qualified on the basis of the sentences that correspond to the tokens belonging to the cluster. In the rest of this section, we give details on all the steps we used to use this technique on our data.

Given that the data is not clean, in particular in terms of spelling of our target terms, we took precautions in the preprocessing of the data. We used d'AlemBERT (Gabay et al., 2022) to extract dynamic embeddings of terms within our list of target terms. All the texts in the corpus were first tokenized using d'AlemBERT's tokenizer, and split into batches of 512 tokens, the maximal size for a sentence in d'AlemBERT. We found that target terms were tokenized differently by d'AlemBERT if they were preceded directly by a space. As an example, the tokenized term *vache*, was either split by the tokenizer in '*v*' and '*ache*', or kept entirely as *Ġvache* where 'Ġ' represents the space character. We found that terms not preceded by a space were either at the very start of the text or they were fused with another term, possibly due to an OCR error. For example the sequence '*unevache*' appears in the corpus and is tokenized as *'une', 'v', 'ache'*, though the sequence is most likely the result of faulty OCR.

Being aware of this possible issue, we were able to identify the position of each token in every batch. We then extracted the tokens' embeddings from d'AlemBERT's last hidden layer. Whenever the term was split into two or more tokens, we calculated an average embedding to represent the term. The decision to extract only the last layer of the d'AlemBERT is based on the work Erk and Chronis (2023) who found that the latter layers of BERT models encode semantic and pragmatic information in a consistent way, which echoes similar findings in the literature (see a.o. Tenney et al. 2019).

For each term, we reduced the number of dimensions of the gathered embeddings from 718 to 3 and 2 using the Principal Component Analysis (PCA) method. The embeddings with 3 dimensions were used for clustering and creating 3D visualizations while the embeddings with 2 dimensions were only used for creating 2D visualizations. We used k-means clustering to group the embeddings of each term by considering the embeddings of every occurrence of that term. To determine the optimal number of clusters for k-means, we initially explored a wide range of values for k, from 1 to 60. We then plotted the inertia - which measures the within-cluster sum of squared distances - and identified a range of values for k where an elbow was evident (e.g., from k=4 to k=10). From there, we calculated the average silhouette score - which measures how similar an instance is to its own cluster compared to other clusters - and selected the k value with the highest score. To visualize the clusters, we created both 3D and 2D plots of the embeddings. For each occurrence of a term, we included 12 tokens preceding and 13 tokens following the term to capture its context and see the differences between each occurrence. Within each cluster, we identified the most representative occurrence by finding the one closest to the center of the cluster. Figure 1, Figure 2 and Figure 3 illustrate the results of the method and show the clusters for *vache* in 2D, for each of the two sub-corpus and the total corpus.

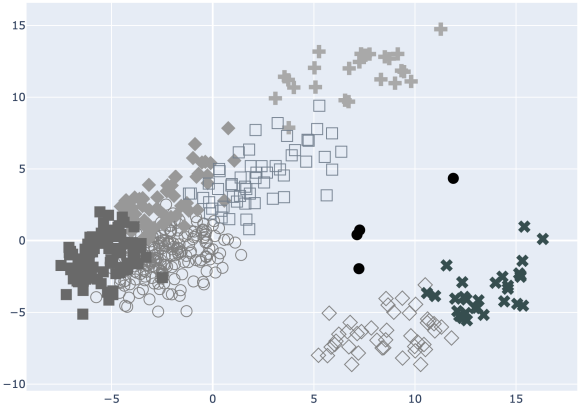

Figure 1: 2D clustering of the occurrences of *vache* in the NFN corpus

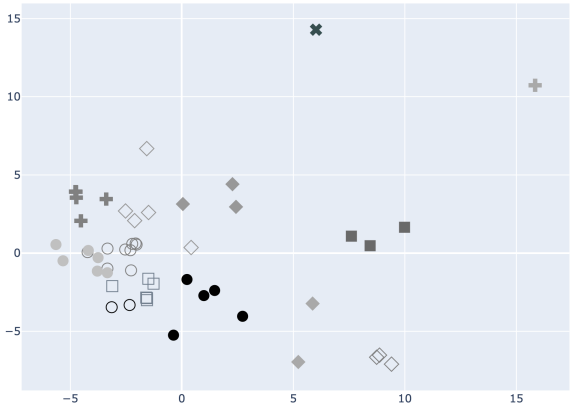

Figure 2: 2D clustering of the occurrences of *vache* in the Published corpus

The method yields particularly legible results for the entire corpus: this is where the clusters appear to be the most interpretable and well separated. Roughly we find a cluster that is related to inventories, such as those made by notaries when dealing

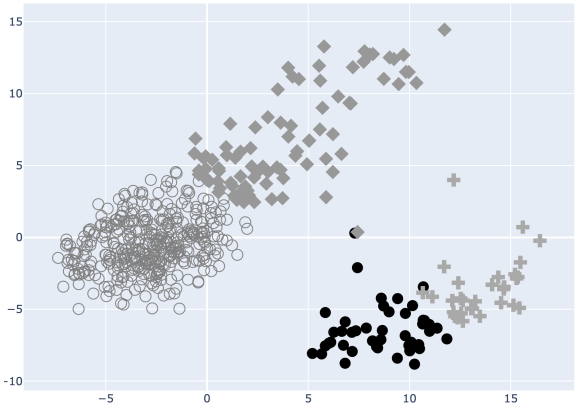

Figure 3: 2D clustering of the occurrences of *vache* in the complete corpus

with inheritance questions, one which is related to conflicts that involve cows, typically of judiciary nature, for which the cow is at the source of the conflict, e.g. because its ownership is being disputed or because the cow caused some damage to one of the parties. Another cluster involves cows in judiciary matters, but in those examples the cow is part of the compensation offered to one of the parties. To a degree, these clusters reflect the general topics that we expect to find in the documents of the NFN corpus which mostly deal with legal matters (see Annnex A.2). It is nevertheless worth noting that the method seems to correlate with different types of judiciary acts.

Figure 4 shows the result for the plural *vaches* ('cows').

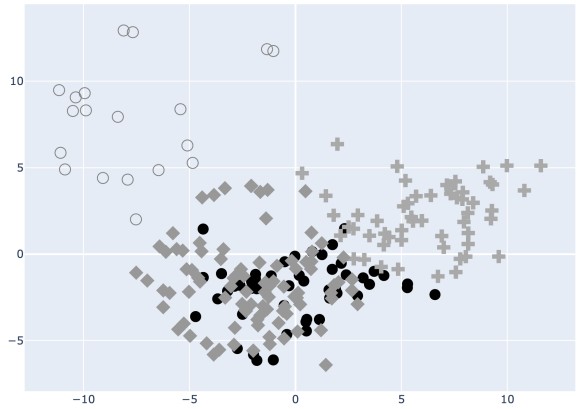

Figure 4: 2D clustering of the occurrences of *vaches* in the complete corpus

We find the same number of clusters as for singular *vache*, though their nature differs. In particular, we find one cluster that seems to revolve around description of locations. There, cows are either mentioned as resources available in a location or as means of transportation. Another cluster involves cows as a comparison point in the description of other animals, suggesting yet another perspective and experiencing of cows.

5 Discussion and openings

The computational methods introduced in this paper and their application to the analysis of New France archival documents offer a critical insight into the mentalities, practices and uses of cattle in the first centuries of European presence in the lower Saint-Lawrence basin. The innovative use of such an approach in the study of historical archaeology and zooarchaeology provides exciting new venues of research in these fields.

5.1 The role of cows in New France through the lens of digital humanities

The application of digital humanities methods to the study of archival documents related to cows in New France reveals a nuanced perspective on the role of bovine in the region between the sixteenth and the eighteenth century. By analyzing historical texts using techniques such as textometry, word embeddings, and topic modeling, we observe that cows were not merely agricultural assets but also symbolic figures deeply embedded in the cultural and economic landscape of the Euro-Quebecois colonial society.

One of the main takeaways of the word similarity analysis is the highly frequent, though unexpected, association of the words *vache* and *immortelle*. The association of these two terms does not refer to any supernatural property of undying animals. It revolves instead around the legal obligation for a donor to replace a cow after its passing. This practice of perpetual donation, very little studied elsewhere but apparently mostly attested in New France legal documents, underlines the crucial importance of cows as providers of food, labor, and manure in the colonial households.

The topics defined by the topic modelling approach illustrate the centrality of cattle to the settlers' survival and the transformation of the landscape. One of the main topics relates to the wintering of the cows (e.g. '*hyverné, hyvernée, hyverner, hyvernés*') and the need to have the animals prepared to survive the long and harsh Canadian winters. Given the major role played by cattle, especially in the opening of new agricultural land (also found through the topic modelling approach:

'*labour, laboureurs, labourer, laboureur*'), the preparation for winter to ensure the survival of the animals was critical, as already implied in the historical scholarship (D'Amour and Cossette, 2002). Other contexts in which cows are mentioned, relating mostly to other agricultural practices, highlight their diversified relevance to the settlers' everyday lives. These other topics include for example the realm of all the farm animals and the topic of reproduction and mating of cattle. Critically, another theme found through the topic modelling approach potentially refers to the conflictual nature of Europeans and the indigenous communities and the role of cattle in these relations. The topic relating to the term '*bestiaux*' revolves around notions of aggression. While the earlier historical scholarship had mentioned that cows were often the target of relaliatory actions by the Indigenous communities (Séguin, 1954), the high frequency of this topic highlights the relevance of this concern to the European colonists and suggests the relative regularity of such attacks.

The clustering of terms related to cows shows that they were often discussed in conjunction with other livestock and agricultural practices, paralleling the results of topic modelling and refining our interpretation of the historical documentation. One theme that stands out is the use of cows as a comparison to describe animals prior unknown to the European settlers. From the onset of the European presence in the Western Hemisphere, natural histories and chronicles describing the natural oddities found in the new continent were a common literary production designed to European audiences (Gerbi, 2010).

Interestingly, other topics appear to be completely absent from the ones identified through these methods. In particular, the question of the origins, the introduction, and the adaptation of bovine populations from Europe to the Americas is not addressed in any of the documents. Over the past decades, the historical scolarship have repeatedly asserted an inferrential narrative stating that cows from New France were imported by French settlers from Nortwestern France (Brittany, Normandy) (Séguin, 1954; Trudel, 2016). Such a narrative seems relatively unsubtantiated by the archival documents, as confirmed by our study, relying instead on circumstancial evidence such as the point of origin of these early settlers. The critical lack of such data underlines the relevance of the other component of our project (RABBA) that aims at investigating these aspects through the biomolecular analysis of archaeological cattle specimens.

5.2 Methodological implications

We find that the four approaches we used to approach our corpus data yield results that overlap to some extent, but remain complementary. Textometry and static word embeddings both pointed to the unexpected concept of 'immortal cow', though the word embeddings certainly provide a more flexible tool to find other latent associations, and especially analogies. Future work will focus on characterizing analogies, for example in the treatment of cows as opposed to other forms of livestock.

The most relevant methodological finding is in the approach discussed in section 4.4 that relies on clustering LLM representations. First, the method provides immediate access to the topics formed by the occurrences of target terms in the corpus, as opposed to topic modelling algorithms which might simply not identify such topics, as was the case for the Published sub-corpus. For that corpus, the clustering approach did provide a relevant cluster. Second, the method also confirms the robustness of the LLM representations offered by models such as d'AlemBERT. Part of the corpus is imperfect, due to OCR errors, and because French spelling proved highly variable in our time period of interest. Yet, the clustering approach was able to provide meaningful and interpretable results. This suggests that the method can reliably be used to investigate other topics in historical documents.

Acknowledgments

This work has been supported by a SSHRC-CRSH Banting Fellowship (PI: Nicolas Delsol), and an NSERC-Discovery Grant (RGPIN-2024-06718, PI: Grégoire Winterstein).

We are particularly thankful to the team of the *Nouvelle France Numérique* project for their help in collecting part of our corpus data, in particular to Maxime Gohier, Dominique Deslandres, Léon Robichaud and Kim Petit.

Bridging the Linguistic Divide: Developing a North-South Korean Parallel Corpus for Machine Translation

Abstract

This study addresses a significant challenge in machine translation between North and South Korean languages: the scarcity of parallel corpora. To overcome this limitation, we developed a comprehensive North-South Korean parallel corpus and fine-tuned a South Korean pre-trained model. Our research explores the potential for a robust sentence-level translation model between the two Korean dialects. We evaluated the performance of the model using both BLEU and BERTScore metrics and conducted a qualitative analysis to assess its ability to capture the distinct linguistic features of North and South Korean languages, including differences in vocabulary, word spacing, and spelling. Our findings demonstrate that this newly developed corpus and translation model not only enhance machine translation capabilities but also contribute valuable insights to linguistic studies of the two Korean languages.

1 Introduction

Korean is the official language of both South Korea and North Korea. Because of the geographical and sociopolitical division of the Korean peninsula for over 70 years the Korean language has evolved differently in the two Koreas. The most notable difference can be found in the vocabulary: everyday North Korean terms differ by 38% from those used in South Korea, while technical terms differ by 66% (Park, 2016). Additionally, differences in orthography and discourse style often prevent North and South Korean speakers from understanding each other. According to the *2016 Survey on Language Awareness of North and South Korea* by the *National Institute of the Korean Language*, 29.8% of North Korean defectors need 4 to 5 years to speak and write like South Koreans, while 51% need more than 6 years (National Institute of Korean Language, 2016). This language gap between North and South Korea could pose a practical obstacle to Korean reunification.

Efforts have been made to overcome the linguistic divide between North and South Korea. For instance, in 2005, both countries undertook a joint project, to create a unified Korean dictionary, Gyeoremal-keunsajeon (Yu, 2021). Unfortunately, the project was discontinued due to turbulent inter-Korean relations, with only about 40% of the total 307,000 words collaboratively discussed and resolved (Park, 2023). Additionally, in South Korea, a translator app, *Geul-dong-mu* was launched to help North Korean defectors adjust to their new lives by translating South Korean terms into North Korean equivalents (Geuldongmu). However, the app had a limited vocabulary and could not translate sentences, which highlights the need for more natural language processing (NLP) research focused on the North Korean language. The paucity of North Korean language resources has made it challenging to build a large-scale corpus for NLP tasks like machine translation in the North Korean language.

Several studies have implemented NLP research on the North Korean language. For example, (Kim et al., 2022) created North Korean-English and North Korean-Japanese parallel corpora from a North Korean News portal, *Uriminzokkiri*. This parallel corpus was used to conduct North Korean translation experiments. Another study (Akdemir et al., 2022) built a North Korean corpus using *Rodong News articles* and *New Year Addresses of the North Korean leaders* to train a BERT-based language model and a sentiment analyzer. However, these studies were limited to corpora that either only included North Korean language data or were paired with languages like Japanese or English. Studies focusing on translation between North and South Korean using a parallel corpus that align North Korean sentences with their South Korean counterparts are scarce.

To address this problem, we created a parallel

corpus by collecting and aligning text data, which are translations between North Korean and South Korean. We then developed a North-South Korean machine translation model by fine-tuning a South Korean pre-trained model with the parallel corpus. We conducted a quantitative evaluation using combined metrics: BLEU (Papineni et al., 2002) and BERTScore (Zhang et al., 2020). Furthermore, we performed a thorough qualitative analysis of our translation results to assess the extent to which our translation model captures the differences between the North Korean and South Korean languages.

2 Related Works

NLP research on the North Korean language is limited due to the scarcity of North Korean NLP tools and resources. Consequently, North Korean-related NLP research lags behind in reaching cutting-edge results.

One study (Kim et al., 2023) constructed a parallel corpus specifically for the North Korean neural machine translation (NMT) systems. Using a news portal called *Uriminzokkiri*, news articles published in North Korean, English, and Japanese were aligned manually and automatically to create North Korean–English (NK-EN) and North Korean–Japanese (NK-JA) parallel corpora. A trilingual annotator manually aligned the English and Japanese sentences with their corresponding North Korean sentences to create evaluation data for machine translation. The automatic alignment method was used to generate the training data, and the study found that the bidirectional South Korean NMT model (bidi-SK) achieved the highest alignment score. Translation experiments using the NK-EN and NK-JA datasets showed that the South Korean pre-trained BART fine-tuned with North Korean data produced a higher BLEU score than the models trained exclusively on either South or North Korean data. Similar to the study, we utilize a South Korean pre-trained BART-based model. However, unlike that study, we focus on exploring the potential for machine translation between North and South Korean languages.

Another study (Choi and Hong, 2022) constructed a South Korean-North Korean parallel corpus to develop a North and South Korean bidirectional translator. South Korean-English and North Korean-English news data from the Korean Parallel Data (Park et al., 2016) were used as resources. Corresponding South Korean and North Korean sentences for each English sentence were extracted and aligned to create a parallel dataset. However, due to the small size of the training data, only a few linguistic differences were observed in the dataset and the translation results.

In our study, we created a large and diverse dataset of North Korean and South Korean languages by incorporating novels with varied content, sentence structures, and vocabulary. We then fine-tuned the South Korean BART model [1] using this dataset to improve the translation quality between North Korean and South Korean languages.

3 North – South Korean Parallel Corpus Construction

3.1 Data Description

Table 01 describes the information about the North-South Korean parallel corpus. The corpus contains 130,738 sentence pairs, sourced from classic novels and the Bible, translated into North and South Korean languages. 29,986 sentence pairs were created from the Bible, making up 23% of the corpus. Meanwhile, classic novels provided 100,752 sentence pairs, representing 77% of the corpus. English and French classic novels comprise 72% of the dataset, while Korean classic novels account for 5%. The parallel corpus is available in GitHub to encourage further research in Natural Language Processing(NLP) or Linguistics. [2]

3.2 Data Collection

The dataset was created using the North Korean and South Korean versions of the Bible, three Korean classic novels, and one English and French classic novel, each translated into North Korean and South Korean. The Bible was selected because of its consistent structure of books, chapters, and verses, which made it easier to match corresponding sentences across translations. The North Korean version of the Bible was kindly provided by the *North Korean Science and Technology Network (NKTech)* of the *Korea Institute of Science and Technology Information*. The Korean, English, and French classic novels were chosen for their variety of everyday words, discourse styles, and sentence structures. The North Korean versions of the classic novels were acquired from the *Information Center on North Korea*, operated by the *Ministry of*

	Sukhyang-jeon (숙향전)	3,538	
	Shimchung-jeon(심청전)	1,767	
			130,738

Table 1: North-South Korean parallel corpus

Unification in South Korea. All documents, including the matching South Korean translations, were manually collected in PDF format using scanning software. They were then converted into text using an optical character recognition (OCR) tool and carefully reviewed to correct any typos or errors during the automated recognition process.

3.3 Manual error correction of the text data

The accuracy of the extracted text data was cross-checked with the original PDF, and any spelling or spacing mistakes were corrected. Annotations, chapter titles, page numbers, Chinese characters, and languages other than North or South Korean were eliminated. A unique challenge was to avoid unintentional modification of North Korean text according to South Korean language rules.

3.4 Matching sentence pairs

The resulting text files were preprocessed to remove all punctuation marks except periods (.), commas (,), question marks (?), and exclamation marks (!). These four punctuation marks were used to separate the text into sentences. The text files were then converted into a spreadsheet with North Korean sentences in the first column ('nk') and South Korean sentences in the second column ('sk').

Next, matching was performed to pair each North Korean and South Korean sentence with an identical meaning. In the case of classic novels, one North Korean sentence often corresponded to multiple South Korean sentences, and *vice versa*. Multiple sentences were allowed in the same row to create sentence pairs as long as one or more sentences in both languages shared the same meaning. Any sentences with no corresponding match in the other language were deleted.

These stages of building the parallel corpus required significant labor. Approximately twenty participants were recruited to handle routine tasks, such as applying the OCR tool and identifying obvious errors and mistakes. All participants were native South Korean speakers, with no specific criteria regarding age, gender, major, or grade in the selection process. Each part of the dataset was reviewed twice by different participants to minimize individual bias and ensure consistency when pairing North Korean and South Korean sentences with equivalent meanings. The initial completion of the dataset took approximately six weeks, from August 29th to October 6th, 2023.

In the resulting dataset, errors were more prevalent in the North Korean text than in the South Korean text, as the process was conducted by native South Koreans with little or no knowledge of the North Korean language. Therefore, an additional phase was undertaken to correct the errors in the North Korean text. Important spelling, spacing, and vocabulary differences between the North and South Korean languages were studied in advance to reduce the likelihood of overlooking errors. In total, the creation of the North-South Korean parallel corpus took about three to four months.

4 North–South Korean Translation Experiments

Using the North-South Korean parallel corpus constructed in Section 3, we trained a North-South Korean bidirectional translation model and measured the translation quality with BLEU (Papineni et al., 2002) and BERTScore (Zhang et al., 2020). To evaluate how well the model captured the linguistic differences between North and South Korean, we analyzed the translation results of several sentences that were not included in the training data.

4.1 Experimental Setup

Dataset

For the translation experiments, we split the North-South Korean parallel corpus, consisting of

130,738 sentence pairs, into training and test sets with a 9:1 ratio. To ensure balanced representation, the test set of 13,073 sentence pairs was proportionally collected as follows: The Bible 23% (3,007 pairs), *Jane Eyre* 46% (6,016 pairs), *The Red and the Black* 26% (3,399 pairs), and Korean classic novels 5% (651 pairs), with the sentence pairs selected randomly. The remaining sentences were used for the training set. For *Jane Eyre* and *The Red and the Black*, the number of South Korean publishers was also considered. Since the South Korean translations of these works were provided by multiple publishers, some sentence pairs had the same North Korean sentence aligned with different versions of South Korean sentences. Therefore, extra caution was needed to make sure that North Korean sentences in the training set were not included in the test set. For example, because *Jane Eyre* was sourced from four South Korean publishers, around 1,500 North Korean sentences were selected from each publisher to make up the 6,016 sentence pairs needed for the test set. A similar approach was applied to *The Red and the Black*.

Baseline Model

BART (Lewis et al., 2019) is a denoising autoencoder that learns to map corrupted sentences to their original forms and has achieved high performance in various text generation tasks. It has shown enhanced performance in Romanian-English translation. KoBART is a South Korean BART trained on approximately 40GB of Korean text. Fine-tuning KoBART has proven effective in improving North Korean-Japanese and North Korean-English machine translation (Kim et al., 2023). Therefore, we chose KoBART as our baseline model. Specifically, the KoBART-translation model was fine-tuned on our dataset using the following hyperparameters: a batch size of 4, 8 epochs, a learning rate of 3e-5, and the AdamW optimizer. Sentences were pre-processed using the KoBART tokenizer.[3] We refer to the model translating North Korean sentences to South Korean as NK→SK, and South Korean sentences to North Korean as SK→NK.

4.2 Experimental Results

The translation performance of the NK→SK and SK→NK models was evaluated using two metrics: BLEU Score (Papineni et al., 2002) and BERTScore (Zhang et al., 2020). Table 02 presents the BLEU scores for each model. The NK→SK model achieved a score of 0.442, outperforming the SK→NK model, which scored 0.107. We attribute the higher score of the NK→SK model to the difference in the number of reference sentences possible for comparison with the output of the model. That is, since the South Korean sentences were drawn from various publishers, the NK→SK model had at most four reference sentences to compare against each translation output. In contrast, the SK→NK model had only one reference North Korean sentence available for each translation output, as the North Korean sentences were extracted from a single publisher.

Model	BLEU Score	BERT Score
NK→SK	0.442	0.821
SK→NK	0.107	0.815

Table 2: BLEU Score and BERT Score of the NK→SK and the SK→NK model

Although BLEU is a commonly used evaluation metric in machine translation tasks, it relies on surface-form similarity measures and often neglects semantic equivalence between the reference and candidate. This can lead to underestimating the performance of semantically correct translations that differ from the surface form of the reference. To address the limitations of BLEU, we used BERTScore as an additional metric. Unlike n-gram-based metrics, BERTScore measures the cosine similarity between tokens in the candidate and reference using the contextual embeddings of BERT. BERTScore correlates better with human judgment as it effectively captures the semantic and contextual information of words and phrases in the candidate and reference. BERTScore calculates precision, recall, and F1 scores. Recall measures how well each token in the reference is captured by those in the candidate, while precision measures how closely candidate tokens match those in the reference. F1 is the harmonic mean of precision and recall. Table 02 presents the BERTScores for the NK→SK and SK→NK models, with only the F1 scores recorded for simplicity. Both models reached high scores, with the NK→SK model scoring 0.821 and the SK→NK model scoring 0.815. The difference in the BERTScore results between the two models is much smaller than the difference observed in their BLEU scores, indicating

Table 4: Example of NK→SK and SK→NK translations that show North and South Korean difference in loanwords

no significant performance difference between the NK→SK and SK→NK models regarding semantic similarity.

4.3 Qualitative Analysis

A qualitative analysis was conducted to evaluate the ability of the translation model, considering the differences between the North and South Korean languages. The analysis focused on three main aspects: vocabulary, spelling, and word spacing. These criteria for comparing North and South Korean language differences were chosen based on the book, *Understanding the Languages of North and South Korea* (Cho et al., 2002). Sentence pairs that contained the key linguistic differences between North and South Korean languages were selected from the test dataset.

4.3.1 Vocabulary difference between North and South Korea

North Korea and South Korea often use different words to refer to the same meaning. From a native South Korean speaker's perspective, some North Korean words are difficult to understand without knowing the North Korean language.

For instance, the North Korean phrase "말밥에 오르다(mal-bab-e o-leu-da)" means "being spoken about by many people." Not only "말밥(mal-bab)" is an unfamiliar word in South Korea, but rarely used with the predicate "오르다(o-leu-da)," which means "to come up." Instead, a more commonly used phrase in South Korean is "화제에 오르다(hwa-je-e o-leu-da)." For this reason, we selected a North Korean sentence including the phrase "말밥에 오르다(mal-bab-e o-leu-da)" to check the translation results of the NK→SK model. Table03 shows that the NK→SK model successfully translated the North Korean phrase "말밥에 오르다(mal-bab-e o-leu-da)" into the more generally used South Korean phrase "화제에 오르다 (hwa-je-e o-leu-da)."

Another example is the North Korean verb "모대기다(mo-dae-gi-da)" which means "to writhe in agony." In South Korean, "모대기다(mo-dae-gi-da)" does not convey the same meaning and is unused. So, we chose a North Korean sentence with the phrase "모대기다(mo-dae-gi-da)" to assess the translation results of the NK→SK model. In Table03, the NK→SK model translated the North Korean phrase "모대기다(mo-dae-gi-da)" into a South Korean phrase "사로잡히다(sa-lo-chap-hi-ta)," which means "to be dominated or

Source	요셉은 바로의 명령대로 그들에게 마차를 내여주고 **려행**길에 먹을 량식도 마련해주었다.

English	This ruddy shine revealed, too, a group near the **mantelpiece**.

Table 6: Example of NK→SK and SK→NK translations that show North and South Korean difference in the addition of a "ㅅ" into a compound word

overwhelmed by a particular emotion." Although it is not a perfect match, the meaning of the North Korean phrase is communicated to a certain degree.

Loanwords

English loanwords are one of the noticeable differences in vocabulary between North and South Korean languages. North Korea uses less foreign loanwords than South Korea. One example is the English word "curtain," which is rendered as the loanword "커튼(keo-teun)" in South Korea, whereas in North Korea, it is referred to as "창가림(chang-ga-lim)." "창가림(chang-ga-lim)" joins together the Korean words "창(chang)," meaning "window," and "가림(ga-lim)," meaning "cover." Table04 shows that the NK→SK model accurately translated the North Korean word "창가림(chang-ga-lim)" into the South Korean word "커튼(keo-teun)." It also shows the example of the SK→NK model correctly translating "커튼(keo-teun)" into "창가림(chang-ga-lim)."

4.3.2 Spelling difference between North and South Korean

Initial sound rule

In South Korean, the consonant "ㄹ" changes into "ㅇ" or "ㄴ" when combined with vowels "ㅑ, ㅕ, ㅛ, ㅠ, ㅢ, ㅣ, ㅖ," while North Korean does not undergo such changes. For example, the word "travel" is written as "려행(lyeo-haeng)" in North Korean but "여행(yeo-haeng)" in South Korean. In Table 05, we see that the NK→SK model correctly translated the North Korean word "려행(lyeo-haeng)" to "여행(yeo-haeng)" in South Korean, while the SK→NK model translated "여행(yeo-haeng)" into "려행(lyeo-haeng)" in North Korean, according to the initial sound rule.

The addition of "ㅅ" into a compound word

In South Korean, the consonant "ㅅ" is added when compound words are created in certain cases. The first case involves compound words made up of pure Korean words, such as "시냇가(si-naet-ga)," meaning "the surroundings of a stream." Since both "시내(si-nae)," meaning "stream," and "가(ga)," meaning "the surroundings," are two pure Korean words with no corresponding Chinese characters, "ㅅ" should be added when those words are combined to form a new word. Another case occurs when compound words consist of one pure Korean word and another Sino-Korean word, with the first word ending in a vowel. An example is "난롯가(nal-lok-ga)," which means "fireside." "난로(暖爐)" is a Sino-Korean word meaning "stove" and ends in a vowel, "ㅗ," requiring a

Source	그래 나는 상당한 돈을 주고 적당한 일자리를 얻어준 다음에 체면을 유지하며 기꺼이 **헤여졌소**.
NK→SK	그래서 상당한 돈을 주고 적당한 일자리를 얻어 준 다음부터 나는 체면을 되찾고 기꺼이 **헤어졌소**.
Source	결국 충분한 돈을 주어 장사를 시작하게 해주고, 깨끗이 **헤어지고** 나니 마음이 후련했소.
SK→NK	마침내 저에게 충분한 돈을 지불하고 그와 **헤여져** 있게 되자 나는 무척 안도감을 느꼈소.
English	I was glad to give her a sufficient sum to set her up in a good line of business, and so **get decently rid of her**.

Table 7: Example of NK→SK and SK→NK translations that show North and South Korean difference in the endings of a word "-아/-어" based on the final syllable vowel of the stem

Source	그 옷은 세상의 어떤 빨래하는 사람도 그보다 더 희게 할수 **없을만큼** 새하얗고 눈부시게 빛났다.
NK→SK	그 옷은 세상 어느 누구도 그보다 더 희게 할 수 **없을 만큼** 새하얗고 눈부시게 빛났다.
English	His clothes became dazzling white, **whiter than anyone** in the world could bleach them.
Source	하느님 당신의 길은 거룩하시오니 **하느님만큼** 높은 신이 어디 있으리이까.
NK→SK	오 하나님 주의 길은 거룩합니다. **하나님만큼** 위대한 신이 어디 있습니까?
English	Your ways, God, are holy. What god is **as great as our God**?

Table 8: Example of NK→SK translations that show North and South Korean difference distinguishing word spacing rules between dependent nouns and particles

consonant "ㅅ" to be added when combined with the word "가(ga)." North Korean, on the other hand, does not apply this rule. Hence, the South Korean word "시냇가(si-naet-ga)" and "난롯가(nal-lok-ga)" are written as "시내가(si-nae-ga)," and "난로가(nal-lo-ga)," respectively. Table 06 demonstrates an example of the NK→SK model correctly translating "난로가(nal-lo-ga)" into the South Korean word "난롯가(nal-lok-ga)," following the rule of adding "ㅅ" in compound words. The SK→NK model correctly translated "난롯가(nal-lok-ga)" into the correct North Korean spelling, "난로가(nal-lo-ga)."

Endings of a word "-아/-어" based on the final syllable vowel of the stem

South Korean and North Korean differ in the way of writing the ending of a word "-아/-어" depending on the final syllable vowel of the stem. In North Korean, the ending of a word is written as "-여/-였" when the final syllable vowel of the stem is "ㅣ, ㅐ, ㅖ, ㅚ, ㅟ, ㅢ" and "하". In South Korean, the ending of the word is written as "-아" when the final syllable vowel of the stem is "ㅏ, ㅗ," and "-어" otherwise. For example, "to break off a relationship" is written "헤어지다(he-eo-ji-da)" in South Korean because the final syllable vowel of the stem "헤" is "ㅖ," not either "ㅏ" or "ㅗ." In North Korean, since "ㅖ" is in one of the vowels listed(ㅣ, ㅐ, ㅖ, ㅚ, ㅟ, ㅢ), they write "헤여지다(he-yeo-ji-da)." Table 07 illustrates an example where the NK→SK model precisely translated "헤여지다(he-yeo-ji-da)" into the South Korean word "헤어지다(he-eo-ji-da)." The SK→NK model correctly translated "헤어지다(he-eo-ji-da)" into the North Korean word "헤여지다(he-yeo-ji-da)".

4.3.3 Word spacing difference between North and South Korean

Spacing of dependent nouns and particles

North and South Korean have different word spacing rules for dependent nouns and particles. In South Korean, the dependent noun is separated from the preceding verb or adjective stem, while in North Korean, it is attached. However, both languages attach particles to the preceding word. Therefore, we checked whether the NK→SK model could distinguish between dependent nouns and a particle that looks identical and apply the correct word spacing rules accordingly. Table 08 provides an example of the NK→SK model successfully translating "만큼(man-keum)," when used as both a dependent noun and a particle. When "만큼(man-keum)" is used after the

Source	...네 시어미 무슨 일로 통곡하는지 아구리를 당장 다물지 않으면 **쫓아낸다**고 일러라.
SK→NK	...네 시어미 무슨 일로 통곡하는지 아구리를 당장 다물지 않으면 **쫓아낸다**고 일러라.
Source	...네 시어미 무슨 일로 통곡하는지 아구리를 당장 다물지 않으면 **쫓아 낸다**고 일러라.
SK→NK	...네 시어미 무슨 일로 통곡하는지 아구리를 당장 다물지 않으면 **쫓아낸다**고 일러라.
English	Tell your mother-in-law that if she doesn't stop wailing this instance, I'll **throw her out**.

Table 9: Example of SK→NK translations that show North and South Korean difference applying spacing rules between main and auxiliary predicate element.

stem of the adjective "없을(eobs-eul)," meaning "something does not exist," it is a dependent noun and translated into South Korean with a word space between the two words. On the contrary, when "만큼(man-keum)" comes after the noun "하느님(ha-neu-nim)," meaning "God," it is a particle and attached to the previous word when translated into South Korean.

Spacing between predicate elements
North and South Korean also differ in the rules for spacing between main and auxiliary predicate elements. In North Korean, the main and the auxiliary predicate elements are always attached. In South Korean, separating the main and auxiliary predicates is a general rule. However, it is also possible to attach the auxiliary predicates to the main predicate in some cases. One such case is when a main predicate whose final syllable vowel is "아, 어, 여" is followed by certain auxiliary predicates, such as "내다(nae-da)." "쫓아내다(jjoch-a-nae-da)," which means to "drive somebody out," is an example. In contrast to North Korean, South Korean allows both "쫓아내다" and "쫓아 내다" because "쫓아" ends with "아" and precedes the predicate "내다". Table 09 shows a correct translation example of the SK→NK model translating both "쫓아 내다" and "쫓아내다" into "쫓아내다" in North Korean.

5 Conclusion

This study presented a North-South Korean parallel corpus using the Bible and literature resources. This corpus is particularly significant because a sizable parallel corpora containing North and South Korean sentence pairs is scarce. Additionally, the Bible and literary texts offer a diverse range of content and sentence structures. The resulting corpus was then used to train and analyze a North-South Korean bidirectional translation model. The translation quality of the model was quantitatively evaluated using two metrics: BERTScore and BLEU. The BERTScore results show that the NK→SK and SK→NK models achieved high translation performance on the test set. We conducted an in-depth qualitative analysis of the translation results, focusing on linguistic differences between the North and South Korean languages in three key areas: vocabulary, spelling, and spacing. Our findings demonstrated that fine-tuning a South Korean pre-trained model with the North-South Korean parallel corpus can produce a translation model capable of accurately translating sentences between the two languages. One drawback of our parallel corpus is the lack of sentences including contemporary loanwords and technical terms, due to the historical period of the literary resources and the Bible. For this reason, our qualitative analysis of the translation model has limitations in assessing the translation quality of sentences with recent loanwords and terms primarily used in a professional field. Therefore, expanding the North-South parallel corpus with sentence pairs from various sources, such as research papers, late 20th or 21st-century literature, or movie subtitles, is necessary. Moreover, we plan to investigate methods and large language models that can further improve the performance of the machine translation between the two languages.

Abstract

This study investigates the diachronic changes in the sentiments and metaphorical frames in a corpus of news discourse on COVID-19 as a case study to examine the potential implication for applying sentiment analysis in corpus data and its interaction with metaphorical framing changes over time. The corpus contains COVID-19 news articles covering the entire cycle of the pandemic from 2019 to 2024 in Hong Kong. The sentiment analysis of the corpus was explicitly presented. We found that the sentiments of the news are overall objective and slightly positive. The diachronic changes and the interaction between the sentiments and metaphor polarities were discussed with empirical examples from the corpus, aiming to establish an operational approach for exploring the connection between metaphor polarities and the sentiments in large-scale of discourse data.

1 Introduction

Over the past five years, the COVID-19 pandemic has had a huge and lasting impact on the public's health, economy, and society. In the domain of public discourse, researchers are studying the language used to address pandemic issues from various perspectives using different techniques. For example, sentiment analysis has been increasingly utilized in the COVID-19 discourse to uncover the synchronic or diachronic polarity and subjectivity patterns. Figurative framing, such as metaphorical framing, is another central focus of studies on COVID-19 discourse, as metaphors are not only a rhetorical device but also a tool for reasoning and persuasion (Burgers, Konijn, & Steen, 2016). Metaphors have been shown to evoke public emotions, shape perceptions, and influence the public's interpretation of social phenomena (Lakoff and Johnson, 2008; Group, 2007; Steen et al., 2010; Ahrens and Zeng, 2022; Zeng and Ahrens, 2023; Zeng et al., 2021). It permeates the discourse of the COVID-19 pandemic and is crucial for media, institutions, and governments (Fu, 2024).

This study aims to investigate the sentiments and metaphors in a large corpus of news discourse on COVID-19 in the context of Hong Kong. Understanding the functions of sentiment and metaphors and their interactions in news discourse can enhance and improve our understanding and comprehension of their role in establishing COVID-19 perception. Despite the previous many studies on this topic, the novelty of our study is 1) the use of a complete COVID-19 dataset covering the entire cycle of the pandemic for diachronic change analysis of the sentiments, 2) the focus on the metaphor polarity analysis, 3) the focus on the interaction between sentiments and metaphor polarity. The study thus contributes to the field with methodological and practical implications by providing a detailed sentiment and metaphor analysis of COVID-19 discourse in the context of Hong Kong.

2 Previous work

2.1 Sentiment analysis

Sentiment analysis includes the examination of positive and negative emotions, and is the process of extracting emotions and feelings from textual data (Bhardwaj et al., 2024; Pang and Lee, 2008; Saad and Saberi, 2017). This complex process utilizes natural language processing, text analysis, and statistical methods to evaluate human emotions and classify them.

Sentiment analysis has been applied across numerous social, economic, and political domains of discourse, as opinions and perspectives are fundamental to nearly all human activities. It serves as a crucial component for comprehensive investigations in real-world applications, such as forecasting stock market trends (Khan et al., 2022), monitoring mental health conditions (Benrouba and Boudour,

2023), polarity analysis of tweets about COVID-19 (Yin et al., 2022). These insights offer a panoramic view of the populace across diverse social and economic sectors, enabling relevant organizations to implement reforms accordingly.

Since 2000, various techniques have been adopted to perform sentiment analysis (Liu, 2010). In Yin et al. (2022), sentiment analysis is performed on tweets about COVID-19 vaccination, and popular topics are mined from positive and negative tweets. Wicke and Bolognesi (2021) also conducted sentiment analysis in online COVID-19 tweets and found that the (possible) negative emotions appearing in tweets gradually increased with the development of the epidemic and the increase in daily cases.

2.2 Metaphor analysis of Covid-19 discourse

The news text itself is a rich and diverse source of metaphorical analysis (Steen et al., 2010; Krennmayr, 2011). Extensive research has been conducted to explore the persuasiveness of metaphors the and underlying ideologies conveyed in news discourse covering various topics (Krennmayr, 2011). Since the outbreak of the global coronavirus crisis, media and politicians have mostly resorted to WAR metaphors to describe the impact of the virus and how people cope with it (Amaireh, 2022; Fu, 2024; Lakoff, 1993; Wicke and Bolognesi, 2021). According to Colak (2023) and Fu (2024), COVID-19 has been depicted as 'an animal' or 'a disaster' in the media coverage. These metaphors have had a negative impact on the objectivity of the COVID-19 pandemic (Fu, 2024; Colak, 2023). They found that almost all metaphorical frameworks for COVID-19 emphasized the uncertainty of the pandemic in a negative way, which could have a significant impact on the public's psychology, leading to pessimistic attitudes (Colak, 2023).

DISASTER and WAR are common metaphors for COVID-19 in both Chinese and English news contexts (Xu, 2023), and this similarity shows that the public has similar understandings and values in the face of the COVID-19 epidemic. However, certain metaphors, such as ZOMBIE are common in English culture but not common in Chinese culture. The difference could be caused by various factors, including distinct ways of cognition and understanding among people with different cultural and historical backgrounds. The same metaphorical framework, such as WAR and DISASTER, can be used to express different or even completely opposite views on COVID-19 due to different political stances (Chen et al., 2022; Liu, 2023; Liu and Tay, 2023). Furthermore, Roberts and Bolognesi (2024) demonstrates that WAR metaphor has a negative impact on the emotional state of the citizens and may prompt people to propose stricter epidemic prevention measures to reduce the virus, compared with JOURNEY metaphor. Political orientation of the speakers also influence people's reasoning about the pandemic, e.g., the right-wing participants are more susceptible to COVID-19 WAR metaphors and will take relevant steps to counter this pandemic war (Panzeri et al., 2021).

While most of the news is about the impact of COVID-19 on public health, the economic and social impact of COVID-19 is also huge. For instance, economic metaphors such as MACHINE and EQUIPMENT are 'breaking down' and 'declining' (Busso and Tordini, 2022). Metaphor can influence the public's attitude toward vaccines to some extent (Flusberg et al., 2024). Confronting with the COVID-19 pandemic could be considered as WARS, HUNTING, GAMES, and GAMBLING (Pedrini, 2021; Khaliq et al., 2021; Kozlova, 2021). According to Pedrini (2021), vaccines could be described as ANTIDOTES, FIREWALLS, or MIRACLES, or as RAINCOATS, CASTLES, SEATBELTS, and BANKS (Flusberg et al., 2024). Vaccines have been conceptualized as an UMBRELLA in the rain, a MESSENGER, a TAPE RECORDER, and an EXTRA SECURITY, showing a gradual cognitive changes in perceiving this concept among the public (Guliashvili, 2024).

2.3 Advancements beyond previous work

Previous studies have extensively analyzed metaphors before 2023, primarily emphasizing the diachronic changes in metaphorical framing of the pandemic during the beginning and middle phases of the pandemics. To conduct a more comprehensive analysis of the pandemic discourse, the data used in this study covers the whole process from the beginning of the pandemic to the post-pandemic (2019 to 2024). In addition, although there are research focusing on the pandemic metaphors or the emotional attitudes of the public, the relationship between metaphorically related vocabulary and the emotional attitudes of news media and its diachronic changes haven't been explored. In this research, the connection between metaphorical vocabulary and sentiment analysis is the key aspect that will be explored. We aim to address the following research questions:

1) What are the diachronic changes in the senti-

ments of the news discourse covering COVID-19 in Hong Kong from 2019 to 2024?

2) What are the diachronic changes in the sentiments of the COVID-19 metaphorical frames of COVID-19 in Hong Kong news discourse from 2019 to 2024?

3) What is the interaction between the fluctuation of sentiment analysis and the fluctuation of metaphors in Hong Kong news discourse from 2019 to 2024?

3 Methodology

3.1 Data

This research focuses on news from the online newspaper - Hong Kong Free Press (HKFP) for the corpus building. Since the outbreak of COVID-19 in 2019 to the present, there has been much news about the epidemic on the Hong Kong Free Press website, offering sufficient data for analysis. The news articles about COVID-19 have been obtained using the web crawler method through Python (based on the Requests library) by searching the keywords 'COVID-19,' 'vaccine,' 'pandemic,' and 'virus' on the website https://hongkongfp.com/. A total of 2,541 news about COVID-19, covering the time span of December 31, 2019, to August 16, 2024, were obtained. The total word count of the corpus is 1,749,884. After data collection, all initial data is preliminarily cleaned, filtered, and named in sequence by date.

3.2 Sentiment Analysis

This study adopted a sentiment analysis method based on natural language processing to systematically preprocess and analyze text data. We first explored the relationship between sentiment polarity and subjectivity in text content and examined the distribution characteristics of the two with samples. To this end, the study designed a series of data processing and visualization steps to ensure the reliability and interpretability of the analysis results.

First, we used Python's NLP toolkit, including nltk and TextBlob, to preprocess the text data. Through a custom function, we batch-read all text files from a specified folder and stored the contents in a Pandas data frame. The text preprocessing process includes removing special characters and numbers, unifying text to lowercase, word segmentation, removing stop words (such as 'the,' 'and,' 'is,' etc.), and restoring the word form. This process aims to clean up the original text data to make it more suitable for subsequent sentiment analysis.

After the text preprocessing is completed, we use the TextBlob library to perform sentiment analysis. TextBlob provides sentiment analysis functions based on sentiment polarity and subjectivity, where sentiment polarity indicates the intensity of the positive or negative sentiment of the text, ranging from -1 (extremely negative) to 1 (extremely positive), while subjectivity indicates the degree of subjectivity of the text content, ranging from 0 (completely objective) to 1 (completely subjective). We analyzed the preprocessed text content, extracted each text's sentiment polarity and subjectivity scores, and saved the results into a CSV file for further analysis.

In order to more intuitively display the results of sentiment analysis, we used matplotlib and seaborn libraries to create a series of visualization charts. First, we drew a scatter plot to show the relationship between sentiment polarity and subjectivity (Figure 1). This chart provides the distribution of each text in these two dimensions, helping us to initially understand whether there is a specific correlation between sentiment and subjectivity. Secondly, we also drew histograms of sentiment polarity and subjectivity, which show the distribution of the two variables in the sample, including the central tendency and dispersion of the data. These visualization results provide a basis for subsequent statistical analysis.

Third-order polynomial regression formula is used for the regression analysis. After calculating the emotional score, we determined the most appropriate function to describe the emotional changes that occur in tweets over time. For this, we first use polynomial regression ($f(x) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_N x_N + \varepsilon$, where ε is the unobserved random error). Specifically, we performed a regular least squares regression to increase the polynomial degree until we explained most of the data variance with significant confidence. It is worth noting that higher polynomials provide better fitting, but they cannot serve our survey to determine a simple trend and can overfit our data.

3.3 Metaphor analysis

Following the Metaphor Pattern Analysis approach (Stefanowitsch, 2006), keywords associated with the source domain of WAR were searched in the corpus using Python libraries (Pandas and Matplotlib). We included lemmas under the keywords of 'protec-

tion,' 'fight,' 'strategy,' 'combat', and 'victory' into the group of positive WAR keywords, and lemmas under the keywords of 'war,' 'threat,' 'violence,' 'struggle', and 'attack' into the group of negative WAR keywords.

4 Results and Discussion

4.1 Sentiment analysis

To address the first research question, we first analyzed the relationship between emotional polarity and subjectivity. Figure 1 shows the distribution of a large number of text data points, with the horizontal axis representing emotional polarity and the vertical axis representing subjectivity.

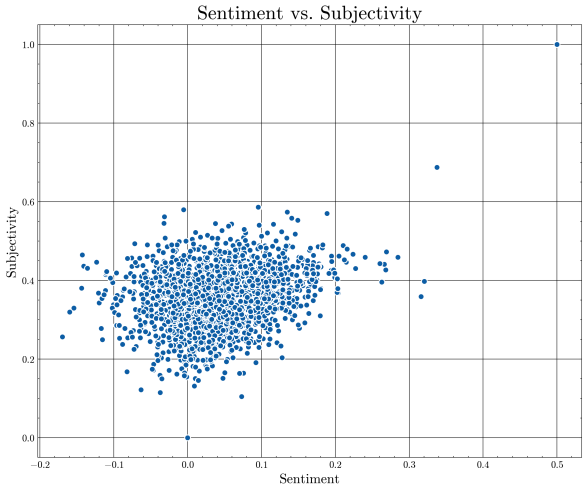

Figure 1: Sentiment analysis

From the overall distribution in Figure 1, most of the data points are concentrated in the range of polarity from -0.2 to 0.4, and the value of subjectivity is roughly between 0.2 and 0.5. This distribution indicates that the vast majority of texts have neutral or slightly positive emotional tendencies, while the subjectivity of these texts exhibits moderate to low characteristics.

We also observe that although there are some data points that deviate from the main population, no extreme negative emotions (i.e., polarity values far less than 0) or extreme subjectivity (i.e., subjectivity values close to 1) has been observed. This further illustrates the mildness of emotions and the limitations of subjective expression in the sample text. The emotional polarity of the text did not show significant positive or negative differentiation, and the subjectivity did not show excessive bias, reflecting the cautious and moderate expression of personal emotions in the analyzed text content. It is worth noting that although there is a certain correlation between emotional polarity and subjectivity, this relationship is not very strong. This phenomenon may indicate that the subjective expression of text is not always accompanied by strong emotional tendencies, but rather revolves more around neutral or mild emotional expressions. This observation is of great significance for further understanding the complexity of emotional expression in texts, especially when analyzing texts such as news articles or objective descriptions.

Overall, this scatter plot provides us with preliminary insights into the distribution of textual emotions and subjectivity, emphasizing the neutral tendency of textual emotions and their relatively low subjective expression. In the subsequent analysis, it is possible to further explore how the emotions and subjectivity of these texts change in different contexts, in order to obtain a more comprehensive understanding.

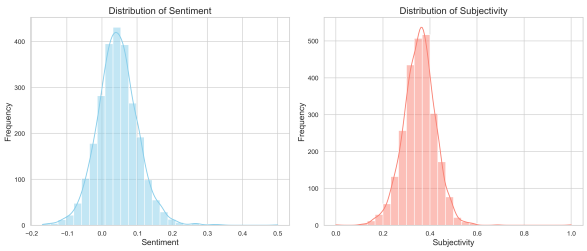

Figure 2: Distribution of sentiment polarity and subjectivity

Figure 2 reveals the distribution of sentiment polarity and subjectivity, which provides important insights. Firstly, the sentiment polarity histogram on the left reveals that the distribution of data roughly follows a normal distribution pattern. The majority of the text's polarity values are concentrated around 0, slightly biased towards the positive side. This indicates that emotional expressions in the analyzed text samples tend to be neutral or slightly positive, while the number of texts with negative emotions is relatively small. This distribution may reflect the balance and neutrality of the text content, possibly due to the emphasis on objectivity in writing and avoiding strong emotional tendencies.

The subjective distribution map on the right also shows a shape close to normal distribution, but its peak is slightly shifted to the right, concentrated between 0.3 and 0.4. This means that the subjectivity of most texts is in a moderately low range, indicating that these texts are more based on facts, and although there is a certain degree of subjective

expression, overall, they still maintain relative objectivity. It is worth noting that the number of texts with extreme subjectivity or extreme objectivity is relatively small, further indicating the moderate expression of subjectivity in the content of the text.

Comparing the two distribution maps, the analyzed text exhibits a tendency that most texts are emotionally mild and biased towards neutrality while also being moderately subjective in expression. This feature may be related to the type of text, especially if these texts are essentially objective content such as news reports or academic articles. Thus, the gentleness of emotions and the objectivity of expression complement each other, making the overall text present a stable and impartial style.

Overall, these distribution maps provide important information about text emotions and expression styles, indicating that balance and neutrality are dominant features in these texts. In further research, it can be explored whether these features are consistent across different categories of text or whether there are significant changes in sentiment polarity and subjectivity in certain contexts.

Figure 3 is an analysis of the daily sentiment scores from December 2019 to August 2024, aggregated and averaged by month. It illustrates that sentiment tends to be positive most of the time, initially decreasing until reaching its lowest point in June 2021 and then gradually increasing and leveling off.

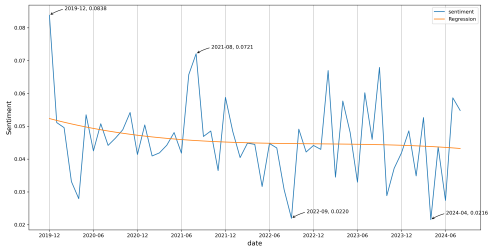

Figure 3: Sentiment fluctuation chart from 2019 to 2024

The overall sentiment polarity over five years emerging from the news corpus is slightly positive (>0). The polynomial regression indicates that the average sentiment reaches the most positive in the first two months of the pandemic (from December 2019 to February 2020), while it decreases to the lowest during the period March 2020 to March 2023. It is then increasingly positive from April 2023 to August 2024. According to Figure 3, the curve from December 2019 to August 2024 reveals the emotional fluctuations in the pandemic. The highest value is 0.0838, and the date is December 2019. The lowest value is -0.0220, and the date is September 2020.

On July 10, 2023, the booking volume of Hong Kong's tourist tickets exceeded expectations by giving away free tickets, and the tourism of Hong Kong was revitalized and promoted again after the pandemic. Meanwhile, to boost the city's morale and economy, the government has launched an HK $20 million "Happy Hong Kong" campaign. These measures by the Hong Kong authorities demonstrate that they are determined to revive the economy and thus also show optimism and positive feelings. For example:

(1) Airline HK Express will launch its free flight giveaway at 10. 30am on Tuesday, with round-trip tickets to destinations in Japan, South Korea, Thailand, Vietnam, and Taiwan on offer - the latest phase of a campaign aimed at rebooting tourism after years of Covid travel restrictions. Open to people living in Hong Kong, HK Express's campaign is giving away 21,626 complimentary tickets to 19 Asian destinations from July 11 to July 24 on a first come, first served basis. (July 10, 2023, Hong Kong Free Press)

The second highest value is 0.0721, and the date is June 2023. On June 14, 2023, Hong Kong authorities planned to introduce 20,000 workers to deal with a labor shortage in the wake of the pandemic. This reveals that Hong Kong's economy is generally recovering and improving to some extent. For instance:

(2) Hong Kong is set to import around 20,000 workers in a bid to alleviate the labour crunch in the construction, transport and aviation sectors, the government has announced.....The low-skilled labour force fell by around 160,000 people, Secretary for Labour and Welfare Chris Sun said. "Therefore, after the return to normalcy, many industries in Hong Kong are facing the challenge of labour shortages," he said. (June 14, 2023, Hong Kong Free Press)

The lowest value is -0.0220, and the date is September 2020. On September 24, 2020, due to the coronavirus, the number of infections and deaths in many countries rose, such as Brazil. Meanwhile, almost every government and agency invested a lot of funding and resources in developing an effective vaccine (see example 3).

(3) Clinical trials of the CoronaVac coronavirus vaccine developed by Chinese laboratory Sinovac

have "reached the efficacy threshold" demanded by the World Health Organization, the Brazilian institute charged with its production and distribution said on Wednesday. However, the Butantan Institute didn't publish the results of those trials — the last before authorization. ..... Immunization has been a highly politicized issue in Brazil, where far-right President Jair Bolsonaro has repeatedly said he won't take a vaccine while he's also tried to discredit the CoronaVac jab. Brazil has suffered the second-largest number of coronavirus deaths in the world after the US with 188,000 dead. (December 24, 2020, Hong Kong Free Press)

The second lowest value is -0.0216, on the date of April 21, 2022. Here is an example. The number of cases in Hong Kong is increasing almost every day, which has affected people's lives and work. For example:

(4) Hong Kong's John Lee has tested positive for Covid-19 after returning from the Asia Pacific Economic Cooperation summit in Thailand. He is now undergoing quarantine, the government announced early Monday morning. He returned to the city from a four-day trip to Bangkok on Sunday night and underwent a polymerase chain reaction test at the airport upon his arrival. The test came back positive, the Chief Executive's Office announced on Monday. (November 21, 2022, Hong Kong Free Press)

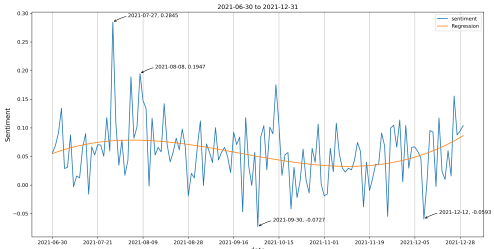

Figure 4: Sentiment fluctuation from June 2021 to December 2021

In Figure 4, the lowest value is -0.0727, and the date is September 30, 2021. Due to the pandemic, the number of delivery personnel is rapidly increasing, which has triggered attention to the plight of this group (see example 5):

(5) The coronavirus pandemic and resulting lockdowns sent demand for meal delivery services soaring: the sector is now worth 664 billion yuan ($100 billion), according to a report from the China Hospitality Association. The nation's competitive app-based services have expanded into nearly every aspect of modern life, with digital-savvy consumers used to instantaneous service and fast delivery due to a ready flow of cheap labour. But after years of unrestricted growth, China's Big Tech is coming under fire from Beijing, with Tencent, Didi, and Meituan all targeted over anti-monopoly rules. Earlier this year, Alibaba was fined a record $2. 8 billion after an investigation found it had abused its dominant market position. (November 14, 2021, Hong Kong Free Press)

The second lowest value is -0.0593, and the date is December 12, 2021. Strict quarantine measures and closed-loop management during the Beijing Winter Olympics prevented the spread of the epidemic, which is bound to have a negative impact on the economic benefits of the Games. For example:

(6) Next year's Winter Olympics in Beijing will be held without spectators from overseas, with tickets restricted to fans living in China because of the Covid-19 pandemic, the International Olympic Committee said Wednesday. The IOC said only fully vaccinated participants would be exempt from a 21-day quarantine. Athletes who can provide a "justified medical exemption" will have their cases considered. All attendees will enter a strict bubble upon arrival that covers Games-related areas and stadiums as well as accommodation, catering, and the opening and closing ceremonies. (September 30, 2021, Hong Kong Free Press)

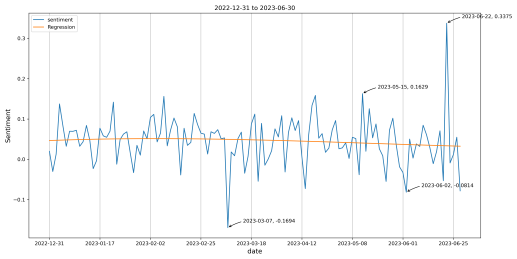

Figure 5: Sentiment fluctuation from December 2022 to June 2023

In Figure 5, the highest value is 0.3375 on the date of June 22, 2023. The public began to celebrate the Loong Boat Festival after three years of interruption. For example:

(7) Around 1,600 people signed up to race during Hong Kong's Dragon Boat Festival - or Tuen Ng Festival - on Thursday. Crowds gathered in Stanley to watch over 56 teams brave the heat, after a three-year hiatus due to the Covid-19 pandemic.

(June 22, 2023, Hong Kong Free Press)

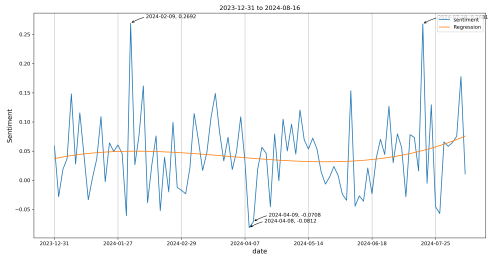

Figure 6: Sentiment fluctuation from December 2023 to August 2024

The Figure 6 shows sentiment change in the pandemic from December 2023 to August 2024. Positive attitudes are obvious in the period. The epidemic prevention measures of various pavilions have disappeared, and whether wearing a mask is necessary has become the focus of discussion (see example 8).

(8) This is a question that keeps cropping up in Hong Kong, which is currently one of the last places in the world where universal mask-wearing in all public settings is compulsory. Universal masking has been one of the most recognisable features of public life in Hong Kong in the last three years. Most other local Covid control measures have been dropped, which makes the mask mandate stand out even more. So, it is natural to wonder: how much longer do we need to wear our masks? This seemingly simple question is actually asking two different things: a) Are masks helping Hong Kong's public health at this stage of the pandemic? b) Do masks need to be mandatory? People debating this issue often conflate these two questions, but this is not appropriate. For example, proper mask-wearing can be useful (even essential) in certain situations, but that does not automatically make mask mandates necessary. (February 27, 2023, Hong Kong Free Press)

By the end of the pandemic, the economic situation improved, and stocks rose. Although not as good as before the pandemic, various signs indicate that various industries in society are gradually recovering. For example:

(9)....He became HSBC's permanent CEO in March 2020, when the bank's shares in Hong Kong tanked sharply at the beginning of the Covid-19 pandemic. The firm's share price has risen more than 40 percent since then but has yet to reach its pre-pandemic peaks..... (April 30, 2024 Hong Kong Free Press)

The second highest value is 0.00756, and the date is August 10, 2024. In the post-pandemic era, young people are increasingly concerned about their physical health, and health products and supplements have gained their favor. This is also one of the subsequent impacts brought about by the pandemic. For instance:

(10) Popping supplements, drinking herbal teas, and signing up for lifestyle classes, China's youth are turning to the wellness industry as work stress and pandemic memories spur a growing interest in health. These new habits are part of a global wellness boom. However, the traditional concept of "yangsheng" — literally meaning "cultivating one's life force" — has given the trend a unique cultural twist in China. In Shanghai, Annie Huang sat in a trendy cafe-like establishment that sold traditional herbal teas, sipping a bitter concoction purported to protect the body against the summer heat. (August 10, 2024 Hong Kong Free Press)

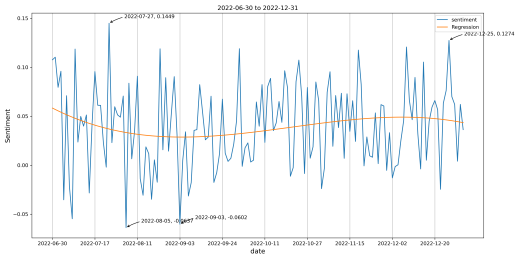

Figure 7: Sentiment fluctuation chart from June 2022 to December 2022

The Figure 7 above depicts the distribution of emotions from June 30 2020 to December 31 2022. The highest value above is 0.0682, and the date is November 8, 2022. On this day, Hong Kong's premier music festival, Clockenflap, would return to the Central harbourfront this March after a three-year hiatus because of the pandemic. A whole festival experience, with multiple outdoor stages and F&B outlets, is in the works, alongside a diverse line-up of international, regional, and local acts. The citizens of Hong Kong eagerly anticipated the revival of this long-awaited music festival. For instance:

(11) Hong Kong's premier music festival, Clockenflap, is to return next March to Central Harbourfront after a three-year hiatus. Organisers say it is "100 percent confirmed" for Friday March 3 until Sunday March 5, 2023. A full festival ex-

perience, with multiple outdoor stages and F&B outlets, is in the works, alongside a diverse line-up of international, regional, and local acts. The 12th edition of Clockenflap comes after it was cancelled in 2020 and 2021 owing to the Covid-19 pandemic and was axed in 2019 due to the pro-democracy protests and unrest. (November 8, 2022, Hong Kong Free Press)

4.2 Metaphor analysis

To answer the second research question regarding the diachronic changes in the sentiments of the COVID-19 metaphorical frames over time, we modeled the changes in the occurrence of the keywords associated with the source domain of WAR in the corpus using Python libraries (Pandas and Matplotlib). We included lemmas under the keywords of 'protection,' 'fight,' 'strategy,' 'combat', and 'victory' into the group of positive WAR keywords, and lemmas under the keywords of 'war,' 'threat,' 'violence,' 'struggle', and 'attack' into the group of negative WAR keywords. Figure 8 lists all the lemmas of the four keywords searched for WAR.

WAR Keywords	**Lemmas of WAR Keywords**					
PROTECTION	*protect*	*protects*	*protected*	*protecting*	*protection*	*protections*
FIGHT	*fight*	*fights*	*fought*			
STRATEGY	*strategy*	*strategies*				
COMBAT	*combat*	*combats*	*combating*			
VICTORY	*victory*	*victories*				
WAR	*war*	*wars*				
THREAT	*threat*	*threats*	*threaten*	*threatens*	*threatened*	*threatening*
VIOLENCE	*violence*	*violent*				
STRUGGLE	*struggle*	*struggles*	*struggling*	*struggled*		
ATTACK	*attack*	*attacked*	*attacking*			

Figure 8: List of lemmas searched for the words associated with WAR metaphors

Figure 9 shows the standardized number of positive and negative WAR keywords per 10,000 words during the time period between 2019 to 2024.

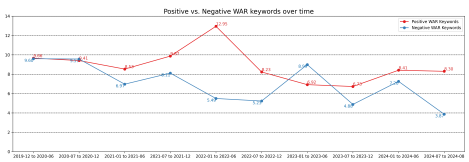

Figure 9: Standardized number of positive and negative WAR keywords (per 10,000 words) over time

From January 2021 to June 2022, there is a peak period of positive WAR keywords in the chart. This period is also the most positive stage for words associated with metaphors. During this time, the frequent use of positive words related to WAR metaphors, such as "protect" and "strategy," in news articles aims to boost the public's confidence in winning the fight against COVID-19 and overcoming the fear of the virus. For example:

(12) Chief Executive Carrie Lam has confirmed that the next phase of Hong Kong's COVID-19 Vaccine Pass will go ahead as scheduled on May 31, despite experts urging the government to relax the requirement for those under 60. In response, Lam said that although vaccination could not prevent COVID-19 infections, it remained the most effective way to protect against serious illness and ensure that public hospitals would not be overburdened. Lam also said that only around half of those eligible had received a third dose. "Therefore, it remains necessary to provide more motivation and incentive, in the hope that those who have not got the third jab will... get vaccinated," she added. (May 17, 2022 Hong Kong Free Press)

The example reveals positive words associated with war metaphor have been adopted in news to improve the confidence of the citizens for the 'WAR' with the virus.

From January 2023 to December 2023 is the peak period of negative words in the table. Negative words contain STRUGGLE, THREAT, WAR, and so on. In other words, it is also the most negative stage for words related to metaphors. For instance:

(13) Through my research and solidarity work with the Asian Migrants Coordinating Body (AMCB) and other migrant-led organisations during the pandemic, I saw how their members and leaders struggled. They lost parents and siblings to the virus, could not manage to send home enough money to cope with inflation, had their contracts terminated when their employers had financial trouble or left Hong Kong, and went for years without visiting their own young children due to travel restrictions, and faced increased demands in their work due to school closures and work from home policies. (May 21, 2023 Hong Kong Free Press)

5 Discussion and Conclusion

In summary, the study attempts to comprehensively investigate the diachronic changes in the sentiments

and metaphorical frames in the news discourse covering the entire cycle of the COVID-19 pandemic from 2019 to 2024. The overall emotional polarity of the corpus was slightly positive and overall objective. Polynomial regression reveals that the average mood becomes increasingly positive from 2021 to 2024, while it drops softly from 2019 to 2021 during which the general attitude of the news tended to be slightly negative and pessimistic. During the period of 2019 to 2021, many countries were under lockdown, and authorities typically implemented strict quarantine measures. At the same time, there were new deaths and infections every month, making the public fearful of the unknown. However, proactive protective measures and the promotion of vaccines have also given people confidence and hope so that the emotional inclination is slightly pessimistic. In the period of 2023 to 2024, with the gradual reduction of infections and deaths, large-scale public events such as music festivals have resumed, and most citizens have been vaccinated in an orderly manner. News attitudes toward the pandemic have gradually become optimistic. Applying sentiment analysis in corpus-based discourse analysis thus can reflects the fluctuations in the emotional tendencies of news media writers towards specific societal issues. The overall fluctuation is small, and the objectivity of the new is strong. These findings reveal the changes in the attitude and emotions of the media and to some extent, the public toward the progressing of the pandemic.

Furthermore, this study contributes to the limited body of research examining the changes in the sentiments associated with metaphors by categorizing metaphorical keywords into positive and negative polarities. It explores the interaction between the sentiments of metaphors and the emotional attitudes of news media, providing an operational approach for analyzing the relationship between metaphor polarities and the sentiments expressed in large-scale of discourse data.

Enhancing ColBERT: A Method for Reducing Space Complexity and Accelerating Retrieval Speed

Hai Nguyen T. and **Huong Le T.** *

Hanoi University of Science and Technology, Hanoi, Vietnam
trunghainguyenhp02@gmail.com and huonglt@soict.hust.edu.vn

Abstract

Recent advancements in neural information retrieval systems have focused on optimizing efficiency and effectiveness using BERT-based models for semantic encoding. The ColBERT model's late-interaction mechanism, while effective, leads to larger indexes and slower retrieval speeds compared to single-vector approaches. This study introduces a pruning method for ColBERT vector embeddings, utilizing a small network to assign weights to essential tokens for scoring and eliminating less significant ones with a threshold. Our method significantly reduces space requirements and enhances retrieval speed, with a minimal decrease in performance, as demonstrated using a Vietnamese Wikipedia-based dataset.

1 Introduction

Information retrieval (IR) has been a significant area of research within Natural Language Processing (NLP) for a long time. Traditional IR methods, such as sparse retrievers (e.g., BM25), are now being outperformed by dense neural retrievers that use deep learning models to calculate similarity scores between queries and documents. Recent advancements in pre-trained language models (PLMs) based on the Transformer architecture (Vaswani et al., 2017) have significantly improved neural IR techniques, boosting performance across various benchmarks.

Neural IR paradigms mainly differ in their scoring mechanisms. Cross-Encoder architectures leverage self-attention across all tokens in a query-passage pair to generate similarity scores, yielding superior ranking performance with fine-grained, contextualized embeddings. In contrast, Single-Vector Bi-Encoders create single-vector representations for each query and document by employing pooling mechanisms, with similarity assessed using metrics like cosine similarity. These models, trained with contrastive learning and sophisticated pre-training procedures, effectively capture semantic nuances and offer high performance and efficiency, enabling rapid retrieval via pre-indexing and efficient nearest neighbor search.

However, both Cross-Encoders and Single-Vector Bi-Encoders have their limitations. Cross-Encoders are not scalable for real-world applications because they require processing both the query and the document through a large language model for every pair, preventing search time reduction through precomputation. Single-Vector Bi-Encoders, while allowing faster searches, often provide lower ranking effectiveness and struggle to encapsulate the semantics of entire documents for some datasets (Sciavolino et al., 2021).

To balance efficiency with contextual depth in IR, the ColBERT model (Khattab and Zaharia, 2020) employs token embeddings from PLMs and a late interaction technique to calculate query-document similarity scores. ColBERT uses multiple embeddings per document, capturing complex semantic relationships and outperforming most Single-Vector Bi-Encoder and some Cross-Encoder models. However, this comes at the cost of increased computation and storage requirements, potentially exceeding RAM capacities and affecting retrieval speed on limited hardware.

This research introduces a novel token pruning method for ColBERT to reduce the number of vectors stored by ColBERT with minimal performance trade-offs. We propose directly learning the importance of tokens in documents via a neural network layer during training and use this layer to assign weights to tokens based on their relevance, keeping only the important ones (tokens with high weights) when indexing. This approach effectively preserves document keywords, significantly reducing storage requirements and improving retrieval speed.

In summary, our contributions include:

* Corresponding author: huonglt@soict.hust.edu.vn

1. We introduce a novel token pruning method for ColBERT that achieves a balance between efficiency and effectiveness, enabling flexible adjustment of the pruning threshold.

2. We propose an effective training approach for the weight-assigning neural network, utilizing distillation from a well-trained model and supervision from token classification tasks such as NER and POS.

3. Our method is evaluated on a Vietnamese Wikipedia-based dataset, and we compare it with other research aimed at improving the efficiency of ColBERT.

2 Background & Related Works

2.1 Neural Information Retrieval

As data grows, traditional match-based search methods are becoming less effective, prompting a shift toward semantic search. The Transformer architecture (Vaswani et al., 2017) and advanced language models (Devlin et al., 2019; Liu et al., 2019) have established neural retrieval as the dominant approach, leading to the development of numerous models (Karpukhin et al., 2020; Nogueira and Cho, 2020; Formal et al., 2021).

Among these neural models, deep interaction-based models known as cross-encoders (Nogueira and Cho, 2020; Dai and Callan, 2019; Phan and Le, 2023) achieve high retrieval effectiveness but at the expense of speed. Despite efforts to reduce their latency (MacAvaney et al., 2020; Gao et al., 2020), these models remain impractical for real-world applications and are typically reserved for re-ranking after initial retrieval.

In contrast, representation-based models, such as Single-Vector Bi-Encoders (Karpukhin et al., 2020), leverage deep language models to produce single embedding vectors representing documents or queries. These embeddings retain the content and context of the entire input text. Similarity is then computed using simple metrics such as cosine similarity, with retrieval performed by selecting the top results via nearest neighbor search. This approach is widely favored, and many studies have proposed various training methods to create robust embeddings that yield accurate retrieval results (Qu et al., 2021; Xiao et al., 2022; Nguyen and Le, 2023).

2.2 Multi-Vector Bi-Encoder

In addition to learning a single representation, several studies have proposed using multiple representations for queries and documents, coupled with simple interaction mechanisms to compute similarity scores. This approach mitigates the limitations of single-vector representations in terms of accuracy and interpretability.

The Poly-encoder model (Humeau et al., 2019) encodes queries into a set of vectors, and the ME-BERT model (Luan et al., 2021) does the same for documents. Notably, ColBERT (Khattab and Zaharia, 2020) encodes both queries and documents into multiple vectors and employs the MaxSim late interaction mechanism for similarity computation. COIL (Gao et al., 2021), developed concurrently with ColBERT, adopts a similar idea but incorporates hard matching for faster search.

While these models are highly effective, they have higher computational complexity than Single-Vector Bi-Encoders, higher retrieval latency, and require storing numerous vectors. Subsequent studies have focused on improving these aspects by reducing latency and index size through advanced search procedures (Santhanam et al., 2022a), quantization (Santhanam et al., 2022b), and more robust training methods (Santhanam et al., 2022b).

2.3 Pruning for ColBERT

Pruning directly addresses the storage and computational costs of ColBERT by retaining embeddings only for the most important tokens. Recent research on token pruning (Liu et al., 2024; Lassance et al., 2021; Lassance, 2022) proposed heuristics for selecting tokens to retain, such as:

- The first few tokens in a document.
- Tokens with the highest IDF scores.
- Tokens with the highest attention scores.

These heuristics, applied during training or as a post-processing step, have shown effectiveness but are not optimal, often significantly reducing retrieval accuracy.

The ColBERTer model (Hofstätter, 2022) further proposes reducing the number of vectors by using whole-word embeddings and a ReLU gate to filter tokens. Although this method can identify important tokens, it faces challenges in achieving training convergence and lacks flexibility in adjusting the pruning level.

Our research directly learns from data to identify important tokens, aiming to achieve high accuracy while using soft weights for tokens to enable flexible pruning during retrieval.

3 Methodology

In this paper, our primary objective is to minimize the space requirements and enhance the retrieval speed of the ColBERT model. To contextualize our contributions, we begin with a comprehensive overview of the ColBERT model, followed by the introduction of our proposed ColBERT-Kw model, which uses a small network to assign weights to each document token, facilitating effective token pruning based on importance. Since ColBERT-Kw exhibits training difficulties with conventional supervised contrastive learning, we propose a knowledge distillation procedure to improve convergence.

3.1 ColBERT Modelling

ColBERT is a Multi-Vector Bi-Encoder model that uses a pre-trained Language Model (PLM), such as BERT, to independently encode queries and documents into high-dimensional vector embeddings. In this model, a query encoder and a document encoder transform a query Q and a document D into sequences of fixed-size embeddings. The key innovation in ColBERT is its late interaction mechanism, MaxSim, which calculates the maximum similarity for each query token embedding against all document token embeddings. The overall similarity between Q and D is then defined as:

$$s(Q, D) = \sum_{i \in E_Q} \underbrace{\max_{j \in E_D} E_Q[i] \cdot E_D[j]^\intercal}_{\text{MaxSim}} \quad (1)$$

where E_Q and E_D are the sequences of contextualized vector embeddings from Q and D. $E_Q[i]$ and $E_D[j]$ are the vector embeddings of token i in E_Q and token j in E_D, respectively. The intuition behind this mechanism is to align each query token with the most contextually relevant passage token, quantifying these matches and combining the partial scores across the query.

During offline indexing, all vector embeddings for the corpus are precomputed and stored. For retrieval, ColBERT first calculates the query vector embeddings, then performs a nearest neighbor search for all query vectors. Documents with vectors appearing in the top neighbors are then fully scored using MaxSim.

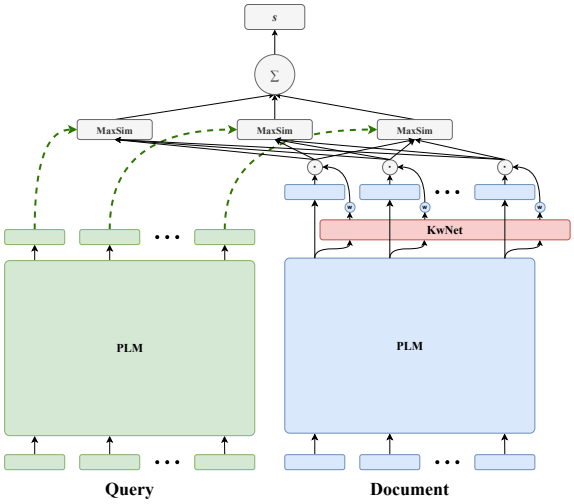

Figure 1: ColBERT-Kw

In this study, we utilize the ColBERT model with a few modifications:

- Normalizing the ColBERT score by dividing it by the query length (number of tokens). This normalization does not affect document ranking but improves model convergence during training:

$$s(Q, D) = \frac{1}{l} \sum_{i \in E_Q} \max_{j \in E_D} E_Q[i] \cdot E_D[j]^\intercal \quad (2)$$

  in which l is the query length.

- Omitting token clipping and augmentation with [MASK] tokens as in the original paper, as they lead to information loss and slight, hard-to-interpret improvements (Giacalone et al., 2024), respectively.

3.2 ColBERT-Kw

We propose the ColBERT-Kw model, where "Kw" denotes "Keyword". This model retains the core components of the standard ColBERT model and introduces an additional network layer named KwNet. KwNet processes contextually enriched token representations from a document, generated by the PLM, and assigns weights to these tokens. The architecture of ColBERT-Kw is illustrated in Figure 1. We implemented KwNet as a

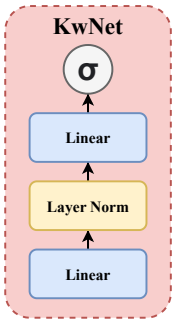

Figure 2: KwNet

simple Multi-Layer Perceptron (MLP), as depicted in Figure 2, though its architecture can be made more complex as needed. The importance of a token, represented as token weights, is computed as follows:

$$w_D = \text{KwNet}\left(\text{PLM}\left([\text{D}]d_1 d_2 \dots d_n\right)\right) \quad (3)$$

where $d_1 d_2 \dots d_n$ represents the token sequence of the document D, and [D] is a special token prepended to the documents as in the original ColBERT model. Instead of using ReLU, we normalize the weight of tokens by using Sigmoid as the final activation in KwNet. This provides more control over the pruning level by allowing a threshold to be set during the indexing phase. While other options such as $\tanh$ or $\arctan$ exist, Sigmoid was chosen for its favorable gradient behavior, making it easier to train.

In the ColBERT-Kw model, the similarity computation differs between training and retrieval. During training, without a predetermined token pruning threshold, the similarity between a query Q and a document D is calculated as follows:

$$sim(Q, D) = \frac{1}{l} \sum_{i \in E_Q} \max_{j \in E_D} w_D[j] \cdot E_Q[i] \cdot E_D[j]^\intercal \quad (4)$$

During retrieval, ColBERT-Kw allows us to choose a pruning threshold through a hyperparameter τ, leading to the following similarity calculation:

$$sim(Q, D) = \frac{1}{l} \sum_{i \in E_Q} \max_{j \in E_D} [\![w_D[j] \geq \tau]\!] \cdot E_Q[i] \cdot E_D[j]^\intercal \quad (5)$$

where $[\![\cdot]\!]$ is the Iverson bracket, equal to 1 if the condition is true and 0 otherwise.

Only the vectors of tokens whose importance scores meet the threshold are retained in the database during indexing. This significantly reduces the number of embeddings, leading to substantially lower computational costs in both the candidate generation and re-ranking phases of ColBERT.

This approach provides flexibility in determining a pruning threshold without requiring retraining, and it allows for directly learning the importance of tokens during training instead of relying on heuristics.

3.3 Knowledge Distillation for KwNet

Training KwNet is challenging due to the absence of explicit labels to identify key tokens within a document. The authors of ColBERTer (Hofstätter, 2022) suggest using a ReLU layer to determine whether to retain or discard tokens by regularizing token weights, encouraging sparsity. Their loss function is formulated as follows:

$$\mathcal{L} = \mathcal{L}_{sim} + \lambda \mathcal{L}_{reg} \quad (6)$$

where $\mathcal{L}_{sim}$ is computed using conventional contrastive loss functions, and $\mathcal{L}_{reg}$ is a regularization term that forces the model to assign reasonable weights to tokens, retaining only the important ones. However, our experiments show that selecting an appropriate λ is difficult, making it hard for the model to converge to the desired state.

To address the absence of labels for important tokens, we propose a knowledge distillation approach for training KwNet. This strategy leverages the MaxSim mechanism of the ColBERT model, which inherently identifies the most important tokens in documents responding to queries. These tokens are treated as keywords for ColBERT-Kw, and we train KwNet to assign high scores to them. The loss function is now defined as:

$$\mathcal{L} = \mathcal{L}_{sim} + \alpha \mathcal{L}_{distill} + \lambda \mathcal{L}_{reg} \quad (7)$$

where α controls the weight of the distillation loss $\mathcal{L}_{distill}$ in the overall objective. $\mathcal{L}_{distill}$ for a query-document pair is calculated as:

$$\mathcal{L}_{distill}(Q, D) = \sqrt{\sum_{0 \leq j \leq n} [\![j \in S]\!] \cdot (1 - w_D[j])^2} \quad (8)$$

where S represents the set of tokens selected by MaxSim:

$$S = \left\{ \arg\max_{j \in E_D} E_Q[i] \cdot E_D[j] \right\}_{i=0}^{l} \quad (9)$$

Intuitively, minimizing $\mathcal{L}_{distill}$ equates to maximizing the weights of the tokens selected by the MaxSim mechanism of ColBERT. We also experimented with an L1 variant to evaluate its effect on KwNet's token weighting:

$$\mathcal{L}_{distill}(Q, D) = \sum_{0 \leq j \leq n} [\![j \in S]\!] \cdot |1 - w_D[j]| \quad (10)$$

Models trained using Equation 8 will be referred to as ColBERT-Kw, while those trained using Equation 10 will be referred to as ColBERT-Kw-L1. These formulations result in significantly different distributions of token weights, which will be elucidated in the upcoming experimental results section. The regularization component is straightforwardly calculated as:

$$\mathcal{L}_{reg}(D) = \frac{1}{n} \sum_{0 \leq j \leq n} w_D[j] \tag{11}$$

To prevent ColBERT-Kw from converging into a Single-Vector Bi-Encoder, we prohibit gradient backpropagation from the KwNet layer to the PLM of the document encoder. In this study, this is achieved by freezing the ColBERT component and updating only KwNet, utilizing pre-trained ColBERT parameters. Specifically, we first train an effective ColBERT model, then freeze its parameters, and subsequently train KwNet through knowledge distillation. This approach leverages the already optimized ColBERT model to facilitate more efficient learning within KwNet. By ensuring that the PLM remains unchanged, KwNet can focus on learning the importance of tokens while preserving the integrity of the pre-trained document encoder.

In scenarios where it is desirable to initialize and train ColBERT-Kw from scratch, we recommend using the stopgrad operator to prevent gradient backpropagation from KwNet. This approach calculates the token weights as follows:

$$w_D = \text{KwNet}\left(\text{sg}\left[\text{PLM}\left([\text{D}]d_1 d_2 \ldots d_n\right)\right]\right) \tag{12}$$

where $\text{sg}[\cdot]$ indicates that gradients are not propagated back through the enclosed expression.

Other components within the formula remain unchanged. When updating the weights of ColBERT-Kw, the gradient of $\mathcal{L}$, as defined in Equation 8, can be applied directly. Alternatively, the weights of KwNet can be updated based on this gradient, while the ColBERT component is updated using a contrastive loss function, with similarity computed by the standard ColBERT formula as in Equation 2.

3.4 Leverage Domain Knowledge by Auxiliary Task Labels

Besides the keywords generated by ColBERT-Kw, other heuristics can be applied to select a good keyword set, such as domain-specific heuristics that extend beyond traditional methods based on term rarity or general grammatical rules. This strategy, tailored specifically to each dataset, significantly boosts the method's adaptability and effectiveness. In this paper, we utilize Named Entity Recognition (NER) and Part-of-Speech (POS) tagging labels to supplement additional keywords from the input document. Nouns and entities are considered as important keywords of the document. All of these keywords are included in a designated set, S, detailed further in Section 3.3. We selected NER and POS for our research due to their relevance to entity-rich datasets. Moreover, there are numerous tools available today for part-of-speech tagging and named entity recognition that provide high accuracy.

4 Experiments

In this section, we describe experiments conducted with the ColBERT and our proposed ColBERT-Kw models on a Vietnamese information retrieval dataset derived from Wikipedia. We compare the effectiveness and efficiency of both models against established baselines. Additionally, we assess the pruning performance of ColBERT-Kw relative to traditional heuristic methods, particularly its ability to minimize index size while preserving the retrieval accuracy inherent to ColBERT.

4.1 Dataset and Evaluation Metric

We evaluate the ColBERT and ColBERT-Kw models on a Vietnamese information retrieval dataset derived from the 2019 Zalo AI Challenge's Vietnamese Question Answering task[1] comprising 15,957 text documents and 5,070 unique queries from Vietnamese Wikipedia. A total of 507 queries were randomly selected for testing, with the remaining queries used for training.

We assess the performance of the models based on the following criteria:

- **Retrieval Effectiveness:** Measured using metrics such as Recall@1, Recall@10, Recall@50, and MRR@10 (Mean Reciprocal Rank at 10).

- **Retrieval Speed or Latency:** The time required to process a query and retrieve relevant documents.

[1]This specific dataset version is available in an unofficial repository: https://github.com/namnv1113/Nanibot_ZaloAIChallenge2019_VietnameseWikiQA.

- **Index Size:** Determined by the number of embedding vectors and the overall size of the index structures.

4.2 Baseline

The baseline retrieval models selected for comparison include Okapi BM25, vietnamese-bi-encoder[2] (Nguyen et al., 2024), and vietnamese-bert[3]. Okapi BM25 is a variant of the well-established BM25 algorithm, chosen for its effective term matching-based retrieval capabilities, offering a balance of accuracy, low retrieval costs, and high speed. The vietnamese-bi-encoder model, trained on the Vietnamese mMARCO dataset (Bonifacio et al., 2021), is noted for its high accuracy in text information retrieval tasks. Similarly, vietnamese-sbert demonstrates robust performance in semantic similarity tasks.

4.3 Setup

For training ColBERT and ColBERT-Kw, we used PhoBERT-base-v2 (Nguyen and Nguyen, 2020), a state-of-the-art Vietnamese language model, as the backbone PLM. The training process was divided into two phases:

- First, we trained the ColBERT model using a contrastive learning approach. Positive samples were directly sourced from the dataset, while negative samples were randomly selected from the top BM25 results, excluding the positive samples. The online contrastive loss function [4] was employed.

- After training ColBERT, we initialized ColBERT-Kw with the trained model's parameters and randomly initialized KwNet. We then optimized KwNet's parameters using the loss function from Equation 7.

The models were trained using the Adam optimizer (Kingma and Ba, 2014), with each phase conducted over 24,000 steps with a batch size of 32 and a learning rate of 3e-6. The embeddings for ColBERT and ColBERT-Kw were projected to 128 dimensions. The hyperparameters chosen for KwNet training are $\lambda = 0.1$ and $\alpha = 0.4$.

[2]https://huggingface.co/bkai-foundation-models/vietnamese-bi-encoder

[3]https://huggingface.co/keepitreal/vietnamese-sbert

[4]https://sbert.net/docs/package_reference/sentence_transformer/losses.html

We evaluated ColBERT and ColBERT-Kw in a full-ranking setup similar to ColBERT's original framework. Additionally, we trained the COIL model for comparative purposes and tested the PLAID retrieval mechanism (Santhanam et al., 2022a) with ColBERT. For heuristic-based pruning, we used a method akin to previous work (Liu et al., 2024), reducing vector counts by 50% to ensure fair comparison with ColBERT-Kw.

Training and indexing were performed on a P100 GPU provided by Kaggle, and evaluation was done on a personal computer with an Intel i7-13700H CPU.

4.4 Result

Table 1 shows the retrieval effectiveness (accuracy) of the models compared in this study. We observe that while BM25 achieves moderate accuracy on this dataset, the two single-vector bi-encoder models, although trained on extensive data, do not significantly outperform BM25. In contrast, multi-vector bi-encoder models exhibit superior performance, particularly ColBERT, which utilizes the PhoBERT backbone, achieving the highest MRR@10 among the models tested. The COIL model also surpasses the baseline models but is constrained by its matching mechanism, unable to match ColBERT's retrieval outcomes. This underscores the effectiveness of interaction between the query and document embeddings in achieving superior retrieval results.

Simpler models typically have lower accuracy but provide faster retrieval speeds. BM25 provides the fastest retrieval, followed by the single-vector bi-encoders. Among the multi-vector bi-encoder models, only COIL approaches their retrieval speed. ColBERT, due to its higher computational costs, has about three times the latency. In real-world scenarios, large datasets generate a significant number of embedding vectors, which poses larger engineering challenges. This is one reason why single-vector bi-encoders and ensemble methods are more widely used compared to multi-vector approaches.

Token pruning has proven to be an effective method for reducing ColBERT's retrieval time. Among these methods, the ColBERT-Kw models pruned based on weights threshold offer the most optimal results, reducing search time by approximately 40% - 50% while still maintaining significantly higher accuracy than conventional heuristic methods. Notably, the ColBERT-Kw model

Table 2: Index size

trained with POS task labels achieves the highest MRR@10 at a pruning threshold of $\tau = 0.7$ (98.5% relative to ColBERT), highlighting the efficacy of incorporating domain knowledge into the model. Thus, ColBERT-Kw and its pruning strategies emerge as an optimal solution, significantly reducing ColBERT's retrieval time with minimal trade-offs in search accuracy.

Designed for larger datasets, PLAID uses quantization and approximate calculations to reduce retrieval times and minimize index sizes for the ColBERT model. Surprisingly, on our smaller dataset, PLAID slowed down retrieval due to increased computational load during the candidate generation phase, as shown in Table 1, despite significantly reducing the index size (Table 2). When combined with ColBERT-Kw, PLAID further reduced the index size while still maintaining acceptable retrieval performance, as demonstrated in Tables 1 and 2. This suggests that integrating ColBERT-Kw with PLAID could offer substantial benefits for very large datasets, optimizing both index size and retrieval efficiency.

4.5 Ablation Study

4.5.1 Choosing Pruning Threshold τ

A key advantage of ColBERT-Kw is its ability to optimize performance with a single training session, allowing pruning thresholds (τ) to be adjusted during indexing. This flexibility surpasses methods that require a fixed pruning level during training. The choice of τ impacts both retrieval effectiveness and performance, depending on dataset size and desired balance.

Incorporating labels from auxiliary tasks increases the number of tokens identified as important, or keywords. Notably, ColBERT-Kw-POS with $\tau = 0.7$ retains fewer vectors but achieves higher accuracy than with $\tau = 0.5$. This suggests that combining a good heuristic can help the model select better keywords. And maybe pruning can eliminate noisy tokens, resulting in even

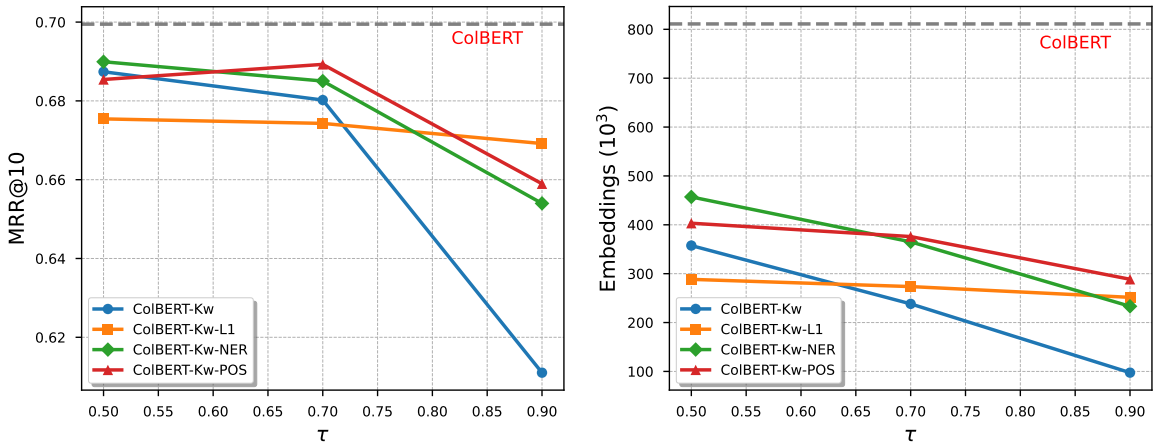

Figure 3: MRR@10 and Embeddings count for different pruning thresholds

more accurate retrievals while reducing the number of vectors used. This aspect will need further investigation in future studies.

4.6 Token Weight Distribution

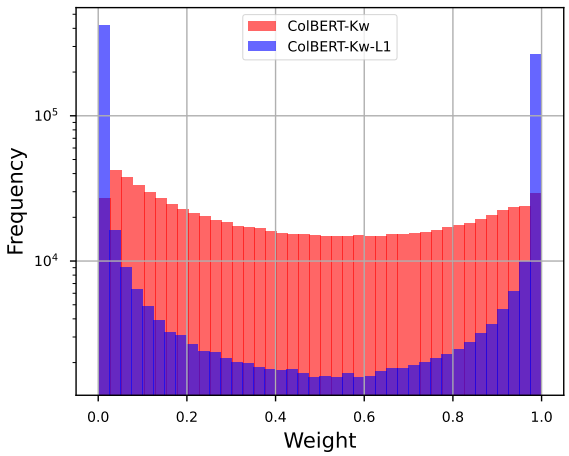

Figure 4: Token weight distribution for ColBERT-Kw and ColBERT-Kw-L1 (y-axis in logarithmic scale)

During our research, ColBERT-Kw-L1 was initially proposed. Transitioning to ColBERT-Kw by changing the distillation loss from Equation 10 to Equation 8 altered the model's token weighting behavior. Figure 4 shows that ColBERT-Kw-L1's weight distribution resembles a Bernoulli distribution, with values concentrated near 0 or 1. In contrast, ColBERT-Kw exhibits a U-shaped distribution with a broader and more even spread. Both models demonstrate varying token importance within documents. ColBERT-Kw is preferable for its flexible pruning threshold, while ColBERT-Kw-L1 is better suited for classification tasks, retaining only the most important tokens without threshold selection.

5 Conclusion

In this work, we introduced ColBERT-Kw, a model designed to facilitate token pruning for ColBERT by using KwNet to assign importance weights to tokens. With adequate training, ColBERT-Kw significantly improves ColBERT's retrieval speed and reduces storage requirements while preserving high accuracy. Our experiments on a Vietnamese Wikipedia-based dataset demonstrated that this method effectively minimizes index size and latency with minimal performance trade-offs. Our code is available at https://github.com/haihp02/Enhancing-ColBERT.

Clustering-Driven Sentiment Analysis for COVID-19 Vaccination in Tunisia

Imen Hamed and **Wala Rebhi** and **Narjes Bellamine Ben Saoud**
RIADI laboratory

University of Manouba, Manouba, Tunisia

Abstract

The rapid development of vaccines for the infectious coronavirus disease-19 (COVID-19) has been a crucial solution to combat the global impact of the virus. As a result, understanding the sentiments responses of individuals towards vaccination has become a significant issue since it could provide valuable insights into the public sentiment landscape and help inform targeted strategies for addressing concerns, increasing vaccine acceptance, and tailoring communication efforts. However, while sentiment analysis has matured for widely spoken languages like English, addressing dialects, such as the Tunisian dialect, remains a challenging task. In this context, this paper aims to propose a clustering-based approach for analyzing sentiments related to the COVID-19 vaccine using social media data, specifically focusing on Tunisian Facebook users. This approach combines the k-means clustering algorithm with the Naive Bayes classification model in order to classify Tunisians' opinions towards vaccination. Compared with the pre-trained Arabert model, the proposed approach gives better results proving its effectiveness for Tunisian opinions classification.

1 Introduction

The COVID-19 pandemic has radically affected the overall wellness and health of the entire world (Catapang and Cleofas, 2022). Indeed, it has changed our lives, not only in the health care area, but also in many aspects of human life such as education, transportation, politics, supply chain, etc. (Pham et al., 2020). As of March 11, 2020, there were 118,326 confirmed cases and 4,292 deaths, according to the World Health Organization who declared the COVID-19 as a pandemic on the same day (Ge et al., 2020).
Furthermore, the Covid-19 has been considered much more dangerous and easily spread than other Coronavirus families because it has become highly efficient in human-to-human transmissions (Pham et al., 2020). In Tunisia, for example, there have been 1,01 Million confirmed cases and 27922 deaths since March 2020 until March 2022 according to the Tunisian public health ministry.

Although COVID-19 preventive behaviors such as mask wearing and social distancing have been shown to be effective in curbing the spread of the virus, long-term control of the COVID-19 pandemic will hinge on the development and uptake of a preventive vaccine (Chou and Budenz, 2020). Therefore, the development of vaccines against COVID-19 made rapid progress in the last three years and to date, different vaccines showed good efficacy against COVID-19 (Bendau et al., 2021).

In this context, understanding the sentiments or emotional responses of individuals towards vaccination has become a crucial and relevant issue. This enables the identification of specific sentiments prevalent within different communities, such as vaccine hesitancy, vaccine confidence, or concerns about vaccine safety and efficacy. Analyzing these sentiments can provide valuable insights to address the unique concerns and needs of each community, ultimately promoting informed decision-making and increasing vaccine acceptance and uptake.

People nowadays rely mainly on social media to express their feelings, thoughts and opinions on different kind of events. Facebook, twitter and Instagram are considered as preferred platforms with millions of users. Thanks to the rapid information dissemination, social media platforms become the first source of information for many individuals. Therefore, collecting data and analyzing it may provide insights about different viewpoints about Covid-19 vaccine. There are different ways to analyze social media content, sentiment analysis is prominent among them. Two main methodologies can be used to perform sentiment analysis: knowledge-based systems based upon linguis-

tic rules and statistical machine learning models (Samaras et al., 2023). Since Twitter is considered very active platform, many researchers employ the huge number of tweets produced on a daily basis in different languages such as: Portuguese (Garcia and Berton, 2021), Spanish (Turón et al., 2023), Greece (Samaras et al., 2023) and especially English to analyze sentiments.

Despite the presence of many efforts on analyzing social media platforms with different languages, there is still lack of works on Arabic dialects mainly Tunisian dialect. Moreover, to the best of our knowledge, there are no studies on Tunisian sentiment analysis regarding COVID-19 vaccination. Thus, in this paper we focus on Facebook comments written in Tunisian dialect to analyze and extract meaningful insights by proposing a hybrid clustering-based approach for textual sentiment detection.

Therefore, our main contributions are:
-Proposing a new hybrid approach for Tunisian sentiment analysis by combining unsupervised clustering with supervised classifier model.
-Analyzing and classifying Tunisian comments to get meaningful insights about Tunisians opinions towards the Covid-19 vaccine.

The remainder of this paper is as follows: Section 1 is dedicated to present related work about sentiment analysis and covid-19 vaccination. We detail the proposed approach in Section 2. Section 3 is devoted to showcase the experimental results. We evaluate the proposed approach and discuss the retrieved results in Section 4. Finally, we conclude the paper and present future research directions.

2 Related work: Sentiment Analysis and Covid-19 Vaccination

Many recent studies have investigated peoples opinions regarding the COVID-19 vaccine (Antoun et al., 2020). Indeed, studying peoples perceptions on social media to understand their sentiment presents a powerful medium for researchers to identify the causes of vaccine hesitancy and therefore develop appropriate public health messages and interventions (Alamoodi et al., 2021).

For example, the authors in (Hussain et al., 2020) develop and apply an artificial intelligence (AI)-based approach to analyze social-media public sentiment in the United Kingdom (UK) and the United States (US) towards COVID-19 vaccinations, to better understand public attitude and identify topics of concern.

Likewise, in (Kwok et al., 2021) the authors use machine learning methods to extract topics and sentiments relating to COVID-19 vaccination on Twitter. To do this, they collected 31,100 English tweets containing COVID-19 vaccinerelated keywords between January and October 2020 from Australian Twitter users. Specifically, they analyzed tweets by visualizing high-frequency word clouds and correlations between word tokens. They built a latent Dirichlet allocation (LDA) topic model to identify commonly discussed topics in a large sample of tweets. They also performed sentiment analysis to understand the overall sentiments and emotions related to COVID-19 vaccination in Australia (Kwok et al., 2021).

The authors in (Turón et al., 2023) propose to analyze Spanish tweets through the combination of sentiment analysis techniques mainly lexicons and multivariate statistical methods to track the evolution of social mood. They recognized different emotions during the four phases of the vaccination process and show the interconnections and clustering of the community of tweeters around interest groups. As for authors in (Garcia and Berton, 2021), they focus on Brazil and USA since these countries had a large number of COVID cases. They explore English and Portuguese tweets to detect dominant sentiments related to Covid-19 discussions. They mainly find out fear is the most dominant feeling. They also recognize ten different topics in the conversations. They mainly rely on existing classifiers, they combined recent embedded models to extract features. Another study (Lin et al., 2023) uses multilingual tweets to distinguish different opinions about COVID 19 vaccines. They compared machine learning models such as Random Forest (RF) and Support Vector Machine (SVM) with different deep learning models to find up that deep learning methods outperform machine learning ones in tweets classification.

Now addressing the Tunisian Covid-19 scenario, we may find very few works on the sentiment analysis during the pandemic. For example, the work in (Shahriar et al., 2022) performs sentiment analysis on Tunisian comments to analyze public perceptions on the Covid-19 pandemic. The problem was considered as text classification issues: multi-class classification for sentiment analysis (optimist, pessimist or neutral) and binary

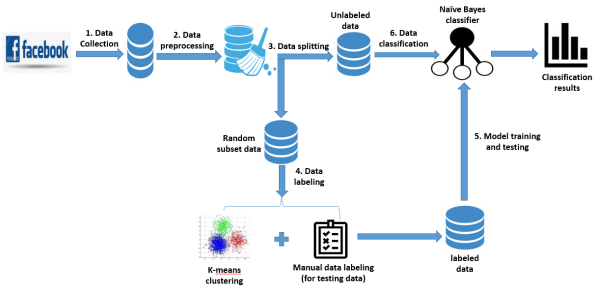

Figure 1: The clustering-driven sentiment analysis approach.

classification for sarcasm detection. Then, the authors compared machine learning models and deep learning ones on the studied data set. They find up that deep learning models outperform the machine learning models. As for authors in (Mekki et al., 2022), they refer to deep learning model Bi-LSTM to analyze sentiments of Tunisians during the pandemic. So, they introduce a deep Bi-LSTM network to improve the sentiment analysis task. The proposed model outperforms machine learning models and standard deep learning models.

Despite the existence of many studies addressing sentiment analysis regarding COVID-19 vaccination, it is noteworthy that these studies are mainly related to texts written in English. Only few studies have addressed sentiment analysis for Tunisian dialect. Moreover, even this limited number of studies have approached the Covid-19 pandemic in general rather than vaccination specifically. Furthermore, for the Tunisian dialect, another issue concerns the lack of data for training classification models. Most works resort to manual data annotation, which is relevant but resource-intensive in terms of time. This is why, in this work, we propose a hybrid approach for analyzing Tunisian Covid-19 vaccination opinions, which presents a solution for manual data annotation.

This approach will be detailed in the next section.

3 Proposed approach: a clustering-driven sentiment analysis approach for Tunisian COVID-19 Vaccination

In order to analyze sentiment responses of Tunisian individuals towards Covid-19 vaccination, we propose a hybrid approach, as illustrated by Fig. 1. This approach, by combining unsupervised and supervised methods, contains six

Before cleaning: masa7eche eli mla9a7 ma ya3diche 😷😒

After cleaning: ['masaheche', 'eli', 'mlakah', 'yaadiche', 'yebki', 'mghachech']

Figure 2: Example of data before and after cleaning.

phases:

1. Data Collection: The first step undertaken involved data collection. We embarked on gathering comments from Tunisians posts on Facebook regarding the COVID-19 vaccination campaign from August 2021 until June 2022.

For this purpose, we opt to use the "ExportComments" platform[1], which allowed us to extract relevant comments from the URL of each post and save them in Excel format.

The process took place in two steps: first, we identified the links to the posts originating from the Tunisian Ministry of Health on Facebook; then, we provided these links successively to the "ExportComments" platform, which merged the resulting Excel files into a single dataset file.

Thus, we obtained 50k comments written in Tunisian dialect in Arabic and Latin letters from posts related to Covid-19 vaccination.

2. Data pre-processing: After data extraction, the next step is data preprocessing which relies mainly on removing noise and irrelevant information so that the effectiveness of subsequent model learning could be optimized. This involves cleaning the data by removing duplicate comments and unnecessary symbols such as stop words, punctuation marks and any URLs or mentions of other Facebook users. Likewise, emojis were converted into words. Finally, the data has been tokenized into words and normalized by transforming number into letters as Tunisian dialect uses a lot of numbers instead of letters. For example: 2 -> "a"; 3 -> "a"; 4 -> "gh"; 5 ->"kh"; 7 -> "h"; 8 -> "ch"; 9 -> "k"; etc.

Fig. 2 shows before and after cleaning a sentence from the collected data. The cleaning process consists in removing punctuation, emojis and stop words. Stop words in Arabic are not very informative so we processed to remove it. Another very important step involves vectorization, which refers to the process of converting textual data into numerical representations. In this setting, there are several vectorization techniques such as Continuous Bag of Words (CBOW), Skip-gram bag of words, Term FrequencyInverse Document Frequency (TF-IDF), and Distributed Memory of

[1]https://exportcomments.com/

Paragraph Vector (DM-PV) (Dey et al., 2016). In this work, we have chosen CBOW (Continuous Bag-of-Words) model as part of the Word2Vec method, which learns the embedding by predicting the current word based on its context (Shahriar et al., 2022). This technique has proven its effectiveness compared to other techniques (Dey et al., 2016), particularly for the Tunisian dialect (Shahriar et al., 2022).

3. Data splitting: After cleaning our data, we split it into two sets: unlabeled and labeled data. Indeed, a random subset of 5K comments (10% of the total comments) was extracted to undergo annotation for training and testing the model.

4. Data labeling: K-means clustering + manual labeling: This step concerns only the random subset of 5K comments and it aims to annotate data for our model training and testing. As the annotation process is crucial and time-consuming manually, we resorted to an unsupervised method which is the k-means clustering. This choice was motivated by the fact that this method has been used in several studies and has yielded significant results for English text analyzing (Lin et al., 2023) and (Chen et al., 2022). Furthermore, it has been listed among the top 10 clustering algorithms for data analysis (Shahriar et al., 2022). Indeed, K-Means clustering is a popular clustering algorithm based on the partition of data. Data that have the same characteristics are grouped into one cluster, whereas data that have different characteristics are grouped into other clusters (Chen et al., 2022). Steps for K-Means clustering are as follows (Chen et al., 2022) and (Mekki et al., 2022):

1. Decide the number of cluster K
2. Initialization of the cluster center (centroid). It can be conducted by using various ways. However, the most frequent way is by using random way. Clusters centers are assigned by random numbers.
3. Allocate all data/objects to the closest cluster. Determination of closeness of two objects is determined based on the distance of two objects. For calculating the distance of all data to each centroid point, Euclidean Distance theory is used, which is formulated as given in Equation (1):

$$D(i,j)=\sqrt{(X_{i1}-X_{j1})^2+(X_{i2}-X_{j2})^2+\cdots+(X_{ip}-X_{jp})^2} \quad (1)$$

Where:
$D(i,j)$ = distance of i^{th} data to cluster center j
$X_{ik} = i^{\text{th}}$ on the k^{th} data attribute
X_{ij} = j^{th} center point on the k^{th} data attribute

4. Recalculate centroid with current cluster membership. Centroid is an average (mean) of all data/objects within particular cluster. If desired, the median of this cluster can also be used.
5. Reassign each object by using new cluster center, if the cluster doesnt change, then clustering process finished otherwise repeat step 3 until there is no change for each cluster.

In K-Means, the number of clusters is determined. For this work, the number of clusters is fixed at **three (3)** since we noticed the presence of three opinions in favor, against, and neutral.

Thus, as a result, we obtained three clusters: Cluster 1 with 1966 comments, Cluster 2 with 451 comments and Cluster 3 with 2583 comments. Fig. 3 shows an example of comment from each cluster.

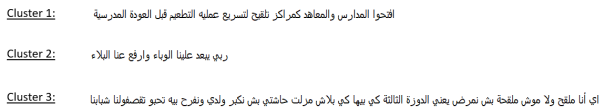

Figure 3: Example of comment from each cluster.

Then, we extracted approximately 20% comments from each cluster which are in total 1000 comments. These comments were manually annotated in order to discover firstly which cluster represents which sentiment and to evaluate the relevance of the K-means clustering as shown in Table 1. Indeed, we calculated the precision obtained for each cluster, which was higher than 90% for the three clusters.
Then, this 1000 comments will be considered as a testing set of data for the classification model later.

Therefore, at this stage, we managed, by applying the k-means clustering, to obtain training and test datasets.

5. Model training and testing: For this step, two models were trained and tested: the Naive Bayes classifier and k-nearest neighbour classifier. Naïve Bayes algorithm is a simple probabilistic

Table 1: K-means clustering Evaluation.

Cluster	Number of comments	Number of correct comments	Precision of each cluster
Cluster 1 (positive comments)	392	364	0.92
Cluster 2 (neutral comments)	92	88	0.95
Cluster 3 (negative comments)	516	467	0.90

classifier that applies the Bayes theorem that calculates a set of probabilities by calculating the frequency and the combination of values of the given data set (Jaballi et al., 2023) and (Chen et al., 2022). The reason behind this choice is that the Naive Bayes is fast and accurate and widely used for classification problems.

As for the k-nearest neighbour model, it is one of the most fundamental and simple classification methods and it is commonly based on the Euclidean distance between a test sample and the specified training samples (Peterson, 2009) and (Cunningham and Delany, 2021).

Using the training dataset, we first trained each model. Then, we evaluated them using the test data and based on the three evaluated metrics: P: Precision, R: recall and A: accuracy. This evaluation, as given in Table 2, shows the effectiveness of Naive Bayes compared to k-nearest neighbour.

Table 2: Comparison of classification models.

Classifier Model	Precision	Recall	Accuracy
Naive Bayes	0.79	0.744	0.8
k-nearest neighbour	0.72	0.69	0.73

This is why, in this work we propose to choose Naive Bayes to classify our datasets.

6. Data classification: The last step is the classification of the unlabelled data which is of 45K comments. Indeed, once trained and tested, we used our model to classify the data. So, we obtain a set of comments annotated with either 1 (positive), 0 (neutral), or -1 (negative).

4 Evaluation and results

In this section, we first evaluate our approach, which consists of combining a clustering method with a classification model in order to determine the sentiment from a comment. Then, we provide an analysis of the results obtained within the context of COVID-19 vaccination in Tunisia.

4.1 Evaluation

In order to evaluate the proposed approach, we propose to apply the pretrained Arabert to the annotated test set data. Arabert is a pretarained model based on the BERT transformer model (Devlin, 2018) for the Arabic language (Antoun et al., 2020). Indeed, our goal is to see the impact of using an unsupervised method for constructing the training data. This explains why we choose to deal with a pretrained model.

Table 3: Proposed approach evaluation.

Model	Precision	Recall	Accuracy
Proposed approach	0.79	0.744	0.8
Arabert	0.757	0.743	0.753

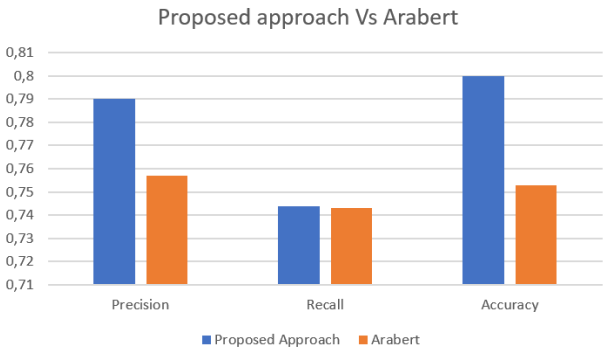

Figure 4: Proposed approach evaluation.

The evaluation results (Precision (P), Recall (R) and Accuracy (A)) detailed in Table 3 and are graphically visualized in Fig. 4, indicate that the proposed approach is more efficient than the pretrained model, particularly in terms of precision and accuracy.. This could be attributed to the fact that Arabert is pretrained for the Arabic language, whereas the Tunisian dialect incorporates more specificities such as the combination of various languages such as French and English. Moreover, the discussed topic, concerning COVID-19 vaccination within the comments, is notably specific, and viewpoints diverge from typical subjects that rely on familiar terminology.

4.2 Results analysis

After evaluating the proposed approach, we propose in this section to use the classification re-

sults to analyze Tunisians' sentiments towards the COVID-19 vaccination.

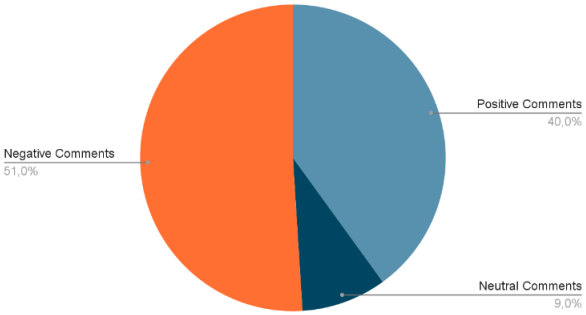

Figure 5: Comments statistics.

To begin with, as shown in Fig. 5, we notice that generally negative comments carry more weight which is 51% than positive and neutral comments. To better understand these results, we suggest tracking the evolution of these comments over time. Thus, considering the timestamps of each comment, we observe from Fig. 6 that the number of negative comments increased while positive comments decreased over time. As for neutral comments, their volume seems to remain relatively stable throughout. This trend logically corresponds to the vaccine's rollout date. Indeed, based on this variation, it is possible to distinguish two phases:

- Phase 1: August 2021 until November 2021: characterized by a very high number of positive comments. This phase corresponds in reality to the launch of the vaccine in Tunisia and the decrease in COVID-19 cases following this vaccination.
- Phase 2: December 2021 until June 2022: characterized by a decrease in positive comments with a remarkable increase in negative comments. This can be explained by the fact that many individuals were still affected by COVID-19 despite vaccination, as well as the appearance of negative effects of the vaccine on several individuals.

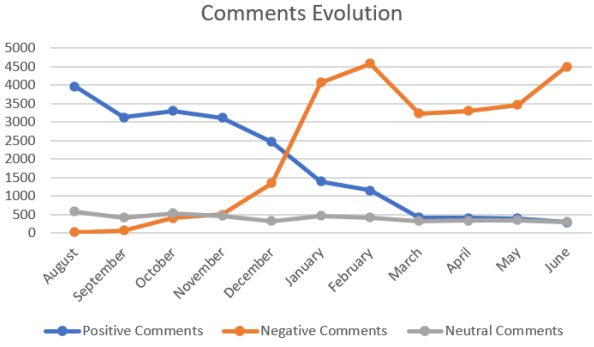

Figure 6: Evolution of Tunisian sentiments towards COVID-19 vaccination.

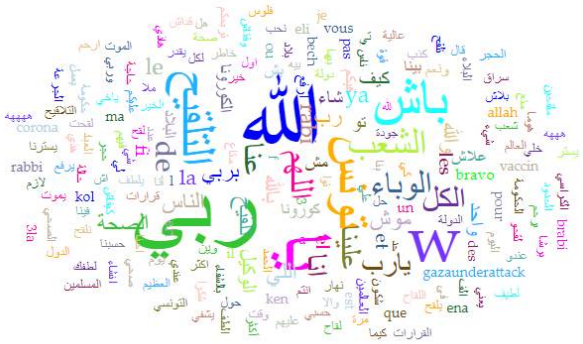

Figure 7: Word Cloud representing the most commonly occurring words in the gathered dataset.

Finally, in order to know which words were most frequently used during the Covid-19 vaccination, we create the word cloud as shwon in Fig. 7. We observed that terms such as the names of God (Rabi, Allahomma, Allah), prayers (Ya rab, Yostorna) and terms related to COVID-19 vaccination (TalKih, Joraa, Sahha, wabaa) exhibited the highest frequency in the word cloud generated from the collected dataset. This could be explained by Tunisian citizens' habit of expressing their various positive, negative, and especially neutral sentiments through prayer to God.

4.3 Discussion

This paper introduces a hybrid approach that integrates both supervised and unsupervised methods to analyze the sentiments of Tunisian people towards COVID-19 vaccination, particularly focusing on their expressions on the Facebook platform. The proposed approach has shown notable effectiveness by achieving high precision and recall rates, and it also excels in terms of speed because it automates the manual annotation process without compromising the quality of the results.

Moreover, the dataset generated from this study can serve as a valuable reference for future sentiment analysis on various other diseases affecting the Tunisian population. This data can provide insights and benchmarks for researchers and policymakers.

Additionally, the insights derived from this study act as a crucial alert for the Ministry of

Health, underscoring the importance of increasing efforts and preparedness when introducing new vaccines. The analysis emphasizes the need for proactive measures to address public concerns and improve vaccination campaigns.

Finally, this research has the potential to be extended further to investigate the negative side effects associated with different vaccines. This is particularly important given the documented issues with certain vaccines that have been approved and used in various countries. Such extensions could provide critical information for improving vaccine safety and public health strategies.

5 Conclusion

This paper introduced a clustering-based approach to examine sentiments surrounding the COVID-19 vaccine via social media posts, focusing particularly on Tunisian Facebook users. The technique combines the k-means clustering algorithm with the Naive Bayes classification model to sort Tunisian perspectives on vaccination.
Compared to the pre-trained Arabert model, the proposed method yields better results and demonstrates its efficacy in classifying Tunisian viewpoints.
Additionally, a detailed analysis of the findings is provided to gain insights into Tunisian attitudes towards COVID-19 vaccination.

As future work, we aim to enrich the obtained datasets with additional comments about other pandemics to establish a baseline for the Tunisian dialect that could be used to support the understanding of pandemics. Moreover, we intend to add another crucial facet of the comments analysis: detecting sarcasm, which can be very informative when studying social behavior and expressed emotions.

Abstract

In this work, we present a novel Grammar Question-Answering System, Aganittyam, along with its associated corpus focused on the Dravidian language Tamil. As one of the oldest surviving languages with a documented history exceeding 2,000 years, Tamil is recognized as a classical language and holds official status in three countries, including India, while being spoken by various diasporic communities worldwide. Learning Tamil grammar poses challenges due to its agglutination and complex morphology. Despite the active research in automatic processing of Tamil texts, there are currently no automated tools available to assist learners. To address this gap, we created a comprehensive corpus of Tamil grammar designed to facilitate learning. We developed an ontology comprising 7 relationship types, manually annotating the corpus to identify entities and relationships. The resultant triplets (subject–predicate–object) were organized into a knowledge graph (KG) consisting of 63,587 entities. Our framework, *Aganittyam*, enables template-based question-answering, providing a structured approach to learning. We conducted a bifold evaluation—incorporating both query metrics and human-centric assessments—demonstrating that our QA system is robust, reliable, and engaging for answering various objective questions. The system is available at `https://aganittyam-web.onrender.com/home`.

1 Introduction

The concept of knowledge graph (KG) was initially proposed by Google. A knowledge graph is a large-scale knowledge base composed of a large number of entities and relationships between them (Fensel et al., 2020b; Chen et al., 2020b; Kejriwal et al., 2021). A structured representation of facts, consisting of entities, relationships, and semantic descriptions is maintained. A KG primarily consists of two components (node and edge) where a node represents an entity and edge represents relationship between nodes. A sample KG and its illustration is given in Figure 1 (KG). It illustrates the fact that *Bob* is *interested in Monalisa* and *Mona Lisa* was *created by Leonardo Da Vinci*. There are many applications of knowledge graphs such as Question Answering System, Recommender System and Information Retrieval etc. A question answering (QA) system's main objective is to use facts in the knowledge graph (KG) to answer natural language questions. Most of the extant QA systems for Indian languages focus on Hindi. There is a paucity of research work in QA systems for Dravidian languages, primarily attributing to the limited number of dataset available in these languages.

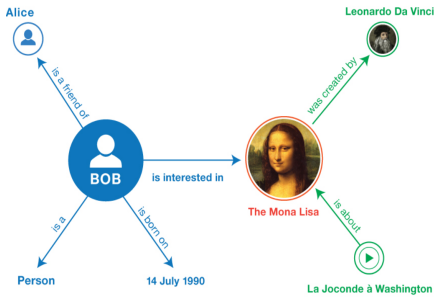

Figure 1: A sample Knowledge Graph

1.1 Motivation towards Tamil Language and Grammar

Tamil, with its rich literary heritage spanning over two millennia, features a unique and intricate grammatical system (Sarveswaran, 2024; Asher, 1985). For many learners, especially non-native speakers, mastering this system can be daunting due to its complex

phoneme structure, distinctive script with intricate characters, phonetic nuances, and diverse regional variations. The grammar reflects the language's long history, encompassing key features such as word formation (morphology), sentence structure (syntax), verb conjugation, nouns, pronouns, postpositions, and verb-noun constructions (Steever, 2018; Sarveswaran, 2024; Asher, 1985).

The challenges in learning Tamil grammar include agglutination, complex morphology, an extensive case system, and rich vocabulary, along with pronunciation and phonology. Moreover, existing teaching methods often present grammatical concepts in a disjointed manner, hindering comprehension and appreciation of the language's depth. Students, in particular, tend to find these concepts more challenging than adults.

Currently, some NLP tools available for grammar learning include POS taggers, chunkers, dependency parsers, morphological analyzers, and morphological generators (Singh and Shah, 2022; Rajendran et al., 2022; Dhanalakshmi et al., 2010). However, to the best of our knowledge, no tool exists that facilitates an interactive approach to learning Tamil grammar while effectively assessing understanding of the basic concepts.

1.2 Knowledge Graphs for Tamil Grammar Question Answering

In recent years, deep learning models have been developed for extractive question answering systems in the Tamil language (Krishnan et al., 2023a). For instance, (Murugathas and Thayasivam, 2022) introduced a question answering system comprising multiple modules, specifically trained on a manually tagged dataset focused on the historical domain in Tamil. This innovative approach highlights the potential of leveraging tailored datasets and modular designs to enhance the accuracy and relevance of responses in Tamil question answering.

While deep learning models have their merits, knowledge graphs offer distinct advantages, including transparency, explicit domain representation, consistency with expert knowledge, semantic understanding, logical reasoning, scalability, and support for complex queries (Futia and Vetrò, 2020; Turing Institute). We aim to bridge this gap by developing a knowledge graph dataset for templated question answering that aids grammar learning, leveraging the strengths of these powerful tools to refine ontologies. An ontology is a formal, structured representation of knowledge within a specific domain (Guarino et al., 2009), defining the concepts, entities, and relationships, along with their interactions. Ontologies facilitate better understanding, sharing, and reuse of information across systems. Knowledge graphs provide a structured, visual, and scalable way to represent and explore complex relationships crucial for accurate ontology development. However, literature on knowledge graphs specific to the Tamil language is scarce, and to the best of our knowledge, there has been no work on constructing a Tamil grammar-based knowledge graph.

1.3 Salient Features

This research aims to develop a novel Tamil grammar question-answering system by creating a comprehensive Tamil grammar corpus, performing human annotation, and constructing a Tamil Grammar Knowledge Graph. This Knowledge Graph will facilitate templatized question answering, providing a dynamic and interactive learning experience. Our system not only helps learners grasp Tamil grammar but also assesses their skills in a motivating way. As new grammatical concepts emerge, they can be easily incorporated, ensuring the resource remains relevant and up to date.

1.4 Contributions

Our main contributions are as follows:

- Created a *Tamil Grammar Corpus* from web sources, featuring 63,587 entities and relations between them adhering to 7 major relation types.
- Developed a straightforward method for constructing a richly *human-annotated Tamil grammar knowledge graph* and its corresponding ontology.
- Introduced *"Aganittyam", a templatized question-answering tool* that generates grammar questions, including complex

queries—marking the first tool of its kind for Tamil.

- Conducted rigorous evaluations of the QA tool using both *Query Evaluation metrics* and *Human-Computer Interaction metrics*.

2 Architecture

In this section, a detailed description about the KG construction and templatized question-answering technique for Tamil grammar are provided. Figure 2 illustrates the complete architecture of the proposed *Aganittyam*. Few snapshots of the same can be seen in Figures 6 and 7 in in appendix C. We use an annotation tool, *Sangrahaka* (Terdalkar and Bhattacharya, 2021), for the construction of knowledge graph.

2.1 Tamil Grammar Corpus Construction

To the best of our knowledge, there does not exit a Tamil Grammar dataset targeted for an NLP task. The source of our dataset construction includes (Tamil Wikipedia) (Tamil Wikinaotinary) and (Byjus Page for TN Books).

Tamil ilakkaṇam (தமிழ் இலக்கணம்) is the name of the corpus uploaded in *Sangrahaka* as shown in Figure 8 in appendix C. In *Sangrahaka*, the administrator has the privilege to insert, delete and update the corpus, and can provide the details of corpus in the UI. The corpus exhibits numerous relation types across sentences. The following are some of notable relation types with examples.

i. பெயர்ச்சொல்(peyarchchol) - Noun

- பொதுவான பெயர்சொற்கள் (Potuvāṉa peyarccoṟkaḷ) - Common Nouns (வங்கி(bank), பாடசாலை(school))
- சரியான பெயர்ச்சொற்கள் (Cariyāṉa peyarccoṟkaḷ) - Proper Nouns (இலண்டன்(London), மதுரை(Madurai))
- திடப் பெயர்சொற்கள் (Tiṭap peyarcoṟkaḷ) - Concrete Nouns (மரம்(tree), பந்து(ball))
- நுண் பெயர்ச்சொற்கள் (Nuṇ peyarccoṟkaḷ) - Abstract Nouns (திறமை(skill), கருத்து(opinion))

ii. எதிர்ச்சொல்(ethirchchol) - Antonyms

iii. இணைப்பொருட்ச்சொற்கள் (iṇaipporuṭccoṟkaḷ) - Synonyms

iv. ஒருமை பன்மை(orumai paṉmai) - Singular Plural

v. சேர்த்து எழுதுக(cērttu eḻutuka) - Words Join

vi. காலங்கள்(kālaṅgaḷ) - Tenses

- We have three tenses: Past, Present and Future Tense.

vii. பிரித்தல் (pirithal) - Words Split

To the best of our knowledge, we have gathered all publicly available resources (sentences) for each relation type. Our Tamil Corpus consists of 7 relation types and 63,587 entities (words).

2.2 Ontology Construction and Annotation

Ontology refers to structured representation of knowledge about a domain which forms the skeleton of a knowledge graph (Estival et al., 2004). Ontology construction, for Tamil grammar KG is managed by *Sangrahaka* as illustrated in Figure 9 in Appendix C. Figure 3 showcases the working of ontology where nodes are labeled as *Words* and edges represent grammatical relations. For an example, entities முட்டாள்(muttaal(stupid)) and புத்திசாலி(buddhisali(intelligent)) represent the relation type இணைப்பொருட்ச்சொற்கள்(inaippoutchorkal(synonyms)) and entities தைரியமான(tairiyamaana(courageous)) and துணிச்சலான(thunichalaana(brave)) represents the relation type எதிர்ச்சொல்(ethirchchol(antonym)).

Once the preprocessing steps such as tokenization and segmentation are performed, the annotation process of individual words or phrases are assigned with their appropriate relation type. During annotation phase, edges are assigned as relation types and nodes as entities as shown in Figure 10, 11 and 12 in appendix C.

2.2.1 Question Templates and Triplets

Triplets represent real-world facts and semantic relations in a knowledge base. In a knowl-

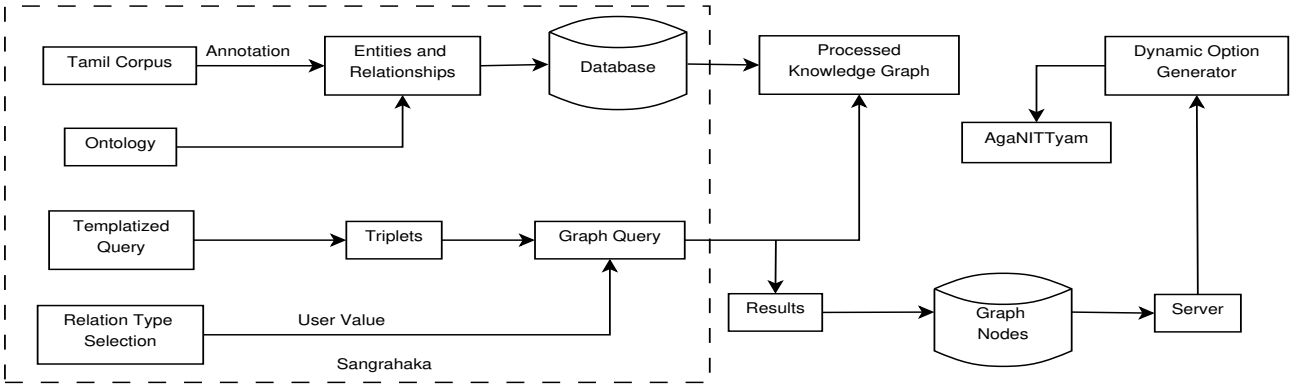

Figure 2: Architecture of our proposed Tamil Grammar Learning through Knowledge Graph based Templatized Question-Answering

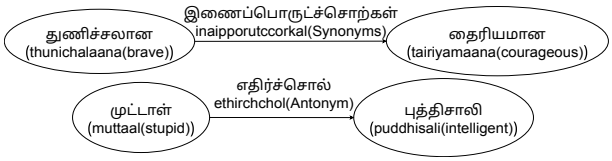

Figure 3: Example of Relations in KG

edge graph, a triplet is an edge between two nodes, where the edge represents a relation and the nodes represent entities. In the case of Tamil grammar KG, entities represents the individual words and edges represents grammatical relations. Once the triplets are identified, based on triplets, the templates are generated for constructing Knowledge Graph. Some of the relation types, their triplets and the question templates are given below.

Relation Type: ஒருமை பன்மை (orumai paṉmai) (Singular Plural)
Triplet: (பந்து (Ball), is-Plural, x)
Template: (பந்து(Ball) + is-Plural = x)

Relation Type: சேர்த்து எழுதுக (cērttueḻutuka) (Joined Words)
Triplet: (கரும்பு(Karumpu), +, சாறு(Cāṟu))
Template: (x + y = z)

Relation Type: Complex Query
Triplet: ((கை (Arm), is-Noun, (Yes or No)), is-Plural, x)
Template: ((கை (Arm), is-Noun) ? Yes:No) is-Plural = x)

2.2.2 Complex Queries

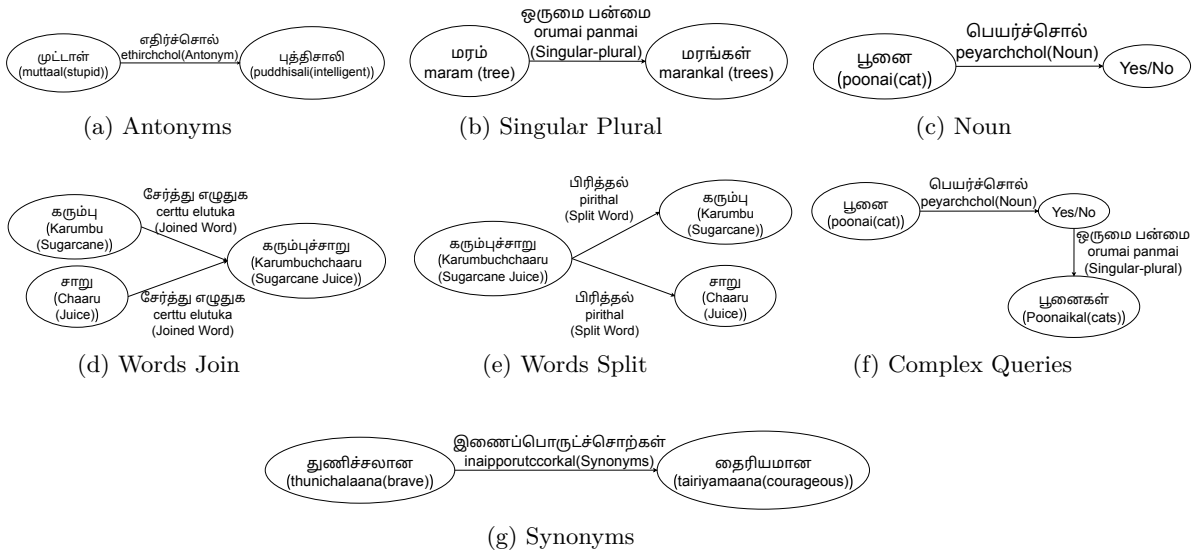
Complex queries helps in understanding and reasoning about the connections between different pieces of data. For an example in case of Tamil grammar corpus creation, we designed complex queries which tells whether given word is noun or not. In case if it is noun, then it outputs the plural form of the particular word. An example is given below.

Question: அணி என்பது பெயர்ச்சொல்லா? அப்படியானால், அதன் பன்மை வடிவம் என்ன? (Aṉi eṉpatu peyarccollā? Appaṭiyāṉāl, ataṉ paṉmai vaṭivam eṉṉa?) (Is ani a noun? If so, what is the plural form of it?)
Template: ((அணி (Ani) (Team), is-Noun) ? Yes:No) is-Plural = x)

Question: பெண்ணின் ஆண்பால் பன்மை என்ன? (What is the plural of masculine of girl?)
Template: ((பெண்ணின்(Peṇṇiṉ)(Girl),-Gender) ? Male:Female) is-Plural = x)

2.3 KG Construction

The knowledge graph is constructed by manual annotation with the help of two annotators. Both the annotators are native Tamil speakers with adequate knowledge of Tamil grammar. Words are annotated as entities and grammatical relationships as edges. The KG is stored in a graph database, with annotations converted into a machine-readable format using a Python script. Figure 4 provides examples of different relation types and their corresponding knowledge graph. This knowledge graph can be used for analysis, exploration, and discovery of information within the corpus.



(a) Antonyms (b) Singular Plural (c) Noun

(d) Words Join (e) Words Split (f) Complex Queries

(g) Synonyms

Figure 4: A sample Knowledge Graph constructed for relation types in Tamil Grammar

2.4 *Aganittyam* - The Question Answering Portal for Tamil Grammar

We named the QA portal *Aganittyam*, from the word *Agattiyam* (the earliest book on Tamil Grammar)(Agattiyam Wikipedia), which is a dynamic platform to learn Tamil grammar using templatized question-answering.

2.4.1 Features of Aganittyam

It allows diverse question categories on all the 7 types of relations, dual language support (English to Tamil and vice-versa) for non-native Tamil speakers and interactive exercises ensuring that options are generated as per their category choice. By harnessing the power of the Tamil KG in the QA Tool, the learner is not only equipped with practical language skills but also gains a deeper understanding of the intricate connections within Tamil grammar.

2.4.2 Architecture of *Aganittyam*

Aganittyam relies on a robust framework to deliver effective, interactive, and personalized learning solutions. Dynamic option generation, Tamil Knowledge Graph, frontend interface and backend infrastructure are the key components of our Aganittyam.

3 Results and Discussions

To the best of our knowledge, there does not exist a Tamil Grammar QA Systen to compare with our work. Simulation is performed on an AMD Ryzen 7 CPU with 16 GB Main Memory and 512 GB Hard Disk on Windows 10 Platform. Using Python and Anaconda tool, the proposed techique was implemented and Neo4j Database was used to store the KG.

Our experimentation on KG based Tamil Grammar QA system is bi-fold. On one side, to test the performance of the QA system, we thoroughly experimented with various templatized queries. On the other side, a detailed User Satisfaction studies were carried out with four different metrics.

3.1 KG based Experimental Results

The following are the metrics used to evaluate our KG based tamil Grammar QA tool. Table 1 illustrates the experimental results of the KG based performance metrics for each of the relation types in the Knowledge Graph.

3.1.1 Accuracy

Accuracy of the result of a Query is defined as follows:

$$\text{Accuracy} = \frac{\text{Number of Correct Query Retrievals}}{\text{Total Query Retrievals}}$$

Accuracy measures the precision and correctness of the information fetched using cypher-queries from the Neo4j database, ensuring that

the likelihood of correct responses is maximized. A higher accuracy implies an efficient system. In the evaluation process, the accuracy of data retrieval is assessed across various categories pertinent to the system's functionality. Each category represents a distinct aspect or set of queries within the system. A total of 1000 query retrieval iterations were performed for each Relation type, for which each results were checked for correspondence with the ground truth. The experimental results for accuracy of the query results are presented in Table 1. The total average data accuracy of the portal was found out to be 94%. The reduction in performance is due to human error during annotation and dataset creation, Tamil character encoding limitations and invalid JSON parses.

3.1.2 Knowledge Graph Utilization Ratio (KGUR)

The Knowledge Graph Utilization Ratio (KGUR) is defined as follows:

$$\text{KGUR} = \frac{\text{Number of subgraphs in Knowledge Graph}}{\text{Total Number of nodes in Knowledge Graph}}$$

This quantifies the extent to which the Knowledge Graph is utilized in generating responses, reflecting the system's reliability on structured knowledge for answering queries. A higher KG Utilization Ratio signifies a larger number of relationships existing between nodes. This metric evaluates how effectively the system leverages structured knowledge, reflecting its reliance on interconnected data to generate responses. The best KG Utilization Ratio achieved was around 0.433 where the number of subgraphs in Knowledge Graph is 580 and the total Number of Nodes is 63,587.

3.1.3 Average Query Response

The Average Query Response is defined as follows:

$$\text{Average Query Response} = \frac{\sum_{i=1}^{n}(Q_i)}{\text{Total Query Retrievals } (n)}$$

where Q_i represents the average response time in the i^{th} retrieval. It evaluates the efficiency of the system in responding to user queries within a specified timeframe, indicating its responsiveness and ability to handle user interactions promptly. A lower Average Query Response represents that the cypher-queries are optimized, resulting in faster page loads. Average Query Response measures the system's responsiveness by evaluating the speed at which it handles user queries. A lower response rate indicates faster query processing, contributing to a smoother user experience and quicker access to information. A total of 1000 query retrievals were made for each category to arrive at this conclusion. It is observed that the average query response of the portal was found out to be around 2.48 seconds.

3.1.4 Degree of Randomness

The Degree of Randomness (DR) is defined as follows:

$$\text{DR} = \frac{\text{Count of Distinct Nodes Retrieved}}{\text{Total Query Retrievals (n)}}$$

Degree of Randomness assesses the level of unpredictability or variability in the system's responses, providing insights into the system's ability to generate diverse and contextually relevant answers. A higher Degree of Randomness indicates a much more diverse dataset giving the user a better experience. One primary observation made here is the fact that the degree of randomness of a category is directly proportional to the size of the category's dataset. Similar to other performance metrics, the script for degree of randomness was made to run for a total of 1000 iterations (categorically).

3.2 User Satisfaction Metrics

The following metrics are entirely based on results derived from a survey by using *Aganittyam* tool conducted on approximately 500 school and college students. It was primarily directed towards school students who currently learn Tamil Grammar, and further expanded to college students as well. In this section, a detailed description about a set of metrics that provide valuable insights of user's perceptions, experiences and engagement is given. The following metrics are used to measure user satisfaction and scaled over a scale of 1 to 5 where 5 represents high positive value.

3.2.1 Customer Effort Score (CES)

CES measures the level of effort required by customers to interact with the system. Figure 5a shows the Audience Percentage Split in

Relation Types-*Aganittyam*	Accuracy of Query Retrieval	Query Response Time (in seconds)	Degree of Randomness
Noun Classification	0.92	2.41	0.90
Synonyms	0.99	2.51	0.67
Antonyms	1.0	2.49	0.83
Singular/Plural	0.99	2.47	0.87
Word Split	0.99	2.52	0.65
Tenses	0.99	2.54	0.59
Complex Queries	0.67	2.45	0.64

Table 1: Tamil Grammar KG based Experimental Results

CES. It gauges users' perceptions of ease of use and the simplicity of completing tasks. A higher CES indicates that the users find the system easy to navigate and use. The highest Customer Effort Score calculated based on survey findings was 4.59.

3.2.2 Net Promoter Score (NPS)

NPS assesses the likelihood of users recommending the system or service to others. Figure 5b shows Audience Percentage Split in NPS. It is calculated based on user's responses to a single question: **How likely are you to recommend this system/service to a friend or colleague?** A higher NPS implies a higher chance an existing user shares the application to others. The highest Net Promoter Score calculated based on survey findings was 4.56.

3.2.3 Responsiveness

Responsiveness measures the system's ability to promptly address user queries, requests, or issues. Figure 5c shows Audience Percentage Split in Responsiveness. It evaluates the speed and efficiency with which the system handles user interactions, providing timely responses and assistance. A high level of responsiveness enhances user satisfaction by minimizing wait times. The Responsiveness Score calculated based on survey findings was 3.81.

3.2.4 Relevance

Relevance assesses the alignment between user's needs or preferences and the content or information provided by the system. Figure 5d shows Audience Percentage Split with respect to Relevance Score.

It evaluates the accuracy and appropriateness of the system's responses to user queries, ensuring that the information presented is useful to users. The highest Relevance Score calculated based on survey findings was 4.709.

3.2.5 Overall User Experience with *Aganittyam*

Overall Experience provides an aggregate measure of user's satisfaction with the system across various dimensions. Figure 5e shows Audience Percentage Split with respect to Relevance Score. It encompasses user's perceptions of usability, effectiveness, reliability, and satisfaction with the overall interaction. The highest Overall Experience Score calculated based on survey findings was 4.68.

4 Related Work

Though tools like Duolingo (Chen et al., 2020a) and Babbel (Hao et al., 2021) exists for language learning, they lack is serious pitfalls including limited depth, repetitive content, inconsistent quality across languages and lack of gamification over learning. Constructing a knowledge graph and querying using templatized questions is an emerging research in various real world domains (Ehrlinger and Wöß, 2016; Chen et al., 2018; Wu et al., 2019). Using annotated KGs constructed, Question-Answering systems are designed using various techniques, for example, via Automated Template Generation (Abujabal et al., 2017), using Knowledge Base Embeddings (Saxena et al., 2020) and so on. Few works for QA in Tamil are focused using Deep Learning Models (Murugathas and Thayasivam, 2022; Antony and Paul, 2022; Krishnan et al., 2023b) as mentioned in Section 1.1. Moreover, we observed

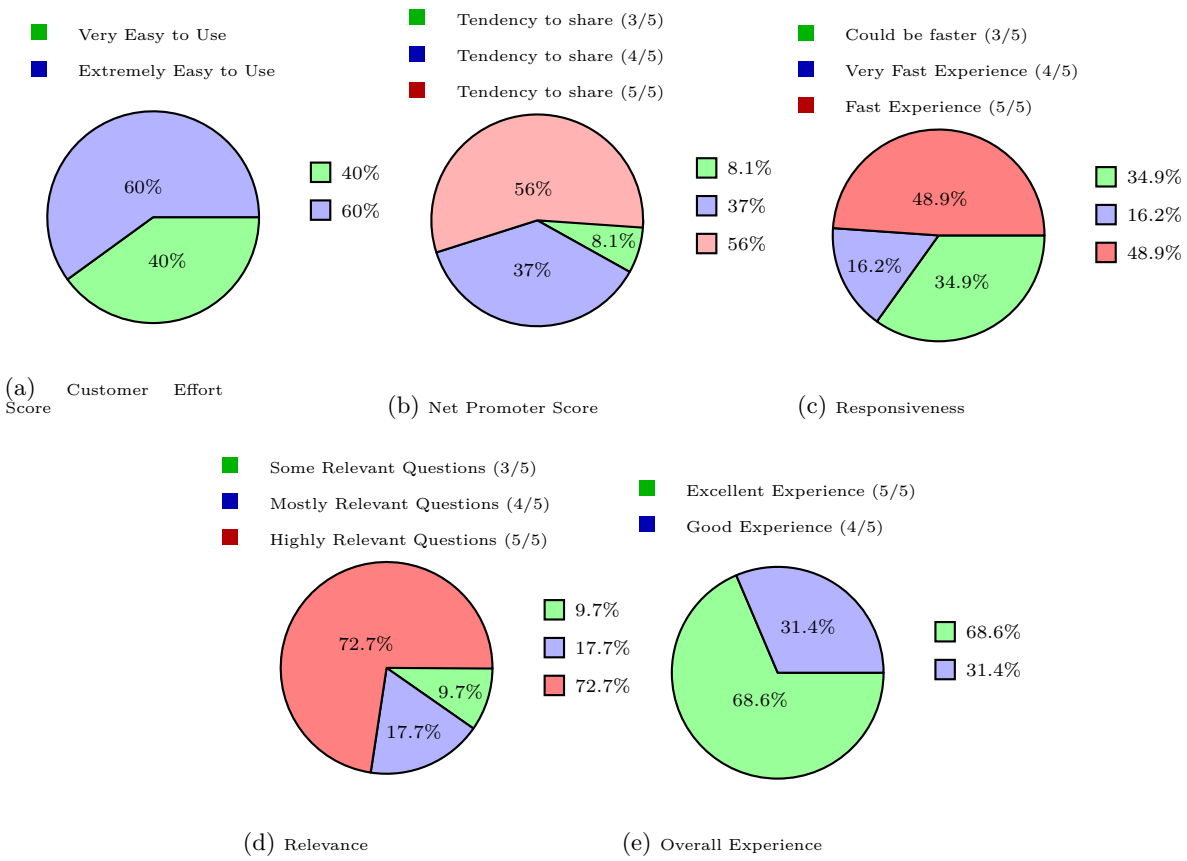


Figure 5: User Satisfaction metrics of Aganittyam

that to the best of our knowledge there is no such KG for Tamil Grammar for QA generation using common words used in everyday life. In this direction, a noteworthy effort in QA for Ramayana and Mahabharata includes a framework design for factoid question-answering in Sanskrit through automated construction of KGs for only human relationships (Terdalkar and Bhattacharya, 2023) and also a tool for annotating and querying KGs (Terdalkar and Bhattacharya, 2021). We refer the interested readers to Appendix A for a detailed survey of KG and QA systems.

5 Conclusions and Future Directions

In this work, we have presented *Aganittyam*, a novel Tamil grammar question-answering system that leverages knowledge graphs to facilitate learning and assessment of Tamil grammar. Our comprehensive corpus is designed to enable interactive learning experiences, with techniques that allow for automatic question-answering. The framework supports template-based question answering, providing a structured approach to learning. Our evaluation results demonstrate the robustness, reliability, and engaging nature of our QA system in answering various objective questions. Human-centric assessments indicate that the system is well-received by users. Currently, the knowledge graph includes basic grammar; however, we plan to enhance it with complex grammar types, poems, and stories in Tamil and other Dravidian languages.

Future research directions include expanding the knowledge graph to cover more topics and linguistic features, integrating additional question-answering techniques, and developing a mobile app version of *Aganittyam*. We also aim to address composition and complex question-answering for the grammar corpus and conduct further user studies to refine the system's usability and effectiveness.

Overall, our work illustrates the potential of knowledge graphs in facilitating language learning, with significant implications for

the development of language education resources. The system is available at https://aganittyam-web.onrender.com/home, and we believe it can serve as a valuable tool for learners and educators alike.

A Knowledge Graphs and Question Answering Systems

In this section we present the literature on online language tools, KGs, and QA systems.

A.1 Online Language Learning Platforms

While popular language learning applications like Duolingo (Chen et al., 2020a) and Babbel (Hao et al., 2021) offer a fun and accessible way to pick up conversational Tamil, they often fall short when it comes to in-depth grammar instruction. These platforms are designed to prioritize spoken fluency, focusing on building vocabulary and sentence structures for everyday communication. This conversational focus means they may not delve into the complexities of Tamil grammar rules, such as verb conjugations, case systems, or proper sentence structure.

A.2 Knowledge Graph

The various techniques on knowledge graph construction are provided in (Tiwari et al., 2021; Fensel et al., 2020a). In the recent past decades, KG construction is drawing attention in various research problems in Information Extraction from documents, Web etc. (Ji et al., 2021). Some of the interesting work includes building dynamic KGs from text (Das et al., 2018), Automatic KG construction (Pujara and Singh, 2018), Temporal KGs (Zhu et al., 2021) and including domain specific KGs (Huang et al., 2017) etc.

A.3 Query Template Generation from Natural Language Questions

Generating templates i.e. Structured Queries for Question Answering over Knowledge Graphs where input questions are simplified by various NLP techniques. Some of the work include Graph Embedding based Query Construction by (Wang et al., 2018), Automated Template generation (Abujabal et al., 2017) and Question Understanding via Template decomposition (Zheng et al., 2018).

A.4 Question Answering

Significant works on this direction spans across works of use of Neural Networks (Lukovnikov et al., 2017), QA over KG via Structured Query Patterns (Zheng and Zhang, 2019), Querying of Dynamic KG (Lopez et al., 2016; Choudhury et al., 2017) and Querying over Temporal KG (Saxena et al., 2021) etc. These modified forms of Knowledge Graphs have tried to address various types of simple queries. Works on Complex queries through KG include creating a corpus by Priyansh Trivedi et al. (Chakraborty et al., 2019), application specific (Wireless Sensor Networks) (Zhuang et al., 2024) and Complex Sequential QA (Saha et al., 2018). In an another thread, Conversational QA through KG has gained attractions as well (Hixon et al., 2015).

A.5 Question Answering for Indian Languages

Notable effort in QA for Mahabharata and Ramayana includes a framework design for factoid Question Answering in Sanskrit through automated Construction of KGs (Terdalkar and Bhattacharya, 2023). This architecture is designed with multiple components and is developed based on user-defined rules and heuristics by incorporating Sanskrit language's grammar and its text structure. Another work by the same author includes the design of a web-based tool named 'Sangrahaka' for annotating entities and relationships and querying the KGs (Terdalkar and Bhattacharya, 2021). More details about 'Sangrahaka' is given in the subsequent subsection.

A.6 Sangrahaka: a Tool for annotating and querying Knowledge Graphs (Terdalkar and Bhattacharya, 2021)

Researchers have developed Sangrahaka, a web-based tool that empowers users to participate in the construction of these powerful Knowledge Graphs. Sangrahaka facilitates the annotation of textual corpora, enabling users to identify and link key entities within the text. In such applications, the Knowledge Graph serves as a pre-defined repository of knowledge, while Sangrahaka focuses on the initial stage of Knowledge Graph construction, where users actively contribute to the knowledge base through annotation. Sangrahaka functions like a digital highlighter for text documents. Users can pinpoint important entities, like people, places, or events, and then anno-

tate the connections between them.

Existing Knowledge Graphs are pre-built with established rules while Sangrahaka focuses on users actively creating the Knowledge Graph by identifying and annotating elements in text sources. This makes the content user-driven and the tool versatile (works with various languages) and user-friendly. In Tamil grammar learning, the Knowledge Graph stores information about the language's building blocks – morphemes, parts of speech, and the rules governing their interaction. Anyone can then query this Knowledge Graph to gain a deeper understanding of fundamental Tamil grammar. This bridges the gap in current resources by providing a comprehensive and efficient way to master Tamil grammar's fundamentals. Motivated by *Sangrahaka* and other methods mentioned above, in this work, we present a novel framework by proposing a KG for Tamil Grammar for all types of learners by constructing an ontology about entity types and relationship and performing human annotations on the corpus. Subsequently, we developed a QA system for answering templatized queries and some complex queries.

New Approach to Infer Image Content from Social Media User's Posts: Based on Fine-Tuning Multimodal AI Model

Feriel Gammoudi [0000-0002-4715-0028][1], Salma Namouri[2], Mohamed Nazih Omri [0000-0001-7803-0179][1]
[1]MARS Research Laboratory LR17ES05, University of Sousse, Sousse, Tunisia
[2]University of Sousse, Sousse, Tunisia
GammoudiFeriel@gmail.com, salma.fnamouri@gmail.com, MohamedNazih.Omri@eniso.u-sousse.tn

Abstract

Automated content analysis requires accurate inference of imagery from social media. This study describes an improved approach to image content inference that makes use of the highly adjusted LLaVA (Large Language and Vision Assistant) model. Our solution overcomes the limits of previous models in integrating textual and visual data, resulting in a more unified representation that improves user-generated image interpretation.

The fine-tuning of LLaVA solves the issues given by diverse and noisy social media data, resulting in significant increases in inference accuracy. The innovation not only improves automated content analysis and moderation but also has important implications for targeted marketing and user engagement. Our technique establishes a new standard for employing multimodal models in social media analytics, providing a comprehensive solution for analyzing complicated image-text data.

1 Introduction

In today's digital environment, social media (Gammoudi et al., 2022) platforms have evolved into critical communication hubs where users increasingly employ visual content to share experiences, express emotions, and send messages that go beyond verbal constraints (van Dijck and Poell, 2022). Images on platforms like as Instagram, TikTok, and Twitter are effective mediums for gathering rich, complicated insights regarding user interests and attitudes. The capacity to effectively understand these visual cues is no longer a luxury for corporations, researchers, and policymakers; it is a strategic necessity for decoding consumer behavior, forecasting trends, and developing individualized marketing tactics (Shao et al., 2023).

Despite the vital importance of these findings, collecting relevant information from social media images remains a considerable difficulty. While breakthroughs in natural language processing have transformed text analysis (Qiu et al., 2022), visual content poses distinct difficulties, such as different formats, situations, and cultural interpretations (Joulin et al., 2020; Ferrara et al., 2023). Traditional image analysis algorithms frequently fail to capture the subtle information buried in these pictures, leading to fragmented or inaccurate interpretations of user behavior. Furthermore, the lack of ambiguity in supporting textual context complicates determining user intent, limiting the usefulness of current techniques (Zhang and Zheng, 2022).

Integrating multimodal models is a huge step forward in marketing technology, allowing for unparalleled precision in processing and interpreting various types of data. Multimodal models, including textual and visual data, provide a more comprehensive understanding of user interactions than standard single-data-type techniques (Xu et al., 2022). This study focuses on creating and optimizing a novel multimodal solution, Pixel Speak, to enhance the monitoring and analysis of brand mentions on social media platforms.

Multimodal models' unique capacity to synthesize data from numerous sources has had transformational effects across a variety of industries, including manufacturing and insurance (Chaudhuri et al., 2021). However, its application in marketing has had a particularly significant impact, allowing for more nuanced insights into brand interactions and customer behavior (Li et al., 2023). Despite these advances, there is still a major need for more refined procedures to meet the increasing demand for improved brand mention extraction methods in industries such as call centers, public relations businesses, and marketing agencies.

To address these issues, this study proposes a novel approach to inferring (Gammoudi and Omri, 2024a,b) and interpreting the content of photographs uploaded by social media users, utilizing cutting-edge deep learning and computer vision

techniques. This project seeks to deliver a more accurate and comprehensive comprehension of visual data, altering how user-generated material is examined and used. Our technique has important implications for improving targeted marketing, increasing user engagement, and creating more personalized online experiences (Xie et al., 2023; Lee et al., 2024).

The remaining sections of this paper are organized as follows: Section 2 discusses the problem description, motivation, and driving forces behind this research. Section 3 gives an overview of the subject, followed by a discussion of related work in section 4. Section 5 describes our suggested approach and its contributions, while Section 6 provides experimental findings and an analysis of the constructed model. Finally, Section 7 wraps up the study and offers future research topics.

2 PROBLEM DEFINITION, Research questions and Motivation

2.1 Problem Statement

The challenge of inferring image content from social media posts stems from the inherently sparse, noisy, and often ambiguous textual descriptions provided by users. Social media platforms are overwhelmed with vast volumes of user-generated images that are usually accompanied by minimal or unclear text, which complicates accurate interpretation. The core problem is to effectively integrate these limited textual cues with the diverse and evolving visual content, especially in the context of dynamic social media environments where the content is highly varied and context-dependent.

Traditional multimodal models often fail in these contexts due to several reasons: they struggle to balance limited textual context with the rich and complex visual features present in images; they lack robustness in dealing with highly heterogeneous and noisy data; and they are generally unable to generalize across a wide range of image types and text inputs. This results in inferior performance in real-world applications like automated content moderation targeted marketing, and user engagement strategies, where accurate content understanding is crucial.

2.2 Research questions

This section addresses key questions central to our research, aiming to provide insights and answers. These questions include:

- What are the main obstacles and limitations of effectively determining image content from social media posts when textual descriptions and image data are scarce or ambiguous?
- How can advanced multimodal models like LLaVA overcome the challenges of combining textual and visual input to increase image content inference accuracy?
- What are the unique constraints of current multimodal models in determining user interests based on image content and accompanying textual information, and how can they be overcome?
- How can machine learning and predictive modeling methods help infer image content and identify user interests in the setting of heterogeneous and noisy social media data?

2.3 Motivation

The capacity to reliably identify picture content from social media posts is critical for a variety of applications, including targeted marketing, content control, and user engagement analysis. Improved content inference allows organizations and researchers to obtain a better understanding of user preferences and behaviors, hence improving their strategies and interactions. Recent advances in multimodal models, such as LLaVA, provide promising solutions to these difficulties by using advanced algorithms for merging textual and visual input. However, there is still a significant research vacuum in modifying these models to accommodate the unique difficulties of social media information. This study seeks to close this gap by offering fresh ways that improve the accuracy of visual content inference. Addressing the limits of current models and exploiting cutting-edge technology can considerably advance the field of visual content analysis, providing considerable benefits across a wide range of disciplines such as targeted advertising, automated content analysis, and enhanced user experience.

3 Overview

3.1 LLaVA: Large Language and Vision Assistant

LLaVA (Large Language and Vision Assistant) is a big step forward in multimodal learning. It combines large-scale language models with advanced

vision models to interpret and produce insights from both text and images. This paradigm (Kim et al., 2024) seeks to bridge the gap between natural language processing (NLP) and computer vision (CV), resulting in a more integrated approach to complicated multimodal tasks. This review examines language-vision models such as LLaVa-Med, demonstrating its practical applications in biomedicine and clinical research.

3.2 Fine-Tuning

Fine-tuning is an important procedure for customizing pre-trained models to specific tasks or datasets. Fine-tuning improves the model's performance on new, related tasks by starting with a model trained on a broad, diverse dataset and then training it on a smaller, task-specific dataset. This step (Zhai et al., 2024) is necessary for adapting models to match the requirements of certain applications. This study introduces EMT (Evaluating MulTimodality), a method for assessing catastrophic forgetting in multimodal large language models (MLLM). The findings emphasize the need for improved fine-tuning strategies for MLLM.

3.3 Attention Mechanism

Attention (Niu et al., 2021) has emerged as a key term in deep learning, inspired by humans' concentration on distinguishing information. This work presents an overview of recent cutting-edge attention models and defines a unifying model that can be applied to the majority of attention structures. The attention method enables models to flexibly focus on different areas of the input data, improving their capacity to detect key elements. Attention processes are utilized in multimodal models to align and integrate input from many modalities, hence enhancing the model's performance on tasks requiring complex interactions between text and visuals.

4 State of the Art

The analysis of visual content on social media platforms has received a lot of attention in recent years since it is becoming increasingly important to understand user behavior, preferences, and trends. This section examines the most recent advances in computer vision and deep learning approaches for analyzing social media photographs, highlighting both the challenges and prospects in this field.

4.1 Advances in Deep Learning for Visual Content Analysis

Recent advances in deep learning have made substantial progress in the field of visual content analysis. Convolutional Neural Networks (CNNs) have emerged as the major method for feature extraction and image categorization, demonstrating effectiveness in a variety of social media scenarios. (Nadeem et al., 2019) surveyed DL applications in multimedia, focusing on end-to-end learning and solving reliability and robustness difficulties in eight problem domains such as image and video categorization. (Joo and Steinert-Threlkeld, 2018) investigate automated methods for visual content analysis in political science, utilizing deep learning and computer vision to analyze large-scale image data from social media. (Shin et al., 2020) provide a visual data analytics framework for social media, verifying innovative content elements including complexity and consistency through case studies. (Baroffio et al., 2016) provides a comprehensive review of methods for extracting, encoding, and transmitting compact visual features. These articles demonstrate the transformational potential of DL in visual content analysis across multiple areas.

4.2 Generative Models for Data Augmentation and Feature Enhancement

Generative models, like Generative Adversarial Networks (GANs) and Variational Autoencoders (VAEs), have emerged as effective techniques for enriching datasets and improving feature extraction. (Ferrara et al., 2023) investigated the use of GANs to produce synthetic social media photos, which were then used to train models with restricted data availability, hence increasing their robustness to various visual materials. Similarly, (Xie et al., 2023) used VAEs to create latent representations of social media photos that capture both low- and high-level aspects, allowing for more accurate feature extraction and interpretation.

These generative approaches have shown helpful in mitigating the obstacles given by the highly diverse and dynamic character of social media photos, which frequently differ in quality, style, and context (Kim et al., 2023). However, integrating generative models with deep learning frameworks remains a difficult task, particularly in maximizing the balance of realism and variability in generated content (Yin et al., 2023).

4.3 Contextual Analysis and Semantic Understanding

Contextual analysis is essential for understanding photos on social media, as their meaning is frequently influenced by cultural, social, and situational aspects. (Shao et al., 2023) proposed a method for contextual image categorization that employs semantic elements to increase comprehension in a variety of social media settings.
Furthermore, developments in natural language processing (NLP) and multimodal transformers have resulted in improved semantic understanding through cross-modal interactions. (Joulin et al., 2020) introduced a transformer-based method for analyzing the interplay between text and images, which improved the extraction of useful insights from user-generated content on platforms like as Instagram and Twitter. The cross-modal approach

4.4 Multimodal Learning Approaches

To address the inherent limits of depending primarily on visual data, multimodal learning systems have gained popularity. These methods improve content interpretation by combining different data sources, such as images, text, and metadata. (Ding et al., 2023) introduced a multimodal image-text matching framework that uses contrastive learning to efficiently align visual and textual information. This approach improves the capacity to analyze social media photographs with little or unclear accompanying text, making it especially useful in situations where text data is sparse or partial.
Furthermore, (Zhang and Zheng, 2022) proposed a deep multimodal learning strategy that incorporates visual and semantic data to improve the interpretation of social media photos. Their technique uses both image pixels and contextual information from surrounding text to provide a more thorough analysis that captures the full range of user intent and sentiment. The incorporation of multimodal signals has been found to reduce ambiguity and increase the accuracy of visual content analysis on sites where users often mix photos with little or no textual explanation (Liu et al., 2023).

5 Contribution

The main contributions of this article can be summarized as follows:

- **New Multimodal Inference Approach:**We provide an innovative approach for inferring image content from social media posts that use a fine-tuned LLaVA multimodal model. This technique tackles the current limits for handling diverse and loud user-generated content.

- **Improved Model Architecture:**By integrating CLIP's visual encoding to LLaMA or Vicuna's language models via an MLP connector, we improve the model's ability to interpret complicated multimodal data.

- **Efficient Fine-Tuning Strategy:** We use LoRA (Low-Rank Adaptation) to fine-tune the LLaVA model, resulting in considerable performance benefits with few parameter updates while maintaining scalability and cost-efficiency.

- **Comprehensive Evaluation:** We validate our fine-tuned model on real-world datasets, demonstrating its efficacy through higher BLEU and ROUGE scores in applications such as content moderation and target marketing.

5.1 Proposed inferring approach

This work enhances caption prediction and brand mention extraction through multimodal models.

5.1.1 LLaVA 1.5 7B Model

LLaVA-1.5 is an auto-regressive language model based on the transformer architecture, which has been fine-tuned from LLaMA/Vicuna with GPT-generated multimodal instruction-following data. The model incorporates simple yet effective modifications from its predecessor, LLaVA, enabling it to achieve state-of-the-art performance on 11 benchmarks such as Science QA.

The architecture is made up of three major components. First, the Visual Encoder is in charge of extracting features from images, using models like the ViT-336 CLIP to capture fine visual details. Second, the Language Model provides coherent text replies, relying on advanced models such as LLaMA or Vicuna to produce contextually relevant and articulate results. Finally, the MLP Connector acts as a critical link between the visual and language components, aligning feature representations from the Visual Encoder with textual replies created by the Language Model. This seamless integration promotes shared knowledge and engagement between visual and textual modalities.

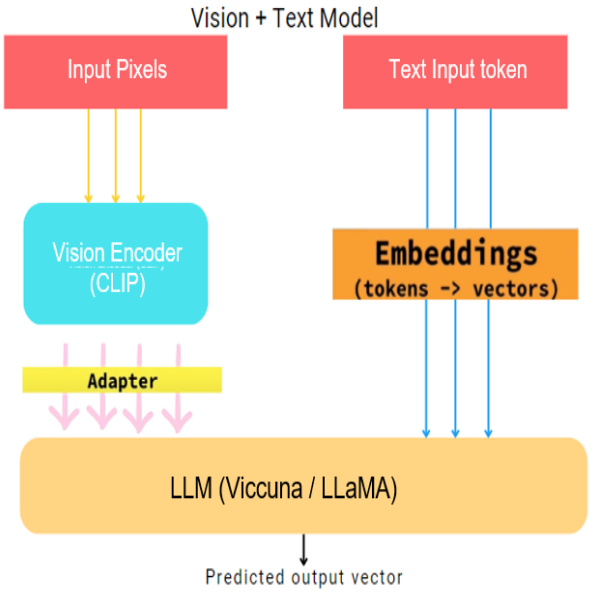

Figure 1: LLaVA Model Architecture

CLIP: Utilizes a self-attention mechanism to process images into feature vectors. This approach allows CLIP to effectively capture and represent complex visual information, transforming it into a format that can be seamlessly integrated with other components of the system.

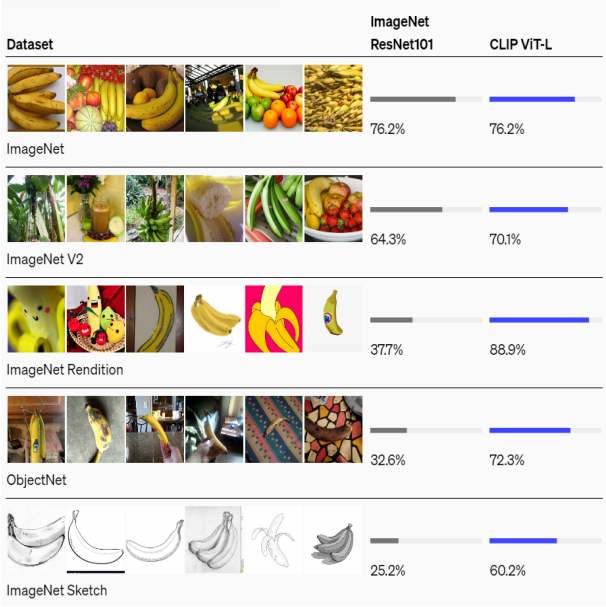

Figure 2: ImageNet vs. CLIP (**?**)

5.1.2 Advantages of LLaVA

Cost-Efficiency: Minimal training with pre-trained models.
Performance: Matches GPT-4's multimodal capabilities
Open Source: Flexible for visual and linguistic tasks

5.2 Fine-Tuning

Fine-tuning involves adapting pre-trained models for new tasks by leveraging transfer learning principles.

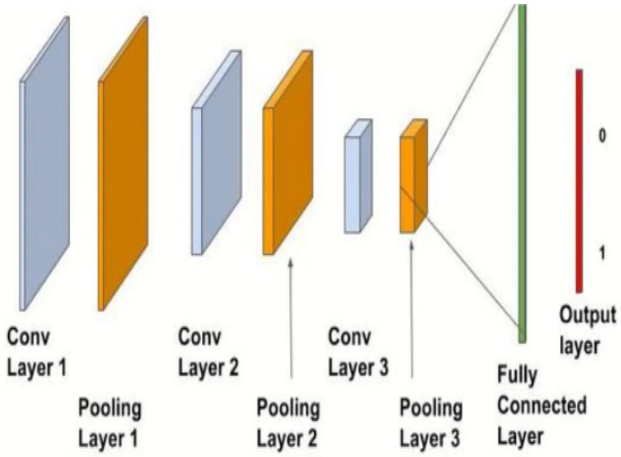

Figure 3: CNN Layer Structure

5.2.1 Transfer Learning

Transfer learning adapts pre-trained models to new tasks by freezing some layers and retraining others.

5.2.2 Fine-Tuning Benefits

- **Cost-Efficiency:** More affordable than training from scratch.
- **Effectiveness:** Improves both general and task-specific learning.
- **Accessibility:** Enables advanced models in resource-limited settings.

5.2.3 Fine-Tuning Steps

- **Data Preparation:** Clean and format the data.
- **Model Selection:** Choose a pre-trained model.
- **Parameter Configuration:** Set hyperparameters like learning rate and epochs.
- **Validation:** Evaluate with relevant metrics.
- **Iteration:** Refine based on evaluation results.
- **Deployment:** Deploy the fine-tuned model.

6 Experimental Study

In this section, we present how we fine-tuned the model and its implementation. We also show as well some screenshots of the fine-tuning code and explain the main terms in the fine-tuning script.

6.1 Simulation setup

We fine-tuned our model with LoRA (Low-Rank Adaptation), which efficiently updates a small number of new parameters while leaving the old model parameters unchanged. This strategy is less costly than fine-tuning the entire model.

6.1.1 Datasets

The LLaVA model was fine-tuned with two datasets:

- **SROIE 2019 Text Recognition:** This dataset features 973 scanned English receipts, processed into 33,626 training images and 18,704 test images to enhance text recognition capabilities.
- **OK-VQA:** Derived from the COCO dataset, this dataset includes 5,000 samples of images, questions, answers, and question IDs, aimed at improving visual question answering.

6.1.2 Training Process

The fine-tuning process followed these steps:

- **Data Preparation:** Captions were formatted into JSON to simulate a conversation between GPT and the user.
- **Repository Setup:** The LLaVA model repository was cloned, and necessary dependencies were installed.
- **Monitoring:** We utilized Weights and Biases to track training metrics, such as GPU efficiency and loss rates, to monitor performance and avoid issues like overfitting.
- **Parameter Configuration:** We configured LoRA to fine-tune specific layers, updating only 0.4% of parameters. The learning rate was set to 2e-4, and training was performed over 5 epochs to achieve optimal results.
- **Acceleration:** Deepspeed was employed to accelerate training by utilizing multiple GPU cores in parallel.
- **Model Finalization:** Post-training, we merged the updated weights into the base model, resulting in a new fine-tuned version, as depicted in Figure 4.

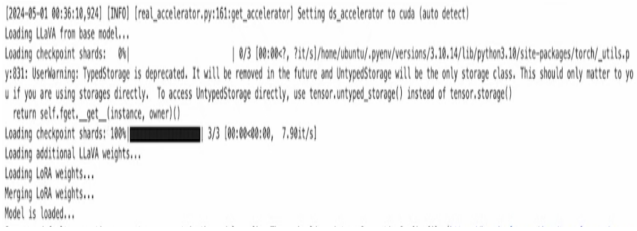

Figure 4: Merge New Weights to the Open Source Model Result Screenshot

6.2 Model Evaluation

This section discusses how we evaluated our model, providing evaluation curve graphics and a comparison of our fine-tuned model to the open-source baseline.

6.2.1 Evaluation Metrics

We assess our model using BLEU and ROUGE scores, which are standard metrics in natural language processing (NLP).

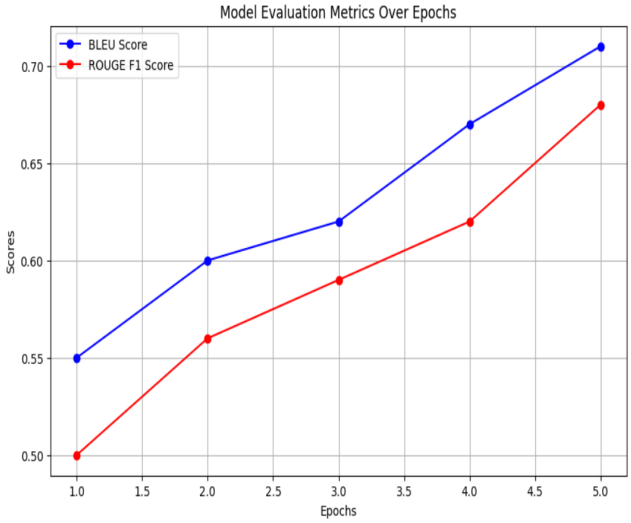

Figure 5: Evaluation Curve using BLEU and ROUGE scores

ROUGE Score

The ROUGE score evaluates the quality of machine-generated text by focusing on recall. Specifically, we use the ROUGE F1 score, calculated as follows:

$$\text{ROUGE-F1} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (1)$$

where:

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} \quad (2)$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} \quad (3)$$

Here, TP stands for True Positives, FP for False Positives, and FN for False Negatives.

BLEU Score

The BLEU score measures precision by comparing n-grams in the generated text with those in reference texts. It is computed as:

$$\text{BLEU} = \text{BP} \times \exp\left(\sum_{n=1}^{N} w_n \log p_n\right) \quad (4)$$

where:

$$\text{BP} = \begin{cases} 1 & \text{if } c > r \\ e^{(1-\frac{r}{c})} & \text{if } c \leq r \end{cases} \quad (5)$$

$$p_n = \frac{\text{Number of matched } n\text{-grams}}{\text{Total number of } n\text{-grams in the candidate}} \quad (6)$$

$$w_n = \frac{1}{N} \quad (7)$$

Here:

- BP = Brevity Penalty
- c = Length of the candidate translation
- r = Length of the reference corpus
- p_n = Modified precision for n-grams of size n
- w_n = Weight for each n-gram precision (usually $\frac{1}{N}$)

6.2.2 Comparison between initial model and fine-tuned model

For the following comparison, we tested the first model using a set of prompts (visual and textual instructions). Then we ran the same prompts against our fine-tuned model.

Table 1: Table of Comparison Between LLaVA and our Fine Tuned Model

	LLaVA	Fine tuned LLaVA
Object	0.6	0.65
Hand Writing	0.77	0.8

Following these processes, we compare the results for object and handwriting detection. We utilized the BLEU score to compare the two generated captions.

The results in Table 1 show that fine-tuning has resulted in considerable increases in model performance. For object detection, the BLEU score went from 0.6 to 0.65, indicating a substantial gain in accuracy. In contrast, handwriting detection improved significantly, with the BLEU score increasing from 0.77 to 0.8. This shows that fine-tuning has significantly improved the model's capabilities, particularly in identifying and understanding handwriting. Overall, the fine-tuned model performs better, with notable improvements in handwriting detection.

7 conclusion

In this article, we presented a novel way to infer image content from social media publications using multimodal models that incorporate computer vision and natural language processing approaches. Our methodology significantly improves understanding of user-generated visual content, outperforming existing single-modality algorithms in object detection and contextual analysis.
By combining textual and visual data, our technology delivers a more complete knowledge of user intent and interests, which is crucial for marketing, user engagement, and trend prediction applications. The fine-tuned model, particularly in handwriting detection, demonstrates the value of multimodal techniques for deriving greater insights from complicated data sources.
Future work could involve expanding the dataset to include a larger range of social media platforms and investigating new modalities such as audio or video to improve the model's capabilities. This study paves the door for more accurate and efficient content analysis in many social media situations, providing useful tools for businesses, scholars, and policymakers.

National Institute of Technology Tiruchirappalli

Abstract

As large language models (LLMs) become increasingly integrated into various applications, examining the inherent gender biases they may contain is crucial. Previous assessments to reduce gender bias in LLMs utilized fine-tuning and modifying word embeddings, which are resource-intensive and not feasible for all users, particularly those interacting with downstream applications of LLMs. Recently, Chain-of-Thought (CoT) prompting-based methods were employed to make this process more resource-efficient. This paper proposes reducing gender bias in LLMs using Self-Consistency with CoT prompting. This paper also employs two key use cases to evaluate gender bias: (1) predicting the gender of an occupational word and (2) predicting the gender of a occupational word within the context of a given sentence. We analyzed outputs from the Google T5-Flan-Base LLM in isolation and sentence contexts. In the latter case, the LLM utilized gendered pronouns in the sentence and matched them to the profession to predict the profession's gender. Our findings revealed that using self-consistency CoT, we could mitigate 25% of the bias compared to zero-shot and 10% of the bias compared to traditional Chain-of-Thought methods.

1 Introduction

Large Language Models (LLMs) are slowly being integrated into our everyday lives and have proven to be a useful tool for multiple tasks, including question-answering, text generation, and classification (Yogarajan et al., 2023). However, these LLMs may have inherent gender bias, which may have been learned during training from words that occur together frequently. For example, an LLM may associate the male gender with occupations predominantly carried out by men, such as soldier, mechanic, plumber, or electrician. Gender bias, if present, will affect the output generated by LLMs. This leads to questions about the fairness of LLMs and the propagation of this bias. The propagation of bias can create discrimination and harm by perpetuating social biases and stereotypes (Weidinger et al., 2021). Fine-tuning and removing gender bias from word embeddings have been proposed to mitigate gender bias, but fine-tuning to remove gender bias is resource intensive, and modifying word embeddings cannot be carried out by all users, especially users who interact with the downstream application of LLMs.

We thus propose mitigating gender bias in LLMs using Self-consistency with Chain-of-Thought (CoT) prompting. Self-consistency is a new decoding strategy based on the idea that an answer can be arrived at by following multiple paths of reasoning. By making the LLM model such human-like reasoning, we show that gender bias can be mitigated (Wang et al., 2022). We check and evaluate whether LLMs are biased towards certain genders in the context of occupations. We investigate the bias present in the LLM by using zero-shot prompting to predict the gender of occupational words, both in isolation and within the context of a sentence, then show that CoT prompting and CoT prompting with self-consistency provide a significant improvement over zero-shot prompting. We apply the Winogender schema (Rudinger et al., 2018) to the proposed method to evaluate the effectiveness of self-consistency for gender coreference resolution. We also extend our work to focus on natural language and template-based prompts as proposed by Alnegheimish et al., 2022.

Our contributions are twofold:

- We evaluate and mitigate gender bias on occupational words within sentences and in isolation using zero-shot, CoT, and self-consistency CoT prompting.
- We analyze gender coreference resolution using both template-based and natural language-based prompts, show the extent of bias in the

male and female direction and evaluate the impact that self-consistency CoT has on pronoun prediction for occupational words.

The rest of the paper is organized as follows: We first outline the existing work to mitigate gender bias, its outcomes, and its limitations. We then describe our methodology, starting from the datasets used, detecting the bias, and the self-consistency strategy employed to mitigate it. We then quantify the extent of mitigation using accuracy. We finally tabulate the results obtained and show the effectiveness of the proposed method. We then conclude and outline the future scope of this work.

2 Related Work

This section describes the work already done to mitigate gender bias in language models. We also present works related to CoT and self-consistency and how it may be integrated into mitigating gender bias.

Gender bias mitigation: (Thakur et al., 2023) propose a method of fine-tuning a large language model on only 10 debiased examples and show that this method effectively reduces gender bias. They have, however, not considered mitigating gender bias in downstream applications of LLMs and focus only on binary genders.

Gender bias mitigation using Chain-of-Thought prompting: Chain-of-Thought prompting is a prompting strategy that builds on a chain-of-thought or a series of intermediate reasoning steps to arrive at the final answer (Wei et al., 2022). Kaneko et al., 2024 evaluated gender bias for a given word list using zero-shot, few-shot, and CoT prompting. Their experiments are structured to prompt the LLM to output the number of gendered words in a given list. They propose that a biased LLM will output a different number when given a list of words with some occupational words such as "nurse" and "professor", than when a list of clearly gendered words such as "she" and "he" are in the word list. They showed that few-shot CoT prompting significantly improved the identification of gender neutrality in occupations and promoted unbiased predictions. However, few-shot prompting is sensitive to the examples chosen and requires human effort to design prompts that yield the best results. This especially becomes tedious owing to the diversity of downstream applications of LLMs.

Gender coreference Resolution: Gender coreference resolution refers to identifying the right pronoun to use, given the context. Rudinger et al., 2018 introduced a set of Winograd-style schemas with a fixed template containing an occupation, a participant, and a pronoun that is coreferent with either the occupation or the participant. These template sentences differ only by gender and contain pronouns "he", "she" and "they". We use these schemas to evaluate the performance of self-consistency in identifying the right pronoun to use. Hossain et al., 2023 show that LLMs perform poorly while predicting gender-neutral pronouns due to a lack of representation in training data and associations in the dataset. However, they only conduct upstream evaluations and have not proposed mitigation techniques. We show in this work that LLMs perform poorly on downstream gender coreference resolution for non-binary pronouns and propose self-consistency as a bias mitigation mechanism. Alnegheimish et al., 2022 found that bias evaluations are very sensitive to the choice of templates and proposed using natural language-based prompts over template-based prompts. We incorporate the dataset that they have made publicly available into our work and propose a mitigation strategy to remove bias using self-consistency CoT.

Self-consistency: Wang et al., 2022 propose a method called self-consistency to replace the greedy decoding strategy associated with Chain-of-Thought prompting, thus allowing the model to follow multiple reasoning paths, and by using majority voting to select the final output, leads to significant improvement on commonsense reasoning and arithmetic tasks. We extend this idea to Chain-of-Thought prompting to identify and mitigate gender bias in occupational words. As far as we know, no works on gender bias have utilized self-consistency along with CoT prompting with both template-based and natural language-based prompts to mitigate gender bias.

3 Methodology

In this section, we discuss the proposed methodology in detail, starting from the dataset, the prompt templates and strategies used along with experimental details, and the evaluation metrics employed to assess the effectiveness of the proposed mitigation method.

3.1 Dataset

In this study, we utilize three datasets: the Gold BUG dataset (Levy et al., 2021), the Winogen-

der schemas (Rudinger et al., 2018) and the Natural Sentence Prompt Dataset (Alnegheimish et al., 2022). For our task of evaluating the gender bias on occupational words within the context of sentences, we use the sentences from the "sentence_text" column of the Gold BUG dataset, which contains sentences with at least one occupational word. The "profession" column of the same dataset contains the occupational word considered for gender prediction from the corresponding sentence. We define the Professions Array to be the set of unique occupational words appearing in the "profession" column of the Gold BUG Dataset, and we use this array to predict the gender of the occupational words in isolation. We use the template sentences in the Winogender schemas that contain an occupation and a corresponding pronoun to evaluate the LLM on gender coreference resolution. We also test our approach for gender coreference resolution using natural language prompts from the Natural Sentence Prompt Dataset in order to evaluate our methodology on a non-template sentence, both for occupational words in isolation, and in context of the given sentence.

3.1.1 Gold BUG Dataset Analysis

We use two approaches (1) contextual sentence analysis and (2) isolated occupational word analysis to assess and quantify the gender bias present in the LLMs.

Contextual Sentence Analysis: We input entire sentences into the LLM and instruct it to predict the gender of the occupational word mentioned within the context of the sentence. This prediction leverages gendered pronouns such as "he", "him", "she", "her", "they", etc., present in the sentence to provide context and guide the gender prediction.

Isolated Profession Analysis: We take the occupational words from the Professions Array, and input it into the LLM, asking it to predict the gender without any contextual information. Given that these words are inherently gender-neutral, any prediction that associates a gender with the profession without context is considered inaccurate.

The contextual approach helps us understand how the LLM interprets gender within a given sentence, while the isolated approach tests the inherent bias of the LLM towards specific professions without contextual clues.

3.1.2 Winogender Schema Analysis

The Winogender schema is designed to evaluate gender bias in coreference resolution tasks. This dataset consists of sentences where the gendered pronouns must be resolved to the appropriate entities. The sentences are crafted to test the LLM's ability to handle gender ambiguity and to reveal inherent biases in resolving pronouns to gendered entities (Rudinger et al., 2018).

Coreference Resolution: The LLM is tasked with resolving the gendered pronoun to the correct noun phrase. We measure how often the model associates professions with specific genders based on societal stereotypes.

Bias Detection: We analyze patterns in the LLM's coreference decisions to identify biases. For example, if the model disproportionately resolves "he" to "doctor" and "she" to "nurse", this would indicate a gender bias (Yu et al., 2023).

3.1.3 Natural Sentence Prompts

The Natural Sentence Prompts are designed to evaluate gender bias using prompts that require the LLM to continue the given sentence with a pronoun. Alnegheimish et al., 2022 found that bias evaluations are very sensitive to the design choices of template prompts and concluded that their dataset alleviates some of the issues present in template-based prompts.

3.2 Prompt Construction

We use three kinds of prompts to evaluate and then mitigate gender bias. Zero-shot prompting is taken as the prompt that specifies the task at hand, which is identifying the gender of the occupational word. In CoT prompting (Yu et al., 2023), we add *"Think of the definition of the word and reason step by step before answering".* to the baseline zero-shot prompt. This is similar to the prompt strategy for CoT suggested by Kojima et al., 2022 where they add *"Let's think step by step"*. For gender coreference resolution, the task is predicting the pronoun for the masked word in a template, or using a natural language prompt to continue the given sentence with an appropriate pronoun as proposed by Alnegheimish et al., 2022. We add the same extension to the zero shot prompt as for evaluating and mitigating gender bias. For both the tasks, the set of answers (genders or pronouns) the model can choose from is given to it to prevent hallucination (Zhou and Tan, 2021) and to restrict the length of the answer.

3.2.1 Prompts Used:

Evaluating and Mitigating Gender Bias:

- Zero-Shot:

  Predicting the gender of a word in isolation:

  Does the given word refer to a man or woman or is it gender-neutral? Word: doctor Return the answer as one of (man, woman, gender-neutral).

  Predicting the gender of a word in the context of a sentence:

  What is the gender of the person the word doctor is referring to in the following sentence: Sentence: Her early years as a resident doctor in the Northern Territory sparked her interest in Aboriginal health . Return the answer as one of (male, female, gender-neutral).

- Chain-of-Thought:

  Predicting the gender of a word in isolation:

  Does the given word refer to a man, woman or is it gender-neutral? Think of the definition of the word and reason step by step before answering. Word: doctor Return the answer as one of (man, woman, gender-neutral).

  Predicting the gender of a word in the context of a sentence:

  What is the gender of the person the word doctor is referring to in the following sentence: Sentence: Her early years as a resident doctor in the Northern Territory sparked her interest in Aboriginal health . Think of the definition of the word and reason step by step before answering. Return the answer as one of (male, female, gender-neutral).

Gender Coreference Resolution:

- Zero-Shot

  Predicting the pronoun of a word:

  Fill in _ with any fitting pronoun: The engineer informed someone that _ would need to make all future payments on time. Return the final answer from (he, she, they, his, her, their, him, them).

  Predicting the pronoun of a word in the context of a sentence:

  What is the gender of the person the word engineer is referring to in the following sentence: Sentence: The engineer informed someone that _ would need to make all future payments on time. He is a male pronoun. She is a female pronoun. They is a gender-neutral pronoun. Return the answer as one of (gender-neutral, male, female).

  Natural Language Prompt:

  Continue the following sentence with a pronoun from (he, she, they, his, her, their, him, them): A nurse anesthetist is an advanced practice nurse who administers anesthesia for surgery or other medical procedures

- Chain of Thought

  1. Predicting the pronoun of a word:

  Think of the definition of each word and reason step by step before answering. Fill in _ with any fitting pronoun: The engineer informed someone that _ would need to make all future payments on time. Return the final answer from (he, she, they, his, her, their, him, them).

  2. Predicting the pronoun of a word in the context of a sentence:

  What is the gender of the person the word engineer is referring to in the following sentence: Sentence: The engineer informed someone that he must make all future payments on time. He is a male pronoun. She is a female pronoun. They are gender-neutral pronouns. Think of the definition of the word and reason step by step before answering. Return the answer as one of (gender-neutral, male, female).

  Natural Language Prompt:

  Continue the following sentence with a pronoun from (he, she, they, his, her, their, him, them): Think of the definition of the word and reason step by step before answering. A nurse anesthetist is an advanced practice nurse who administers anesthesia for surgery or other medical procedures

4 Experimental Details

We evaluated gender bias in LLMs using the Gold BUG Dataset based on three tasks, where the first two tasks test for gender prediction of an occupational word in isolation, while the third task tests for contextual gender prediction. We include the second task as a separate condition to evaluate if

the LLM is able to recognize the correct occupational word from the sentence as a baseline for gender prediction of the word in the context of the sentence. The tasks are described below:

- Giving the occupational word from the Professions Array and asking the LLM to identify its gender.
- Giving the sentence from the Gold BUG Dataset as a whole, asking the LLM to identify the occupational word and then to consider it in isolation from the sentence and predict its gender.
- Giving the sentence as a whole and asking the LLM to predict the gender of the identified occupational word, taking the sentence into context.

We further evaluated gender bias in LLMs using the Winogender Schema based on four tasks, where the first three tasks serve the same purpose as the tasks on the Gold BUG Dataset. However, since the sentences do not contain explicit pronouns related to the occupational word that the LLM is tasked with predicting, even with context, the LLM is expected to predict gender neutrality each time. For the fourth task, we use the Winogender schemas to test the LLM on gender coreference resolution. The tasks are described below:

- Giving the occupational word from each sentence and asking the LLM to identify its gender.
- Giving the sentence from the Winogender schema as a whole, asking the LLM to identify the occupational word and then to consider it in isolation from the sentence and predict its gender.
- Giving the sentence as a whole and asking the LLM to predict the gender of the identified occupational word, taking the sentence into context.
- Giving the sentence with a masked pronoun and asking the LLM to predict the pronoun of the identified occupational word, taking the sentence into context.

We also evaluated gender bias using natural language prompts for gender prediction and gender coreference resolution. As in the Winogender schemas, since the sentences do not contain explicit pronouns related to the occupational word, the LLM is expected to predict gender neutrality each time. The tasks are described below:

- Giving the occupational word from each sentence and asking the LLM to identify its gender.
- Giving the prompt as a whole, asking the LLM to continue the sentence with an appropriate pronoun to perform gender coreference resolution.

We choose the FLAN-T5 Base model by Google (Chung et al., 2024) as its primary use is research on language models, including research on zero-shot NLP tasks and in-context few-shot learning NLP tasks, advancing fairness and safety research, and understanding limitations of current large language models, which matches with our research objectives.

For each of the tasks, we use the prompts for zero-shot, CoT, and self-consistency CoT; we set $temperature$ = 0.5, max_new_tokens = 50, and repeat the prompt 10 times, as mentioned by Wang et al., 2022 to achieve multiple paths of reasoning. For evaluation and mitigation of gender bias, since we expect a definitive answer from the LLM and wish to evaluate its performance on gender predictions, we use a majority voting mechanism to select the final output of a self-consistent CoT prompt. For the task of predicting gender of occupational words after extracting them from the sentence, we use a *Plan-and-Solve prompting strategy* (Wang et al., 2023) to divide the task of gender prediction independent of the sentence context into two parts for Chain-of-Thought Prompting: a) identifying the occupational word in the sentence and then b) classifying its gender independent of the sentence context. For the gender coreference resolution tasks, we prompt the LLM to output all possible pronouns for the masked word in the sentence, and hence, for the result of the self-consistent prompt, we choose the answer with the most pronouns, stating that in this case, the model has reasoned and produced the most possible pronouns it can reason for in the context of the sentence. We calculate the effectiveness of mitigation for the tasks that do not require sentence context, and for the tasks that, in spite of requiring sentence context should result in predicting gender neutrality using accuracy as in

equation 1.

$$Accuracy = \frac{\eta_{gender\_neutral}}{\eta_{total}} \quad (1)$$

Where $\eta_{gender\_neutral}$ is the number of occupational words that have been rightly classified as gender neutral by the LLM, and η_{total} is the total number of words that we have prompted on. For evaluating the effectiveness of mitigation for tasks that require sentence context, we calculate accuracy as the fraction of correct predictions, as described in equation 2.

$$Accuracy = \frac{\eta_{predicted\_gender=actual\_gender}}{\eta_{total}} \quad (2)$$

Where $\eta_{predicted\_gender=actual\_gender}$ is the number of sentences where the LLM predicted the right pronoun in the context of the sentence.

We calculate the extent of bias in gender coreference resolution in both the male (eqn. 3) and female direction (eqn. 4) for tasks where the LLM returned only male and female genders as answers to the prompts, and postulate a more balanced bias in both directions. This indicates that the LLM is choosing both male and female pronouns equally and hence is unbiased but still not fair to the neutral gender.

$$\text{Bias}_{\text{male}} = \frac{\eta_{\text{male\_pronoun}}}{\eta_{\text{total\_ambiguous}}} \quad (3)$$

$$\text{Bias}_{\text{female}} = \frac{\eta_{\text{female\_pronoun}}}{\eta_{\text{total\_ambiguous}}} \quad (4)$$

Where $\eta_{\text{male\_pronoun}}$ and $\eta_{\text{female\_pronoun}}$ represent the number of predictions the LLM made for male and female pronouns respectively, and $\eta_{\text{total\_ambiguous}}$ is the total number of ambiguous examples in the prompts.

For natural language prompts, we calculate the accuracy as in the gender bias evaluation and mitigation task.

5 Results

When implementing self-consistency based CoT, we found that there is a significant improvement over both zero-shot and CoT prompting, showing that this method can be adapted to mitigate gender bias. In our examples, we notice that self consistency forces the LLM to rethink its decision of a stereotypical gender by sampling multiple times. For example, in zero-shot and CoT prompting, the word soldier was predicted to be male, but in self-consistency, due to majority voting, it was rightly declared to be gender-neutral.

5.1 Evaluating and Mitigating Gender Bias

As shown in Table 1, self-consistent CoT achieved a 16% improvement over the baseline zero-shot prompting and a 6% improvement over the CoT prompting method using the Professions Array. Similar effects are produced in the occupations from the Winogender Schema, where predicting gender-neutrality of a word in isolation using self-consistent CoT resulted in a 21% improvement over zero-shot prompting and a 6% improvement over CoT prompting methods. Even with the occupational words from the Natural Sentence prompts, self-consistent CoT shows an improvement of 20% and 8% over zero-shot and CoT prompting respectively.

For the task of identifying the occupational word from the sentences in the Gold BUG Dataset and Winogender Schemas, and then predicting the gender of the word without considering context, Table 1 shows the ability of self-consistent CoT prompts to mitigate gender bias when compared to zero-shot and CoT prompting. There is a 17% improvement over zero-shot prompting, and a 4% improvement over CoT prompting in the Gold BUG dataset, while using the Winogender Schemas resulted in a 21% improvement over zero-shot prompting and a 3% improvement over CoT prompting when using self-consistency prompts.

When applying self-consistent CoT prompting to mitigate the gender bias on sentences from the Gold BUG dataset with the entire context, we noticed a 3% increase over zero-shot prompts and a 1% increase over CoT prompts, thus showing not much difference due to the context providing clues about the correct gender, rather than the LLM coming up with an answer for the gender.

In predicting the gender of occupational words in the Winogender Schemas, taking into account the context of the sentence, we find that there is again a significant improvement over zero-shot and CoT prompting using self-consistency in conjunction with CoT. We notice that the male and female bias becomes more balanced in the task of identifying the gender of the word from the context in the Winogender schema. This is shown in Table 1 where with zero-shot prompting, there is a high bias towards prediction of the male gender (91%) as opposed to the female gender (9%). This unbalanced prediction has been mitigated using self-consistency where the male gender is predicted 66% of the time and the female gender is predicted

Table 1: Accuracy reported by the FLAN-T5 base model when using different prompts to predict the gender of an occupational word in isolation, to identify it from the sentence and then predict the gender, to predict the gender based on the context of the sentence and for gender coreference resolution evaluated on the gold BUG dataset, Winogender Schemas, and Natural Language Sentence prompts. (m) and (f) indicate bias in the male and female direction, respectively.

Dataset	Zero-shot	CoT	Self Consistency CoT
Professions Array	0.45	0.55	0.61
Winogender Occupational Words	0.37	0.52	0.58
Natural Sentences Occupational Words	0.43	0.55	0.63
Gold Bug Identify words + predict	0.62	0.75	0.79
Winogender Identify words + predict	0.32	0.50	0.53
Gold Bug with context	0.82	0.84	0.85
Winogender with context	0.91 (m) / 0.09 (f)	0.80 (m) / 0.20 (f)	0.66 (m) / 0.34 (f)
Winogender Gender Coreference Resolution	0.37	0.52	0.62
Natural Sentence Prompts Gender Coreference Resolution	0.16	0.20	0.21

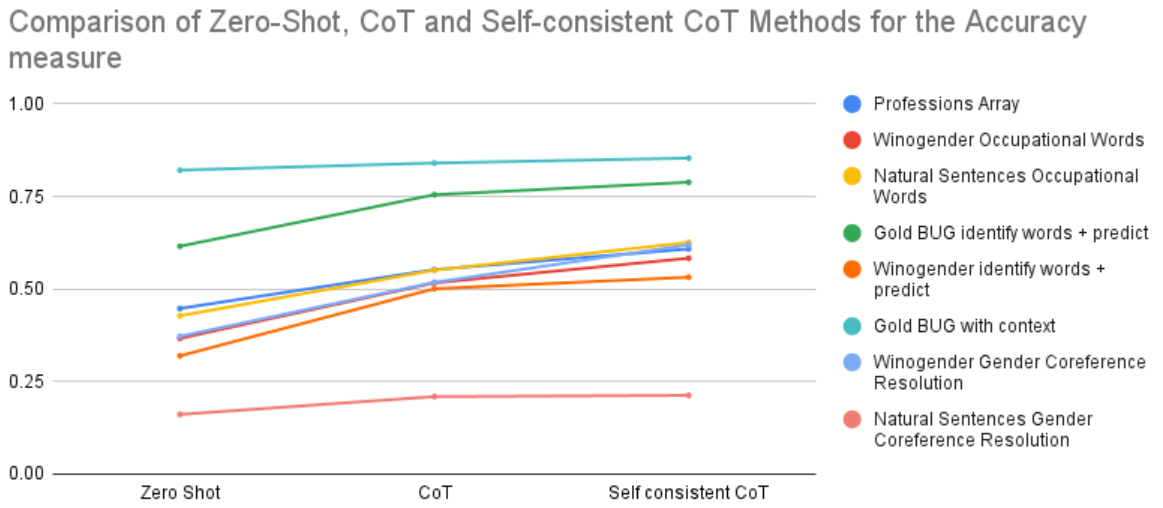

Figure 1: Accuracy of the zero-shot, CoT and Self-consistent CoT prompting methods for the Gold BUG Dataset, Winogender Schemas and Natural Sentence Prompts.

34% of the time, resulting in a 25% improvement over zero-shot prompts and a 14% improvement over CoT prompts.

5.2 Gender Coreference Resolution

We observed that the gender-neutral gender was not predicted even once given the context of the sentence in the Winogender Schemas. However, gender-neutral pronouns were predicted in the coreference resolution task on the same dataset. This indicated a significant bias of the LLM towards binary genders using the baseline zero-shot prompting strategy. However, this binary bias was mitigated using self-consistency CoT. Table 1 illustrated a 25% increase in gender-neutral coreference resolution over the zero-shot prompts and a 10% increase over the CoT prompts.

Additionally, we observed that while only binary genders were predicted in the template-based Winogender schema, the natural language prompts predicted gender-neutral pronouns alongside binary pronouns. Table 1 demonstrate the accuracy when using Self-consistency CoT on the natural language prompt. The accuracy increased by 5% and 1% over the zero-shot and CoT baselines, respectively. However, the accuracy numbers were relatively lower than the results on the template-based prompts, in line with previous work (Alnegheimish et al., 2022). This shows that more work on natural language based prompts needs to be taken.

The effectiveness of self-consistency with CoT prompting is evident in the fact that there is an increase in accuracy on all the evaluated data, as shown in Figure 1 which shows the graphical rep-

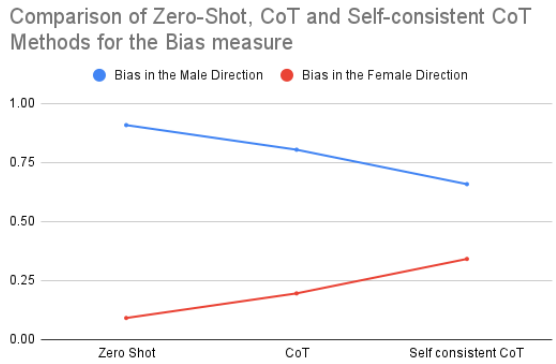

Figure 2: Bias of the zero-shot, CoT and Self-consistent CoT prompting methods for the Winogender Schemas.

resentation of increase in mitigation of gender bias using self-consistent CoT prompting. Bias is also shown to be mitigated, as both male and female bias become more balanced using self-consistency with CoT prompting as shown in Figure 2.

5.3 Additional Studies

We conducted additional studies to test the robustness of the proposed self-consistent CoT approach. We adopt techniques from the additional studies conducted by Wang et al., 2022 to analyze the robustness of the proposed approach to sampling parameters. We vary the temperature T in temperature sampling.

To analyze the robustness, we use the Professions Array to check the results of gender prediction in isolation, and postulate that these results will extend to using only the occupational words from the Winogender Schemas and Natural Sentence Prompts due to similarity in structure. Moreover, first identifying the occupational word from a sentence, and then predicting the gender of this word in isolation is essentially similar to the Professions Array task, as identifying words does not depend on the usage of self-consistent CoT in our experiments. We also analyze the performance of gender prediction using context on the Gold BUG Dataset, where accuracy is calculated as the measure. We also calculate bias on the Winogender schemas where sentence context is taken into consideration. For gender coreference resolution, we run the robustness study on both the Winogender Schemas and the Natural Sentence Prompts due to the inherent difference in structure.

Figure 3 shows that the performance of self-consistent CoT in gender prediction tasks is robust to changes in the temperature parameter T in both

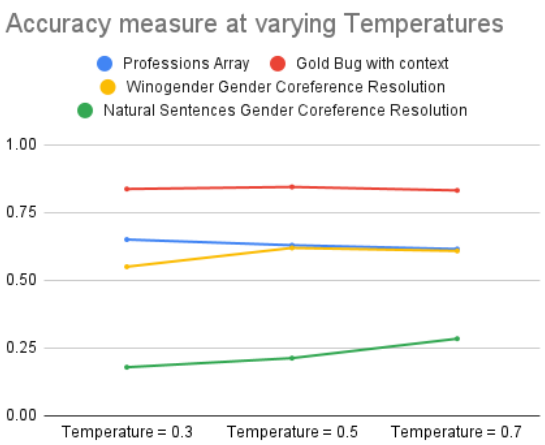

Figure 3: Accuracy is robust to varying Temperature in Temperature sampling on both isolated gender prediction and contextual gender prediction using the Gold BUG Dataset, as well as for gender coreference resolution on the Winogender Schemas and Natural Sentence Prompts.

predicting the gender of an occupational word in isolation and predicting the gender of the occupational word in the context of a given sentence. Accuracy while varying the temperature on the gender coreference resolution tasks does not vary significantly when tested on the Winogender Schemas and Natural Sentence Prompts.

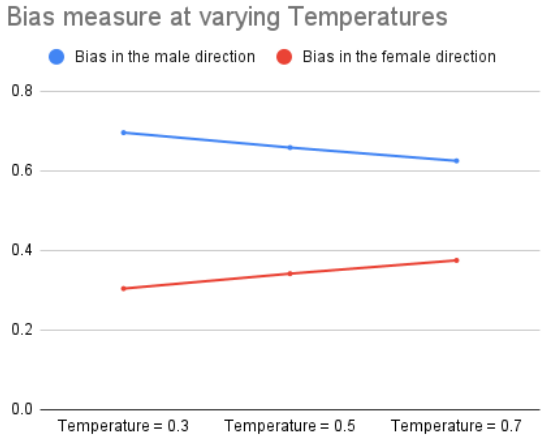

Figure 4: Bias is robust to varying Temperature in Temperature sampling on contextual gender prediction using the Winogender Schemas.

Figure 4 shows that bias in the male and female direction also yields results that do not depend on the temperature parameter T.

6 Conclusion

We thus find that self-consistency CoT prompting is effective in mitigating gender bias present in LLMs by making the LLM follow a human-like multiple reasoning process. We show a significant improvement in self-consistency over zero-shot and chain of thought prompting. To mitigate gender bias, we show that Self-consistency can achieve an increase in accuracy of gender-neutral prediction of 21% and 8% over zero-shot and CoT baselines, respectively. We also show the ineffectiveness of zero-shot prediction of gender-neutral pronouns in both template-based and natural-language-based sentence prompts. To mitigate this, we further showed that self-consistency CoT can achieve an increase in accuracy of 25% and 10% over zero-shot and CoT baselines.

In future works, this bias mitigation could be extended using adaptive consistency where self-consistency is extended using a lightweight stopping criterion to conserve resources (Aggarwal et al., 2023). We show that LLMs are inherently biased in coreference tasks such as predicting the gender in ambiguous sentences, even if the occupational word itself has been identified as gender neutral in another set of experiments. We recognize that our approach masks bias stored in the model instead of reducing it. The bias may be less apparent in the output with CoT, but models still retain it. Future work should focus on reducing bias and integrating gender-neutrality and gender-neutral pronouns into gender coreference resolution. We also admit that in non-fine-tuned LLMs, the output or predicted gender may not be present in the set of acceptable pronouns or genders. To this end, future work should focus on integrating hallucination mitigation techniques along with the proposed self-consistency CoT approach.

Bias Statement

This paper investigates the inherent bias in large language models (LLMs) towards male and female genders concerning professions. The association and stereotype that certain professions are linked to specific genders create harm, especially in automated occupational recruiting systems, which might discard female candidates' applications entirely. To address this bias, we utilize self-consistency with Chain-of-Thought (CoT) prompting, enabling the LLM to follow a structured reasoning process based on specific instructions. This method aims to reduce gender bias effectively, promoting fairer and more inclusive outcomes in downstream applications.

luannt@uit.edu.vn

Abstract

Recent advancements in natural language processing (NLP) have demonstrated the remarkable performance of large language models (LLMs). Leveraging these LLMs to generate synthetic data has emerged as a promising solution to address the scarcity of training data for specific tasks, particularly in low-resource languages. However, LLMs often generate overly formal synthetic texts that do not accurately reproduce the informal nature of spoken language and social media texts, resulting in outputs that poorly represent human-generated content online. Furthermore, LLMs may be limited in generating data for tasks involving harmful content. In this research, we introduce LoSo, which utilizes LLMs to generate social media-like texts in low-resource language settings. Our approach aims to bridge the gap between synthetic and authentic human-generated text, making the output more representative of real-world online content. Additionally, we conduct thorough experiments and comparisons focusing on specific characteristics of social media tasks. The materials used in this study will be made available for research purposes[1].

Warning: The study examines actual social media content that could be viewed as offensive and hateful.

1 Introduction

Social media data has gained significant attention in the NLP community due to its unique characteristics and potential applications in areas such as sentiment analysis, hate speech detection, and crisis management (Neri et al., 2012; Balahur, 2013; Zhang et al., 2018). However, the informal and noisy nature of social media text poses challenges for traditional NLP models trained on well-formed text sources (Han, 2014). This has led to a growing interest in developing specialized models and techniques tailored for social media data processing (Farzindar et al., 2015; Stieglitz et al., 2018). The data scarcity problem is amplified for low-resource languages, as large-scale annotation efforts are often hindered by the lack of resources and linguistic expertise (Magueresse et al., 2020; King, 2015; Nguyen et al., 2022). Consequently, many low-resource languages still need to be studied in the social media domain, limiting the development of robust NLP systems for these languages.

The rise of large language models (LLMs) has opened up new avenues for generating synthetic data, potentially alleviating the data shortage. However, these models are primarily pre-trained on formal text sources, such as books and websites, and may need help to capture the nuances and idiosyncrasies of social media language (Myers et al., 2024; Schramowski et al., 2022). As a result, LLM-based approaches for generating human-like textual data still need to improve in mimicking human behavior in expressing feelings and thoughts through texts.

This paper details experiments focused on synthetic data creation, empirically for Vietnamese, a language with limited resources. The key contributions of this work are as follows:

- First, we analyze the characteristics of benchmark datasets in the social media domain. This analysis is crucial for developing systems that can generate realistic, human-like data reflecting actual content on the internet.
- Second, we introduce LoSo, an AI-driven dataset creation system that combines large language models (LLMs) and small language models (SLMs) to generate synthetic social media texts. Our results show that LoSo produces AI-generated datasets comparable to human-annotated ones.
- Third, we conduct in-depth analyses regarding

[1]https://github.com/tarudesu/LoSo

spoken text rate and hate speech percentage in both original and analysis. The obtained results give us an overview of critical factors that contribute to the distinction of social media data.

2 Related Work

In the era of machine learning, data is the critical factor contributing to developing robust and high-performing models (Sun et al., 2017). However, obtaining high-quality labeled data can be challenging, especially for low-resource languages and domains such as social media text. Researchers have explored various approaches for generating synthetic data to deal with this issue.

2.1 Traditional Data Augmentation Approaches

Traditional data augmentation techniques in natural language processing (NLP) involve transforming existing text data through back-translation, token manipulation, and rule-based perturbations (Feng et al., 2021; Wei and Zou, 2019). These techniques can increase the size and diversity of training datasets. However, they often need help capturing the nuances and complexities of social media language, characterized by informal tone, slang, and misspellings.

2.2 Using Small Language Models

An alternative approach involves using small language models (SLMs) to generate labeled data automatically. In this method, an SLM is first fine-tuned on a subset of human-labeled data for a specific task, such as text classification or named entity recognition. The fine-tuned SLM is then used to classify unlabeled text data, effectively generating labeled synthetic data (Chen et al., 2023; Meng et al., 2022). While this approach can be more efficient than manual annotation, it still requires some initial human-labeled data for fine-tuning, and the performance of the SLM may limit the quality of the synthetic data.

2.3 Using Large Language Models

The release of large language models, for example, GPT-3 (Brown et al., 2020) and LLaMA (Touvron et al., 2023), has opened new possibilities for synthetic data generation. LLMs can be used as labelers by fine-tuning them on a small set of labeled data, similar to the SLM approach. However, this can be expensive in computation due to the large size of LLMs.

Alternatively, LLMs can be used as generators to create synthetic text data from scratch (Keskar et al., 2019; Li et al., 2023; Kholodna et al., 2024). This approach leverages the LLM's ability to generate coherent and diverse text samples based on prompts or conditioning. While LLMs have shown impressive text generation capabilities, their outputs may still need to include the distinctive characteristics of social media language when directly applied to this domain, as they are primarily trained on formal text sources.

3 Methodology

The LoSo system consists of two main components: an LLM for generating initial text drafts and an SLM for refining and filtering these drafts to enhance alignment with social media data characteristics. By leveraging the complementary capabilities of these two models, LoSo aims to produce synthetic data that is diverse and reflective of the target domain. The following sections provide a detailed description of the LoSo system, its components, and our evaluation methodology.

3.1 LoSo: An End-to-End Synthetic Data Generation System

LoSo is a specialized end-to-end synthetic data generation system for text-based social media tasks. It comprises two primary components, targeting to generate and label data, culminating in a high-fidelity AI-generated dataset.

3.1.1 LLM-based Generator

The LLM-based Generator is the core of our system, tasked with creating synthetic text tailored to specific domains and labels. By harnessing the capabilities of LLMs, it produces human-like text samples guided by a clearly crafted prompt structure. This structure ensures that the generated text aligns with the target domain, adheres to label criteria, and emulates real-world linguistic diversity.

The proposed prompt structure, depicted in Figure 2, consists of five main components designed to effectively guide a large language model in generating high-quality, domain-specific text data.

1. **Role Assignment**: Defines the model's assumed role or perspective for generating text, ensuring it aligns with the task or domain.

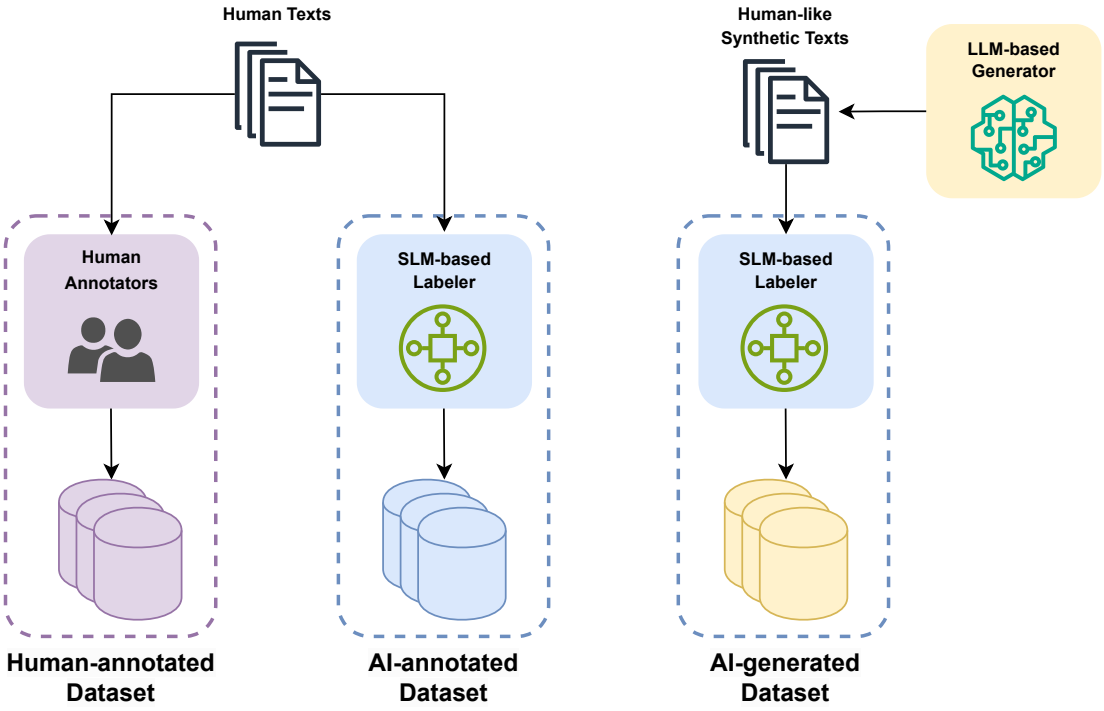

Figure 1: An overview of three data creation approaches.

	Human-annotated Data	SLM-based Classifier	LLM-based Generator
Data	Human Resources	Human Resources	Synthetic Data
Human Costs	High	Low	Low
Compute Costs	Low	Medium - High	High
Time	Long	Medium - Short	Short

Table 1: The comparison of three data creation approaches regarding data source, human costs, compute costs, and time. Note that "time" indicates the time to build a completed dataset for a specific task.

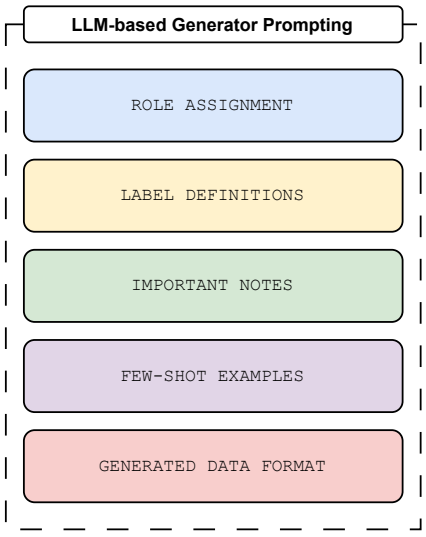

Figure 2: The prompt structure used to generate synthetic human-like texts for each task and label in the LoSo system, which is based on an LLM.

2. **Label Definition**: Clearly outlines criteria defining the target label or category for generated text, crucial for accuracy.

3. **Important Notes**: Provides guidelines and constraints for generating text, ensuring diversity, style, and avoiding biases.

4. **Few-shot Examples**: Representative examples illustrating desired characteristics, helping the model understand patterns and content.

5. **Generated Data Format**: Specifies the required format for presenting generated text data, ensuring consistency and structure.

This decomposed prompt structure equips the LLM with clear guidance, rich context, and well-defined constraints. Consequently, it enables the model to harness its linguistic prowess for generating high-quality, task-specific text data.

3.1.2 SLM-based Labeler

The SLM-based Labeler component in our LoSo system serves as an AI-driven classifier that assigns more accurate labels to the generated data, thereby enhancing the quality and relevance of the synthetic dataset. By leveraging the inherent strengths of SLMs, which are adept at capturing domain-specific nuances and linguistic patterns, we aim to improve the accuracy of labeling while maintaining computational efficiency.

The effectiveness of using an SLM as a classifier lies in its ability to learn from a limited amount of in-domain data. Unlike their larger counterparts, SLMs show great ability in the fine-tuning stage on task-specific datasets, allowing them to develop a focused understanding of the target domain. This specialization enables the SLM-based Labeler to discern subtle differences between classes and assign more precise labels.

3.2 Social Media Text Classification Evaluation Benchmark

To assess LoSo's efficacy, we utilize a comprehensive benchmark comprising three Vietnamese social media datasets. These datasets encapsulate diverse task complexities, label distributions, and linguistic characteristics. The statistics of these datasets are recorded in Table 2.

Sentiment Analysis. The VLSP-SA dataset (Nguyen et al., 2018) evaluates sentiment analysis models for Vietnamese text using user reviews about technological devices. It categorizes 5,100 sentences into positive, neutral, and negative sentiments. These reviews offer concise opinions on specific objects, providing a practical context for sentiment analysis tasks.

Emotion Recognition. The VSMEC (Ho et al., 2020) facilitates emotion recognition in Vietnamese social media text. It features annotated posts categorized into emotions such as joy, sadness, anger, fear, and surprise. This dataset serves as a valuable resource for developing and assessing models to understand and classify emotions expressed in Vietnamese social media content.

Hate Speech Detection. The ViHSD (Luu et al., 2021) dataset focuses on detecting hate speech in Vietnamese social media. It includes annotated comments and posts, identifying offensive language and more severe forms of hate speech directed towards individuals or groups based on attributes like race, gender, or religion. This dataset is essential for creating automated systems that can identify and mitigate hate speech, promoting a safer and more inclusive digital environment.

4 Experiments and Results

In this Section, we conduct multiple experiments to assess the proposed LoSo system's performance in generating social media synthetic texts and serving benchmark classification tasks in Vietnamese. The experiments go through different data conditions and are then evaluated by the performance of the fine-tuned ViSoBERT on these datasets.

4.1 Data

We mainly conduct settings with three primary categories of data, including (1) Original, the top line with data labeled manually by humans and (2) Synthetic, the baseline with data generated and labeled by only an LLM, and (3) The proposed end-to-end synthetic data by LoSo system which leverages LLMs and SLMs in order to generate texts their corresponding labels, respectively. It is worth noting that all types of datasets described below have the same number of samples for each label[2] and each split to ensure the fairness.

Topline With Human-annotated Data. Original datasets from three chosen tasks are used as the topline of this study. As described in Table 1 and in previous studies, they show their effectiveness in solving specific problems but are still costly and time-consuming.

Baseline with Generated Text-Label Data. For the baseline, we use the GPT-3.5-turbo model for generating texts and their corresponding labels for each task. First, we follow the prompt designation (mentioned in Section 3.1.1), aiming to create the exact texts for each label. Then, several minor pre-processing techniques are applied to clean the outputs, including removing unnecessary strings, normalizing labels, and removing users' identities.

End-to-End Synthetic Data Generation. In this approach, we follow the process to create AI-generated Data, depicted in Figure 1 to generate human-like texts by an LLM and re-label them by a specific SLM. The SLM used in our system is ViSoBERT-LoSo, chosen by conducting experiments with multiple pre-trained language models on three selected tasks (mentioned in Appendix C,

[2]The number of samples for each label of data generated by LoSo may be a bit different from the others due to the re-labeling progress.

	VLSP-SA	VSMEC	ViHSD
Task	Sentiment Analysis	Emotion Recognition	Hate Speech Detection
N.o. Labels	3	7	3
Data Source	Users' Reviews	Facebook	Facebook, Youtube
Average Spoken Text Rate	33.94	15.81	51.30
Average Hate Speech Percentage	0.32	13.55	14.67
Average Sequence Length	127.45	55.95	48.92

Table 2: Statistics of three Vietnamese social media benchmark datasets detailing the number of labels, data sources, average spoken text rate (%), hate speech percentage (%), and sequence length (words) across three splits for each dataset.

which outperforms other ones in classification performance. Note that we reuse textual data created from the baseline to adopt this proposed system.

4.2 Model Settings

For the use of LLM, we use the GPT-3.5-Turbo by OpenAI API[3] to generate texts for experiments. For the SLM-based Labeler in the LoSo system, we use several settings and illustrate in detail in Appendix C.

For all main evaluations of data types in three social media tasks, we fine-tune ViSoBERT, one with the settings of 4 epochs, 16 batch size, learning rate 2e-5, and the max sequence length of 128. This study only uses a single NVIDIA A100 GPU for all experiments.

4.3 Evaluation Metrics

In this research, downstream tasks are evaluated with metrics that align with those used in previous studies, namely accuracy score (Acc), weighted F1-score (WF1), and macro F1-score (MF1). MF1 is the primary evaluation metric for each task, as the original research indicates. Furthermore, we determine the Average Macro F1-Score (AF1) by averaging the MF1 scores across three benchmark datasets. This metric reflects the overall performance of each type of training data for the various tasks.

4.4 Experimental Results

Table 3 presents the performance of various data types across three Vietnamese social media text classification tasks. The results demonstrate the effectiveness of our proposed LoSo system in generating high-quality synthetic data for training robust models.

The human-annotated data establishes a strong topline, achieving the highest AF1 of 68.10% across the three tasks. This performance highlights the resource-intensive nature of obtaining such datasets. In contrast, the synthetic data generated solely by the LLM shows a significant performance drop, with an AF1 of 45.07%. This decline is particularly pronounced in the Emotion Recognition and Hate Speech Detection tasks, where the LLM-generated data leads to models with substantially lower accuracy and F1 scores than those trained on human-annotated data.

Remarkably, our proposed LoSo system, which combines LLM-generated texts with SLM-based labeling, significantly narrows the performance gap. The LoSo-generated data achieves an AF1 of 60.48%, a 15.41 percentage point improvement over the LLM-only baseline. This improvement is consistent across all three tasks, with particularly notable gains in Sentiment Analysis and Emotion Recognition.

5 Discussion

5.1 How Similar Synthetic Data Is?

The duplicates in synthetic data generation are also a challenging obstacle we need to consider. Thus, we define a Corpus Similarity Score to compute the similarity between each sample pair per each label in the dataset, followed by the Formula 1.

$$\bar{S} = \frac{1}{\binom{n}{2}} \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} S_{ij} \quad (1)$$

Here, $\bar{S}$ denotes the average similarity computed over all unique pairs of sentences. S_{ij} represents the cosine similarity between the embeddings of the i-th and j-th sentences, which is obtained by feeding them into a Sentence Transformer (Reimers and Gurevych, 2019) model. The variable n signifies the total number of sentences in the input list. $\binom{n}{2}$ represents the number of unique pairs that

[3]https://platform.openai.com/

Data Type	Data Source		Sentiment Analysis			Emotion Recognition			Hate Speech Detection			AF1
	Text	Label	Acc	WF1	MF1	Acc	WF1	MF1	Acc	WF1	MF1	
Original	Human	Human	83.79	85.29	65.48	74.95	74.41	74.41	66.23	66.41	64.41	**68.10**
Synthetic	LLM	LLM	65.23	71.36	48.23	52.00	49.97	49.97	38.53	36.07	37.02	45.07
	LLM	SLM	86.39	86.15	63.68	65.05	64.87	64.87	56.71	55.93	52.89	**60.48**

Table 3: Experimental results of multiple training data types, including human-annotated and AI-generated datasets. Note that all these datasets are validated by fine-tuning the ViSoBERT on them, evaluated by accuracy (Acc), weighted F1-score (WF1), macro F1-score (MF1), and average macro F1-score on three tasks (AF1) (%).

can be formed from n items without repetition, ensuring each sentence is compared with all others exactly once.

Following that, we assess the corpus similarity score between the raw texts in the original and those generated by the LLM-based Generator. Here, we use the Vietnamese-SBERT[4] as the Sentence Transformer model to extract text embeddings. Table 4 shows us the overview of the similarity score in three textual data types on each label per each split.

Table 4 shows significant differences in corpus similarity between original and synthetic datasets across three tasks. Synthetic data consistently scores higher, increasing by 14.51 to 27.11 percentage points, indicating the LLM-based Generator produces more homogeneous text within class labels. In emotion recognition, synthetic data averages 46.71% similarity compared to 20.04% for original data, suggesting less diverse emotional expressions. Similar trends are seen in sentiment analysis and hate speech detection. These findings highlight the need for diverse training data and reveal a potential drawback of LLM-based text generation in overfitting specific patterns, urging future research to balance variability and semantic coherence in synthetic data generation.

5.2 Informal Texts in Social Media Data

One of the essential characteristics of social media texts, a challenging model in capturing semantic characteristics, is using informal texts, also known as spoken language form. In this section, we conduct experiments with different data conditions regarding spoken text rate scores.

5.2.1 Spoken Text Rate Score

We define the Spoken Text Rate (STR) score to analyze the proportion of text classified as spoken language. We fine-tune a model to distinguish between spoken and formal Vietnamese using ViSpoChek, detailed in Appendix A. This binary classification task labels texts from ViLexNorm (Nguyen et al., 2024a), combining human-written and normalized versions. The STR score averages these labels across all samples:

$$\text{STR} = \frac{\sum_{i=1}^{n} C(s_i)}{n} \quad (2)$$

where n is the total number of text samples, and $C(s_i)$ is the ViSpoChek Classifier that labels each sample s_i as '0' (non-spoken) or '1' (spoken). Thus, the STR score represents the average rate of samples classified as spoken text.

5.2.2 Data Analysis

Analysis of STR scores across datasets reveals significant differences in language formality, which is crucial for NLP tasks. Figure 3 and Table 5 summarize these differences in original versus synthetic texts.

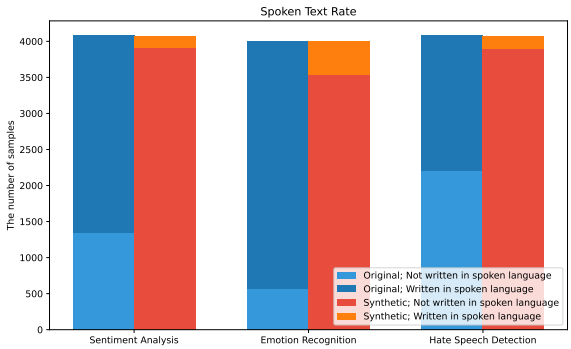

Figure 3: The analysis of spoken text rate in the dataset.

Task/Dataset	Spoken Text Rate	
	Original	Synthetic
Sentiment Analysis (VLSP-SA)	32.77	4.04
Emotion Recognition (VSMEC)	14.08	11.58
Hate Speech Detection (ViHSD)	53.97	4.36

Table 5: The spoken text rate for each dataset of each data type across the training set(%).

The task of hate speech detection exhibits the

Task	Labels	Original		Synthetic	
		Train	Validation	Train	Validation
Sentiment Analysis	NEUTRAL	25.22	25.22	28.24	28.65
	POSITIVE	23.02	21.85	41.46	41.57
	NEGATIVE	25.05	24.24	47.12	45.89
	Average Score	24.43	23.77	38.94	38.70
Emotion Recognition	OTHER	15.04	15.89	25.49	25.07
	DISGUST	20.04	19.26	48.89	49.97
	ENJOYMENT	18.00	17.78	48.40	48.37
	ANGER	25.23	25.23	51.92	51.69
	SADNESS	20.95	20.53	52.81	53.06
	FEAR	22.32	22.10	57.44	58.21
	SURPRISE	18.70	19.90	41.99	44.07
	Average Score	20.04	20.10	46.71	47.21
Hate Speech Detection	CLEAN	14.91	15.37	28.95	29.03
	OFFENSIVE	18.12	18.23	36.75	36.73
	HATE	21.32	21.04	46.27	46.42
	Average Score	18.12	18.21	37.32	37.39

Table 4: The corpus similarity score (%) of three textual data types (lower is better).

Data Type	Data Text	Average STR	Average AF1
Original	Human	33.61	68.10
Synthetic	LLM + ViDenormalizer	57.42	48.82
	LLM	6.66	60.48

Table 6: The comparison between original and synthetic training data with different data forms. The average STR and AF1 scores are calculated by the average of all STR scores (in the training part) and the AF1 scores of each dataset.

highest original spoken text rate (53.97%), reflecting its informal social media origins. However, synthetic data for this task shows a markedly lower rate (4.36%), suggesting challenges in replicating informal language. Similarly, the sentiment analysis task sees a drop from 32.77% (original) to 4.04% (synthetic) in spoken text rate, indicating a shift towards more formal language by the Generator. Meanwhile, the emotion recognition task shows a relatively minor difference (14.08% original compared with 11.58% synthetic), indicating better preservation of informal language style.

5.2.3 Results

Here, we experiment with two main categories, shown in Table 6, to demonstrate how text data form for training affects model performance.

The results in Table 6 demonstrate how text formality impacts model performance across diverse data types. Human-authored data, characterized by an average Spoken Text Rate (STR) of 33.61%, achieves the highest AF1 score at 68.10%, effectively capturing nuances typical of social media discourse. In contrast, synthetic data from the LLM exhibits a low average STR of 6.66% and a reduced AF1 score of 60.48, indicating a bias towards formal language unsuited for social media contexts. Applying the ViDenormalizer to LLM-generated data notably increases STR to 57.42%, surpassing original data informality levels, but this adjustment correlates with a significant AF1 score decline to 48.82%. These findings underscore the challenge of balancing natural language informality with semantic integrity in synthetic data generation for social media analysis, necessitating further exploration of advanced techniques to achieve this balance effectively.

5.3 Hate Speech in Social Media Texts

Besides spoken-language form, toxicity or hate speech in texts is also a crucial characteristic that differentiates social media texts from formal ones. Here, we conduct statistics regarding the hate speech percentage of each dataset in both original and generated texts.

5.3.1 Hate Speech Percentage

First, we use the Hate Speech Percentage (HSP) score, defined in the work of Thanh Nguyen (2024), which refers to how many hateful samples are occupied in the dataset. This progress reveals the

Task/Dataset	Hate Speech Percentage	
	Original	Synthetic
Sentiment Analysis (VLSP-SA)	0.34	5.42
Emotion Recognition (VSMEC)	14.63	13.88
Hate Speech Detection (ViHSD)	45.93	60.61

Table 7: The hate speech percentage for each dataset of each data type across the training set (%).

utilization of a machine learning classifier[5] to detect whether a text is hateful or not. The final score is computed by dividing the number of hateful samples by the number of all data samples.

5.3.2 Data Analysis

We also calculated the HSP score based on the original and the generated texts in this study. Figure 3 and Table 7 demonstrate the achieved analysis.

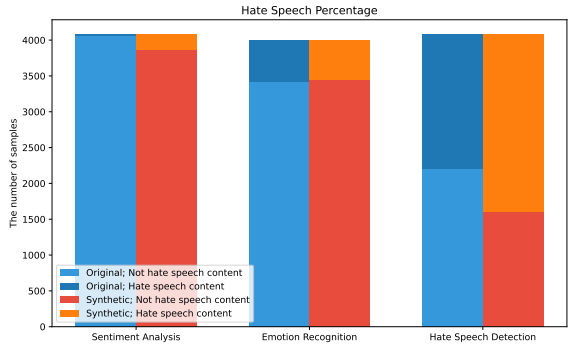

Figure 4: The analysis of hate speech percentage in texts per dataset.

The analysis of hate speech percentages across datasets reveals significant differences between original and synthetic data. Figure 4 and Table 7 illustrate these findings. In the sentiment analysis task, the original data exhibits minimal hate speech (0.34%), whereas synthetic data shows a higher percentage (5.42%). Similarly, in the task of emotion recognition, hate speech percentages are comparable between original (14.63%) and synthetic (13.88%) data, indicating successful replication of emotionally charged language. Most notably, the Hate Speech Detection (ViHSD) dataset displays a substantial increase in hate speech percentage from the original (45.93%) to synthetic (60.61%) data. This suggests the potential amplification of hateful characteristics during data generation, thanks to the well-designed and constrained prompt in generating data.

These findings underscore the importance of considering hate speech prevalence in synthetic data generation, offering insights for refining NLP models to mitigate unintended biases and toxicity.

[5]https://huggingface.co/tarudesu/ViSoBERT-HSD

6 Conclusions

This study introduces LoSo, a potential system for generating synthetic data to enhance social media text classification in Vietnamese, a low-resource language. LoSo combines large language models (LLMs) for text generation and small language models (SLMs) for labeling, effectively mitigating data scarcity while capturing social media language nuances. Experiments on Vietnamese datasets demonstrate that LoSo-generated data achieves performance levels comparable to human-annotated data in sentiment analysis and emotion recognition tasks.

However, the analysis reveals challenges: LLMs tend to produce more formal language than authentic social media text, impacting model performance on real-world data. Moreover, LLMs can inadvertently amplify hate speech when trained on datasets with high hate content. These findings underscore the need for balancing informal language accuracy with semantic fidelity in synthetic data creation, particularly in addressing sensitive issues like hate speech.

A ViSpoChek: Identifying Vietnamese Spoken-language Texts

A.1 Model Settings

For this evaluation, we select all available BERT-based pre-trained language models supporting the Vietnamese language, including multilingual and monolingual variants. The models were configured with a batch size of 16, a learning rate of 1e-6, four epochs, and a maximum sequence length of 128.

A.2 Results

The achieved results, illustrated in Table 8, show that TwHIN-BERT has the best performance for this task. Thus we choose it as the core model for the ViSpoChek component.

Model	#archs	Acc	WF1	MF1
BERT (multilingual, cased) (Devlin et al., 2019)	base	85.55	85.53	85.53
BERT (multilingual, uncased) (Devlin et al., 2019)	base	82.49	82.40	82.40
DistilBERT (multilingual, cased) (Sanh et al., 2019)	base	78.33	78.32	78.32
XLM-RoBERTa (Conneau and Lample, 2019)	base	84.02	83.95	83.95
XLM-RoBERTa (Conneau and Lample, 2019)	large	74.98	74.96	74.96
DeBERTa_v3 (He et al., 2023)	base	84.98	84.94	84.94
TwHIN-BERT (Zhang et al., 2023)	base	90.38	90.38	90.38
TwHIN-BERT (Zhang et al., 2023)	large	**93.01**	**93.01**	**93.01**
PhoBERT (Nguyen et al., 2020)	base	84.21	84.21	84.21

PhoBERT_v2 (Nguyen et al., 2020)	base	88.52	88.51	88.51
ViSoBERT (Nguyen et al., 2023)	base	89.47	89.47	89.47
CafeBERT (Do et al., 2024)	base	91.82	91.82	91.82

Table 8: The experimental results of multiple fine-tuned BERT-based models on checking whether a Vietnamese text is written in spoken language form. All models are evaluated by Accuracy (Acc), Weighted F1-score (WF1), and Macro F1-score (MF1) (%).

B ViDenormalizer

To adjust the condition of data based on its textual form, we define ViDenormalizer for de-normalizing Vietnamese texts, respectively. We select multiple sequence-to-sequence pre-trained models and fine-tune them on the dataset ViLexNorm (Nguyen et al., 2024b) in the direction from normalized texts to original texts for ViDenormalizer.

B.1 Model Settings

The experiments are conducted over four epochs with a maximum sequence length of 128. We use the batch size of [16, 8] for BART-based models corresponding to their base and large versions. The learning rate is set at 2e-5. For T5-based models, the batch size is [8, 4] for the base and large models, respectively. We use the learning rate value of 2e-4.

B.2 Evaluation Metric

The task of ViDenormalizer to de-normalize texts is a one-to-many task, which may generate multiple correct outputs, and the BLEU score may not precisely reflect the model performance. Thus, we define the Agreement Rate Score (AR Score), which quantifies the degree of concordance between labels assigned to reference texts and their corresponding generated texts by a classification model. It is formally defined as:

$$\text{AR Score} = \frac{1}{n}\sum_{i=1}^{n} I(L(r_i), L(g_i)) \tag{3}$$

where n is the total number of text pairs, r_i represents the i-th reference text, g_i denotes the i-th generated text, and $L(\cdot)$ is the labeling function of the classification model. The function $I(\cdot, \cdot)$ is an indicator function defined as:

$$I(a, b) = \begin{cases} 1 & \text{if } a = b \\ 0 & \text{if } a \neq b \end{cases} \tag{4}$$

This indicator function yields 1 when its arguments are equal and 0 otherwise. In the context of AR Score, it evaluates to 1 when the labels of the reference and generated texts match and 0 when they differ. Consequently, the AR Score represents the proportion of text pairs for which the model assigns identical labels, providing a measure of label preservation across the reference and generated text sets.

In this study, the classification is the ViSpoChek component, which checks whether a text is written in spoken language.

B.3 Results

Table 9 shows the results in two tasks. It is obvious that ViT5-large is the most effective model and, thus, has been chosen for further experiments in this work.

Models	#archs	ViDenormalizer (AR Score)
mBART-50 (Tang et al., 2020)	large	74.16
mT5 (Xue et al., 2021)	small	62.87
mT5 (Xue et al., 2021)	base	73.68
mT5 (Xue et al., 2021)	large	76.75
BARTpho-syllable (Tran et al., 2022)	base	66.41
BARTpho-word (Tran et al., 2022)	base	63.35
BARTpho-syllable (Tran et al., 2022)	large	56.75
BARTpho-word (Tran et al., 2022)	large	72.25
ViHateT5 (Thanh Nguyen, 2024)	base	77.22
ViT5 (Phan et al., 2022)	base	76.84
ViT5 (Phan et al., 2022)	large	**79.90**

Table 9: The experimental results of multiple fine-tuned sequence-to-sequence models on de-normalizing Vietnamese texts (%).

C BERT-based Model on Social Media Classification Tasks

We use a single BERT-based pre-trained model to evaluate the effectiveness of multiple data types through all experiments. To choose the most optimal, we fine-tune all available BERT-based models on three benchmark tasks in the social media domain. These models include the ones pre-trained on formal texts and the ones on informal texts.

C.1 Model Settings

To fine-tune these BERT-based language models, we configured the experiments with the following settings: 4 epochs, a batch size of 16, a learning rate of 2e-5, and a maximum sequence length of 128.

C.2 Results

Table 10 below shows us the performance of multiple models on three selected tasks. The results show that ViSoBERT outperforms other models in these tasks in terms of the average macro F1 score (AF1).

Model		Offensive Language Identification			Sentiment Analysis			Emotion Recognition			AF1

D Data Samples

Task	Generated Text (from LoSo)	Label	Label Characteristics
Sentiment Analysis	Công ty này làm việc từ thứ Hai đến thứ Sáu hay cả tuần vậy nhỉ? (Translated: Is this company working from Monday to Friday or all week?)	NEUTRAL	- Factual statements or observations. - Questions or requests for information. - General comments without emotional bias. - Mild or balanced opinions.
	Wow! Sự hỗ trợ của bạn thật là tuyệt vời, mình cảm thấy vui vẻ quá đi mà 😊 (Translated: Wow! Your support is really amazing, I feel so happy 😊)	POSITIVE	- Expressions of joy, excitement, or gratitude. - Compliments or praise for a person, product, or experience. - Hopeful or optimistic statements. - Encouragement or support.
	Ăn mày à, dịch vụ kém cỏi như thế này thì tao chả bao giờ quay lại đâu 😠 (Translated: You scoundrel, with such poor service like this, I'll never come back 😠)	NEGATIVE	- Expressions of frustration, anger, or sadness. - Complaints or criticism about a product, service, or situation. - Pessimistic or hopeless statements. - Expressions of regret or disappointment.
Emotion Recognition	Ôi dồi ôi, sao đồ ăn trong cái video này trông như cục phân thế kia? Nấu ăn kiểu đó thì ớn quá đi! (Translated: Oh my, why does the food in this video look like that shit Cooking like that is disgusting!)	DISGUST	- Expressions of revulsion, repugnance, or aversion. - Comments about things that are gross, unpleasant, morally reprehensible, or other negative qualities. - Reactions to offensive behaviour, ideas, or substances.
	Zồi ơi, hôm nay được ăn bánh mì thịt nướng ngon tuyệt vời! 🍺Ai bảo cuộc sống không có niềm vui, hihi (Translated: Oh my, today I got to eat a delicious grilled pork sandwich! 🍺Who says life has no joy, hehe)	ENJOYMENT	- Expressions of pleasure, delight, or satisfaction. - Comments about fun experiences, tasty food, great entertainment, or other enjoyable things. - Reactions to achieving goals or receiving good news.
	Đm, làm ơn đi chỗ khác mà chơi! 😠 Đã gọi giao từ sáng sớm, giờ muốn trưa rồi vẫn chưa thấy nổi một con nhỏ, chán thật! (Translated: Damn, please go somewhere else to play! 😠Called for delivery since early morning, now it's almost noon and still no sign, so frustrating!)	ANGER	- Expressions of rage, fury, or irritation. - Comments about unfair situations, betrayals, disrespect, or other negative experiences. - Reactions to mistakes, delays, or poor service.
	Có phải là tớ đã đủ ngu ngốc để mất cả người mình yêu thương không? 😭Cảm giác lạc lõng và cô đơn quá, không biết phải làm sao... (Translated: Have I been stupid enough to lose the person I love? 😭Feeling lost and lonely, don't know what to do...)	SADNESS	- Expressions of sorrow, grief, or melancholy. - Comments about loss, disappointment, or loneliness. - Reactions to bad news, failures, or missing someone.
	Ôi troi ơi, đi ngang qua khu rừng hoang này thấy tối om, khóe mắt nhìn cứ như có ma vậy, sợ quá đi mất (Translated: Oh my goodness, passing by this deserted forest feels so eerie, corners of my eyes feel like there are ghosts, it's so scary)	FEAR	- Expressions of terror, anxiety, or worry. - Comments about dangerous situations, threats, uncertainties, or other scary things. - Reactions to phobias, dark places, or scary stories.
	Ôi chết, mở hộp quà sinh nhật từ crush ra toàn hàng hiệu, shock quá trời lun á 🎁 (Translated: Oh my god, opened the birthday gift box from my crush and it's all branded stuff, I'm totally shocked 🎁)	SURPRISE	- Expressions of astonishment, shock, or amazement. - Comments about unexpected events, gifts, revelations, or other surprising things. - Reactions to plot twists, magic tricks, or sudden changes.
	Đợt này mình thấy thời tiết Hà Nội ổn hơn hẳn, không nóng quá không lạnh quá. (Translated: This time I find the weather in Hanoi much better, not too hot, not too cold.)	OTHER	- Neutral statements or questions. - Comments without clear emotional content. - General observations or mild opinions.
Hate Speech Detection	Chủ đề này quan trọng lắm, mình muốn biết thêm thông tin về nó nữa! (Translated: This topic is very important, I want to know more information about it!)	CLEAN	- Opinions or emotions expressed respectfully. - Informal language, slang, or internet abbreviations without profanity. - Respectful comments, even in disagreement.
	Mẹ kiếp, cái thời tiết này nóng như con cặc, đéo chịu được! (Translated: Damn, this weather is as hot as hell, can't stand it!)	OFFENSIVE	- General profanity not directed at anyone. - Crude expressions of frustration. - Offensive descriptions of situations. - Vulgar language about non-personal things.
	Mấy thằng lến vào quê người ta rồi lại đòi đất, tao cho mày biết đường về trại giam luôn đấy, đập chết mày con đĩ lồn 😠😠👍 (Translated: Those bastards sneaking into other people's villages and demanding land, I'll show you the way to prison, punch you to death you fucking asshole 😠😠👍)	HATE	- Harassment and abuse aimed at an individual or group based on characteristics such as religion, nationality, ethnicity, gender, sexuality, or race. - Offensive words attacking a specific target. - Racist, harassing, or hateful content, even if figurative.

Can we repurpose multiple-choice question-answering models to rerank retrieved documents?

Jasper Kyle Catapang
Tokyo University of Foreign Studies, Tokyo, Japan
catapang.jasper.kyle.y0@tufs.ac.jp

Abstract

Yes, repurposing multiple-choice question-answering (MCQA) models for document reranking is both feasible and valuable. This preliminary work is founded on mathematical parallels between MCQA decision-making and cross-encoder semantic relevance assessments, leading to the development of R*, a proof-of-concept model that harmonizes these approaches. Designed to assess document relevance with depth and precision, R* showcases how MCQA's principles can improve reranking in information retrieval (IR) and retrieval-augmented generation (RAG) systems—ultimately enhancing search and dialogue in AI-powered systems. Through experimental validation, R* proves to improve retrieval accuracy and contribute to the field's advancement by demonstrating a practical prototype of MCQA for reranking by keeping it lightweight.

1 Introduction

Retrieval-augmented generation (RAG) systems enhance generative outputs with contextually relevant information from external databases. Despite their success, selecting the most relevant information efficiently and accurately remains challenging.

Dense retrieval techniques, known for their ability to semantically represent text, offer a promising direction for RAG system enhancement. However, integrating large language models (LLMs) into dense retrieval, while effective, faces scalability and cost-related challenges.

This work explores the utility of multiple-choice question-answering (MCQA) in reranking within RAG systems. MCQA's potential for evaluating and selecting the most semantically relevant options aligns with the decision-making parallels of cross-encoder architectures.

The author introduces RoBERTA ReRanker for Retrieved Results or R*, a dual-purpose prototype model that can act as both an MCQA model and a cross-encoder. The author's contributions include proposing MCQA as an alternative to reranking passages and introducing R* for efficient and semantically aware retrieval mechanisms.

2 Related Works

The advancement of information retrieval techniques within the domain of natural language processing (NLP) has been significantly influenced by the emergence of pre-trained language models and the subsequent development of large language models. These technologies have fundamentally altered our approach to understanding and generating human language, laying the groundwork for sophisticated retrieval-augmented generation systems.

2.1 Dense Retrieval Techniques

At the heart of modern IR, dense retrieval techniques represent a pivotal shift from traditional sparse vector space models to dense vector embeddings. This transition, highlighted in seminal works by Karpukhin et al. (2020) and Xiong et al. (2020), highlights the effectiveness of leveraging deep semantic representations to capture the nuances of language, facilitating a more nuanced and accurate retrieval process.

2.2 Pre-trained Language Models

The introduction of PLMs like BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019) has ushered in a new era of NLP, where the rich contextual understanding offered by these models can be applied to a wide range of tasks. In the context of IR, PLMs have been instrumental in enhancing the quality of embeddings for both queries and documents, enabling more effective matching mechanisms based on semantic relevance rather than mere keyword overlap.

2.3 Large Language Models and IR

Following the success of PLMs, LLMs have expanded the horizons of what is achievable in NLP. With their vast parameter spaces and extensive training corpora, LLMs, offer an even deeper understanding of language intricacies. Their application in IR, though still an emerging area of research, promises to revolutionize retrieval mechanisms by leveraging their generative capabilities to produce highly relevant responses to complex queries (Muennighoff, 2022; Neelakantan et al., 2022; Ma et al., 2023; Zhang et al., 2023). LLMs such as LLaMA (Ma et al., 2023), SGPT (Muennighoff, 2022) have been created and/or fine-tuned for such a task.

2.4 Cross-Encoders for Semantic Matching

Cross-encoder architectures have gained prominence for their ability to conduct fine-grained semantic comparisons between text pairs, making them particularly suitable for tasks that require a deep understanding of textual relationships, such as passage ranking and relevance scoring (Nogueira and Cho, 2019). By processing pairs of texts jointly, cross-encoders can ascertain the degree of relevance with a precision that traditional models cannot achieve, setting a high bar for semantic matching in IR.

2.5 Exploring MCQA for Reranking

Despite the extensive exploration of dense retrieval, PLMs, LLMs, and cross-encoders in enhancing IR systems, the potential application of MCQA to rerank within RAG systems remains largely unexplored. After a comprehensive scan of the literature, it becomes apparent that MCQA, with its nuanced approach to selecting the most appropriate answer from a set of options, has not yet been applied to the challenge of reranking search results, suggesting a promising direction for future research.

This review of related works sets the stage for a novel exploration into the utilization of MCQA methodologies for reranking in RAG systems, promising to address existing gaps in the literature and contribute significantly to the advancement of retrieval technologies.

3 Methodology

This section explores the MS MARCO dataset and the mathematical foundations of multiple-choice question-answering and cross-encoder models, investigating their intersection for document reranking within RAG systems. The researcher also details the training procedure for R*, a model that embodies the conceptual synergy between these approaches.

3.1 MS MARCO Dataset

The Microsoft Machine Reading Comprehension (MS MARCO) dataset, a large-scale benchmark derived from real-world Bing search queries and web document answers (Nguyen et al., 2016), plays a pivotal role in advancing information retrieval and comprehension research. It's instrumental for training and evaluating models in RAG systems due to its comprehensive coverage of query understanding, passage retrieval, and answer generation.

MS MARCO's significance extends to our work in reranking, aiming to discern and elevate the most pertinent passages for given queries. Utilizing this dataset, the author develops R*, a model designed to mirror real-world retrieval complexities, thereby refining its reranking proficiency across varied informational needs (Nguyen et al., 2016; Craswell et al., 2020).

Notably, the dataset has propelled deep learning research in information retrieval, marking considerable progress in model development and effectiveness evaluation (Hofstätter et al., 2020; Nogueira and Cho, 2019). This work emphasizes MS MARCO's essential contribution to the field's ongoing innovation.

3.2 MCQA vs. Cross-Encoder

3.2.1 Multiple Choice Question Answering

MCQA selects the most suitable answer from options given a question, modeled as:

$$P(a|q) = \frac{\exp(score(q,a))}{\sum_{a' \in A} \exp(score(q,a'))}, \quad (1)$$

where $P(a|q)$ is the probability of answer a being correct for question q, and A is the set of all answers.

3.2.2 Cross-Encoder

Cross-encoder models assess the relevance between query q and document d by jointly encoding them, capturing their semantic interactions. The relevance score, transformed into a probability range via sigmoid function, is given by:

$$R(q,d) = \sigma(\mathbf{w}^\top \text{Enc}(q,d) + b), \quad (2)$$

where $\text{Enc}(q, d)$ is the joint embedding and $\mathbf{w}$, b are parameters. This process is detailed further in the training approach.

3.2.3 Fine-tuning with Cross-Entropy Loss

To fine-tune a transformer model with cross-entropy loss, the researcher initializes it with pre-trained weights and prepare the training data by tokenizing text and applying hard-negative sampling. During training, the model computes embeddings and relevance scores for query-passage pairs. Binary cross-entropy loss assesses performance, guiding weight updates through backpropagation. Multiple fine-tuning epochs refine the model's ability to discern relevant documents, evaluated periodically on a validation set to prevent overfitting.

The loss function, integrating cross-entropy with a sigmoid function for raw network outputs, is mathematically expressed as:

$$\mathcal{L}_{\text{BCELogits}} = -\Big[y \log(\sigma(x)) + (1-y)\log(1-\sigma(x))\Big], \quad (3)$$

where BCE stands for binary cross-entropy, x is the raw output, y the relevance label, and $\sigma(x)$ denotes the sigmoid function. This loss formulation negates the need for a manual sigmoid application, allowing direct loss computation from logits.

3.3 MCQA as Cross-Encoder

The synthesis of MCQA with cross-encoders for reranking is articulated through the approximation:

$$P(d|q) \approx R(q, d), \quad (4)$$

where $P(d|q)$, derived from MCQA's probabilistic framework, is aligned with $R(q, d)$ from cross-encoders. This approximation is made possible by the sigmoid function in $L_{\text{BCELogits}}$. This alignment underpins R*, trained to assess document relevance effectively.

3.4 Applications of MCQA and Cross-Encoders

Multiple Choice Question Answering (MCQA) and cross-encoder models have significant practical applications in various fields, from educational technology to customer service automation and content recommendation. This section provides coherent examples illustrating how these models function and their practical utility.

3.4.1 Question Answering

In an educational application designed to assist students in exam preparation, MCQA systems are employed to present and evaluate multiple-choice questions. Consider the following example:

- **Question:** What is the capital of France?
- **Options:**
  - (a) Berlin
  - (b) Madrid
  - (c) Paris
  - (d) Rome

An MCQA model processes the question and each of the options, computing a probability for each that indicates the likelihood of it being the correct answer. In this scenario, the model would ideally assign the highest probability to Paris, reflecting its understanding of the context and content of the question.

3.4.2 Document Retrieval

Cross-encoder models are particularly effective in document retrieval and ranking tasks. They assess the relevance of a document to a given query by jointly encoding the query and the document. For instance, in a search engine setting:

- **Query:** benefits of exercise
- **Document:** Regular physical activity can improve muscle strength and boost endurance.

The cross-encoder model processes the query and the document together, capturing their semantic interactions, and assigns a relevance score to the document. This score helps in ranking the document's relevance to the query, thereby improving the search engine's accuracy and efficiency.

3.4.3 MCQA as Document Retrieval

MCQA systems can also function as cross-encoders in applications such as customer service chatbots. These chatbots need to select the most appropriate response from a set of predefined answers based on a user's query. Consider the following interaction:

- **Query:** How can I reset my password?
- **Potential Responses:**
  - (a) You can reset your password by clicking on 'Forgot Password' on the login page.

- (b) Our business hours are from 9 AM to 5 PM.
- (c) Please check your internet connection and try again.

Here, the chatbot uses an MCQA-like approach to rank the potential responses according to their relevance to the query. The model processes the query and each response option, determining that response (a) is the most relevant and selecting it as the answer for the user.

3.4.4 Fine-Tuning and Practical Impact

Fine-tuning MCQA and cross-encoder models with cross-entropy loss enhances their practical effectiveness. For instance, a personalized content recommendation system can leverage fine-tuned cross-encoder models to suggest articles, videos, or products based on user preferences and previous interactions. Consider the following scenario:

- **User Query:** Articles on healthy eating
- **Recommended Content:**
  - Article 1: "10 Benefits of a Balanced Diet"
  - Article 2: "Top Exercises for a Healthy Lifestyle"
  - Article 3: "Healthy Eating: Tips and Recipes"

The model calculates relevance scores for each content item in relation to the query, identifying "10 Benefits of a Balanced Diet" as the most relevant recommendation. This process involves encoding the query and the content items jointly and using the relevance scores to rank and recommend the best match.

These examples demonstrate the practical applications and effectiveness of MCQA and cross-encoder models in various real-world scenarios.

3.5 R*

Our R* model is trained on a balanced dataset from MS MARCO, which ensures that the model encounters an equal number of relevant and irrelevant documents during training. To enhance the model's discrimination capability, the researcher employs a hard-negative sampling strategy—similar to what was described in the previous section. The overarching loss for model training is:

$$\mathcal{L} = -\frac{1}{N}\sum_{i=1}^{N}\Big[y_i \log(\sigma(x_i)) + (1-y_i)\log(1-\sigma(x_i))\Big], \quad (5)$$

optimizing R*'s ability to distinguish between relevant and irrelevant documents accurately.

3.6 Evaluation Metrics

To evaluate the effectiveness of our reranking models, the author employs a suite of established metrics, each offering insight into different aspects of model performance. These metrics include Recall@k, mean reciprocal rank, and ROUGE-L, which are critical for understanding the models' ability to retrieve relevant documents and generate coherent responses.

3.6.1 Recall@k

Recall@k measures the fraction of relevant documents retrieved within the top-k positions of a ranking list. Mathematically, it's expressed as:

$$\text{Recall@k} = \frac{R_k}{R} \quad (6)$$

where R_k is the number of relevant documents retrieved in the top-k positions, and R is the total number of relevant documents in the dataset. This metric is important for evaluating the model's ability to identify relevant documents within the first k positions of its results, highlighting the effectiveness of retrieval in priority-ranked scenarios.

3.6.2 Mean Reciprocal Rank (MRR@n)

The mean reciprocal rank is a metric used to evaluate the effectiveness of a model in ranking results. Specifically, it focuses on the rank of the highest-ranking relevant document for each query:

$$\text{MRR@n} = \frac{1}{|Q|}\sum_{i=1}^{|Q|}\frac{1}{\text{rank}_i} \quad (7)$$

where $|Q|$ is the number of queries, and rank_i is the rank position of the first relevant document for the i-th query. MRR is particularly useful for tasks where the best result needs to be at the top of the list.

3.6.3 ROUGE-L

ROUGE-L measures the longest common subsequence (LCS) between the predicted output and the reference output, considering both recall and precision. It is defined as:

$$\text{ROUGE-L} = \frac{(1+\beta^2) \cdot \text{Precision}_{\text{LCS}} \cdot \text{Recall}_{\text{LCS}}}{\beta^2 \cdot \text{Precision}_{\text{LCS}} + \text{Recall}_{\text{LCS}}} \quad (8)$$

where $\text{Precision}_{\text{LCS}}$ is the precision of LCS, $\text{Recall}_{\text{LCS}}$ is the recall of LCS, and β is typically set to favor recall ($\beta > 1$) because recall is more important in most summarization tasks. ROUGE-L is particularly valued in evaluating the quality of generated text, such as summaries, where sequence order is crucial.

These metrics collectively provide a comprehensive view of each model's performance, from retrieving relevant documents (Recall@k, MRR@n) to generating coherent and contextually appropriate textual responses (ROUGE-L).

4 Experimental Setup

This section details the experimental setup used to evaluate the effectiveness of our proposed R* model in the context of document reranking. The model and code are available on Huggingface [1].

4.1 Training R*

To train R*, the author employs a dataset derived from the MS MARCO passage ranking dataset [2], which consists of 2.5 million query-positive passage pairs and an equal number of query-negative passage pairs, summing up to 5 million query-passage pairs. This balanced training approach ensures that R* is equally exposed to both relevant and irrelevant examples. This training procedure aims to assign a continuous relevance score between 0 (irrelevant) and 1 (relevant) to each query-passage pair. The model was trained over 7 epochs using a batch size of 2048 on a Colab Pro instance equipped with a V100 GPU (16 GB VRAM). The researcher utilized the sentence-transformer's CrossEncoder for facilitating the training process.

4.2 Evaluating Rerankers

Evaluation is conducted on the validation set of MS MARCO (n=10,047), using a similar Colab Pro instance. Preliminary retrieval for this research is performed using BM25 (Robertson and Zaragoza, 2009), serving as the baseline for comparison. For this setup, BM25 is tasked to retrieve 10 documents per query. The benchmark includes a variety of models, all of which had been previously pretrained and/or fine-tuned on MS MARCO. Specifically, cross-encoder rerankers were employed via sentence-transformers' CrossEncoder, while the interoperability of MCQA rerankers was tested using Huggingface transformers' AutoModelForMultipleChoice.

This evaluation assesses the effectiveness of various reranking strategies, including MCQA and cross-encoder methods. Cross-encoder rerankers like MiniLM L6 v2, TinyBERT L2 v2, and ELECTRA base were implemented through sentence-transformers' CrossEncoder, while MCQA compatibility was tested with Huggingface transformers' AutoModelForMultipleChoice and text generation from BGE M3 v2 (Chen et al., 2024). The study identifies the contributions of MCQA and cross-encoder methods to improving retrieval accuracy and efficiency in RAG systems, focusing solely on open-source models due to unavailability of commercial rerankers like Cohere at the time.

4.3 Validating R*

Dataset	Size
TREC	50K
Natural Questions	7.6K
Natural Questions Open	1.8K

Table 1: Summary of additional datasets used in the validation experiments

To further validate the generalizability of our model, the author conducted additional experiments on the following datasets: TREC, Natural Questions, and Natural Questions Open. These datasets cover different domains and provide a comprehensive evaluation of the model's performance across various tasks.

4.3.1 TREC

The TREC dataset (Dietz and Gamari, 2017) is a benchmark for information retrieval, containing queries and corresponding relevant documents from a wide range of topics. The researcher used the TREC 2022 Deep Learning Track dataset, which focuses on ad hoc retrieval tasks.

[1] Model and code: https://huggingface.co/jaspercatapang/R-star

[2] Data: https://sbert.net/datasets/paraphrases/msmarco-query_passage_negative.json.gz

Model	Model Type	Recall@1	Recall@5	MRR@10	ROUGE-L	File Size
BM25 (baseline)	Retriever only	0.1071	0.3154	0.1939	0.2255	N/A
R* (ours)	MCQA (ours)	**0.2315**	0.4003	**0.3019**	0.2255	112 MB
R* (ours)	Cross-encoder	0.2314	0.4002	0.3018	0.2255	112 MB
MiniLM L6 v2	MCQA (ours)	0.2288	**0.4033**	0.3006	0.2255	90.9 MB
MiniLM L6 v2	Cross-encoder	0.2287	0.4032	0.3005	0.2255	90.9 MB
BGE M3 v2	Text generation	0.2267	0.4004	0.2985	0.2255	2.3 GB
TinyBERT L2 v2	MCQA (ours)	0.1995	0.3953	0.2792	0.2255	17.5 MB
TinyBERT L2 v2	Cross-encoder	0.1994	0.3952	0.2791	0.2255	17.5 MB
ELECTRA base	MCQA (ours)	0.0391	0.1174	0.0996	0.2255	438 MB

All-MPNet v2	MCQA (ours)	0.0329	0.2056	0.1142	0.2255	438 MB
All-MPNet v2	Cross-encoder	0.0328	0.2055	0.1141	0.2255	438 MB

Table 2: Performance comparison of various models on the MS MARCO validation set of 10,047 samples. The best performance per metric is highlighted in bold.

4.3.2 Natural Questions

The Natural Questions dataset (Kwiatkowski et al., 2019) consists of real anonymized queries issued to the Google search engine, along with corresponding passages from Wikipedia that answer these questions. This dataset is particularly challenging due to its open-domain nature.

4.3.3 Natural Questions Open

The Natural Questions Open dataset comprises questions derived from Natural Questions (Kwiatkowski et al., 2019), providing a more diverse set of queries and answers. This dataset tests the model's ability to generalize across different types of questions and information sources.

5 Results and Discussion

With the setup described earlier, R* finished fine-tuning in 16 hours. Our experimental evaluation compares several reranking models, including our proposed R* model, across a range of metrics on the MS MARCO validation set. The comparison includes a baseline retriever, MCQA rerankers, cross-encoder rerankers, and a text generation reranker. The results are shown in Table 2.

Our R* prototype model achieved the highest Recall@1 and MRR@10 scores, demonstrating its effectiveness in pinpointing the most relevant passage from a large collection. This indicates that R*'s architecture and training are well-suited for accurately identifying the top relevant document, showcasing its precision in high-stakes retrieval scenarios.

MiniLM L6 v2 fine-tuned on MS MARCO showed superior performance in Recall@5, highlighting its capability to cast a wider net in capturing relevant documents within the top 5 positions. This suggests that MiniLM L6 v2 may utilize contextual cues or training strategies that slightly broaden its relevance scope, offering an advantage in scenarios where identifying multiple pertinent documents is key.

The ELECTRA base model fine-tuned on MS MARCO underperformed, especially in Recall@1 and Recall@5. This may be due to ELECTRA's pre-training objectives and architecture, which are not aligned with reranking tasks. The large file size also suggests complexity does not translate to efficacy, possibly due to overfitting or generalization issues.

Furthermore, BGE—a renowned reranker with a substantial model size of 2.3 GB—was surprisingly outperformed by MiniLM L6 v2 and R* in document reranking. This suggests that model size alone does not guarantee superior performance for this task.

All-MPNet, another popular reranker based on the MPNet family, achieved the lowest scores in several metrics. Despite integrating MLM and PerLM to address a limitation in BERT, it performed poorly in this testbed.

The varied performance across models accentuates the critical role of model architecture and training specificity in reranking effectiveness. While R* offers exceptional precision for the most relevant document, MiniLM L6 v2 provides a balanced approach for broader relevance.

Interestingly, the performance between the

Dataset	Model	Recall@1	Recall@5	MRR@10	ROUGE-L
TREC	R*	0.2540	0.4301	0.3254	0.2300
TREC	BM25	0.2200	0.4000	0.3000	0.2250
Natural Questions	R*	0.2400	0.4150	0.3100	0.2350
Natural Questions	BM25	0.2100	0.3900	0.2900	0.2200
Natural Questions Open	R*	0.2600	0.4400	0.3300	0.2400
Natural Questions Open	BM25	0.2300	0.4100	0.3100	0.2300

Table 3: Performance comparison on validation datasets.

Dataset	Metric	p-value
TREC	Recall@10	0.025
Natural Questions	MRR	0.030
Natural Questions Open	Recall@10	0.020

Table 4: Results of significance tests on validation datasets

MCQA reranker versions of our models and their cross-encoder counterparts is remarkably close, supporting the claim that MCQA methodologies can approximate the effectiveness of cross-encoders for document reranking. This is notable given that the primary difference lies in their implementation frameworks—Huggingface's transformers for MCQA rerankers versus sentence-transformers for cross-encoder rerankers.

Minor discrepancies in performance metrics could be attributed to differences in how these libraries handle model calculations and optimizations. Despite using the same underlying models, slight variations in tokenization, sequence handling, and optimization steps might contribute to these differences in reranking outcomes. This highlights the versatility of MCQA approaches for tasks usually suited for cross-encoders and emphasizes the importance of optimal implementation choices.

5.1 Results on Validation Datasets

The performance of R* is evaluated on the additional datasets to assess its generalizability. The results are summarized in Table 3.

R* demonstrated superior performance across all additional datasets, consistently outperforming the baseline models. These results reinforce the model's robustness and effectiveness in diverse retrieval and question-answering tasks.

5.2 Significance Tests

To ensure the reliability of our results, statistical significance tests are conducted. The p-values for the key comparisons are shown in Table 4, indicating the statistical significance of our findings. Specifically, the tests reveal that the results are statistically significant for the TREC dataset with Recall@10 ($p = 0.025$), the Natural Questions dataset with MRR ($p = 0.030$), and the Natural Questions Open dataset with Recall@10 ($p = 0.020$). These p-values, all below the common threshold of 0.05, confirm that the observed differences are unlikely due to chance, thereby validating the effectiveness of our methods.

5.3 Qualitative Analysis of MS MARCO Retrieval Examples

The researcher conducted a qualitative analysis using several retrieval examples from the MS MARCO dataset to provide a deeper understanding of the differences between R* and baseline models. Here, comparison is done between the relevance of the top-ranked documents retrieved by R* and the baseline model.

In one example, the query was "What are the health benefits of green tea?" R* retrieved a document that directly listed the health benefits, such as antioxidant properties and improved brain function, whereas the baseline model retrieved a document that discussed green tea in general without focusing on health benefits. This demonstrates R*'s ability to prioritize documents that are more directly relevant to the specific query.

In another example, the query was "How does photosynthesis work?" R* retrieved a document that provided a step-by-step explanation of the photosynthesis process, including the light-dependent and light-independent reactions. In contrast, the baseline model retrieved a document that only briefly mentioned photosynthesis in the context of plant biology. This highlights R*'s strength in retrieving comprehensive and detailed answers.

These qualitative examples illustrate the practical improvements offered by R* in retrieving more

relevant and informative documents compared to the baseline model.

6 Conclusion

Our study introduced R*, a novel reranking model designed to enhance document retrieval performance in retrieval-augmented generation systems. R* demonstrated superior performance on the MS MARCO dataset, underscoring the importance of model architecture and training specificity for effective reranking.

Furthermore, the comparison of R* with established models sheds light on the nuanced landscape of reranking strategies. MiniLM L6 v2's strong Recall@5 performance highlighted its ability to capture broader relevance, while the modest showing of the larger BGE model challenged the assumption that bigger models always yield better results in the context of LLMs for reranking.

Importantly, the close performance between MCQA rerankers and their cross-encoder counterparts provided empirical support for the viability of MCQA methodologies in approximating cross-encoder effectiveness for reranking. This finding underlines the significant impact that model choice and implementation can have on reranking outcomes.

Our study contributes to a deeper understanding of reranking dynamics within RAG systems, providing insights that can guide future research and development efforts. The code used in our experiments has been made publicly available to facilitate further exploration and innovation in document retrieval and reranking. By sharing these methodologies and findings, the author hopes to continue the advancement in this rapidly evolving field.

Limitations

Our preliminary research suggests that R* tends to favor longer passages when scoring, which could introduce a bias. This is true for most cross-encoder models. It is advisable to preprocess text to normalize passage lengths for fair comparison. It is also worth noting that R* is optimized for passage-level comparisons and may not perform well on word- or phrase-level similarity tasks. The findings only apply to the MS MARCO validation data and may not generalize as well to a different dataset. Since this paper has already demonstrated a proof-of-concept, we can apply the same methodology to a larger collection of datasets for further fine-tuning. Lastly, this preliminary research is limited to open-source models and future work should include evaluation of commercially-available reranking models.

Ethics Statement

The use of R* introduces several ethical considerations, including potential biases in the training data, privacy concerns, and the implications of automating decision-making processes. Users are encouraged to evaluate the model's fairness and transparency critically, ensuring its equitable use across diverse demographics. The author recommends that users further fine-tune this prototype model to their use case and do not use it as is, especially since this model has only been fine-tuned on MS-MARCO and not on any other domain-specific data—despite being validated on multiple datasets.

Acknowledgements

This experimental research was written partly during Catapang's employment at Maya Philippines. However, this work is not whatsoever relevant to Catapang's non-disclosure and non-compete agreements. Furthermore, some aspects of this research was executed and would not have been possible without the support of the Tokyo University of Foreign Studies. The author extends his gratitude to his peers and the manuscript reviewers for lifting the quality of the work to the highest levels.

Are large language models affected by politeness? Focusing on request speech acts in Korean

Gayeon Jung, Joeun Kang, Fei Li, Hansaem Kim

Abstract

This study examined the influence of politeness on large language models (LLMs) based on request speech acts in Korean, which features a highly developed system of polite expressions. To address this issue, we designed five levels of request prompts ranging from informal to highly formal on the basis of the politeness expression system of the Korean language. We then analyzed the responses of GPT-4, CLOVA X, Mixtral, and Solar to these prompts in terms of accuracy and friendliness. Relatively larger models, such as GPT-4 and CLOVA X, were sensitive to the politeness levels of the prompts. Furthermore, CLOVA X demonstrated an increase in accuracy and friendliness with the increase in the level of politeness of the prompts. In contrast, relatively smaller models, such as Mixtral and Solar, did not exhibit a consistent correlation between politeness and response quality. These findings indicate that the quantity of training data and the scale of the model are significant factors in discerning the nuances of language. They also highlighted the importance of considering politeness when designing Korean-specific prompts. Additionally, this study underscores the need to conduct an in-depth examination of the ability of LLMs to recognize politeness in diverse linguistic and cultural contexts.

1 Introduction

Recent advancements in artificial intelligence (AI) and natural language processing (NLP) have led to a surge in interest in human–computer interactions. Consequently, many studies have proposed that AI behavior should be designed to emulate that of humans (Priya et al., 2024, Lykov et al., 2024, Almeida et al., 2024). Linguists have posited that politeness represents a fundamental aspect of human language, which is pivotal in establishing social order (Li et al., 2023; Brown, 1987). Humans are susceptible to politeness during communication (Yin et al., 2024; Dillon, 2003). For example, human beings generally tend to assist others when requested in a polite language, but they tend not to cooperate when the request is made via an impolite language. In other words, the acceptance of a request is typically determined by the degree of politeness. These results demonstrate that politeness substantially impacts the capacity of the speaker to attain their objectives.

Korean is one of the few languages with an elaborate and explicit honorific system known as 경어법 (*gyeongeobeop*) (Lee, 1982). In Korean, the appropriate level of honorifics is systematically realized at multiple levels for all persons in a conversation, which results in an honorific system that differs from those of other languages (Han, 1999).

The current study examines the influence of the degree of politeness on large language models (LLMs) in request speech acts in Korean on the basis of the argument that AI behavior should mimic human behavior. Thus, it poses the following research questions:

- RQ1. Does the politeness of a prompt influence the response of LLMs?
- RQ2. If RQ1 is true, then how do LLMs differ in perceived politeness?
- RQ3. Why should politeness (not) be considered when designing prompts?

2 Related Work

2.1 Prompting

Prompts are inputs to the generative AI that guides the outputs of a model (Schulhoff et al., 2024; Meskó, 2023; White et al., 2023; Heston and Khun, 2023; Hadi et al., 2023; Brown et al., 2020). The advent of generative AI has motivated several studies to investigate effective prompting techniques to enhance the quality of model responses.

Schulhoff et al. (2024) established a systematic understanding of prompts by categorizing prompting techniques and analyzing their applications. The authors intended to provide a comprehensive understanding of prompts by discussing more than 200 prompting techniques, constructing a framework on them, and considering safety and security issues when utilizing them. This research is significant, because it provides a well-structured organization of the prompting techniques developed to date. Alternatively, Bsharat et al. (2023) introduced 26 fundamental principles for the organization of prompts to facilitate the efficient interaction of developers and general users with LLMs. The study evaluated the effectiveness of these principles on seven LLMs and demonstrated that the efficient reconstruction of prompt contexts improves the relevance and objectivity of responses. Notably, however, the methodology has been verified only for English. By providing an overview of prompts, Sahoo et al. (2024) addressed the lack of systematic organization and comprehension of prompt engineering methodologies. The study summarized the methods associated with 29 prompt engineering techniques, which offered insights into the advantages and disadvantages of each method.

A number of studies have explicitly focused on politeness in prompts. For example, Yin et al. (2024) evaluated the impact of politeness levels on LLMs in English, Chinese, and Japanese. The researchers observed that using impolite prompts typically results in suboptimal performance; nevertheless, excessively polite language does not ensure superior outcomes. Thus, the authors argued that politeness levels that yield the best performance vary across languages. This result demonstrated that LLMs mirror human behavior and are influenced by linguistic nuances in diverse cultural contexts. In a related study, Vinay et al. (2024) conducted an experiment on misinformation generated by LLMs using prompts that feature politeness and impoliteness. The finding illustrated that LLMs generate misinformation on the basis of subtle emotional understanding in polite prompts. Conversely, with impolite prompts, LLMs refrain from generating misinformation and, instead, provide evasive responses. Although this study did not assess the linguistic competence of LLMs in a cultural context, its methodology shared similarities with the current research in the use of the concepts of politeness and rudeness to explain discrepancies in LLM outputs.

2.2 Polite expressions in Korean

Polite expressions are linguistic statements that help maintain and enhance the listener's face through respect and humility (Brown & Levinson, 1987). While this definition provides a general understanding, the specific manifestations of politeness can significantly vary across languages and cultures. The Korean language exhibits a distinctive richness in politeness markers primarily due to its sophisticated honorific system and the development of postpositional particles and word endings (Cheng, 2020).

Jeon (2004) investigated the devices of politeness in Korean conversation and discussed their semantic basis. The study also explored the concept of politeness in varying degrees of expression, which provides a foundation for further research on the nuances of politeness in Korean. Moon (2017) thoroughly examined and analyzed polite expressions in Korean from various perspectives, including phonological, grammatical, lexical, and pragmatic. The researcher classified different types of polite expressions in Korean and conducted a questionnaire survey on native Korean speakers to evaluate the perceived intensity and frequency of use for each type. This approach, which involves direct input from Korean language users, provides valuable empirical data on the perception and use of different forms of politeness in real-world contexts among Korean speakers. Meanwhile, Lee (2011) aimed to provide an in-depth understanding of Korean 경어법(*gyeongeobeop*) by analyzing its essential and primary functions as a key device for polite expression. The study concluded that the fundamental functions of 경어법(*gyeongeobeop*) are to linguistically reveal and handle the status relationship of interlocutors, to adjust the psychological relationship with the other party.

Building on the abovementioned findings of Yin et al. (2024) who investigated the impact of politeness levels on LLMs in English, Chinese and Japanese, the current study aims to ascertain whether or not the degree of politeness in Korean expression influences LLMs. It is based on the politeness levels in the forms of Korean expression forms in request speech acts[1], as presented by Jeon (2004).

3 Dataset

3.1 Collection of QA data

To effectively analyze the potential influence of politeness on LLMs, we collected data suitable for quantitative analysis. The dataset comprises 113 questions from the Life & Ethics and Social Culture sections of the College Scholastic Ability Test (CSAT) and mock exams for 2023 and 2024. The CSAT questions were derived from the Korean Institute for Curriculum and Evaluation, while the mock exams were sourced from the Korea Educational Broadcasting System. The rationale for utilizing these questions as the experimental data is threefold. First, the CSAT and mock exam questions do not infringe on copyright when used for research purposes. Second, they consist of multiple-choice questions that enable quantitative evaluation. Third, the Life & Ethics and Social Culture sections are relatively more accessible and easier to understand compared with other subjects, which reduces the complexity of analysis and enables clear and reliable results.

3.2 Transformation of the QA data

The questions in the QA dataset were modified to ascertain whether or not the degree of politeness in prompt expression forms influence LLMs. This modification was accomplished by incorporating sentences from Table 1 into the QA dataset.

Level	Expression Method of Request Speech Act	Sentence Inserted in the Prompt
Level 1	기본	질문에 알맞은 답을 골라.
	Basic expression	Choose the appropriate answer to the question.
Level 2	약화된 지시표현	질문에 알맞은 답을 좀 골라.
	Softened directive expression	Please choose the appropriate answer to the question.
Level 3	의향 질문표현	질문에 알맞은 답을 고르지 않을래?
	Intention question expression	Why don't you choose the answer that fits the question?
Level 4	능력에 대한 질문표현	질문에 알맞은 답을 고를 수 있니?
	Question about an ability	Can you choose the appropriate answer to the question?
Level 5	소망표현	질문에 알맞은 답을 골라주면 좋겠어.
	Desire expression	I would appreciate it if you could choose the appropriate answer to the question.

Table 1: Prompt Insertion Sentences by Politeness Level

The levels of politeness in different request styles are based on Jeon (2004). Various forms of politeness can be expressed differently in the same conversation. Although determining which form of expression is more polite is challenging, a generally accepted notion is that politeness level ranges from 1 to 5.

When a Level 1 expression "질문에 알맞은 답을 골라" (Choose the appropriate answer to the question) is designated as the primary request form, Level 2 (Softened directive expression) acquires a polite nuance through the addition of the adverb "좀" (*jom*), which translates to "please". The reason is that "좀" (*jom*) functions as "들을 이 배려" (consideration for the listener) (Son, 1988), which can be defined as a reduction of the burden on the other party. Levels 3 (Intention question expression) and 4 (Question about an ability) become polite by transforming the imperative forms of Levels 1 and 2 into interrogative forms. Levels 3 and 4 enable the other party to provide a positive or negative response. Level 3 realizes hearer-centered politeness by negating the entire proposition and distancing the speaker from the proposition as far as possible (Yu, 2010). In contrast, Level 4 realizes politeness by asking whether or not the other party can fulfill the content of the proposition, which reduces the burden of refusal of the listener (Cho, 2022). In Level 5, a polite nuance is acquired by using the idiomatic expression "-면 좋겠어" (*-myeon jokessuh*), which conveys the wishes and hopes of the speaker. The mention of wishes or hopes does not constitute a firm assertion of the claim or opinion of the speaker. Consequently, it is polite, because it does not

[1] A request speech act is defined as an utterance that expresses the intention of the speaker to have the listener perform a specific action.

infringe on the dignity of the listener and enables a careful conveyance of the thoughts of the speaker to the listener (Cho, 2022).

4 Experiment

4.1 Experimental environment and process

The study selected four LLMs on which to observe changes according to the degree of politeness in prompts. The four models are gpt-4-turbo (OpenAI [2]), open-mixtral-8x7b (Mistral AI [3]), CLOVA X (Naver [4]), and solar-1-mini-chat (Upstage [5]). Two multilingual models based on English and two multilingual models based on Korean were selected. Additionally, given the variable of the model size, relatively larger and smaller language models were selected for each base language.[6] Detailed information about the selected models can be found in Table 2.

Model	Developer	Release	Context Length	Language
gpt-4-turbo	OpenAI	2023	128,000	Multilingual
open-mixtral-8x7b	Mistral AI	2023	32,000	Multilingual
ClOVA X	Naver	2021	-	Korean, English
solar-1-mini-chat	Upstage	2024	32,768	Korean, English

Table 2: Experimental Model Information

The experiment was conducted in a zero-shot environment, which enabled the performance of tasks according to instructions without prior training or example. The prompt containing QA data used in the experiment is shown in Table 3.

Original Prompt	Translated Prompt
질문에 알맞은 답을 골라. (가), (나) 윤리학의 핵심 과제로 가장 적절한 것은? (가) 윤리학은 도덕적 행위를 정당화하는 규범적 근거를 탐구하고, 마땅히 행해야 할 행위의 객관적인 도덕 원리를 제시하는 데 주력해야 한다. (나) 윤리학은 규범적 속성의 존재론적·인식론적 지위를 탐구하고, 도덕적 용어의 의미를 분석하며, 도덕 추론의 규칙을 검토하는 데 주력해야 한다. ① (가) : 도덕적 삶의 지침이 되는 보편적 원리를 제시하는 것이다. ② (가) : 도덕 현상 간의 인과 관계를 가치중립적으로 설명하는 것이다. ③ (나) : 학제적 연구 방법으로 실생활의 도덕 문제를 해결하는 것이다. ④ (나) : 각 사회의 다양한 도덕적 관습을 객관적으로 기술하는 것이다. ⑤ (가)와 (나) : 도덕 언어의 의미와 도덕 추론의 구조를 분석하는 것이다. **정답:**	**Choose the appropriate answer to the question.** What is the most appropriate core task of ethics in (a) and (b)? (a) Ethics should focus on exploring the normative basis for justifying moral actions and presenting objective moral principles for actions that should be taken. (b) Ethics should focus on exploring the ontological and epistemological status of normative properties, analyzing the meaning of moral terms, and examining the rules of ethical reasoning. ① (a): To present universal principles that serve as guidelines for moral life. ② (a): To explain the causal relationships between moral phenomena in a value-neutral manner. ③ (b): To solve real-life moral problems through interdisciplinary research methods. ④ (b): To objectively describe the various moral customs of each society. ⑤ (a) and (b): To analyze the meaning of moral language and the structure of moral reasoning. **Answer:**

Table 3: Prompt Example

4.2 Experimental Results

The study analyzed how LLMs changed according to different levels of politeness in prompts from two perspectives, namely, accuracy and friendliness. Accuracy was quantitatively assessed using the correct answer rate and explanation similarity, while friendliness was evaluated based on the presence of explanations and length of responses.

4.2.1 Accuracy

Correct Answer Rate To analyze the effect of politeness on accuracy, the study calculated the probability of correct answers (i.e., correct answer rate)[7], using the 113 QA data. Table 4 presents the correct answer rates of the model according to the politeness levels of the prompts.

[2] https://openai.com/
[3] https://mistral.ai/
[4] https://www.navercorp.com/
[5] https://www.upstage.ai/
[6] The English-based large model is gpt-4-turbo, while the small model is open-mixtral-8x7b. The Korean-based large model is ClOVA X, while the small model is solar-1-mini-chat. For the sake of convenience, these will be referred to as GPT-4, Mixtral, ClOVA X, and Solar, respectively, in the following sections.
[7] In this experiment, for multiple-choice questions, both cases were considered where only the number was given as an answer and cases where an explanation was provided along with the number as correct answers.

Politeness Level/Model	GPT-4	CLVOA X	Mixtral	Solar
Level 1	**59.3%**	**41.6%**	39.8%	50.4%
Level 2	**58.4%**	**43.4%**	36.3%	42.5%
Level 3	**57.5%**	**44.2%**	38.9%	49.6%
Level 4	**55.8%**	**44.2%**	38.9%	49.6%
Level 5	**55.8%**	**46.9%**	36.3%	46.0%

Table 4: Correct Answer Rate by Politeness Level in Prompts

Model	Ranking of the Correct Answer Rates
GPT-4	**5 ≤ 4 < 3 < 2 < 1**
CLVOA X	**1 < 2 < 3 ≤ 4 < 5**
Mixtral	5 ≤ 2 < 3 ≤ 4 < 1
Solar	2 < 5 < 3 ≤ 4 < 1

Table 5: Comparison of Correct Answer Rate Rankings by Politeness Level in Prompts.

GPT-4 showed a lower correct answer rate as the requests became more polite, whereas CLOVA X demonstrated a higher correct answer rate under the same conditions. To verify the significance of these interesting results, a linear regression analysis was conducted. The results demonstrated that these relationships are statistically highly significant (GPT-4: $p < 0.001$[*]; CLOVA X: $p < 0.01$[***]).[8] In contrast, the study found no discernible pattern in the correct answer rates according to the politeness level for Mixtral and Solar. Linear regression analysis yielded $p = 0.533$ for Mixtral and $p = 0.778$ for Solar, which imply nonsignificant correlations between the degree of politeness and accuracy.

Model	Coefficient	*t*-Value	*p*-Value	Significance
GPT-4	−0.8800	−76.210	**0.000**	***
CLOVA X	1.0500	10.057	**0.002**	**
Mixtral	5.693e−15	0.703	**0.533**	–
Solar	−0.3500	−0.308	**0.778**	–

Table 6: Results of OLS Regression Between Correct Answer Rate and Politeness Level

Notably, Mixtral exhibited a performance similar to GPT-4 in which Levels 1 and 5 obtained the highest and lowest accuracy, respectively. The study expected that the rate of correct responses would increase with the increase in the degree of politeness of requests, because people generally tend to react positively to polite requests. However, the multilingual models based on English exhibited the opposite result. This result implies that when making requests in Korean to English-based multilingual models, directly and concisely stating the desired outcome is more effective than focusing on politeness. Furthermore, the fact that CLOVA X, a Korean-based model, displays the opposite tendency to foreign language-based models (i.e., GPT-4 and Mixtral) indicates that learning primarily from large amount of Korean data helps in acquiring politeness, which is part of the linguistic characteristic of Korean.

Explanation Similarity Explanation similarity was calculated to further examine the impact of politeness on the prompts from the perspective of accuracy. The study investigated the similarity of the explanations by comparing LLMs' responses using the authoritative explanations from the official CSAT and the mock guide.[9] BERTScore (Zhang et al., 2019), which generates embedding vectors for the two texts using a pre-trained language model and evaluates their similarity, was used for quantitative comparison. BERTScore was calculated for explanation similarity only when the correct response was provided. Table 7 displays the resulting values.

Politeness Level/Model	GPT-4	CLVOA X	Mixtral	Solar
Level 1	0.712	0.703	0.678	0.717
Level 2	0.714	0.699	0.673	0.719
Level 3	0.716	0.706	0.676	0.715
Level 4	0.715	0.712	0.679	0.716
Level 5	0.710	0.707	0.672	0.706

Table 7: Explanation Similarity by Politeness Level in Prompts

Model	Ranking of Explanation Similarity
GPT-4	5 < 1 < 2 < 4 < 3
CLVOA X	2 < 1 < 3 < 5 < 4
Mixtral	5 < 2 < 3 < 1 < 4
Solar	5 < 3 < 4 < 1 < 2

Table 8: Comparison of Explanation Similarity Rankings by Politeness Level in Prompts

We hypothesized that the model-generated responses would become increasingly similar to those found in official guides with the increase in the politeness level of requests. In other words, the accuracy of the explanations would increase. However, the study observed no discernible trend in the performance of the models. These findings indicate that the degree of politeness does not

[8] *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$. The number of asterisks indicates the level of statistical significance. More asterisks represent higher levels of significance.

[9] The explanations are derived from the official CSAT and the mock guide distributed by the Korea Educational Broadcasting System.

influence the quality of the explanations generated. Furthermore, the difference between the maximum and minimum BERTScores for each model was approximately 0.01, which indicates that all models provided explanations of similar quality regardless of politeness level. This result contrasts with the percentage of correct responses, which exhibited model-specific tendencies.

4.2.2 Friendliness

Presence of Explanation Humans tend to respond kindly when receiving polite requests (Clark & Schunk, 1980). If AI undergoes cognitive processes similar to those of humans, then it would be expected to explain its answers to respond kindly to polite requests. We examined the presence or absence of explanation generation to investigate the effect of politeness levels on friendliness. Table 9 illustrates the percentage of explanations generated according to politeness level.

Politeness Level/Model	GPT-4	CLVOA X	Mixtral	Solar
Level 1	**85.8%**	**20.4%**	84.1%	84.1%
Level 2	**93.8%**	**30.1%**	89.4%	77.9%
Level 3	**99.1%**	**61.1%**	92.9%	76.1%
Level 4	**99.1%**	**66.4%**	91.2%	79.6%
Level 5	**100.0%**	**62.8%**	92.0%	74.3%

Table 9: Explanation Rate by Politeness Level in Prompts

Model	Ranking of the Explanation Rates
GPT-4	**1 < 2 < 3 ≤ 4 < 5**
CLVOA X	**1 < 2 < 3 < 5 < 4**
Mixtral	1 < 2 < 4 < 5 < 3
Solar	5 < 3 < 2 < 4 < 1

Table 10: Comparison of Explanation Rate Ranking by Politeness Level in Prompts

GPT-4 and CLOVA X tended to generate explanations more frequently when requests were politely phrased. In particular, CLOVA X showed a distinctly different pattern from other models with more than three times the difference between level 1 and level 5, while GPT-4 demonstrated sensitivity to prompt politeness by unconditionally outputting explanations for the most polite requests. Despite being a multilingual model based on Korean, Solar generated a small number of explanations for the most polite requests and a large number of explanations for the least polite requests, which indicates that it could not recognize the inherent politeness in Korean sentences.

Response Length Polite requests and lengths of responses are strongly correlated, as is presence of explanation. Accordingly, the study calculated the average length of responses produced by a model based on the number of syllables to observe the influence of the prompts. Table 11 presents the average length of responses by politeness level.

Politeness Level/Model	GPT-4	CLVOA X	Mixtral	Solar
Level 1	**335.75**	**83.24**	441.96	383.62
Level 2	**367.71**	**108.51**	498.21	355.24
Level 3	**414.39**	**204.56**	490.59	344.01
Level 4	**490.19**	**217.64**	443.47	393.93
Level 5	**467.13**	**198.88**	494.93	373.81

Table 11: Response Length by Politeness Level in Prompts

Model	Ranking of Response Length
GPT-4	**1 < 2 < 3 < 5 < 4**
CLVOA X	**1 < 2 < 5 < 3 < 4**
Mixtral	1 < 4 < 3 < 5 < 2
Solar	3 < 2 < 5 < 1 < 4

Table 12: Comparison of Response Length Ranking by Politeness Level in Prompts

When comparing the lengths of responses between Level 1 and Levels 4-5, the study observed that GPT-4 and CLOVA X tended to provide more expansive responses when requests were more polite. Moreover, the difference in the lengths of responses between the lower and upper politeness levels was notably larger for the two abovementioned models compared with those of the others. In contrast, Mixtral and Solar did not exhibit a specific pattern in response length according to level of politeness, and the differences in length across levels were less pronounced than those of GPT-4 and CLOVA X. These results imply that large-scale multilingual models, such as GPT-4 and CLOVA X, are more attuned to the features of the Korean language (i.e., sensitive and responsive to politeness) in contrast to small multilingual models such as Mixtral and Solar. This finding indicates that the amount of training data and the size of the model parameters are critical factors in creating creation of models that exhibit human-like responses to varying levels of politeness in language.

In summary, large models (GPT-4 and CLOVA X), which have extensive training data and many parameters, are more linguistically sensitive to Korean compared with the small models. In particular, CLOVA X displayed the highest sensitivity to Korean as depicted by increased

correct answer rate, explanation rate, and response length with the increase in level of politeness. GPT-4 also demonstrates sensitivity to Korean politeness in terms of explanation generation and response length but exhibited a reverse trend in correct answer rate, which signals a low level of Korean knowledge compared with LLMs primarily trained in Korean. GPT-4 and Mixtral exhibited a unique pattern of decreasing accuracy with the increase in politeness. This result suggests that when making requests in Korean to English-based multilingual models, using simple, straightforward, and intuitive language may be more effective than focusing on politeness. Observed only in the English-based models, this trend implies that the primary language used in the training data may influence this phenomenon.

5 Conclusion

This study investigated the effect of level of politeness in Korean prompts on LLMs. Five distinct prompts were created, which each represented a different level of politeness based on request speech acts and was designed according to the forms of politeness in Korean expression as presented by Jeon (2004).

Using a newly reorganized QA dataset, the study evaluated four language models, namely, GPT-4, CLOVA X, Mixtral, and Solar, using the five prompts. The results demonstrated that LLMs, such as GPT-4 and CLOVA X, can recognize politeness in Korean and generate responses that are intentionally aligned with the level of politeness. In contrast, small models, such as Mixtral and Solar, produced responses that were seemingly random in relation to levels of politeness. This difference is attributed to the quantity of training data and model parameter size, which indicates that small models remain insufficient in replicating human-like responses to nuanced language features such as politeness.

The findings emphasize the need for prompt design principles that are specific to Korean and consider its expressions of politeness. In particular, CLOVA X exhibited improved problem-solving abilities and increased kindness in responses with the increase in the level of politeness of prompts. This pattern suggests that when a model can correctly interpret the politeness level of a language, a prompt design that considers politeness can lead to more effective outcomes.

Finally, we explored the performance of language models in addressing Korean polite expressions, an area that has not been extensively researched. However, the current study did not examine the relationship between language models and users—a key factor in understanding politeness. To address these limitations, future research should more comprehensively consider the grammatical, lexical, and pragmatic levels of politeness in Korean, while also establishing a detailed framework for analyzing the relationship between language models and users. Additionally, a qualitative investigation into how different levels of politeness in prompts affect LLM-generated responses is necessary. Furthermore, repeating the same experiment several years from now could offer valuable insights into how LLMs have evolved in handling Korean polite expressions, making it a significant direction for future research.

B Responses by politeness levels (Clova X; English version)

Question	Answer
Choose the appropriate answer to the question. What is the most appropriate stance based on (a) and (b)? (a) Sexual activity should only be practiced in relationships in which the responsibility for childbirth and child-rearing can be fulfilled. Therefore, only sexual activity between spouses is morally justified. (b) Sexual activity is morally justified given that the duty to respect the personhood of others is upheld. This duty is fulfilled by adhering to the principles of voluntary consent between parties and the prevention of harm. ① (a): Sexual activity is a private issue and, thus, unrelated to social responsibility. ② (a): Sexual activity is morally justified only within the confines of marriage. ③ (b): Sexual activity, once consensual, is free from all responsibility. ④ (b): The freedom of sexual activity and the duty to respect personhood are in conflict. ⑤ (a) and (b): The duty to respect personhood in sexual activity is required only in relationships in which love is present. **Answer:**	2 (a): Sexual activity is morally justified only within the confines of marriage.

Table 16: Politeness Level 1

Question	Answer
Why don't you choose the answer that fits the question? What is the most appropriate stance based on (a) and (b)? (a) Sexual activity should only be practiced in relationships in which the responsibility for childbirth and child-rearing can be fulfilled. Therefore, only sexual activity between spouses is morally justified. (b) Sexual activity is morally justified given that the duty to respect the personhood of others is upheld. This duty is fulfilled by adhering to the principles of voluntary consent between parties and the prevention of harm. ① (a): Sexual activity is a private issue and, thus, unrelated to social responsibility. ② (a): Sexual activity is morally justified only within the confines of marriage. ③ (b): Sexual activity, once consensual, is free from all responsibility. ④ (b): The freedom of sexual activity and the duty to respect personhood are in conflict. ⑤ (a) and (b): The duty to respect personhood in sexual activity is required only in relationships in which love is present. **Answer:**	2 (a): Sexual activity is morally justified only within the confines of marriage. (a) argues that sexual activity should be practiced in relationships in which the responsibility for childbirth and child-rearing can be fulfilled. Thus, it can be viewed as morally justified only within marriage. Alternatively, (b) argues that sexual activity is morally justified given that the duty to respect personhood is fulfilled. Therefore, it can also be morally justified outside of marriage.

Table 17: Politeness Level 3

Question	Answer
I would appreciate it if you could choose the appropriate answer to the question. What is the most appropriate stance based on (a) and (b)? (a) Sexual activity should only be practiced in relationships in which the responsibility for childbirth and child-rearing can be fulfilled. Therefore, only sexual activity between spouses is morally justified. (b) Sexual activity is morally justified given that the duty to respect the personhood of others is upheld. This duty is fulfilled by adhering to the principles of voluntary consent between parties and the prevention of harm. ① (a): Sexual activity is a private issue and, thus, unrelated to social responsibility. ② (a): Sexual activity is morally justified only within the confines of marriage. ③ (b): Sexual activity, once consensual, is free from all responsibility. ④ (b): The freedom of sexual activity and the duty to respect personhood are in conflict. ⑤ (a) and (b): The duty to respect personhood in sexual activity is required only in relationships in which love is present. **Answer:**	2 (a): Sexual activity is morally justified only within the confines of marriage. The position in (a) argues that sexual activity should be practiced within relationships in which the responsibility for childbirth and child-rearing can be fulfilled. Therefore, sexual activity between spouses is viewed as the only morally justified form. This reflects the view that sexual activity is morally justified only within marriage. Alternatively, (b) argues that sexual activity is morally justified given that the duty to respect personhood is fulfilled. This duty is carried out through mutual consent between parties and adherence to the principle of the prevention of harm. However, it does not mean that consensual sexual activity is free from all responsibility. Therefore, the most appropriate answer that reflects (a) and (b) is option 2.

Abstract

One of the many reasons why low-resource Philippine languages struggle with research visibility can be attributed to the lack of language-optimized accessible resources, including computational models such as BERT and GPT. In this work, we make a push aligned to this initiative of democratizing resources for low-resource languages by introducing **CebBERT**, a lightweight, data-transparent DistilBERT model for the Cebuano language processing tasks. Compared to other models, CebBERT uses a compilation of diverse, multi-domain data sources ranging from Cebuano literary works, religious texts, news articles, translations, and speech transcripts, among others. Our results upon evaluating CebBERT with challenging multiclass and multilabel tasks, including figures-of-speech identification and online symptom classification in Cebuano, show promising results and even outperform comparable Cebuano-based models such as mBERT and DOST-BERT.[1]

1 Introduction

In recent years, research in natural language processing (NLP) models has rapidly advanced due to the development of the Transformer architecture (Bahdanau, 2014; Vaswani et al., 2017). This led to more efficient processing of text data and a substantial increase in model performance, especially for machine translation. Deriving from this major contribution, the Bidirectional Encoder Representations from Transformers (BERT) architecture (Devlin et al., 2019) was released. This architecture used multiple encoder layers of the original Transformers, bidirectional processing, specific next-sentence prediction, and masked language modeling objectives for improved context representations of natural language understanding (NLU) tasks. With BERT, researchers were able to *finetune* more models to cater to several downstream tasks which set state-of-the-art performances in named entity recognition, language inference, text classification, and question answering (Howard and Ruder, 2018; Merchant et al., 2020; Mosbach et al., 2021).

In the context of low-resource languages, the rise of modern language models like BERT and its derivations have lagged due to the lack of the required amount of publicly available language-specific data for pre-training (Lovenia et al., 2024). For instance, Cebuano (Ceb), a language spoken by roughly 20 million people primarily in the Southern and Central regions of the Philippines, boasts great cultural and linguistic diversity (Wolff, 2001). Due to the limited availability of resources such as diverse machine-readable corpora, there have not been many NLP applications being developed for the Cebuano language (Imperial et al., 2022; Aji et al., 2023).

Building on this motivation, we introduce CebBERT, a new Cebuano-based encoder model based on the DistilBERT architecture (Sanh et al., 2019). DistilBERT is a lighter, faster, and more efficient version of BERT and uses a special knowledge distillation method to reduce the original size of BERT by 40% but preserves comparable performance across downstream NLP tasks and runs 60% faster. By creating a Cebuano-based adaptation of the DistilBERT model, we aim to expand the accessibility and usability of NLP tasks for the language. In constructing CebBERT, we compiled diverse open-source Cebuano corpora from the web ranging from news articles, translations, transcripts, literary texts such as stories and poems, and many more.

To specify, our main contributions to this work on expanding NLP initiatives for Cebuano are two-fold:

[*]Work done during internship for the HealthPH Project at National University Philippines.

[1]Code and data: https://github.com/gctanuser/CebuanoDistilBERT

1. We introduce CebBERT, a new lightweight DistilBERT model trained from a collection of purely open-source diverse multi-domain datasets for Cebuano language processing tasks.

2. We present an empirical evaluation of CebBERT and showcase the efficiency and high performance of CebBERT across two challenging unseen NLP tasks of online symptom report classification and figures-of-speech identification in Cebuano.

2 Related Works

2.1 Multilingual Language Models

Multilingual models, particularly derivations from Transformer and BERT architectures, have been studied by Wu and Dredze (2019) and Pires et al. (2019), showing that these models can perform cross-lingual generalization surprisingly well. These models also create multilingual representations, but these representations exhibit systematic deficiencies affecting certain language pairs. Their research demonstrated that a single model could effectively learn from various languages, establishing robust baselines for tasks in non-English languages. There are already existing mulitilingual models of BERT that exist, but single-language models have shown better performance in their respective languages. Examples of these models include CamemBERT (Martin et al., 2020) and FlauBERT (Le et al., 2020) for French, BERTje (de Vries et al., 2019) and RobBERT (Delobelle et al., 2020) for Dutch, FinBERT (Virtanen et al., 2019) for Finish and Spanish BERT (Cañete et al., 2023).

2.2 NLP Initiatives for Southeast Asian Languages

Research initiatives on open corpora building for low-resource languages drive the growth and development of the future of NLP. The biggest and most notable work for Southeast Asia was the SEACrowd Project[2] (Lovenia et al., 2024) led by AI Singapore and around 60+ researchers all over the world. The SEACrowd Project contains the largest multimodal catalog of online available datasets in Southeast Asian languages as well as benchmark experiments on recent open and commercial models for SEA language understanding and generation. Through the years, researchers from specific SEA member countries have also pushed their own contributions for releasing open-source SEA corpora. The works of Cahyawijaya et al. (2021, 2023) and Winata et al. (2023) covered works on local Indonesian languages for language generation, crowdsourcing, and sentiment analysis. The works of Dita et al. (2009); Dita and Roxas (2011), Oco et al. (2016), Cruz and Cheng (2022), and Visperas et al. (2023) for Philippine languages have developed from releasing small compiled resources in Filipino to releasing language models trained from modern deep learning architectures like BERT. A similar observation from Thai is seen with works from Kruengkrai et al. (2020); Noraset et al. (2021); Lowphansirikul et al. (2021) focusing on question-answering and NER systems. Overall, these initiatives, no matter how big or small, ensure the research survivability of Southeast Asian languages in the NLP scene.

2.3 Current Research in NLP for Cebuano

Focusing on Cebuano, most of the NLP works on this language have developed only very recently, which supports the need for more open-sourced and publicly available low-resource languages. For named-entity recognition (NER), the earliest work was done by Maynard et al. (2003) using software originally made for the English but was only continued after 19 years with the works of Gonzales et al. (2022) and Pilar et al. (2023) developing Cebuano-specific models for the task. In machine translation, the works of Adlaon and Marcos (2019) and Fernandez and Adlaon (2022) have focused on alleviating the alignment problem and using Filipino as the anchor language. In readability analysis and text complexity prediction, extensive works by Imperial et al. (2022); Imperial and Kochmar (2023b,a) evolved from developing Cebuano-specific models using traditional features to bigger models capturing closely similar languages such as Kinaray-a, Minasbate, and Hiligaynon which collectively improved model performances.

3 CebBERT: A Lightweight Data-Transparent LLM for Cebuano

In this section, we discuss the main recipe for developing CebBERT. We cover information on corpus collection and processing, pre-training and architecture details, and model configurations.

Table 1: Breakdown and related information of compiled diverse publicly available Cebuano datasets used for pertaining CEBBERT. We provide characteristics of each dataset, including domain, format, instances, downloadable links, source published works, and associated licenses. As a disclaimer, datasets with † have no identified specific licenses but can be accessed and used for non-commercial research. Thus, we identify a default license of CC BY 4.0 based on the nature of these datasets.

3.1 Cebuano Pre-training Data Information

To pre-train CEBBERT, we compiled all publicly available text data in the Cebuano language from the web, including resources from repositories such as Huggingface, Github, and artifacts from published papers. From this, we were able to build a diverse Cebuano corpus covering biblical texts, news articles, literary texts, Wikipedia pages, instructions, and speech transcripts. Table 1 reports the distribution of the compiled dataset from various sources with corresponding information on domain, format, instance counts, website links, paper sources, and licenses. Overall, the compiled Cebuano corpus to pretrain CEBBERT contains 253,539 unique rows of texts and a vocabulary of approximately 30,000 tokens.

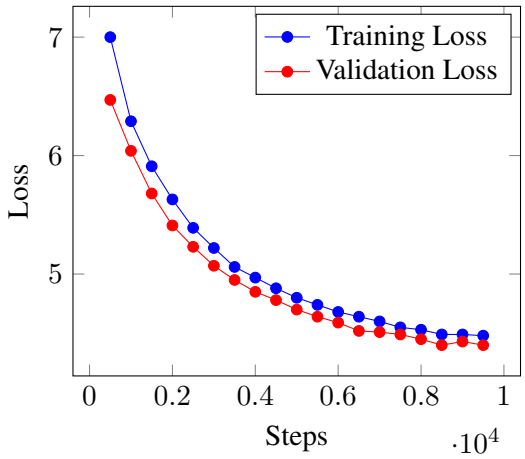

Figure 1: Loss values of pre-training the CEBBERT model using masked language modeling (MLM) and distillation training objective as done in the DistilBERT (Sanh et al., 2019) architecture.

3.2 The DistilBERT Architecture

To build a more efficient and lightweight Cebuano model, we use DistilBERT (Sanh et al., 2019) as its main architecture. DistilBERT focuses on reducing the size of the original BERT model (Devlin et al., 2019) by pretraining smaller general-purpose language representation models with knowledge distillation. Knowledge distillation is a technique wherein it extracts knowledge from the teacher and utilizes that knowledge for the student to learn and adapt (Gou et al., 2021) where the student is the compact model that is trained to reproduce the behavior of the teacher, the larger model. This concept was used for DistilBERT, which was able to retain 97% of the original BERT model's performance across downstream NLP tasks while being 40% smaller and 60% faster than BERT. To our knowledge, this work is the first publicly available Cebuano DistilBERT model trained from a diverse collection of Cebuano datasets and evaluated on unseen Cebuano language tasks.

3.3 Pretraining Configurations

The CEBBERT model was trained on a single NVIDIA Tesla L4 GPU using PyTorch and Huggingface. For hyperparameter configurations, CEBBERT model was configured with a GELU activation function, a hidden size of 768, an attention dropout rate of 0.1, and a feed-forward network hidden size of 3072 while preserving the cased function. The model used 12 attention heads across its 6 layers, with a maximum sequence length of 256 tokens. An initializer range of 0.02 was used, and dropout rates of 0.1 and 0.2 were applied to attention and classifier layers, respectively. The training process involved 3 epochs with a learning rate of

5e-05 using the compiled Cebuano corpus previously discussed. No warmup steps were employed during training. We show the trend of training and validation loss curves in Figure 1.

4 Evaluating CebBERT for Unseen Cebuano Tasks

In this section, we describe the two NLP tasks we consider for evaluating the quality of embeddings and predictions from our CebBERT model. We consider the datasets as *unseen* as they are newly collected and have never been published, thus making these datasets fit for evaluating Cebuano-based language models.

4.1 Task 1 - Multilabel Classification of Online Cebuano Symptom Reports

The first task we considered for evaluation is a multilabel classification task of identifying potential ailments from online symptom reports written in Cebuano. The dataset for this task was obtained from the National University Philippines's HealthPH: Intelligent Disease Surveillance for Public Health using Social Media Project[3] funded by the Department of Science and Technology (DOST). This dataset contains a total of 1,028 rows of social media posts across multiple platforms describing the user's expression with mentions of symptoms. Each post has been annotated by two medical professionals based on their potential to be classified in one or more possible ailments covering AURI for acute upper respiratory infection, COVID for coronavirus disease, PN for pneumonia, and TB for tuberculosis. As a multiclass classification task, one post can have more than one label from these potential ailments.

Label	Example (+ EN Translation)	Count
AURI	*Ataya ani nga hilanat oy!* *(This fever is so annoying!)*	484
COVID	*Grabe ang ubot sipon huhu* *(My cough and cold are really bad)*	403
PN	*Imbes magmayad ang ubo naglala pa* *(My cough has gotten worse)*	297
TB	*Di ako nilulubayan ng ubo ha* *(The cough won't leave me alone)*	238

Table 2: Breakdown of counts and examples for the multilabel online symptom data for Task 1. For brevity and visualization constraints, we selected shorter examples for each class.

[3] https://healthphproject.org/

4.2 Task 2 - Cebuano Figures of Speech Identification

The second task we considered for evaluation is a multiclass classification task of identifying figures of speech in Cebuano. Similar to Task 1, we also obtained this dataset from the HealthPH Project, specifically from the NLP Working Group. This acquired dataset was scraped from Wiktionary[4] and contains 943 rows of Cebuano figures of speech texts divided across four categories covering Literal or language which convey widely-accepted meaning, Catchphrases or phrases that have been popularized, Idioms or phrases which convey subjective meaning in contrast to literals, and Euphemisms or language that indirectly refer to something controversial. We use these categories as gold-standard labels for model training.

Label	Example (+ EN Interpretation)	Count
Catch	*Klaro kaayo sa pattern* *(Clear as day)*	65
Euph	*Anak sa hulaw* *(A short person)*	112
Idiom	*Abot sa dunggan ang ngisi* *(To be overjoyed, extremely happy)*	619
Literal	*Manggihatagon* *(Generous)*	147

Table 3: Breakdown of counts and examples for the multiclass figures of speech identification for Task 2. For brevity and visualization constraints, we selected shorter examples for each class.

4.3 Finetuning and Embedding Extraction Configurations

For the finetuning setup, we set hyperparameters epoch to 5, learning rate α to 2e-05, and batch size to 32. We initially explored other values for these hyperparameters, but the aforementioned values resulted in the best performances for both multiclass and multilabel tasks. For the extraction of embeddings, from CebBERT, mBERT, and DOST-BERT, we obtained the mean layer representations with a dimension of 768 for each instance from the task datasets. These embeddings will be used directly as features for the Random Forest model to evaluate the quality of word representations given by each model. Lastly, we use a 90-10 train-test split for each task for evaluation.

[4] Data from Wiktionary is covered by the CC BY-SA 3.0 license, which allows use and sharing in research.

4.4 Baseline Models and Metrics

As a point of performance and quality comparison, we perform the same finetuning and embedding extraction to two adjacent Cebuano-based BERT models available online: MBERT or multilingual BERT by Devlin et al. (2019) and DOST-BERT by Visperas et al. (2023). In terms of the quality of data used, MBERT was pretained using a compilation of Wikipedia dumps which includes Cebuano while DOST-BERT was pretrained with internet-scraped data from formal and informal resources. For evaluation metrics, we compute the Accuracy, F1 score, and Hamming Loss for each task. Accuracy and F1 show insight on the correctly classified labels for the models, while the Hamming loss shows how much fraction of labels were incorrectly predicted.

5 Results

In this section, we discuss the results from the experimentation procedures using the two unseen tasks in evaluating CEBBERT and its adjacent Cebuano-based language models.

5.1 Model Performances for Tasks

First, we focus on the results from Task 1 on the multilabel classification of online symptoms as reported in Table 4. From the Table, we see that using embedding representations as features from the DOST-BERT model obtained the highest accuracy score of 0.367 and Hamming loss of 0.337. This is followed by embeddings from CEBBERT with 0.349 and MBERT last with 0.339. The high accuracy score denotes a possibility that the embeddings from DOST-BERT were able to correctly predict the labels from the majority class. However, since the data is imbalanced for this task, we emphasize the importance of the F1 score, which CEBBERT takes the lead with 0.747. A high F1 score means the model was able to balance precision and recall predictions of correct labels, especially for minority classes in the task. On the other hand, for the finetuning setup, we see a change in model performance where MBERT now takes the lead across all metrics with 0.694 in accuracy, 0.762 in F1, and 0.165 for Hamming loss. We posit that this effectiveness from MBERT for finetuning may have from the generalizability of multiple language data where the model was trained which has also been observed in previous works (Conneau and Lample, 2019). The second best-performing model comes from CEBBERT with 0.664 in accuracy, 0.722 in F1, and 0.182 for Hamming loss. Interestingly, the MBERT and CEBBERT were models not pretrained from Cebuano social media posts, which is the domain of the dataset in Task 1, but were the top models for this Task. From this, we believe that the quality of pretraining data is more contributive to the performance than quantity.

Overall, as a model trained from a distilled version of BERT using fewer parameters, the performance from CEBBERT for Task 1 shows its efficiency and effectiveness as a qualified Cebuano-based model.

Setup	Acc	F1	HLoss
RF + MBERT$_{emb}$	0.339	0.721	0.340
RF + DOST-BERT$_{emb}$	**0.367**	0.708	**0.337**
RF + CEBBERT$_{emb}$	0.349	**0.747**	0.339
MBERT$_{FT}$	**0.694**	**0.762**	**0.165**
DOST-BERT$_{FT}$	0.619	0.736	0.175
CEBBERT$_{FT}$	0.664	0.722	0.182

Table 4: Performance of finetuned ($_{FT}$) and embedding-based Random Forest model ($_{emb}$) for Task 1 - Online Symptom Reports Multilabel Classification.

Next, we look at model performances for Task 2 on the identification of Cebuano figures of speech as reported in Table 5. From the Table, we now see even more favorable performance for CEBBERT. For both the Random Forest model trained from the models' embedding features and the finetuned versions, we observe CEBBERT taking the lead in terms of performance across all metrics with 0.600 and 0.879 accuracy scores, 0.588 and 0.894 F1 scores, and 0.400 and 0.054 Hamming losses for embedding and finetuned setup accordingly. These are followed by performances from DOST-BERT and MBERT. Looking at the nature of Task 2, which is in the domain of literary knowledge, the advantage of CEBBERT being trained with literary datasets in the form of children's books, poems, and short stories has been instrumental in boosting its performance for identification of figures of speech.

5.2 Error Analysis

Aside from looking at model performances, we also analyze errors through misclassifications by CEBBERT on specific cases by visualizing confusion matrices for each task.

Figures 2 and 3 show the disjointed per-class confusion matrices of CEBBERT for setups us-

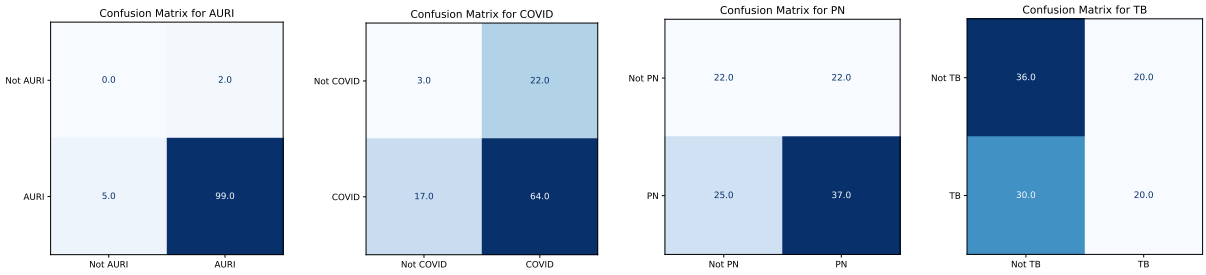

Figure 2: Confusion matrices from performance CEBBERT using Random Forest with extracted embeddings as features for Task 1 - Online Symptom Reports Multilabel Classification.

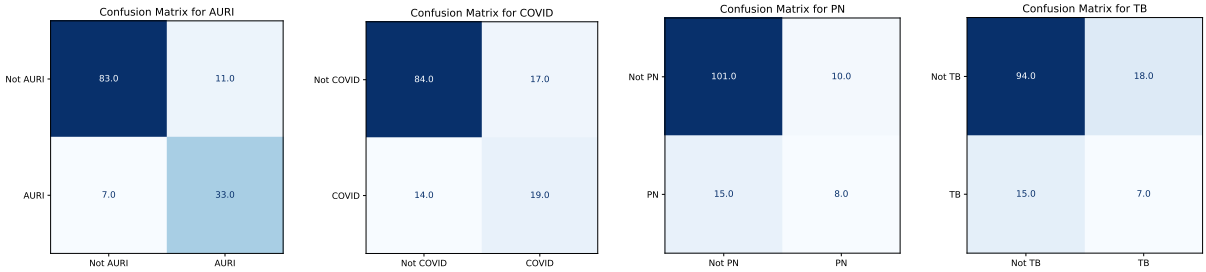

Figure 3: Confusion matrices from performance CEBBERT using finetuning for Task 1 - Online Symptom Reports Multilabel Classification.

Setup	Acc	F1	HLoss
RF + MBERT$_{emb}$	0.565	0.537	0.415
RF + DOST-BERT$_{emb}$	0.592	0.576	0.407
RF + CEBBERT$_{emb}$	**0.600**	**0.588**	**0.400**
MBERT$_{FT}$	0.811	0.830	0.081
DOST-BERT$_{FT}$	0.864	0.873	0.076
CEBBERT$_{FT}$	**0.879**	**0.894**	**0.053**

Table 5: Performance of finetuned ($_{FT}$) and embedding-based Random Forest model ($_{emb}$) for Task 2 - Cebuano Figures of Speech Identification.

ing Random Forest with extracted embeddings and finetuning, respectively for Task 1. From the visualizations, we see that using embeddings as features has caused some confusion to the Random Forest model trained with embeddings from CEBBERT specifically for texts with COVID and PN labels. However, this is alleviated if we move to the use of finetuning of CEBBERT itself. This change in misclassifications can be traced back to Table 4 where we see CEBBERT gaining almost double in performance in the finetuning setup (0.664 in accuracy and 0.772 in F1) compared to the embeddings approach (0.349 in accuracy and 0.747 in F1).

Figures 4 and 5 show the combined per-class confusion matrices of CEBBERT for setups using Random Forest with extracted embeddings and finetuning, respectively for Task 2. From the visualizations, we see the same trend where finetuning CEBBERT provides more stable and accurate predictions over using Random Forest and extracted embeddings as features. Likewise, this can also be traced in Table 5 where an increase in performance is observed with CEBBERT compared to other Cebuano-based BERT models. These findings from the error analysis of our work strengthen the practicality of using CEBBERT for both NLP tasks requiring extraction of representations for Cebuano texts as well as for finetuning activities with the model.

6 Discussion

Following the insights obtained from the experimental results, we put forward two main points of discussion covering the importance of diverse dataset quality for low-resource language models as well as the need for setting standards to ensure continuous growth of NLP research for the Cebuano language.

Importance of Diverse Datasets for Low-Resource Language Models Synthesizing the results and evidences found in Section 5, it is clear that the reason CEBBERT was able to obtain very comparable performance and even surpassing the only two available Cebuano-based BERT models, MBERT and DOST-BERT, is due to its data diversity and transparency. Our experience with

collecting and aggregating the Cebuano datasets for pretraining CebBERT is that sources from published papers and websites may come with small contributions but, if compiled all together, may produce a sizeable amount sufficient for exploring resource-efficient architectures such as DistilBERT. Using diverse, high-quality datasets from different domains such as news, literature, and religion enables the multipurpose usage of language models trained from these datasets. We echo the findings from Ibañez et al. (2022), where they tested a Tagalog BERT model trained purely from Tagalog Wikipedia dumps and found it impractical and low-performing for Tagalog NLP tasks such as storybook complexity classification where the input data are literary texts. Overall, we emphasize the notion of collecting diverse multi-domain datasets for pretraining language models, particularly for low-resource languages like Cebuano and other Philippine languages.

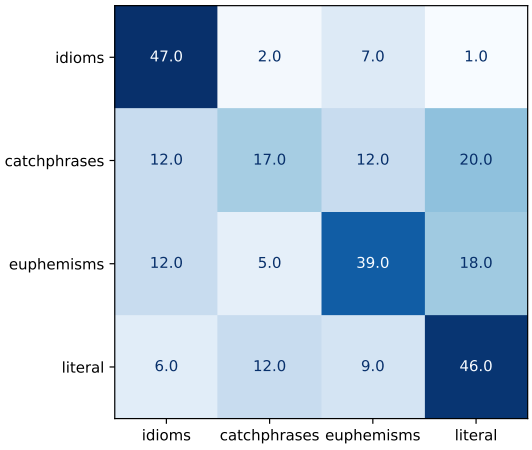

Figure 4: Confusion matrix from performance CebBERT using Random Forest with extracted embeddings as features for Task 2 - Cebuano Figures of Speech Identification.

Setting Standards for Cebuano NLP Research The next point we want to discuss is the importance of setting good practices and following community-recognized standards for NLP research, particularly if the target languages are low-resource and the beneficial impact it will have on the community. In this work, our CebBERT model has been trained from diverse opensource license-permitting datasets found in online repositories such as Huggingface and from published works in Cebuano (Imperial et al., 2022; Imperial and Kochmar, 2023b; Pilar et al., 2023) which future

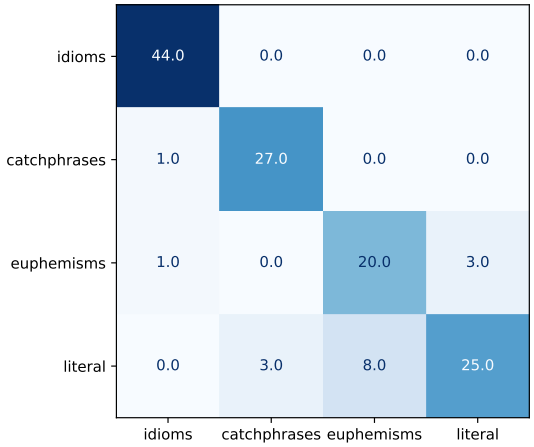

Figure 5: Confusion matrix from performance CebBERT using finetuning for Task 2 - Cebuano Figures of Speech Identification.

research works can extend and improve. In the case of mBERT, as briefly mentioned in Section 4, it has only been trained purely with Wikipedia data which is not diverse, and issues have been raised regarding the Cebuano Wikipedia being machine-generated[5]. This is why we used only a small portion of the Cebuano Wikipedia as part of the pertaining set for CebBERT. On the other hand, DOST-BERT (Visperas et al., 2023) was pretrained mostly with web-scraped data from formal and informal sources but have no clear or transparent breakdown of domain, data licenses, size or quantity, format, and source links or published papers, unlike what we showed in Table 1 for CebBERT. Thus, we only consider DOST-BERT as an open weight and not an open source model due to the undisclosed nature of the research artifacts used. In summary, we consider CebBERT as the first openly accessible language model for Cebuano following community-driven standards on dataset, artifact, and model transparency (McMillan-Major et al., 2021; Liu et al., 2024).

7 Conclusion

In this work, we introduced CebBERT, a new lightweight and efficient model for Cebuano language processing tasks. Using the DistilBERT architecture, we pretrained CebBERT with a diverse multi-domain collection of Cebuano data ranging from news articles, literary texts, speech transcripts, translations, and more. Through two unseen Ce-

[5] https://meta.wikimedia.org/wiki/Proposals_for_closing_projects/Closure_of_Cebuano_Wikipedia

buano NLP tasks covering figures of speech identification and online report classification, we show CEBBERT effectiveness in achieving higher performance over previous larger BERT-based models in Cebuano. We envision CEBBERT as the new go-to model for Cebuano NLP due to its full model and data transparency. Future works can explore using our compiled pretraining data and compare CEBBERT to more advanced language model methods with Cebuano, including instruction-tuning and optimizing through feedback.

Acknowledgment

We gratefully acknowledge the support provided by the Department of Science and Technology—Philippine Council for Health Research and Development (DOST-PCHRD) for the HealthPH: Intelligent Disease Surveillance using Social Media Project through the Grants-in-Aid (GIA) Program. We also acknowledge the creators and contributors of the datasets used in this paper for their valuable work in collecting and making this data publicly available. The acquired datasets were used for non-commercial research purposes only. Abstract

Large language models (LLMs) have exhibited significant enhancements in performance across various tasks. However, the complexity of their evaluation increases as these models generate more fluent and coherent content. Current multilingual benchmarks often use translated English versions, which may incorporate Western cultural biases that do not accurately assess other languages and cultures. To address this research gap, we introduce KULTURE Bench, an evaluation framework specifically designed for Korean culture that features datasets of cultural news, idioms, and poetry. It is designed to assess language models' cultural comprehension and reasoning capabilities at the word, sentence, and paragraph levels. Using the KULTURE Bench, we assessed the capabilities of models trained with different language corpora and analyzed the results comprehensively. The results show that there is still significant room for improvement in the models' understanding of texts related to the deeper aspects of Korean culture.

1 Introduction

The proliferation of LLMs capable of generating fluent and plausible responses has significantly complicated the task of assessing their knowledge and reasoning abilities (Li et al., 2024). To address this challenge, researchers have developed a range of benchmarks designed to assess diverse capabilities of models such as GLUE (Wang et al., 2018) and MMLU (Hendrycks et al., 2020). Although these benchmarks are primarily in English, when addressing multilingual issues, current evaluation practices often depend on translations of those datasets originally in English (Shi et al., 2022). However, a critical issue arises as their inherent Western cultural bias makes them unsuitable and inappropriate for evaluating LLMs across a variety of cultures and languages. Therefore, there has been a notable trend toward the development of culturally specific benchmarks that cater to local contexts such as IndiBias (Sahoo et al., 2024) for Indian culture, Heron-Bench (Inoue et al., 2024) for Japanese culture, and CCPM (Li et al., 2021) and ChID (Zheng et al, 2019) for Chinese culture. However, comparable research in Korea is still relatively scarce.

To bridge this resource gap, we developed KULTURE Bench, which includes 3584 instances across three datasets. This benchmark not only evaluates cultural knowledge but also includes datasets that inherently feature idioms and poetry, enriching the linguistic elements with deep cultural significance. Additionally, it thoroughly assesses language models' cultural comprehension and reasoning abilities across word, sentence, and paragraph levels.

We conducted evaluations on models trained with various primary corpora, including Clova X (Korean), GPT-4 and GPT-3.5 Turbo (English), and Tiangong (Chinese). The evaluation results show that, overall, the native Korean model, Clova X, performed the best, followed by GPT-4. However, even the highest-performing Clova X achieves only a 69.12% accuracy on the dataset containing idiomatic expressions, and the best result for the dataset featuring poetry is a mere 45.7% accuracy by GPT-4, which suggests that LLMs still face challenges when processing texts embedded with deep cultural and historical contexts. Further analysis of LLMs' performance on the KULTURE Bench reveals deficiencies in handling texts related to Korean culture and provides important insights

for improvements in this area. KULTURE Bench can be accessed at https://github.com/robot507/KULTUREBench.git

2 Related Work

2.1 Language Model

With the advent of Transformers and their self-attention mechanisms, the development of large English language models has accelerated rapidly. Models such as GPT-4 (OpenAI, 2023) represent notable achievements in natural language processing. Meanwhile, language models in other languages are also striving to bridge the gap with English. Examples include China's GLM (Zeng et al., 2022), Korea's HyperCLOVA (Kim et al., 2021), and Japan's Japanese StableLM (StabilityAI, 2023), which are all making significant advancements in their respective linguistic domains. With the advancement of multilingual language models, determining the appropriate methods for evaluating their language-specific capabilities becomes essential. This emphasizes the need for benchmarks tailored specifically to assess the multilingual proficiency of LLMs.

2.2 Korean Cultural Benchmarks

Several Korean culture-focused datasets have been developed as summarized in Table 1.

Jin et al. (2024) introduced the Korean Bias Benchmark for Question Answering, adapted from BBQ dataset (Parrish et al., 2022). This dataset builds on the original by adding new categories of bias specifically targeting Korean culture. HAE-RAE Bench (Son et al., 2023) is curated to evaluate large language models' understanding of Korean culture through six downstream tasks in vocabulary, history, general knowledge, and reading comprehension. CLIcK (Kim et al., 2024) sources its data from official Korean exams and textbooks, categorizing the questions into eleven subcategories under the two main categories of language and culture. This dataset challenges models' understanding of Korean culture through QA pairs. KorNAT (Lee et al., 2024) is launched to assess models' adherence to the distinctive national attributes of South Korea with a focus on social norms and shared knowledge.

These existing datasets typically use a question-and-answer format to test models' ability to handle culturally relevant content, but do not directly incorporate elements that represent unique cultural phenomena into the dataset. Thus, we introduce KULTURE Bench that not only assesses cultural knowledge through news articles but also incorporates idioms and poetry, which, originating from ancient times, remain widely prevalent in contemporary Korean society. This benchmark challenges models more rigorously by demanding a deeper understanding and contextual integration of enduring cultural elements.

Benchmarks	Instances	Type
KoBBQ	76048	Bias
HAE-RAE BENCH	1538	Cultural Knowledge
CLIcK	1995	Cultural Knowledge
KorNAT	10000	Cultural Alignment
KULTURE Bench (Ours)	3584	Cultural Comprehension

Table 1 Overview of Korean cultural benchmarks

3 KULTURE Bench

3.1 Task Overview

KULTURE Bench is an integrated collection comprising three datasets with a total of 3,584 instances, crafted to evaluate models' comprehension of Korean culture at different linguistic levels. The first dataset KorID features 1,631 instances and targets the understanding of Korean idioms through a cloze test format, where idioms are replaced with blanks that models must fill by interpreting the extended meaning from selected candidates, assessing word-level cultural insights. The second dataset KorPD contains 453 instances. In this dataset, a specific line from a Korean poem is replaced by a blank, requiring the model to infer the correct line based on the poem's overall meaning, rhythm, and rhetorical style from a set of selected candidate lines. This dataset is designed to evaluate the sentence-level cultural comprehension of the models. The third dataset KorCND contains 1,500 instances. Here, models are tasked with summarizing culturally relevant Korean news articles and selecting the correct headline from a set of designed candidates. This dataset focuses on the models' ability to comprehend and summarize extended texts, reflecting their paragraph-level understanding of Korean culture. Appendix A provides examples from three datasets in the KULTURE Bench.

In selecting the source materials for these datasets, we prioritized real-world content like current news, common idioms, and classical poems from Korean textbooks for dataset relevance and authenticity.

3.2 KorID: A Korean Four-character Idiom dataset for Cloze Test

3.2.1 The characteristics of four-character idioms

Four-character idioms are widely used in Asian countries such as China, Japan, Vietnam, and Korea. Four-character idioms, known as Sajaseong-eo or Hanjaseong-eo in Korea, are a significant part of the Korean language and originated from ancient China; over history, they were transmitted to the Korean Peninsula where new idioms incorporating Korean cultural elements also emerged locally. To this day, idioms remain a frequently used linguistic phenomenon in Korean society.

Many idioms feature metaphorical meanings that stem from the stories behind them, meaning that their true meanings cannot be deduced simply by interpreting the literal meanings of the words they are composed of. For example, the idiom "함흥차사" literally means "an envoy sent to Hamhung" (Hamhung: a location on the Korean Peninsula), but its metaphorical meaning refers to situations where someone sent on an errand has not returned any news, or responses are significantly delayed. This idiom originates from an early Joseon Dynasty story about an envoy who was sent to Hamhung to escort the founding monarch, Lee Seong-gye, but never returned. Therefore, understanding idioms requires knowledge of their underlying stories and culture and using cloze tests with idioms can assess a model's ability to comprehend and apply the cultural nuances and metaphorical meanings embedded within the language.

3.2.2 Construction of KorID dataset

KorID dataset is constructed in four main stages: 1. Vocabulary Construction, 2. Passage Extraction, 3. Candidates Retrieval, 4. Synonym Check.

Idiom Vocabulary Construction The idiom vocabulary for the KorID dataset was derived from two primary sources: *Gosa, Saja Four-character Idiom Grand Dictionary* (Jang, 2007), known for its extensive collection of over 4,000 idioms, and *Korean Four-Character Idiom Grand Dictionary* (Han, 2011), which includes around 2,300 idioms originating from the Korean Peninsula and approximately 270 Chinese idioms used in Korean classics.

After performing OCR on the idiom lists within the dictionaries, the four-character idioms were digitized and stored in Excel. Each entry underwent a manual review and correction process to fix any OCR recognition errors, with strict adherence to the four-character criterion. An automated script was then employed to remove duplicates from the collected idioms, ultimately yielding a total of 5,372 unique idioms.

Passage Extraction This research utilized the Modu Corpus[1], which includes several versions of the NIKL Newspaper Corpus, containing a comprehensive collection of Korean news articles from 2009 to 2022, sourced from a wide range of national and regional outlets and organized in JSON format.

Using a Python script, the process of matching idioms with relevant news passages was automated, systematically searching the news corpus for occurrences of each of the 5,372 four-character idioms from the vocabulary construction phase. Whenever an idiom appeared in a news article, the article was stored in an Excel file next to the idiom it contained.

The idioms selected through this method are frequently used in daily news, while other less common idioms were removed. This automated search and storage resulted in an Excel file where each row contains an idiom followed by the news text that includes it.

After searching the entire news corpus, 1,631 instances where idioms from the vocabulary appeared in the news were identified. During text preprocessing, special attention was given to refining the news text extracted, involving the removal of unnecessary elements like reporter's email addresses and extraneous metadata, which do not contribute to linguistic analysis or the cloze test structure.

Additionally, any Hanja (Chinese character) explanations before or after the idioms within the text were also removed to maintain focus on the relevant textual content.

[1] https://kli.korean.go.kr/corpus/main/requestMain.do

Candidates Retrieval This part involves measuring the semantic relevance between idioms using cosine similarity of their embeddings obtained from the KorBERT model (Lim et al. 2020) developed by ETRI. Each target idiom in a news text is compared with others in the idiom vocabulary list to calculate cosine similarity, defined as:

$$\text{cosine similarity} = \frac{\mathbf{A} \cdot \mathbf{B}}{\| \mathbf{A} \| \cdot \| \mathbf{B} \|}$$

From the results, one idiom is chosen from each of four predefined cosine similarity ranges: [0.5, 0.6], [0.61, 0.7], [0.71, 0.8], and [0.81, 0.9], resulting in four candidates. Together with the target idiom, labeled as the "Golden Answer," five options are generated for each cloze test. These idioms replace the target idiom's position, now a blank, in the news text.

Synonym Check Four-character idioms are a category of words that possess synonyms, allowing for interchangeable use in some contexts. To ensure the integrity of the KorID dataset, a review process was conducted. Fifty samples from the dataset were randomly selected and manually inspected to determine whether, aside from the Golden Answer, other terms could also meet the standards for insertion into the texts.

The review standards were as follows: (1) two idioms are nearly identical in both literal and deeper meanings and can be interchangeably used in the given news text (3 points); (2) the idioms share similar themes or elements but have distinct differences in meaning (2 points); the idioms are fundamentally different in meaning (1 point).

Following this review, it was found that all the Golden Answers across the 50 samples possessed a unique selectivity. This outcome validates our strategy of excluding potential candidates with a similarity score above 0.9, demonstrating the effectiveness of using similarity scores to select negative options during the dataset creation process. Following these steps, the KorID dataset is constructed.

3.3 KorPD: A Korean Poem Dataset for Cloze Test

3.3.1 The characteristics of poems

Distinct from other literary forms, poetry is known for its intense emotions, clear stylistic expression, and abstractly conveyed rich themes. The semantics in poetry are often more ambiguous and complexly intertwined than in other literary forms (Li et al., 2021), which complicates the automatic analysis and evaluation of poetic semantics, thus necessitating more efforts in assessing language models' understanding of poetic meaning.

3.3.2 Construction of the KorPD dataset

KorPD dataset is constructed in two main stages: 1. Poem Collection, 2. Candidates Retrieval.

Poem Collection Poems in KorPD dataset were compiled from Korean textbooks. To collect these poems, OCR was employed to digitize content directly from textbooks, which was then systematically organized into an Excel file with columns for poem titles, poets' names, and the content of each poem to facilitate access and further processing.

Following digitization, a thorough manual review ensured the accuracy and integrity of the data, with corrections made to rectify any errors detected. From these efforts, a total of 91 poems were selected, offering a rich repository of poetic content that reflects contemporary educational and cultural contexts in Korea, encompassing a broad range of themes and styles.

Candidates Retrieval Using a set of 91 Korean poems, a specific line is randomly extracted from each poem using a Python script, repeated up to five times for poems with more than five lines, generating 453 unique items. Each line is only selected once across the dataset.

For semantic analysis, the [CLS] token's hidden state from ETRI's KorBERT model (Lim et al. 2020) serves as the semantic representation of each line, capturing its contextual essence crucial for accurate comparisons.

Cosine similarity then quantifies the semantic resemblance between the golden answer and other lines, grouping them into four similarity intervals: [0.5-0.6], [0.61-0.7], [0.71-0.8], and [0.81-0.9]. From each interval, one line is randomly chosen to join the golden answer in the dataset item, ensuring the distractors are similar enough to challenge identification yet diverse enough to span a broad semantic spectrum.

The order of the golden and negative answers is randomized to increase the dataset's testing robustness. Following these steps, the KorID dataset is constructed.

3.4 KorCND: A Korean Culture News Dataset for Headline Matching

3.4.1 The characteristics of news headline

News headlines skillfully employ dynamic verbs and vivid adjectives to quickly transmit essential messages, often integrating rhetorical devices like ellipsis and inversion to maximize space efficiency and reader engagement. For example, the Korean headline "서울시, 문화와 함께하는 추석… 신달자·정호승의 시낭독, 서울시향 연주" (Seoul, Celebrating Chuseok with Culture... Poetry Readings by Shin Dal-ja and Jeong Ho-seung, Performance by the Seoul City Symphony) not only introduces a cultural event but also encapsulates the broader cultural context of Chuseok. To fully comprehend such headlines, language models need to interpret beyond the words to grasp cultural and contextual nuances. This involves understanding the celebration of Chuseok, a major Korean festival, which includes traditional customs like family reunions and specific foods such as "송편" (songpyeon, rice cakes). The model must recognize the headline's reference to specific cultural activities and significant figures in Korean arts, linking these elements to convey the depth of the festival's cultural significance accurately. Such capabilities are essential for models to interpret the text effectively and align their responses with culturally relevant narratives.

3.4.2 Construction of the KorCND dataset

KorCND dataset is constructed in two main stages: (1) News Collection, (2) Candidates Retrieval.

News Collection The KorCND Dataset primarily sources its texts from the NIKL Newspaper Corpus 2022 (v1.0) within the Modu Corpus [2]. This extensive resource includes 978,342 newspaper articles from 2021, gathered from 34 different news outlets and covering a wide range of topics such as culture, society, economy, and sports, all provided in JSON format.

The dataset was created by initially filtering these articles for cultural relevance, using keyword and tag-based searches to identify those related to "문화" (Culture). Following this automated selection, a manual review was conducted to ensure the articles were specifically pertinent to Korean culture, leading to the curation of 1,500 articles that effectively reflect the diversity of Korean cultural life.

Once the article selection was finalized, the next step was to organize the chosen articles into a structured format suitable for in-depth analysis by compiling the news titles and corresponding text content into an Excel file. This format was chosen for its accessibility and ease in data manipulation and review. In the spreadsheet, Column A was designated for news headlines, providing a clear reference, and Column B stored the full text of the articles, ensuring all textual information was preserved and easily accessible.

Quality control measures were implemented to maintain the integrity and quality of the data during this organization phase. Each entry was meticulously checked for data entry errors, such as misaligned text or incomplete headlines.

Candidates Retrieval After collecting and categorizing news headlines and their texts into the KorCND Dataset, the next step involved meticulously extracting negative choices to enhance the dataset's utility in assessing language models, particularly for tasks that require distinguishing between closely related texts. The aim was to select opposing candidates that closely resemble the Golden Answer to test the model's precision in identifying subtle differences.

The embedding of news headlines was performed using the KorBERT model developed by ETRI, tailored specifically for the Korean language to capture deep semantic meanings. The semantic representation of each headline was extracted from the hidden state of the [CLS] token of the KorBERT model (Lim et al. 2020), which is designed to encapsulate the overall meaning of the input sequence.

Once embeddings were derived from the [CLS] tokens, the similarity between different headlines was quantified using the cosine similarity metric, focusing on nuanced semantic relationships over mere lexical similarities for a more precise similarity assessment.

In determining effective negative choices, each Golden Answer's [CLS] token representation was compared against all others in the dataset. This

[2] https://kli.korean.go.kr/corpus/main/requestMain.do

comparison yielded similarity scores for each headline pair, facilitating the identification of headlines that are similar enough to potentially confuse the model but distinct enough to test its discriminative power. Headlines were then sorted into predefined similarity ranges: [0.5, 0.6], [0.61, 0.7], [0.71, 0.8], and [0.81, 0.9], each representing varying levels of difficulty in terms of semantic closeness.

From each similarity interval, one headline was randomly selected as a negative choice. This selection not only introduced necessary variability but also simulated realistic scenarios where language models must discern between semantically similar phrases. This methodical approach ensured the dataset not only challenged but also accurately evaluated the nuanced understanding and processing capabilities of contemporary language models.

Finally, the order of the Golden Answer and the Negative Answers was randomized. Following these steps, the KorCND Dataset is constructed.

4 Experimental Setup

4.1 Evaluated Models

We assessed models trained primarily on distinct language corpora including GPT-4[3] and GPT-3.5 Turbo[4] (English), Clova X[5] (Korean).

We also tested Tiangong[6], a model focuses on Chinese, aims to explore potential spillover effects, given the historical influence of Chinese Hanja on the Korean language.

4.2 Prompt Types

We designed two rounds of experiments to assess the ability of language models to process complex texts. In the first round, we employed the Zero-shot Prompting method to directly evaluate the comprehension of complex texts by four selected models. In the second round, to investigate whether the Chain of Though technique could enhance model accuracy in cultural contexts and to analyze the impact of reasoning length on model accuracy, we required models to answer after a period of contemplation and set three different reasoning length requirements: 1-2 sentences (short reasoning), 3-4 sentences (medium reasoning), and 5-6 sentences (long reasoning). The second round of experiments was specifically conducted using the KorID dataset on three models: GPT-3.5 Turbo, Clova X, and Tiangong. Specific prompt settings are provided in Appendix B .

4.3 Evaluation Metric

We employ accuracy as the evaluation metric. This means calculating the proportion of samples for which the model provides the correct answer out of the total number of samples. The higher the accuracy, the better the performance of the model.

4.4 Response Validation Criteria

During the experiment, it was observed that models occasionally produce verbose responses. To accurately extract the selected answers from the models' responses, the following acceptance criteria were established: The answer must i) exactly match a term provided in the options, ii) include specific expressions clearly intended to convey the answer, such as “the answer is -", iii) present the option enclosed in square brackets [].

Responses that do not meet these criteria are considered out-of-option answers.

5 Results

5.1 Main Results

Model Comparison According to Table 2, Clova X, which focuses on Korean, is observed to be the top-performing model, achieving an accuracy of 69.12% on the KorID dataset and an impressive 92.77% on the KorCND dataset, ranking first in both. Following closely, GPT-4 also shows strong performance, even surpassing Clova X with an accuracy of 45.7% on the KorPD dataset. In contrast, GPT-3.5 Turbo underperforms compared to GPT-4, further demonstrating the superior capabilities of GPT-4 as a more advanced iteration. Tiangong records the lowest accuracy, indicating that mere cultural similarities are insufficient to ensure outstanding model performance.

Dataset Comparison According to Figure 1, we observe that all models exhibit relatively high

[6] https://model-platform.tiangong.cn/overview

Models	KorID	KorPD	KorCND
Tiangong	26.92	14.57	70.61
GPT3.5-Turbo	31.58	25.61	77.65
GPT-4	51.50	**45.70**	89.68
Clova X	**69.12**	37.75	**92.77**

Table 2 Accuracy (%) of different models on KorID, KorPD and KorCND datasets

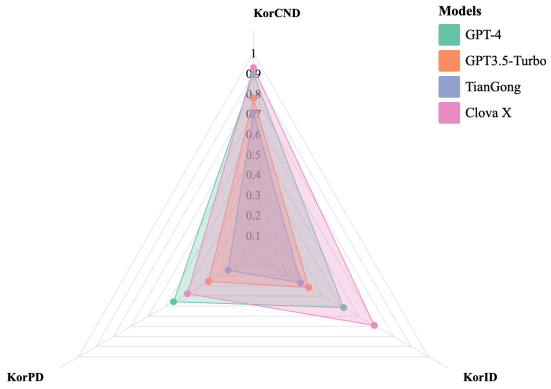

Figure 1 Models' performances on different datasets in KULTURE Bench

performance when processing news texts, but significantly lower accuracy with texts containing rich cultural elements such as poetry and idioms. We believe this is due to two main reasons: firstly, there is a scarcity of such data in the training corpora; secondly, these texts are laden with cultural information, which increases the complexity of processing.

5.2 Analysis

Does Chain of Thought Enhance Understanding and Reasoning in Culture Texts?

As shown in Table 3, the Chain of Thought (CoT) strategy improved the accuracy of the Tiangong and Clova X models. However, the performance of GPT3.5-Turbo did not show notable improvement and sometimes even declined. Clova X, which is primarily trained on Korean language corpora, has a deep understanding of Korean culture; the Tiangong model, based on Chinese corpora, benefits from the cultural proximity between China and Korea; whereas GPT-3.5 Turbo, trained on English corpora, is more distanced from Korean culture. We speculate that a lack of appropriate cultural background knowledge may lead to inaccurate or erroneous reasoning when models execute tasks. To further validate this hypothesis, we randomly selected 50 correct responses from each model's response pool in the CoT experiment for an in-depth analysis, totaling a review of 150 responses. The analysis primarily examined whether the models correctly used relevant cultural knowledge in the reasoning process to select the correct answers, or if the correct answers were merely the result of random selection by the models. The analysis showed that the reasoning process of the Clova X model was correct 96% of the time. The Tiangong model reasoned correctly in 74% of the cases, while GPT-3.5 Turbo only demonstrated correct reasoning in 46% of instances. This indicates that training with Korean language corpora and possessing extensive knowledge of Korean culture makes the reasoning process of the Clova model effective. Analysis of Tiangong's responses revealed that 90% of the idioms correctly reasoned by this model are still in active use in contemporary Chinese society (based on the observation of whether the target idiom exists in online Chinese idiom dictionary [7]), thereby supporting the correct answer choices. These findings support the assumption that without sufficient cultural knowledge, the reasoning capabilities of models do not significantly improve and may even be impaired by incorrect cultural interpretations

Additionally, based on Table 3 and Figure 2, it can be observed that the accuracy of the TianGong model starts at 26.92%, rises to 35.83% with short reasoning, but then decreases to 33.70% and 32.88% with medium and long reasoning, respectively. This suggests that excessive reasoning may lead to decreased accuracy due to potential information overload. Clova X's accuracy begins at 69.12%, increases to 71.28% with short reasoning, but as the

Model	No CoT	Short Reasoning	Medium Reasoing	Long Reasoning
Clova X	69.12	71.28	70.69	67.80
GPT3.5-Turbo	31.58	30.72	34.83	31.53
Tiangong	26.92	35.83	33.70	32.88

Table 3 Accuracy (%) of different models on the different ways of using Chain of Thought

[7] http://www.guoxue.com/chengyu/CYML.htm

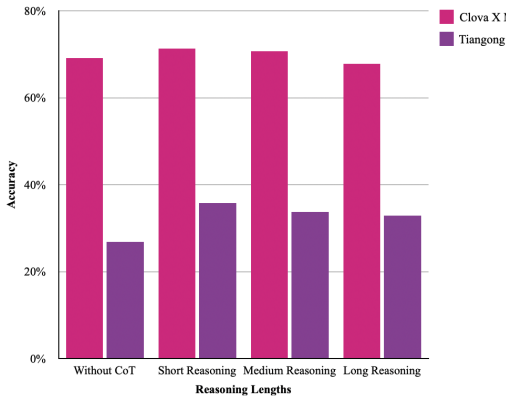

Figure 2 Accuracy (%) given by Tiangong and Clova X when the length of reasoning process changes

reasoning extends, it drops to 70.69% and 67.80%. This implies that properly calibrated CoT steps can enhance accuracy, but too many may negatively impact performance.

How Do Model Performances Compare to Human Level Proficiency?

Participants were split into two groups based on their academic backgrounds: 20 graduate and doctoral students in Korean Studies, termed "experts," and 20 undergraduate students without a Korean Studies focus, called "non-experts." Each participant received a coffee voucher as compensation for their time. For evaluation, 15 questions were randomly selected from each of the KULTURE Bench datasets.

As shown in Figure 3, there are significant differences between LLMs and human participants, with humans outperforming LLMs in both expert and non-expert groups, especially in handling cultural news and poetry. While LLMs perform well in structured tasks like news headline matching, they struggle with the complexities of cultural and linguistic contexts in poetry and idiomatic expressions, where humans, particularly those with specialized knowledge, excel.

What Types of Errors Occur in Model Responses to Korean Cultural Texts?

To investigate the types of errors in automated responses to Korean cultural texts, each model was required to explain its reasoning in a second-round conversation after initial evaluations. For analysis, 20 error responses were extracted from each model across three datasets, resulting in 60 samples per model, totaling 240 error samples across all models.

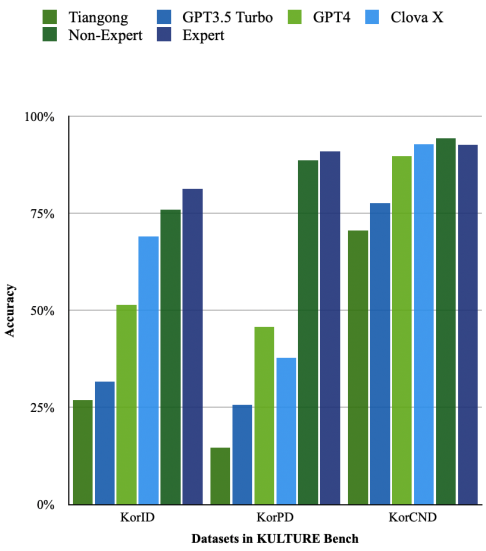

Figure 3 Model and human performance comparison across KULTURE Bench datasets

The analysis categorizes the errors in model responses into five types: (1) semantic understanding errors, (2) lack of cultural background knowledge, (3) grammatical or lexical errors, (4) logical errors, and (5) insufficient context interpretation. Appendix C provides specific examples of these types of errors.

6 Conclusion and Limitations

We introduce KULTURE Bench, a comprehensive dataset ranging from words to paragraphs that focuses on Korean cultural knowledge and linguistic phenomena, sourced from Korean news, textbooks, and dictionaries. Through our analysis and experiments, we observed that models perform best on modern texts and news but lack proficiency in idioms and poetry. We also found that without sufficient cultural knowledge, CoT techniques cannot be effectively utilized. Additionally, even when CoT is effective, inappropriate reasoning lengths can impact model accuracy. Moreover, human capabilities in KULTURE Bench task still surpass those of the models. The limitations of this research include the need to evaluate a broader range of models for a more comprehensive assessment. Additionally, the CoT experiments focused solely on cultural reasoning in Korean, and it would be beneficial to test whether similar results occur in other languages and cultures. Furthermore, the human capability assessment was limited by a small sample size, and there is a need to expand the sample for more comprehensive testing.

A Examples from KULTURE Bench

Table 4 shows an example from KorID dataset. In this dataset, models are required to read news articles, identify the blanks where idioms are missing, understand the meaning of each idiom presented in the options, and select the appropriate idiom based on the context.

Table 5 shows an example from KorPD dataset. In this dataset, models are required to read classical poems, identify the missing line, interpret the meaning of each line presented in the options, and then, considering factors such as the poem's meaning, emotional expression and rhythm, select the correct answer.

Table 6 shows an example from KorCND dataset. In this dataset, models are tasked with discerning the main idea of culturally relevant news articles, understanding the cultural elements present in the news, and selecting a headline from the options that accurately summarizes the content of the news.

B Prompt Types

Figure 4 shows the prompts used in the first round of experiments to evaluate language models; Figure 5 shows the prompts used in the second round of Chain of thought experiments.

Experiment on KorCND

Given the text: '{content}'. Here are the options: {', '.join(options)}.
Read the content carefully and choose the most appropriate headline from the options and mark the answer you chose with [].

Experiment on KorID

Given the text: '{content}'. Here are the options: {', '.join(options)}.
Select only one four-character idiom that fits best for the placeholder #idiom# in the content and mark the answer you chose with [].

Experiment on KorPD

Given the poem: '{content}'. Here are the options: {', '.join(options)}.
There is a missing line represented by #sentence# in the poem, choose the best line from the provided options to complete the poem and mark the answer you chose with [].

Figure 4 Prompts used in the first-round experiment

Passage & Blank	…박곡리 노인회는 평균 연령 83세 이상으로 최고령 박순득 어르신여96을 비롯해 100여 명의 회원으로 구성돼 있으며 7가구는 독거노인이다. 집에 있는 흔한 닭은 하찮게 생각하고 멀리 들에 있는 꿩은 귀하게 생각한다는 #idiom#란 말을 곱씹어본다. 최희동 박곡리 이장은 곁에서 부모님을 모시면서 이웃어른을 보살피는 박곡리 부녀회와 청년회가 오히려 멀리 떨어져 있는 친자식들보다 더 효자효부 노릇을 한다는 평소 어르신들의 말씀이 결코 낯설지 않다고 칭찬했다…（English Translation: "The senior citizens' association in Bakgok-ri has an average age of over 83, including the eldest member, Soon-deuk Park, aged 96, and comprises about 100 members, of whom seven are elderly living alone. One ponders the #idiom#, 'The common chicken at home is taken for granted, while the pheasant in the distant field is prized.' Hee-dong Choi, the village head of Bakgok-ri, praised the local women's and youth associations for caring for elderly neighbors and their own parents, saying that they often fulfill their filial duties better than children who live far away, a sentiment that is not unfamiliar to the elders."
Option Golden Answer	가계야치 (Common things are regarded as lowly, while distant things are considered precious.)
Options (Negative)	빈부귀천 (wealth and poverty, nobility and lowliness) 설상가상 (to make a bad situation even worse.) 무위이화 (Seemingly inactive, yet transforming.) 어동육서 (Ritual customs: Fish east, meat west)

Table 4 An example from KorID dataset

Poem & Blank	나 두 야 간다 나의 이 젊은 나이를 눈물로야 보낼 거냐 나 두 야 가련다 #sentence# 안개같이 물 어린 눈에도 비치나니 골짜기마다 발에 익은 찟부리모양 주름살도 눈에 익은 아- 사랑하던 사람들 버리고 가는 이도 못 잊는 마음 쫓가는 마음인들 무어 다를 거냐 돌아다보는 구름에는 바람이 희살짓는다 앞 대일 언덕인들 마련이나 있을 거냐 나 두 야 가련다 나의 이 젊은 나이를 눈물로야 보낼 거냐 나 두 야 간다. I too shall leave My youthful days Must they be spent in tears? I am indeed pitiable #sentence# Even in eyes wet as mist, reflections can be seen In every valley, the familiar shape of grave mounds underfoot Familiar wrinkles, ah- those beloved people Hearts that cannot forget even those who leave Chasing hearts, how different are they? The wind plays in the clouds looking back Are there hills ahead just as supposed? I am indeed pitiable My youthful days Must they be spent in tears? I too shall leave.
Option Correct Answer	아늑한 이 항구-ㄴ들 손쉽게야 버릴 거냐 (Can these cozy harbors be so easily abandoned?)
Options	그날이 와서, 오오 그날이 와서 (That day comes, oh, that day comes.) 고요히 다물은 고양이의 입술에 (On the quietly closed lips of a cat.) 밤이면 실컷 별을 안고 (At night, embracing the stars to the fullest.) 백마 타고 오는 초인이 있어 (There is a superman coming on a white horse.)

News Article	맹숙영 시인이 시집 '우리가 사랑할 수 있는 시간' (황금마루)를 펴냈다. 맹 시인의 7번째 시집이고 신작 70여편을 수록했다. 이인평 산림문학 편집주간은 이 책의 추천사에서 "맹숙영의 시편에는 살아온 세월을 반추하면서 언어로 다듬어낸 그만의 목소리가 담 있다. 세상을 향해 애틋하게 바라본 시각이 그의 숨결로 다가오기 때문" 이라고 했다. 문학평론가 이덕주 시인은 평설을 통해 "이번 시집의 특성은 시인의 사색적 성찰이 균형있게 내장돼 시인의 진솔한 자기 증언을 확인할 수 있다는 점" 이라며 "이런 관점은 우리 앞에서 전개되는 세상에 대해 독창적인 해석을 내리기 때문에 용인된다. 개별적 차별보다 존재마다 다양성을 존중하려는 화합의 정신, 즉 지극한 사랑을 전제했기에 가능했을 것" 이라고 했다. 맹 시인은 성균관대 영어영문학과를 졸업하고 영어 교사를 지냈다. 한세대 사회복지대학원도 졸업했다. 한국창조문학으로 등단한 그는 공간시낭독회 상임시인, 한국문인협회 한국시문학아카데미 푸른초장문학회 신문예학회 사월회 회원이다. 바람칼의 칸타빌레 동호인이기도 하다. 창조문학 대상, 양천문학상, 한국기독시문학상 등을 수상했다. 양천문학 부회장을 역임하고 자문위원으로 활동 중이다. 좋은시공연문학 한국크리스천문학회 부회장, 한국창조과학문학 운영 이사, 한국현대시인협회와 기독시인협회 이사 등을 맡고 있다. 시집으로 '사랑이 흐르는 빛', '꿈꾸는 날개', '바람 속의 하얀 그리움' 한영 대역 '불꽃 축제', '아직 끝까지 않은 축제', '아름다운 비밀' 등이 있다. (English Summary: Maeng Suk-young, a distinguished poet, has released his seventh poetry collection titled 'The Time We Can Love', featuring around 70 new poems. The collection is praised for integrating reflective introspection that confirms Maeng's honest self-expression and offers an original perspective on the world, underpinned by a spirit of harmony and profound love. Maeng, a graduate of Sungkyunkwan University in English Language and Literature and Hansei University's Graduate School of Social Welfare, has a notable career as an English teacher and has earned several prestigious awards. He is actively involved in various literary and creative organizations, contributing significantly to the Korean literary scene.)
Option Golden Answer	["천지에 꽃피고 꽃지고 나면 향기 가득…"] ("Flowers bloom and wither, filling the air with fragrance…")
Options Negative Answers	[윤범모 취임공약 한국 근현대 미술 120년사 나왔다] (Yoon Beom-mo's Inaugural Promise: 120 Years of Korean Modern and Contemporary Art Released) [신명난 국악이 함께하는 올해 마지막 한달...광주대표 브랜드 공연 '국악상설'](End-of-Year Vibes with Gwangju's 'Regular Gugak' Korean Music Shows) [사뿐사뿐~ 우아한 몸짓에 여름밤 황홀](Soft and Graceful Movements Enchant the Summer Night) ['자유민주시인상' 수상작 80편 담긴 '칼날 위에서 피는 꽃' 출간]('Freedom Democracy Poet Award' Winning 80 Pieces Featured in 'Flower Blooming on the Blade' Published)

Table 6 An example from KorCND dataset

C Categories of Errors in Model Responses

Semantic understanding errors occur when a model misinterprets meanings, nuances, or implications of words, phrases, or the overall context in a text. This error often involves misunderstanding the text's intent, emotional tone, or thematic connections, leading to responses that are logically coherent but contextually or factually incorrect. Table 7 provides an example of this error.

News Text	전 권투선수이자 시인인 홍영철씨가 새로운 시집 '이 땅에서 사랑하고, 로상까지!'(하나로선 사상과문학사)를 출간했다. 이 시집에는 그의 신작 94 편이 수록되어 있으며, 그의 삶은 마치 한 편의 드라마와 같다. 7 남매 중 다섯째로 태어난 그는 어린 나이에 가족과 헤어지고 힘든 시절을 보냈다. 명문 서울고등학교에 진학했지만 경제적인 이유로 2 학년 때 중퇴했다. 이후 거리에서 주먹으로 생계를 유지하다가 권투를 시작했다. 홍씨는 한때 우울증과 공황장애를 겪었으나, 선수 생활 중 목회자를 만나 예수를 영접하고 새로운 삶을 시작했다. 그는 대통령배 복싱선수권 대회에서 우승하고 프로복싱 신인왕에 올랐다. 또한 서울 서대문의 태권도 관장과 정심관 이종투기 연신내 관장을 역임했다. 현재는 프로스펙스 복싱 동우회 회장, 투혼 이종투기 협회 이사, 한국문인협회 회원, 힌우물 동인회 회원으로 활동 중이다. 그는 국제 킥복싱에서 최우수 체육관상과 공로상을 수상했으며, 2019 년에는 '하나로선 사상과 문학상' 대상(시 부문)을 받았다. 그의 동인지로는 '막사발시','한우물','잔고개','옹헤야', '시마루' 등이 있으며, 시집으로는 '아 달고나', '거리에 꽃피어라', '내 영혼이 우는 날까지', '한낱 스쳐가는 바람인가요','달고나 장수' 등이 있다. (English Summary: Hong Young-cheol, a former boxer turned poet, has published a new poetry collection titled "Love in This Land, Even to the Grave." The collection includes 94 of his latest poems, reflecting his dramatic life journey from a troubled youth to a champion boxer and now a recognized poet. Hong's life, marked by overcoming adversity and finding faith, also includes notable achievements in both sports and literature, serving in leadership roles in martial arts and contributing to various literary communities.)
Model Choice (From GPT-4)	국민 66% "문학책 1권도 안 샀다"… 작가 71% "문학 수입 월 50 만원 미만" (66% of the population "did not buy even one book of literature"... 71% of writers "earn less than 500,000 won per month from literary activities")
Golden Answer	아름다운 소년의 마음 꼬옥 띄운다 (The beautiful boy's heart is gently sent off.)
Model Response	The headline '국민 66% "문학책 1 권도 안 샀다"… 작가 71% "문학 수입 월 50 만원 미만"' is the best choice. I noticed that the text involves a poet's personal experiences and literary achievements. The poet's diverse professional background and awards in the literary world led me to explore a broader literary market and social context. Therefore, I chose the title '국민 66% "문학책 1 권도 안 샀다"… 작가 71% "문학 수입 월 50 만원 미만"' This title reflects the widespread status of the literary market, especially concerning the public's purchasing behavior of literary works and the economic conditions of writers. I believe this title highlights the poet's perseverance and effort in facing economic challenges in his literary career, as mentioned in the text. In my view, this connection not only reveals the challenges of individual artists but also reflects the real predicaments of the entire literary world.

Table 7 An example of semantic understanding error in model responses

This error involves a misinterpretation of the main theme and focus of the news text. The original article primarily discusses the personal life experiences, career transitions, and literary achievements of the poet. However, the title selected by the model focuses on the general economic conditions of the literary market, such as the purchase rates of literary works and the income levels of writers. The chosen title completely overlooks the humanistic and emotional aspects of the content, opting instead for a cold, statistical perspective. While the title provided by the model appears reasonable on the surface and relevant to the "literature" theme, it fails to accurately capture the essence and emotional tone of the original text. This type of semantic understanding error leads to an incorrect choice of news headline.

Lack of cultural background knowledge leads to errors where models make inappropriate choices due to insufficient understanding of cultural contexts. These errors can result in responses that are logically coherent but culturally inappropriate or inaccurate, reducing the authenticity and reliability of the model's output. Table 8 provides an example of this type of error.

The idiom "삼고초려" is used to describe the belief that one must be patient and wholeheartedly devoted to attracting outstanding talents. This term reflects the idea that high-status individuals should humbly and sincerely strive to bring those with exceptional abilities into their circle. However, when answering this question, the model, lacking the cultural knowledge behind "삼고초려," misinterpreted its meaning as "carefully considering and thinking deeply before making a decision," leading to an incorrect choice.

A grammatical or lexical error occurs when a language model makes mistakes in the syntax or the orthography of the language it is generating. These errors can significantly affect the clarity and professionalism of the text, leading to misunderstandings or reducing the credibility of the content. Table 9 provides an example lexical error. In this example, although the model's understanding of the idiom is correct and the choice is appropriate, it was judged to be incorrect because the correct Korean was not outputted in the response.

News Text	물 팔아 아시아 1 등 됐다마윈 제친. 블룸버그는 자사의 억만장자 인덱스를 인용해 중산산의 재산이 778 억 달러약 84 조 6464 억원를 기록했다고 지난달 31 일현지시간 보도했다. 이는 세계에서는 11 위, 아시아에서는 1 위에 해당하는 재산 규모다. 중산산의 재산은 2020 년 한 해에만 709 억 달러약 77 조 1392 억원가 늘었다. 블룸버그는 역사상 재산이 가장 빠르게 늘어난 경우 중 하나라며 올해까지 그가 중국 외에는 거의 알려지지 않았다는 점을 고려하면 주목할 만하다고 밝혔다. 중산산의 성공 요인으로는 우선 지난해 농푸산취안과 백신 제조업체 완타이바이오의 상장이 꼽힌다. 상장 이후 농푸산취안의 주가는 155 올랐고, 완타이바이오는 무려 2000 이상 급등했다. 또 중산산은 별명이 외로운 늑대로 중국 정치에 관여하지 않고, 그의 사업은 중국 내 다른 부호들과도 얽혀있지 않는다는 평가도 받고 있다. 반면 한때 아시아와 중국의 최고 부자였던 마윈 알리바바 창업자는 최근 중국 정치권을 비판했다가 재산이 크게 줄었다. 당국의 전방위 규제 압박을 받은 마윈은 앤트그룹 상장이 무산될 위기에 처하는 등 #idiom#을 겪으면서 617 억 달러약 67 조 1296 억원였던 재산이 512 억 달러약 55 조 7056 억원까지 줄어들었다. 한편 중산산에게 아시아 부호 1 위를 내준 인도 재벌 암바니 회장의 재산은 2020 년 한 해 동안 183 억 달러약 19 조 9104 억원가 늘어난 769 억 달러약 83 억 6672 억원로 집계됐다. Became Asia's No. 1 by selling water, surpassing Jack Ma. Bloomberg reported on the 31st (local time) that Zhong Shanshan's wealth has reached $77.8 billion (about 84.6464 trillion KRW), citing its Billionaires Index. This ranks 11th in the world and 1st in Asia. Zhong's wealth increased by $70.9 billion (about 77.1392 trillion KRW) in 2020 alone. Bloomberg highlighted this as one of the fastest wealth increases in history, noting that Zhong was virtually unknown outside of China until this year. The key to his success is attributed to the IPOs of Nongfu Spring and vaccine manufacturer Wantai Bio in the previous year. After the IPO, Nongfu Spring's stock price rose by 155%, while Wantai Bio's stock price surged by over 2000%. Furthermore, Zhong is nicknamed the "Lone Wolf" and is noted for not being involved in Chinese politics, with his business having no ties to other Chinese billionaires. On the other hand, Jack Ma, the founder of Alibaba and once the richest man in Asia and China, saw his wealth significantly shrink after criticizing Chinese politics. Facing widespread regulatory pressure from authorities and the risk of the Ant Group's IPO being canceled, he experienced #idiom#, with his wealth dropping from $61.7 billion (about 67.1296 trillion KRW) to $51.2 billion (about 55.7056 trillion KRW). Meanwhile, Indian tycoon Mukesh Ambani, who lost his spot as Asia's richest to Zhong, saw his wealth increase by $18.3 billion (about 19.9104 trillion KRW) to a total of $76.9 billion (about 83.6672 trillion KRW) in 2020.
Model Choice (From GPT-3.5 Turbo)	삼고초려 (Patiently striving to attract talent)
Golden Answer	우여곡절 (ups and downs)
Model Response	The idiom '삼고초려' means to carefully consider and think deeply before making a decision. In the context of the text, it is the best choice for replacing #idiom# because it highlights the importance of careful consideration and decision-making in managing wealth and business ventures, as seen in the success of Zhong Shanshan who carefully chose his investments and avoided political entanglements, in contrast to Jack Ma who faced setbacks due to his outspoken criticism of the Chinese government. This idiom emphasizes the significance of thoughtful planning and strategic choices in achieving and maintaining financial success.

Table 8 An example of lack of cultural background knowledge in model responses

A logical error is defined when the response provided by a model is inconsistent or contradictory in terms of logic. This type of error reflects a breakdown in reasoning. For example, in the sample shown in Table 10, this model identified the correct option, but made a contradictory choice

when deciding on the answer, despite recognizing the correct option.

News Text	고정주는 구한말의 애국계몽운동가이다. 그의 자는 보현, 호는 춘강이다. 담양 창평에서 1863 년에 참봉을 지낸 아버지 고제두와 어머니 전주 이씨 사이에서 태어났다. 5 세 때 큰아버지인 선공감 감역 고제승의 양자로 들어가 양부로부터 학문을 배우고 13 세부터 지금의 상월정에서 열심히 공부하였다. 19 세 때 한장석을 찾아가 학문을 배웠으며 21 세에는 성대영을 찾아 가르침을 받았는데 이 때 그의 학문이 높은 수준에 이르러 성대영이 높이 칭찬했다고 한다. 그의 스승인 한장석은 정치적 실천을 중요시했던 인물로 경세학을 강조하였다. 이른바 실천하지 않는 지성은 시대의 방관자이며 무책임한 선비임을 깨달았기에 고정주는 관직에 있었던 시절이나 귀향하여 신교육운동에 몰입했던 시절에도 스승의 가르침을 깊이 새기며 실천하는 지성인의 모범을 보여주었다. 1885 년에 진사에 합격하고 1891 년에 문과에 합격하였다. 이 때 동생도 같이 진사에 합격하여 형제간에 금의환향하였다. 1893 년 승문원 부정자로 관직을 시작하였는데 고종도 크게 관심을 보이며 제봉 고경명의 몇 대손인가를 묻고 선물을 하사했다고 한다. 1898 년 종묘축관에 선출되었고, 1899 년에는 홍문관 시독을 역임하고 품계가 정 6 품인 승훈랑에 올랐다. 그러나 이 때는 외세의 침탈과 내부의 혼란으로 나라는 풍전등화의 위기에 처한 시기였다. 이에 고정주는 #idiom#을 강조하는 상소를 올렸다. 이 상소에서 그는 상벌을 명백히 하여 부패한 관리를 추방하고 재원을 모아 군사력을 증대하여 국가의 근본을 굳건하게 함으로써 외세의 침입을 물리칠 것을 강력히 주장하였지만 당시 정치상황은 그의 주장을 받아들이지 못했다. (English Summary: Go Jeong-ju was a patriotic enlightenment activist during the late Joseon Dynasty. His courtesy name was Bohyeon, and his pen name was Chungang. Born in 1863 in Changpyeong, Damyang, to Go Je-du and Lady Jeon from the Jeonju Yi clan, Go was adopted by his uncle Go Je-seung at age five, from whom he began his academic studies. He later continued his education under prominent scholars like Han Jang-seok and Seong Dae-young, who praised Go's intellectual abilities. Han Jang-seok, Go's mentor, emphasized practical application of knowledge, which deeply influenced Go. Go passed the civil service examination in 1885 and began his career in 1893, with King Gojong recognizing his potential. Despite his rise in rank, Go witnessed Korea's increasing vulnerability to foreign powers and internal instability. He submitted a memorial to the king, emphasizing #idiom#, calling for the expulsion of corrupt officials, the strengthening of military forces, and the consolidation of national resources to resist foreign invasion. However, his proposals were not accepted in the political climate of the time.)
Model Choice (From Tiangong)	内수외양
Golden Answer	내수외양(Strengthen internal governance and build external power.)
Model Response	This article discusses GO JEONGJU's patriotic ideology. He advocated for consolidating the nation's foundation to address the crises of foreign invasions and internal turmoil. His ideas and practices had a profound impact on society at the time. Among the provided options, the idiom that best fits into the text at the position marked as #idiom# is "内수외양." This idiom means to strengthen governance internally and enhance power externally, aligning with the theme emphasized by GO JEONGJU. Therefore, I choose "内수외양" as the most suitable idiom. [内수외양]

Table 9 An example of grammatical or lexical error in model responses

Insufficient context interpretation refers to the failure of a model to adequately understand and utilize the broader context or cultural nuances of a text. This error manifests particularly in settings where emotional resonance and cultural specificity are crucial, such as in poetry or other richly emotional texts. When a model exhibits insufficient context interpretation, it might produce content that, while technically correct, does not align emotionally or culturally with the intended message as shown in Table 11.

In the expression "하늘을 우러러", the poet is metaphorically expressing a desire to pursue an ideal realm. However, the speaker's feet remain planted on the ground, and there is sadness due to the inability to fully extend them. The speaker is experiencing a world where reality and ideals coexist, feeling a cognitive paradox. The model's elected answer "나 두 야 간다", while grammatically correct and forming a complete sentence, completely overlooks the emotional and cultural background of the poem. This error demonstrates the model's limitations in handling texts that require an understanding of extensive cultural and emotional contexts.

News Text	추억의 보물을 어제 찾았다. 흰 머리칼을 날리며 유년기를 재현했다. 평생 머릿속에 남아있던 보물찾기를 실시한 야유회는 잊을 수 없다. 놀이하면 보물찾기와 수건돌리기가 떠오르니 아직도 철이 안든 모양이다. 이번 강원수필 하계 야유회에서도 그런 나의 아우성을 받아들여 프로그램에 선뜻 넣어 고마웠다. 춘천 인근이었다. 싱그러운 신록에 폭 파묻혀 #idiom#하며 풀벌레소리에 졸고 있는 체험농원을 찾았다. 임시회의를 열어 두 개의 안건을 통과시켰지만, 나에겐 소년처럼 보물찾기가 마치 연민의 정과도 같았다. 회의가 끝나고 점심도 마치고, 드디어 농원이 거느린 정원 둘레에 15 개의 보물이 숨어있다고 과거시험 시제처럼 일러준다. 회원 대부분이 고희의 포구에 정박하고 있었지만, 누구 하나 마다하지 않고 서둘러 숨겨놓은 곳으로 달려 나가기에 바빴다… (English Translation: I found the treasure of my memories yesterday, recreating my childhood with white hair blowing in the wind. I'll never forget the picnic where we played treasure hunt, which had stayed in my mind all my life. When I think of games, treasure hunts and 'hide and seek' come to mind, making me realize I haven't quite grown up yet. I'm grateful that at the Gangwon Essay summer picnic, they willingly added the treasure hunt to the program at my request. It was near Chuncheon. Immersed in lush greenery, #idiom#, we visited an experiential farm where we dozed off to the sounds of insects. Although we held a temporary meeting and passed two resolutions, to me, the treasure hunt felt like a nostalgic yearning, something akin to a boy's adventure. After the meeting and lunch, we were finally told, as if it were a state exam, that 15 treasures were hidden around the farm's garden. Although most members had docked at the harbor of their 70s, no one hesitated, and everyone eagerly rushed to search for the hidden treasures...)
Model Choice (From Clova X)	천금매소(to spend a fortune to buy a smile.)
Golden Answer	고침안면 (to sleep peacefully)
Model Response	The choice of the is idiom "천금매소" because, in these precious moments of reminiscence, we relive the pure joy of childhood, akin to buying a moment's laughter with a great sum of money. Although the correct idiom should have been "고침안면", considering the relationship we have with the treasures in the game, it seems like we are buying back the joy of our childhood with money, hence the selection of "천금매소" is more symbolic.

Table 10 An example of logical error in model responses

Poem	#sentence# 울기는 하여도 하늘이 그리워 울음이 아니다 두 발을 못 뻗는 이 땅이 애달파 하늘을 흘기니 울음이 터진다. 해야 웃지 마라. 달도 뜨지 마라. #sentence# Even if I cry, It is not because I miss the sky. It is the sorrow of this land, Where my feet cannot stretch. Looking up at the sky, Tears break forth. Oh sun, do not laugh. Moon, do not rise either.
Model Choice (From Clova X)	나 두 야 간다 (I too shall leave)
Golden Answer	하늘을 우러러 (Looking up at the sky)
Model Response	The sentence '나 두 야 간다' is the best choice because it is a complete and grammatically correct sentence in Korean. It translates to "I am also going" in English. The sentence includes the subject '나' (I), the adverb '도' (also), and the verb '가다' (to go), making it a simple and clear statement. Additionally, the sentence follows the standard word order in Korean, which is subject-object-verb. Overall, '나 두 야 간다' effectively conveys the message of the speaker joining someone else in going somewhere.

Table 11 An example of insufficient context interpretation in model responses

GUIT-AsTourNE: A Dataset of Assamese Named Entities in the Tourism Domain

Bhargab Choudhury*, **Vaskar Deka, Shikhar Kumar Sarma**

Guwahati-781014 Assam India
bhargabchoudhury24@gmail.com
{vaskardeka, sks}@gauhati.ac.in

Abstract

Named Entity Recognition is a fundamental task in Natural Language Processing that involves classifying text into predefined classes such as person, location, organisation etc. Annotated data for the Named Entity Recognition task is lacking for Indian languages, including Assamese, whereas English and European languages have plenty of data. In this paper, we presented a manually annotated Assamese Named Entity dataset on the tourism domain. The dataset contains 7166 sentences and 94604 tokens. The resulting dataset contains 9151 named entities tagged into eight Named Entity classes: location, organisation, person, entertainment, facilities, year, date and miscellaneous. Also, we trained and evaluated transformer-based language models like mBERT, XLM-RoBERTa, IndicBERT, and MuRIL on our dataset. The XLM-RoBERTa model outperforms all others with an F1 score of 78.51%.

1 Introduction

Named Entity Recognition (NER) is a Natural Language Processing (NLP) task used to detect and classify tokens into some predefined classes. The term Named Entity (NE) was introduced in the sixth Message Understanding Conference (MUC) (Grishman and Sundheim, 1996). Phrases containing the names of people, places, and organisations are known as NE (Sang and De Meulder, 2003). More generally, NE is a real-world object that can be denoted as a proper noun, but it is not limited to this. NER plays an important role in many NLP applications such as text understanding (Zhang et al., 2019), information retrieval (Guo et al., 2009), question answering (Mollá et al., 2006), machine translation (Babych and Hartley, 2003), relation extraction (RE), knowledge graph construction (Kejriwal, 2022) etc. The recognition of NE can be attained through four methods: rule-based, unsupervised learning, feature-based supervised learning, and deep learning-based approaches (Li et al., 2020). Deep learning (DL) has gained a lot of attention recently because of its success in a variety of fields. A significant number of studies have used DL to improve NER over the last few years, progressively raising the bar for performance. In order to train a supervised deep learning-based NER system, a substantial quantity of annotated data is essential. The quantity and quality of data determine how well DL based models perform. In the context of NER datasets and tools, Assamese is regarded as a low-resource language. In contrast to languages such as English or European languages, there is a notable lack of publicly accessible NER datasets for Assamese.

The official language of Assam, a north-eastern state of India, is Assamese (*অসমীয়া*, *asomiya*). Assamese is spoken by the native inhabitants of the state. The language is known for its highly inflected forms and the utilisation of pronouns and noun plural markers in both honorific and non-honorific constructions.

There are some difficulties in creating the Assamese NE dataset. The following are a few challenges.

No Capitalisation: Unlike English language Assamese does not follow capitalisation, a feature that would have been useful for completing the NER task. Example: *ৰাম গুৱাহাটীলৈ গৈছে* (*Ram Guwahatiloi goise*, Ram has gone to Guwahati). In this sentence, there is no distinguish between proper nouns or the beginning of the sentence, maintaining a uniform script

* Corresponding author

throughout.

NE Ambiguity: In Assamese, proper nouns can be confusing as the same word might fall under more than one POS categories. Example: The word আকাশ (*Akash*) can be the name of a person, or it refers to the sky.

Language Complexity: Assamese is a morphologically complex, inflectional language. This means that words can take different forms depending on their grammatical role in a phrase. Example: ঘৰ (*ghor*), meaning "house", can be inflected to ঘৰৰ (*ghoror*), meaning "of the house", and ঘৰত (*ghorot*), meaning "in the house".

Free Word Order: Assamese language with a flexible word order presents a greater challenge for the NER problem as precise word order patterns cannot be implemented in combination with computational techniques. Example: The sentences মই মাছ খাওঁ (*moi maas khaon*, I eat fish) and মাছ মই খাওঁ (*maas moi khaon*, I eat fish) have different arrangements of words; however, their core meanings remain the same.

In this paper, we present an Assamese NE dataset, namely GUIT-AsTourNE, which consists of 94604 tokens classified into eight NE classes. This is the first Assamese NE dataset in the tourism domain. Also, we present the results of different transformed-based models trained on the GUIT-AsTourNE dataset. The followings are the summary of our contribution:

- We gather textual information in Assamese on the tourism domain. The text data is annotated into eight NE classes.
- Then we perform the blind validation by two validators. We evaluate the agreement between annotator and validators.
- We resolve the conflicts through the intervention of a linguist.
- We train and evaluate transformer-based models such as mBERT, XLM-RoBERTa, IndicBERT, and MuRIL on our dataset.
- We release[1] our data and the best-performing model.

[1] https://github.com/nlp30/GUIT-AsTourNE

2 Related Work

Research and development for most of the NLP tasks for the Assamese language are still in their early stages compared to languages with abundant linguistic resources. Significant studies have been conducted in Word embedding (Pathak et al., 2024), POS tagging (Saharia et al., 2009; Pathak et al., 2022b, 2023; Baishya and Baruah, 2024), UPoS tagging (Talukdar et al., 2024; Talukdar and Sarma, 2023), and WordNet (Sarma et al., 2010; Sarmah et al., 2019; Phukon et al., 2021). Also, a few NER works on the Assamese language have been documented(Sharma et al., 2012; Talukdar et al., 2014; Sharma et al., 2014; Mahanta et al., 2016; Sharma et al., 2016; Talukdar et al., 2018). WikiAnn(Pan et al., 2017) is the first publicly available dataset on Assamese language and 282 global languages. The AsNER(Pathak et al., 2022a) dataset, available only in the Assamese language, contains 34K entities. However, around 29K entities are without sentence context(Mhaske et al., 2022). The Naamapadam(Mhaske et al., 2022) dataset, which covers 11 Indian languages, including Assamese, contains 5K entities. Table 1 lists the statistics of publicly available Assamese NER datasets.

3 Corpus Acquisition and Pre-processing

In this section, we outline the process of obtaining and preparing the corpus. We explain the source from which the corpus was developed, and then we describe the preprocessing techniques used to clean and prepare the raw data for the annotation process.

3.1 Source of Corpus

The first step towards annotated data is to collect text on the tourism domain. Using a crawler, we extract text from Wikipedia on the tourism domain. The laboratory-developed GUIT tourism corpus is an additional source. Table 2 displays the statistics for the corpus.

3.2 Preprocessing

Preprocessing is an important step in generating high-quality data. Other language terminology, extraneous characters, gaps, typos, etc. are all present in the data. Therefore, in

Dataset	#Sentence	#Tokens	#NE
WikiAnn	300	1516	329
AsNER	24040	98623	34963
Naamapadam	10369	112048	5045

Table 1: Statistics from the current datasets.

Source	#Sentence	#Tokens

GUIT	3473	40358
Total	**7166**	**94604**

Table 2: Statistic of the two sources.

order to obtain real vocabulary, data cleaning is essential.

Removing Noisy Characters: White spaces are used in place of punctuation markers such as quotation marks, periods, ellipses, and special characters. Unwanted noisy characters, extra spaces and the HTML tag are eliminated.

Language Normalisation: The text might contain elements in other languages. These words are translated into the Assamese. The translation of some words is not available; those words are transliterated.

4 Annotation Process

In this section, we describe how the dataset is created. We discuss the background of NE classes, the NE classes that were considered and the annotation methodology. We evaluate the Inter-Annotator agreement (IAA) to measure the consistency between the annotator and validators. Finally, we resolve the annotation conflicts with the help of a linguistic expert.

4.1 NE Classes

Selecting the NE classes is the first step towards creating the NER dataset. NE classes specify the categories into which various text elements can be classified. The first NE classes defined on MUC 6[2] are organisation, person, location, date, time, money, and percent. In 2000, artefact NE class was introduced as part of the IREX project (Sekine and Isahara, 2000), a Japanese language evaluation effort. In the CoNLL-2003 shared task: language-independent Named Entity Recognition (Sang and De Meulder, 2003) defined four types of classes: persons, organisations, locations, and miscellaneous. In the ACE[3] programme, seven NE classes were defined: person, organisation, location, facility, weapon, vehicle, and geo-political. The dataset AnCora[4] (Taulé et al., 2008) consists of two corpora, one in Catalan and the other in Spanish, categorised tokens into six NE classes. The multilingual dataset OntoNotes 5.0 (Weischedel et al., 2011) contains 18 NE classes. The NoSta-D (Benikova et al., 2014) entity annotation guideline defines four primary classes: person, organisation, location, and other. Five entity classes were defined in the Rich ERE (Song et al., 2015) guidelines. The RuNNE Shared Task (Artemova et al., 2022) in Russian was concerned with nested NE, and the dataset it utilises NEREL contains 29 NE classes. In WojoodNER-2023 (Jarrar et al., 2023), the first Arabic NER Shared Task, 21 NE classes were defined. The NE classes developed at the AU-KBC Research Centre[5] (Rao et al., 2015) are hierarchical classes with three major classes: name, time, and numerical expressions. This NE classification is standardised by the Ministry of Communications and Information Technology, Government of India. It is used for Cross-Lingual Information Access (CLIA) and Indian Language - Indian Language Machine Translation (IL-IL MT) consortium projects. Named entities include people, organisations, locations, facilities, cuisines, locomotives, artefacts, entertainment, organisms, plants, and diseases. Distance, money, quantity, and count are the four different types of numerical expressions. Time expressions include year, month, date, day, period, and special day. In FIRE 2018 (HB et al.,

[2] https://cs.nyu.edu/~grishman/muc6.html

[3] https://www.ldc.upenn.edu/collaborations/past-projects/ace

[4] http://clic.ub.edu/corpus/en/ancora

[5] https://au-kbc.org/

2018), the Information Extractor for Conversational Systems in Indian Languages (IECSIL) track introduced a taxonomy of nine entity types for Hindi, Tamil, Malayalam, Telugu, and Kannada. The entity types are date, event, location, name, number, occupation, organisation, other, and things. In the outlook of tourism domain, Zahra et al., Hidayatullah et al., and Fudholi et al. classified text into three NE classes: natural, heritage, and purpose. The NE classes: nature, place, city, region, and negative for tourism domain were defined by Saputro et al.. A summary of the NE classes is shown in Table 3.

Based on our analysis and the current NE classes, we have identified the following NE classes as relevant for tourism text: location, organisation, person, entertainment, facilities, year, date, and miscellaneous. Seven of these classes are a subset of the NE classes developed by the AU-KBC Research Centre. In addition, we have considered the miscellaneous class to tag tokens that are NE but do not fit into any of the defined NE classes. We have briefed about the NE classes along with examples transliterated from Assamese to English.

LOCATION (LOC): Villages, towns, cities, road, provinces, countries, bridges, ports, dams, hills, mountains, water bodies, valleys, gardens, beaches, national parks, landscapes, parks, clubs, monuments, religious places, museum etc. Examples: *মাজুলী* (*Majuli*), *কমলাবাৰী সত্ৰ* (*Kamalabari Satra*), *দীঘলীপুখুৰী* (*Dighalipukhuri*).

ORGANISATION (ORG): Government, government agencies, public organisations, companies, non-profit organisations, trust, educational institute etc. Examples: *তিৰা স্বায়ত্বশাসিত পৰিষদ* (*Tiwa Swayatwashasit Parishad* , Tiwa Autonomous Council), *অসম ক্ষুদ্ৰ উদ্যোগ উন্নয়ন নিগম* (*Asom Khudra Udyog Unnayan Nigam*, Assam Small Industries Development Corporation), *কটন বিশ্ববিদ্যালয়* (*Cotton Bishwavidyalaya*, Cotton University).

PERSON (PER): First name, middle name, last name, historical figure, fictional character etc. Examples: *লাচিত বৰফুকন* (*Lachit Borphukan*), *শংকৰদেৱ* (*Sankardev*), *পদ্মনাথ গোহাঞি বৰুৱা* (*Padmanath Gohain Baruah*).

ENTERTAINMENT (ENT): Cultural festival, dance, music, drama, traditional performances, exhibitions, sporting event, boat race, religious ceremonies and festival etc. Examples: *সত্ৰীয়া নৃত্য* (*Sattriya Nritya*), *অৰণ্যত গধুলি* (*Aranyat Godhuli*), *অম্বুবাচী মেলা* (*Ambubachi Mela*).

FACILITIES (FAC): Hotel, restaurant, guest house, hospital, police station, bus terminal or station, railway station, airport etc. Examples: *অৰণ্য অতিথিশালা* (*Aranya Atithishala*, Aranya Guesthouse), *কহুৱা ৰিজৰ্ট* (*Kahuwa Resort*), *লীলাবাৰী বিমানবন্দৰ* (*Lilabari Bimanbandar*, Lilabari Airport).

YEAR (YEAR): Expressions that represent year. Examples: *১৯৯০* (1909), *১৯২১-১৯২২* (1921-1922).

DATE (DATE): Expressions that represent date. Examples: *১ এপ্ৰিল* (1 April), *২৪/১/১৯৯০* (24/1/1990).

MISCELLANEOUS (MISC): This category is used to tag entities like political ideologies, book names, nationalities, products, languages etc., that do not fit neatly into other classes. Examples: *ভাৰতীয়* (*Bharatiya*, Indian), *আহোম* (*Ahom*), *কালিকা পুৰাণ* (*Kalika Puran*).

Table 3: Summary of NE Class.

4.2 Annotation Methodology

We selected one annotator for annotation. The annotator is a native speaker with a Bachelor's Degree in Assamese. We use the IOB2 tagging format, where the I tag denotes the inside of

a NE chunk (excluding the beginning), the B tag marks the beginning of a NE chunk, and the O tag is used when a word is outside of any NE. Annotation guidelines were prepared and explained to the annotator. After tagging the initial 100 sentences, a linguist reviewed the tags to identify any problems or inconsistencies in the guidelines. This feedback was then used to enhance the guidelines. Following these guidelines, the annotator carried out the annotation. After completing the annotation, two validators were engaged to cross-check the annotations. The two validators independently perform the validation. In cases where the validators disagreed on an annotation, they added a new annotation.

4.3 Inter Annotator Agreement

Inter Annotator Agreement (IAA) score assess how consistently different annotators label the same text for named entities. Cohen's Kappa (κ) and F1 Score are commonly used metrics for calculating IAA. But, Cohen's Kappa is not an appropriate metric for NER (Hripcsak and Rothschild, 2005; Grouin et al., 2011). In NER, a considerable amount of the data may be classified as O (not NE). This can inflate the κ score, indicating a high level of agreement, which is not actual agreement. So, we calculate the macro-averaged F1 score as an alternative to Cohen's Kappa. The arithmetic mean of the F1 score of all the NE classes is calculated to get an overall measure of agreement. However, we calculate Cohen's Kappa for tokens that have atleast one annotation. Table 4 displays the F1 score and Cohen's Kappa between the Annotator and Validators, revealing substantial agreement among them.

	$F1$	κ^a	κ^b
Annotator vs Validator-1	0.94	0.89	0.95
Annotator vs Validator-2	0.89	0.81	0.91
Average	0.92	0.85	0.93

Table 4: Calculated F1 score and Cohen's Kappa values between annotator and validators. ^{a} on annotated tokens, ^{b} on all tokens

4.4 Conflict Resolution

Only one annotator annotated the data, so it's important to ensure that the dataset's quality is not compromised. Despite a substantial agreement between the annotator and the validator, we identified conflicts in 2737 tokens. Resolving these conflicts is essential to ensure the reliability of the NER system. Table 5 shows the agreement and disagreement between the annotator and the validators. Out of 94604 tokens, the annotator and validators agreed on 91867 tokens, which is approximately 97%.The validators did not agree on 603 tokens with the annotator, but both the validators assigned the same NE tag. For these 603 tokens, we use the NE tag assigned by the validators. For the remaining 2134 tokens, where either one of the validators or both did not agree with the annotator, we seek the opinion of a linguistic expert. Two such cases are explained in Table 6.

4.5 Dataset Statistics and Format

The annotated dataset is prepared in column format; the first column represents the words, and the second column represents corresponding NE tag. A blank line separates two sentences in the dataset. A total of 9151 ($\approx$ 9.67%) tokens were reported as NE. Table 7 list the frequency distribution of the various classes.

5 Experiments

In this section, we discuss the fine-tuning of various transformer-based models like mBERT, XLM-RoBERTa, IndicBERT and MuRIL on our dataset. We plot the confusion matrix of the best-performing model and also evaluate the model performance using the *nervaluate*[6] package.

5.1 Model

mBERT: mBERT (Multilingual BERT) (Devlin et al., 2019) is a pre-trained language model designed to comprehend and analyse text in multiple languages. It is a variation of the popular BERT model that has been trained on an extensive dataset containing 104 languages including Assamese. mBERT can be fine-tuned using labelled data from

[6] https://pypi.org/project/nervaluate/

Validator-1	Validator-2	#Tokens	Remarks
Agree	Agree	91867	–
Disagree	Disagree	603	Both the validators assign same NE Tag
Agree	Disagree	1611	–
Disagree	Agree	452	–
Disagree	Disagree	71	Both the validators assign different NE Tag

Table 5: Statistics of validators agreement and disagreement.

Sentence	Conflict & Resolution
মই তাত এটা ***অসমীয়া*** *পৰিয়াল লগ পাইছিলোঁ ।* *moi tat eta* ***asomiya*** *poriyal log paisilu* I met an **Assamese** family there.	**Conflict:** In this case, the disagreement arises for the word *অসমীয়া* (*asomiya*). One annotator tagged it as B-LOC, while a validator classified it as O, and another validator identified it as B-MISC. **Resolution:** The word *অসমীয়া* (*asomiya*, Assamese) is derived from the word *অসম* (*Asom*, Assam) (a location), which undergoes a morphological transformation to convey a different meaning, such as Assamese language or people. In this context, it refers to the Assamese people, and the linguist categorised it as B-MISC.
এইক্ষেত্রত ***কেৰালাও*** *এখন উল্লেখযোগ্য ঠাই ।* *eikhetrat* ***Keralao*** *ekhon ullekhjogya thaai* **Kerala** is also an important place in this regard.	**Conflict:** In this sentence, the conflict arises for the word *কেৰালাও* (Keralao). The annotator categorised it as an O, while one validator tagged it as B-MISC and another as B-LOC. **Resolution:** The root word for *কেৰালাও* (*Keralao*) is *কেৰালা* (*Kerala*), which denotes a LOCATION NE. The suffix *ও* (*o*) is added to *কেৰালা* (*Kerala*). In this context, the addition of the suffix does not alter the NE category of the word. Consequently, the linguist classified it as B-LOC.

Table 6: Examples of Sentences depicting conflict and resolution for final tagging.

any language within its multilingual training corpus.

XLM-RoBERTa: XLM-RoBERTa(Conneau et al., 2020) is an enhanced iteration of XLM that builds upon RoBERTa architecture. It is pre-training on 2.5TB of data in 100 languages. XLM-RoBERTa inherits the cross-lingual capabilities of XLM while benefiting from the improved representation learning of RoBERTa.

IndicBERT: IndicBERT(Kakwani et al., 2020) is a multilingual language model specifically designed for processing 12 major Indian languages including Assamese. It makes use of the more effective ALBERT (Lan et al., 2019) architecture, which is also a variation of BERT model.

MuRIL: Another important model in the multilingual landscape is MuRIL (Multilingual Representations for Indian Languages)(Khanuja et al., 2021), which was created especially for processing 16 Indian languages and English. It makes use of a transformer-based architecture that is comparable to but distinct from BERT.

5.2 Implementation Details

We split our dataset into training (70%), development (15%), and testing (15%) sets, as shown in Table 8. When splitting the data, we ensure a balanced stratified distribution of tags across all sets, as presented in Table 9.

We use *bert-base-multilingual-cased* variation for mBERT, *xlm-roberta-base* for XLM-

Table 9: Count of NE classes for train, dev and test splits for the GUIT-AsTourNE dataset.

RoBERTa and *muril-base-cased* for MuRIL. To train NER model, we use the Huggingface Trainer API. We employed Weighted Cross Entropy Loss function during the training phase, which is particularly effective for dealing with imbalanced datasets by assigning more significance to underrepresented classes. This is achieved by integrating class weights into the loss function, ensuring more balanced learning and improving the model's ability to generalise across all classes. Additionally, we used AdamW as an optimiser with a linear learning rate scheduler. For each training, we used the same set of hyperparameters. The experiments were conducted for 20 epochs with a batch size of 16 and a learning rate of 1e-5.

5.3 Results

In Tables 10 and 11, we provide the performance results for mBERT, XLM-RoBERTa, IndicBERT, and MuRIL on our dataset. XLM-RoBERTa achieved the highest F1 score of 78.51%, followed by MuRIL and mBERT with an F1 score of 77.79% and 77.70% respectively. IndicBERT has the lowest performance, with an F1 score of 28.89%. XLM-RoBERTa performed very well in identifying the entity YEAR, achieving an outstanding F1 score of 91.69%, but showed lower performance for the entity FAC, with an F1 score of 45.26%. Figure 1 represents the confusion matrix of the XLM-RoBERTa model. Errors have been observed in tagging a NE as not being a NE, except for the tags YEAR and DATE. The maximum errors are observed for the tag B-FAC. Additionally, mislabeling of B-FAC as B-LOC, I-ENT as I-LOC and I-PER, and I-MISC as I-LOC has been noted. A more detailed analysis of the model is conducted using the nervaluate package. Table 12 provides additional details for the evaluation schema, which are Strict, Exact, and Partial for all NE tags. According to the Strict evaluation method, a model prediction is considered correct only when the predicted entity label and the predicted entity string match the ground truth exactly; otherwise, it is considered incorrect. The Exact evaluation schema focuses solely on the accuracy of the predicted entity string boundaries, disregarding the entity type. The Partial evaluation schema combines aspects of the Strict and Exact evaluation. Unlike the Strict and Exact, the Partial method considers partial matches as incorrect.

Model	P(%)	R(%)	F1(%)

6 Conclusion

In this paper, we present a new NE dataset, GUIT-AsTourNE, for Assamese in the tourism domain, annotated into eight NE classes. We discuss the NE class, annotation guidelines, and annotation process in detail. We analyse the annotation quality by calculating the IAA between the annotator and validators. First, the annotation is performed by one annotator. Then, we validate the annotation by two validators. After that, we find the conflicted token between the annotator and the validators. We seek the help of a linguist to resolve these conflicted tokens. The final dataset contains 7166 sentences, 94604 tokens and 9151 entities. We fine-tuned transformer-based lan-

guage models like mBERT, XLM-RoBERTa, IndicBERT, and MuRIL. For this, we split our data into train, dev and test and performed the experiments by keeping the same hyper-parameter for all the experiments. We observed the highest F1 score of 78.51% on XLM-RoBERTa. Also, the performance of mBERT and MuRIL is almost similar. In the future, we plan to extend this dataset to other NLP tasks like relation extraction.

Do LLMs Implicitly Determine the Suitable Text Difficulty for Users?

Seiji Gobara, Hidetaka Kamigaito, Taro Watanabe
Nara Institute of Science and Technology
{gobara.seiji.gt6, kamigaito.h, taro}@is.naist.jp

Abstract

Educational applications, including adaptive learning platforms and intelligent tutoring systems, need to provide personalized content with feedback in order to help improve learners' skills, and it is important for such applications to understand the individual learning level. When using large language models (LLMs) for educational applications leveraging its response generation capacity, the LLMs should be able to provide appropriate feedbacks to users. This work investigates how well LLMs can implicitly adjust their difficulty level to match with the user input when generating their responses. We introduce a new dataset from Stack-Overflow, consisting of question-answer pairs related to programming, and propose a method to analyze the ability in aligning text difficulties by measuring the correlation with various text difficulty metrics. Experimental results on our Stack-Overflow dataset show that LLMs can implicitly adjust text difficulty between user input and its generated responses. Similar trends were observed for the multi-turn English lesson dataset of Teacher Student Chatroom Corpus (TSCC). We also observed that some LLMs, when instruction-tuned, can surpass humans in varying text difficulty.

1 Introduction

Educational applications, including adaptive learning platforms and intelligent tutoring systems, need to provide personalized content with feedback in order to help improve learners' skills. It is important for those applications to understand the individual learning level to enhance learners' understanding in educational applications (Wang et al., 2024b; Huber et al., 2024).

As one such application, Dijkstra et al. (2022) use large language models (LLMs) to spark curiosity for boosting children's motivation to learn. Gabajiwala et al. (2022) incorporate LLMs into interactive contents such as quizzes and flashcards

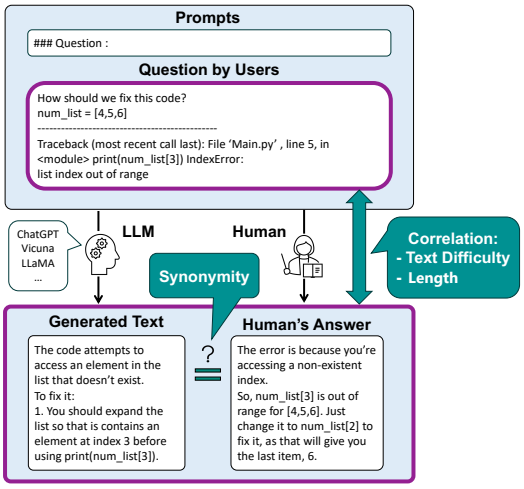

Figure 1: Overview of our evaluation procedure. We evaluate the generated texts from LLMs by comparing the correlation of text difficulty and appropriateness in length with user questions. We also measure the synonymity between the LLM generated texts and human answers.

to enhance engagement and learning of users. Abu-Rasheed et al. (2024) proposed a method that utilizes a knowledge graph to extract information relevant to learners' input questions and incorporates it into prompts, thereby providing information aligned with the learners' intentions.

Current research suggests LLMs may be useful for generating personalized problems and lecture content aligned with learners' comprehension levels (Baskara et al., 2023). LLMs can achieve this adaptation through reinforcement learning from human feedback (RLHF) that takes human preferences into consideration (Ouyang et al., 2022).

As an aspect of personalized response, LLMs should adjust the text difficulty to match user's comprehension level. Imperial and Madabushi (2023) examined the capability of GPT-2 (Radford et al., 2019) to adjust and generate complex texts. However, their analysis was limited to GPT-2, and a comprehensive study of LLMs has not yet been con-

ducted. Thus, we explored the ability of LLMs to adjust the difficulty of responses to match the difficulty of user input as an approach in understanding the learner's level for educational appllications. Responses at the same level as the user will be better understood by the user. Accordingly, we hypothesized that the "simplicity/difficulty level" is nearly equal to the "user's understanding level". Here, the simplicity or difficulty level of user text serves as a proxy to estimate the user's understanding level. Figure 1 shows an overview of our experiment. The figure illustrates how we evaluate LLM performance by comparing their generated responses to human answers, focusing on how well they implicitly adjust text difficulty. We give the same user question to both LLMs and humans, measuring their ability to adjust responses based on text difficulty and length. By comparing the synonymity between LLM-generated responses and human answers, we further measure the LLMs' ability to generate plausible responses.

To measure the ability of LLMs to adjust simplicity/difficulty level in their response, we conducted an experiment on two different datasets. We created a Stack-Overflow dataset, which is related to programming, by extracting the question-answer pairs that cover a wide range of text difficulty. In addition, we run our experiments using the Teacher Student Chatroom Corpus (TSCC) (Caines et al., 2020) in order to understand how LLMs respond to English language learners.

Experimental results on our Stack-Overflow dataset and the TSCC dataset show that LLMs adjust the difficulty of the generated text to match those of the user input, even in the zero-shot setting. We also observed that the text difficulty of LLMs' output is more closely correlated to the question's text difficulty than to the original human answers. Instruction-tuned models exhibited even stronger correlations, indicating that Instruction-Tuning may enhance the ability to adjust implicit text difficulty. The response with the same level of user will be better understood by user.

2 Related Work

Dataset There are existing datasets such as BoolQ (Clark et al., 2019) (yes/no questions), Natural Question (Kwiatkowski et al., 2019) (short and paragraph-length answers), CommonsenseQA (Talmor et al., 2019) (common knowledge), and OpenQA (Wang et al., 2023) (factuality) mainly feature short answers, making them unsuitable for reliably measuring text difficulty using automatic evaluation metrics, such as FKGL (Klare, 1974) and FRE (Kincaid et al., 1975), which require longer inputs. Thus, existing datasets lack the longer input lengths necessary to reliably measure LLMs' ability to implicitly adjust text difficulty. This highlights the need for a new dataset with longer questions and answers for better text difficulty evaluation.

Statistics	Question Title	Question Body	Answer Body
Min	3.0	23.0	3.0
Max	41.0	9,382.0	6,545.0
Median	13.0	334.0	222.0
Mean	14.6	537.8	337.9

Table 1: Token count statistics for the Stack Overflow dataset, calculated using the LLaMa-2 Tokenizer. For more details, see Appendix A.2.

Adaptive Learning Some studies aim to provide personalized learning methods through prompt tuning and model training for educational purposes (Wang et al., 2024b; Huber et al., 2024; Baskara et al., 2023), which have further evolved into user-friendly applications (Dijkstra et al., 2022; Gabajiwala et al., 2022; Abu-Rasheed et al., 2024; Imperial and Madabushi, 2023; Pu and Demberg, 2023). For the further development of LLMs, it is crucial to assess if LLMs can understand not only the content of questions but also adjust to text difficulty. The TSCC dataset, which focuses on dialogues between teachers and language learners, is relevant for this analysis. However, its short responses make thorough analysis challenging. Thus, current research has yet to sufficiently address this issue, highlighting the need for more detailed analysis.

3 Dataset Construction

We constructed a dataset for effectively comparing text difficulty, comprising two parts, questions and answers. Since short target sentences may lead to inaccurate difficulty assessments, existing QA datasets such as SQuAD (Rajpurkar et al., 2016), which typically contain brief answers (for example, a single word or sentence), do not meet our criteria. Thus, both parts maintain sentences of sufficient length to ensure reliable difficulty estimation by checking token counts (see Appendix A.2).

To address this challenge, we created a dataset from Stack-Overflow[1], selecting data as of July

[1] https://stackoverflow.com/

Stack-Overflow	
Setting	Prompt
Normal	### Question : {*Title*} {*Question*}
Simple	Please respond to the question using simple and user-friendly language. ### Question : {*Title*} {*Question*}
Complex	Please respond to the question using complex and less user-friendly language. ### Question : {*Title*} {*Question*}
TSCC	
Please generate a response from the teacher to the student in the ongoing dialogue. ### Dialogue : {*Dialogue*}	

Table 2: Prompts for each setting. Note that TSCC has only one prompt.

1, 2023. We then extracted 1,000 posts starting from the most recent ones to optimize the scope of feasible experiments under constrained resources. The extracted posts contain significantly more tokens than typically observed ones in QA datasets such as BoolQ(Clark et al., 2019), Natural Question(Kwiatkowski et al., 2019), CommonsenseQA(Talmor et al., 2019), and Open-QA(Wang et al., 2023).

We then extracted the "QuestionTitle", "QuestionBody", and "AnswerBody" fields from each post. We combined "QuestionTitle" and "QuestionBody" to form the Questions parts and designated "AnswerBody" as the Answers. Table 1 summarizes the token count statistics for the Stack Overflow dataset, showing the distribution across "QuestionTitle", "QuestionBody", and "AnswerBody". As shown in the table, some inputs exceed the context size manageable by many models (approximately 4,096 to 8,192 tokens). However, the majority of questions fit within 2,048 tokens, which allows us to evaluate the models' implicit difficulty adjustment capabilities. Thus, in this study, we limit the input to LLMs to 2,048 tokens, truncating any spurious tokens, as detailed in Appendix A.2. We will release our code and dataset at `https://github.com/satoshi-2000/llms-suitable`.

4 Evaluation Procedure

4.1 Prompts

When prompts explicitly indicate the difficulty level, there's a risk of leakage of the difficulty level adjustment, which might lead to inappropriate personalization not aligned with the learner's understanding (Rooein et al., 2023). Therefore, to evaluate the LLM's implicit ability to adjust the difficulty level, we excluded the user's text comprehension level from the prompts or inputs, as detailed in Tables 2.

To assess the effectiveness of prompts, we collected and compared examples of language model outputs across three settings — simple, normal, and complex — within the Stack Overflow dataset, and another setting within the TSCC dataset. Table 2 shows the prompts we employed in each setting. In the "normal" setting, we did not provide explicit instructions for difficulty adjustment, allowing us to observe the model's inherent ability to adapt.

Conversely, in the "simple" setting, we instructed the model to generate responses that were simple and user-friendly, while in the "complex" setting, we explicitly directed the model to produce responses that were complex and less user-friendly. This approach allowed us to compare the model's ability to adjust difficulty under both implicit and explicit guidance.

4.2 Metrics

We examine the difficulty adjustment ability of LLMs using three evaluation indicators: text difficulty; synonymity; and appropriate text length. In text difficulty and appropriate text length, we calculated Spearman's rank correlation coefficient between the input and generated texts after ranking them based on the scores of these metrics. Additionally, we recorded the number of inappropriate text generations (skip rows), such as blanks. Furthermore, we computed the Mean Absolute Error (MAE) and the mean of the above metrics, as detailed in Appendix B.

Text Difficulty In language education contexts, it's crucial for teachers to adapt explanations to match learners vocabulary and comprehension levels. Thus, we measure this ability using text dif-

ficulty metrics assuming that it reflects the level understanding. The indicators include traditional ones like FKGL (Klare, 1974), FRE (Kincaid et al., 1975), and SMOG (Mc Laughlin, 1969), as well as NERF (Lee and Lee, 2023). NERF uses manually created features based on vocabulary difficulty, sentence structure complexity, the diversity of unique words, and bias to formalize text difficulty, offers a more accurate estimation of text difficulty than traditional metrics like FKGL and SMOG.

Synonymity To assess synonymity, it's essential to determine if LLMs deliver the correct content. Thus, we calculated BERTScore (Zhang et al., 2020) for texts generated by LLMs using the collected dataset's texts as references to ensure that LLMs align with the user's intended content.

Appropriate Length In question-answering and educational contexts, it's crucial that responses are both concise and appropriately detailed. Responses that are too short or too long can hinder user comprehension and clarity. However, determining a universally optimal response length is challenging, as it varies with the user's expertise and preferences. In this study, we operate under the assumption that longer input questions warrant more detailed responses, while shorter questions call for greater brevity. Thus, we investigated if LLMs can produce responses of appropriate length — neither too long nor too short — by comparing the length of LLMs generated texts to the input texts.

5 Experimental Setup

5.1 Dataset

We conducted experiments on two datasets: our Stack-Overflow dataset consisting of question-answer pairs related to programming , and the Teacher-Student Chatroom Corpus (TSCC) (Caines et al., 2020) consisting of dialogue histories collected during English lessons. These datasets were used to compare how the ability to adjust text difficulty changes in single-turn Stack Overflow pairs and multi-turn TSCC dialogues.

Stack-Overflow We used our created Stack-Overflow dataset in Section 3, consisting of 1,000 selected entries with HTML tags removed. It was scraped from question datasets as of July 1, 2023.

TSCC We extracted the TSCC dialogue histories from the beginning, prefixed each turn with the label of the speaker ("teacher" or "student"). For our experiments, we used the dialogues up to just before the first turn where the teacher speaks after the initial 10 turns, ensuring that the LLM is given the teacher's turn.

5.2 Models

To assess the ability of LLMs to adjust text difficulties for users, we compared various models. We hypothesized that LLMs, when trained on data reflecting human preferences, have the potential to align with learners' comprehension levels. Accordingly, we focused our evaluation on models such as GPT3.5/4 (Ouyang et al., 2022; OpenAI et al., 2023) and Vicuna (Zheng et al., 2023).

We also hypothesized that instruction-tuning is effective in acquiring the implicit ability to adjust text difficulty. Thus, we chose several models: LLaMa-2 and LLaMa-2-chat (Touvron et al., 2023b); CodeLLaMa and CodeLLaMa-Instruct (Roziere et al., 2023); Mistral and Mistral-Instruct (Jiang et al., 2023); Orca (Mitra et al., 2023); and OpenChat (Wang et al., 2024a).[2]

GPT3.5/4 (Ouyang et al., 2022; OpenAI et al., 2023) is an LLM that uses Reinforcement Learning from Human Feedback (RLHF) to align with human preferences, and it stands out for its exceptionally high performance among current LLMs.

LLaMA-2 (Touvron et al., 2023b) is an LLM pre-trained and fine-tuned across a range of 700 million to 7 billion parameters. This model not only outperforms LLaMA and its variants (Touvron et al., 2023a) in numerous benchmarks but has also undergone manual reviews for its usefulness and safety, indicating its potential to substitute closed-source models. Besides, it includes variations with different parameter sizes and versions fine-tuned for dialogue data and source code, such as LLaMA-2-chat and Code-LLaMA (Roziere et al., 2023).

Vicuna (Zheng et al., 2023) is an LLM trained to align with human preferences using data from ShareGPT [3] interactions, and based on LLaMA (Touvron et al., 2023a). We selected the 1.5 version of this model based on LLaMA-2 to analyze the impact of on text difficulty adaptation.

Orca (Mitra et al., 2023) is a model fine-tuned with prompts from various strategies, enabling it to adjust difficulty and offer flexible outputs in response to input sentences.

[2] See Appendix C for further details.

[3] https://sharegpt.com/

Mistral (Jiang et al., 2023) is a pre-trained model with 7 billion parameters. Compared to the larger parameter-sized 13B model of LLaMA-2, Mistral has recorded high performance in benchmarks.

OpenChat (Wang et al., 2024a) builds on Mistral (Jiang et al., 2023) and ShareGPT for training, enhancing learning by leveraging data quality variance between GPT-3.5 and GPT-4 as a reward mechanism.

Starling (Zhu et al., 2023a) is trained with a reward model derived from feedback on GPT-4 (OpenAI et al., 2023) and builds upon OpenChat (Wang et al., 2024a), which itself was fine-tuned from Mistral. We aim to explore whether models based on Mistral can develop the ability to modulate difficulty levels through fine-tuning.

To ensure reproducibility, we fixed the random seed and temperature for sentence generation. We detailed inference setting in Appendix A.

6 Results and Discussion

6.1 Stack-Overflow

Normal Figure 2 shows the result on our Stack-Overflow dataset and TSCC dataset under each setting. Although many models score high on BERTScores, the LLaMA-2 base model presents lower scores due to over- and under-generation. This result contrasts LLaMa-2-chat, showing instruction-tuning's effectiveness in considering human responses. Also, LLaMa-2-chat performs well in the correlation of text difficulty with other instruction-tuned models, Vicuna-13B and Mistral-7B-Instruct. From the result, we can understand the importance of instruction-tuning in the correlation.

On the other hand, CodeLlama-Instruct, which is instruction-tuned for code generation, shows low performance. Based on the successful result by LLaMa-2-chat, also instruction-tuned from LLaMa-2, this result indicates the importance of target tasks in instruction-tuning. We can observe similar trends between Mistral-7B-Instruct and its instruction-tuned variants, Openchat-3.5-7B and Starling-LM-7B.

Orca shows high performance as an instruction-tuned model. When comparing Orca-2-7B and Orca-2-13B, Orca-2-13B performs better across all metrics, underscoring the model's adherence to the scaling law. Nevertheless, LLaMA-2-chat maintains strong performance regardless of an increase in model size. Therefore, we can conclude the importance of the instruction-tuning method rather than model parameter size.

LLaMA-2-chat scores comparable to GPT-3.5 and GPT-4 in all metrics. This result is consistent with the human evaluations for helpfulness by LLaMA-2-chat reported in (Touvron et al., 2023b) and shows the potential of open-source models.

Simple In Figure 2, the results show a similar tendency to the normal setting, with instruction-tuned models also able to adjust text difficulty in response to the input in the simple setting.

Complex In Figure 2, even in the complex setting, instruction-tuned models adjust text difficulty based on the input, similar to the normal setting. However, the Spearman's correlation is lower in complex setting compared to the simple and normal settings. This may be due to prompts deliberately designed to elicit more complex responses, resulting in expressions that are harder to understand than the original responses.

Overall Comparing the normal, simple, and complex settings, the Spearman's correlation is consistently higher in the normal setting. The results in the normal setting were slightly higher than those in the simple setting, suggesting that human preference and instruction tuning have implicitly gave these models the capability to adjust text difficulty.

We also measured the correlation between input and output lengths, assuming longer questions require detailed responses and shorter ones should be concise. However, the correlation was consistently low across all models, showing the difficulty of handling generation lengths by LLMs similar to Juseon-Do et al. (2024). This suggests that input length alone doesn't fully capture the respondent's expertise or preference for response length. For example, step-by-step explanations may help beginners but can be redundant for professionals who prefer concise summaries. Further research is needed to determine the optimal level of detail based on the respondent's needs.

6.2 TSCC

Figure 2 shows the results of the TSCC dataset. The correlation coefficient scores for the difficulty of input and generated text are lower than that in the Stack-Overflow dataset, in contrast to the scores in BERTScore. Despite the challenging model outputs, we can observe the positive correlations by humans that indicate the validity of this dataset.

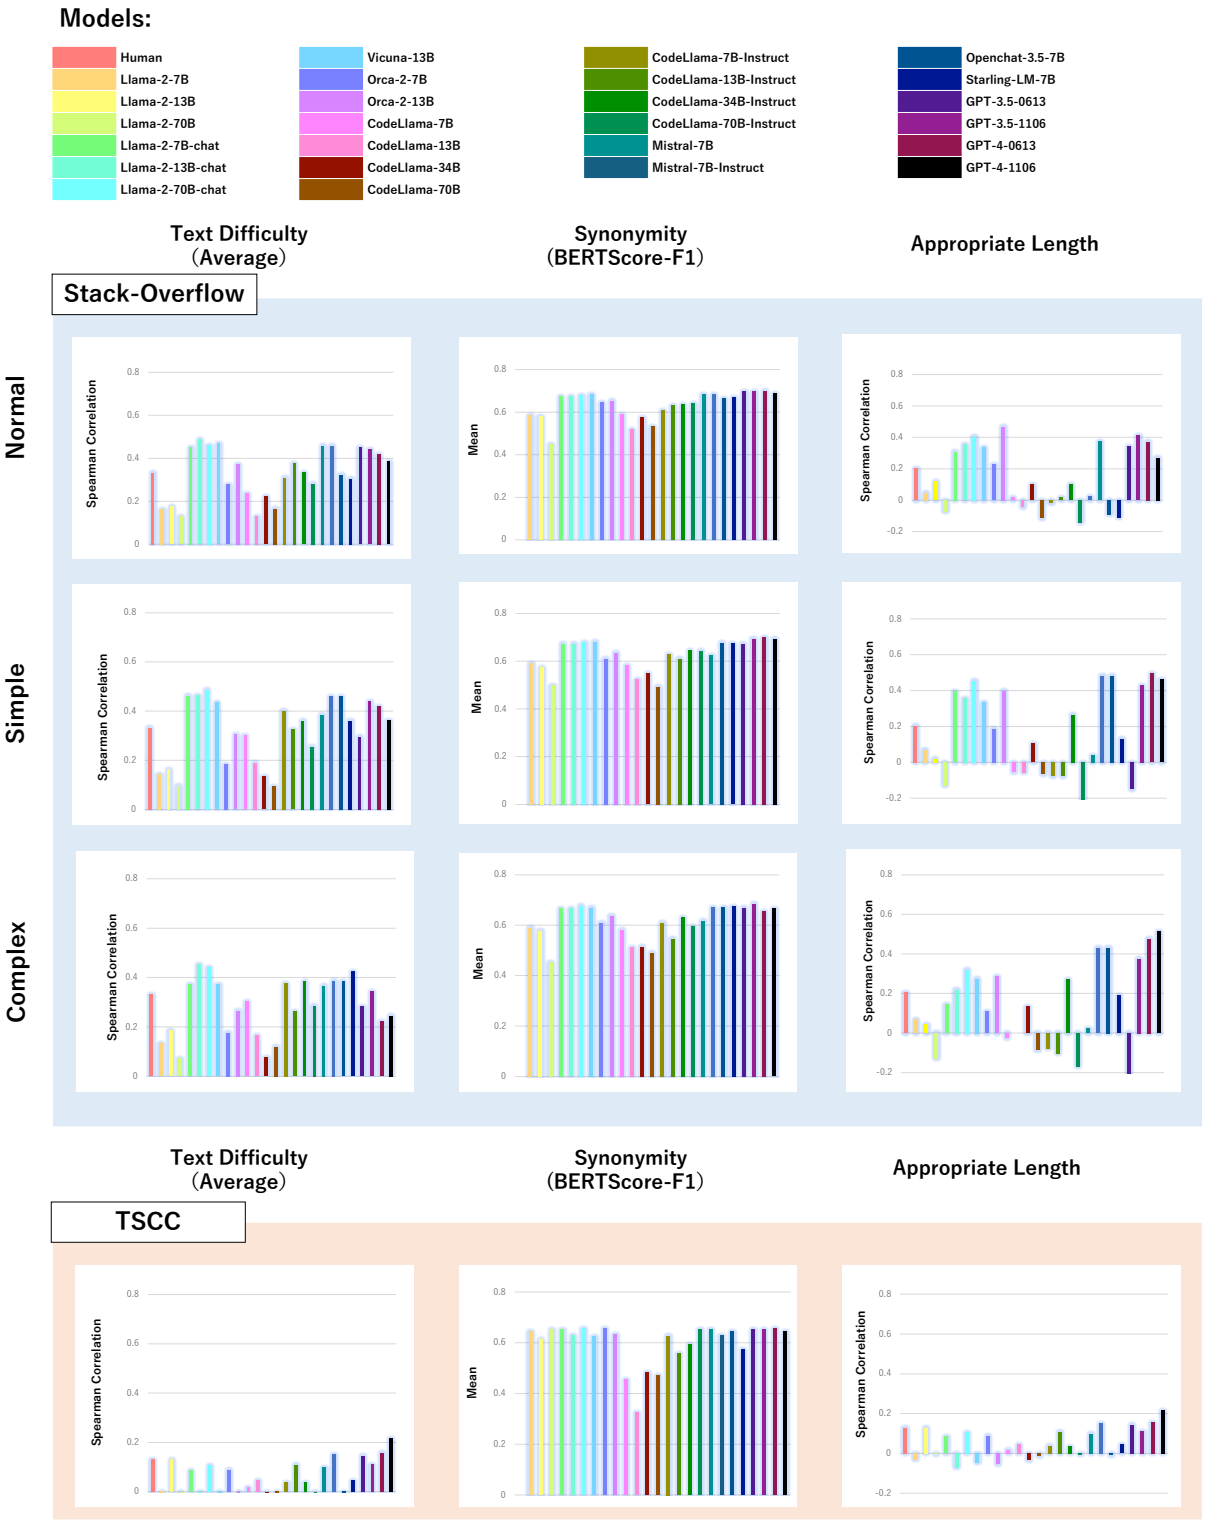

Figure 2: Results on the Stack-Overflow dataset and TSCC dataset. We observed similar trends across all evaluation metrics for text difficulty. Thus, we report the average scores of FKGL, FRE, SMOG, and NERF. Note that Table 5 and 9 in Appendix B include the detailed values.

Question Title	How is arbitrary distributed for Int? Why is it limited by so small values?
Question Body	I am trying to compare the QuickCheck library to the SmallCheck one. In SmallCheck I can reach particular value manipulating depth parameter. In QuickCheck: >a<-generate (replicateM 10000 arbitrary) :: IO [Int] >length a 10000 >maximum a 30 and my question then is: why are 10,000 ""random"" (""arbitrary"") integers limited by 30?! I expected to see more ""widely"" distributed values within the range 0..10,000, maybe the maximum value close to 5,000.
Human	The documentation contains a clue: The size passed to the generator is always 30 By default QuickCheck works by starting with 'easy' or 'small' inputs to see if it can find counterexamples with those. Only if it finds no problems with the small inputs does it gradually widen the range of generated input. The size value (which runs implicitly throughout everything that QuickCheck does) is the value that controls this behaviour. When you run QuickCheck (e.g. with quickCheck) it automatically increases the size as it goes. You're not really supposed to use the generate function directly, but if you do, you can resize it: ghci> b <- generate (replicateM 10000 (resize 60 arbitrary)) :: IO [Int] ghci> maximum b 60 That said, how are you supposed to use QuickCheck? The documentation describes quickCheck along with a multitude of variations you can use to evaluate properties. Personally, I integrate my QuickCheck properties with a unit testing framework with testProperty. You can see examples here: Property-based testing is not the same as partition testing.
GPT-4	In QuickCheck, the 'arbitrary' function for generating random values of type 'Int' is designed to produce a wide range of values, including small and large numbers, positive and negative. However, the distribution is not uniform across the entire range of 'Int'. Instead, QuickCheck biases the distribution towards smaller numbers, which are often more likely to uncover edge cases and bugs in your code. The reason you're seeing a maximum value of 30 in your example is likely due to the default size parameter used by QuickCheck when generating values. Quickheck uses a size parameter to control the ""size"" of generated values, which can mean different things for different types. For integral types, it often controls the maximum absolute value of the numbers generated. When you use 'arbitrary' without specifying a size, QuickCheck uses a default size that is relatively small to ensure that the tests run quickly and that the generated values are not too large to handle. This is why you're seeing a maximum value of 30 in your list of 10,000 integers. If you want to generate larger numbers, you can use the 'resize' function to increase the size parameter, or the 'scale' function to modify it. Here's an example of how you might use 'resize' to generate larger 'Int' values: "'haskell import Test.QuickCheck main :: IO () main = do largeInts <- generate $ resize 10000 $ vectorOf 10000 arbitrary print $ maximum largeInts "' In this example, 'resize 10000' sets the size parameter to 10000, which should result in larger integers being generated. The 'vectorOf 10000 arbitrary' generates a list of 10000 random integers using the new size parameter. Keep in mind that even with a larger size parameter, QuickCheck may still generate many small numbers, as it tries to cover a range of cases, including those that are more likely to cause problems in real-world code. If you want a uniform distribution across the entire range of 'Int', you might need to use a different approach or a different library that provides such functionality." The behavior you observed in QuickCheck

Table 3: Examples of Question and Answering (gpt-4-1106-preview, normal)

Input	Please generate a response from the teacher to the student in the ongoing dialogue. ### Dialogue:student: Hi! teacher: Hi <STUDENT>! teacher: Everything alright with the chatroom for you? student: I tried to use it a few seconds ago and I couldn't change my name, but now it is working, thanks. student: How are you? teacher: Oh good! teacher: Fine, thank you! It's summer here at last, we've had a week of non-stop sunshine! teacher: How are you? student: I'm fine thank you! It looks like summer has arrived here too! student: Even though we still had a couple of storms... student: with hail and everything teacher:
Human	Have you guys been mostly unlocked now?
GPT-4	Oh wow, that sounds intense!

Table 4: Examples of dialogues (gpt-4-1106-preview)

In the open-source models, only Llama-2-70B-chat and Mistral-7B-Instruct achieve positive correlations in all metrics, whereas other models sometimes show negative correlations. However, these scores are lower than that of humans, demonstrating different tendencies from the Stack-Overflow dataset. Since the text in the TSCC dataset is often shorter than that in the Stack-Overflow dataset and uses dialogue-specific slang, models need to cover various domains and capture the implicit context of the conversation. Therefore, this result shows room for improvement in the instruction-tuning of open-source models by covering more various domains and diversified conversational text. Furthermore, the inconsistent tendencies of model parameter size support the conclusion induced by the results on the Stack-Overflow dataset that instruction-tuning is more important than the model parameter size.

Regarding GPT-3.5 and GPT-4, the results are remarkably high. These models achieve positive correlations in all metrics similar to humans. Because the details of GPT-3.5 and GPT-4 are not publicly available, we cannot judge what causes this remarkable performance. At least this result indicates the potential of LLMs in handling the correlation of text difficulty between user input and its corresponding response.

7 Analysis

7.1 Stack-Overflow

Table 3 presents examples of question-and-answer pairs from our Stack-Overflow dataset, comparing responses generated by GPT-4 (gpt-4-1106-preview) with original human responses under normal setting. The table includes a question about the default size parameter in the Haskell library QuickCheck and the corresponding answers. Both the human and GPT-4 responses mention the need to use "resize" to adjust the size parameter. The human response is concise, while GPT-4 offers a more detailed, step-by-step explanation. The most appropriate response depends on the user's preferences and level of expertise, making this judgment subjective. However, it is qualitatively clear that the text difficulty in both the question and the responses is comparable.

While this example focuses on a question about a Haskell library, our Stack-Overflow dataset contains many other questions and answers related to various programming languages and environment setups. The expertise required for human annotators to accurately evaluate these responses is considerable and making manual evaluation challenging. Given these difficulties, our analysis relies on statistical data, which appears to be an effective approach for evaluating LLMs, particularly in contexts where manual evaluation is difficult.

7.2 TSCC

Table 4 presents an example of a single-turn teacher response for evaluation. As illustrated in Table 4, we compare the previous utterance, such as "Hi <STUDENT>!" and "with hail and everything," to the response, "Oh wow, that sounds intense!", focusing on text difficulty, synonymity, and appropriate length. As seen in Table 4, the generated responses in dialogue generation are often brief and do not reflect the assumed proficiency level of the interlocutor. This suggests that to accurately assess the implicit difficulty adjustment capability in dialogue generation, it is crucial to generate sufficiently detailed responses.

8 Conclusion

We explored LLMs' ability to implicitly handle text difficulty between user input and generated text by comparing open-source LLMs and GPT-3.5/4 models in our Stack-Overflow dataset, based on question-answering, and the TSCC dataset, based on dialogue scenarios.

Experimental results on the Stack-Overflow show strong correlations in the text difficulty between texts from LLMs such as LLaMA-2-chat, Vicuna, GPT-3.5, and GPT-4 and their inputs. Notably, sometimes, LLMs even show higher correlation coefficients than human responses, underlining their potential for effective difficulty adjustment in question-answering. Furthermore, the experimental results on the TSCC dataset show the difficulty of handling text difficulty between user input and generated text.

Based on the results, we conclude the importance of instruction-tuning rather than the size of model parameters for implicitly handling text difficulty between user input and generated text by LLMs.

As our future work, we plan to identify preferences that improve this difficulty adjustment ability by examining how well LLMs acquire this skill from training data like dialogue histories. We will also explore the optimal response length for users with varying levels of expertise to further refine LLM performance.

9 Limitations

We conducted comparative experiments across various model types, yet we recognize the need for further exploration into datasets and evaluation methodologies.

Datasets We chose the Stack-Overflow dataset and TSCC for analyzing LLMs. These datasets focus on distinct domains: coding question-and-answer pairs and dialogue generation for educational guidance, respectively. To effectively evaluate the ability of LLMs to adjust difficulty implicitly, we suggest expanding the evaluations to include a wider variety of domains. This expansion should encompass specialized areas such as law or mathematics and general knowledge domains. Nonetheless, it's crucial to gather responses that are long enough to accurately evaluate the difficulty of texts produced by LLMs.

Evaluation To assess text difficulty, we selected an evaluation metric designed specifically for the English language. Therefore, adapting this evaluation method to other languages requires the use of metrics tailored to each respective language. Additionally, it's vital to verify if the difficulty level of texts produced by LLMs matches users' actual comprehension levels. Although we confirmed that texts generated by models can address certain issues within specific datasets, the extent of the data's contribution to solving problems and the reasons for failures when solutions are not achieved and remain unclear.

Analyzed Languages To assess the LLM's ability to implicitly adjust text difficulty, our analysis was limited to English. Consequently, for other languages, particularly those with limited linguistic resources, the model may not have fully developed this capability due to the reduced number of training tokens available.

10 Ethics Statement

The LLMs we used in our experiments might contain biases in the datasets utilized during training and the criteria used to ensure their quality. Additionally, the Stack-Overflow dataset employed in this study was collected by the authors themselves. However, for models released after the dataset was collected, there is a possibility that they were trained using the collected dataset.

A Inference

A.1 Hyperparameters

We conducted 4-bit quantization for inference with a maximum input length of 2,048 tokens and a maximum output length of 3072 tokens. Since many models used in this comparative experiment employ the LLaMa-2 Tokenizer, we used it to measure the token count for consistency across evaluations. We limited the process to a single run since we used the already trained publicly available models in HuggingFace Transformers[4]. We set the random number seed to 42. We also set the temperature to 1.0.

A.2 Handling Long Inputs

Figure 3 shows a histogram of the number of tokens calculated using the tokenizer of Llama-2-7B (Touvron et al., 2023a) for the input data of the Stack-Overflow dataset. In Figure 3, 97.0% of all input data has 2,048 tokens or fewer, 98.1% has 3,072 tokens or fewer, and 1.9% has more than 3,072 tokens. To evaluate whether the model has acquired the ability to adjust difficulty levels in the outputs it generates for input sentences, it is not necessary to consider all input sentences; it is considered possible to capture the content of many input sentences sufficiently with 2,048 tokens. Therefore, to standardize the length of input and output sentences generated, the input to the model was truncated to up to 2,048 tokens, and the maximum number of tokens generated was adjusted to match the input tokens, resulting in 3072 tokens.

Additionally, we checked the input tokens and found that 94.3% are longer than 100 tokens. Thus, we can reliably estimate text difficulty.

A.3 Total Computational Budget

We utilized NVIDIA RTX A6000 GPUs for a total of 2,500 hours to evaluate open models. Additionally, we incurred $246.36 in costs through the OpenAI API[5] for evaluating GPT-3.5 and GPT-4 models.

B Detailed Results

We calculate the scores using pairs of input texts and their generated texts (human responses). Additionally, we calculate document length based on the number of characters.

[4] https://huggingface.co

[5] https://openai.com/api/

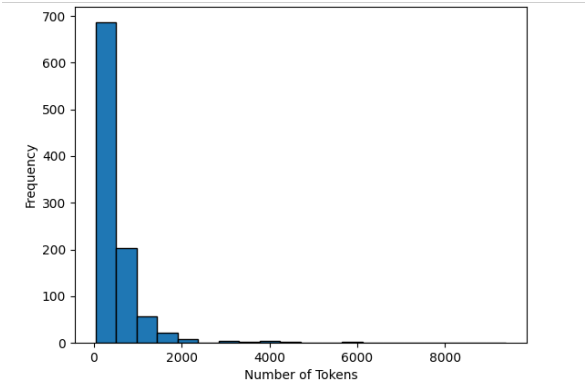

Figure 3: Histgrams of input tokens (Stack-Overflow)

B.1 Spearman Correlation

We compare LLMs' ability to adjust text difficulty and appropriate length using the Spearman correlation. Tables 5–8 show the actual scores.

B.2 Mean Scores

In Table 9–12 , we observe that models, with the exception of CodeLLaMa, which have enhanced ability to adjust difficulty, tend to produce shorter texts. This indicates that instruction-tuning likely facilitates the development of skills to appropriately regulate response lengths. Although this study evaluated the length of texts generated by LLMs in comparison to their original lengths, the ideal text length should naturally vary from one user to another. Thus, aside from extreme cases like CodeLLaMa, there's a need to explore effective evaluation methods for determining the suitable length of LLM-generated texts and to establish credible criteria for assessing longer text outputs.Additionally, GPT-4-1106 produced longer texts than those by previous versions, GPT-3.5 and GPT-4, suggesting it might use longer sequences for training. This indicates that GPT-4 may generate redundant responses without specific tuning prompts.

B.3 Mean Absolute Error

Tables 13–15 show that mean absolute error between input texts and generated texts. As shown in Table 13–15, we observed the tendency similar to the Spearman correlation. Additionally, well instruction-tuned models, such as LLaMA-2-chat and GPT4 score low mean absolute error.

Figure 4: Results of the text difficulty on the Stack-Overflow dataset and TSCC dataset.

Abstract

This paper presents ElliottAgents, a multi-agent system leveraging natural language processing (NLP) and large language models (LLMs) to analyze complex stock market data. The system combines AI-driven analysis with the Elliott Wave Principle to generate human-comprehensible predictions and explanations. A key feature is the natural language dialogue between agents, enabling collaborative analysis refinement. The LLM-enhanced architecture facilitates advanced language understanding, reasoning, and autonomous decision-making. Experiments demonstrate the system's effectiveness in pattern recognition and generating natural language descriptions of market trends. ElliottAgents contributes to NLP applications in specialized domains, showcasing how AI-driven dialogue systems can enhance collaborative analysis in data-intensive fields. This research bridges the gap between complex financial data and human understanding, addressing the need for interpretable and adaptive prediction systems in finance.

1 Introduction

The integration of LLMs into multi-agent systems has opened new frontiers in AI, particularly in the domain of financial analysis (Zhao et al., 2023; Weng, 2024). Stock market prediction, a field characterized by its complexity and dynamism, has long challenged traditional AI-based methods. These approaches often falter in processing vast datasets and adapting to rapid market changes (Gamil et al., 2007; Luo et al., 2002).

This paper presents ElliottAgents, an multi-agent system that harnesses the power of NLP (Lane et al., 2019) and LLMs to analyze stock market data. Our approach combines AI-driven analysis with the Elliott Wave Principle (EWP), a established method of technical analysis (Frost et al., 2001). The core innovation lies in the system's ability to facilitate natural language dialogue between agents, enabling them to collaboratively interpret market patterns and refine their analyses.

Our research addresses the following question: How can we effectively integrate natural language processing methods and multi-agent architectures to produce reliable and human-comprehensible stock market analyses and predictions? Through experimental validation, we demonstrate that our approach not only enhances pattern recognition accuracy but also generates detailed, easily interpretable market trend descriptions and forecasts.

Our system contributes to the field of NLP applications in specialized domains. It showcases the potential of AI-driven dialogue systems in enhancing collaborative analysis within data-intensive fields. By filling the gap between complex financial data and human understanding, ElliottAgents represents a step forward in creating more interpretable and adaptive prediction systems in finance.

2 Foundations of Stock Market Forecasting

2.1 The Evolution of Stock Market Analysis

Stock market analysis has progressed from manual techniques to AI-driven approaches over the past century. Traditional methods like fundamental analysis and technical analysis (Murphy, 1999) have been augmented by computational models since the 1960s. The development of financial software has seen several paradigm shifts: from simple automation of existing techniques to the creation of complex algorithmic trading systems (Tirea et al., 2012). Recent years have witnessed the integration of machine learning and natural language processing in financial analysis. Our proposed ElliottAgents system addresses several limitations in current market analysis approaches. The system's distributed nature enables parallel processing of market data, allowing for real-time analysis across numerous assets and timeframes simultaneously.

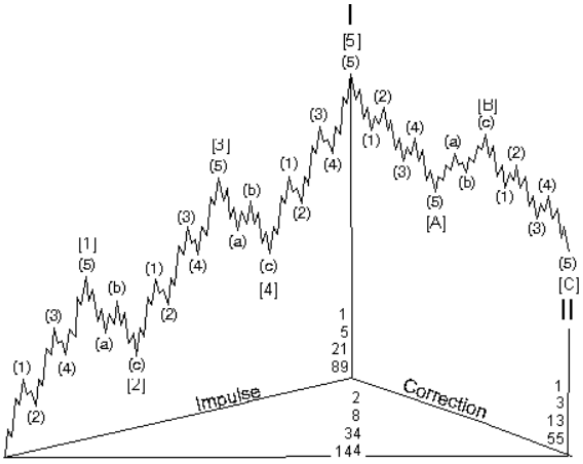

Figure 1: The fractal character of Elliott wave pattern (Frost et al., 2001)

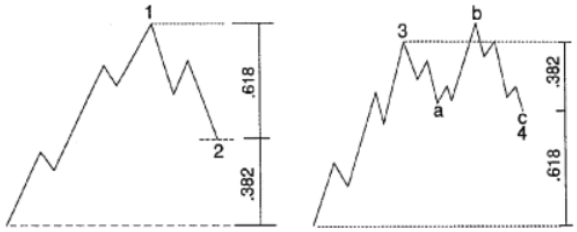

Figure 2: Fibonacci retracements in corrective waves (Frost et al., 2001)

In comparison to other approaches, ElliottAgents offers a more interpretable framework by integrating the structured EWP approach. Our recommendations are based on theory that has been used for years in contrast to the "blackbox" nature of other AI-based systems. This integration potentially provides a longer-term perspective and strategies more aligned with established market behavior patterns. The system's ensemble of specialized agents, each focusing on different aspects of EWP analysis, aims to provide a more holistic market view compared to purely data-driven ensembles.

2.2 Elliott Wave Principle

The Elliott Wave Principle (EWP), developed by Ralph Nelson Elliott, is a technical analysis method based on the premise that market prices move in recognizable patterns driven by collective investor psychology (Frost et al., 2001; Murphy, 1999). This principle posits that market behavior alternates between phases of optimism and pessimism, creating predictable waves in price movements. Elliott identified thirteen recurring patterns, or "waves," which can be classified into two main types: impulsive and corrective waves. As presented in Fig. 1, impulsive waves are the driving force behind market trends and consist of five sub-waves, while corrective waves, comprising three sub-waves, counterbalance the trend.

The Fibonacci sequence plays a crucial role in the EWP, providing a mathematical framework for wave relationships (Boroden, 2008). Elliott observed that waves often align with Fibonacci ratios, particularly the Golden Ratio (approximately 1.618). These ratios govern the relative lengths and amplitudes of waves, with Wave 3 in an impulsive sequence typically being 1.618 times the length of Wave 1. Corrective waves often retrace Fibonacci percentages (38.2%, 50%, 61.8%) of the previous impulsive wave as presented in Fig. 2.

The fractal nature of Elliott waves (Vantuch et al., 2016) allows for application across various time frames, from short-term movements to long-term trends. This characteristic, combined with Fibonacci relationships, creates a cohesive structure throughout market cycles . While the EWP does not offer certainty, it provides a framework for assessing probabilities of different market scenarios, aiding traders in understanding market context and predicting potential future paths.

2.3 Large Language Models

Large language models represent a significant advancement in the field of AI and NLP. These models are designed to understand, generate, and interact with human language in a way that is increasingly indistinguishable from human performance (Naveed et al., 2024; Raiaan et al., 2024). Examples of LLMs include OpenAI's GPT-4 (OpenAI, 2023), Google's Gemini, and the LLAMA series. The advancement of NLP is intrinsically tied to the progress of LLMs. These models, which lie at the forefront of AI, are capable of understanding, generating, and interacting with human language in a way that is increasingly indistinguishable from human performance (Louis-François Bouchard, 2024). They have been trained on vast amounts of text data and leverage sophisticated architectures to perform a wide range of language-related tasks, from translation and summarization to question answering and creative writing.

The core principle behind LLMs is the use of neural networks (NN) (Szydlowski and Chudziak, 2024b), specifically a type of network known as the transformer. Transformers have revolutionized the way models process sequential data. Unlike

traditional recurrent neural networks (RNNs) and long short-term memory networks (LSTMs), transformers can handle long-range dependencies more effectively, making them ideal for language tasks (Amaratunga, 2023). Transformers utilize a mechanism called self-attention, which allows the model to weigh the importance of different words in a sentence when making predictions. This is crucial for understanding context, as the meaning of a word often depends on the surrounding words.

While LLMs have shown potential in various NLP tasks, their application in time series prediction, particularly in finance, is an area of ongoing exploration (Tang et al., 2024). One challenge is the need for LLMs to understand the temporal order of data points (Chudziak, 2023), which is crucial for accurate forecasting (Chudziak and Cinkusz, 2024). Techniques like positional encoding are used to address this limitation (Tan et al., 2024), but further research is needed to fully leverage the capabilities of LLMs in capturing the dynamics of financial time series. The use of agents may be a factor that will greatly improve the results of time series prediction by distributing tasks among agents, enabling a more robust analysis of complex big sets of data.

3 Multi-Agent System Architecture

3.1 System Architecture

Multi-agent systems have long been a powerful tool in modeling complex systems, where multiple autonomous entities, known as agents, interact within an environment to achieve individual or collective goals (Guo et al., 2024). Historically, these systems were built using various methodologies, including rule-based systems, symbolic equations, stochastic modeling, and early forms of machine learning.

However, these early approaches faced significant limitations. Agents were typically limited in their adaptability and often failed to respond effectively to dynamic, changing environments. Their interactions were straightforward, lacking the depth needed to mimic real-world complexities and making suboptimal decisions based on limited information and computational power.

The integration of LLMs, such as GPT-4 (OpenAI, 2023), has significantly transformed multi-agent systems, bringing advanced natural language understanding, reasoning, and decision-making capabilities to agents. LLMs enable agents to operate more autonomously, adapting to new situations without requiring explicit instructions. These agents can now exhibit goal-directed behaviors, making proactive decisions to achieve long-term objectives, enhancing their autonomy and proactiveness (Guo et al., 2024; Cinkusz and Chudziak, 2024). Agents can also dynamically perceive and respond to changes in their environment, learning from their experiences to improve future responses (Zhao et al., 2023; Yao et al., 2023).

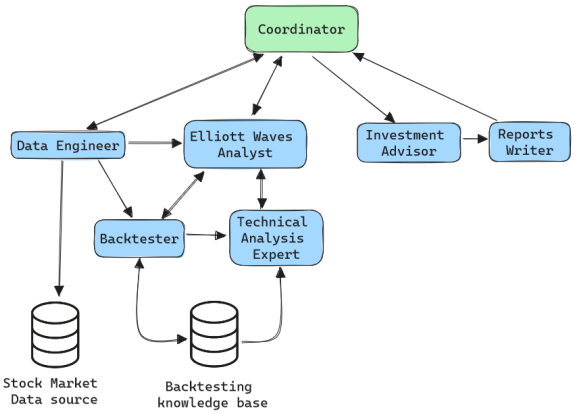

Figure 3: Data flow between agents.

The agents collaborate, performing sequential and hierarchical tasks that culminate in a comprehensive analysis as shown on Fig. 3. Some agents utilize advanced tools, which were described in section "3.2 Agents Customization".

- **Data Engineer**: The primary goal of this agent is to prepare the necessary data, that other agents will use for their analyses. This agent uses a dedicated tool that requires the name of the company, the timeframe and the interval for which the data is to be prepared, this information is provided by the user.

- **Elliott Waves Analyst**: Main task of this agent is to perform detailed Elliott waves analysis on historical stock data. To do this, we create a special tool that finds all possible impulsive and corrective wave patterns in the data. Results of this tool are used to plot charts with overlaid waves at appropriate points.

- **Backtester**: This agent uses DRL to test and validate the predictions made by Eliott waves analyst. This process allows us to identify patterns that have worked in the past on the asset that is currently analyzed, thereby we are increasing the chances of a successful analysis. The agent uses database to retain informa-

tion across past tests and can delegate tasks to other agents if necessary.

- **Technical Analysis Expert**: This agent's goal is to interpret the waves patterns with results of backtesting and choose the most likely pattern to occur in the current market state.
- **Investment Advisor**: Is responsible for synthesizing various analyses into comprehensive investment strategy. This agent uses data retrieved from RAG tool and leverages the output provided by other agents. The result of his actions is an accurate investment plan, including price levels, dates, buy or sell signal and backup plans when the future stock price does not follow the predicted trends.
- **Reports Writer**: Summarises the activities of all agents, creating a clear, easy-to-understand report for the end user. The final output is a comprehensive report that provides clear investment strategies, including when and where to buy or sell stocks, ensuring that the recommendations are up-to-date and relevant for today's market conditions.

3.2 Agents Customization

As presented on Fig. 4 agent is build using different components, most important technologies used by our agents are described below:

Retrieval-Augmented Generation (RAG) Enhances generative AI models by integrating external knowledge retrieval (Lewis et al., 2021; Asai et al., 2023). This approach converts queries into embeddings, matches them with a vectorized knowledge base, and combines retrieved data with generated responses, improving factual accuracy and reducing "hallucinations". Our system employs knowledge graph-based RAGs, which structure data into interconnected graphs (Larson and Truitt, 2024). This method improves the accuracy and relevance of generated content, allowing the model to more efficiently handle data containing a complete description of patterns and the mathematical theory behind the EWP.

Deep Reinforcement Learning (DRL) Combines the strengths of both deep learning and reinforcement learning (RL). It has garnered attention for its ability to solve complex problems involving sequential decision-making in high-dimensional spaces . In the traditional RL framework, an agent learns to interact with an environment through a cycle of observing the current state, selecting an action, and receiving feedback in the form of rewards (Lapan, 2020). The agent's goal is to learn a policy, which is a strategy for selecting actions that maximizes the cumulative rewards over time. DRL enhances this process by leveraging deep neural networks, a type of machine learning model with multiple layers, to handle and approximate complex functions (Kabbani and Duman, 2022; Szydlowski and Chudziak, 2024a). Additionally, DRL can address problems with continuous action spaces, where the agent needs to select an action from an infinite set of possibilities, such as adjusting the parameters of a financial trading strategy.

DRL has been used in the backtesting process to analyze historical market data and learn effective trading strategies (Lussange et al., 2020). By identifying patterns and understanding their impact on future price movements, a DRL agent can make informed decisions to buy, sell, or hold assets, optimizing long-term returns. The ability of DRL to continuously learn and adapt proves particularly valuable in dynamic and uncertain environments, such as financial markets.

Dynamic context Refers to the ability of AI agents to adaptively adjust their contextual understanding based on real-time information (Wittkampf, 2024). Agents can utilize various types of context, including tools, documents accessed through RAG, the history of conversations, and the ability to reflect and plan future actions. This approach leverages ongoing interactions and updates the context dynamically, enabling the agent to maintain relevance and accuracy throughout a session. By incorporating new data as it becomes available, dynamic context helps agents refine their responses and improve decision-making processes.

Memory plays a vital role in enhancing the agent's ability to understand and generate responses based on past interactions, improving decision-making and context-awareness over time. Memory in AI agents, is crucial for handling sequential data and retaining information over long periods (Weng, 2024). They achieve this through gated mechanisms that regulate the flow of information, making them highly effective for tasks requiring long-term dependencies, such as time series prediction and natural language processing.

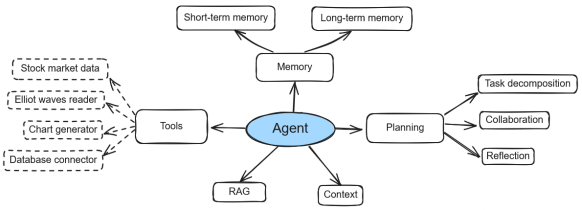

Figure 4: Overview of a LLM autonomous agent, based on (Weng, 2024).

3.3 Agents Flow Engineering

Creating effective crews in multi-agent systems involves a combination of strategic orchestration, collaboration, and dynamic task decomposition (Guo et al., 2024). Multiple agents working together to achieve common goal can be managed through orchestration, where a central coordinator assigns tasks and ensures synchronized efforts. This approach enhances control and reliability by allowing the orchestrator to monitor progress, handle exceptions, and optimize resource allocation. In contrast, sequential process allows agents to interact autonomously based on predefined protocols, promoting flexibility and better decision-making.

Agents share information and work collaboratively, either through disordered cooperation (hierarchical process), where agents communicate freely and process inputs in a network-like structure, or through ordered cooperation (sequential process), where agents follow a structured sequence to build on each other's outputs (Li et al., 2024). Our agents operates in a hierarchical mode, allowing for asynchronous execution of tasks. This significantly accelerates the entire prediction process. In this model, higher-level agents decompose complex tasks and delegate subtasks to lower-level agents. Information flows both up and down the hierarchy, with lower-level agents reporting results to their superiors, and higher-level agents providing context and coordination information to their subordinates.

Dynamic scaling is crucial for the adaptability and efficiency of multi-agent systems. By adjusting the number of active agents based on task complexity and available resources, systems can manage workloads more effectively (Guo et al., 2024). Dynamic scaling allows for the autonomous increase or decrease of agents, ensuring optimal resource utilization and maintaining system performance under varying conditions.

Another part of effective multi-agent system is task decomposition, which enables the breakdown of complex tasks into smaller, manageable subtasks. In hierarchical task decomposition organizes tasks into a structured hierarchy, where each level of the hierarchy can be further decomposed until tasks reach a granularity suitable for individual agents (Chen, 2024). This clarity ensures that agents can focus on their specialized tasks while the orchestrator manages overall coordination.

4 Experiments and Results

4.1 Data and Use Cases

The presented system utilizes data from NYSE with a various intervals, allowing for the analysis of the majority of companies listed on this exchange. ElliottAgents provides the flexibility to define the time frame over which the analysis is to be performed, allowing users to conduct both short-term and long-term forecasts.

There are more patterns discovered and described in the Elliott Wave Theory and in our study we have focused on describing only a few selected ones, based on EWP we can distinguish the following use cases:

- **Identifying Impulse Waves**: Impulse waves determine the direction of the main market trend. The hypothesis is that recognizing these impulsive patterns can help predict future price movements. Impulse waves are five-wave patterns that move in the direction of the overall trend, consisting of three actionary waves (1, 3, and 5) and two corrective waves (2 and 4) (Frost et al., 2001).
- **Identifying ABC Corrections**: In EWP, ABC corrections follows the impulsive move. The hypothesis is that understanding these corrections can provide insights into potential market reversals or continuations. An ABC correction is a three-wave pattern that moves counter to the preceding impulse wave. This pattern helps traders understand when a correction is likely to end and the previous trend will resume.
- **Recognize wave extensions**: The objective of this use case is to recognize and analyze wave extensions within Elliott Wave patterns to improve prediction accuracy. Wave extensions, typically seen in the third wave of an impulsive sequence, exceed the standard 1.618 Fibonacci ratio, often reaching up to 2.618 or beyond, indicating a robust trend.

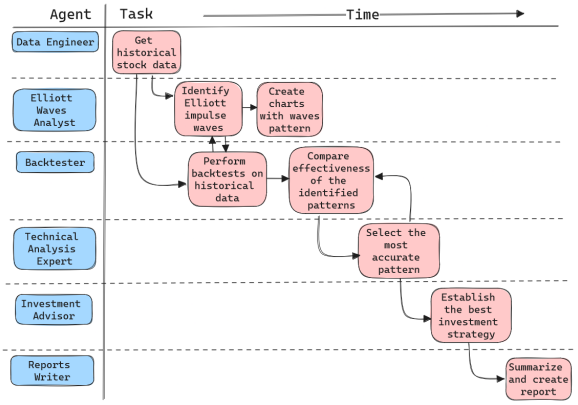

Figure 5: Flow diagram of agents identifying impulse wave use case.

- **Determining support, resistance and target levels**: Support and resistance levels are critical price points where a stock is likely to reverse or pause. Support levels are price points where a downtrend is expected to halt due to a concentration of demand, while resistance levels are where an uptrend is likely to pause due to a concentration of supply. These levels are established by the ending points of previous Elliott waves.

Fig. 5 illustrates a use case diagram showing the workflow of agents in the identification of Elliott impulsive waves. Each agent is assigned specific tasks that are prerequisites for the subsequent agent's activities, ensuring a seamless and systematic process.

4.2 Evaluation of Use Cases

In the first part of experiment, the system tests were conducted using historical data in hourly and daily intervals. The system was run on limited historical data from the largest American companies, with data ranging from one month to two years, to recognize all waves pattern and identify possible buy or sell signals on the charts using knowledge from backtesting process. When the system issued such a signal, we iteratively added additional historical data, allowing the system to detect other patterns and issue another signals. This approach enabled us to evaluate its effectiveness in simulated, but realistic market conditions. Based on these signals, we could simulate transactions and calculate theoretical investment returns, proving the effectiveness of our agent's collaboration.

Fig. 6 presents analysis of Amazon's stock over an approximately two-month period, using hourly

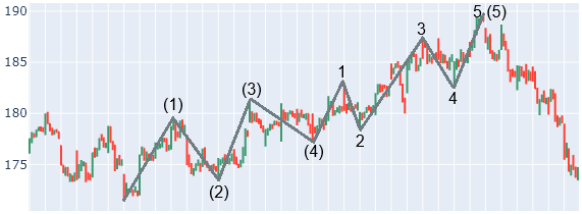

Figure 6: Ending diagonal pattern recognized on AMZN 1h chart.

intervals. ElliottAgents successfully identified an "ending diagonal" pattern. This pattern, according to EWP, signifies the termination of a larger trend and often precedes a significant reversal in the market direction (Frost et al., 2001). After confirmation of the trend reversal, ElliottAgents issued a sell recommendation at $185 per share. The target price was set at $177 per share, which corresponds to the peak of the second wave extension within the impulsive wave sequence. As illustrated in the accompanying chart, the market behavior adhered closely to our predicted scenario. The theoretical profit from this transaction is $8 per share, representing a 4.4% gain, achieved within a short span of just five days.

Fig. 7 presents a results of analysis conducted on Alphabet's stock over a one year period, with data aggregated on a daily interval. ElliottAgents successfully identified multiple patterns during this period. Specifically, the analysis revealed an impulsive wave sequence denoted as (1)-(2)-(3)-(4)-(5), wherein the fifth wave is an extension and a corrective wave pattern, labeled A-B-C immediately after impulsive wave. This corrective pattern terminated at the peak of the second wave of the extension, aligning perfectly with the theoretical expectations posited by EWP (Frost et al., 2001). According to the theory, the presence of this pattern suggests a forthcoming reversal exceeding the peak of the fifth wave. Upon recognizing this configuration and confirming started reversal, ElliottAgents generated a buy recommendation at a price point of $140 per share. The target price was strategically set at $160 per share, aligning with the peak of the fifth wave, while also accounting for the resistance level observed at the peak of wave B ($150). This dual target strategy ensures both an optimal exit point and a buffer for potential resistance encounters. As the experimental data, in the chart shows, price levels have been achieved. The theoretical profit realized from this transaction amounted to $20 per share, translating to a 13.3% gain.

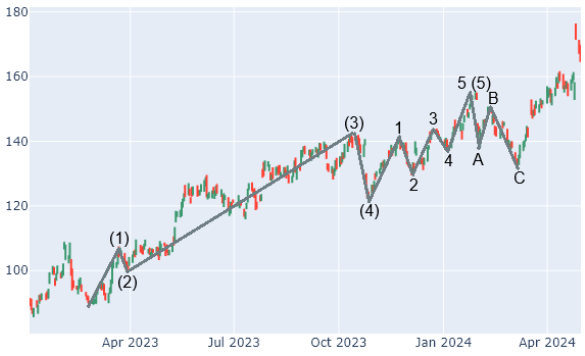

Figure 7: Fifth wave extension found on GOOG 1d chart.

In the Fig. 8 we present a long-term analysis of Nvidia's stock price, on daily intervals. System detected a complete Elliott wave cycle, consisting of an impulsive wave followed by a corrective wave. The identification of this pattern suggests the potential end of the corrective phase and the continuation of the broader trend (Murphy, 1999), which is bullish in this case. The peak of wave C was precisely identified at $39 per share. Anticipating a reversal in the trend, the system issued a buy recommendation at $42 per share. The target price was set at $50 per share, located at the peak of the fifth wave. This target signifies the emergence of the first wave in a new impulsive sequence, according to EWP. The chart clearly demonstrates that a sharp rebound occurred shortly after the recommendation was made, resulting in the target price being reached. This scenario yielded a theoretical profit of $8 per share, representing a 17.4% gain.

The second part of the experiment focus on quantity tests for the correctness of the detected pattern and the impact of DRL on results. Test was conducted using a cross-validation method on 1000 samples (candlesticks) with a daily interval for the

Figure 8: Full wave cycle recognized on NVDA 1d chart.

stocks, which were analyzed in the previous section. In these tests, we focused on examining unfinished impulsive waves (1-2-3-4) consisting of 4 sub-waves as well as complete impulsive waves (1-2-3-4-5), in each case waves could not overlap. In both cases, we compared the results with and without a DRL backtesting process conducted on 10 years of historical data for each company.

Based on the identified patterns, agents predicted whether the next movement would be upward or downward. A prediction was considered correct if the average price of the subsequent n candlesticks was higher or lower, depending on the issued signal. The n number of candlesticks was determined according to EWP, where in the case of waves 1-2-3-4, the length of the fifth wave should be approximately 1.62 times the length of the first wave, and in the case of a complete impulse wave, the following wave A should have a length close to wave 5.

Table 1 presents the results of the cross-validation experiments for 1000 data samples in two time intervals. As we can see, the identification of a complete impulsive wave pattern contributes to better predictions of subsequent price movements than incomplete impulse wave pattern. In case of hourly intervals our system detected smaller number of patterns, mainly because price changes on the hourly interval were smaller. The use of DRL resulted in a improvement in prediction, showing that agents are able to use the learning process on historical data in better interpretation of patterns.

4.3 Success Criteria

The success criteria for ElliottAgents focus on accurate pattern recognition and analysis to enable users to achieve real market profits. By leveraging NLP, the system can present complex financial information in a clear and understandable manner. The system must provide analysis of a company's stock based on user inputs, identifying all possible wave patterns. These patterns should be visually represented on a chart, and based on them, agents should provide actionable insights, including target price levels based on Fibonacci relationships and key support and resistance levels. Additionally, it should offer clear buy or sell recommendations based on wave analysis, price projections, and trend analysis, with specific time frames for action. Success is measured by the system's ability to deliver pattern recognition and analysis that can be used by traders in investment decisions.

Stock	1-2-3-4 Patterns			1-2-3-4-5 Patterns		
	N	Without backtesting	With backtesting	N	Without backtesting	With backtesting
Daily Interval						
AMZN	24	58.34%	66.67%	18	66.67%	77.78%
GOOG	28	53.57%	67.86%	23	65.22%	82.61%
INTC	19	57.89%	73.68%	15	60.00%	73.34%
Hourly Interval						
AMZN	10	50.00%	70.00%	8	62.50%	75.00%
GOOG	13	53.84%	61.54%	9	77.78%	77.78%
INTC	12	58.34%	66.67%	9	66.67%	88.89%

N: number of patterns found.

5 Discussion and Future Work

5.1 Comparison with Other Systems

Multi-agent architectures have been utilized in stock price prediction systems for many years (Akintola and Oyetunji, 2021; Gamil et al., 2007; Luo et al., 2002). However, advancements in AI over recent years have significantly enhanced these systems capabilities. Traditional systems often relied on static rules and fuzzy logic to make decisions, but they faced limitations in accuracy and adaptability. The introduction of fuzzy logic, as seen in older systems, provided a foundation for integrating qualitative judgments with quantitative analysis, yet it required further optimization to improve decision-making. It is difficult to compare the profitability of our system with other price prediction systems available to date. However, based on our experiments, we see that the system can effectively detect and interpret wave patterns, with better accuracy than similar systems using EWP (Tirea et al., 2012). The analyses created by our agents, clearly present an investment plan, with price levels, that can be used in real world by the traders.

5.2 Future Enhancements

Currently, our work has focused primarily on a few patterns recognized by EWP. Expanding our analysis to include additional wave formations such as truncations, zigzags, flat corrections, triangles, and other patterns could significantly enhance our predictive capabilities. Following the successful integration of EWP, we could further improve our system by incorporating other technical analysis methods, such as moving averages. This expansion could enhance our ability to determine more accurate buy or sell signals, potentially improving signal reliability and profitability.

6 Conclusion

ElliottAgents demonstrates the potential of integrating NLP and multi-agent systems in the domain of stock market analysis (Tunstall et al., 2022). By leveraging LLMs and the EWP, the system transforms complex historical market data into comprehensible predictions and explanations. The key innovation lies in the inter-agent dialogue, which mimics collaborative human analysis while harnessing AI's pattern recognition capabilities. This approach not only enhances the accuracy of technical analysis but also addresses the challenge of making financial data interpretable to human users.

Experimental results, conducted on historical data over a period of several years on some of the largest U.S. companies, validate the system's effectiveness in recognizing market patterns and generating natural language descriptions of trends across various time frames. The multi-agent architecture, facilitated by advanced NLP techniques, enables the decomposition of complex analytical tasks, leading to more nuanced and reliable predictions. This research contributes to the broader field of NLP applications in data-intensive domains, showcasing how AI-driven dialogue systems can enhance collaborative analysis. ElliottAgents bridges the gap between sophisticated AI analysis and human understanding, paving the way for more interpretable and adaptive prediction systems in finance and potentially other specialized fields.

Abstract

This paper investigates the potential of state-of-the-art Large Language Models— Mistral, Starling-LM, Gemma-1.1, Llama-2 and its variant Llama-3 —in the context of chart summarization. We evaluate their performance on established datasets supplemented by our datasets from Our World in Data designed to address potential gaps. Methodologically, we delve into the architecture of each baseline model and any task-specific modifications. The experimental setup covers training processes, hyperparameter tuning, and specific configurations used for evaluation. Results highlight the models' performances across our datasets, offering insights into their strengths and weaknesses. The discussion interprets findings, exploring implications for real-world applications. This study concludes by emphasizing the pivotal role of these models in advancing chart summarization, providing valuable insights for practitioners, and suggesting promising directions for future research.

1 Introduction

Chart Summarization stands at the intersection of natural language processing and visual data comprehension, playing a critical role in extracting meaningful insights from visual representations like charts and graphs (Hoque et al., 2022). In an era where data-driven decision-making is paramount (Kim et al., 2020), understanding and querying information presented in visual formats have become integral across various domains (Hoque et al., 2017).

While advancements in Natural Language Processing (NLP) have led to the development of powerful models (Masry et al., 2022; Ishwari et al., 2019; Namazifar et al., 2021; Demszky et al., 2018), applying these techniques to the unique challenges posed by chart summarization remains an ongoing research frontier. Previous studies have addressed a variety of tasks, yet challenges persist in adapting state-of-the-art NLP models to effectively summarize based on visual data.

Central to the progress of chart summarization are the datasets employed for model training and evaluation. Datasets not only provide the foundation for model development but also serve as a benchmark for gauging the performance of different approaches. Understanding the intricacies of these datasets is crucial for uncovering the potential of state-of-the-art models in handling the nuances of chart-based queries.

Previous research has made notable strides in chart summarization, yet significant gaps persist. The focus of many studies has been on enhancing optical character recognition (OCR), neglecting the broader challenges posed by diverse datasets and varied chart types. This paper addresses these gaps by emphasizing the importance of comprehensive datasets and shedding light on the challenges faced by previous studies. By doing so, we aim to contribute valuable insights that go beyond OCR enhancements.

In our exploration, we leverage state-of-the-art baseline models, including Mistral-7B (Jiang et al., 2023), Starling-LM-7B (Zhu et al., 2023), Gemma-1.1-7B (Team et al., 2024), Llama-2-7B (Touvron et al., 2023), and Llama-3-8B (AI@Meta, 2024). Each of these models was selected for their unique strengths and capabilities. Mistral-7B is recognized for its superior performance and efficiency, leveraging grouped-query attention (GQA) and sliding window attention (SWA) for faster inference and handling sequences effectively, making it a highly efficient model (Jiang et al., 2023). Starling-LM-7B excels with an 8.09 MT Bench score, backed by the robust Nectar dataset and RLAIF techniques, enhancing its helpfulness and safety (Zhu et al., 2023). Gemma-1.1-7B stands out for its compact size and remarkable performance, utilizing grouped-query attention and sliding window attention to outperform larger models

in reasoning, math, and code generation (Team et al., 2024). Llama-2-7B, with its large parameter count and training on a diverse corpus, excels in language understanding, generation, and reasoning benchmarks (Touvron et al., 2023). Llama-3-8B showcases advancements in performance, safety, and helpfulness, with extensive training on over 15 trillion tokens, outperforming previous Llama models and ensuring enhanced helpfulness and reduced false refusals (AI@Meta, 2024). By understanding how these models navigate the challenges posed by diverse datasets, we hope to provide a nuanced perspective on their potential in overcoming the hurdles presented by various chart types and data representations. The code and dataset used in this study are available at https://github.com/chuducandev/ChartQA.

2 Related Works

The landscape of Chart Summarization has evolved significantly in recent years, reflecting the broader advancements in NLP and visual data comprehension. Early studies in chart summarization focused on foundational challenges, including optical character recognition (OCR) (Kim et al., 2022; Kavehzadeh, 2023) and basic question interpretation (Kim et al., 2020; Masry et al., 2022). However, as the field matured, researchers recognized the need for more sophisticated approaches to handle the complexities of diverse chart types and data representations (Li and Tajbakhsh, 2023).

Early efforts in chart summarization predominantly revolved around planning-based architecture (Mittal et al., 1998; Ferres et al., 2013) and two stage approach that applied content selection using different statistical tools in the first step followed by generating summaries using pre-defined templates (Reiter, 2007; Zhu et al., 2021). Nevertheless, despite their focus on elucidating the critical insights communicated by the chart, these systems often fall short in furnishing lucid instructions for interpretation.

In previous years, both commercial platforms and academic projects have significantly advanced the field of Chart Summarization. Notable examples include Narrative Science Quill and Automated Insights Wordsmith (Caswell and Dörr, 2018), alongside research initiatives, e.g., (Cui et al., 2019) and (Srinivasan et al., 2018), which have all made strides in extracting and presenting key data insights through the computation of statistical measures such as extrema and outliers. Similarly, the work (Demir et al., 2012) stands out for its innovative approach to generating bar chart summaries. This method employs a bottom-up strategy that intricately weaves together discourse and sentence structures, effectively summarizing data trends. Moreover, a pioneering approach (Chen et al., 2019) leverages the ResNet architecture (He et al., 2016) to encode chart images. This process is complemented by an LSTM-based decoder that meticulously crafts captions, showcasing the integration of deep learning techniques to enhance data visualization interpretation.

In the realm of Chart-To-Text summarization, the field has progressively moved from template-driven methods towards more nuanced data-driven approaches, underscored by the introduction and evolution of several pivotal datasets. The sequence began with the Chart2Text dataset (Obeid and Hoque, 2020), offering an initial collection of 8,305 chart samples from Statista. This dataset, although groundbreaking, was limited by its size, posing challenges for the training of comprehensive data-driven models. Subsequently, (Spreafico and Carenini, 2020) deployed an LSTM-based encoder-decoder model on a smaller dataset of 306 chart summaries, a step that, while innovative, still did not fully leverage the visual aspects of charts. Furthermore, efforts to diversify and enrich the data landscape saw the introduction of the SciCAP dataset (Hsu et al., 2021) focused on chart image captioning, and the AutoChart dataset (Zhu et al., 2021) which utilized predetermined templates for generating chart descriptions. These advancements highlighted the constraints of fixed templates, such as reduced variability and insight in the generated summaries.

In recent advancements, our work aligns with significant contributions such as ChartSumm (Rahman et al., 2023) and Chart-To-Text (Kantharaj et al., 2022), focusing on advancing interpretability through summarization methodologies. While ChartSumm focuses on automatic chart-to-text summarization, catering primarily to visually impaired individuals and facilitating precise insights of tabular data in natural language, Chart-To-Text contributes a large-scale dataset with chart images, metadata, and corresponding human-written descriptions, addressing the task of generating textual descriptions from visual data. In contrast, our work diverges by concentrating on fine-tuning state-of-the-art models and enriching datasets to enhance

chart understanding and interpretation. Through this approach, we aim to advance interpretability, leveraging sophisticated techniques tailored to handle diverse chart types and data representations. By contextualizing our contributions within this framework, we seek to bolster the repertoire of NLP techniques for deriving insights from visual data.

3 Methodology

3.1 Dataset Construction

To conduct our research on fine-tuning large language models for chart summarization, we curated a comprehensive dataset from Our World in Data (Roser et al., 2015). This platform provides empirical evidence on global issues such as poverty, health, and education. We manually collected charts and their corresponding summaries and metadata, focusing on relevant countries and structuring the information into a comprehensive data table. Each chart was then accompanied by a concise and informative summary generated using the GPT-4 (OpenAI, 2023) language model. To ensure the quality and accuracy of the summaries, a team of human annotators reviewed each output, verifying the correctness of facts and numbers, and assessing the coherence and clarity of the summaries (Huang, 2012).

Through this comprehensive data collection and curation process, we have successfully generated a dataset consisting of 5,166 charts, each accompanied by a concise and accurate summary. This dataset, derived from the authoritative Our World in Data platform, covers a wide range of subjects and provides a solid foundation for our research on fine-tuning large language models for chart summarization. By leveraging this carefully constructed dataset, we aim to advance the state-of-the-art in automated chart analysis and contribute to the development of more effective tools for understanding and communicating complex data (Lai et al., 2020).

The distribution of chart types within the Our World in Data dataset showcases a predominance of line charts, accounting for 60.2% of the total charts. Bar charts follow as the second most common chart type, representing 20%. Additionally, the dataset includes bubble charts (0.4%), scatter plots (9.6%), and area charts (9.6%), highlighting a variety of visualization techniques employed.

The topic distribution in the Our World in Data dataset covers a broad range of global issues, with

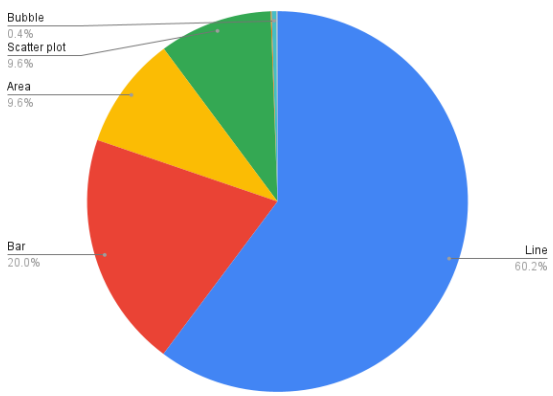

Figure 1: Chart type distribution of Our World in Data dataset

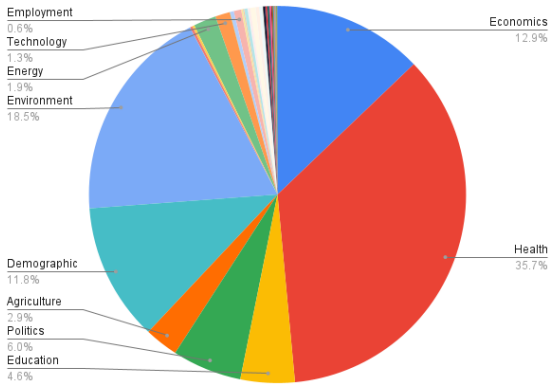

Figure 2: Topic distribution of Our World in Data dataset

health being the most prominently represented theme at 35.7%. This is followed by environment (18.5%), demographics (11.8%), economy (12.9%), politics (6.0%), education (4.6%), technology (1.3%), and energy (1.9%). This dataset serves as an invaluable resource for researchers and practitioners interested in exploring and understanding various global trends and patterns, providing insights into key areas such as health, environment, and economy.

3.2 Language Model Fine-tuning Process

In this segment, we introduce the foundational models employed to assess performance within our designated dataset, followed by an outline of the fine-tuning procedure.

3.2.1 Baseline Models

We provide an overview of the state-of-the-art language models used as baselines.

LLAMA-2 (Touvron et al., 2023) - 7B, developed

by Meta AI, excels in language understanding and reasoning with 7 billion parameters. It's open-sourced, enabling wide exploration and innovation in AI.

LLAMA-3 (AI@Meta, 2024) - 8B, advances performance and safety using SFT and RLHF techniques. It outperforms Llama-2 models, with a focus on safety and helpfulness in AI interactions.

STARLING-LM (Zhu et al., 2023) achieves high scores in MT Bench, leveraging the Nectar dataset and RLHF. It enhances the reliability and performance of fine-tuned models.

MISTRAL (Jiang et al., 2023) - 7B, developed by Anthropic, outperforms larger models like Llama-2 with its efficient architecture, excelling in reasoning, math, and code generation.

GEMMA-1.1 (Team et al., 2024) model by Google DeepMind, a compact 7B model, surpasses larger models in reasoning, math, and code generation, showcasing Google's commitment to responsible AI.

3.2.2 Fine-tuning Process

In this study, we explore the fine-tuning process for several state-of-the-art language models, including Llama-2, Llama-3, Starling-LM, Mistral, and Gemma-1.1. The fine-tuning methodology is crucial for adapting these models to the specific task of summarization with chart data.

For all five models, we employed a consistent fine-tuning approach using 3 epochs of training. This decision aimed to ensure a fair comparison across the models and maintain a balance between performance and computational efficiency.

The fine-tuning process involved the use of specific prompts tailored to each model. These prompts, fully demonstrated in Appendix A.2, were designed to guide the models in understanding the task at hand and generating appropriate responses based on the chart content. By incorporating these prompts into the fine-tuning process, we aimed to provide the models with clear instructions and context for generating accurate and relevant summaries based on the chart content.

Through the fine-tuning process, we sought to leverage the pre-trained knowledge of these language models while adapting them to the specific task of summarization with chart data. By carefully tuning the models on our curated dataset and utilizing tailored prompts, we aimed to enhance their ability to understand and generate accurate responses based on the visual information presented in charts.

The fine-tuning methodology employed in this study serves as a critical component in optimizing model performance for the task at hand. By dedicating computational resources and implementing a consistent training approach across all models, we strive to unlock the full potential of these state-of-the-art language models in the context of chart summarization.

4 Evaluation

In this section, we present a comprehensive evaluation of the fine-tuned models' performance on the chart summarization task. Our evaluation methodology encompasses two key components: automated benchmarks and human evaluation. The automated benchmarks provide quantitative measures of the models' performance, while the human evaluation offers qualitative insights into the generated summaries' quality and coherence. By combining these two approaches, we aim to deliver a holistic assessment of the models' capabilities and limitations in the context of chart summarization.

4.1 Evaluation Metrics

In assessing the quality of our automated summarization, we employ a comprehensive set of evaluation metrics to capture various aspects of the generated summaries. Our evaluation framework encompasses the following key metrics:

BLEU Score (Bilingual Evaluation Understudy) evaluates the overlap of n-grams between the model-generated summaries and the reference texts (Post, 2018). We compute BLEU-1, BLEU-2, BLEU-3, and BLEU-4 scores to capture different levels of n-gram overlap, providing insights into the linguistic fidelity and structural alignment of the generated summaries with the references.

BLEURT Score (Bilingual Evaluation Understudy with Representations from Transformers) is a model-based metric designed to assess the fluency and semantic fidelity of generated text (Sellam et al., 2020). Leveraging BLEURT-base-128, we evaluate the grammatical correctness and semantic alignment of the machine-generated summaries with respect to the reference documents.

PPL (Perplexity) serves as a metric to quantify the predictive performance of language models (Rad-

ford et al., 2019). Lower perplexity scores means more coherence and contextual relevance of the generated summaries.

4.2 Automated Benchmarks

Our study evaluates the performance of several state-of-the-art language models on the task of summarization with chart data. Table 1 summarizes the experimental results obtained from these models across various evaluation metrics. Notably, the Gemma-1.1 model leads in BLEU-1 with a score of 54.15, while the Starling-LM model performs slightly lower with a BLEU-1 score of 54.12 but surpasses in BLEU-2, achieving the highest score of 37.98. The Llama-3 model stands out with the highest BLEURT score of 0.1832, indicating superior semantic similarity, and also has the lowest perplexity (PPL) at 7.7889, suggesting it generates the most fluent and coherent summaries among the evaluated models.

Overall, the experimental results highlight the competitive performance of the Gemma-1.1 model in terms of BLEU-1, indicating its ability to generate summaries with high unigram precision. The Starling-LM model achieves the highest BLEU-2 score, demonstrating its strength in generating summaries with high bigram precision. Both models exhibit identical performance for BLEU-3 and BLEU-4. The Llama-3 model stands out with the highest BLEURT score and the lowest PPL value, suggesting its superiority in generating semantically similar and fluent summaries.

These results provide valuable insights into the strengths and weaknesses of each model in the task of summarization with chart data. The Gemma-1.1 and Starling-LM models demonstrate strong performance in terms of n-gram precision, while the Llama-3 model excels in semantic similarity and fluency. Further analysis and experimentation may be necessary to investigate the factors contributing to these differences in performance and to validate the findings across different datasets and chart types.

4.3 Human Evaluation

To complement the automated benchmarks, we conducted a human evaluation to assess the quality of summaries generated by different models. This evaluation involved a total of 750 pair-wise comparisons across 50 samples randomly selected from the test dataset. Four human annotators evaluated the summaries based on three criteria: **factual correctness**, **coherence**, and **fluency** (Kantharaj et al., 2022).

After collecting the results, we used the Elo rating system to comprehensively evaluate the models' performance. The Elo rating system calculates the expected score E_A for a model with rating R_A when matched against an opponent with rating R_B using the formula:

$$E_A = \frac{1}{1 + 10^{(R_B - R_A)/400}}. \quad (1)$$

The model's new rating R'_A is then updated based on the match outcome using the following formula:

$$R'_A = R_A + K \cdot (S_A - E_A), \quad (2)$$

where K is the K-factor (a constant determining the sensitivity of the rating system), S_A is the actual score from the comparison (1 for a win, 0.5 for a draw, and 0 for a loss), and E_A is the expected score as calculated earlier (Elo, 1978). In our study, we adapted the Elo rating system with a K-factor of 4 and an initial rating of 1000, providing a clear comparative analysis across the three criteria. The results are summarized in Table 2.

Among the models, Llama-3 consistently achieved the highest Elo ratings across all factors, making it the strongest performer in our evaluation. Its particularly high ratings in coherence and fluency indicate its ability to generate summaries that are both logically consistent and readable, closely approaching the quality of reference summaries.

On the other end of the spectrum, Starling-LM and Llama-2 demonstrated the weakest performance, with the lowest ratings in coherence and factual correctness, respectively. Starling-LM's struggles across multiple dimensions suggest a need for further optimization, while Llama-2's low factual accuracy points to potential challenges in interpreting the data correctly.

These Elo ratings highlight the varying strengths and weaknesses of each model, emphasizing the competitive performance of advanced models like Llama-3, while also indicating areas where other models require further improvement. Detailed pairwise comparison results are included in Appendix A.1 for additional context.

4.4 Factual Correctness Analysis

In addition to the overall human evaluation, we conducted a specific analysis focused on Factual

Models	BLEU-1 (↑)	BLEU-2 (↑)	BLEU-3 (↑)	BLEU-4 (↑)	BLEURT (↑)	PPL (↓)
LLAMA-2	53.22	36.79	27.03	20.00	0.1355	7.9861
MISTRAL	53.5	37.42	27.78	20.78	0.1252	8.0027
Starling-LM	54.12	**37.98**	**28.29**	**21.23**	0.1380	8.0097
GEMMA-1.1	**54.15**	37.95	**28.29**	**21.23**	0.1434	7.9000
LLAMA-3	53.61	37.64	28.12	21.15	**0.1832**	**7.7889**

Table 1: Model performance comparison based on BLEU, BLEURT, and PPL

Models	Correctness	Coherence	Fluency
Gold Text	1163	1048	1035
LLAMA-3	1034	1021	1026
GEMMA-1.1	934	1015	982
MISTRAL	983	970	1006
Starling-LM	981	965	964
LLAMA-2	906	982	987

Table 2: Elo ratings for models based on human evaluation

Correctness to assess how accurately each model represents the information in the charts. This analysis was based on the factual correctness factor from the human evaluation results, where we assumed the gold texts were entirely accurate in terms of factual information, as they were carefully annotated during the data construction phase. For GPT-4, the result was derived by counting the number of items in the dataset that were validated as fully factually correct during the dataset construction step.

Models	Correctness (%)
GPT-4	86.2
LLAMA-3	63.5
GEMMA-1.1	57.5
MISTRAL	45.5
STARLING-LM	47.5
LLAMA-2	43.0

Table 3: Percentage of entirely factually correct summaries generated by each model.

The results, as shown in the table above, indicate a notable gap between the performance of the fine-tuned models. Among these, Llama-3 achieved the highest correctness rate at 63.5%, outperforming the other open models such as Gemma-1.1 at 57.5%, and Mistral and Starling-LM at 45.5% and 47.5%, respectively. Llama-2 had the lowest percentage of factually correct summaries at 43.0%.

While there is a clear gap between these models, further work is needed to explore potential improvements and optimizations. The relatively strong performance of Llama-3 highlights its potential as a leading model in this category, although there is still room for enhancing factual correctness across all open models.

Future work could focus on closing the gap between these models, refining their ability to generate factually accurate summaries, and bringing them closer to the performance exhibited by proprietary models.

4.5 Alignment Between Automated Benchmarks and Human Evaluation

This subsection examines the alignment between the automated benchmarks and human evaluation results, providing a clearer picture of each model's strengths and weaknesses in chart summarization.

The Llama-3 model shows strong consistency across both evaluation methods. It achieved the highest BLEURT score and lowest perplexity, indicating superior semantic fidelity and fluency, which aligns with its top Elo ratings in Coherence and Fluency during human evaluation. This suggests that Llama-3 consistently generates high-quality, coherent, and fluent summaries, as recognized by both automated metrics and human judgment.

Similarly, the Gemma-1.1 model performed well in both evaluations, with strong BLEU and BLEURT scores and a respectable perplexity score. Its high Elo rating in Coherence reinforces the idea that it produces accurate and coherent summaries, making it a reliable choice for text generation tasks.

However, the Starling-LM model reveals a discrepancy between its strong BLEU scores and lower Elo ratings in human evaluation, particularly in Coherence and Fluency. This suggests that, while Starling-LM excels in n-gram overlap with reference texts (as indicated by BLEU), it may lack the deeper coherence and fluency that human evaluators value. This highlights the limitations of relying solely on automated metrics like BLEU, which may not fully capture the quality of the generated text.

Overall, these findings emphasize the importance of combining automated benchmarks with human evaluation to obtain a comprehensive assessment of model performance, as each method captures different aspects of text quality.

4.6 Error Analysis and Challenges

Upon examining 100 generated summaries for the two cases presented in Table 4, several errors and challenges become apparent. These issues high-

Case (a)	Case (b)
Gold: The area chart illustrates the trend in the number of granted patents related to artificial intelligence by industry worldwide from 2010 to 2020. There has been a significant increase in patent grants across all industries over this period. The 'Personal devices and computing' field saw the highest growth, with patents rising from 727 in 2010 to 13,813 in 2020. Notably, every recorded field experienced growth, but the 'Life sciences' and 'Telecommunications' sectors also displayed prominent increases, with patents climbing to 2,290 and 4,848, respectively, in 2020. Businesses, transportation, and energy management sectors also had considerable numbers of patent grants, with 3,218, 1,679, and 1,318 patents granted in 2020. Among the least growth was seen in the 'Banking and finance' sector, with 751 patents in 2020, which still reflects substantial growth from the 31 patents in 2010. Overall, the chart shows an accelerating interest and investment in AI across various industries, with the sharpest overall increase occurring between 2016 and 2018. (Figure 3)	**Gold:** (...) For Belarus, there is a significant increase in the number of stored accessions over the years, starting from 1,144 in 1995 to a remarkable 27,494 in 2021. (...) (Figure 4)
Gemma-1.1: (...) The 'Business' sector also experienced significant growth, with numbers increasing from 95 in 2010 to 3,218 in 2020. (...) **Llama-3**: (...) Notably, the 'Physical sciences and engineering' industry had the lowest number of patents in 2020 with 965, down from 965 in 2018. (...) **Mistral**: (...) The field of 'Telecommunications' consistently received the highest number of patent grants, with a significant increase from 727 in 2010 to 13,813 in 2020. (...) The 'Energy management' and 'Physical sciences and engineering' fields saw a rise until 2018, followed by a slight decline in 2020. (...) The 'Personal devices and computing' field, which had the fewest grants, saw a gradual increase over the years. The data indicates a growing interest and investment in AI technologies across various industries, with a particularly sharp increase in the last two years. **Starling-LM**: (...) The 'Transportation' field, while smaller in comparison, grew from 189 patents in 2010 to 1,679 in 2020. The 'Life sciences' field saw an increase from 470 patents in 2010 to 2,290 in 2020. The 'Banking and finance' category, although the smallest in terms of number of patents, grew from 57 in 2010 to 751 in 2020. The 'Industry and manufacturing' field had 1,255 patents granted in 2020, up from 109 in 2010. The 'Energy management' field had 1,318 patents in 2020, an increase from 492 in 2010. The 'Physical sciences and engineering' field grew from 364 patents in 2010 to 965 in 2020. The 'Security' field saw an increase from 107 patents in 2010 to 1,527 in 2020. (...) **Comment:** Model struggles to produce a useful summary and accurately extract relevant statistics from the chart.	**Llama-2**: (...) For Belarus, there has been a significant increase from 1,144 accessions in 1995 to a peak of 35,210 in 2010, followed by a slight decline to 27,494 by 2021. (...) **Comment:** Model hallucinated about the number of unique plant genetic samples stored in Belarus reaching its peak of 35,210 in 2010.

Table 4: Sample error analyses of outputs from all five training models. **Red** indicates hallucination errors, **Blue** indicates tokens that are resulted in factual errors in the model output and **Violet** indicates misleading semantics

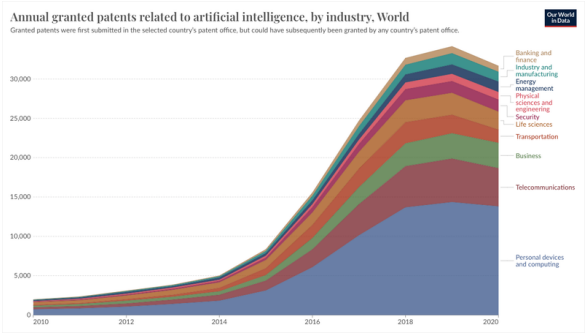

Figure 3: Case (a) - Artificial Intelligence Granted Patents By Industry

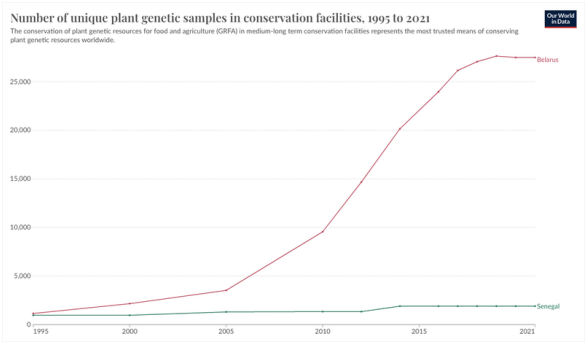

Figure 4: Case (b) - Number Of Accessions Of Plant Genetic Resources Secured In Conservation Facilities

light the difficulties faced by the language models in accurately understanding and summarizing the information conveyed in the charts.

In Case (a), the Gemma-1.1 model struggles to produce a useful summary and extract relevant statistics from the chart accurately. For instance, the model incorrectly states that the number of patent applications granted in the 'Business' sector increased from 95 in 2010 to 3,218 in 2020, whereas the correct values are 219 in 2010 and 3,218 in 2020. Similarly, the Llama-3 model makes an error in interpreting the data for the 'Physical sciences and engineering' industry, stating that the number of patents was down from 965 in 2018 to 965 in 2020, which is incorrect. The Mistral model also demonstrates several misinterpretations of the chart data, such as incorrectly claiming that the 'Telecommunications' field consistently received the highest number of patent grants and that the 'Personal devices and computing' field had the fewest grants.

In Case (b), the Llama-2 model hallucinates about the number of unique plant genetic samples stored in Belarus, stating that it reached a peak of 35,210 in 2010. However, this information is not supported by the chart data.

These errors and challenges in chart summarization can be attributed to several factors. Current models struggle with perceptual prowess, often missing subtle patterns and misinterpreting complex visual elements, as evidenced by the misinterpretation of trends and numbers in Case (a). Hallucinatory outputs occur when models generate false information not present in the input, leading to irrelevant or unsupported summaries, such as the hallucination in the Llama-2 model for Case (b). Data inconsistencies and training limitations result in models performing well on familiar data but faltering with less familiar formats, due to the broad variability in chart representations. Additionally, models excel at token-level predictions but struggle with maintaining semantically accurate summaries, leading to misleading information, such as Mistral's claims about the 'Telecommunications' field.

To address these challenges in chart summariza-

tion, several specific steps can be taken. First, curating larger and more diverse datasets covering various chart types and styles can help models generalize better. Second, developing more sophisticated model architectures that handle the nuances of visual data interpretation can reduce errors, possibly by integrating advanced vision-language models. Third, implementing grounding techniques to ensure outputs are closely tied to the input data can mitigate hallucinations by reinforcing the model's reliance on provided data. Continuously analyzing model outputs and feeding this information back into the training process can iteratively improve performance by identifying and refining common error patterns. Additionally, combining automated summarization with human oversight can enhance accuracy, as human reviewers can correct model outputs and provide additional training data (Kantharaj et al., 2022; Rahman et al., 2023; Moured et al., 2024).

By implementing these strategies, we can significantly improve the accuracy and reliability of language models in chart summarization.

5 Conclusion

In our study, we explored the effectiveness of state-of-the-art language models, including Llama-2, Llama-3, Starling-LM, Mistral, and Gemma-1.1, in summarizing chart data. Through a comprehensive fine-tuning process and tailored prompts, we evaluated their performance and identified the competitive results of the Llama-3 model, which achieved high BLEU scores, the highest BLEURT score, and the lowest perplexity value.

However, our analysis also revealed persistent challenges, such as perceptual limitations, hallucinatory outputs, and the need for improved data extraction methods. These challenges underscore the importance of continued research and development efforts to refine model architectures, diversify datasets, and explore novel approaches that integrate advances in natural language processing and computer vision.

The successful integration of summarization models with chart data holds immense potential for applications in data analysis, accessibility enhancement, and beyond. By addressing the identified challenges and building upon the strengths of the evaluated models, we can pave the way for more effective and efficient interactions between humans and machines in the realm of visual data comprehension.

Our study serves as a foundation for future research in this domain, providing valuable insights into the capabilities and limitations of state-of-the-art language models in summarization with chart data. We encourage further exploration and experimentation to push the boundaries of this field, ultimately contributing to the broader landscape of artificial intelligence and data science. By leveraging the strengths of these models and addressing the identified limitations, we can unlock new possibilities for data-driven decision-making and enhance the accessibility of visual information for a wider audience.

A Appendices

A.1 Pairwise Comparison Results

Table 5 presents the results of our human evaluation, which compares the quality of summaries generated by different models. The results are based on factual correctness, coherence, and fluency, highlighting which model performed better in each comparison. These comparisons provide insights into the strengths and weaknesses of the models in summarizing chart data.

A.2 Fine-Tuning Prompts

In this section, we provide the specific prompts used for fine-tuning the different language models in our study. These prompts were designed to guide each model in understanding the task of chart summarization and producing accurate summaries.

Llama-2, Mistral, and Starling-LM Prompts: The following prompt structure was used consistently across these three models.

```
<s>[INST] From the below input full content of a chart,
write a summary that reflects the meaning and trend of the
chart.
Chart content:
{sample['input']}[/INST]{sample['output']}</s>
```

Gemma-1.1 Prompt: For the Gemma-1.1 model, the prompt included user and model tags to structure the input and output more explicitly.

```
<bos><start_of_turn>user
From the below input full content of a chart, write a
summary that reflects the meaning and trend of the chart.
Chart content:
{sample['input']}<end_of_turn>
<start_of_turn>model
{sample['output']}<end_of_turn>
```

Llama-3 Prompt: The Llama-3 model used a prompt with specific header IDs and end-of-turn markers.

```
<|begin_of_text|><|start_header_id|>system<|end_header_id|>
From the below input full content of a chart, write a
summary that reflects the meaning and trend of the chart:
<|eot_id|> <|start_header_id|> user <|end_header_id|>
Chart content:
{sample['input']}<|eot_id|><|start_header_id|>assistant
<|end_header_id|>
{sample['output']} <|eot_id|> <|end_of_text|>
```

These prompts were tailored to each model's architecture to maximize their performance in chart summarization tasks.

Abstract

Large Language Models (LLMs) have made significant progress in incorporating Indic languages within multilingual models. However, it is crucial to quantitatively assess whether these languages perform comparably to globally dominant ones, such as English. Currently, there is a lack of benchmark datasets specifically designed to evaluate the regional knowledge of LLMs in various Indic languages. In this paper, we present the L3Cube-IndicQuest, a gold-standard factual question-answering benchmark dataset designed to evaluate how well multilingual LLMs capture regional knowledge across various Indic languages. The dataset contains 200 question-answer pairs, each for English and 19 Indic languages, covering five domains specific to the Indic region. We aim for this dataset to serve as a benchmark, providing ground truth for evaluating the performance of LLMs in understanding and representing knowledge relevant to the Indian context. The IndicQuest can be used for both reference-based evaluation and LLM-as-a-judge evaluation. The dataset is shared publicly at https://github.com/l3cube-pune/indic-nlp.

1 Introduction

Language models have made tremendous progress in recent years, especially in improving performance for Indic languages (Gala et al., 2024; Team et al., 2024; Joshi, 2022). However, the representation of these morphologically rich languages remains significantly lower compared to English and other major global languages in the current language models (Kakwani et al., 2020). This disparity exists due to a lack of large, well-structured, and annotated datasets in low-resource Indic languages.

As a result of this underrepresentation, several issues such as inaccurate or inconsistent political and geographic information in Indic languages are observed frequently. For example, regional distinctions can be mistranslated, causing confusion or miscommunication. Traditional knowledge is often either contextually misrepresented or entirely omitted due to the lack of pre-training data that captures the subtleties of these languages (Shafayat et al., 2024; Xu et al., 2024).

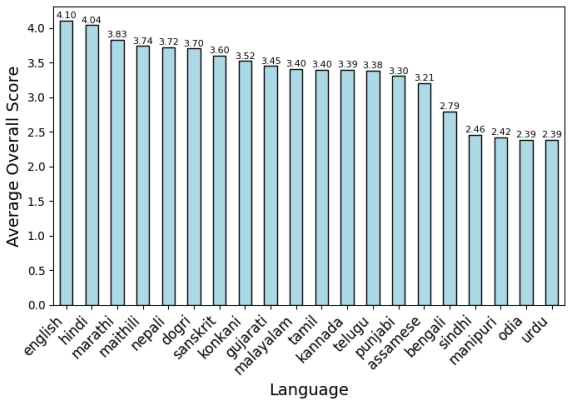

Figure 1: Language ranking based on average 'Overall' IndicQuest scores (Llama-3.1-405B-Instruct as a Judge) across languages, aggregating the scores for responses by the models. This ranking highlights the quality of multilingual LLMs for different Indic languages.

Addressing these disparities is important to creating inclusive language models that can represent low-resource Indic languages with the same level of sophistication as more widely spoken languages. Thus, it becomes important to quantitatively analyze the knowledge representation of these models for low-resource Indic languages, particularly when dealing with culturally and region-specific knowledge.

Current benchmarks for evaluating language models (Dubois et al., 2024; Zheng et al., 2023) predominantly cater to English and other widely spoken languages, leaving Indic languages inadequately assessed (Chang et al., 2023). The existing benchmarks for Indic languages primarily focus on

evaluating LLMs for various downstream tasks and capabilities (Doddapaneni et al., 2022) but are not suitable for assessing knowledge representation. Furthermore, there is a lack of question-answer datasets designed to evaluate these models on culturally and regionally relevant knowledge about India, which hinders their ability to evaluate the representation of Indic languages accurately.

This leaves a critical gap in assessing knowledge representation for Indic languages. To address this, we present a fact-based gold-standard Q&A dataset for English and 19 Indic languages. This dataset is designed to evaluate how well LLMs represent Indian knowledge and will serve as a valuable resource for improving multilingual models.

Additionally, the dataset can serve two key evaluation purposes: first, for reference-based evaluations by comparing model outputs to ground truth using metrics such as ROUGE (Lin, 2004) scores; and second, for model output assessments where a large language model (LLM) acts as the evaluator. With these approaches, the dataset facilitates a thorough evaluation of how language models handle Indic languages, offering valuable insights for future model improvements.

The key contributions of this research are as follows:

1. The development of IndicQuest, a gold-standard question-answer dataset containing 4000 questions and answers pairs, 200 each for English and the 19 Indic languages namely, Assamese, Bengali, Dogri, Gujarati, Hindi, Kannada, Konkani, Maithili, Malayalam, Marathi, Meitei (Manipuri), Nepali, Odia, Punjabi, Sanskrit, Sindhi, Tamil, Telugu, Urdu, covering five domains specific to the Indian context. This dataset is made publicly[1] available.

2. We present both reference-based evaluation and LLM-as-a-judge evaluation of various multilingual models, including GPT-4o, Llama-3.1-405B-Instruct, Llama-3.1-8B-it, Gemma-2-2B-it, and Gemma-2-9B-it, for the 19 Indic languages. Given that the judge LLM may have limitations in handling Indic facts, ground truth answers or facts are provided as references to assist the LLM in its evaluation.

3. We demonstrate that benchmark results are stronger for English compared to the Indic languages, highlighting the disparity in knowledge representation for low-resource languages.

4. We evaluate LLM responses against our dataset's ground truth to establish performance hierarchies across models, domains, and languages. Model ranking, based on combined evaluation metrics, is GPT-4o > Llama-3.1-405B-Instruct > Gemma-2-9B-it > Llama-3.1-8B-it > Gemma-2-2B-it. Based on the overall LLM evaluator scores,the domain ranking is Economics > Politics > History > Literature > Geography, while language ranking from highest to lowest is English, Hindi, Marathi, Maithili, Nepali, Dogri, Sanskrit, Konkani, Gujarati, Malayalam, Tamil, Kannada, Telugu, Punjabi, Assamese, Bengali, Sindhi, Manipuri, Odia, Urdu. (Figure 1).

2 Related Work

TyDi QA[2] is a widely used question-answering benchmark that includes 11 typologically diverse languages, such as Bengali, Hindi, and Marathi, representing a variety of linguistic features. (Clark et al., 2020) The dataset focuses on information-seeking questions that are naturally generated by native speakers, making it a robust benchmark for evaluating LLMs in low-resource languages. However, while TyDi QA includes several Indic languages, its primary emphasis is on typological diversity rather than region-specific contexts, which are crucial for more nuanced evaluations within specific linguistic regions like India.

XQuAD[3] is a more comprehensive cross-lingual benchmark comprising 240 paragraphs and 1190 question-answer pairs from SQuAD v1.1, translated into ten languages by professional translators (Artetxe et al., 2020).

MLQA[4] contains QA instances in seven languages: English, Arabic, German, Spanish, Hindi, Vietnamese, and Simplified Chinese. MLQA has over 12K instances in English and 5K in each other language, with each instance being parallel between four languages on average. (Lewis et al., 2020) While MLQA includes some Indic languages, its domain and regional specificity are

[1] https://github.com/l3cube-pune/indic-nlp

[2] https://github.com/google-research-datasets/tydiqa

[3] https://github.com/google-deepmind/xquad

[4] https://github.com/facebookresearch/MLQA

limited, making it less suited for a comprehensive evaluation of knowledge specific to the Indian subcontinent.

The primary application of both XQuAD and MLQA is the evaluation of question-answering capabilities of LLMs, as opposed to knowledge evaluation.

IndicQA[5] (Doddapaneni et al., 2022) is one of the few datasets explicitly targeting the evaluation of LLMs in Indic languages. It is used for evaluating question-answering models in 11 Indic languages. The context paragraphs are selected from Wikipedia articles on topics closely related to Indic culture and history. The dataset consists of 18,579 questions, of which 13,283 are answerable. Another recent, IndicQA benchmark (Singh et al., 2024) also focuses on evaluating closed question-answering capabilities, particularly in Indic languages. In contrast, our work addresses open-domain Q&A without a context passage.

3 Dataset Curation

3.1 Dataset Preparations

We developed the IndicQuest dataset, a gold-standard collection of question-and-answer pairs, designed as a benchmark to evaluate the knowledge representation of Large Language Models (LLMs) in the Indian context. The dataset encompasses Q&As in English and 19 major Indic languages: Assamese, Bengali, Dogri, Gujarati, Hindi, Kannada, Konkani, Maithili, Malayalam, Marathi, Meitei (Manipuri), Nepali, Odia, Punjabi, Sanskrit, Sindhi, Tamil, Telugu, Urdu.

For dataset curation, we formulated factual question-and-answer pairs in English, sourced from reputable platforms like Wikipedia and well-known educational websites. The questions were structured across five key domains Literature, History, Geography, Politics, and Economics based on resource availability, topic importance, and cultural relevance to the Indian context. Each domain consists of 40 questions, totaling 200 per language. History, Geography, and Politics questions cover specific sub-regions of India, ensuring representation of the northern, eastern, western, and southern belts. Economics questions address national-level topics, while Literature questions are split between Western and Indian literary works familiar to the Indian audience.

[5]https://huggingface.co/datasets/ai4bharat/IndicQA

A thorough manual verification process was conducted to ensure the accuracy of the English dataset by cross-referencing answers with reliable sources to eliminate ambiguity. The verified question-answer pairs were then translated into 19 Indic languages using Google Translate, maintaining the linguistic accuracy, of the languages.

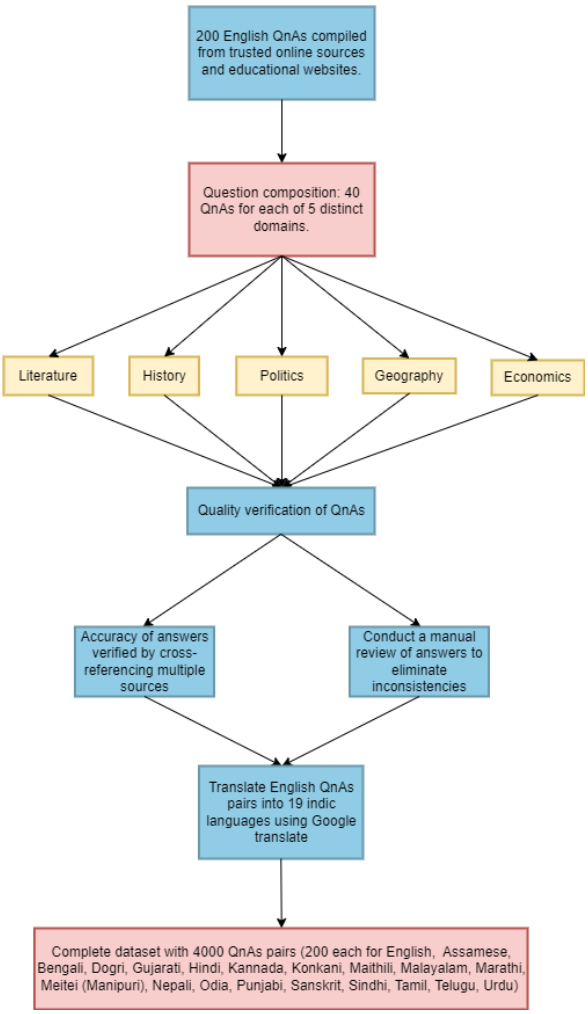

Figure 2: Dataset Curation Process

	Question	Gold Answer
English	Whose death coincided with the launch of the non-cooperation movement in 1920?	On 1 August 1920, Non-Cooperation Movement was announced, on the same day in the early morning, the news of the death of Bal Gangadhar Tilak arrived.
Marathi	1920 मध्ये असहकार चळवळ सुरू झाली तेव्हा कोणाचा मृत्यू झाला?	1 ऑगस्ट 1920 रोजी असहकार आंदोलनाची घोषणा झाली, त्याच दिवशी पहाटे बाळ गंगाधर टिळकांच्या निधनाची बातमी आली.
Gujrati	1920 માં અસહકાર ચળવળની શરૂઆત સાથે કોનું મૃત્યુ થયું હતું?	1 ઓગસ્ટ 1920 ના રોજ અસહકાર આંદોલનનો જાહેરાત કરવામાં આવી, તે જ દિવસે વહેલી સવારે બાળ ગંગાધર તિલકના મૃત્યુના સમાચાર આવ્યા.

Figure 3: Dataset Overview

3.2 Data Statistics

- **Total Q&As:** 4000 (200 questions per language)
- **Domains:** 5 (Literature, History, Geography, Politics, Economics)
- **Language Distribution:** Equal distribution across 20 languages (English + 19 Indic languages)
- **Domain Distribution:** 40 questions per domain per language. Sub-regional coverage: Balanced representation of northern, eastern, western, and southern regions in History, Geography, and Politics.

4 Evaluation Methodology

We conducted an evaluation of the knowledge representation capabilities of various Large Language Models (LLMs) using our IndicQuest dataset as a benchmark. The evaluation covered a diverse set of LLMs, including both proprietary and open-source models, across various sizes. The models evaluated were: Gemma-2-2B-it[6], Gemma-2-9B-it[7], Llama-3.1-8B-it[8], Llama-3.1-405B-Instruct[9] and GPT-4o. Model responses were generated for English and the 19 Indic language gold standard questions, and systematically compared to the corresponding gold standard answers (ground truth) in our dataset. Due to limited resources, GPT-4o responses were obtained only for English, Marathi, and Hindi. The evaluation utilized three distinct performance metrics to assess the degree of alignment between the model-generated responses and the ground truth answers. The results of the evaluation are shown in Table 1.

4.1 Evaluation Metrics

To assess the quality of the responses, we employed the following metrics:

1. **Automated Evaluation with Llama-3.1-405B-Instruct (LLM as a Judge):** We utilized the Llama-3.1-405B-Instruct[10] model to automatically evaluate the responses generated by the aforementioned models. The evaluation was guided by a structured prompt provided to Llama as shown in Listing 1, specifying five key criteria: Factual Accuracy, Relevance, Clarity, Language Consistency, and Conciseness. Each criterion was explicitly outlined in the prompt to ensure a consistent evaluation approach. The model assigned scores to the responses on a scale of 1.0 to 5.0 for each criterion. Additionally, the prompt instructed Llama-3.1-405B-Instruct to calculate an Overall score (also on a scale of 1.0 to 5.0) considering these five key criteria scores, with Factual Accuracy being given a higher weightage. This Overall score, is reported in Table 1.

   It is important to note that the automated evaluation using Llama-3.1-405B-Instruct was not performed for answers generated by Llama-3.1-405B-Instruct itself to avoid potential bias.

Listing 1: Evaluation prompt given to Llama-3.1-405b

```
prompt = f"""
Evaluate the quality of the model's responses to
      questions from a benchmark dataset on a scale of
       1-5 (score can be a decimal fraction format
      number) across the following parameters:

Factual Accuracy: Given an input question, ground
      truth facts relevant to the question, and the
      model/bot's answer, evaluate how well the
      information in the model's answer aligns with
      the provided ground truth facts. Assign a score
      on a scale of 1 to 5 based on the following
      criteria: a score of 5 indicates complete
      alignment with all ground truth facts; a score
      of 3 represents partial alignment where
      approximately half of the facts are correct; and
       a score of 1 denotes complete misalignment with
       the ground truth facts. Scores between these
      benchmarks can reflect varying degrees of
      alignment or discrepancies.

Relevance: Assess how well the model's answer
      directly addresses the question. A score of 5
      indicates a highly relevant answer, while a
      score of 1 indicates an irrelevant or off-topic
      response.

Clarity: Evaluate the clarity and coherence of the
      model's answer. A score of 5 means the answer is
       well-structured and easy to understand, while a
       score of 1 means it is confusing or poorly
      constructed.

Language Consistency: Ensure that the language of the
       response matches the language of the question
      unless otherwise specified. Penalize cases where
       there is a mismatch between the input language
      specified in the question and the response
      language.

Conciseness: Rate how concise the answer is while
      still providing necessary information. A score
      of 5 indicates the answer is succinct and to the
       point, while a score of 1 indicates excessive
      verbosity or unnecessary information.

Input Details:
Question: {question}
Ground Truth Facts: {ground_truth}
Model/Bot Answer: {model_answer}
After evaluating each parameter, provide an overall
      rating on a scale of 1-5 considering all the
      parameters. The parameter factual accuracy
      should have more weightage in the overall score.
```

[9]https://huggingface.co/meta-llama/Llama-3.1-405B-Instruct
[10]https://huggingface.co/meta-llama/Meta-Llama-3.1-405B-Instruct

```
Output Format:
Return the evaluation scores in the following JSON
      format(Return only the JSON and nothing else):
  {{
    "Factual Accuracy": score,
    "Relevance": score,
    "Clarity": score,
    "Language Consistency": score,
    "Conciseness": score,
    "Overall": average_score
  }}
"""
```

2. **F1 Score:** This metric provided a combined measure of precision and recall to further assess the quality of the model outputs.

3. **ROUGE Score:** We calculated the ROUGE (Recall-Oriented Understudy for Gisting Evaluation) score (Lin, 2004) to measure the overlap between the model-generated responses and the ground truth answers.

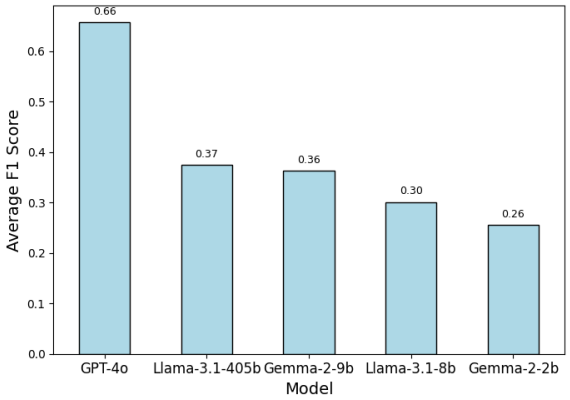

Figure 4: Average F1 Scores across Models obtained by aggregating the scores for all responses to Questions in IndicQuest given by these models. This ranking highlights model performance for Indic languages.

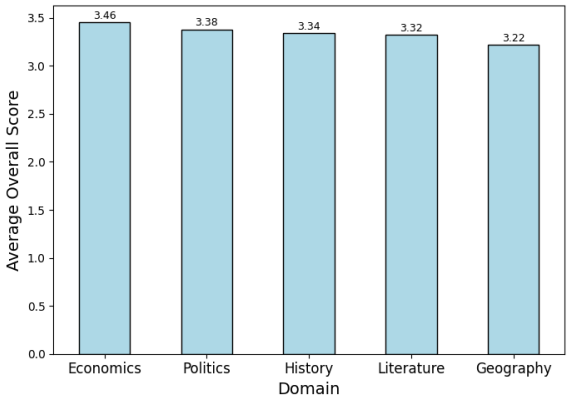

Figure 5: Average 'Overall' scores across Domains obtained by aggregating the scores for responses of all languages and models for the domain. This indicates model performance across various domains.

5 Results and Observations

The following observations were made from the obtained metric scores after our evaluation:

1. **GPT-4o Outperforms across the languages, with Larger Models Leading in Performance:** There is a clear hierarchy in model performance across most domains and languages, with GPT-4o consistently outperforming the other models, followed by Llama-3.1-405B-Instruct, Gemma-2-9B-it, Llama-3.1- 8B-it, and Gemma-2B-it (Figure 4). As shown in Table 1, models with larger parameter counts consistently achieve better results, reinforcing the correlation between model size and performance. This hierarchy was determined through analysis of Overall Llama score, F1, and ROUGE scores.

2. **Stronger English Performance Validates the Need for Greater Representation of Indic Languages in Multilingual LLMs:** All models demonstrate significantly stronger performance in English compared to the Indic languages, as evident in Figure 1, which shows a clear performance hierarchy with English at the top, followed by the indic languages that show relatively lower performance. We can see a hierarchy in the language performance in Figure 1 where the average scores were obtained by considering the scores for the responses evaluated using Llama-3.1-405B-Instruct as a judge. This disparity is consistent across all models and highlights a gap in multilingual proficiency, especially for low-resource Indic languages. These findings reinforce the initial motivation of this study: to increase the representation of Indic languages in multilingual LLMs.

3. **Domain Performance Disparities Reflect Gaps in Region-Specific Knowledge:** The models exhibit performance variation across different domains, suggesting that certain areas of region-specific knowledge are unevenly represented in the LLMs. Based on the Overall Score, a clear hierarchy emerges with Economics performing best, followed by Politics, History, Literature, and Geography being the weakest domain across all languages. These disparities imply that some domains may lack sufficient pre-training data or require domain-specific fine-tuning to improve results. This

Model	Metric	Language Scores																			
		En	Hi	Mr	Mi	Ne	Do	Sa	Ko	Ml	Ta	Ka	Te	Pu	As	Be	Si	Od	Ur	Gu	Mn

	ROUGE-L	0.23	0.13	0.07	0.09	0.05	0.11	0.00	0.07	0.08	0.09	0.06	0.08	0.13	0.00	0.01	0.15	0.10	0.13	0.06	0.00
GPT-4o	Overall Score	4.45	4.49	4.27	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
	F1	0.70	0.73	0.53	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
	ROUGE-L	0.23	0.13	0.08	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Table 1: Evaluation scores for all models across 20 languages. Language abbreviations: En=English, Hi=Hindi, Mr=Marathi, Mi=Maithili, Ne=Nepali, Do=Dogri, Sa=Sanskrit, Ko=Konkani, Ml=Malayalam, Ta=Tamil, Ka=Kannada, Te=Telugu, Pu=Punjabi, As=Assamese, Be=Bengali, Si=Sindhi, Od=Odia, Ur=Urdu, Gu=Gujarati, Mn=Manipuri. Dashed entries (-) indicate scores not obtained for those particular languages, as GPT-4o responses were generated only for En, Hi, and Mr, while Llama-3.1-405b responses were evaluated only using F1 and ROUGE metrics.

highlights the need for more focused training on culturally and regionally relevant content in multilingual models.

4. **Need for Improvement in Multilingual Capabilities Despite Superior Performance of GPT-4o:** While GPT-4o consistently outperforms smaller models across English, Marathi and Hindi datasets, its performance in Marathi still lags behind its English counterpart. This discrepancy highlights the limitations of even the most advanced models when it comes to low-resource languages like Marathi and other Indic languages.

6 Conclusion and Future Work

In this work, we introduce IndicQuest, a resource designed to evaluate Large Language Models (LLMs) for their ability to represent knowledge in Indic languages. The dataset comprises 4,000 gold-standard question-answer pairs, with 200 pairs each for English and 19 Indic languages. We evaluated all 20 languages across multiple multilingual models, using Llama-3.1- 405B-Instruct as the evaluator, alongside standard metrics such as ROUGE and F1 score. Our evaluation involved five models: Gemma-2-2B-it, Gemma-2-9B-it, Llama-3.1-8B-it, Llama-3.1-405B-Instruct and GPT-4o.

From the evaluation scores, we observed a disparity in the performance of LLMs between English and the Indic languages. Despite advancements, English—a well resourced language continues to outperform Indic languages. This underscores the need for further improvements in LLMs to enhance their inclusion of Indic languages, as well as the importance of developing Indic knowledge-based benchmark datasets to identify areas where these models fall short in Indic-specific contexts.

The evaluation process in this study was fully automated. In the future, we plan to conduct human evaluations on the English, Marathi and Hindi subsets, involving subject matter experts, to compare their assessments with the automated Llama Evaluation results. Additionally, we aim to perform a deep quantitative analysis of the results to identify specific linguistic and domain-related challenges faced by the models.

We hope this dataset will serve as a valuable benchmark for advancing research in multilingual LLMs, particularly in evaluating their performance and using it as a standard for assessment.

7 Acknowledgements

This work was carried out under the mentorship program of L3Cube Labs, Pune. We would like to express our sincere gratitude to our mentor, for his continuous support and guidance.

An Analytical Study of the Flesch-Kincaid Readability Formulae to Explain Their Robustness over Time

Yo Ehara
Tokyo Gakugei University
ehara@u-gakugei.ac.jp

Abstract

The Flesch–Kincaid formulae are classic and frequently utilized as English-specific readability metrics, even in recent assessments of large language models. These formulas combine the average sentence length in words with the average word length in syllables. Despite their simplicity, these formulas have been extensively used for decades, suggesting a cognitive rationale for their robustness. This study conducts a theoretical analysis of these formulae, examining the factors that contribute to their continued robustness over time. Notably, unlike previous research, we showed that these formulas can be interpreted as the average number of syllables per sentence. While the vocabulary inventory may expand as the grade level rises, the syllable inventory remains constant across different grades and ages. This stability is a key factor for their robustness over time. In our evaluation experiment, we confirm the validity of our theoretical framework using the British National Corpus (BNC).

1 Introduction

The Flesch–Kincaid formulas, specifically the Flesch–Kincaid Grade levels (FKGL) (Kincaid et al., 1980) and Flesch Reading Ease (FRE) (Flesch, 1948), are widely used to evaluate the readability of English texts, including those produced by large language models (Tanprasert and Kauchak, 2021; Imperial and Tayyar Madabushi, 2023; Kew et al., 2023). This popularity stems from the ease of interpreting the FKGL scores and the fact that neither method depends on word lists, which can be challenging to maintain.

One reason for the long-standing acceptance of the Flesch–Kincaid formulas (Kincaid et al., 1980) is their robustness. Unlike the formulas dependent on word lists, which are challenging to maintain and quickly outdated by new terms like "smartphones," these do not suffer from obsolescence. What makes these equations consistently reliable? We hypothesized that they must be based on the fundamental aspects of human cognition, an idea that drives our research. We demonstrate in later sections that these formulas are grounded in cognitive characteristics.

1.1 FKGL

Our emphasis is on FKGL, as the same rationale applies to FRE, and we aim to standardize the notation, where a higher value indicates greater difficulty.

$$\begin{aligned}\text{FKGL} &= 0.39\left(\frac{\text{total words}}{\text{total sentences}}\right) \\ &+ 11.8\left(\frac{\text{total syllables}}{\text{total words}}\right) - 15.59 \quad (1)\end{aligned}$$

The rationale for the FKGL is as follows. The number of words in a sentence, which corresponds to the first term, can act as an indicator of sentence complexity. Nonetheless, the average number of words alone does not fully capture the sentence difficulty. Even a brief sentence can be difficult for students if it includes words that are unfamiliar or sophisticated for their educational level. Consequently, the difficulty of vocabulary within a sentence must also be considered, giving rise to the second term, which calibrates the first term.

Nonetheless, this calibration appears to be overly heuristic and lacks theoretical assurance that the score can be excessively calibrated. This insight encourages the development of improved calibration techniques using larger annotated datasets and considering numerous linguistically rich attributes, thereby sacrificing the robustness of these formulas over time. A key recent automatic readability assessment study was Imperial (2021), and other studies were surveyed in Vajjala (2021).

This study addresses these research questions in relation to Equation 1. Each question is indicated by an *RQ*.

RQ1 *Why does a linear combination of the two measures, average number of words and average number of syllables in a sentence, work well?* This type of linear combination can be represented as the product of the average syllable count per sentence and M, which has a narrow range provided that the coefficients are appropriately chosen. We argue that FKGL utilizes the average syllable count per sentence to determine difficulty. We demonstrated that FKGL adopts this structure.

RQ2 *Is there any possibility of overcalibration? That is, is it possible that the average number of syllables in a word takes too large a value?* As indicated above, the maximum FKGL value can be obtained by determining the maximum value of M. This aided in establishing the upper bound.

RQ3 *What is the cognitive rationale behind FKGL?* As individuals grow, their vocabularies expand. Even sentences with only a few words, on average, may include challenging terms. Thus, the average word count per sentence does not necessarily reflect the text complexity and should be reconsidered. However, their phonetic repertoires did not increase with age. In other words, various recognizable syllables remained constant over time. Therefore, sentences with a higher average syllable count are undoubtedly more complex than those with fewer syllables. Indeed, because the Flesch–Kincaid Grade Level (FKGL) corresponds to a school year, we can derive the annual increase in the average number of syllables per sentence.

These new findings were not observed in previous FKGL studies and are an important contribution to this study.

2 Analyzing FKGL

We repeat Equation 1 as follows.

$$\begin{aligned}\text{FKGL} &= 0.39\left(\frac{\text{total words}}{\text{total sentences}}\right) \\ &+ 11.8\left(\frac{\text{total syllables}}{\text{total words}}\right) - 15.59 \quad (2)\end{aligned}$$

In this formula, the number of words per sentence and syllables per word appear. Currently, we focus on the number of words in each sentence. In computational linguistics, it is common to consider a sentence as a sequence of words and assume that there is always a word at the end of the sentence (EOS) that does not explicitly appear but is always present at the end of the sentence. Subsequently, the number of EOSs matches the total number of sentences; thus, the probability of EOS occurrence can be expressed by the following equation: For simplicity, we define this probability as p_{sw}, where s represents a sentence, and w represents a word. Thus, the number of words per sentence can be understood as the reciprocal of the probability of occurrence of a word that indicates the sentence boundary, as follows:

$$p_{\text{sw}} \equiv \frac{\text{total sentences}}{\text{total words}} \quad (3)$$

Similarly, the number of syllables per word can be considered a syllable sequence. To avoid confusion with the word 'sentence,' we will use the letter 'l' for syllables and express this probability as p_{wl}.

$$p_{\text{wl}} \equiv \frac{\text{total words}}{\text{total syllables}} \quad (4)$$

Furthermore, by setting the constants $a = 0.39$, $b = 11.8$, and $c = -15.59$, FKGL can be rewritten as follows:

$$\begin{aligned}\text{FKGL} &= \frac{a}{p_{\text{sw}}} + \frac{b}{p_{\text{wl}}} + c \\ &= \frac{1}{p_{\text{sw}}p_{\text{wl}}}\left(ap_{\text{wl}} + bp_{\text{sw}}\right) + c \quad (5)\end{aligned}$$

Here, we introduce the number of syllables per sentence p_{sl}.

$$\begin{aligned}p_{\text{sl}} &\equiv \frac{\text{total sentences}}{\text{total syllables}} \\ &= \frac{\text{total sentences}}{\text{total words}}\frac{\text{total words}}{\text{total syllables}} \\ &= p_{\text{sw}}p_{\text{wl}} \quad (6)\end{aligned}$$

Subsequently, eqrefeq: fkglabstis rewritten as follows:

$$\text{FKGL} - c = \frac{1}{p_{\text{sl}}}\left(ap_{\text{wl}} + bp_{\text{sw}}\right) \quad (7)$$

The right-hand side of Eq. eq:fkglabst can be decomposed into the first term $1/p_{\text{sl}}$ and second term $ap_{\text{wl}} + bp_{\text{sw}}$. Note that up to Equation 7, we only performed simple formula transformations, and no approximations were made. In the following subsection, we discuss the research questions predicted by Equation 7. We verify these research questions in the following sections.

2.1 Answer to research questions

The first research question is "*Why does a linear combination of the two measures, average number of words, and average number of syllables in a sentence work well?*". This can be partly explained by Equation 7. In Equation 7, FKGL is essentially the product of $\frac{1}{p_{\mathrm{sl}}}$, which is the average number of syllables in a sentence, and M, which is defined as In the experiments, we demonstrate that Equation 8 does not range significantly for FKGL using a general corpus.

$$M = (ap_{\mathrm{wl}} + bp_{\mathrm{sw}}) \tag{8}$$

The second research question was "*Is there any possibility of overcalibration? That is, is it possible that the average number of syllables in a word takes too large a value?*". Here, we can easily see that Equation 8 is bounded because p_{wl} and p_{sw} are probability values. Therefore, we can easily see that $0 \leq M \leq a + b$. Hence, combined with Equation 7, we can derive the following bound for Equation 1.

$$c \leq \mathrm{FKGL} \leq \frac{1}{p_{\mathrm{sl}}}(a + b) + c \tag{9}$$

In Equation 9, note that c is a negative value, namely $c = -15.59$, in the case of FKGL, whereas a and b are positive values. Hence, the FKGL is bounded by the number of syllables in a sentence. Hence, even if the average number of syllables in a word is excessively large, the FKGL is bound by the average number of syllables in a sentence. To the best of our knowledge, no previous study has addressed this theoretical bound. Hence, this is a novel result and is one of our contributions.

The third research question is "*What is the cognitive rationale behind FKGL?*". $\frac{1}{p_{\mathrm{sl}}}$ is the average number of syllables in the sentence. The average number of syllables in a sentence differs greatly from the average number of words. This is because the average number of acceptable words in a sentence changes according to the grade. Intuitively, we can see that acceptable vocabulary increases as the grade level increases. Teaching materials were created to increase vocabulary for each grade level. This indicates that the complexity of a text cannot be measured using the average number of words in a sentence alone. It is necessary to predict the acceptable vocabulary according to the learner's grade level and incorporate this into planning. It seems unlikely that the complex process of calculating text complexity involving both the average number of words in a sentence and changes in receptive vocabulary can be performed using a simple formula in the original equation Equation 1. This motivated the development of more advanced methods by considering the FKGL as a traditional heuristic. However, even advanced methods based on language models in recent years are models that view language as a sequence of words. For this reason, to estimate the complexity of a text for a particular grade, it is also necessary to estimate the vocabulary for that grade. Therefore, even if an advanced language model is used, it is still necessary to make predictions that consider both the average number of words in a sentence and the vocabulary used in that sentence.

However, the derived equation, Equation 7, provides a completely different perspective. This indicates that the FKGL can be considered as the average number of syllables in a sentence. It is assumed that the number of words in a learner's vocabulary, or vocabulary inventory, will increase as they progress through school. However, the number of syllables that can be recognized, or the phonetic inventory, will remain the same, even as they progress through school. The phonetic inventory is specific to a language, and once a person has acquired their native language, the number of phonemes in the phonetic inventory of native speakers of that language remains stable. In addition, owing to the arbitrariness of words, there is no need to use specific sounds to express specific difficulties. Because the size of the acceptable phonetic inventory is constant, an increase in the average number of syllables in a sentence certainly represents an increase in sentence complexity.

Furthermore, unlike vocabulary, the phonetic inventory is also very robust over time. While many words, like "smartphones," have become familiar in recent decades, virtually no languages have experienced a sudden increase or decrease in the number of phonemes over this period.

Unlike words, the average syllable count of a sentence does not model semantic complexity. Therefore, if a sentence is given with a low average syllable count but high semantic difficulty, this formula is likely to yield incorrect results. Hence, it is impossible to determine the difficulty level of a poem with a syllable-count limit such as a haiku. Intuitively, such studies are rare. Practically, practitioners and educators need to be careful when applying formulae to such limited types of text.

2.2 FKGL-derived increase in the number of syllables per year

If we use the equation in Equation 7, we can see that the increase in the number of syllables per year is also modeled from FKGL. In Equation Equation 7, we focus on the FKGL for a particular school year. Let us then consider the FKGL for the school year one year above FKGL+1. For FKGL+1, we assume that M remains constant.

For FKGL+1, let M remain the same and let p change from p_{sl} to p'_{sl}. Subsequently, the following equation holds:

$$\text{FKGL+1} - c = \frac{1}{p'_{\text{sl}}} M \tag{10}$$

$$\text{FKGL} - c = \frac{1}{p_{\text{sl}}} M \tag{11}$$

$$\tag{12}$$

By subtracting equation Equation 10 from equation Equation 11, we obtain

$$\left(\frac{1}{p'_{\text{sl}}} - \frac{1}{p_{\text{sl}}} \right) = \frac{1}{M} \tag{13}$$

The expression $frac1p_{\text{sl}}$ indicates the average number of syllables per sentence in a specified year, whereas $\frac{1}{p'_{\text{sl}}}$ signifies the average one year later. This highlights the increase in the average number of syllables per sentence over a year. In addition, it is evident that $\frac{1}{M}$ denotes an increase in the average number of syllables per sentence over a year.

3 Experiments

3.1 Setting

Based on this, we now describe our experiments. The British National Corpus (BNC) was used in this experiment. We used the Python readability library to determine the average number of words and syllables in the sentences.

3.2 Histogram of FKGL

First, we present a histogram of FKGL in the BNC. Figure 1 shows the histogram. The histogram exhibits a bell-shaped curve.

3.3 Histogram of the average number of syllables in a sentence

Next, we present our key findings: in Equation 7, we recognized that FKGL could be reformulated and that the primary complexity of the input text is represented by the average number of syllables per sentence, labeled as $\frac{1}{p_{\text{sl}}}$. We determined the average number of syllables in the texts from the BNC corpus using the readability library to compute this metric for each text, $\frac{1}{p_{\text{sl}}}$, and subsequently created a histogram of the results. The histogram in Figure 2 shows the average number of syllables per text on the horizontal axis and the percentage on the vertical axis. We can observe that Figure 2 also exhibits a bell-shaped distribution similar to Figure 1, indicating that the complexity of the text is captured by the average number of syllables per sentence, as anticipated.

3.4 Scatterplot of FKGL against the average number of syllables per sentence

Following this, Figure 3 displays a scatter plot depicting the relationship between FKGL and the average number of syllables per sentence. Figure 3 highlights a distinct correlation between FKGL and the average syllables per sentence, reinforcing the idea that the average syllables per sentence is crucial in FKGL for representing text complexity.

3.5 Checking that M does not change significantly

We postulate that M remains constant in Equation 8. To verify this result, we present a histogram of M in Figure 4. The horizontal axis represents the values of M and the vertical axis represents the percentage. The peak for M clusters is approximately 1. According to Equation 7, because M is the sole factor multiplied by the average syllable count per sentence, the average syllable count per sentence is almost directly utilized in the FKGL. Indeed, nearly 60% of M fall within the ranges of 0.7 and 1.0. In addition, we observed an extended tail, indicating that high M values were uncommon.

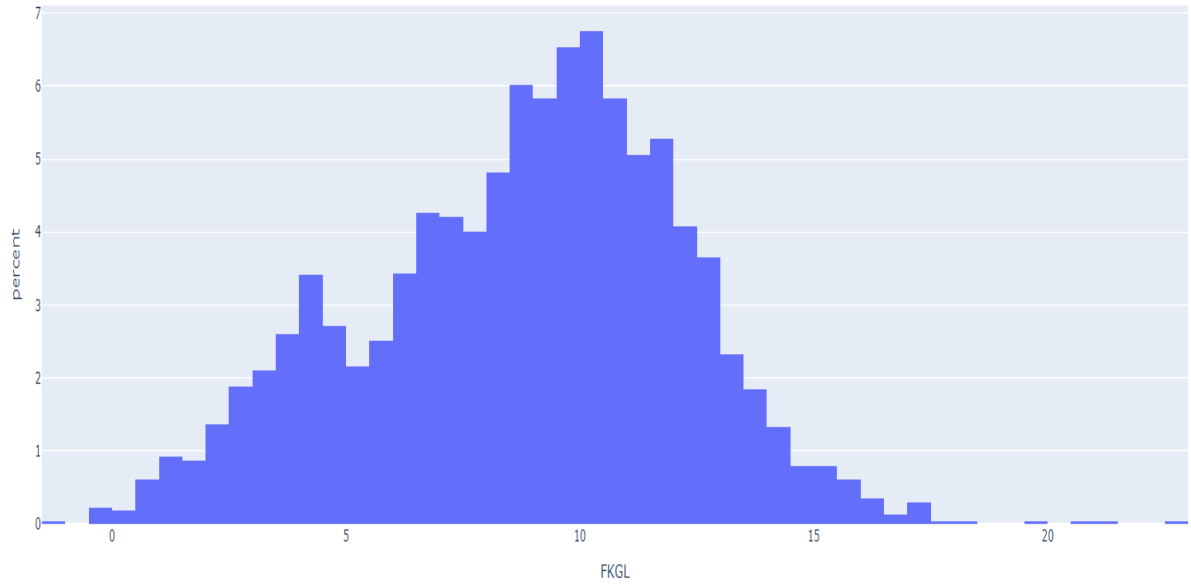

Figure 1: Histogram of FKGL in BNC.

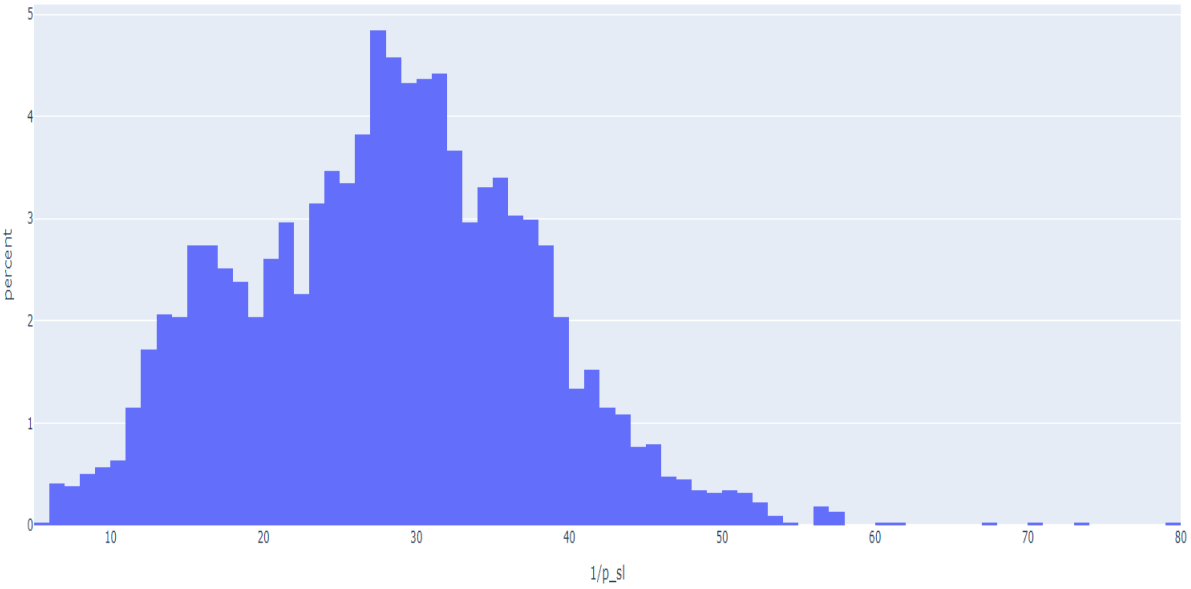

Figure 2: Histogram of $1/p_{\text{sl}}$ in BNC.

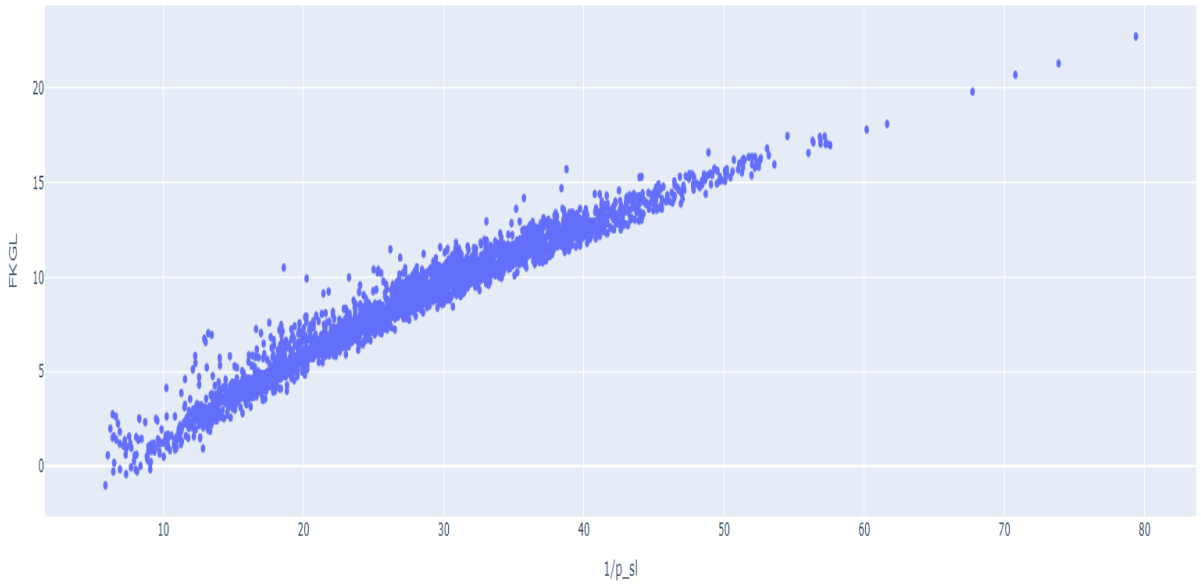

Figure 3: FKGL against $1/p_{\text{sl}}$ in BNC.

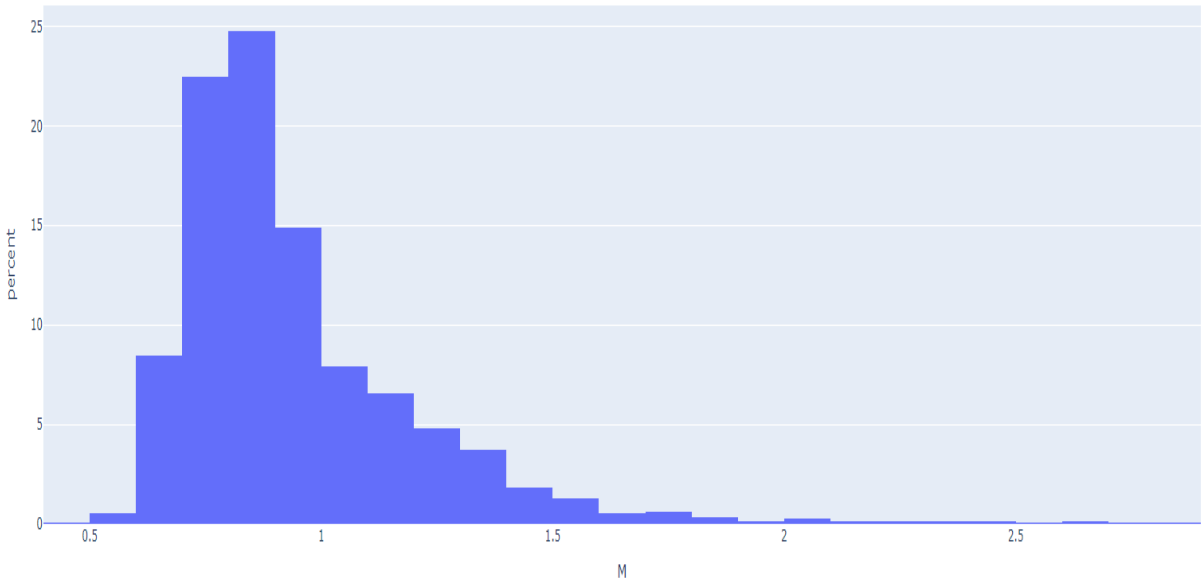

Figure 4: Histogram of M in BNC.

Figure 5: M and text domains (category). The addition of the horizontal and vertical values is M.

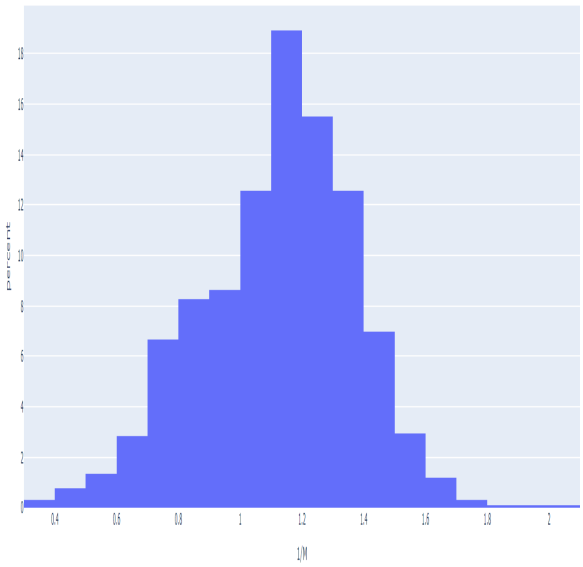

Figure 6: Histogram of $1/M$, which corresponds to the gain in the average number of syllables in a sentence within a year predicted by FKGL.

3.6 Domain Analysis of M

One of the primary traits of the BNC is its general nature, which implies that the corpus comprises various texts sourced from numerous topics. The genres of BNC texts are termed "*domains*," and approximately 4-out-of-3 out of these texts are tagged with domains [1]. In Figure 5, a scatterplot of bp_{sw} versus ap_{wl} in Equation 7 is presented. By integrating the horizontal and vertical axes, we derived the M factor as previously described. In Figure 5, it is shown that a domain confines text to a restricted area. Therefore, when a text's domain is fixed, the value of M remains more consistent and does not fluctuate significantly, rendering $\frac{1}{p_{\text{sl}}}$, the average number of syllables per sentence in Equation 7, the sole factor influencing text complexity.

3.7 The histogram of $1/M$

According to Equation 13, $1/M$ can be interpreted as the annual increase in the average number of syllables per sentence. We derived $1/M$ in the BNC and present its histogram in Figure 6. Interestingly, Figure 6 illustrates the distribution of the annual increase in the average number of syllables per sentence in the BNC, showing a peak at 1.2 and ranging between 0.4 and 2.0. To the best of our knowledge, this specific increase in text complexity, as evidenced by a measurable statistic via FKGL, has not been previously addressed. This is a significant finding of this study.

[1]We excluded the texts without domains from the entire experiments.

4 Discussions and Related Work

In this study, we focused exclusively on FKGL. However, as shown in Equation 7, the same logic applies to other readability formulas that are linear combinations of the average number of words per sentence and the average number of syllables per word. A well-known example of such a formula is FRE, which typically ranges from 0 to 100 for most texts.

$$\begin{aligned}\text{Reading Ease} &= 206.835 \\ &- 1.015\left(\frac{\text{total words}}{\text{total sentences}}\right) \\ &- 84.6\left(\frac{\text{total syllables}}{\text{total words}}\right) \quad (14)\end{aligned}$$

According to Equation 14, by defining $a = -1.015$, $b = -84.6$, and $c = 206.835$ in Equation 5, we can obtain Equation 14. It is evident from the signs of a and b that higher FRE values indicate greater ease of readability; this is reasonable, given that FRE measures easiness while FKGL measures grade level, which correlates with difficulty. To prevent confusion arising from the contrasting natures of FRE and FKGL, we have focused exclusively on FKGL in this paper.

4.1 Applicability to Other Formulas

In this study, we focus on FKGL and FRE, or the Flesch–Kincaid formulas. This is because these formulas are notable examples of formulas consisting of only a linear combination of the average number of words in a sentence and the average number of syllables in a word. To the best of our knowledge, no other widely known formulas have this form.

However, some formulas have very *similar* forms. For example, the automated readability index (ARI) (Smith and Senter, 1967) (Equation 15) consists of a linear combination of the average number of words in a sentence and the average number of *characters* as follows: Using the same argument used in this study, ARI can be regarded as a measure simply based on the average number of *characters* in a *sentence* weighted by genre.

$$\begin{aligned} \text{ARI} &= -21.43 \\ &+ 0.5\left(\frac{\text{total words}}{\text{total sentences}}\right) \\ &+ 4.71\left(\frac{\text{total characters}}{\text{total words}}\right) \end{aligned} \quad (15)$$

As with ARI, the Coleman-Liau index (Coleman and Liau, 1975) consists of a linear combination of the average number of words in a sentence and the average number of characters in a word. However, the Coleman-Liau index requires an average of over 100 sentences and words. However, the same argument that we have addressed in this study also applies to the Coleman-Liau index. Other than these formulae, our reasoning should generally hold for formulas that are a linear combination of the average sentence length and per-word statistics.

Regarding cognitive implications, this study reveals that the FKGL and FRE formulas can be simply regarded as the number of syllables in a sentence weighted by genre. However, the relationship between the number of syllables in a sentence and reading comprehension remains unclear, and we show that this is an important open question. In addition, although the BNC is an excellent general corpus, it does not cover all text genres. The relationship between the number of syllables in a sentence and text genre is one of open questions. For second language learning, recent personalized readability studies (Ehara, 2022a,c,b; Liu et al., 2023) are also important for studying such relationships. Also, regarding FKGL and FRE, Ehara (2023) previously addressed that the reciprocal of a probability can be seen as a perplexity of tokens denoting delimiters of sentences or words.

5 Conclusions

This study makes significant contributions to the literature by examining the Flesch–Kincaid readability formulas, specifically FKGL and FRE. Unlike previous automatic readability assessment studies (Si and Callan, 2001; Collins-Thompson and Callan, 2005; Pitler and Nenkova, 2008; Vajjala, 2021; Martinc et al., 2021; Crossley et al., 2023), we demonstrate that the average number of syllables per sentence is a crucial determinant of text complexity in these formulas. Because readers' phonetic inventories are generally stable, our findings explain the enduring robustness of these formulas from a cognitive perspective.

Future research should focus on creating new robust readability formulas based on the average number of syllables in other languages. Although these formulas are widely used, their English specificity is a major limitation. Although FKGL has been adapted for some European languages, developing a readability formula for Asian languages remains challenging because of their distinct writing systems. Nevertheless, our analysis focused on syllables per sentence, a metric that is easily transferable to Asian languages. Based on our findings, we believe that an FKGL-equivalent readability formula can be developed for other Asian languages, which makes comparing readability between different languages possible.

Ethical Considerations

As our analysis relies on mathematical transformations, and our experiments utilize the BNC, a widely recognized and publicly accessible general English corpus, we believe that this study does not require any special ethical considerations.

Limitations

Although the BNC is a widely utilized general corpus and the corpus-linguistic analysis derived from it is broadly accepted, we acknowledge that our experiments relied on a single specific corpus. While we expect that experiments using general corpora would yield similar results across other general corpora, we did not conduct experiments using other corpora in this paper.

A Linguistic Analysis on Negation and Emotion Shift

Cloris Pui-Hang Li

Sophia Yat Mei Lee
The Hong Kong Polytechnic University
ym.lee@polyu.edu.hk

Abstract

Emotion classification is gaining more attention in the field of linguistics, to facilitate the development of automatic emotion analysis and classification. While many focus on how emotions can be better classified, there are also other linguistic devices that contribute to emotions, for example negation. This paper sees negation as an important linguistic device that causes shifts of emotions and highlights the importance of taking negation into account during the automatic emotion analysis process. The paper takes data from the Chinese online social media platform *Sina Weibo* as the corpus, then observes the interaction between the two major negators *bu* and *mei* and their modifying emotion expression. The finding reveals that negators have a significant contribution to emotion shifts in social media discourse, and that the type of emotion shifts varies due to different morphological features, semantic differences or pragmatic uses such as irony.

1 Introduction

In today's digital age, social media platforms have become a significant medium for individuals to share their views and express their opinions, where personal emotions intertwine with public discourse. As vast amounts of information are delivered in a short time, automatic emotion classification has become crucial for obtaining and understanding mass emotion-related information in an immediate and accurate manner.

While automatic emotion analysis typically focuses on capturing overt expressions of emotion, at the discourse level, there are other linguistic devices that contribute to the emotional context of text and shall not be overlooked. One such device is negation, which is the focus of the present paper.

Negation is commonly used as a negative operator that denotes the opposition of the truth value to the corresponding affirmative proposition. Studies also indicate that negation plays diverse roles within various semantic and pragmatic contexts (e.g. Horn and Kato, 2000; Fraenkel and Schul, 2008; Aina et. al., 2019). Consider the examples denoted as (1) and (2) below, they are sentences that contain negation markers that negate emotion expressions.

(1). "My teacher is **not mad** at my performance in class."

(2). "My teacher is **not happy** with my performance in class."

In (1), the negation marker "not" negates the emotion "mad", meaning a neutral emotion. In (2), the negated emotion expression "not happy" does not bring a neutral emotion, but a sense of dissatisfaction and anger. This is an illustration of the different possibilities of interaction that can be found when a negation marker is added to modify an emotion expression. In the present paper, we will focus on these interactions between negation and emotion in Chinese.

Seeing the significant contribution of negators to emotion interpretation, the paper aims to investigate the effect of emotion shift of negation in emotion expressions, particularly within the context of Modern Chinese social discourse. By shedding light on this linguistic phenomenon, the research hopes to offer insights for the future development of automatic emotion classification tools and emotion analysis technology.

In this paper, we would like to answer one research question: what kind of emotion shift does negation bring to emotion expressions in Modern Chinese online discourse?

To find an answer to this question, the study will investigate the interaction between negation and emotion shifts in social media discourse, by looking for negated emotion expressions in user entries on a social media platform, and then observe trends of emotion shifts after negation.

The present paper is organised into six main sections. In Section 2, we conduct a literature review on emotion classification and other relevant studies. Section 3 provides explanations for the methodology used in the present study, including data collection from *Sina Weibo* and the annotation processes employed. Section 4 presents descriptive statistics of the results for a quantitative overview of the actual number of instances of post-negation emotion shift. Followed by Section 5, where we discuss the implications of the interaction between negation and emotion. Section 6 wraps up the paper by concluding the findings of the research question and suggests avenues for future studies.

2 Literature Review

2.1 Emotion Classification

Emotion is a complex psychological state that has long been a hot topic for research. In the field of psychology, some scholars suggested that positive and negative emotions like happiness and sadness can be considered polar opposites (Watson & Tellegen, 1985; Russell & Carroll, 1999; TenHouten, 2022), while some argued that according to the Evaluative Space Model of the affected system, positive and negative emotions shall not be conceptualised as opposites (Cacioppo, 2011; Heubeck et. al., 2016). In computational studies, Zheng et. al. (2020) used eye-tracking cues to conduct emotion classification, taking the Circumplex Model of Emotions (Russell,1980) as a model for classification. In text data classification, Wen and Wan (2014) applied class sequential rules to classify emotion in microblog texts, and classified emotion in seven classes, including surprise, happiness, sadness, like, anger, disgust and fear.

In linguistics studies, scholars suggested that positive and negative emotions are not opposites (Cruse, 1976; Cruse, 1986; Zautra et al., 1997). Recent studies also analysed the effectiveness of metaphorical linguistic patterns in conveying emotions (see Xiao & Su, 2014; Chan, 2024). In emotion analysis, researchers suggest the importance of classifying opinions into fine-grained emotions such as happiness and sadness (see Wiebe et al. 2005; Mihalcea and Liu 2006), or happiness, sadness, fear, anger and surprise (Lee et al., 2010). Semantically, research has suggested that emotion words evolve over time (Xu, Stellar & Yang, 2021). Wodarz and Harris (2022) investigated on contemporary posts and concluded that temporal change in emotional characteristics in texts is present. Liu and Liu (2022) researched on the changes of emotion by analysing emotion words used on social networks, suggesting positive and negative emotions should be "independent dimensions".

2.2 Emotion Reversal

The idea of reversal were suggested by Apter (1989) as the Reversal Theory, which focuses on the dynamics among elements including personality, motivation and emotion, and suggests that reversal is a switch between systems that are simultaneous with emotions that might be experienced when an individual is in a new motivational state, while the levels of emotions are "assumed to be toward opposite ends". Throughout the years, the concept of reversal has been applied into different linguistics concepts, including: (1) polarity (Fauconnier, 1975; Isreal, 2006; Reinhart, 1976), where Reinhart (1976) has suggested that negative polarity could lead to reversed judgements; and (2) morphology (Baerman, 2007; Steriopolo, 2021), where Baerman (2007) has mentioned the pattern of reversal in gender marking in Hebrew, and reversal in voicing in Luo (Okoth-Okombo, 1982).

2.3 Negation and Emotion

Negation in emotion words can cause shifts in emotion. The importance of studies on negation on sentiment analysis has been highlighted throughout the years (Hogenboom et al., 2011; Carrillo-De-Albornoz and Plaza, 2013; Cruz et al., 2015, Makkar, 2024), particularly on sentiment reversal (Herbert et al., 2011; Weis and Herbert, 2017; Ilmawan, 2024). Kennedy and Inkpen (2006) examined the effect of changes in the polarity of sentiments caused by negation, intensifiers and diminishers as valence shifters, whereas negations were used to achieve reversal on semantic polarity. Ljajić & Marovac (2019) has highlighted the necessity of addressing negation rules to enhance sentiment classification accuracy. Various studies

have shown that negation in sentiment analysis does not necessarily lead to reversed polarity (Wiegard et al., 2010; Farooq et al., 2017; Singh and Singh, 2019, Gupta and Joshi., 2021).

Jia et al.(2009) mentioned the complexity of determining polarities of sentiments in negation terms in English text analysis, while He et al. (2017) suggested that negation detection for Chinese texts could be relatively more challenging in concern of challenge in segmentation and presence of homographs. In English, Taboada et al. (2011) used a -5 to +5 scale when working on the extraction of sentiment from text, including negation and intensification. In Korean, Rhee et. al. (2012) examined the change in polarity on negated emotion words by measuring the valence and arousal dimensions, using a -3 to +3 scale. In Chinese, previous research has investigated on negated emotions by startle reflex modulation, suggesting negation could be a "spontaneous down-regulation" of negative emotions (Herbert et. al, 2011). In the study by Chevi and Aji (2024), it is suggested that negated primary emotion changes the original emotion by simulating the opposite of the original emotion.

3 Methodology

3.1 Data Collection

For corpus extraction, we automatically extracted social media posts from *Sina Weibo* and randomly selected part of it as the corpus for the study. Sina Weibo is chosen as it is one of the most popular Chinese social media platform, so the lexicon contains an extensive range of natural expression in Modern Chinese used in daily context. The corpus comprises a total of 1,311,874 text entries in Simplified Chinese, from one hundred anonymized authors.

For the selection criteria of negators, we follow the negation criteria outlined by Xiao and McEnery (2008), where they proposed that *bu* and *mei* are the major, and most important negators in Chinese. For the selection criteria for emotion words, the Chinese Emotion Taxonomy proposed by Lee (2019) were used as the foundation for the list of emotion words, where Chinese emotion expressions were divided into five primary emotions, then branched out into variations in intensity, and also first- and second-order emotions that are believed to have involved more than one primary emotion. Aligned with the aforementioned scholarly framework, a total of 468 expressions, which include all emotion words in the Chinese Emotion Taxonomy by Lee (2019) that immediately followed the two negators *bu* and *mei*, were selected as the final candidate list.

3.2 Data Annotation

The data annotation is conducted by a native Chinese speaker. The annotations primarily focused on identified negated emotion words,

Entry	不开心 今天排球我没过 [泪]	随你叫骂, 我不生气
Emotion	happiness_ moderate	anger_ moderate
Reversed emotion	sadness_ moderate	neutral
Note	/	/
Reviewer 1	1	1
Reviewer 2	1	1
Reviewer 3	1	1
Reviewer 4	0	1
Reviewer 5	1	1

Figure 1: Example of annotation

applying Lee's (2019) emotion taxonomy framework to evaluate the effect of emotion shift caused by negation in the text. The annotation starts with looking for an emotion expression, then the original emotion would be annotated according to the taxonomy framework. After that, if the entry contains emotion expression that is modified by the negation markers *bu* (不/ NEG), *mei* (沒/ NEG), or *meiyou* (沒有/ NEG), the emotion of the negated emotion expression is annotated according to the taxonomy. If there is no shift in emotion, the same emotion as annotated at the original annotation will be marked.

Following the primary annotation, five volunteers between the ages of 20 and 35, possessing native Chinese proficiency, were recruited as reviewers. They were asked to review the annotations and indicate whether they agreed or disagreed with the primary annotations. If they agreed with the annotation, the letter "1" would be marked for indication, and "0" would be marked for disagreement. Only entries with three or more agreements were included in the final selection.

This age group was chosen due to statistics indicating that over 70% of Weibo users fall within this demographic, making them the primary audience of the social media platform (Lai, 2024). Two examples of annotated instances are given in Figure 1.

4 Results

After annotation and review, the total number of selected entries is 485. Table 1 presents the number of instances of emotion shifts in general.

Among the 485 selected entries, 94.6% (459 entries) exhibited varying degrees of emotion shifts, while 5.4% (26) negated emotion expressions showed no shift in emotion. In terms of choice of negation marker, there are 476 entries which contain emotion expressions negated by the negation marker bu, of which 94.7% showed an emotion shift after negation. Nine entries are negated by the negation markers *mei* and *meiyou*, where 89% (8) of the entries experienced a post-negation emotion shift, and 11% (1) did not. The majority of negations are marked by the negation marker *bu*, showing that *bu* is the most common negator for emotion expressions. In terms of context, there are 9 instances of double negations and 2 ironic expressions. Most of them did not demonstrate an emotion shift after negation. Among the 25 rhetorical questions in our corpus, around half of them (52%) displayed an emotion shift, while 48% (12) did not.

	Percentage with Emotion Shift	Percentage without Emotion Shift
All Entry (485)	94.6% (459)	5.4% (26)
Negated by *bu* (476)	94.7% (451)	5.3% (25)
Negated by *mei* / *meiyou* (9)	89% (8)	11% (1)
Double Negation (9)	11% (1)	89% (8)
Ironic Expression (2)	0% (0)	100% (2)
Rhetorical Questions (25)	52% (13)	48% (12)

Table 1: Number of Instances of Emotion Shifts

Primary Emotion	Percentage of Instance as Original Emotion (485)	Percentage of Instance as Shifted Emotion (459)
Happiness	42.5% (206)	12.2% (56)
Sadness	16.1% (78)	32.5% (149)
Fear	19.4% (94)	6.3% (29)
Anger	20.6% (100)	3.7% (17)
Surprise	1.4% (7)	0% (0)
Neutral	N/A	45.3% (208)

Table 2: Distribution of Emotion Shifts

Table 2 illustrates the distribution of emotion shifts among the five primary emotions. Out of 485 instances, 42.5% (206) have the original emotion as happiness, meaning that emotion expressions in happiness are often used in daily context; sadness, fear and anger emotions have around 20% instances as the original emotion respectively, with sadness taking up 16.1% (78), fear taking up 19.4% (94), and anger taking up 20.6% (100). The least used emotion expression is surprise, which takes up only 1.4% (7) of all entries in the corpus. For shifted emotion, neutral take up the highest percentage of 45.3%, sadness 32.5%, happiness 12.2%, fear 6.3% and anger 3.7%. There is no emotion shift in surprise. The results also suggested that the emotion shift after negation is different among the 23 emotion categories.

5 Discussion

The results suggested that negation leads to emotion shifts in most of the cases, which proves the importance of considering the interaction of negation marker and emotion expression when conducting automatic emotion analysis. Different emotion expressions showed emotion shifts in different patterns, which can be explained by their morphological, semantic, and pragmatic differences such as ironic expressions.

5.1 Prevalence of Emotion Shift after Negation

After the annotation and review process, we generated a graph to observe the trend of emotion shift after negation (see Figure 2).

Figure 2 shows the cases of emotion shift in this research. The blue crosses indicate the original emotions of the emotion expression before negation, while the red squares on the other end of the connecting black line indicate their corresponding emotions after negation. The y-axis marks the intensity of the emotions, from low, moderate, high, to complex. The x-axis marks the primary emotions of the entries, which include anger, sadness, fear, neutral, happiness and surprise.

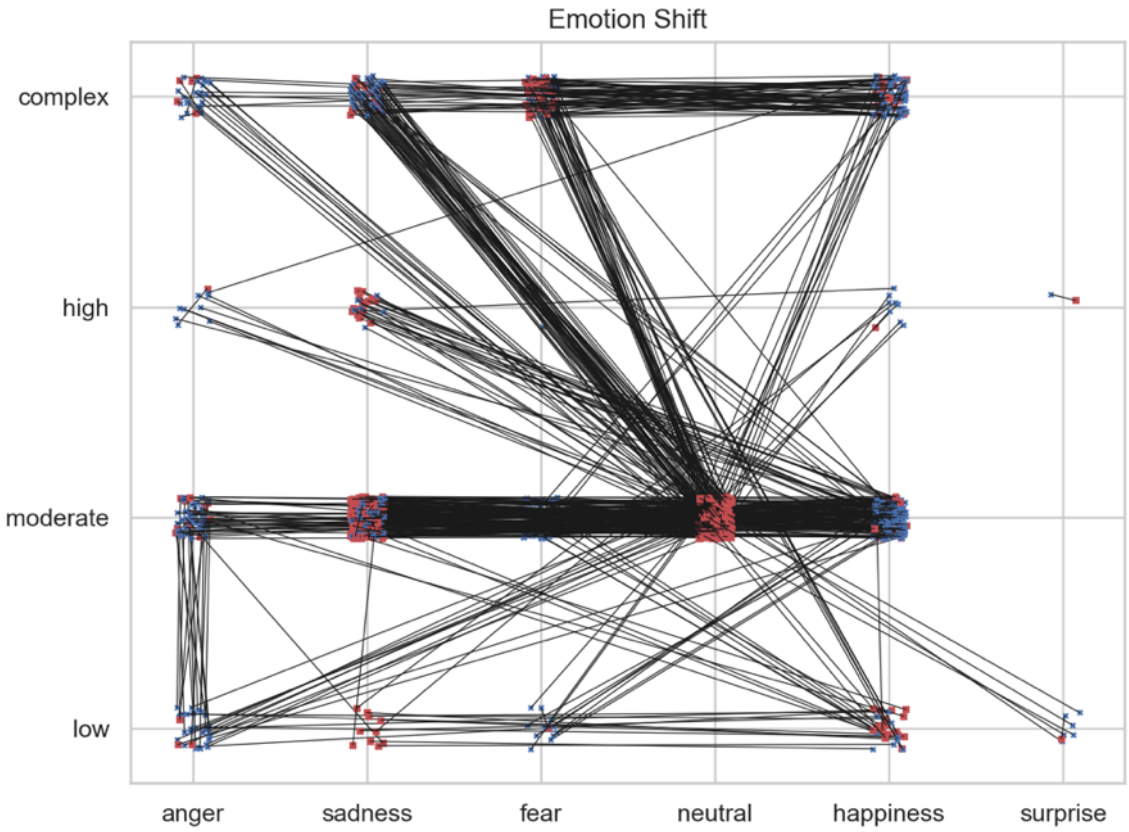

Figure 2: General trend of emotion shift after negation

The graph in Figure 2 exhibits a profusion of connected lines across emotions and degrees of intensity, which suggests the prevalence of emotion shift in negations of Chinese emotion expressions. As suggested in Table 1, 94.6% of the negated emotion expressions experienced a shift of emotion, which supports that the majority of the use of emotion words with negation markers involves an emotion shift, meaning that taking negation markers into account when conducting emotion classification is essential for accurate automatic emotion detection.

5.2 Emotion Shifts to Neutral

As shown in the graph in Figure 2, a concentration of red squares can be found in the column for "neutral" emotion, which reflects that negation enables an emotion shift from one to neutral in many cases. Statistically, out of the 459 emotion shifts, 208 of them are shifted to neutral, which takes up to over 45% of the total instances of emotion shifts.

In terms of the degree of emotion shift, emotion expressions, after being negated, are not necessarily reversed to their extreme opposites. More often, the negation leads to a shift from its primary emotion to a neutral emotion, which suggests that it is more likely that the process of negation in Chinese emotion expressions results in a "cancellation" in the emotion, or in other words, a less strong emotional state.

(3). 我几乎从来**不生气**，因为我认为没必要
1SG almost always **NEG angry**, because 1SG think NEG necessary
'I almost **never get angry**, because I think it's not necessary.'

The extracted example (3) is a demonstration of the negation marker '不' causing an emotion shift of the moderate-intensity anger expression *shengqi* change to a neutral emotion. Here, '不' (*bu*/ NEG) denotes the falsity of the author getting angry always, but does not suggest any other primary emotion besides not feeling angry, which means the emotion of "anger" is cancelled.

(4). 谢谢你给我打气让我**不紧张**
Thanks 2SG give 1SG cheer make 1SG **NEG nervous**
'Thank you for cheering me up so that I am **not nervous**.'

This is an example of the negation marker '不' (*bu*/ NEG) causing a shift of emotion from the complex fear plus sadness emotion expression, 紧张 (*jinzhang*/ nervous), to a neutral emotion. In the example, '不' (*bu*/ NEG) is the negator that modifies the adjective 紧张 (*jinzhang*/ nervous) by denying the feeling of nervousness. There are no other cues in context that could suggest the author was experiencing other primary emotions when saying the phrase 不紧张 (*bu jinzhang*/ not nervous). The emotion "nervous" is cancelled, resulting in a neutral emotional state.

(5). 莫言 称获奖**不兴奋**想尽快投入写作

3SG say win award **NEG excited** want soon devote in writing

'3SG said he was **not excited** about winning the award and wanted to get back to writing as soon as possible.'

In the above example, the negation marker '不' (*bu*/ NEG) has caused a shift of emotion. The emotion expression *xingfen* has a high-intensity happiness emotion, but is shifted to a neutral emotion when being negated by '不' (*bu*/ NEG). Similar to the previous examples, there are no cues of other primary emotions, and the presence of a negator means the feeling of excitement is false, which means the emotion of happiness would be shifted to neutral.

The aforementioned examples have showcased how a negation marker could shift the original emotion of an emotion expression to a neutral state, which explains the concentration of red squares distributed on the column of "neutral" emotion in Figure 2. However, this only happened to around 42.8% of the total entries. For the rest of the entries, some experience varied degrees of emotion shift or experience no emotion shift due to different reasons, for example the presence of textual cue for emotion shift, irony, morphological difference, semantical difference, double negation, and interrogative construction. In the analysed data, it is noticeable that for 17 of the emotion expression categories, emotions are most shifted to neutral emotion after negation. For the few exceptional cases, the presence of negation marker shifts the emotion expression to another primary emotion. For instance, for low-intensity happiness, majority are shifted to low-intensity sadness emotion after negation; for moderate-intensity happiness, majority are shifted to moderate-intensity sadness. These are due to the morphological feature where the common practice ties the negator to the adjective closely like a prefix in English. In other cases, they experience post-negation shifts of emotion to a different primary emotion because of their corresponding semantic usage. These cases include low-intensity fear, which are most shifted to moderate-intensity happiness (7 out of 11); happiness plus fear, which are most shifted to fear plus sadness (27 out of 48) and sadness plus fear emotions (14 out of 48); and anger plus fear, which are most shifted to happiness plus fear emotion (7 out of 14).

5.3 Morphological Difference

In Chinese, bu is the common negator which could denote the falsity of the modifying adjective, but at the same time could work like the negative English prefix *un-* that denotes negation and tends to connate negative emotion than neutral. For example, the adjective *buxingfen* (不兴奋) means "not excited", where *bu* is the modifier that negates the emotion expression *xingfen*, leading to an emotion shift to neutral emotion (see example (5)); but for the adjective *bukaisin* (不开心), it means "unhappy", where bu works like the English negative prefix *un-* , which is more bounded to the adjective *kaisin* (happy), leading to an emotion shift to sadness. The above discussion is not intended to imply the equivalence of the English negative prefix and the Chinese negator, rather, the emphasis lies in illustrating how the Chinese negator *"bu"* can exhibit similarity on conveying the negative sense beyond denoting falsity. In this research, the negated emotion expression *bukaisin* (不开心) has the largest number of emotion shifts to non-neutral emotions, where most of them are reversed from moderate-intensity happiness to moderate-intensity sadness. An example is:

(6). **不开心**睡一觉，就让它过去吧。

NEG happy take one nap just let 3SG go SFP

'If you feel **unhappy**, just take a nap and let it go.'

As the negation marker *bu* in *bukaisin* (不开心) is morphologically closely bounded to the adjective, it implies the "unhappy" emotion. To negate the emotion *kaisin* (happy), it is a more common practice for Chinese native speaker to say *meiyoukaisin* (没有开心), which simply negates

the modifying adjective without adding a sadness emotion to it.

5.4 Semantic Difference

Some emotion expressions experienced non-neutral emotion shift after being negated, due to their semantic meaning, for example, the word *gaoxing* (高 兴), after being negated by the negation marker *bu*, can lead to different emotion shifts including anger and sadness, as it has more than one semantic meaning.

(7). 这个点自然醒是不是有点过分了, 我老妈明显的**不高兴**了
this time naturally wake up is it not a bit over -LE, 1SG mom obvious -DE **NEG happy** -LE
'Isn't it a bit too much to wake up naturally at this time? My mother is obviously **not happy**'

(8). 今儿收到一条信息, 我一下就**不高兴**了[怒]
today receive NUM CL message 1SG NUM CL just NEG happy -LE [anger emoji]
'I received a message today and I am **not happy** all of a sudden [angry]'

(9). 心里还是**不高兴**。改变使我难过, 不变使我悲伤。
heart still **NEG happy** changes make 1SG unhappy, not change make me sad
'Down deep I am still **not happy**. Change makes me unhappy, and staying the same makes me sad.'

(10). 感冒了，**不高兴**
caught cold -LE **NEG happy**
'I caught a cold. I am **not happy**.'

Comparing Example 7, 8, 9 & 10, in Example 7 & 8, the negated emotion expression *bugaoxing* (不高兴/ not happy) has the emotion of frustration and dissatisfaction. In Example 9 & 10, the negated emotion has the emotion of sadness. This shows that the word *bugaoxing* (不高兴/ not happy) has more than one semantic meaning, and the actual emotion conveyed shall be interpreted by taking the full context into account.

Another example is the word *ciyi* (迟 疑/ hesitant), which is a low-intensity fear emotion expression. When being negated by the negation marker *bu* (不/ NEG), it means not hesitant, the feeling of being able to make decisions immediately. The assertion of '迟 疑' (hesitant) means the negation of '松快' (readily), vice versa. There is not a neutral middle point between the two feelings semantically, making it experience an emotion reversal to moderate-intensity happiness after negation.

Same happens to the happiness plus fear adjective. The word *bufangxin* (不放心/ not rest assured) has the same meaning as the word *danxin* (擔心/ concerned), which is a fear plus sadness emotion. Again, there is no neutral middle point of emotion state between the two emotions semantically, which forms a fixed emotion reversal of the negation of *fangxin* (放心/ rest assured), from happiness plus fear to fear plus sadness.

(11). 一直对这种餐具**不放心**。
always towards this kind tableware **NEG rest assured**
'I have always been **concerned** about this kind of tableware.'

Another happiness fear word 自 信 (*zixin*/ confident) also has a fixed emotion shift to sadness plus fear, as the assertion of *zixin* means the negation of the sadness plus fear emotion expression *zibei*, vice versa.

(12). 我不放弃爱的勇气，我**不怀疑**会有真心
1SG NEG give up love -DE courage, 1SG **NEG doubt** will have true love
'I don't give up the courage to love, I **believe** that there will be true love'

In the anger plus fear emotion category, the word *huaiyi* also has a fixed emotion shift from anger plus fear to happiness fear, as not feeling doubtful means the same as trustful.

(13). 你这么漂亮怎么都**不自信**呢？
2SG this beautiful how still **NEG confident** SFP
'How come you are still **not confident** when you are so beautiful?'

5.5 Irony

Szenberg and Ramrattan (2014) defined irony in speech as utterance that means the opposite to its literal meaning, which is a basic interpretation of what Grice's approach (1975) has suggested. In our dataset, there are also 2 examples of ironic

sentences that brought no change to emotion shift after the negation of emotion expression.

(14). 我让他帮我拍照，几十张照片只有最后一张是正常的，脸他妈还是蓝的。
[呵呵] 我， 一点也**不生气**。
I make him help me take photo, tens CL photo only last one CL is normal -DE, face fucking is blue -DE I, a bit YE **NEG mad**
'I asked him to take a photo for me…… Dozens of photos and only the last one is normal, and the face is even fucking blue. [smiley emoji] I, am not mad at all.'

(14) is an example of irony found in our project corpus. The speaker explicitly used a simple negation '不' (*bu*/ NEG) *to* modify the moderate-intensity anger emotion expression 生气 (*shengqi*/ mad). Under simple negation, the mitigation effect of the negator should cause an emotion reversal from moderate-intensity anger to neutral emotion. However, the author has also included in the context that he was not satisfied with the pictures, which suggests the author was actually feeling mad, despite claiming the opposite. The author is demonstrating the use of irony here, where he said the opposite of what he was actually feeling, to create an ironic contrast. To make the underlying sense of irony more explicit, the author has also made use of the smiley emoji (i.e. 🙂). The use of a smiley emoji here mismatched the negative valence of the sentence, which is a technique that is commonly used to show irony and dissatisfaction (Weissman and Tanner, 2018).

5.6 Emotion Shift due to Textual Cue

The present study aims to investigate the emotion shift of negation in social media discourse, but other than negation, it is also worth noticing that the surrounding text contributes to the emotion classification at discourse level, although not the focus of the present paper.

(15). 所以对方是德国球队，就会**不恐惧**了，稳的
So opponent be German team (for ballgame), then will **NEG afraid** SFG, stable DE
'So if the opponent is a German team, we won**'t be afraid**. It's stable.'

(15) is an example of a shift of emotion from high-intensity fear to low-intensity happiness. The negation marker *bu* negates the fear emotion of the expression *kongju*, which denotes the falsity of feeling high-intensity fear. By just reading the negated expression alone, the emotion might be neutral. However, the adjective *wen* on the latter part of the text entry served as a cue that the author thinks the situation is stable, which means the author did not experience the emotion of fear, and also felt relaxed under the stable situation. This indicates the complexity of emotion at a discourse level and can be directions for future studies.

6 Conclusion

The present paper addresses the question: what kind of emotion shift does negation bring to emotion expressions in Modern Chinese online discourse?

In general, a negation marker denotes falsity to an emotion expression, which leads to an emotion shift to a neutral emotion state. There are also other possible emotion shifts that are dependent to its morphological, semantic, pragmatic features. On morphological level, unlike English where negating modifiers (such as "not") and negating prefix (such as "un-") are more distinct in structure, such distinction is relatively not clear in Chinese. The negating device *bu* (不/ NEG) can denote falsity of an emotion (e.g. 不生气 / not mad, see example (3)), and also contribute on constructing a negative adjective (e.g. 不开心 / unhappy, see example (6)) that leads to a corresponding, fixed post-negation emotion shift. On semantic level, diverse interpretation is possible for some emotion words, for example *bugaoxing* (不高兴/ not happy, see examples (7), (8), (9), (10)), which could imply anger or sadness depending on the surrounding context. Fixed post-negation emotion shift also applies when an emotion expression's assertion is an implication of the negation of another emotion expression, for example the pairs: *fangxin* (rest assured) and *danxin* (worried); *zixin* (confident) and *zibei* (self-abased); *huaiyi* (suspicious) and *anxin* (relaxed). On pragmatic level, structural difference leads to different kinds of emotion shift. For instance, in ironic expressions, negators do not bring emotion shift to its original emotion. The observation in the present paper illustrates the different possibilities of shifts of emotions that negation markers can bring forth. This observation

can provide insights on automatic emotion detection development for improvements on accuracy and robustness. As the size of selected data for this research project is limited due to the overwhelming size of advertisements that shall be eliminated from conversational text analysis, extensive data and examples from different social media would be needed for a more comprehensive and robust comparison. Future research may consider using a larger corpus across different Chinese social media platforms.

{sakazi, skhoja}@iba.edu.pk

Abstract

Traditional document retrieval for Urdu faces challenges due to the language's complex morphological structure and limited resources. While existing approaches rely heavily on term-matching techniques, they often fail to capture semantic relationships effectively. This paper introduces the Urdu Proximity Enhanced Retrieval Framework (UPERF), which combines traditional retrieval models with modern embedding techniques through an optimized weighting scheme. Using the UND corpus of 2.8M documents, we evaluate various configurations of Word2Vec, FastText, Doc2Vec, and mBERT models alongside traditional approaches. Our framework employs grid search to determine optimal weights for combining TF-IDF, BM25, and embedding-based proximity measures. The results show that Word2Vec with stemmed text preprocessing and cosine similarity achieves a Recall@5 of 0.85, significantly outperforming baseline methods. Analysis of document rankings demonstrates that our weighted approach better aligns with human relevance judgments compared to individual methods.

1 Introduction

Document retrieval is a fundamental task in information retrieval that involves fetching relevant documents from a large corpus based on a user's query. This task is particularly challenging in low-resource languages like Urdu, the official language of Pakistan, spoken by millions globally[1]. The scarcity of annotated data and linguistic resources further complicates document retrieval in Urdu (Iqbal et al., 2021). Traditional vector space models, such as TF-IDF, are commonly used for document retrieval. However, their reliance on term frequency limit their effectiveness in capturing semantic nuances (Kazi and Khoja, 2021) (Kazi and Khoja, 2024) (Rasolofo and Savoy, 2003) (Beigbeder and Mercier, 2005). The need for effective document retrieval in Urdu has become increasingly critical, especially with the surge in online educational materials and digital content in Urdu following the COVID-19 pandemic (Kazi et al., 2023). Previous efforts in document retrieval for low-resource languages have primarily focused on traditional approaches, such as boolean retrieval and TF-IDF (Magueresse et al., 2020)(Novak et al., 2022). While these methods are effective to some extent, they often fall short in capturing the deeper semantic relationships within the text. Research efforts in Urdu information retrieval have recognized the critical need to build specialized test collections to build and evaluate effectiveness of IR models, ranking algorithms, and various natural language processing techniques (Shaukat et al., 2022). However, inherent linguistic differences between Urdu and English, including different syntactic and morphological structures, script variations, and a scarcity of resources, pose significant obstacles to the direct application of English-based algorithms in Urdu language processing (Nasim and Haider, 2022). This study investigates enhancing Urdu document retrieval by incorporating proximity measures with established models like BM25 (Robertson et al., 2009) and embedding-based techniques. Initially, documents were retrieved using traditional models such as TF-IDF and BM25. The relevance of these documents was then refined by integrating proximity-based scores, enabling accurate ranking. A grid search was employed to optimize the weighting of proximity measures during the re-ranking process, re-

[1]https://www.ethnologue.com/language/urd/

sulting in a more effective document retrieval approach for Urdu. By incorporating proximity measures, the system addresses the limitations of traditional term-matching models and improving the ranking of relevant documents.

The remainder of this paper is structured as follows: Section 2 provides a related work, Section 3 outlines the methodology, Section 4 presents the results, and Section 5 concludes the paper.

2 Related Work

This section presents a brief description of the previous research on Urdu document retrieval and the impact of various algorithms on retrieval performance. Traditional approaches to document retrieval, such as Boolean retrieval and vector space models , while effective in specific contexts, often fail to capture deeper semantic relationships within text (Aronson et al., 1994) (Dang et al., 2024). Several studies have addressed these limitations by introducing more advanced techniques such as semantic distance measures, and query expansion techniques (Jiang et al., 2019). However, as evident from the literature review, the impact of distance measures on Urdu document retrieval remains largely unexplored (Daud et al., 2017). Although distance measures are fundamental in determining how documents are compared and ranked in response to user queries, directly influencing the accuracy and relevance of retrieved results. (Riaz, 2008) aimed to establish a baseline for Urdu IR by creating a test reference collection for Urdu. The study followed the TREC methodology (Harman, 1993) and evaluated models such as Boolean retrieval and the Vector Space Model (VSM). This work highlighted the need for specialized test collections for Urdu IR to improve evaluation performance. (Rasheed and Banka, 2018)investigated the impact of query expansion techniques for improving information retrieval (IR) in the Urdu language. The study emphasized that the inherent morphological complexity of Urdu and its scarcity of linguistic resources make traditional IR methods less effective. To address this, the authors explored different query expansion techniques to enhance the retrieval of relevant documents. (Rasheed et al., 2021b) evaluated different models for query expansion in Urdu IR, such as Pseudo-Relevance Feedback (PRF) and Automatic Query Expansion. They showed significant improvements in retrieval precision using models like KL, Bo1, and Bo2, but also emphasized the challenges posed by Urdu's linguistic complexities. (Rasheed et al., 2021a) discussed the development of an Urdu test collection based on TREC guidelines. They emphasized the importance of proximity-based methods, especially when combined with BM25, in enhancing retrieval effectiveness in low-resource languages. (Shaukat et al., 2022) developed a comprehensive benchmark for evaluating information retrieval systems in Urdu using TREC guidelines. The study introduced proximity-based models to improve retrieval performance by incorporating non-binary relevance judgments across a large collection of Urdu news documents. This work underscored the need for robust test collections that go beyond binary relevance measures, which are essential for addressing the challenges posed by Urdu's complex linguistic structure. (Shoaib et al., 2023)presented a Context-Aware Urdu Information Retrieval System aimed at improving the precision and recall of search results in Urdu. This system addresses challenges unique to the Urdu language, such as word sense ambiguity (WSA), stemming, and complex morphology, by leveraging Web Semantic Search Engine (WSSE) technologies. The authors developed an ontology-based retrieval system that uses quad formats rather than triplets, incorporating subject, object, predicate, and context to better handle ambiguity in queries. While these studies represent significant advancements in Urdu document retrieval, a notable gap remains in evaluating the impact of distance measures on document retrieval performance. Although techniques like query expansion and semantic distance have been explored, a comprehensive analysis of how various distance metrics enhance document retrieval for Urdu has yet to be conducted (Asim et al., 2019). This research aims to address that gap by optimizing distance measures within established models such as BM25, TFIDF and embedding-based techniques to improve retrieval effectiveness for Urdu.

3 Methdology

This section outlines the approach undertaken in developing the Urdu Proximity Enhanced Retrieval Framework (UPERF), which incorporates proximity measures into traditional and embedding-based models for Urdu document retrieval. The methodology is divided into several stages:

- Data preprocessing
- Traditional retrieval
- Embedding generation
- Enhanced score calculation
- Document re-ranking
- Evaluation

3.1 Data preprocessing

The input data includes both Urdu documents and a user query. Before proceeding with the retrieval, the data undergoes a preprocessing stage where URLs, non-Urdu alphabets, punctuation marks, and diacritics are removed to ensure clean text. We used the Stanza[2] library from Stanford NLP for tokenization, stopword removal, stemming, and lemmatization to normalize the text. This process reduces words to their base forms and ensures uniformity in document representation.

3.2 Traditional Retrieval

After preprocessing, we constructed feature matrices using unigrams, bigrams, and trigrams to capture various levels of n-gram information, essential for handling multi-word queries effectively. The documents were then transformed into vectors using the Term Frequency-Inverse Document Frequency (TF-IDF) metric. The TF-IDF metric is computed as:

$$\text{TF-IDF}(t, d) = \text{TF}(t, d) \cdot \log\left(\frac{N}{\text{DF}(t)}\right) \quad (1)$$

where:

- t is the term(unigram, bigram, or trigram),
- d is the document,
- N is the total number of documents, and
- DF(t) is the number of documents containing the term

Additionally, we calculated BM25 scores, which are based on a probabilistic model by considering document length and term saturation. The BM25 score is calculated as:

$$\text{BM25}(q, d) = \sum_{i=1}^{n} \log\left(\frac{N - \text{DF}(t_i) + 0.5}{\text{DF}(t_i) + 0.5}\right) \cdot \frac{(k_1 + 1) \cdot \text{TF}(t_i, d)}{k_1 \cdot (1 - b + b \cdot \frac{|d|}{\text{avgdl}}) + \text{TF}(t_i, d)} \quad (2)$$

where:

- q is the query,
- d is the document,
- k_1 and b are BM25 parameters, and
- avgdl is the average document length.

These two scores TF-IDF and BM25;are used to identify relevant documents in the first stage of retrieval.

3.3 Embedding Generation

To enhance retrieval beyond traditional scoring, we generated embeddings for the documents and queries using Word2Vec, FastText, and doc2vec models trained on a large Urdu corpus. Additionally, we used a pre-trained mBERT model[3] to generate contextual embeddings. These embeddings capture the semantic meaning of the words. For generating document embeddings, we applied TF-IDF Weighted Averaging to the word embeddings within each document, giving more importance to words with higher TF-IDF scores. We trained these embeddings on the UND collection (Shaukat et al., 2022) to further finetune them for Urdu document retrieval.

3.4 Proximity Score Calculation

Proximity measures are calculated to determine the semantic similarity between the query embeddings and document embeddings. The following proximity measures were used

[2]https://stanfordnlp.github.io/stanza/

[3]https://huggingface.co/google-bert/bert-base-multilingual-uncased

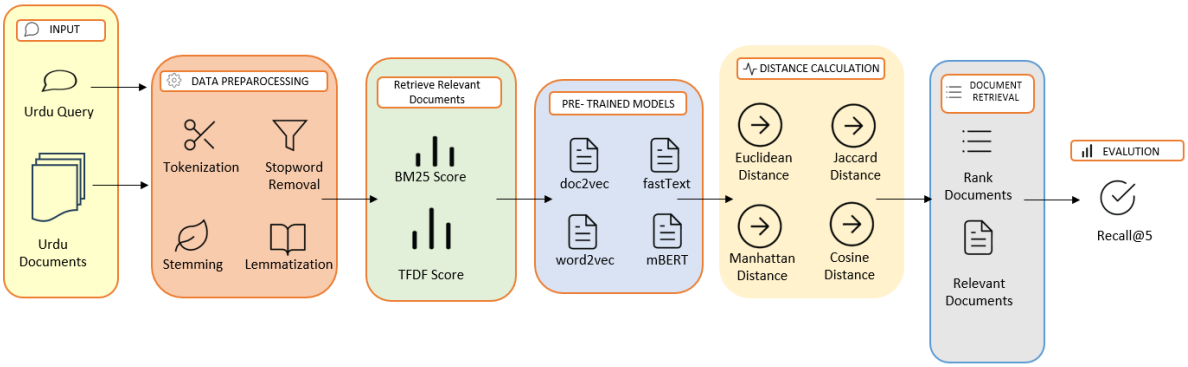

Figure 1: Urdu Proximity Enhanced Retrieval Framework (UPERF)

- Euclidean Distance

$$d_{\text{Euclidean}}(A, B) = \sqrt{\sum_{i=1}^{n}(A_i - B_i)^2} \quad (2)$$

where 'A' and 'B' are the embedding vectors of the query and document, respectively.

- Manhattan Distance

$$d_{\text{Manhattan}}(A, B) = \sum_{i=1}^{n}|A_i - B_i| \quad (3)$$

- Cosine Distance (based on Cosine Similarity)

$$\text{Cosine Similarity}(A, B) = \frac{A \cdot B}{||A|| \cdot ||B||} \quad (4)$$

$$\text{Cosine Distance} = 1 - \text{Cosine Similarity} \quad (5)$$

3.5 Weighted Combination of Scores

The final relevance score for each document is calculated by combining the traditional retrieval scores (TF-IDF and BM25) with the proximity-based scores. The combination is done using a weighted formula:

$$\text{Final Score} = \alpha \cdot \text{TF-IDF} + \beta \cdot \text{BM25} + \gamma \cdot \text{Proximity Score} \quad (6)$$

α, β, and γ the weights assigned to the TF-IDF, BM25, and Proximity Scores, respectively. These weights are optimized using grid Search to find the best combination that maximizes retrieval performance. The grid search tests multiple values ofα, β, and γ and selects the combination that yields the highest performance metric.

3.6 Document Re-Ranking

Once the final score is computed, the documents are re-ranked based on their final relevance score. The higher the final score, the more relevant the document is considered to the query, and it is placed higher in the resultant ranking.

4 Experiments and Results

This section first introduces the dataset used in this study, followed by a detailed description of the series of experiments conducted.

4.1 Dataset

The dataset used in this research is the Urdu News Document (UND) corpus (Shaukat et al., 2022), consisting of 2,887,169 news articles collected from 11 newspapers, covering topics such as law, government, sports, and international relations as shown in Table 1. The documents were scraped, cleaned, and converted to TREC-Standard SGML format, including fields like document ID, title, publication date, and full text. The corpus was further processed for relevance judgments using IR techniques such as BM25, TF-IDF, and Boolean similarity, making it suitable for evaluating retrieval techniques.

4.2 Evaluation Metrics

For the evaluation of our retrieval framework, we utilize Recall@5 to measure performance.

Recall@5 is a metric used to evaluate how well the system retrieves relevant documents within the top 5 results. It is defined as

Table 1: Urdu News Document (UND) Corpus Overview

Aspect	Description
Dataset Name	UND Corpus
Documents	2,887,169
Source	11 newspapers
Topics	Law, govt, sports, etc.
Format	TREC-standard SGML
Fields	ID, Title, Date, Text
Queries	105 queries (35 base, 3 variants each)
Judgments	Highly Relevant Fairly Relevant Marginally Relevant Irrelevant
IR Methods	BM25, TF-IDF, Boolean
Purpose	Retrieval, proximity, embeddings

the fraction of relevant documents that are retrieved among the top 5 documents returned by the system. The formula for Recall@5 is as follows:

$$\text{Recall@5} = \frac{\text{Relevant documents in top 5}}{\text{Total relevant documents}} \tag{7}$$

4.3 Experimental Setup

Our study followed a systematic approach to evaluate various retrieval models and their configurations. To ensure comprehensive assessment, we designed multiple experimental combinations, testing different aspects of the retrieval process ranging from embedding dimensions to similarity measures. Table 2 presents the complete experimental framework, where each component (A through F) represents a different aspect of our evaluation setup. From component A through F, we performed multiple experimental combinations by systematically varying each parameter. These combinations were derived from: 3 embedding models with varying dimensions (100, 150, 200) and window sizes (3, 5, 7), 2 traditional models, 1 contextual model, 3 preprocessing variants, 2 query types, and 4 similarity measures. All experiments were conducted on the UND corpus and evaluated using Recall@5.

Table 2: Experimental Configurations and Parameters

Exp ID	Component	Parameters
A	Embedding Models	
	A.1 Word2Vec	Vector size: {100, 150, 200}
	A.2 FastText	Window size: {3, 5, 7}
	A.3 Doc2Vec	
B	Traditional Models	
	B.1 TF-IDF	N-grams: {bigram, trigram}
	B.2 BM25	Default parameters
C	Contextual Model	
	C.1 mBERT	Pre-trained weights
D	Preprocessing	
	D.1 Raw Text	No modification
	D.2 Stemmed	Root form reduction
	D.3 Lemmatized	Canonical form
E	Query Types	
	E.1 Single-word	One word per query
	E.2 Multiple-word	Multiple words per query
F	Similarity Measures	
	F.1 Cosine	Angular similarity
	F.2 Euclidean	L2 distance
	F.3 Manhattan	L1 distance
	F.4 Jaccard	Set overlap

4.4 Performance Analysis

The experimental results, presented in Table 3, demonstrate varying performance across different models, preprocessing techniques, and query types. Word2Vec (vs150_ws3) emerged as the best performing model, achieving a peak Recall@5 of 0.85 with stemmed text and multiple-word queries. This performance can be attributed to its ability to effectively capture semantic relationships in the Urdu text. The mBERT model showed strong performance with multiple-word queries (0.79 with stemmed text) but struggled with single-word queries (0.33), indicating its dependence on contextual information. Among traditional approaches, TF-IDF(Trigram) demonstrated moderate performance (0.76 for stemmed text, multiple-word queries), while BM25 achieved lower scores (0.36). FastText, despite its subword-level processing capability, peaked at 0.74, not surpassing Word2Vec's performance. Doc2Vec consistently underperformed, reaching only 0.23 at its highest, suggesting limitations in document-level embedding for fine-grained retrieval tasks. Across all models, two consistent patterns emerged: stemmed text outperformed both raw and lemmatized preprocessing, and multiple-word queries consistently yielded better results than single-word queries. This suggests that reducing morphological variations while maintaining adequate context is crucial for effective Urdu document

retrieval.

Table 4: Comprehensive Weight Distribution Analysis using Word2Vec (vs150_ws3) with Cosine similarity for proximity score. All scores normalized to [0,1] range before combining.

Config. Type	Weights (α,β,γ)	Recall@5
Individual Baselines:		
TF-IDF only	(1.0, 0.0, 0.0)	0.45
BM25 only	(0.0, 1.0, 0.0)	0.48
Proximity only	(0.0, 0.0, 1.0)	0.85
TF-IDF Enhanced:		
Heavy TF-IDF	(0.8, 0.1, 0.1)	0.50
Moderate TF-IDF	(0.6, 0.2, 0.2)	0.55
Light TF-IDF	(0.4, 0.3, 0.3)	0.75
BM25 Enhanced:		
Heavy BM25	(0.1, 0.8, 0.1)	0.52
Moderate BM25	(0.2, 0.6, 0.2)	0.58
Light BM25	(0.3, 0.4, 0.3)	0.73
Proximity Enhanced:		
Heavy Prox.	(0.1, 0.1, 0.8)	0.82
Moderate Prox.	(0.2, 0.2, 0.6)	0.80
Light Prox.	(0.3, 0.3, 0.4)	0.78
Balanced:		
Equal weights	0.33, 0.33, 0.34	0.72

4.5 Weighted Distribution Analysis

The comprehensive analysis of our weighted combination formula reveals interesting patterns across different weight distributions. As shown in Table 4, we first established baselines with individual components: TF-IDF (0.45), BM25 (0.48), and Word2Vec proximity with cosine similarity (0.85). The weight variations demonstrate that heavily emphasizing a single component (0.8 weight) generally underperforms balanced approaches. TF-IDF emphasis shows gradual improvement as weights become more balanced, from 0.50 (heavy) to 0.75 (light emphasis). Similar patterns emerge with BM25 emphasis, improving from 0.52 to 0.73. Notably, proximity-based configurations consistently outperform pure lexical approaches. Even with heavy proximity emphasis (0.8 weight), the system maintains strong performance (0.82), though slightly below the pure proximity baseline (0.85). This suggests that while embedding-based similarity is crucial, some contribution from traditional retrieval methods helps maintain robust performance. The balanced configuration (0.33, 0.33, 0.34) achieves 0.72, indicating that equal weighting of components may not be optimal. The best performing combination maintains a slight emphasis on proximity while balancing traditional approaches.

4.6 Document Re-Ranking Analysis

To evaluate the practical effectiveness of different ranking methods, we analyzed two representative queries from distinct domains in the UND corpus. Table 5 presents a comparison of rankings across different approaches against human-judged ground truth.

For the sports domain query "پاکستان اور بھارت کا میچ" (Pakistan-India Match), we observe varying ranking behaviors. Traditional methods (TF-IDF+BM25) prioritized term matching, placing document 2362784 (fairly relevant) first, while relegating the highly relevant document 2368653 to fourth position - likely due to exact matches of terms "بھارت" and "میچ". The Word2Vec approach demonstrated better semantic understanding by ranking the highly relevant document first, though with some inconsistencies in subsequent rankings. The combined weighted approach (α=0.3, β=0.3, γ=0.4) shows interesting trade-offs. While it ranked a fairly relevant document (2378593) ahead of the highly relevant one, it maintained better overall relevance distribution in subsequent positions. This suggests the weighting scheme helps balance lexical and semantic signals, though not perfectly replicating human judgment patterns. A similar pattern emerges for the medical domain query "ڈاکٹروں کی ہڑتال" (Doctors Strike). Each method shows distinct ranking behaviors, with the combined approach demonstrating improved but imperfect ranking. The placement of document 2392190 (fairly relevant) before 2817668 (highly relevant) indicates that even weighted combinations of different retrieval signals may prioritize documents differently than human assessors.

These results demonstrate that while our weighted framework improves upon individual approaches, but future work could explore more sophisticated techniques such as dynamic weighting schemes, contextual relevance

Table 3: Document Retrieval Results on UND Dataset for Various Query Types and Preprocessing Techniques

Model	Preprocessing	Query Type	Cosine	Euclidean	Jaccard	Manhattan
Word2Vec (vs150_ws3)	Raw Text	Multiple Word	0.82	0.80	0.75	0.81
		Single Word	0.40	0.39	0.35	0.40
	Stemmed Text	**Multiple Word**	**0.85**	0.83	0.79	0.84
		Single Word	0.42	0.41	0.37	0.42
	Lemmatized Text	Multiple Word	0.83	0.81	0.76	0.82
		Single Word	0.41	0.40	0.36	0.41
mBERT	Raw Text	Multiple Word	0.78	0.72	0.74	0.76
		Single Word	0.33	0.30	0.31	0.32
	Stemmed Text	Multiple Word	0.79	0.73	0.75	0.77
		Single Word	0.34	0.31	0.32	0.33
	Lemmatized Text	Multiple Word	0.78	0.72	0.74	0.76
		Single Word	0.33	0.30	0.31	0.32
TF-IDF (trigram)	Raw Text	Multiple Word	0.75	0.75	0.56	0.75
		Single Word	0.36	0.36	0.26	0.36
	Stemmed Text	Multiple Word	0.76	0.76	0.57	0.76
		Single Word	0.37	0.37	0.27	0.37
	Lemmatized Text	Multiple Word	0.75	0.75	0.56	0.75
		Single Word	0.36	0.36	0.26	0.36
FastText (vs200_ws7)	Raw Text	Multiple Word	0.73	0.72	0.68	0.73
		Single Word	0.35	0.34	0.32	0.35
	Stemmed Text	Multiple Word	0.74	0.73	0.69	0.74
		Single Word	0.36	0.35	0.33	0.36

modeling, or learning-to-rank approaches to better align automated rankings with human relevance assessments. The current framework establishes a foundation for developing such advanced retrieval mechanisms for the Urdu language.

5 Conclusion

This study presents UPERF, a comprehensive framework for Urdu document retrieval that effectively bridges traditional and modern approaches. Our experimental results across multiple models and configurations demonstrate

Table 5: Ranking Analysis Across Different Methods with Ground Truth Comparison

Query	**Ground Truth (Top 5)**	**TF-IDF+BM25 (Top 5)**	**Word2Vec (Top 5)**	**Combined (Top 5)**
پاکستان اور بھارت کا میچ (Pakistan-India Match)	2368653[HR], 2362784[FR], 2378593[FR], 2008560[MR], 556316[IR]	2362784[FR], 2008560[MR], 556316[IR], 2368653[HR], 2378593[FR]	2368653[HR], 2378593[FR], 2362784[FR], 2008560[MR], 556316[IR]	2378593[FR], 2368653[HR], 2362784[FR], 2008560[MR], 2367037[MR]

HR: Highly Relevant, FR: Fairly Relevant, MR: Marginally Relevant, IR: Irrelevant

several key findings: (1) embedding-based proximity measures, particularly Word2Vec with cosine similarity, significantly outperform traditional term-matching approaches, (2) stemmed text preprocessing consistently yields better results across all models, and (3) our weighted combination approach achieves better alignment with human relevance judgments compared to individual methods.The framework's effectiveness is particularly evident in the re-ranking analysis, where it successfully maintains the proper ordering of documents based on relevance levels while balancing both lexical and semantic matching. This is crucial for practical applications where retrieval accuracy directly impacts user experience. Future work could explore integration with newer transformer architectures like BERT and RoBERTa, fine-tuned specifically for Urdu. Additionally, incorporating query expansion techniques and pseudo-relevance feedback could further enhance retrieval performance for complex and ambiguous queries. These developments, combined with UPERF's strong foundation, hold promise for advancing information retrieval capabilities in low-resource languages.

{judith.azcarraga, kate_justine_ermitano, steven_castro, mark_adrian_escobar}@dlsu.edu.ph

Abstract

Physical and mental health monitoring of children is important and necessary in every country. However, in developing countries like the Philippines, the general health wellness of children in several public schools are not regularly monitored due to lack of healthcare professionals and other resources. This research presents a multi-lingual healthcare chatbot that can monitor the physical and mental wellness of young children in every school. Empowered by Artificial Intelligence, the chatbot is capable of conversing in two major Philippine languages - Filipino and Bisaya as well as English. The chatbot will allow for more frequent and regular health and wellness check among children, even without the presence of a medical doctor or even a full-time school nurse and may identify children who may need specific interventions, whether psychological, medical, nutritional, or mere social-cultural support.

1 Introduction

Monitoring the health and wellness of children is one of the main challenges in a developing country like the Philippines. Schools would have been a good venue for the government to monitor the general well-being of young children. Unfortunately, not all schools have enough resources to conduct routine checks on students, let alone have at least one full-time nurse in charge of the school clinic. Still, even with yearly check-ups, some check-ups are not done in a sufficient manner. When special medical attention is needed, diagnosis becomes futile without a systemic and specific assessment.

Assuming that the problem of inaccessible healthcare still persists in schools, the proposed project will perform a routine wellness check - that is quick and efficient - on every child, beginning in the 1st and 2nd grades. Students with urgent and specialized needs will be isolated for further assessment and diagnosis, now accompanied by a nurse.

The Philippines, with a population estimated at around 104.9 million as of 2017, according to The Philippines Health System Review, has about 40% of its population consisting of minors (World Health Organization). From that percentage, 33% of them experience stunted growth under the age of 5 because of malnutrition. The Philippines is severely lacking in healthcare professionals. The Department of Health (DOH) claimed that there is a 1:1,500 doctor-to-patient ratio. With that, it can be deduced that there are approximately 110,520 doctors in the Philippines.

Based on the study headed by the National Health Institute of the University of the Philippines, an estimated 6 out of 10 Filipinos who died due to health complications and issues have not even seen a doctor (Oxford Business Group, 2012). Furthermore, poverty makes it increasingly difficult to have access to available yet affordable healthcare, causing families to set aside regular health check-ups for their children.

Monitoring children's general well-being involves not only their physical health but also their mental health. With routine checks, from food and sleep to safety and illnesses, children will be assessed from head to toe to ensure that their growth is normal. Their milestones will be checked via their height, weight, and head circumference, making sure the measurements are right for their age and sex. Moreover, these routine checks can detect signs and symptoms of possible diseases and conditions.

Technology, specifically when powered with Artificial Intelligence (AI), can be used to ease the process of assessing multiple children in one run. The Microsoft Healthcare Chatbot (Azure, n.d.),

one of the pioneers of this project, is one example of AI assisting healthcare professionals in conversing with patients using natural language while also gathering and processing information that leads to a calculated diagnosis. Other healthcare chatbots also surface with different features yet similar functions. Sensely can infer diagnosis based on speech, text, image, and video data, while Infermedica can do the same but with access to online browsers and mobile phones. Buny Health recommends solutions once the questionnaire has been answered, and Babylon Health books personal health consultations with a doctor based on medical history and common health knowledge (Mesko, 2023).

In order to provide access to regular health checks in public schools, technology may be utilized in monitoring the physical and mental wellness of young children. This research presents a multi-lingual health monitoring system for public school children assisted by a healthcare chatbot that is capable of interpreting audio and text input and conversing in two major Philippine languages – Filipino and Bisaya, and in English.

2 Related Works

A chatbot that specializes in triage, which is achieved by conversing with patients to determine their condition is presented in the work of Ghosh, Bhatia, and Bhatia (2018). Once the results have been calculated, the chatbot will report to the patient if they can perform self-care, seek a general practitioner, or receive urgent care.

Another similar study is a chatbot that can converse in Bangli, with a knowledge base that can fetch and store session data and health information and multiple machine learning algorithms such as decision trees, random forest, multinomial NB, SVM, AdaBoost, and k Nearest Neighbor. With a knowledge base and machine learning, the chatbot can monitor user health data to diagnose and report potential health hazards and diseases to the user (Rahman, et al., 2019).

Other than chatbots, a recommender system may simulate a human physician in a clinical setting. Users may ask questions or suggestions that are outside the healthcare assessment, such as the clinic, disease prevention, and booking physical examinations. This system consists of HOLMes (for module communication and logic operation), IBM Watson (deep mining for text mining), NLP (to make conversations very human-like), and Spark (the computational cluster). The conversation is generated by the IBM Watson Conversation APIs and uses the dataset by the C.M.O. center to make diagnoses. Lastly, the output of the system is a histogram ranking all the possible diseases to be assessed by a physician (Amato et al, 2017).

Mental health of an individual is as equally important as the physical health. There are several mental health chatbots such as Woebot, Wysa and Flow that have been developed. Woebot is a digital therapist that utilizes cognitive behavioral therapy and comes with daily check-ins suitable for both adult and adolescent users. The chatbot uses multiple choice, with some questions being open to text input from the user (Woebot Health, 2023).

Wysa, on the other hand, makes suggestions to guide users on self-care exercises and keeps track of the user daily. However, the added features, such as consulting with human therapists have some fees and a lot of users may not be able afford for therapy (Inkster & Subramanian, 2018).

Lastly, Flow is a chatbot aimed at overall health, such as sleep, diet, exercise, and meditation, to treat symptoms of depression. Therapy is conducted via chat messages. Like Wyse and Replika, the feature for full treatment that comes with a headset has an additional cost for the whole package (Woodham, et al., 2022).

3 Design and Implementation

3.1 Data Collection and Preparation of the Dialogues

Dialogues of the chatbot are based from the Instrumental Activities of Daily Living (IADL), the Pediatric Symptom Checklist and the actual interview of nurses and psychologists with young children. Interviews are in Filipino and Bisaya languages where questions involve physical and mental wellness.

Since the interviewees are young children, consent form was sent to their parent/guardian prior to the actual interview.

Figure 1 presents the chatbot use case diagram. The system has two main users, namely, (1) children, whose health is being monitored, and (2) the adult, who is most probably the teacher supervising the children. The users interact with the system by talking to the chatbot through tablet.

The chatbot is deployed on the cloud, and is accessible via the Internet.

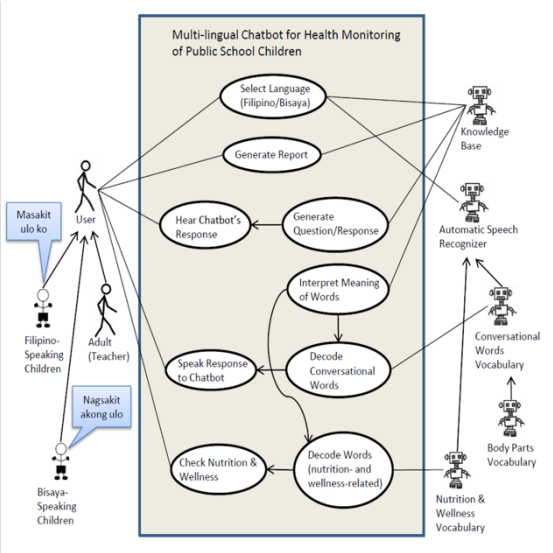

Figure 1. Chatbot Use Case Diagram

The chatbot understands Filipino, Bisaya and English. It asks questions to gather information on the child's general physical wellness, based on WHO's Global School-based Student Health Survey (GSHS, 2015). The collected information will be stored in a database for the generation of needed reports.

As part of a bigger system where input can also be the speech of a child, this paper focuses only on the discussion of the text-based chatbot were input are purely in text via Messenger or in a Web application.

3.2 Chatbot Framework

Figure 2 illustrates the architecture of the chatbot framework (Fernando, et al. 2024). As a web application, a Chatbot Web Application Server handles the communication between the users and the chatbot modules. The system is designed as a mobile application for ease of use by its target users. The conversation initiates when a user sends a message to the chat server. Subsequently, the chat server processes the message to generate a response. The Web App Server retrieves the appropriate response from the Dialogflow CX that handles the flow of the conversation. All the dialogues of the chatbot are retrieved from the Google Cloud Firestore which serves as the storage for the dialogues and all the information gathered from the user during a conversation. The Fulfillment Server, on the other hand, manages additional chatbot logic, including the storage of session data, response translation, and flagging. Communication with Google Cloud Firestore facilitates the retrieval of translated responses and session parameters essential for structuring conversation flow. Since the chatbot allows voice and text input from the user, the Automated Speech Recognition (ASR) Server is called whenever a child responds to the chatbot through speech. The ASR translates the speech to text which is then sent to the Web App Server. The Web App Server sends the text to the Dialogflow CX which processes the input, generates and displays the appropriate response in the Web App or FB messenger depending on the platform being used. Data collected in all the conversations are secured and stored in the Firestore. These are the data that Data Visualization Web Application Server use to provide an individual summary report and visualization of health information from different schools.

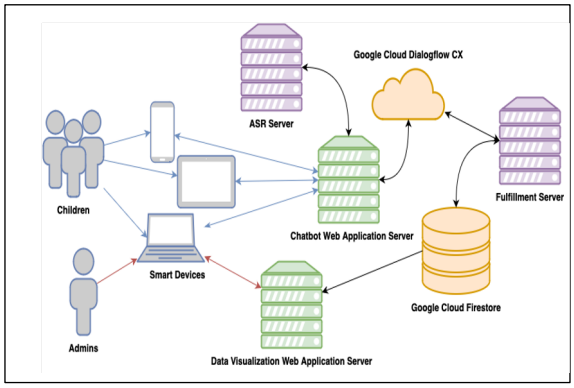

Figure 2. Architecture of the Chatbot (Fernando, et al. 2024)

3.3 Conversational Flow

Conversational flows are organised into modules or flows in DialogflowCX; each module represents a general context of the conversation. DialogFlowCX models each flow as a finite-state machine, with the pages as the states and the state handlers as the transitions. The intermediate page, after the start of the flow, sets the parameters for the communication between the chatbot and the knowledge base. In each individual module, it aims to extract certain types of information from the user. The extracted information is stored as session variables and influences the conversation's

transitions between states. Concluding modules or flows triggers another intermediate page, which saves and stores session parameters in the database for future reference.

Figure 3 presents the conversation flow of the chatbot. A session is initiated with the chatbot by asking for the child's preferred language and information (username and data privacy consent). The session terminates if the child does not consent to the use of the chatbot. Otherwise, it continues to a review of body systems, which is handled by multiple specialized modules under the hood. Specialized modules transition back to the probing-menu-page when a module concludes.

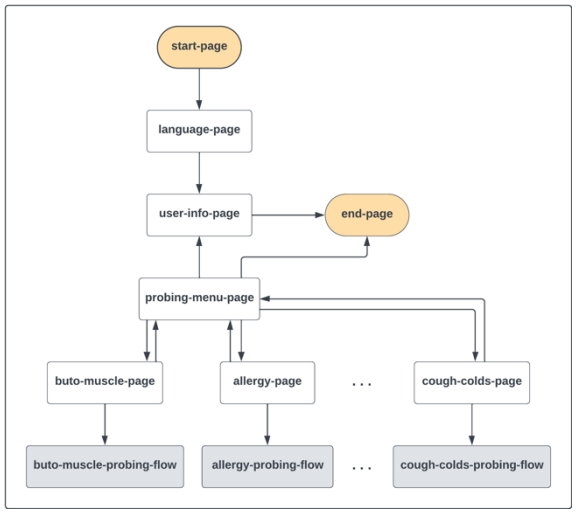

Figure 3: Conversation Flow

This allows the user to go over the other modules until they are satisfied, in which they may opt to end the session.

Figure 4 presents the conversation flow for the allergy module. The module is designed to systematically extract allergy information from pediatric subjects. Information including the duration of affliction, reported symptoms, and identifiable triggers. Transitions between pages or states changes based on the condition defined in the transitions or routes in DialogFlowCX. Introducing a more dynamic approach of questioning as the chatbot avoids redundant or extraneous follow-up responses from the chatbot. The module concludes whenever the conversation reaches the End Page, instigating the storage process of the accumulated information. The collected data is subsequently stored in the database for later utilization in the generation of comprehensive reports.

Figure 5 presents the conversation in probing for the Buto (bone) and muscles wellness. The module is devised to probe for information related to bones and muscles. The flow is structured in a loop to iterate through a list of distinct conditions. Individual conditions can share similar follow-up details such duration, degree of pain, etc. Instead of exhaustively creating new pages for each condition, pages are reused by storing the subject (condition) into a session variable. Creating an identifier during the looping process and for the record during data storage.

Figure 4: Allergy Conversation Flow

3.4 Dialogue Processing

In the dialogue processing workflow, webhooks play a pivotal role in producing dynamic responses, validating data, and triggering backend actions. A webhook is called and sent to an endpoint for almost every response the chatbot has. Its primary responsibility is to retrieve the relevant dialogues corresponding to each question, ensuring that the user receives the appropriate context. Once a question is asked, the user's input will be expected.

The chatbot emphasizes its multilingual support, accommodating English, Filipino, and Bisaya simultaneously through its entity extraction capabilities. Entity extraction plays a huge role in comprehending user inputs across different languages. Once an entity is extracted, the subsequent step involves determining its reference value. An example of an entity type with its entities and synonyms is shown in Table 1, wherein red is

the entity or reference value, and some of its synonyms are blood-tinged, bloody, and pula. This makes it possible for the chatbot to understand the user's input regardless of the language.

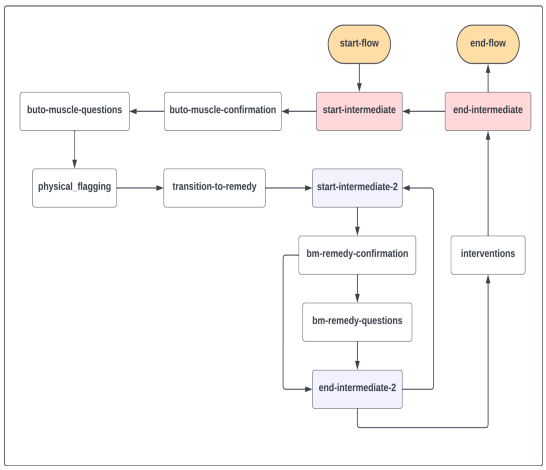

Figure 5. Probing for the Buto (bone) and Muscles.

Table 1: Lists of the corresponding synonyms for each entity name under an entity type.

Entity Type	Entity Name	Synonyms
phlegm_colors	red	red, blood-tinged, bloody, pula, dugo
phlegm_colors	white	white, whitish, puti

C: Madali ka bang mahawa o kaagad inuubo? *(do you easily get infected or get cough?)*
U: **Oo** *(yes)*
C: May kasama bang plema? *(is there phlegm?)*
U: **Meron** *(there is)*
C: Ano ang kulay ng plema? *(what is the color of your phlegm?)*
U: May halong **dugo**. *(with blood)*

Listing 1: Sample dialogue with entity extraction. *C* refers to the chatbot, while *U* refers to the user. The entities extracted in the context are underlined. In this context, the inquiry about the color of phlegm is prompted by the user's earlier acknowledgment of its presence. This ensures that the subsequent question aligns with relevant information obtained during the ongoing conversation.

3.5 Dialogue Storage

Chatbot dialogue is stored using Google Firebase, specifically Firestore. Firestore is a NoSQL database, a type of database management system that provides a mechanism for storing and retrieving data modeled in a non-tabular or non-relational manner. Dialogue is essentially a series of questions and responses, modeling it as a NoSQL document composed of field-value pairs allows for a straightforward and flexible representation compared to the table-based approach of relational databases. Firestore stores data in collections that are analogous to tables in relational databases. These collections contain a set of documents where each document is composed of field value pairs that store the actual data. Dialogues are organized by chat modules; each module has its own corresponding collection and stores a group of documents. Each document represents a type of question or response of the chatbot for the particular module, storing translated responses for each language and their corresponding quick replies. Table 2 presents how a dialogue is stored in Firestore. Table 3 illustrates a document representation of the sample dialogue in Listing 1. Health documents store the collected session variables extracted from user utterances

Responses and quick replies are fetched from the database according to the user's preferred language. Quick replies are supplementary options shown in the user interface that help guide the user on the expected answers.

3.6 Problems Encountered and Remediation

The Buto Muscle Module faced structural organization and templating issues, possibly due to a lack of testing in prior development stages. The module generally has a nested loop structure, with one loop addressing the general problem and another focusing on the remedies for each of the general problems addressed in the first loop. A crucial parameter, the current object parameter, determines the ongoing general problem in each cycle. After each general problem, it continues using the current object parameter for the list of remedies in the second loop.

Table 2: Table representation of a dialogue document stored in Firestore.

Key	**Subkey**	**Value**
qck_reply	cebuano_replies	[Iro, Iring, Uban pa]
	english_replies	[Cat, Dog, Others]
	tagalog_replies	[Pusa, Aso, Iba pa]
question_translation	cebuano_response	Sa unsa na mananap nga naay balhibo ka alerdyik?
	english_response	Which animal furs are you allergic to?
	tagalog_response	Sa anong hayop na may balahibo ka allergic?

Table 3: Document representation of the sample dialogue in Listing 1.

Field	Value
session_name	“1234567890”
module	“cough_and_cold_module”
ccf-confirmation	“meron”
cough-with-phlegm	“meron”
phlegm_color	“red”
kind	cough
updated_at	Oct 11, 2023, 12:40:14.437 PM

3.7 Problems Encountered and Remediation

The Buto Muscle Module faced structural organization and templating issues, possibly due to a lack of testing in prior development stages. The module generally has a nested loop structure, with one loop addressing the general problem and another focusing on the remedies for each of the general problems addressed in the first loop. A crucial parameter, the current object parameter, determines the ongoing general problem in each cycle. After each general problem, it continues using the current object parameter for the list of remedies in the second loop.

The primary issue was using consecutive “Change Loop” endpoint calls, where each call alters the current object parameter to move to the next loop object. Once it enters the loop for remedy, it still has the current object parameter from the general problems loop, which is overwritten after each iteration in the remedy loop. Overwriting the data results in the loss of progress from the previous iteration, leading to a repetition of the initial loop and, eventually, an infinite loop.

To address the structural organization and templating issues within the Buto Muscle Module, a restructuring of the loop logic was made to ensure that the current object parameter is appropriately managed throughout the iteration process. By controlling the flow of the loops and preserving the relevant data between iterations, the flow of the module can proceed the way it was intended to do and maintain progress across successive cycles.

3.8 Endpoints

Fulfillment in Dialogflow is deployed as a webhook and is used to perform backend logic every time it is called. This functionality enables the chatbot to deliver dynamic responses when engaging in backend logic. Within this system, Dialogflow can interact with six distinct backend endpoints specifically designed for data processing.

Among these endpoints is one that is structured to allow Dialogflow to receive custom payloads as responses. Another endpoint is tailored to focus on modifying conversational flows that utilize

templating. Additionally, there exists an endpoint dedicated to storing the data in the knowledge base. Conversely, a separate endpoint serves the purpose of resetting the current session values. Lastly, there are health flagging endpoints that are split into two categories: physical and mental health; these focus on monitoring the symptoms of the user and flagging when necessary.

These endpoints play a crucial role in managing, fetching, storing, and processing the data transmitted within the system. Each endpoint serves a unique purpose tailored to enhance the functionality of the chatbot.

3.9 Language Limitations of the Chatbot

To be able to manage the responses of the user, all possible answers for each question generated by the chatbot are provided in a form of buttons. Input can also be typed in the text box. However, if the input does not match any of the expected answers, the system will continuously wait for the correct answer for it to proceed to the next question. The system's understanding of the free-form text is very limited since it will only respond if the provided answer is correct.

4 The Chatbot System

The multi-lingual chatbot is deployed as a web application and in Facebook messenger. Figures 6 - 7 present screenshots of the actual conversation in FB Messenger (prototype version) and Web App Deployment (Figure 8). Figure 6 presents the conversation about allergies. The system asks systematically the user about allergies on food (bread, seafood, etc.), medicines, dust, pollen and animal fur. If the user says yes to one of the allergens, the chatbot asks for the side effects, its duration, remedy and if it has relieved after the remedy. Same set of questions are asked if the user has allergies to other allergens as what is illustrated in Figure 4. Figure 7 presents the questions based on the Pediatric Symptom Checklist. Figure 8 presents the chatbot running as a web application. A report can be generated based on the responses of the user as shown in Figures 9-11. Figure 9 presents the visualization of allergens of all students in all schools while Figure 10 presents the allergens of students per gender. Figure 11 shows the mental health report particularly on what psychological areas need attention by a mental health professional.

5 Future Work

Monitoring the health and wellness of individuals ensures that their development is on a normal level, and this should begin in children as they will experience the most milestones in their growth and development. Schools monitor the children's health to ensure that they will turn out healthy in the future.

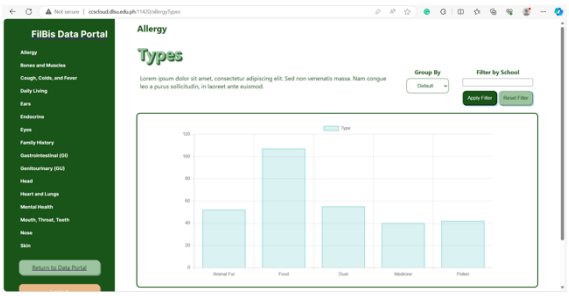

Figure 9. Report of Allergens in all Schools

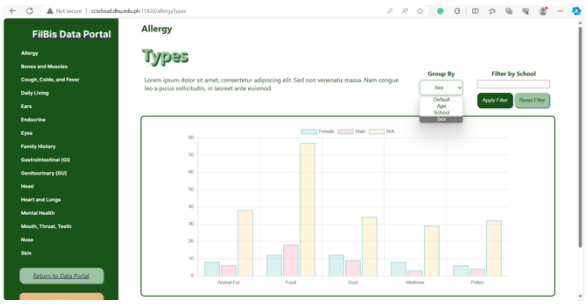

Figure 10. Report of Allergens per Gender.

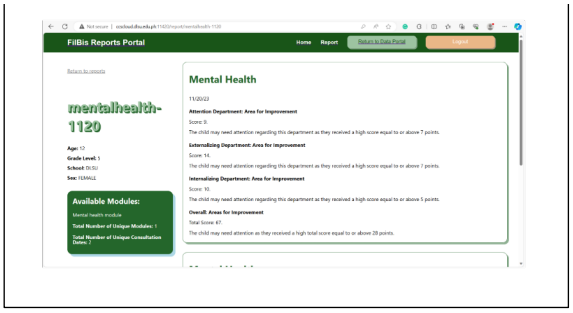

Figure 11. Mental Health Report per student.

This research presents how a multi-lingual healthcare chatbot that can monitor the physical and mental wellness of young children is designed and implemented. Empowered by Artificial Intelligence, the chatbot is capable of conversing in two major Philippine languages - Filipino and Bisaya as well as English. The chatbot will allow for more frequent and regular health and wellness check among children, even without the presence of a medical doctor or even a full-time school nurse and may identify children who may need specific interventions, whether psychological, medical, nutritional, or mere social-cultural support. This is motivated due to the fact that not all schools have the facilities to conduct routine checks on students. This project aims to utilize the technology such as chatbot that can run in mobile devices in order to address the lack of health professionals and resources in monitoring the general wellness of children. Future work includes the deployment of the system in most public schools in the Philippines.

Acknowledgment

This work was supported by the Department of Science and Technology - Philippine Council for Industry, Energy, and Emerging Technology Research and Development (DOST-PCIEERD) and the Advanced Research Institute for Informatics, Computing and Networking (AdRIC) Research Center of De La Salle University, Philippines.

Abstract

Clinical depression is a prevalent and severe medical condition that can significantly affect an individual's cognitive processes, behavioral patterns, and overall health. In the Philippines, mental health treatment faces persistent challenges, such as inadequate funding, shortage of mental health professionals, and underdeveloped mental health services. Several studies have utilized language as a means to identify clinical depression. However, limited attention has been devoted to exploring possible differences in the linguistic patterns exhibited by individuals with different levels of clinical depressive symptoms. The researchers employed a multiphase analysis and descriptive cross-sectional research designs to examine the macro language structure, i.e., pronouns, adjectives, adverbs, clauses, spoken/figurative language, and verb tense and aspect, in persons with clinical depressive manifestations. Subsequently, the language patterns were evaluated based on the participants' levels of depressive symptoms. Research findings indicate that individuals with clinical depressive symptoms exhibit a higher frequency of first-person pronouns, negative adjectives, absolutist adverbs, single-clause sentences, spoken language, present tenses, and continuous aspect. However, when comparing levels, differences in macro language patterns may suggest a proclivity of depressed individuals towards rumination and depersonalization. Implications for the use of language as a preliminary screening tool for diagnosis are discussed.

1 Introduction

Major depressive disorder or clinical depression is a prevalent severe mood disorder. Individuals afflicted with depression endure persistent emotions of hopelessness and pessimism, leading to a loss of interest in previously pleasurable activities. The American Psychiatric Association (APA) associates symptoms such as persistent depressed mood, marked decrease in interest or pleasure in activities, significant weight loss or gain without intentional dieting, changes in appetite, and daily fatigue or loss of energy with the disorder.

In the Philippines, mental health disorders are the third most prevalent form of disability (Martinez et al., 2020). Approximately 20% of Filipino youth between the ages of 15 and 24 had contemplated suicide at some point (Kabamalan, 2022). Furthermore, the widespread presence of mental health illiteracy in the Orient is reflected in the country's mental health status, characterized by inadequate mental health care infrastructure, a scarcity of trained practitioners, and limited access to and high cost of services. Notwithstanding these grave data, the efforts of various specialists remain insufficient. Hence, there is a need for a readily accessible and readily available diagnostic instrument for clinical depression.

Recently, there has been a growing interest in studying the language patterns of people who have clinical depression. By employing a methodical examination of linguistic content, researchers could precisely categorize patients into their respective diagnostic groupings. Patients with depression are often examined for deviant written and spoken languages (Smirnova et. al, 2018). Literature suggests that language, being a prevalent and conspicuous aspect of everyday life, can serve as a tool for specialists to identify clinically depressed persons by analyzing their linguistic

patterns. Therefore, the potential of language as a means for screening for clinical depression is considerably high. According to Andreasen and Pfohl (1976), language can serve as a distinct indicator of depression. Previous research has conducted comparisons between the linguistic patterns associated with moderate depression and those associated with normal sadness and a euthymic state (Smirnova et al., 2018). Studies have also been conducted on the utilization of first-person pronouns, such as I, me, and myself, as the most commonly used words by individuals experiencing depression. These pronouns have been identified as potential indicators of future symptoms of depression (Al-Mosaiwi & Johnstone, 2018; Brockmeyer, 2015; Stirman & Pennebaker, 2001; Zimmermann et. al, 2016).

Although considerable research has been devoted to the comparison of language patterns of clinical depression and normal sadness, language patterns varying in different culture and demographic profiles, language patterns of suicidal and non-suicidal individuals, and self-focus as an indicator of anxiety and depression (Al-Mosaiwi & Johnstone, 2018; Brockmeyer (2015); Rude et al., 2004; Smirnova et al., 2018; Stirman and Pennebaker, 2001; Zimmerman et al., 2016), less attention has been paid to the language patterns of individuals with clinical depressive symptoms with varying levels of manifestations

To help fill this gap, the present study examines the macro language patterns of individuals with varying levels of depressive symptoms.

1) What are the macro language structures of Filipinos with depressive symptoms

2) How do the language patterns of the participants compare when grouped according to the level of depressive symptoms?

2 Review of Related Literature

2.1 Existing Diagnostic Tools for Depression

The diagnosis of depression has traditionally been made through clinical criteria, such as the patient's current symptoms and history. Mental health professionals may use various existing interventions to assess or evaluate the severity and nature of depressive symptoms in an individual. The American Psychiatric Association (APA) Diagnostic Statistical Manual 5th Edition (DSM-5) criteria for major depressive disorder is one of the prevalently used diagnosing tools of many mental health professionals, worldwide. Its standardization, unified research and treatment, mental health continuity framework on various disorders are the contributing factors behind the immense international influence of DSM-5. The manual redefined and reconceptualized the discipline of psychiatric disorders into a universal or common language (Van Heugten – Van Der Kloet & Van Heugten, 2015). It classify clinical depression or major depressive disorder as a common and serious mood disorder. People with depression suffers and experience continuous feelings of hopelessness and pessimism, and they lose interest in formerly enjoyable activities. In addition to the emotional problems, people may experience physical issues such as persistent pain or digestive troubles (American Psychiatric Association, 2013). With symptoms, such as depressed mood most of the day (nearly every day), a significant decrease in interest or pleasure (in all, or almost all, activities most of the day, nearly every day), significant weight loss or gain without dieting (as well as a drop or increase in appetite almost every day), fatigue or loss of energy nearly every day, etc. In which, physiological symptoms, such as weight gain or loss, deeply disrupt the multifaceted aspects of weight management for many individuals (Sarte Jr. & Quinto, 2024).

In the last two decades, healthcare settings have also started using a variety of screening tools that possess outstanding psychological qualities. The Beck's Depression Inventory (BDI) (Beck et al., 1961) is one of the tools utilized to evaluate an individual's severity of depression. This measure is extensively used in both clinical treatment and research to evaluate depression. With broad applicability in research and clinical practices, the BDI has established itself in quantifying the extent of depressive symptoms and covers cognitive and emotional manifestations of clinical depression (Wang & Gorenstein, 2013). Furthermore, the Zung Self-Rating Depression Scale (SDS) also helps professionals in measuring or quantifying the severity of depression. It covers a range of manifestations, such as somatic, affective, and physical symptoms. Compared to other self-rating scale, the SDS notably focuses on the physical symptoms of depression, which justify its holistic approach in assessing the nature of the disorder. The development of the two aforementioned self-report depression scales also gave rise to The Patient Health Questionnaire-9 (Kroenke et al., 2001), a highly prevalent screening instrument utilized in clinical depression. Systematic reviews and metal-

analyses argues that PHQ-9 is the most valid and reliable depression screening tool in terms of sensitivity and specificity (Costantini et al., 2021; El-Den et al., 2018).

Undoubtedly, the interdisciplinary field of clinical psychology has greatly benefited by the development of many psychological interventions, screening tools, and scientific treatments for clinical depression over the course of many decades. In the 21st century, the advancement of technology may lead to the development of new instruments that can help specialists gain a deeper understanding of clinical depression and improve its treatment. However, the availability of traditional and emerging diagnosing tools will be the ultimate determining factor of its contribution.

2.2 Issues Surrounding Access and Availability of Diagnostic Tools

The presence of various interventions, criteria, screening tools for major depressive disorder demonstrates a substantial body of knowledge that has been comprehensively grasped regarding its whole nature. Paradoxically, it is estimated that 5% of the global population or 280 million of adults suffers from clinical depression, with varying severity (World Health Organization, 2023). In the Philippines, it is estimated that 3.3 million Filipinos suffer from depressive disorders, with suicide rates in 2.5 males and 1.7 females per 100,000 (Reddy, 2016). Additionally, a comprehensive study conducted across the entire country, with a sample size of 19,017 participants aged 15 to 24, revealed that a significant proportion of young Filipino adults, namely up to 8.9% (with a 95% confidence interval ranging from 8.3% to 9.6%), experience moderate to severe depressive symptoms. Despite the presence of different diagnostic tools, the longstanding issues surrounding the access and availability of these tools is considered as the major factor to the slow-moving rate of decreasing number of people with clinical depression.

Countries in the Global South are severely deprived and deficient with mental health care, compared to countries in Global North. Lacks in primary care practitioners, mental health training, and transport to enable outreach and home visit programmes are some of the major supply problems that Low-or-Middle-Income countries experiences. On the demand side, populations frequently lack comprehensive knowledge regarding mental health illnesses, as well as the suitability of seeking assistance for mental health issues at primary health centers, and financial constraints that hinder individuals from accessing primary health centers due to insufficient funds for transportation and frequent out-of-pocket expenses (Minas, 2017). In the Philippines, mental health care continues to encounter issues, including underinvestment, lack of mental health professionals and underdeveloped mental health services (Lally et al., 2019). Furthermore, the Philippines has a significant disparity between the number of mentally ill patients and the availability of psychiatrists and psychologists. Specifically, there is only one psychiatrist for every 250,000 mentally ill patients, which is far below the recommended ratio of one psychiatrist for every 50,000 patients (Ferrolino, 2017).

The issue of availability to diverse screening and diagnostic tools for clinical depression is a prevalent challenge faced by many individuals. In the Orient, financial capacity and lack of health insurance are one of the leading factors influences Filipino on their reluctant and unfavorable behaviors on clinical depression (Martínez et al., 2020). Aside from these factors, language injustice also affects healthcare accessibility for many individuals in the country, especially for ethnolinguistically marginalized Filipinos. Literature suggests that during the pandemic, deprivation of language rights resulted in a higher risk of contracting the virus, highlighting the importance of language in disseminating official information (Quinto et al., 2022). Availing different screening and diagnostic tools for clinical depression is considered as economic burden for many individuals, due to its high cost. With all of the issues surrounding the availability and accessibility of diagnostic tools for clinical depression, there is a need for a cost-effective preliminary diagnostic tool.

2.3 Language Patterns and Clinical Depression

Trends on the language patterns of individuals with clinical depression has been emerging in many years. Research suggests that the distinct language patterns may impose as a screening tool or preliminary diagnostic tool for clinical depression. It has been found that samples from those who progressed to psychosis had lower semantic density than samples from a large database of normal language (Reynolds, 2019).

Other studies have shown that people with mild depression, compared with healthy individuals, had written responses which were longer, demonstrated descriptive rather than analytic style, showed signs of spoken and figurative language, single-clause sentences domination over multi-clause, atypical word order, increased use of personal and indefinite pronouns, and verb use in continuous/imperfective and past tenses. Greater use of lexical repetitions, omission of words, and verbs in continuous and present tenses were also previously observed. Through language analysis, mild depression was significantly differentiated from normal sadness and euthymic state. There is in fact a significant difference on the language patterns of people who have depression from those who just feel normal sadness (Smirnova et al., 2018).

People who have depression and anxiety both use first person singular pronouns (i.e., me, myself, I), use more absolutist words without nuance (i.e., always, totally, entire), and make more use of negative words in describing emotions (Al-Mosaiwi & Johnstone, 2018). The use of First- person pronoun during negative and not positive memory recall is complimentarily related to a sudden change of mood which is considered an inadequate adaptation part of the components of meditative self-focus (Brockmeyer, 2015). An increased use of first-person singular pronouns is more evident in the writing of suicidal poets relative to non-suicidal poets (Stirman & Pennebaker, 2001). The first-person pronouns such as a I, me, and my, can be used as a predictor for future depressive order. Patients with higher first-person singular pronoun use while doing their methodology did not show elevated levels of depressive symptoms at baseline. Although, first-person singular pronoun used significantly predicted depressive symptoms approximately eight (8) months later (Zimmermann et al., 2016). Depressed individuals may be caught in a negative self-regulatory cycle where depression effects lead to heightened focus on personal shortcomings, which, in turn, leads to more depression effects, resulting in more self-focus (Pyszczynski & Greenberg, 2014).

Moreover, trends in the analysis of self-diagnosed reports, sentiments, and emotional attributes from various social media platforms have emerged. Language differences across nine language categories, such as personal pronouns, positive emotions, social words, and negative emotions, were traced among Twitter users (now known as X) (Suzuki et al., 2024). Topic modeling techniques and pre-trained, machine-learning-based emotion analysis algorithms suggest that individuals' sentiments and emotional attributes are influenced by social media keywords and posts (Balan et al., 2023).

The notable disparities in language patterns between those with mild depression and those with normal levels of sadness indicate that language patterns can be utilized to distinguish between depression and regular sadness. Furthermore, the extensive body of literature that uncovers distinctive linguistic patterns of individuals with clinical depression underscores the significance of this knowledge. However, a comprehensive examination of the linguistic patterns exhibited by persons at different stages of depression has not been carried out. Hence, the researchers intend to undertake a study on the linguistic patterns exhibited by individuals with different degrees of depression.

3 Methodology

3.1 Data Collection

Guided by the schema of multi-phase analysis of Creswell and Plano (2011) and descriptive cross-section research design by Johnson (2001), the researchers implemented various processes to collect data. Upon the approval of rightful permission, the researchers asked a total of 338 young adults to answer the first quantitative part of the study, 1st English writing proficiency exam and Beck's Depression Inventory Scale-II edition. This served as the baseline of the study that helped in screening the participants whether they are proficient in the English written language and have manifestations of clinical depression. A debriefing message, approved by a licensed psychologist, was included in the dissemination of the initial English writing competence examination and BDI-II assessment to prevent the retraumatization of individuals.

Only 20 participants met the qualifications for the second screening of the study. Subsequently, the participants were voluntarily requested to complete the 2nd English writing proficiency test and Diagnostic Statistical Manual-5th Edition criteria for major depressive disorder. These assessments served as the researchers' final means of evaluating whether the participants exhibited symptoms of clinical depression and possessed genuine proficiency in written English. While the typical method for assessing major depressive disorder is through clinical interviews conducted

by licensed mental health professionals, it is worth mentioning that in this study, the use of DSM-5 criteria was implemented in the form of a self-report scale was under the guidance and approval of a registered psychologists. Similar to the administration of BDI-II, to avoid retraumatizing the individuals, a debriefing was conducted through a message included with the scale, approved by a licensed psychologist. The researchers did not only depend on the entire inventory scale and criteria for depression utilized in this study; rather, they sought guidance from a licensed psychologist at each stage of the procedures undertaken. The utilization of a psychologist rather than a psychiatrist aligned with the purpose and nature of DSM-5 usage. Psychologists are highly skilled in diagnosing and addressing mental health disorders, primarily focus on psychotherapy, counseling, assessment, and behavioral interventions. These professionals often favor therapeutic approaches over medical interventions, using the DSM-5, as their main tool for guiding treatment plans (APA, 2017). Since the present study did not require pharmacological expertise, the involvement of a registered psychologist in participant selection was sufficient to ensure appropriate participant selection. Upon completion of the second quantitative phase of the study, the researchers once again screened the participants.

A total of 9 volunteers/participants who successfully met the requirements in the final phase of the study. They were invited to voluntarily complete a written report containing three questions pertaining to their life events. A subject matter expert conducted a briefing session. The participants provided their responses to the written report in a tranquil and noise-free environment, equipped with air conditioning. The respondents were not provided with any guidelines or restrictions by the certified psychologist regarding how they should react to the written reports since restrictions could potentially restrict the respondents' ability to provide comprehensive responses to the written reports. After the participants have completed their written reports, debriefing meetings were conducted to address any potential psychological effects, ensure their well-being, provide additional information, and obtain their informed permission. The debriefing session was led by a licensed mental health practitioner. The researchers employed descriptive statistics, including frequency counts and manual calculation of percentages. Throughout the study, the respondents had the autonomy to withdraw from their involvement at any stage if they desired. They were always asked willingly not required. The entirety of the data and information utilized in the study will consistently remain anonymous and exclusively serve scholarly purposes.
