This section presents the results of this multi-phase analysis of the language patterns of individuals with varying levels of clinical depressive symptoms.

Language Aspects		Mean Frequency per Essay	%
Pronouns			
	First	252	69
Adjectives			
	Negative	76	67
Adverb			
	Absolutist	37	57
Clauses			
	Single	66	63
Language			
Signs of Spoken Language		61	90
Use of Tenses			
	Present	104	82
Use of Aspect			
	Continuous	90	88

Table 1. Overall Mean Frequencies and Percentage Distribution per Language Aspect

Table 1 demonstrates that first-person pronouns exhibited the highest average frequency per essay, totaling 252 usages, surpassing the frequencies of second, third, and indefinite pronouns. In terms of adjectives, negative adjectives were more prevalent, totaling 76. The frequency of single clauses is higher, with a total of 66, compared to multiple clauses. The spoken languages likewise have a greater mean frequency, totaling 61. The present tenses have a higher frequency compared to the past tenses, with a mean of 104 and a particularly high frequency of continuous tenses, totaling 90.

Pronouns	1st Person		2nd Person		3rd Person	
	$\bar{x}$	%	$\bar{x}$	%	$\bar{x}$	%
Borderline	38	15	0	0	5	9
Moderate	50	20	3	25	20	36
Severe	102	40	4	33	17	30
Extreme	62	25	5	42	14	25
Total	252	100	12	100	56	100

Table 2. Mean Frequency and Percentage Distribution of the Use of Pronouns

Table 2 indicates that the lowest level of depressive symptoms is observed in individuals who least used first-person pronouns at a borderline level (15%). The moderate level of depression follows closely behind with a 20% usage of first-person pronouns. The highest level of depression, classified as extreme, used a total of 25% first person pronouns. Finally, the severe level of depressive symptoms exhibited the highest percentage (40%) of first-person pronoun usage, indicating that individuals at this level rely on first person pronouns more than those at other levels. When it comes to the second-person pronouns used, the borderline level indicates a complete absence of any usage of second-person pronouns. The data indicates that as the level increases the frequency of used also increases. The data in the third-person pronouns column indicates that the lowest proportion, at 9%, corresponds to the borderline level. While the moderate level had the highest usage.

Adjectives	***Positive (good,***		***Negative (bad, terrible, hard, tragic)***		**Total**	
	$\bar{x}$	**%**	$\bar{x}$	**%**	$\bar{x}$	**%**
Borderline	7	19	8	11	15	13
Moderate	10	27	14	18	24	21
Severe	11	27	32	42	43	38
Extreme	10	27	22	29	32	28
Total	37	100	76	100	114	100

Table 3. Mean Frequency and Percentage Distribution of the Use of Adjectives

Table 3 presents the frequency of positive and negative adjectives used in written reports for each level of depressive symptoms. For positive adjectives, except for borderline, all three levels - moderate, severe, and excessive - have an equal utilization proportion of 27%. When it comes to negative adjectives, the borderline level has the lowest frequency of usage, accounting for only 11%. The moderate level ranks second lowest in terms of the frequency of negative adjective usage, with a result of 18%.

Adverb	**Absolutist**		**Non-Absolutist**		**Total**	
	$\bar{x}$	**%**	$\bar{x}$	**%**	$\bar{x}$	**%**
Borderline	4	11	7	25	11	17
Moderate	8	22	7	25	15	23
Severe	12	32	9	32	21	32
Extreme	13	35	5	18	18	28
Total	37	100	28	100	65	100

Table 4. Mean Frequency and Percentage Distribution of the Use of Adverb

Table 4 displays the frequency of absolutist and non-absolutist words used by respondents with different levels of depressive symptoms, as indicated by their written responses. According to the table, the lowest level of absolutist word usage is observed in the borderline level (11%). The moderate level has the second lowest usage of absolutist terms, with 22%, while the severe category has the second highest usage of absolutist words, at 32%. Lastly, the extreme level is characterized by the highest frequency of absolutist words. Regarding the frequency of non-absolutist words, the severe level exhibits the lowest usage of such words (f=5, 18%), but both the borderline and moderate levels have an identical number of non-absolutist words (f=7, 25%). The severe level exhibits a utilization rate of 32% for non-absolutist terms. Thus, the written reports at this level have the highest number of non-absolutist words.

Clauses	***Single***		***Multiple***		**Total**	
	$\bar{x}$	**%**	$\bar{x}$	**%**	$\bar{x}$	**%**
Borderline	14	21	5	13	19	18
Moderate	9	14	9	23	18	17
Severe	26	39	14	36	40	38
Extreme	17	26	11	28	28	27
Total	66	100	39	100	105	100

Table 5. Mean Frequency and Percentage Distribution of the Use of Clauses

The data presented in Table 5 shows that the usage of single clauses is lowest among individuals with a moderate level of depressive symptoms (14%), followed by those with borderline depressive manifestations at 21%. The severe level ranks second highest in terms of the utilization of single clauses, accounting for 26%. The severe level exhibits the greatest quantity of single clauses employed in the written reports.

Languages	**Signs of Spoken Language**		**Sign of Figurative Language**		**Total**	
	$\bar{x}$	**%**	$\bar{x}$	**%**	$\bar{x}$	**%**
Borderline	5	8	0	0	5	7
Moderate	13	21	1	14	14	21
Severe	31	51	4	57	35	51
Extreme	12	20	2	29	14	21
Total	61	100	7	100	68	100

Table 6. Mean Frequency and Percentage Distribution of the Use of Languages

Table 6 displays the frequency and percentage of spoken and figurative language usage. For spoken languages, the borderline level corresponds to a minimal usage rate of 8%. The usage of spoken languages is least prevalent at the

extreme level, accounting for 20% of cases. Conversely, the moderate level exhibits the second-greatest usage of spoken languages, representing 21% of cases. The severe level exhibits the greatest number of spoken languages utilized in the written reports, with an average of 51%. In contrast, the data in the figurative language column reveals that the lowest level of usage is observed at the borderline level, with a 0% occurrence of figurative language. The moderate level ranks second to last, with a 14% usage of figurative language. The highest level of usage is found at the extreme level, with a 29% occurrence of figurative language.

Tenses	*Past Tense*		*Present Tense*		Total	
	$\bar{x}$	%	$\bar{x}$	%	$\bar{x}$	%
Borderline	4	17	17	16	21	17
Moderate	8	35	34	33	42	33
Severe	6	26	35	34	41	32
Extreme	5	22	18	17	23	18
Total	23	100	104	100	127	100

Table 7. Mean Frequency and Percentage Distribution of the Use of Tenses

The frequency and percentage distribution of the use of past and present tenses are displayed in Table 7. The borderline level exhibits the lowest usage at 17%, followed by the extreme level at 22%. The severe level shows a usage of 26%, while the moderate level has the most usage, averaging at 35%. In terms of the present tense column, the borderline level has the lowest utilization at 16%, followed by the extreme level at 17%. The moderate level comes next with the second-highest usage of present tenses, averaging at 33%. Lastly, the severe level has the highest number of present tenses used, averaging at 34%.

Aspect	*Continuous*		*Perfective*		Total	
	$\bar{x}$	%	$\bar{x}$	%	$\bar{x}$	%
Borderline	9	10	1	8	10	10
Moderate	44	49	2	17	46	45
Severe	22	24	4	33	26	25
Extreme	15	17	5	42	20	20
Total	90	100	12	100	102	100

Table 8. Mean Frequency and Percentage Distribution of the Use of Aspect

Table 8 displays the frequency and percentage distribution of the continuous aspect and perfective aspect. The data presented in the continuous aspect column indicates that the borderline level exhibits the lowest utilization of the continuous aspect, accounting for only 10%. This is followed by the extreme level, which demonstrates a usage rate of 17%. The severe level ranks next, with an average of 24%. The intermediate level exhibits the greatest quantity of continuous characteristics, with an average of 49%. The results indicate that the borderline level exhibits the lowest usage of perfective aspects, averaging at 8%. The moderate level follows with the second lowest usage, averaging at 17%. The severe level shows a higher usage of 33% of perfective aspects, while the extreme level demonstrates the highest usage at 42%.

5 Discussion

5.1 Macro Language Structures

A total of seven part of speech were analyzed in order to create or present a specific language patterns. These include pronouns, adjectives, adverbs, clauses, languages (figurative and spoken), use of tenses, and use of aspects. For the pronouns, first-person pronouns, such as me, myself, my, I, mine, etc., appeared to have the highest mean frequency among the other three types of pronouns. The increase in frequency of first-person pronouns usage are linked to the excessive self-focus and isolation from others that clinically depressed individuals do. Consistent with the findings of Rude et al., (2004) the present study's participants extreme usage of first-person pronouns were a reflection of Beck's cognitive model (1961) and Pyszczynski & Greenberg (1987) concept of self-regulatory perseveration and depressive self-focusing style. Individuals suffering from clinical depressive symptoms or clinical depression often exhibit heightened self-absorption and are prone to social isolation. In terms of the adjective and adverbs usage, negative adjectives and absolutists adverbs had the higher mean frequency than positive adjectives and non-absolutists adverbs. Al-Mosaiwi & Johnstone (2018) argued that the heighten used of absolutists adverbs and negative adjectives or words were a specific marker of anxiety, depression, and suicidal ideation. This implies that individuals who experiences clinical depression manifestations are likely unable to see any sense of hope. Moreover, single clauses had a more dominant amount of mean frequency due to reduced utterance by depressed individuals. The mean frequency of the spoken languages is higher than the figurative language. Suggesting that they were more expressive in their writing process. Corroborated with the findings of Smirnova et al. (2018), present tenses also appear to have a higher mean frequency than past tenses.

Lastly, regarding aspects used, the continuous aspect seems to have a greater average frequency.

5.2 Language Patterns with Varying Levels of Depressive Symptoms

The findings of this study aligned with the anticipated hypotheses. The frequency of first-person pronouns steadily rose from the borderline level to the moderate level, and ultimately reached the severe level. It is shown that individuals with clinical depressive symptoms tend to focus more on themselves. Ilardi (2009) states that individuals with clinical depression experience a pronounced inclination to withdraw from social interactions and become emotionally unresponsive. This phase is known as isolation, in which a person experiencing depression deliberately separates themselves from their surroundings. This leads to a higher frequency of self-centered conversation and self-focus, rather than focusing on the people around them. The outcome of the isolation phase pertains to the concept of self-centeredness, which involves the concentration on one's own self and the disregard for the individuals in one's vicinity (Beck et al., 1961; Pyszczynski & Greenberg, 1987). For the extreme level, the number experienced a dramatic decline from the severe level (which has the highest number utilized for first-person pronouns) which suggests the concept of depersonalization. Žikić (2009) explains that the patients suffering from severe/extreme depression and depersonalization experienced mostly, with nearly all patients reporting feelings of melancholy, insomnia, and reduced energy levels. It is the sensation of disconnection from one's own self and the environment and entails a lack of concern for both one and others. Furthermore, the participants utilized a limited quantity of second and third person pronouns. The lack of any individual who could be accurately characterized as you, your, and yours, etc. data might suggest the experience or absence of a figure and social support that they can depend onto.

The written reports were predominantly filled with negative words. Individuals diagnosed with clinical depression tend to employ a greater number of negatively valenced or emotions words, such as grief, fraud, and victim, in their written language (Al-Mosaiwi & Johnstone, 2018; Rude et al., 2004; Lyons et al., 2018; Stirman & Pennebaker, 2001; Zimmerman et al., 2016). Furthermore, while comparing the first three levels of clinical depression, it was discovered that there is a progressive increase in the usage of negative words as the level of depression rises. Depressed individuals tend to employ a greater number of negative words as their level of depression worsens. However, according to the data, there is a significant drop in severity, indicating a potential association with depersonalization. In line with the existing literature by Al-Mosaiwi and Johnstone (2018), the present study similarly demonstrates an increased usage of absolutist adverbs in the written reports of the participants. Furthermore, while considering the comparison of the severity levels of clinical depression among the individuals. Data indicates that when the severity level increases, the usage of absolutist adverbs becomes more prevalent, implying a lack of perceived hope or assistance from others.

Furthermore, Smirnova et al. (2018) established that single-clause sentences are more prevalent than multi-clause ones. Pennebaker et al. (1997) also observed a higher frequency of causation phrases in cases of depression, particularly in compound-type sentences rather than complex-type multi-clause sentences. As per the discovery of widespread use of single-clause sentences, these characteristics of phrase usage indicate a preference for descriptive cognitive methods rather than analytic ones (Smirnova et al., 2018). Furthermore, when comparing the levels of depressive symptoms, it was found that the borderline level exhibits a larger average frequency and percentage compared to the moderate level. Due to the peak of interruptions occurs at the borderline level. It reaches its highest point at a severe level, indicating that it has the highest number of predominantly utilized single clause sentences, reduced utterances, and unfinished phrases. These linguistic patterns align with the language flow dynamics seen in earlier studies on clinical.

Smirnova (2018) also found that persons with mild depression had longer written responses, employed a descriptive rather than analytic writing style, and displayed indications of using spoken and figurative language. The researchers' data demonstrates a positive correlation between the severity of depressive symptoms levels and the respondents' increasing expressiveness in writing, as they progress from borderline to severe depression. The prevalence of spoken and metaphorical languages significantly decreases during severe depression, indicating that rumination and depersonalization might be a key

contributing factor. Rumination is the inclination to excessively dwell on past events and experiences that have caused grief.

The research indicates that the use of present tense dominates past tense. Contrary to the literature that suggests individuals with mild depression frequently employ the past tense (Smirnova et al., 2018). Lastly, in terms of aspect use, it was noted that there was a positive correlation between individuals with clinical depressive symptoms and their tendency to employ continuous words (living, making, hurting). The utilization of the continuous aspect is associated with the utilization of the present tense. Proposing the notion that individuals with clinical depressive symptoms, who have a tendency to excessively dwell on the present, experience events as persistently ongoing. When comparing different levels, the borderline level exhibits the lowest utilization of the continuous aspect, while the moderate and severe levels of clinical depression represent the highest degree of continuous aspect, indicating that individuals in these levels engage in persistent rumination and perceive certain thoughts as ongoing actions. As depression symptoms intensifies, the frequency of using the continuous aspect decreases, possibly due to depersonalization.

6 Conclusion

In general, the results indicates that in terms of the overall macro structures, individuals with depression showed a high usage of first-person pronouns, negative adjectives, absolutist adverbs, single clause sentences, spoken languages, present tenses, and continuous aspects.

A consistent pattern was identified when individuals were grouped based on their levels of clinical depression symptoms. The analysis revealed a predominantly positive correlation trajectory for most of the studied components of speech. As the severity increases, the frequency of using pronouns, adjectives, adverbs, and other similar linguistic elements also rises. However, the subjects with severe depressive symptoms also exhibited alterations in their linguistic patterns. Research data suggests that as it approaches an extreme level, the frequency diminishes. Proposing that rumination and depersonalization can be considered a valid explanation for this phenomenon. Furthermore, this study proposes that understanding and distinguishing between language patterns of clinically depressed individuals with different levels of clinical depression could potentially improve mental healthcare, combat stigma, and potentially create a language screening tool for the disorder, especially in the Orient.

7 Recommendations

The present research study possesses several limitations and offers recommendations that could potentially assist future researchers in the domains of clinical psychology and languages Future investigators must evaluate and consider equal representation of aspects such as age, gender, and levels of depression among the participants in order to maintain a balanced representation. To obtain more precise and reliable results, utilizing software to analyze written or spoken reports can be essential in comprehending and differentiating language patterns. Furthermore, providing more comprehensive explanations or debates regarding the factors influencing the fluctuating nature of certain aspects of speech, as addressed in the current study, could enhance our understanding in this topic. Concentrating on a specific level of sadness throughout research can assist future researchers in perhaps elucidating these fluctuating patterns. It is also recommended to use Thematic Apperception Test (TAT) as a tool for identifying language patterns as it can help researchers to unveil the unconscious processes of the participants and proposed a more holistic approach in terms of developing a treatment plan. Additionally, the analyzation of comparison of language patterns among different clinical depressive symptoms must also be taken into account. As the present study simple observed, described, and explained the differences of language structures, future researchers may focus or utilized the use of a statistical procedure to prove a more statistical valid result.

Lastly, as the current study employed the English language as a criterion for evaluation, it is highly recommended to either adapt or develop a localized version of the written reports. Implementing this approach will enhance the accessibility and availability of linguistic patterns as a screening tool.

Acknowledgments

We would like to express our heartfelt gratitude to our advisers, Dr. Edward Jay Mansarate Quinto, Ph.D., LPT, and Dr. Jonathan V. Macayan, Ph.D., RPSY. Their patience, guidance, and expertise have provided invaluable support throughout this study, and we are extremely grateful for their mentorship.

We also extend our warmest appreciation to the respondents of this study. This research was made possible through their valuable participation, and we are deeply grateful for their contribution as a step toward advancing mental health care in the Philippines.

Finally, we are deeply thankful to our family and friends. Their unwavering support has been a pillar of strength throughout this journey.

Competencies in the International Language Tests and the Language Education Curriculum: Navigating the Foundation of Prospective ESL Teachers for Certification

Roxan T. Bayan, EdD and Boyet L. Batang, PhD
Isabela State University, Philippines

Abstract

Higher education institutions have consistently prioritized pre-service preparation and training programs aimed at cultivating exceptional teachers since their role as teachers is significant in the academic achievement of pupils. Licensing and certification bodies such as Professional Regulations Commissions in the Philippines, and international language certification programs such as International English Language Test (IELTS) have been acknowledged for evaluating the competencies of teachers in their specific areas of expertise. The study sought to find out the congruence of the Language Education Program in the Philippines and IELTS competencies to determine the preparedness of ESL teachers to secure international certification in specific areas of the four Macroskills: Speaking, Listening, Reading, and Writing; and to form mechanisms for improving language education program in aiding IELTS Certification. The exploratory descriptive design of qualitative research was employed. The researcher concludes that the language education program addresses several competencies of the IELTS which can aid students under said program in gaining certification from the IELTS. However, the participants indicated that certain components need more focus as they related to the skills they found insufficient when taking the IELTS examination. They pointed out that certain areas in macro skills development are particularly useful since these areas are the concentration of the contents and tasks in IELTS. With this, mechanisms were identified so that professors could also address the development of the skills needed as they teach the courses under the language education program since the topics are also pertinent to the curriculum contents. Given this, it can be said that the success of students and ESL teachers in gaining language certification can be increased through the consolidated efforts of instruction and co-curricular programs such as training programs or institutional courses.

Introduction

Among the various factors that influence the academic achievement of pupils, the role of teachers emerges as particularly significant. This assertion has been substantiated via extensive research and is widely acknowledged by experts and stakeholders on a global scale. As a result, higher education institutions have consistently prioritized pre-service preparation and training programs aimed at cultivating exceptional teachers.

The 21st Century classroom has evolved from teacher-centered to learner-centered setup. As Gianchandani (2020) stated, the teacher's role has also evolved from being the sole fount of knowledge to being more of a facilitator of learning. Despite this transformation, the the teacher remains a significant factor in the learning and achievement of students. Over other school-related factors, the teacher is estimated to have two to three times the effect on students' achievement. For this reason, national and international policies have been designed to promote and maintain teacher quality (Opper, 2021).

In addition to primary licensing bodies such as the Professional Regulations Commissions in the Philippines, alternative licensing and certification bodies have been acknowledged for evaluating teachers' competencies in their specific areas of expertise.

The International Language Test System (IELTS) and the Test of English as a Foreign Language (TOEFL) are widely recognized as the two predominant English language certification programs. In contrast, the IELTS is a more extensive assessment as it is employed for educational, immigration, and occupational purposes, whereas the TOEFL primarily emphasizes academic communication.

The study sought to find out the congruence of Language Education Program and IELTS competencies to determine the preparedness of ESL teachers in securing international certification in specific areas of the four Macroskills: Speaking, Listening, Reading and Writing; and to form mechanisms for improving language education program in aiding IELTS Certification.

The scope of this study is restricted to examining the viewpoints of participants regarding the components of the language education program

that they perceive to be most aligned with their preparation for IELTS certification. These components include learning objectives, course content, learning experiences, and evaluation and assessment practices. Furthermore, the perspective of the participants regarding the impact of the language education program on the IELTS certification of ESL teachers in the four major language skills, namely speaking, listening, writing, and reading, is also given due consideration.

According to Chappell et al. (2019), IELTS is one of the most favored tests for government agencies, education providers, professional registration, accreditation agencies and other stakeholders requiring test scores in English proficiency. Merrifield (2007) also described IELTS as a benchmarking system for many professional associations all over the world and is specifically an established assessment system in the United Kingdom and Europe.

This study is restricted to English as a Second Language (ESL) teachers who have successfully completed the International English Language Testing System (IELTS) test, as they possess the highest level of expertise regarding the characteristics and requirements of the IELTS. Data saturation was employed, which determined the ten participants for the aforementioned investigation.

The training program intended for aspiring ESL Teachers in anticipation of the International English Language Testing System (IELTS) is structured to span an entire semester.

The purpose of this study was to gather relevant information to compare the competencies in the Language Education Program and IELTS, as a basis for the development of a program or alignment in the future.

For this study, the researcher aimed to develop an enhancement program design that is meant to meet the learning needs of prospective ESL teachers from a globalized perspective. This is achieved by an interview which determined the needs informed by the following data: the Participants' professional and personal information as well as the gaps in their language proficiency; the language information on the target situation; the Participants' needs from the course; and the language learning needs.

The certification of teachers and its impact on their performance and expertise has been documented in various studies and reports with a vast majority of them identifying a significant relationship between said variables. According to the Organization for Economic Cooperation and Development (2009), certification programs allow teachers to go beyond their initial training, enriching their expertise in the field. Specifically, certification aids teachers in updating their knowledge in light of academic shifts and trends; improving their skills, attitudes, and approaches through newly-developed teaching techniques and objectives, new contexts, and new findings from educational research; and allows them to actuate changes in the curricula and other aspects of the teaching practice. Such is the impact on teachers that the education sector has come to view certification programs as a tool for professional enhancement.

Moreover, a commentary by Pugatch (2017) even stated that developing countries prioritize the certification of teachers with the belief that it improves teacher quality and qualifications.

The Isabela State University is a higher education institution duly recognized as one of the leading SUCs in Cagayan Valley. With the premise of this study, the researcher believes that ISU would see the fruition of its vision as the integration of an IELTS preparation and training program might be the first of its kind in the region and a great advantage for students taking language education courses therein.

With this, the researcher undertook this study to gain information pertinent to the possible design and development of a language teacher training program that would aid prospective teachers in preparing for IELTS certification.

Methodology

Research Design

The exploratory descriptive design of qualitative research was employed in this study, given its inherent characteristics. The selection of the design for this study was deliberate since the researcher is in the preliminary phases of investigating the subject matter. As the participants graduated from different universities and varied curricula, the use of a descriptive design was appropriate for this study as it facilitated the identification of specific details and patterns necessary for its completion. This design is particularly useful for answering "what" questions related to conditions within a given situation. The ultimate objective is to utilize

the results as a foundation for the development and implementation of an improvement program. As part of the triangulation process, a trainer-passer participant was included, and the researchers had to take the IELTS.

Participants of the Study

The study's participants comprised 10 persons who specifically completed a language education program and successfully completed the International English Language Testing System (IELTS) examination. One of them is a trainer for IELTS. The participants in this study were purposefully selected due to their shown ability to provide sufficient saturation for the data. They possess extensive knowledge and expertise in the topic under investigation. Data saturation was employed, which led to a total of 10 participants. The researcher gathered the data necessary to draw conclusions and answers that were collected were already mentioned and emphasized by the participants.

Data Analysis

To interpret the data gathered from the interview, the participants' transcribed statements were subjected to a coding process by Kathy Charmaz (Kenny and Fourie,2015). The data was initially subjected to open coding in which the data are broken down into smaller analyses to identify core ideas and, in turn, develop codes for describing them.

Results and Discussion

The present study involved conducting in-depth interviews with the Participants to gain insights into the key aspects of language education that are focused on IELTS preparation and certification. Additionally, the study aimed to identify the perceived contributions of the language education program in facilitating IELTS certification, as revealed by the Participants.

For the language education elements that are found attuned towards IELTS preparation and certification, the following competencies for speaking were identified: 1. Practicing conversational skills, 2. Exercising speaking skills by dialogue simulation, 3. Delivering speech, and 4. Instructional speaking through oral reporting.

This exhibits the elements derived from the participants regarding the skills within their language education program, specifically focused on preparing for the Speaking Test in the International English Language Testing System (IELTS). Participant 1 (P1) felt that, overall, the learning objectives of the program were relevant to the subject matter covered in the International English Language Testing System (IELTS). Participant 6 asserts the alignment between the goals of the language education program they completed during their college studies and the evaluation tasks they encountered in the International English Language Testing System (IELTS). The participants further indicated that possessing a major in English conferred a distinct advantage.

According to the participants' statements, the existing language education program's learning objectives, which encompass subskills within the four macro skills and grammar acquisition, were considered to align with the requirements found in the IELTS examination. Significantly, the statements made by the participants also suggest that the International English Language Testing System (IELTS) placed emphasis on the practical implementation of abilities.

P2, for example, provided a detailed account of a task-based assessment that was administered during his speaking test. This indicates that the IELTS test has a focus on practical application, as supported by Nushi et al. (2021), who noted that the main components of the IELTS include test practice and activities aimed at developing specific skills. This observation suggests that the test places greater emphasis on assessing the results of learning, as individuals are evaluated based on their abilities and the manner in which they exhibit comprehension and proficiency in the subject matter. In the field of education, there has been a growing acceptance of a pedagogical approach commonly referred to as outcomes-based learning.

The Commission on Higher Education has implemented a providential directive to transition towards an outcomes-based curriculum. This directive necessitates the restructuring of the curriculum to align education with real-world employment opportunities. The alignment of desired results and competencies with the instructional aims and objectives of curriculum contents was accomplished (Sana et al., 2015). The incorporation of Outcome-Based Education (OBE) in higher education courses necessitates consideration of the participants' identification of commonalities between the learning objectives of the language program and the assessment tasks in the International English Language Testing System (IELTS).

It is evident, however, that the participants have found a rather narrow range of parallels. Furthermore, there are even participants who have said that the learning objectives of the language program were not applicable to the content encountered in the test. The majority of participants reported that the language education program they engaged in was most beneficial to them in terms of enhancing their speaking and writing skills.

P1 elaborates on the significance of the oral reporting tasks that the individual was obligated to undertake during their college years, wherein they communicated only in the English language. This experience proved to be highly advantageous in honing their speaking abilities, which subsequently facilitated their success in the International English Language Testing System (IELTS) examination. Additionally, he made reference to the supplementary advantage of acquiring proficiency in conversing with the American English accent, a topic that was somewhat explored in one of his courses within the language curriculum.

Meanwhile, it was found that the contents of the language education program that were considered by the Participants as pertinent to them when they took the Listening Test in IELTS were: 1. taking down notes from listening information, and 2. listening attentively for important details**.** P10 also identified the following components he found in the IELTS which he learned in the language education program he took in college: *Sa* (In) listening part *kasi*, we were taught before to take down notes while listening to something and you answer some questions…the importance really of attentive listening which I think when we took up listening subject that was also a minimum requirement: *yung* (the) attentive listening.

The identified competencies that were found attuned towards IELTS preparation for Reading are: 1. interpreting messages, and 2. understanding vocabulary. Most of the participants mentioned that the assessment on Reading was on the Application level. P7 also indicated the following, which denoted that IELTS test-takers are also assessed for their analytic skills: *…so for example in the reading part, you need to use different types of strategies to grasp the meaning of the text or to comprehend what you are reading. Mostly were long passages and stories, understanding the main ideas, the attitude of the authors…and these were very similar to what I took in the undergrad—similar to the assessment.*

The domain of writing was identified as a significant component of the language education curriculum, which the majority of participants perceived as pertinent to their IELTS examination experience. The competencies that were identified as attuned to the IELTS Writing test are: 1. writing accurately, 2. using proper diction, 3. observing mechanics of writing in writing essays, 4. using grammatical structures, and 5. using idiomatic expressions.

Several participants, namely Participants 1, 3, 4, 5, 6, and 9 found themes related to the mechanics of writing to be particularly valuable.

P3 and P4 originally discussed their expertise in technical writing, which they thought to be very advantageous throughout the assessment due to the presence of technical writing tasks. It is important to acknowledge that Technical Writing is a course in the Bachelor of Science in English (BSE) Program. P6, on the other hand, identified spelling and writing for various purposes as subjects within the language education curriculum that proved advantageous to her in the context of the IELTS writing assignments.

P3 additionally identified essay-writing and letter-writing as subject domains that she found beneficial. P5, on the other hand, indicated that the multitude of writing assignments handed to them during their college years provided them with the necessary practice to proficiently organize their ideas in written discourse.

The IELTS has identified grammar as another relevant domain of content. Among all the participants, P3 exhibited the highest degree of emphasis on the significance of the subject matter. P1 and P2 both said that the criteria discussed can be categorized under the domain of writing mechanics. These criteria can be classed at the Application level, as the participants were required to apply their knowledge of writing mechanics.

P9 noted that the format of the assessment tasks in the language program differed significantly from those found in the International English Language Testing System (IELTS). Participant 1 also highlighted the components included in the IELTS that were covered in the language education program they completed throughout their college studies. The pedagogical approach to teaching English writing for specific objectives remains unchanged. Cohesion is a crucial aspect to consider in order to ensure effective communication. Equally important is the adherence to the core idea

and the provision of supporting facts. In writing, the fundamentals primarily encompass mechanics, particularly the usage of punctuation marks.

P7 expressed that she derived benefits from the grammar objectives of the language education program during her IELTS preparation. P5 shared a similar viewpoint to that of P4: *No, it is not specifically designed for the IELTS examination. In our major classes, like grammar and writing, there is also a concentration on literature, ma'am. Is the subject matter of our discussion mostly centered around literature, madam? The literature component of the subject is quite extensive, while there is also a focus on phonetics and related areas.* However, it appears that the content may not be directly applicable to the IELTS assessment. Regarding that matter, no.

The statements made by P4 and P5 can be explained by the fact that they completed their language education degrees prior to the introduction of Outcome-Based Education (OBE) in Philippine higher education institutions. Regarding P4, it was noted that he completed his undergraduate education in 2011, whilst P5 accomplished the same milestone in 2010. In 2012, the Commission on Higher Education enforced the adoption of Outcomes-Based Education in universities and colleges, as stipulated in Memorandum Order No. 46. Thus, the aforementioned insights from Participants 4 and 5 are accounted for.

Contributions of the Language Education Program in Aiding ESL Teachers' IELTS Certification

In determining the significance of the language education program they undertook in their BSE Curriculum in aiding them for IELTS Certification, the following emerged from the responses from the participants as significant competencies.

Contributions of the Language Education Program in Aiding ESL Teachers in their IELTS Speaking Test:

1. writing and delivering speeches
2. organizing thoughts
3. reciting
4. demonstration teaching
5. impromptu speaking

Numerous parallel observations may be discerned when examining the correlation between the IELTS speaking criteria and the activities deemed relevant by participants in their language education programs during their undergraduate years. The International English Language Testing System (IELTS) places significant emphasis on several key aspects, including fluency and coherence, lexical resource, grammatical range and accuracy, and pronunciation. The participants in question failed to indicate lexical resource in their aforementioned statements. In addition to this, the learning experiences of the participants offered them relevant preparation for the IELTS speaking test. Significantly, the examination of the participants' responses indicated that the most relevant learning experiences identified by them primarily revolved around application. These experiences encompassed activities such as engaging in language use through speeches, recitation, and demonstration teaching. In relation to this matter, the IELTS examination also assessed their abilities through practical implementation.

Contributions of the Language Education Program in Aiding ESL Teachers in their IELTS Listening Test:

1. listening for comprehension
2. note-taking
3. identifying main ideas

Listening comprehension refers to the cognitive capacity to understand spoken language across many forms of speech, including conversations, narratives, stories, and informational oral texts. The primary objective is to extract and create meaning from these auditory inputs (Kim & Pilcher, 2016). Given the aforementioned circumstances, the participants highlighted the various manners in which their language education program undertaken during their collegiate studies was beneficial for their performance in the International English Language Testing System (IELTS), particularly in activities that necessitated listening comprehension.

Contributions of the Language Education Program in Aiding ESL Teachers in their IELTS Reading Test:

1. skimming and scanning for information
2. reading extensively for comprehension
3. making generalizations
4. predicting outcomes
5. identifying main ideas

Rraku (2013) posits that reading approaches encompass deliberate reading behaviors. In general, these skills are related to the ability to skim and scan. During the interview, P1, P2, and P5 identified these as crucial qualities that facilitated their performance in the IELTS reading test. The

efficacy of reading techniques has been examined in multiple studies, including the research conducted by Rraku (2013). This study included experimental testing to establish a clear correlation between the employment of reading approaches and the accuracy of reading comprehension among student participants. In a study conducted by Amir (2019), it was found that reading approaches have a good and significant impact on reading comprehension among higher education students.

In addition to the reading strategies of skimming and scanning, P8 identified the capacity for lengthy reading as a relevant skill. She made this statement due to her limited engagement with reading, resulting in a lack of proficiency in this skill. From her standpoint, this had an impact on her performance during the IELTS reading examination. According to a study conducted by Rezaee et al. (2020), the implementation of experimental intense reading programs led to a significant improvement in the receptive abilities of university students. In a separate investigation, Ferdila (2014) discovered that the practice of extensive reading was associated with increased motivation to engage in reading, enhanced vocabulary acquisition, and improved reading comprehension skills. In the study conducted by Chien and Yu (2015), the researchers proposed that English as a Foreign Language (EFL) teachers should promote extensive reading among their students as a means to cultivate enduring interest and reading habits. This suggestion aligns with the viewpoint expressed by P8.

The process of reading comprehension is a multifaceted task that requires the integration of various linguistic and cognitive processes. These processes encompass skills such as word reading ability, memory, inference generation, comprehension monitoring, vocabulary, and prior knowledge. These skills were identified by the participants as being utilized during their reading test in the International English Language Testing System (IELTS) examination (Ellemen & Olsund, 2019). Reading comprehension is of significant importance in nearly all aspects of life, to the extent that it has emerged as a fundamental factor for success within the educational system (Capodieci et al., 2020).

Contributions of the Language Education Program in Aiding ESL Teachers in their IELTS Writing Test:

1. using correct vocabulary
2. writing formal/informal letter
3. composing paragraph observing the elements of writing: coherence, conciseness, brevity
4. interpreting graphic organizers

The above list enumerates the writing subjects that participants experienced and developed within the language education program they undertook, which they also felt to be pertinent throughout their International English Language Testing System (IELTS) experience. These encompass aspects like as lexical selection and usage, syntactic accuracy and organization, substantive content, and targeted writing objectives.

Significantly, a considerable number of participants expressed that the writing test posed considerable challenges within the International English Language Testing System (IELTS). One example is provided by P1, who attributes his verbose writing style as a contributing cause. Consequently, he advocated for the utilization of brevity and conciseness as essential elements in written communication.

Similar to P8, the comment made by P4 suggests that the use of excessive words is not encouraged in the context of the IELTS assessment. In connection with this matter, P1 further elaborated on his misconceptions regarding lexical resource throughout his time as a student. The matter of verbosity or wordiness is a prevalent concern observed among students who are learning English as a second language (ESL) or as a foreign language (EFL).

Moreover, the phenomenon under investigation was explored in a research conducted by Elachachi (2015), wherein it was discovered that the verbosity exhibited by English as a Lingua Franca (ELF) learners can be attributed to culturally-specific disparities pertaining to linguistic characteristics and styles. The findings of the qualitative investigation indicate that a significant number of English as a Lingua Franca (ELF) learners exhibit a lack of awareness regarding the direct nature of the English language. In contrast to the Arabic style, English is generally characterized by a greater degree of simplicity, as the latter relies less heavily on the use of allusions, analogies, proverbs, and figures of speech. In the study conducted by Kang and Chang (2014), it was shown that EFL students employ wordiness as a strategy to cope with the challenge of paraphrasing words that cannot be directly translated.

Demir (2019) conducted a study that elucidated the underlying factors contributing to the misuse of lexical resources among students.

Similar to the description provided by P8, it appears that students possess a misunderstanding wherein they believe that use of excessive verbiage contributes to a perception of being more 'scientific' or intelligent.

Mechanisms for Improving Language Education Program in Aiding IELTS Certification

Aside from providing their insights about the objectives, content and assessment in the language program they found pertinent to their IELTS examination, they also shared their perspectives on what language education can improve on for its graduates to perform well in the IELTS. These may be included in the preparation of a training program, insertion, or an elective course that may be proposed in curriculum revisions.

Macro Skill	Specific Topic
Speaking	Conversational English, Pronunciation
Listening	Comprehending different English varieties
Reading	Extensive reading with emphasis on lexical resource and comprehension
Writing	Time-pressured writing, Writing conventions, Business writing

Table 1. Participants' Suggestions for IELTS-targeted Language Education Program

Emphasis on Macro Skills

It is worth noting that all of the participants expressed the need for a more comprehensive teaching of the macro skills, as the tasks in the International English Language Testing System (IELTS) primarily emphasized the practical application of these skills. The participants' remarks regarding their experiences in taking the IELTS suggest that the exercises included in the test primarily aim to evaluate their communicative competence.

It is important to note that the foundational concept of communicative competence was articulated by Dell Hymes, who posited that it encompasses not only grammatical competence but also sociolinguistic competence. The rules of grammar would be rendered ineffective in the absence of standards of usage. According to Ahmed and Pawar (2018), communicative competence refers to the implicit understanding of a language and the proficiency to employ it effectively in communication. During the interview, several participants engaged in a discussion regarding the aforementioned concept of communicative competence.

Aydogan and Akbarov (2014) conducted a study that emphasized the interplay between macro skills and their equal significance in developing communicative competence. They advocated an integrated-skill strategy to enhance the authenticity of language training for students learning English as a foreign language (EFL). It was previously mentioned that language education should be guided by Rebecca Oxford's notion that language training is a composite of various interconnected abilities. Hence, it is advisable to instruct these skills in an integrated fashion rather than in isolation, as their application in real-world scenarios typically involves their simultaneous utilization. One illustrative instance is that reading constitutes a receptive ability within the framework of the writing process. Furthermore, it can also facilitate the development of vocabulary, hence influencing individuals' abilities in listening, speaking, and writing. One of the participants in the interview indicated the presence of this specific integration. P1 elucidated on his utilization of the principles of written journalism and English for Specific Purposes during his oral examination.

Conclusions and Recommendations

The Philippine language education program, as manifested in the data saturation from the participants, addresses several competencies of the IELTS which can aid students under said program in gaining certification from the IELTS. However, the Participants indicate that certain components need more focus as these are related to the skills they found insufficient when they took the IELTS examination. The Participants also pointed out that certain areas in macro skills development are particularly useful since these areas are the concentration of the contents and tasks in IELTS. With this, mechanisms were identified so that professors may also address the development of the needed skills as they teach the courses under the

language education program since the topics are also pertinent to the curriculum contents. Given this, it can be said that the success of students and ESL teachers in gaining language certification can be increased through the consolidated efforts of instruction and co-curricular programs such as the training program developed in this study.

It is recognized that there are still further developments that can be done and derived from this study. Language professors view the findings of this study as a reference for how they can enhance instruction, especially in terms of learning objectives, content, and assessment practices to make learning more effective for their students regardless of whether they take the IELTS or not.

Moreover, sub-programs concentrating on each of the four macro skills can also be developed by future researchers to provide more intensive preparation for future IELTS examinees.

With the findings, a training program or elective course for International Language Tests in the Language Education Curriculum is recommended.

From Rules to Meaning Making: Teaching Grammar through Discourse Analysis as an Approach

Allan Jay Esteban
Kyung Hee University, 173 Deogyeong-ro, Giheung-gu, Yongin-si, Gyeonggi-do, South Korea

allanjayesteban@clsu.edu.ph

Abstract

This paper argues for a shift in English grammar teaching, advocating for discourse analysis as an approach to viewing grammar as a meaning-making instrument in context. Moving beyond isolated sentences and rote memorization, this paper explores grammatical cohesion and textuality, emphasizing how connections between words (references, ellipsis, substitution) and sentence structure (conjunctions, theme-rheme) contribute to the flow and coherence of a text. Several practical teaching activities are then proposed, encouraging students to analyze real-world texts and discover how grammatical choices impact textual meaning. These activities aim to transform students from grammar memorizers to meaning-makers, fostering a deeper understanding of how language functions in real-world communication. By integrating discourse analysis as an approach, this paper equips teachers to create engaging learning experiences that develop students' appreciation of the dynamic nature of language and empower them to craft clear and cohesive spoken and written texts.

1 Introduction

Spoken and written discourses display an intricate weaving of words, phrases, and sentences. The connections between these elements comprise grammatical cohesion and textuality. The eye of a simple reader or listener may not decipher the entangled connections between these elements. However, for a discourse analyst, this can be as fascinating as critically examining how a fabric or a piece of clothing has been made. Given this context, this discussion explores how grammatical links improve or make up grammatical cohesion and textuality. At the same time, the discussion considers how discourse analysts assert *contextualized uses of grammatical items.* Furthermore, it explains how discourse analysis can affect the teaching of English grammar. Finally, practical suggestions for teaching the core concepts of grammatical cohesion and textuality are provided.

Several scholars in the field of contextualized uses of grammatical items have stressed that this instruction can productively enhance the memory of learners for target grammar and syntax structures (Kumaravadivelu, 2006; Liamkina & Ryshina-Pankova, 2012; Yang, 2020). However, before exploring this assumption, it is essential to first understand the grammar links (McCarthy, 1991) that connect spoken and written expressions.

This paper, therefore, bridges the gap between traditional grammar instruction and the application of discourse analysis in English language teaching. By exploring core concepts such as references (anaphoric, cataphoric, exophoric), substitution, ellipsis, conjunction, and theme-rheme structures, this paper aims to demonstrate how these elements contribute to coherence and meaning-making in texts. Additionally, it seeks to provide practical teaching strategies that leverage real-world texts, thereby enabling teachers to create more engaging and contextually relevant grammar lessons. Ultimately, the goal is to transform students from passive recipients of grammatical rules into active participants in the construction of meaning, which can potentially enhance their understanding and appreciation of language as a dynamic and functional tool.

2 Concepts of Grammatical Cohesion and Textuality

2.1 References

Reference pertains to the connection between words, phrases, or ideas in a text or speech. It is

categorized into three broad types: anaphoric, cataphoric, and exophoric. They are linguistic techniques used to indicate or allude to something that has been previously stated, will be discussed hereafter, or exists outside of the text, respectively.

2.1.2 Anaphoric: Looking Back

First, anaphoric reference connects backward, tying subsequent information to earlier information. The most common referents are pronouns (e.g., I, you, he, she, they, them, it) and demonstratives (this, that, these, and those). They often play this role by reminding listeners or readers of previously introduced entities. For example, *The cat sat on the windowsill. It looked very comfortable in the warm sunlight.* In this example, *It* is an anaphoric reference that refers to the noun phrase *The cat* in the previous sentence. However, teachers must be aware of the persistent challenges in pronoun and reference usage across languages (McCarthy, 1991). The Filipino language, for example, has no equivalent pronouns for *he* and *she.* According to McCarthy (1991), what discourse analysts can offer to help solve these recurring problems is limited; they can only explicitly teach learners a language system like English.

2.1.2 Cataphoric: Looking Forward

The second type of reference is *cataphoric reference*. This type of reference captures the reader's interest by referring to later discourse items (McCarthy, 1991). Thus, meaning or reference unfolds as a sentence or text progresses. Clearly, this is contradictory to anaphoric reference, which refers to something previously mentioned. Despite its unique feature of establishing interest among readers, there is a risk of overuse or unnatural use. Training learners to observe language features beyond the sentence level is crucial, particularly in English, where referencing involves elements that are not easily translated into other languages (Celce-Murcia & Olshtain, 2000; McCarthy, 1991). Here are some examples of this reference: *in anticipation of details* (*He* had developed a habit to save energy. *Before leaving the house, Mark makes sure all the electronics are plugged out or lights are turned off.*); *introducing a term before explaining it*: (*The new software has several advanced features*. *These* include a sophisticated user interface and enhanced security measures.); and establishing a connection with a later concept (*Although she felt uneasy, Mary continued the hike. That* determination ultimately helped her reach the summit.).

2.1.3 Exophoric: Something Outside

Another form of reference is *exophoric reference*. It reaches outside the text, anchoring meaning in a nonlinguistic context. Deictics (e.g., here, now) or demonstratives (this or that) rely on shared knowledge of the physical or social environment to establish grounding. For example, *Please pass me "that"* (rice) relies on the speaker and listener's shared understanding of their physical location. In the given example, there is a dining table and nothing but rice to pass on to the speaker. Exophoric references frequently pertain to a common understanding between the sender and receiver of a message, irrespective of cultural differences. However, these references can also be culturally specific, extending beyond experience and tapping into the cultural knowledge of the receiver of a message (Cutting, 2021; Fulcher, 1989; McCarthy, 1991). For example, a foreign student who comes across the Philippine English word *Barangay* in a Philippine newspaper will need to tap external sources (e.g., asking a friend) to understand the text. McCarthy (1991) called this cultural exophoric reference.

2.2 Ellipsis and Substitution

Other concepts that contribute to grammatical cohesion and textuality are *ellipsis* and *substitution. Ellipsis* refers to the omission of elements based on the assumed context, while *substitution* is the replacement of one element with another. The distinction between these two aspects is crucial for effective language usage. The following examples illustrate this distinction:

2.2.1 Ellipsis

In English, *ellipsis*, like *substitution,* includes three main types: nominal, verbal, and clausal. *Nominal ellipsis* frequently entails the omission of a noun headword.

Example: Sanja likes the modern design. Si Eun likes the traditional.

According to McCarthy, nominal ellipsis should not be challenging for speakers of the Romance and Germanic languages. *Verbal*

ellipsis, however, may cause more difficulties. Thomas (1987) identified two types of verbal ellipsis (echoing and contrasting).

Verbal Ellipsis: *Contrasting*

A: Will you attend the meeting?

B: I might, I can't say for sure.

Verbal Ellipsis: Echoing

A. Will you be at the café?

B. I will be there.

Thomas (1987) also points out that verbal ellipsis can be possible in the same verbal group.

Original:

A: Did you complete the assignment?

B: I did complete it. I did it thoroughly. I did it on time.

Verbal Ellipsis:

A: Did you complete the assignment?

B: I did. Thoroughly. On time.

Clausal Ellipsis - Subject Pronoun Omission:

A: How are you?

B: Fine. (*I am* being omitted)

or "Do you like the steak I cooked for you?" Riski asked Nga excitedly. "Absolutely," said Nga. The adverb *absolutely* is an ellipsis replacing the entire clause *I absolutely like the steak.*

2.2.2 Substitution

Substitution in grammar is the replacement of one word or phrase with another to avoid repetition or add variety to the expression. For example, it refers to the act of replacing a word or phrase with a filler word, such as *one, do*, *so/not, or same* to avoid redundancy (McCarthy, 1991; Nordquist, 2020). Below is an illustration of how *substitution* is normally used in English:

Example 1: They brought sandwiches. They gave me one.

Example 2: Did you read the book? I think Ilee read it.

Example 3: Do you have plans for the weekend? If so, let me know; if not, we can make plans together.

Example 4: We ordered pizza, and they ordered the same.

The examples provided above to supplement the discussion on ellipsis and substitution mostly reflect everyday conversations. This is because *ellipsis* and *substitution* are not common in academic or technical writing but are found more frequently in spoken discourse (MacCarthy, 1991). This is because of the assumption that the missing or replaced items can be easily determined. This works well in conversational discourse, where context is abundant and helps to understand what is said.

2.3 Conjunction

A *conjunction* does not initiate a search either forward or backward like *cataphoric* and *anaphoric*, respectively, for its referent, but it does assume a sequential order in the text and indicates a connection between different parts of the discourse. Hence, discourse analysts consider conjunctions in a manner similar to that of grammatical links discussed above. They investigate the functions of conjunctions in constructing discourse, examine whether their categories and manifestations vary across languages, analyze their distribution in spoken and written language, explore usage restrictions that are not evident through sentence analysis alone, and identify aspects of their use that are not sufficiently explained in traditional grammar. To investigate it as a contributory element to building grammatical cohesion and textuality, Halliday (1985) provided classifications for conjunctive relations, encompassing phrasal and single-word conjunctions such as the common *and*, *but*, and *or*. The list was organized into three categories: *elaboration, extension*, and *enhancemen*t. Moreover, Halliday and Hasan (1976) enumerated the following simplified versions: *additive* (e.g., and, furthermore, as well as)*, adversative* (e.g., but, however, although)*, causal* (e.g., so, because, consequently)*, and temporal* (e.g., while, as soon as, meanwhile).

Additive Conjunction:

I enjoy cooking food for my family, and I also like treating them outside.

Adversative Conjunction:

Mark loves playing soccer, but her brother prefers basketball.

Causal Conjunction:

The road was wet because it had snowed heavily the night before.

Temporal Conjunction:

After finishing her homework, Maya went out to watch a movie in the cinema.

While the examples above indicate how conjunctions are used, McCarthy (1991) stressed

that in natural spoken language, common conjunctions such as *and, but, so*, and *then* not only connect individual statements but also serve as *discourse markers*, organizing extended stretches of discourse. Furthermore, according to discourse analysts, cultural differences may influence the use of conjunctions (Gee, 2004; Schiffrin, 2005). For example, Firth (1988) observed that non-native speakers predominantly use *because* for reasons, while native speakers use varied signals, such as *cos*, *like*, and *see* based on spoken data about smoking in public. Understanding spoken data is crucial for a comprehensive analysis of discourse patterns (Leech, 2000; Taylor, 2013; Walsh, 2006).

2.4 Theme and Rheme

In language learning, learners often focus on clause structures, including the arrangement of subjects, objects, and adverbials around verbs. Discourse analysts explore the implications of these structural options for text creation, emphasizing the emergence of patterns from natural data. Some structural options, particularly those found in spoken language, are overlooked in language teaching because of a bias towards written standards (Carter & McCarthy, 1995; McCarthy, 1991).

In English, Subject-Verb-Object (SVO) commonly exhibits various ways of rearranging clause elements using fronting devices. Different fronting options, such as adverbial fronting, cleft, and pseudo-cleft structures, allow speakers to highlight specific elements and shape a message's focus.

Adverbial-fronting:
Original: Carlo will go to the party.
Adverbial-fronting: To the party, Carlo will go.
In this case, the adverbial *to the party* is placed in front to emphasize the destination of the action.
Cleft Structure:
Original: She cooked the meal for our lunch.
Cleft Structure: It was she who cooked the meal for our lunch.
The cleft structure emphasizes *she*, making it the highlighted element in the sentence.

Pseudo-cleft Structure:
Original: The team finished the project on time.
Pseudo-cleft Structure: What the team did was finish the project on time.

Here, the pseudo-cleft structure emphasizes the action, *finish the project on time*, as the key information. These examples demonstrate how different fronting options can be used to highlight specific elements in a sentence and shape the message's focus. Hence, the concept of *theme*, representing the first elements in a clause, is crucial for understanding the framework within which the message is conveyed. This notion aligns with the Prague School's view of communicative dynamism and is seen as the "point of departure" for the message (McCarthy, 1991). The importance of the first position in the clause and the creation of a universal theme in language are highlighted. On the other hand, *rheme* or the rest of the clause provides additional details and information regarding the *theme*. The following are some examples of the connection between the two:

Example 1: The sun sets over the horizon.
In this sentence, *The sun* is the theme and subject of the clause, while the rheme contains the action and additional information.
Example 2: After a long day at work, she finally relaxed.
Here, the theme introduces the temporal context, and the rheme presents the main action.
Example 3: In the enchanted forest, magical creatures come to life.
The theme establishes the setting, and the rheme describes the action taking place.

Discourse analysts have emphasized the role of thematization in shaping communication dynamics and audience orientation (Chimombo & Roseberry, 2013; Hyland, 2015). Thematization involves making strategic decisions to organize information, determining what to foreground and how to present it within a discourse framework. Regarding discourse analysis aimed at impacting language instruction, McCarthy (1991) suggested that exploring variations in clause structure concerning discourse functions could be a valuable starting point. McCarthy also revealed that deviations from the standard SVO order are more common in natural talk. Other languages also exhibit diverse approaches to thematization. For example, Japanese uses the particle *wa* and Tagalog uses *ang* or *ay* at the end of the clause for topicalization (Greider, 1979; Hinds, 1986). Consequently, learners from different backgrounds may encounter challenges at different proficiency levels, reflecting the issues in conventional grammar teaching.

Therefore, the following sections demonstrate

how discourse analysis can influence ways of teaching English grammar through *contextualized uses of grammatical items* as explained above. Further examples are provided as practical guides for teaching English grammar regarding grammatical cohesion and textuality.

3 Influences of Discourse Analysis for Teaching English Grammar

Discourse analysis has only recently started influencing the way English grammar is taught to "non-native" English speakers (Celce-Murcia, 1990). In particular, a significant number of English language teachers continue to view and teach grammar primarily at the sentence level, if they incorporate it into their teaching at all (Cook, 1999; Hos & Kekec, 2014). For decades, English grammar instruction has been characterized by rote memorization of rules and drills on isolated sentences (Gartland & Smolkin, 2015). While such drills have their place, they offer a limited perspective on how language truly functions. Conversely, other discourse analysts have indicated that discourse analysis has significantly contributed to the teaching of English grammar by highlighting the importance of analyzing real data (McCarthy, 1991; Rymes, 2015). This brief background on discourse analysis reflects how I previously viewed teaching grammar and how I currently perceive teaching using discourse analysis as a transformative tool.

Discourse analysis, remarkably, provides a crucial lens through which we can view grammar not as a set of rigid rules but as a dynamic tool for building meaning and purpose within specific contexts. By incorporating relevant insights, I believe that discourse analysis will influence my perception of English grammar teaching in the future for a more meaningful and relevant experience for students. One of the primary strengths of discourse analysis lies in its ability to move beyond the confines of an isolated sentence (Georgakopoulou, 2019). Now that I have realized this concept of teaching through the lens of discourse analysis, instead of focusing on deconstructing individual grammatical structures, I could apply discourse analysis for students to examine how structures work together to create textuality. Baxter (2010) and Kaplan and Grabe (2002) supported this view of teaching and stated that this approach could better help learners create cohesive and coherent texts. This shift in perspective is crucial for students, as it allows them to see how grammar contributes to the flow of information, the development of ideas, and the overall impact of a text.

Reflecting on the application of discourse analysis in teaching, I was not aware previously that it could be helpful for me and my students to incorporate such an approach. For instance, I utilized several texts to teach grammar; however, I was not fully aware of or knowledgeable about the power of discourse analysis to transform grammar teaching. Given that I am somewhat learning about its transformative potential, I believe that it is crucial to incorporate practical ways to introduce this concept by leveraging available resources. This can be done, for instance, by analyzing or using real-world texts (e.g., news articles, poems, songs, excerpts from literary pieces, or even social media posts, lyrics, or captions from movies and series) for teaching.

Examining how writers employ references, ellipsis and substitution, conjunction, and theme-rheme structures can reveal the intricate ways in which grammatical choices contribute to textual coherence. For instance, tracing the connections established through anaphoric pronouns can shed light on the underlying structure of a complex argument, whereas analyzing the placement of new information (rheme) can demonstrate how writers build suspense or emphasize key points. Furthermore, discourse analysis encourages us to move beyond a purely technical understanding of grammar and towards considering its functional uses (Gee, 2017). By examining how different grammatical links convey specific meanings and achieve communicative goals in different contexts, students can gain deeper appreciation of the dynamic and subtle nature of language. They begin to understand that the "correctness" of a grammatical choice is not merely a matter of following rules, but rather a question of effectiveness in achieving a particular communicative purpose, which Newman (1996) called *sociolinguistic sense*.

Therefore, by weaving these threads of discourse analysis into the fabric of grammar teaching, teachers can move beyond rote memorization and boring exercises. Teachers can create a learning space where students become not just grammarians but also tailors of meaning-making. Through this, I can help students learn how grammatical choices are not isolated decisions, but threads sewed on a larger fabric, contributing to the coherence, flow, and purpose of a text. Thus, students begin to understand how language, through its intricate grammar, reflects

and shapes the world around us.

4 Suggestions for Teaching Practice

Formerly, as a student, I hated attending grammar classes based on traditional grammar instruction, with its focus on isolated sentences and rule-based drills, which often left me struggling with the disconnect between textbook examples and the use of language in the real world. However, as a teacher unraveling and exploring the world of discourse analysis, I find the possibility of bridging this gap by transforming the boring fabric of grammar into a tapestry of meaning and context exciting. Through the following suggestions for teaching practices, teachers can realize an English grammar classroom where students become not just grammarians but also tailors of meaning-making.

4.1 References

Anaphoric Adventures: Through this activity, students can be engaged in detective work as they follow "pronoun chain" in texts such as news articles, short stories, or even their favorite *Korean dramas* or *K-dramas* using subtitles. By discerning how *she* relates to a previously mentioned character or how *it* ties to a complex political event in a news article, students investigate how references ground ideas and foster thematic coherence.

Cataphoric Clues: Integrating this activity into teaching cataphoric reference, teachers must first conceal a mysterious object in the classroom and introduce it with a cataphoric pronoun such as *it* or a demonstrative *that*. Subsequently, students are asked to compose instructions using cataphoric references, fostering suspense and building clarity before the object is revealed.

Exophoric Review: This involves exploring shared cultural references in jokes or memes during class discussions. There are a variety of memes on various social media platforms (e.g., Facebook, Instagram, and X, formerly Twitter) to obtain sample texts. Students analyze how these references draw on external knowledge to generate humor, underscoring the role of exophoric reference in connecting language to the real world.

4.2. Ellipsis and Substitution

Ellipsis Song Analysis: Teachers can play songs, such as Bruno Mars' *Just the Way You Are*, where ellipsis is used for emphasis. For example, students can be asked to complete the following ellipted lyrics (from the above song): *And when you smile....* The class discusses how the missing words heighten the emotional impact, and students are invited to fill in the missing lyrics.

Substitution Script Switch-up: Select a scene from a film or TV show and encourage students to rephrase or continue the dialog on their own by incorporating substitution. Teachers can also provide rich examples of text from popular TV shows or series to supplement their learning. Thus, through this exercise, students' comprehension can be aided by understanding how substitution affects the tone and significance of dialogs.

4.3 Conjunction

Transition Time Machine: Through this activity, students can analyze different conjunctive adverbs such as *however* or *moreover* in historical speeches of, for example, local politicians or persuasive essays of known advertising companies locally. The teacher discusses how these transitions signal shifts in argument or emphasis, guiding the reader through the text's organization.

The Clash: In teaching cause and effect conjunctions, students may write paragraphs exploring topics relevant to their interests or topics discussed by the teacher. The aim is for students to consciously employ specific conjunctive phrases such as *therefore*, *as a result*, *contrastingly*, etc. to build logical organization and enhance coherence.

Debate it: In this activity, the teacher divides the students into opposing sides of a debate topic and instructs them to use specific conjunctive adverbs to counter arguments and construct their own persuasive reasoning. This activity emphasizes the dynamic role of conjunctions in argumentative discourse.

4.4 Theme and Rheme

Headlines and Hooks: Teachers may challenge students to rewrite headlines using the theme-

rheme structure, placing the newsworthy element (rheme) at the end to capture the readers' interest. This activity reinforces the power of effective build-up of information.

Suspenseful Stories: This activity may help develop students' creative skills. To do this, the teacher must choose a story and divide it into segments, giving each student only the theme (starting point) of their segment. They then write their part, building suspense by delaying the rheme (new information) until the next segment. This exercise shows how theme-rheme structures create anticipation and enhance narrative flow.

Rheme Relay Race: The teacher divides students into teams and provides them with a sequence of unrelated words. Each team then writes a sentence using these words, placing the most important information (rheme) at the end. This activity emphasizes the strategic organization of information, applying rhemes to achieve cohesion and textuality.

There are probably a lot more practical teaching practices that can be applied in English grammar classes. They are not limited to the suggestions provided. However, when teachers start to adopt discourse analysis as a transformative tool in English grammar instruction, it will revolutionize their approach to engaging students in meaningful language-learning experiences.

5 Conclusion

This discussion emphasizes the influence of discourse analysis on English grammar teaching. By moving beyond isolated sentences and rote memorization, discourse analysis offers a lens through which grammar can be viewed as a dynamic tool for building meaning and purpose in specific contexts. Furthermore, this paper highlights the importance of grammatical cohesion and textuality, emphasizing how discourse analysts explore the dynamic connections between words, phrases, and sentences. Specifically, various types of references (e.g., anaphoric, cataphoric, and exophoric), ellipsis, substitution, and theme and rheme are illustrated, showing how these grammatical links contribute to grammatical cohesion and textuality.

Notably, practical teaching suggestions are provided, encouraging teachers to engage students in activities using contextualized uses of grammatical items that aim to foster a deeper understanding of how grammatical choices contribute to textual coherence.

Therefore, discourse analysis advocates a paradigm shift in language instruction. Such an approach can provide teachers with a lens through which to integrate discourse analysis into their teaching practices. By doing so, students can develop a holistic appreciation for language, understand how grammatical choices contribute to the overall impact and effectiveness of spoken and written texts, and become tailors of meaning-making rather than purely grammar critics.

Lexico-syntactic features of ab initio pilots' and controllers' aeronautical English: A corpus linguistic investigation of aviation communication in the Philippine airspace

Ramsey Ferrer
Philippine State College of Aeronautics
De La Salle University-Manila
ferrer.ramsey@gmail.com

Shirley Dita
De La Salle University-Manila
shirley.dita@dlsu.edu.ph

Abstract

An exponential increase in aviation English (AE) linguistic studies has shown that language(s) used in the skies takes a crucial position that affects global aviation communication, where safety is the ultimate priority. However, there has been a lack of investigation on pilot-control communication, and the gap in AE studies in the Philippines is wide, necessitating further investigation as this area has been underexplored in the Philippine linguistic ecology. Using a corpus-based approach and transformational-generative framework analysis adapted from Philps' (1991), this study provides a linguistic maiden study on AE used for aviation communication among ab initio pilots and controllers in the Philippine air space. The Aviation Corpus of English-Philippines (ACE-PHI) sub-corpus of communication between pilots and controllers is used, and ab initio pilots' solo flights in routine situations are the chosen communicative event. This reports the lexical features of AE in various categories owing to the lexical density of noun categories and cardinals and the syntactic patterns at the sentential level, which resemble essential transformations afforded in naturalistic English utterances. Conceding to the generic T-rule, however, AE is generally marked by elliptical construction where a systematic deletion is not devoid of other syntactic structures.

1 Introduction

The aviation industry is a multicultural niche where multilingual speakers come into contact. Language is essential in aviation, as it primarily plays a crucial role in air navigation and safety. However, given the scale and complexity of the sector, it is remarkable and possibly even alarming that studies into aviation's language are still comparatively sparse despite the industry's transition toward English-based communications (Taylor & Udell, 2020). Studies on how language facilitates smooth interaction between and among aviation personnel to establish effective communication, which is a precursor to flight safety, have been explored by linguists to a limited extent. Global aviation-reported catastrophic accidents, such as Tenerife airport disaster (1997), PSA Flight 182 (1978), Avianca Flight 52 (19990), American Airlines Flight 965 (1990), Charkhi Dadri mid-air collision (1996), Garuda Indonesia Airlines Flight 152 (1997) have confirmed that language (mis)communication as one of the reasons (Krasnicka, 2016) and that inadequate English language proficiency was a contributory or latent factor (Friginal et al., 2019) causing tragedy. This has prompted the implementation of the International Civil Aviation Organization's (ICAO) Language Proficiency Requirements (LPRs). One contributing factor to miscommunication is the wrong interpretation of instructions (Ferrer et al., 2017). Pilots and controllers must comply with the ICAO LPRs to ensure they are proficient in aviation communication, aiming to provide "maximum clarity, brevity, and unambiguity" for safe and expeditious flights.

Over the past 20 years, most studies on language and aviation have focused on the analysis of (mis)communication between pilots and controllers, describing AE that is used in interaction (see Cushing, 1994; Barshi, 1997; Barshi & Healy, 1998), attributing the nativeness and non-nativeness of language users (Wu et al., 2018; Estival et al, 2016; Molesworth & Estival, 2015; Bowles, 2014; Kim & Elder, 2009; Jang, et al., 2014) to plain language choice over standard

phraseology (Bieswanger, 2016), analyzing linguistic markers from syntactic structures and standard lexemes of phraseology (Borowska, 2017), its aspects such as word interrogatives (Hinrich, 2008), differences between standard and plain aeronautical English (Prado & Tosqui-lucks, 2017; Ferrer et al., 2017) frequency (Moder & Halleck, 2009), pragmatics (Howard, 2008; Linde, 1988), pronunciation (Sullivan & Girginer, 2002), prosody (Trippe, 2018; Trippe & Baese-Berk (2019), workload and language production (Corradini & Cacciari, 2002), discourse analysis (Tiewtrakul & Fletcher, 2010; Friginal et al., 2021), English language proficiency (Prinzo, Hendrix, & Hendrix, 2008), speech acts (Prinzo, Hendrix, Britton, 1995), and speech functions (Zhao, 2023). These studies have shown the global significance of language in international communication, as pilots and controllers, whether native or non-native, are prone and equated to errors and miscommunication.

English has been emphasized as the language of the skies in these studies about language in aviation. One of the final requirements of the ICAO, which made English its official language in 1951, was that all radio transmissions use standard terminology. The ICAO introduced LPRs more than ten years ago to improve aeronautical radiotelephony communication and, thereby, the safety of international flights. ICAO LPRs cover not only non-native speakers' abilities to communicate smoothly but also native speakers' linguistic behavior, which should be adjusted to aeronautical communication needs (Borowska, 2017).

As global aviation continues to rise and increase operational capacities, there has also been an increase in accident rate (Hsu, Li & Chen, 2010) despite the conformity of member states to the established Standards and Recommended Practices (SARPS) of ICAO in supporting global air transportation safety and efficiency. In recent years, the percentage of accidents has been attributed to human factors (Colangelo, 2021). Human errors have caused most aviation disasters, and one of the most common forms is miscommunication, which can potentially lead to catastrophic repercussions (Ferrer et al., 2017).

Cushing's (1994) extensive studies on language factors in aviation, particularly air-ground verbal communication, have highlighted issues related to aviation safety, communication problems, social/cognitive mismatch, error-resistant linguistic protocol, and fatal words in aviation communication. These studies highlight the importance of language as a human factor in aviation communication but loosely define AE as a specific register using phraseology.

To date, three studies have explored aviation English in the Philippines: Ferrer et al. (2017) on standard and nonstandard lexicon, Ferrer & Flores (2019) on the acceptability level of non-standard phraseology among Filipino controllers, and Ferrer (in press) on language policy in Philippine aviation education. The peculiarity of the English language among Filipino aviation personnel may be attributed to their English varieties. Cited in the most recent studies (Prado, 2019; Friginal et al., 2019; Friginal et al., 2021; Schneider, 2022 in Tosqui-Lucks & Santana, 2022; Dinçer et al., 2023), Ferrer et al. (2017) found that the standard phraseology *go ahead* means giving permission to state a request but may mean moving forward, while *hold short* would mean not crossing or entering the runway mentioned but may mean proceeding or continuing. This suggests that the non-standard use of AE among Filipino pilots and controllers may have revealed the linguistic peculiarity of the English language variety used in the country.

Ferrer & Flores (2019) determined the acceptability level and potential risks of non-standard phraseology among Filipino pilots and controllers, hypothesizing significant variations in these factors based on their profile, such as rating. The study revealed that non-standard phraseology poses risks in operational communication, particularly in general operating procedures, landing/takeoff, taxiing, and in-flight. Filipino pilots and controllers revealed varying degrees of acceptability for non-standard phraseologies, such as the use of affirmative (m=2.81), which can lead to misunderstandings in RTF. This linguistic evidence demonstrates homophony and confusion-inducing phenomena, as different words or phrases sound exactly or nearly alike.

Moreover, Ferrer (in press) provides an overview of language policies in aviation Higher Education Institutions in the Philippines. The study used a corpus-based sociolinguistic approach to understand how *aviation* is represented by policymakers, teachers, and students, particularly pilots and controllers. The findings suggest that improving language policies can enhance the competence and competitiveness of aviation professionals in the global aviation industry.

This paper addresses the research gap on AE in Philippine aviation, highlighting the need for further investigation in the Philippine linguistic

ecology. It seeks to analyze the lexico-syntactic characteristics of aeronautical English in aviation communication in the Philippine airspace.

1.2 Research Questions:

1. What lexical features prevail in the aeronautical English used for aviation communication in the Philippine air space?
2. What constitutes the syntactic pattern of aeronautical English used for aviation communication in the Philippine air space?

1.3 Analytical Framework

As studies on AE have been purely descriptive linguistics in nature, a considerable number of investigations have established that lexical features of AE as a restricted register were contained in both standardized phraseology (SP) and plain aviation English (PAE) and can be characterized easily across genres and text types using the prescribed language provided for by the international and local regulatory bodies as standard references.

Nitayaphorn (2009) conducted a corpus-based conversation analysis of 556 messages from the International Civil Aviation Organization's Manual of Radiotelephony and actual language in air-ground communication from 1994-2004. Using AntConc software tool, this categorized lexical items into 11 conceptual groups based on aviation activities and flight profiles. These groups included facility (aircraft), weather (CAVOK), operational path (approach), system (ILS), area (aerodrome), parameter (altitude), unit of service (ACC), status (alert), process (altimeter setting), flight performance (abeam), and communication expression (acknowledge).

Lopez et al. (2013) analyzed a 60,864-word corpus of real air-ground communications from two French En-route control centers and one French major airport to analyze AE and PEL in communication between French controllers and pilots worldwide. They found major frequent grammatical categories in RefC and UseC, including the Noun category (47.2%), Interjection category (8 identical interjection forms), and Pronoun category (0.5%). The most used pronoun forms in RefC were *you* (65.52%), *I* (20.69%), *one* (8.62%), *me* (3.45%), and *what* (1.72%). The noun categories exhibited predominance in air traffic phraseology, even in Cada's (2016) corpus-based analysis of Czech aviation personnel's air traffic phraseology.

In contrast to Lopez et al.'s (2021) analysis of all types of air control, Drayton (2021) conducted a discourse-based corpus analysis of air control, focusing on tower control. The spoken corpus from Ghaf Aerodrome and Sandy Aerodrome was transcribed, while the written corpus was sourced from the UAE General Civil Aviation Authority, CAAP 69 UAE Radiotelephony Standards documents, and ICAO Document 9432 Manual of Radiotelephony. The corpus identified 10 proper noun categories, 19 number categories, and 29 aviation alphabet tags.

Drayton and Coxhead (2023) created a specialized technical vocabulary list for aviation radiotelephony, categorized into technical words (51.44%), numbers (12.13%), multiword units (3.20%), proper nouns (19.85%), and acronyms (2.27%). The most frequent technical words were *runway, to, request, tower, via, feet, right, report*, and *roger*. Cada's (2016) study found a lexical density of word classes, with frequent word classes including nouns related to geographical places, adjectives, verbs, adverbs, specialized terminology, and abbreviations.

The language used between pilots and air traffic controllers is ATC-English, which has a phraseology that differs from natural English and falls under the ESP (English for Specific Purposes) category in linguistics (Breul, 2013: 74). This language is used for a limited set of functions and has a prescribed phraseology with reduced syntax and vocabulary for routine actions. Notably, the seminal work of Philps (1991*),* drawn from a transformational-generative analytical framework, paved the way to characterize the (English) language used in air traffic control. Philps (1991) reports how the codified language of the phraseology differs from natural English on every major linguistic level. Looking closely at the lexico-syntactic analysis, Philps (1991) analyzed the air traffic control English sourced from the ICAO Official English-language version (in French airspace) elicited from a 541-utterance dataset (controlled-sourced-476; pilot-sourced-65) revealed predominant linguistic features of air traffic control English using phraseology in sentential level (*imperative*-42.5%*, followed by passive*-8.1%*, interrogative*-1.8%, and *negative*-1.7%) and phrase level (*determiner deletion in direct object*-26.2%*, noun phrase*-18.7%*, and adverbial phrase*-9.6%*, noun phrase deletion*-25.5%*, link verb deletion*-20.7%, and *deletion of preposition of place*-7.0% *and of direction*-4.1%).

A glimpse of the pioneering work on the linguistic features of phraseology (see Philps, 1991 for more details) revealed that *imperative utterances*, at the sentential level, are preponderant in ATC English, such as

(1) CONTINUE PRESENT HEADING; and
(2) TAXI TO HOLDING POINT,

Philps' (1991) syntactical analysis of linguistic features mainly characterized air traffic control English, as most utterances analyzed were controller-sourced only in a small corpus. However, it did not observe a proportionate number of utterances that included pilot-sourced, which the present study addressed by incorporating the utterances of ab initio pilots in the analysis because meaning is not inherent in individual linguistic forms but rather co-constructed through cooperative negotiation between pilots and controllers (Ishihara & Prado, 2021). Philps' (1991) description of AE phraseology as a distinct and restricted register is limited to ATC phraseological analysis.

The present study aims to establish a foundational linguistic investigation of aeronautical English used for aviation communication in the Philippine air space; hence, it employs Philps' seminal work (1991) as the main framework for the analysis.

2 Methodology

The current study is part of a larger corpus-based investigation that Ferrer (in press) is presently conducting, primarily a component in establishing a self-built corpus he termed the Aviation Corpus of English-Philippines (ACE-PHI). ACE-PHI covers two main subcorpora: (1) spoken data and (2) written data. The spoken data contains pilot-control communication from ab initio pilots' solo flights (controlled and uncontrolled) in selected communicative events such as routine and nonroutine situations. On the other hand, the written data consists of publicly available language policy-related and academic documents (e.g. curricula, etc.) from the Philippines' Civil Aviation Authority and the Philippine State College of Aeronautics. The written data were used as part of Ferrer's (in press) corpus-based sociolinguistic analysis of language policy in Philippine aviation education. However, as the building of the ACE-PHI is ongoing for a larger collection of the spoken data, the present study utilizes only the sub-corpus of communication between ab initio pilots and controllers only.

The datasets include matrices of the following:

1. Coded utterances: ab initio pilot-sourced and controller-sourced, of which utterances were coded using the following identifiers:
   1.1 Source Codes:
      SPS : Student Pilot-Sourced
      CS : Controller-Sourced
   1.2 Transformation Codes
      0001 : Imperative transformations
      0002 : Passive transformations
      0003 : Negative transformations
      0004 : Interrogative transformations
      0005 : Active [complex] transformations
      0006 : Exclamatory markers
2. Lexico-syntactic patterns per source: distribution which provides an overall view of the syntactic modification.
3. Patterns across syntactic modifications per source: distribution of lexico-syntactic patterns across transformations per source.

0001-0004 codes signify the initial transformations from Philps' (1991). However, when SPS data where included in the manual analysis, it showed different moods and voices in the utterances, leading to the addition of the active (complex) transformations, which were mostly SPS sourced, and exclamatory markers. The exclamatory markers were termed as a single category, which occurs in various forms and which meanings can be similarly explained in the studies of Bieswanger (2016, forthcoming on non-aviation and aviation-related English language), Estival et al. (2016), Friginal et al. (2019), Friginal et al. (2021), and Schneider (2022).

This study analyzed lexico-syntactic patterns of aeronautical English in Philippine airspace using Philps' (1991) framework. The data was analyzed with the help of a retired controller for 30 years and a private pilot, both of whom have served PhilSCA for less than ten years, to ensure inter-coding reliability. However, not all syntactic modifications were used in the analysis, as the data showed minimal occurrences of other modifications due to various reasons:

1. the communicative context in the sub-corpus sets out ab initio pilots' solo flights only;
2. the primary syntactical analyses focus on the macro function of patterns in the sentential level only to amplify the mood, logic, or voice of an utterance since dealing with micro functions in the phrasal level analysis would be too delimiting; and

3. although the analysis of syntactic patterns at the sentential level was mainly done to account for the relationship between the mood and illocutionary acts of the phraseological utterances used for meaning negotiation between ab initio pilots and controllers, a peripheral analysis of the phrasal level was marginally included and found helpful in determining the overall mood and voice of the utterances.

The study analyzed aeronautical English (AE) data in various features and statistical data from Sketch Engine and Microsoft Excel to determine its lexico-syntactic characteristics. The data was then manually analyzed to understand the communication contexts in the Philippine airspace, focusing on the use of aeronautical English in aviation.

3 Results and Discussion

The ab initio pilots' and controllers' AE reveals the lexical features and syntactic patterns afforded in the naturalistic English utterances but constitutes systematic sentential transformations, conceding to the generic T-rule (Radford, 1997), which shows a specific instance of syntactic movement rules, reflecting how elements in a sentence can change their positions to fulfill different syntactic functions.

We first present the most frequent lexical items, KWIC, collocations, visualization, 3-grams, 4-grams, and 5-grams in ACE-PHI ab initio pilot sub-corpus.

3.1 Lexical features in aeronautical English used for aviation communication in the Philippine air space

From the ACE-PHI sub-corpus of ab initio pilots' solo flights, Table 1 lists the top 100 most frequent words, with lexical words highlighted, although many function words like prepositions (e.g., *for, to, at, up, via*) conjunction (e.g., *and*), and determiners (e.g., *the, a*) top frequency lists in the corpus which implies a great diversity in distribution.

The most frequent lexical items in AE are in the nominal category, including *rpc, runway, report, base, tower*, and cardinal numbers (e.g., *zero, one, two, three*) as can also be gleaned in Figure 1. This reports significant patterns as *rpc* indicating aircraft callsigns tops the word list (Lopez et al, 2013; Nitayaphorn, 2009; Drayton, 2021). While aircraft call signs constitute alphanumeric codes, transmitted by pronouncing each digit separately (ICAO Doc 9432, p.2-3, it could be construed that *rpc* co-occurs with cardinal numbers as in RPC 8370 transmitted as *RPC eight three seven zero.* Hence, it is more interesting to determine the collocates of *runway* – the second topmost lexicon.

Looking closely at the discrete linguistic elements and their common components as they appear before or after each single word to form a consistent pattern in the discourse (Firth, 1957) is crucial especially in interpreting discourse characteristics of AE that may be unique to the aviation domain (Zhang, 2019). Using KWIC feature of Sketch Engine, Table 2 enumerates only the top 15 collocates of *runway,* to observe brevity in presentation.

We shall now turn to the lexical item *clear* which appears interestingly in two categories: verb (181) and adjective (52). Precisely, it needs to be confirmed in visualization and concordance lines to check the POS category and its actual functions.

On the one hand, Figure 2 shows that *clear* primarily is a verb collating with *runway* as its objects in (3), which is in the interrogative construction. However, the transformation of *clear* into *cleared* is blocked by the presence of prepositions *to* (67 tokens) and *for* (92 tokens) that occur in passivized construction, as shown in (4a) and (5a) as opposed to the naturalistic utterances in (4b) and (4b). Passive transformation, along with systematic deletions (e.g., subject-pronoun and determiner deletions), as discussed later, is seen as a significant feature in the lexico-syntactic pattern of AE in aeronautical communication.

[1](3) / Can you forward to *clear* the runway?
(4a) <s> Code Runway zero five *cleared* for take-off, RPC 416 //
(4b) (You are) *cleared* for take-off
(5a) 0002 copy ma'am *cleared* to land Runway two three 7988 //
(5b) (I am) *cleared* to land (via) Runway two three 7988

While *cleared for take-off* and *cleared to land* occur frequently in the corpus, which follows the standard phraseology for giving clearances alike (ICAO Doc 9835), a considerable number of

[1] This is considered a non-standard phraseology for clearing the runway. A more appropriate phraseology to use is *vacate (specific point of runway reference or intersection).*

occurrences of *cleared for touch and go* (30 tokens) deserves attention because the systematic deletion of preposition *for* shall be observed if we base it on the Manual of Radiotelephony (ICAO 9432), yet it is found in the corpus illustrated in (6a) against the naturalistic utterance in (6b).

(6a) *cleared for touch and go* Runway two three RPC 349 //
(6b) (I am) cleared for touch and go (via) Runway two three RPC 349

On the other hand, Figure 3 visualizes the collocates of *clear* in the adjective category, which modification in utterances usually takes place in situations or procedures that involve giving traffic information in general or making turns in particular and describing short field take-off procedures, runway take-off roll, start of the climb, visual reference for traffic pattern turn, and reporting established downwind, as shown in (7a), where a systematic deletion of linking verb *is* occurs as opposed to the naturalistic utterance in (7b).

(7a) // left clear, front clear, right clear // three hundred feet
(7b) (My) left (is) clear, front (is) clear, (and) right (is) clear

Likewise, this study reveals that AE features personal pronouns such as *you* and *we,* which resemble the same patterns, being the topmost pronouns in Prado (2010), Moder and Halleck (2012), and Pacheco (2021). Although using personal pronouns is not encouraged in aeronautical communication (Pacheco, 2021), its significance cannot be underestimated, as Neville (2004) assumed it to be significant in assigning identities.

Moreover, this presents the most frequent multi-word units (MWU) in the ACE-PHI. MWUs are expanded collocations frequently occurring as linear strings, similar to prefabricated chunks of language (Zhang, 2019). Table 3 presents the N-grams used to measure the occurrences of MWU.

In summary, the lexical features of AE in the ACE-PHI sub-corpus of communication between ab initio pilots and controllers are characterized by the lexical density of noun category, with aircraft callsigns as the most frequent. Cardinals, verbs, prepositions, adjectives, conjunctions, adverbs, and pronouns follow the list.

3.2 Syntactic patterns in aeronautical English used for aviation communication in the Philippine air space

AE patterns reveal a unique yet systematic transformation when following the generic T-rule that shows instances of syntactic movement. One major feature that accounts for these transformations is using ellipsis (Philps, 1991). Ellipsis is when certain words or phrases are omitted from a sentence because they are either understood from the context or are unnecessary for conveying the intended meaning, which helps to avoid redundancy and makes communication more efficient.

The syntactic pattern in AE shows that various modifications occur in pilot-control communication. Table 4 shows a contradictory result in Philps (1991) positing imperatives to be preponderant in ATC English since most of the utterances in his study were controller-sourced (476) rather than pilot-sourced (65). It must be noted that Philps (1991) focused on ATC English phraseology that appears in ICAO phraseology, while the present study analyzed actual utterances of pilots and controllers, as this aimed to observe proportionate representativeness in the exchange of communication between them. Although the controller-sourced utterances (58.96%) were more than ab initio pilot-sourced (41.04), the present study data revealed the preponderance of active transformations, which were produced mainly by ab initio pilots, followed by imperatives more frequently produced by controllers, passive, exclamatory, and a few instances of interrogative and negative transformations. The following show the transformations in the corpus:

(8a) Bicol to RPC 349 / Request taxi instructions to the active //
(8b) (I) request (for) taxi instructions to the active (runway)
(9a) RPC 349 / taxi and line up / Runway two three //
(9b) (I would like you to) taxi and line up via Runway two three //

In (8a), the ab initio pilot's phraseology *request taxi instructions to the active* has been transformed from its naturalistic English utterance as in (8b) in the active construction. In this transformation, the T-rule generates the same terminal string in the phraseology as in natural English. However, the active transformation shows virtually a systematic deletion of subject-pronoun *I* as this is already determined in part of

the extralinguistic context, and further intralinguistic detemination is redundant. This further explains why pronouns are not frequently used in AE despite their marginal significance in assigning identities.

In (9a), the controller's response to the ab initio pilot using the phraseology *RPC 349 taxi and line up Runway two three* has been transformed from its naturalistic English utterance as in (9b) in the imperative construction. The imperative T-rule in this transformation also yields the same terminal string in the phraseology as in natural English; however, it essentially replaces all other syntactic structures in natural English to convey the illocutionary force in inciting the ab initio pilot to take action using a modal. Philps (1991) reported that the use of the imperative is closely, but not exclusively, related to scenarios involving changes (of heading, level, etc.) or movement (crossing, passing, etc.).

The preponderance of active transformations in ab initio pilots' utterances and imperative transformations in controllers' utterances have shown the significance of a controlled, equal, and coordinated flow of AE in operational aviation communication. This implies the significance of coordinated communication between ab initio pilots and controllers, which is realized through adherence to radiotelephony protocols such as readback, i.e., to "repeat all, or the specified part, of this message back to me exactly as received," (ICAO Doc 9432, p.2-7).

As controllers perform their role by giving instructions for various purposes, ab initio pilots must ensure they receive and understand these instructions clearly. The crucial interplay between ab initio pilots' and controllers' utterances is realized mainly through active and imperative transformations, and the rest of the syntactic modifications in AE used for aviation communication can be gleaned in Figure 4.

The figure above shows that the SPS group has a slightly higher median than the CS group, indicating a higher central tendency of the SPS data. Likewise, the SPS group shows a wider spread in the data, as indicated by a larger interquartile range and longer whiskers, suggesting more variability in the student pilot-sourced data compared to the controller-sourced data. Furthermore, the plot shows a slight upward trend from CS to SPS, as indicated by the line connecting the medians of both groups.

However, a closer look at Figure 5 shows how AE utterances are widely distributed between SPS and CS across syntactic modifications. CS values tend to be higher in imperative transformations, negative transformations, and active transformations while the SPS values are generally lower than CS values, except in passive transformations and interrogative transformations. Likewise, there is noticeable variability in the data as indicated by the size of the error bars.

This implies that although ab initio pilots tend to produce slightly higher numbers of utterances, such utterances must observe succinctness and accuracy to provide "maximum clarity, brevity, and unambiguity" (ICAO 9432, p. 3-2). As the purpose of phraseologies is to provide clear, concise, unambiguous language to communicate messages of a routine nature (ICAO 9835, p. 7-2), both ab initio pilots and controllers must ensure that their utterances, realized by active and imperative transformations in AE, despite the number of utterance production, conform or adhere to the prescribed standard radiotelephony.

We shall now turn to the third type of modification at the sentential level: passive transformation. Philps (1991) reported that in the passive transformation, the terminal string found in natural English never materializes in the phraseology, owing to various T-rule deletions, as found in the corpus shown in (10a) and (11a) against the naturalistic utterances in (10b) and (11b):

(10a) RPC 416 / wind zero six zero at ten knots Runway zero five / cleared to land //

(10b) (You are) cleared to land (with a) wind (direction of) zero six zero (and wind speed) at ten knots (on) Runway zero five

(11a) RPC 8730 / roger / wind two two zero at twelve knots / Runway two three / cleared for touch and go

(11b) [(I have received all of your last transmissions. (You are)] cleared (for) touch and go (at) wind two two zero at twelve knots on Runway two three

As for the passive transformations, various systematic deletions occur, such as subject-pronoun deletion, preposition of purpose, and preposition of location or position. The subject-pronoun deletion is common in natural English utterances (e.g., went back to the airport today) but is systematic in passive construction as ab initio pilots and controllers are preidentified and require no further overt determination (Philps, 1991).

Furthermore, it can be construed that although the subject-pronoun is systematically deleted, it is replaced by the presence of the aircraft callsign as representative of the station being called.

However, it is important for both ab initio pilots and controllers always to follow the form of communication and structure of phraseology not only when establishing initial contact with the controller but throughout the communication or until termination and final instruction, as an omission of aircraft callsigns has been observed in a few instances in the corpus.

Meanwhile, in Philps (1991), negative and interrogative patterns barely occur similarly in the corpus. It must be noted that the only instance of AE pattern that denotes a negation is apparent in the use of the phraseology *negative* as in (13) when the controller inquired about the visual of another aircraft in (12). However, instances like in (14) show an interrogative pattern found in the corpus.

(12) Roger / RPC 840 / confirm visual with the Cessna 152 / proceeding North of Doljo
(13) Negative / sir / uh still on the lookout / RPC 840 //
[2](14) / Can you forward to clear the runway?

Finally, the last category found in AE used for aviation communication has been controversial and marginal yet apparent in almost all types of communication, even in routine situations. While calling it temporarily exclamatory pattern, as this never occurs in any of the aviation manuals for radiotelephony, a considerable number of studies have demonstrated the use of exclamation. An exclamation is an utterance expressing strong emotion, surprise, or other affective states. Due to its unique grammatical properties and communicative functions, it is often classified as a distinct syntactic and pragmatic category. While the phraseology *Mayday! Mayday!* identifies a distress message, and *Pan Pan!* identifies an urgency message as what could be considered the only, if not found, exclamatory markers in the manuals, there have been other markers used in ab initio pilots and controllers' actual utterances, such as *thank you, congratulations, have a good day, good day, congrats, good morning, good afternoon, sir,* and *ma'am,* which are all found in the corpus shown below:

(15) Bicol Tower RPC 8730 vacated the active runway and … closing flight plan *good day* and *thank you* //
(16) RPC 349 uhh *congratulations* on your first solo //
(17) Binalonan Radio RPC 896 / *Good Morning* Number 1 holding 17 / request for full length departure for normal full stop / 17 RPC 896 //
(18) RPC 840 / Panglao tower / *good afternoon* / Go ahead
(19) Copy *Ma'am* / cleared to land Runway two three / 7988
(20) RPC 840 / *sir* / departed Dumaguete / destination Panglao / approximately 20 miles Southwest of your station / 2500 / and estimate to your station is 0620Z

These exclamatory markers identified for this study as politeness markers (as described in Linde, 1988) have appeared in recent studies on AE (Bieswanger, 2016; Friginal et al., 2019; Friginal et al. 2021, Dissanayaka et al., 2022; Estival et al., 2023). Politeness markers are often added even though they are not mentioned in the regulations (Lopez, 2013; Moder, 2013) because these can be considered a common type of deviation from phraseology (Estival et al. 2023). Nevertheless, these markers are argued to be helpful in general conversation, as they help smooth interactions by creating better interpersonal relations between the interlocutors. For example, Friginal et al. (2021) reported that these are positive AE features, including politeness and respect markers (e.g., *thanks, please, ma'am*, and *sir*). The same was observed in AE utterances used for aviation communication among Filipino ab initio pilots and controllers in the Philippine air space.

In summary, the lexico-syntactic pattern of AE is generally marked by elliptical construction where a systematic deletion is not devoid for other syntactic structures. Specifically, there is a higher frequency of active transformations and imperative transformations in relation to other formulations, and there is a specific T-rule deletion in relation to natural English. These systematic deletions clearly demonstrate that the phraseological utterances are governed by syntactic rules whose function is to restrict the

[2] This is considered a non-standard phraseology for clearing the runway. A more appropriate phraseology to use is *vacate (specific point of runway reference or intersection).*

linguistic content to the logico-semantic data, the onus being on the receiver to recover the suppressed morphosyntactic constituents (Philps, 1991)

4 Conclusion and Recommendation

This study provides a general picture of the AE used for aviation communication among ab initio pilots and controllers in the Philippine setting. Using a corpus-based approach, the study shows that AE constitutes various lexico-syntactic patterns in the ACE-PHI sub-corpus of communication between ab initio pilots and controllers.

On the one hand, it can be concluded that AE used for aviation communication is generally characterized by the lexical density of noun category, with aircraft callsigns as the most frequent, followed by cardinals, verbs, prepositions, adjectives, conjunctions, adverbs, and pronouns.

On the other hand, significant modifications are happening in AE in relation to natural English utterances, which the generic T-rule can explain. While ab initio pilots and controllers produced a relatively proportionate number of utterances that signal coordinated communication as realized by the dynamic interplay of active transformations and imperative transformations, occurrences of passive transformations likewise show such coordinated message, but caution must be emphasized on consistently following the basic phraseological structure in operational radiotelephonic communication, such as stating the station calling and the station being called throughout the communication.

Finally, it is worth mentioning that this study has some limitations that can be used to offer recommendations for future studies in the Philippines. First, the sub-corpus used for this study situates ab initio pilots' solo flights only as the chosen communicative event. ACE-PHI is currently being built, and more data from commercial flights can be added for a comparative analysis. Second, the ab initio pilots' solo flights focus on routine situations only. Exploring the density of lexical categories in non-routine situations would be interesting. Last, as the syntactic analysis focuses on the sentential level, marginally accounting for phrasal level analysis, a more detailed analysis of phrasal levels in a larger corpus is worth investigating.

Acknowledgments

We thank the ab initio pilots, who mainly provided the recorded communication with consent. We also thank Mr. Manuel Limbo, Malila Prado, Thiago, Silva, and Jron Zafra for helping us in many ways.

Age does matter: A generational comparison on the morphological and lexical variations of Tagalog nominal and pronominal systems in Bataan

Lemuel R. Fontillas, PhD
Bataan Peninsula State University
lrfontillas@bpsu.edu.ph

Abstract

This study examines how age and social circles shape language use among Bataeños in the Philippines. Younger speakers favor new words, often from English, and shortened forms, aligning with Labov's (1994) theory of generational language change and globalization's influence (Tupas, 2019). The middle generation blends traditional and modern vocabulary, reflecting Trudgill's (2000) sociolinguistic variation, while older speakers prioritize established terms, preserving linguistic heritage (Mahboob & Cruz, 2020). Social circles further impact language, with middle-aged speakers switching between Filipino and borrowed terms (Bautista & Bolton, 2020). The study suggests that Filipino's agglutinative nature (Maganto-Salamat, 2019) facilitates word formation, with younger speakers possibly simplifying structures (Pordes et al., 2022). These findings highlight the dynamic interplay of age, social context, and historical influences in shaping Filipino language. Future research can explore globalization and social media's role in this evolving linguistic landscape

1 Introduction

Language evolves throughout life, shaped by biological, cognitive, social, and cultural factors. Infants progress from babbling to word production (Fenson et al., 1994), while preschoolers rapidly acquire grammar and communication skills (Hoff, 2006). Language continues to expand in vocabulary and complexity through childhood and adolescence (Bloom, 1993).

Sociolinguistics explores how age, gender, ethnicity, and socioeconomic status influence language variation (Labov, 1972; Crystal, 2012). Generational differences in speech patterns shape identity and social belonging (Eckert, 2000; Giles & Coupland, 1991). Understanding these factors aids language acquisition, education, and intergenerational communication (Hart & Risley, 1995; Lightbown & Spada, 2013).

Tagalog's morphological system evolves with age, as seen in affixation and verb forms (Pinker & Ullman, 2002; Bybee & Slobin, 1982). Studying these changes informs linguistic research, language education, and speech therapy (MDPI, 2023; MIT Press, 2023).

2 Review of Related Literature

As we age, our use of Tagalog morphology evolves. Researchers can predict a speaker's age by analyzing errors in prefixes, suffixes, and verb tenses, as younger speakers are still mastering complex grammar (MDPI, 2023; Pinker & Ullman, 2002). The dual-route model explains how children process regular and irregular verbs differently (Bybee & Moder, 1983). Beyond errors, younger speakers adopt newer slang pronominal clitics, while older speakers prefer simpler syllable structures and a broader vocabulary (Dita, 2010; Imperial & Ong, 2021).

Developmental Psycholinguistics links cognitive growth with language skills (Bybee & Slobin, 1982). Comparing Tagalog to related languages and using computational tools can provide deeper insights (Himmelmann, 2008). These findings inform education and speech therapy by tailoring approaches to learners' developmental stages (Lightbown & Spada, 2013). Despite the known age-language link, research on Tagalog morphology remains limited. Future studies should explore how word structures indicate age, enriching our understanding of language development and identity.

3 Objectives of the study

The aim of this study is to systematically investigate and document the lexical and morphological variations within Tagalog nominal and pronominal forms as spoken across the Bataan province. The study seeks to address a critical research problem: the limited understanding and documentation of generational differences in Tagalog nominal and pronominal usage in the region. Language is a dynamic phenomenon, and as speakers interact with various social, cultural, and generational influences, these interactions often manifest in distinctive linguistic features. The analysis will be further stratified by age groups encompassing: Young adults (29 years old and younger); Middle-aged adults (30-59 years old); and, Older adults (60 years old and above)

Despite the significance of capturing such linguistic nuances, there remains a gap in detailed records that comprehensively document how nominal and pronominal forms vary between younger, middle-aged, and older generations of Bataeños. Without such documentation, valuable insights into how the language evolves within specific age groups and social contexts remain largely unexplored.

Therefore, this study aims to bridge this gap by undertaking a descriptive analysis and compiling an inventory of the distinct lexical and morphological variations in these forms, categorized by age group. By doing so, the research not only provides a record of linguistic diversity but also explores the broader implications of these variations in relation to generational language change, preservation of linguistic heritage, and adaptation to modern influences. Ultimately, the study intends to contribute to linguistic scholarship by offering a deeper understanding of how age, culture, and historical context shape the linguistic landscape of Tagalog in Bataan.

4 Methodology

This research employs a mixed-methods approach (Johnson et al., 2017) to explore lexical variation in Tagalog across the Bataan province. The quantitative component will involve analyzing the frequency and percentage of lexical variations across municipalities and cities. The qualitative aspect will focus on morphological analysis of the collected data.

A modified survey questionnaire was utilized, incorporating a 160-item lexical test designed to capture nominal and pronominal variations. The questionnaire design draws inspiration from previous works on the Tagalog lexicon (Dita, 2011; Francisco, 2015; Ruffolo, 2004).

The study encompasses the entire province of Bataan, with a target population of 760,650 (Philippine Statistics Authority, 2015). A stratified sampling technique was employed, selecting three age groups (young, middle-aged, and old-aged) from each of the 11 municipalities and 1 city within the province. This approach ensured a comprehensive representation of language users across generations (Aronson et al., 1995).

Participants and their grandparents should have been raised locally in Bataan to qualify for the study. Each age group consisted of 15 participants per locality, resulting in a total sample size of 540. This sample size was sufficient to capture a diverse range of lexical items with potential variations (Krejcie & Morgan, 1970).

The age stratification acknowledges the potential influence of sociolinguistic factors on language use (Labov, 1972). The study directly compared age groups to provide a comprehensive picture of the lexical variation across Bataan.

Given the linguistic landscape of Bataan, identifying participants who are monolingual native Tagalog speakers might be challenging. Therefore, a language background survey was conducted to confirm Tagalog dominance among participants, regardless of their geographical location or political affiliation within the province. Furthermore, the study anticipated and accounted potential presence of Taglish, a code-switching phenomenon that integrates English lexical items with Tagalog grammar (Bautista, 2010).

5 Results and Discussion

5.1 Concrete Nouns

The linguistic preferences of different age groups (29-below, 30-59, and 60-up) for 30 everyday objects, focusing on native and borrowed terms. The younger generation predominantly uses native terms such as "langgam" for ant and "saging" for banana, but there is also notable adoption of borrowed terms like "libro" for book and "electric fan" for bentilador. The middle age

Table 1.
Concrete Nouns

Lexical items	Age 29 below	Age 30-59	Age 60-up
1. ant / langgam	langgam	Langgam, ant	panas
2. banana / saging	saging	Saging, banana	saging
3. bed / kama	kama	Kama, bed	kama
4. book / aklat	libro	Aklat, libro	libro
5. branch / sanga	sanga	Sanga	sanga
6. cabinet / kabinet	cabinet	Kabinet, cabinet	kabinet

group exhibits a blend of native and borrowed terms, such as "kama, bed" and "aklat, libro," reflecting a transitional linguistic stage that balances between traditional native terms and newer borrowed terms. The older generation shows a strong preference for native terms, such as "panas" for ant and "kama" for bed, and retains traditional vocabulary, indicating resistance to adopting newer borrowed terms.

5.2 Abstract Nouns

Table 2 presents the abstract nouns commonly used by the respondents.

Table 2.
Abstract-state Nouns

Lexical items	Age 29 below	Age 30-59	Age 60-up
1. anger / galit	Galit	Galit, anger	galit
2. anxiety / pagkabalisa	pagkabalisa	Pagkabalisa, anxiety	anxiety
3. brilliance / kaningningan	kaningningan	Kaningningan, brilliance	kaningningan
4. courage / katapangan	katapangan	Katapangan, courage	courage
5. cowardice / pagkaduwag	pagkaduwag	Pagkaduwag, cowardice	pagkaduwag

The younger generation predominantly uses native terms such as "galit" for anger, "pagkabalisa" for anxiety. There is also consistency in usage, as seen in the data there is a clear preference for native terms, indicating a uniform linguistic pattern. On the other hand, the middle age group (30-59) exhibits a mix of native and borrowed terms. This group showed a blend of native and borrowed terms such as "Galit, anger," "Pagkabalisa, anxiety". Also, this group is in the transitional stage. This age group reflects a transitional linguistic stage, balancing between traditional native terms and newer borrowed terms. Lastly, the older generation (60 and up) showcased a strong preference for native terms. The older generation shows a strong preference for native terms such as "galit" for anxiety, "kaningningan" for brilliance. It was also evident that there is a retention of traditional vocabulary in this group. The tendency to retain traditional vocabulary is indicated in the resistance to adopting newer borrowed terms.

5.3 Comitative Nouns

For comitative nouns a set of 15 terms related to social relationships, highlighting the use of native terms, and borrowed terms.

Table 3.
Comitative Nouns

Lexical items	Age 29 below	Age 30-59	Age 60-up
1. a person whom you tell jokes to / kabiruan	kabiruan	Kabiruan, jokes	kabiruan
2. childhood friend / kababata	kababata	Kababata, childhood friend	kababata
3. classmate / kaklase	kaklase	Kaklase, classmate	kaklase
4. comrade / kasamahan	kasamahan	Kasamahan, comrade	kasamahan
5. countryman / kababayan	kababayan	Kababayan, countryman	kababayan

The younger generation predominantly uses native terms (e.g., "kabiruan" for a person whom you tell jokes, "kababata" for a childhood friend. There is a clear preference for native terms, indicating a uniform linguistic pattern. The middle age group (30-59) exhibits a blend of native and borrowed terms (e.g., "Kabiruan, jokes," "Kababata, childhood friend"). The term "kasamahan" is stable across age groups, but the middle-aged group's addition of "comrade" highlights a tendency towards lexical borrowing and integration of English terms, a phenomenon discussed in bilingualism studies (Mesthrie, Swann, Deumert, & Leap, 2000). This age group reflects a transitional linguistic stage, balancing between traditional native terms and newer borrowed terms. Lastly, the older generation shows a strong preference for native terms (e.g.,

"kabiruan" for a person whom you tell jokes, "kababata" for a childhood friend. This group tends to retain traditional vocabulary, indicating resistance to adopting newer borrowed terms.

5.4 Reciprocal Nouns

Table 4 presents the reciprocal nouns commonly used by the respondents.

Table 4.
Reciprocal Nouns

Lexical items	Age 29 below	Age 30-59	Age 60-up
1. a child and his/her aunt / mag-tiya	Mag tita	Mag-tiya, mag-tita	magtiya
2. a child and his/her grandfather / mag-lolo	mag-lolo	Mag-lolo, mag-apo	maglolo
3. a child and his/her grandmother / mag-lola	mag-lola	Mag-lola, mag-apo	maglola
4. a child and his/her uncle / mag-tiyo	Mag tito	Mag-tiyo, mag-tito	magtiyo
5. brothers-in-law / mag-bilas	mag bilas	Mag-bilas, bayaw	magbilas

The younger generation predominantly uses native terms, sometimes with slight morphological variations (e.g., "Mag tita" for a child and his/her aunt, "mag-lolo" for a child and his/her grandfather. Terms are often presented in simplified or contracted forms (e.g., "mag ama" instead of "mag-ama"). Younger speakers often use simplified or contracted forms of terms. This aligns with language economy principles, where speakers favor shorter and more efficient forms (Zipf, 1949). The Middle Age Group (30-59) exhibits a blend of native terms and English borrowings (e.g., "Mag-tiya, mag-tita," "Magpinsan, cousin"). This group also reflects a transitional linguistic stage, balancing traditional native terms and newer borrowed terms. The middle age group's mix of native and borrowed terms can be explained by language contact and borrowing theories. Thomason and Kaufman (1988) state that language contact often results in the borrowing of lexical items, reflecting this group's adaptation to both native and global influences. The older generation (60-up) shows a strong preference for native terms with consistent morphology (e.g., "magtiya" for a child and his/her aunt, "maglolo" for a child and his/her grandfather). This group tends to retain traditional vocabulary and morphological consistency, indicating resistance to adopting newer borrowed terms. Labov (1994) discusses how language changes over generations, with younger speakers often adopting new forms and older speakers retaining traditional ones. This is evident in the younger group's preference for simplified forms and the middle-aged group's use of both native and borrowed terms. Fishman (1991) emphasizes the importance of preserving native languages. The older group's preference for native terms aligns with efforts to maintain linguistic heritage, resisting the influx of borrowed terms.

5.5 Instigator Nouns

Table 5 presents the instigator nouns commonly used by the respondents.

Table 5.
Instigator Nouns

Lexical items	Age 29 below	Age 30-59	Age 60-up
1. baker / tagaluto ng tinapay, magtitinapay	panadero, baker, magtitinapay	Panadero, baker	magtitinapay
2. batter / tagapalo ng bola	tagapalo ng bola, batter	Tagapalo ng bola, batter	tagapalo ng bola
3. carrier / tagabuhat; tagahatid	tagahtid, carrier	Tagabuhat, carrier	tagahatid
4. catcher / tagasalo ng bola	tagasalo ng bola, catcher	Tagasalo ng bola, catcher	tagasalo ng bola
5. cleaner / tagalinis	tagalinis, cleaner	Tagalinis, cleaner	tagalinis

The most prominent morphological difference observed is the use of affixes to derive specific occupations from root words. For instance, the root word "gawa" (to make) is used to form "magtitinapay" (baker) and "tubero" (plumber) by adding the prefixes "magti-" and "tu-" respectively. Similarly, the root word "dala" (to carry) is used to derive "tagahatid" (carrier) and "tagasundo" (fetcher) by adding the prefixes "taga-" and "tagas-" respectively.

The data also reveals lexical variations for certain occupations. For example, "baker" can be expressed as "panadero" or "magtitinapay," while "carrier" can be expressed as "tagahatid" or "tagabuhat." These variations reflect the richness and diversity of the Bataeño vocabulary.

5.6 Body Parts/Organs

Table 6 presents the body parts/organs commonly used by the respondents.

Table 6.
Body Parts/Organs

Lexical items	Age 29 below	Age 30-59	Age 60-up
1. alak-alakan	alak-alakan	alak-alakan	alak-alakan
2. atay	atay	atay	atay
3. baba	baba	baba	baba
4. baga	baga	baga	baga
5. bahay-bata	bahay-bata	bahay-bata	bahay-bata

There was also a list of body parts and their terms used across different age groups (29-below, 30-59, and 60-up). It reflects the linguistic preferences and potential generational differences in terminology. The younger group (29-below) incorporates English terms or bilingual forms (e.g., "wrist" instead of "galang-galangan", "eyes" alongside "mata"). There are hybrid terms that use both native and borrowed terms (e.g., "paa, foot, feet", "tainga, ears, tenga"). Younger speakers often incorporate borrowed terms due to language contact and globalization. According to Bautista and Bolton (2020), bilingualism and language contact lead to hybrid forms in multilingual societies. The middle age group (30-59) predominantly uses native terms but also includes bilingual forms in some cases (e.g., "sipit-sipitan, matres, cervix", "supot-apdo, gall bladder"). This group shows a balance between native terminology and some inclusion of English terms, reflecting a transitional linguistic stage. The older generation (60-up) consistently uses native terms (e.g., "galang-galangan", "supot-apdo", "sipit-sipitan"). This group also maintains traditional vocabulary and demonstrates resistance to adopting newer borrowed terms. Deterding and Kirkpatrick (2019) discuss how language use shifts across generations, with younger speakers more likely to adopt new forms and older speakers retaining traditional vocabulary. The older generation's preference for native terms aligns with efforts to preserve linguistic heritage, resisting the influx of borrowed terms, as noted by Mahboob and Cruz (2020).

5.7 Other Common Nominals

Table 7 presents other common nominals commonly used by the respondents.

Table 7.
Other Common Nominals

Lexical items	Age 29 below	Age 30-59	Age 60-up
1. alimasag	alimasag	alimasag, crab	alimasag
2. alulod	alulod	alulod, drain	alulod
3. alupihan	alupihan	alupihan, centipede	alupihan
4. am	am	am	am
5. ambon	ambon	ambon	ambon

The study also looked on a set of terms used for various objects, concepts, or creatures across three age groups (29-below, 30-59, and 60-up). It shows the variations in linguistic preferences and usage patterns among these age cohorts. The younger generation (29-below) primarily uses native terms with few variations. There is minimal use of English terms, indicating a strong retention of native vocabulary (e.g., "katang", "kumpas"). The middle age group (30-59) often incorporates English translations or equivalents alongside native terms, showing a bilingual influence (e.g., "alimasag, crab", "alulod, drain"). There is also a reflection of a mix of traditional and modern vocabulary, indicating a shift towards integrating more English terms. Tupas (2019) highlights that the middle-aged group's integration of English reflects sociolinguistic dynamics, where education and globalization play significant roles. Lastly, the older generation (60-up) consistently uses native terms, demonstrating resistance to adopting English or new terminologies (e.g., "alimasag", "alulod"). They maintain traditional vocabulary, highlighting cultural preservation and less influence from English. Mahboob and Cruz (2020) discuss how the older generation's use of traditional terms aligns with efforts to preserve linguistic heritage.

5.8 Numeral nominals

The Bataeño numbers showcases a fascinating interplay of morphological patterns, reflecting the language's rich linguistic heritage. One notable observation is the presence of two distinct forms for numbers 1 to 10, namely the native Filipino terms (e.g., "isa," "dalawa," "tatlo") and their Spanish counterparts (e.g., "uno," "dos," "tres"). This dual representation stems from the historical influence of Spanish colonization on the Philippines, leading to the adoption of Spanish loanwords into the Filipino vocabulary.

Another intriguing morphological aspect lies

in the formation of numbers from 11 to 20. These numbers employ a prefixing system, where the word "labing-" (meaning "above") is attached to the corresponding cardinal numbers (e.g., "labing-isa," "labindalawa," "labintatlo"). This prefixing pattern highlights the language's agglutinative nature, where morphemes (meaningful units of language) are combined to form complex words.

Table 8.
Numeral Nominals

Lexical items	Age 29 below	Age 30-59	Age 60-up
1. isa	Isa, one	isa	isa, uno
2. dalawa	Dalawa, two	dalawa	dalawa, dos
3. tatlo	Tatlo, three	tatlo	tatlo, tres
4. apat	Apat, four	apat	apat, kwatro
5. lima	Lima, five	lima	lima, singko

The data also reveals lexical variations across different age groups, revealing the dynamic nature of Filipino language usage. For instance, the younger generation (29-below) tends to use Spanish-influenced forms more frequently, reflecting the influence of modern education and media. On the other hand, older generations (60 and up) often prefer the native Filipino terms, reflecting their linguistic heritage and exposure to pre-colonial Filipino culture.

Additionally, the data reveals regional variations in the pronunciation of certain numbers. For example, the number "10" is pronounced as "sampung" in some regions, while others use the Spanish-influenced "dyis." These variations demonstrate the diversity of Bataeño dialects and the rich tapestry of linguistic expressions across the archipelago.

It is worth noting that the data presents a simplified overview of Filipino number systems. In practice, there may be regional variations in the usage of certain forms, and the choice of number form may also be influenced by social and cultural factors. Additionally, the data does not include the formation of larger numbers (e.g., millions, billions), which involves more complex morphological patterns.

5.9 Ordinal Nominals

This analysis of ordinal numbers in Filipino builds upon the understanding of Bataeño morphology and potential language change. The data presents Filipino ordinal numbers, which indicate the position or rank within a sequence. Unlike cardinal numbers that simply quantify (e.g., isa, dalawa, tatlo), ordinal numbers specify the order (e.g., una, pangalawa, pangatlo).

Table 9.
Ordinal Nominals

Lexical items	Age 29 below	Age 30-59	Age 60-up
1. una	una, first	una	una
2. pangalawa	pangalawa, second	pangalawa	pangalawa
3. pangatlo	pangatlo, third	pangatlo	pangatlo
4. pang-apat	pang-apat, fourth	pang-apat	pang-apat
5. panglima	pang lima, fifth	panglima	panglima

Examining the data reveals a consistent morphological pattern for forming ordinal numbers. Each ordinal number is constructed by adding the prefix "pang-" to the corresponding cardinal number. For instance, "una" (first) is derived from "isa" (one), "pangalawa" (second) from "dalawa" (two), and so on. This prefixing system reflects the agglutinative nature of Filipino, a language where morphemes (meaningful units) are attached sequentially to form complex words [Maganto-Salamat, 2019]. The prefix "pang-" carries the meaning of "order" or "rank," and its addition to cardinal numbers transforms them into ordinals.

The data also highlights subtle lexical variations across different age groups. While the overall morphological pattern remains consistent, a study by [Pordes et al., 2022] suggests that the younger generation (29-below) tends to use a more streamlined form by separating the prefix "pang" from the cardinal number. For example, instead of "panglima" (fifth), they might say "pang lima." This separation might reflect a tendency towards language simplification, potentially reducing the number of syllables in certain words.

5.10 Deictics and Demonstratives

Filipino demonstrative pronouns exhibit a consistent morphological pattern, employing the initial consonant "n" or "p" to distinguish categories. The "n" demonstratives (e.g., "ito," "iyan," "iyon") are used for things near the speaker, while the "p" demonstratives (e.g., "parito," "paroon," "pariyan") indicate things

farther away [Nieva & Ramos, 2020]. This distinction reflects the spatial deictic function of these pronouns, allowing speakers to clearly convey the relative distance of the referent to their position. Additionally, "ganito," "ganyan," and "ganoon" refer to manner or quality, while "nito," "niyan," and "noon" indicate possession or ownership.

Table 10.
Deictics and Demonstratives

Lexical items	Age 29 below	Age 30-59	Age 60-up
1. ito	ito	ito	Ito
2. iyan	iyan	iyan	Iyan
3. iyon	iyon	iyon	Iyon
4. dito	dito	dito	Dito
5. diyan	diyan	diyan	Diyan

While further research is needed to confirm this observation, it aligns with the concept of language change, where languages evolve through social and cultural factors [Bautista, 2019]. However, the core meaning, and grammatical function of the demonstrative pronouns remain unchanged.

The analysis of Filipino demonstrative pronouns demonstrates the language's morphological system, its use of deixis for spatial reference, and potential generational variations in usage. Understanding these features contributes to a deeper knowledge of Filipino grammar and its evolution.

6 Conclusion

The study "Age does matter: A generational comparison on the morphological and lexical variations of Tagalog nominal and pronominal systems in Bataan" reveals significant implications regarding age and language use. The findings emphasize the dynamic interplay between generational influences and linguistic preferences among Bataeños.

The younger generation's inclination to embrace new terms, especially those borrowed from English, along with their tendency to abbreviate, reflects a shift toward a more streamlined language aligned with globalization and educational changes (Tupas, 2019). This generational adaptation mirrors Labov's (1994) theory of language change, where younger speakers actively incorporate emerging vocabulary, contrasting with the more conservative tendencies of older generations.

The middle-aged cohort, positioned between the older and younger speakers, exhibits a transitional linguistic pattern. Their use of both traditional and modern lexicon highlights their role as mediators in the evolving linguistic landscape, resonating with Trudgill's (2000) concept of sociolinguistic variation. This cohort's linguistic behavior showcases their adaptability in response to significant socio-cultural and linguistic shifts experienced over their lifetimes.

In contrast, the older generation's stronger adherence to traditional words underscores their efforts to preserve the linguistic heritage of their youth. This aligns with Mahboob and Cruz's (2020) observations of language conservation practices within communities that prioritize cultural preservation.

Beyond generational differences, the study underscores the role of social circles in shaping language use. The observed code-switching and hybrid forms among the middle-aged group reflect Bautista and Bolton's (2020) notion of bilingualism fostering dynamic language contact in multilingual societies. This adaptability to context further illustrates how social factors intertwine with linguistic choices.

Additionally, the study notes the use of agglutinative morphology in word formation among Bataeños, as described by Maganto-Salamat (2019). The younger speakers' subtle simplification of these morphological patterns hints at a potential trend toward linguistic efficiency, in line with Pordes et al.'s (2022) theory of language simplification in fast-paced environments.

In conclusion, the study highlights the intergenerational negotiation between traditional and modern linguistic practices in Bataan, illustrating how language evolves amid changing social and cultural influences. The ongoing interplay of globalization, bilingualism, and social media will likely continue to shape the Filipino language landscape, showcasing the resilience and adaptability of Bataeño speakers.

7 Implications

The findings of this study demonstrate how age plays a critical role in shaping the language practices of Bataeños, highlighting a dynamic interplay between traditional linguistic features and evolving speech patterns influenced by globalization and modern societal trends. Consistent with Labov's (1994) theory of generational language change, younger speakers show a marked openness to incorporating new words, including borrowed English terms, and exhibit a tendency toward linguistic abbreviation. This phenomenon suggests that younger generations are responding to the fast-paced demands of a globalized society, where efficiency and adaptability in language use are highly valued (Tupas, 2019).

The middle-aged cohort occupies a unique linguistic space, serving as a bridge between the traditional vocabulary of the older generation and the innovative linguistic trends of the youth. This generational positioning aligns with Trudgill's (2000) notion of sociolinguistic variation, reflecting the influence of both traditional and modern language practices. The findings indicate that this group navigates a complex linguistic landscape, balancing the use of conventional words with an openness to new, borrowed terms.

In contrast, the older generation appears more resistant to linguistic change, favoring traditional vocabulary and expressions. This adherence to established linguistic norms aligns with Mahboob and Cruz's (2020) observations on the preservation of linguistic heritage. Such resistance can be interpreted as an effort to maintain linguistic identity in the face of rapid changes, reflecting broader societal trends of safeguarding cultural and linguistic legacies.

The study also emphasizes the impact of social contexts on language use, particularly among middle-aged speakers who shift between traditional Filipino words and borrowed terms depending on the social situation. This aligns with Bautista and Bolton's (2020) insights on bilingualism and language contact, suggesting that speakers in multilingual societies navigate varying linguistic norms based on context. The findings underscore the fluidity and adaptability of language in response to social influences.

Another significant insight pertains to the role of agglutinative morphology in the creation of new words. As described by Maganto-Salamat (2019), the agglutinative nature of Philippine languages facilitates the formation of new words by attaching meaningful units. The study reveals that younger speakers may be shortening these word-building elements, which aligns with the broader trend of linguistic simplification noted by Pordes et al. (2022). This shift toward a more streamlined linguistic structure could reflect the increasing emphasis on efficiency in communication.

These findings have practical implications for language policy and education in the Philippines. Policymakers and educators should consider these generational and contextual variations when designing curricula that promote linguistic flexibility while preserving traditional language elements. Emphasizing a balanced approach could facilitate a deeper understanding and appreciation of the Filipino language's dynamic nature.

Overall, this study contributes to the growing body of literature on language change and sociolinguistic variation by demonstrating the influence of age, social context, and historical factors on the speech of Bataeños. As globalization and social media continue to shape language practices, future research could explore the evolving linguistic trends among younger generations and their implications for the preservation and transformation of the Filipino language.

8 Recommendations

Based on the findings of the study, It is recommended that further explorations and documentation of the linguistic patterns across

different age groups in the Bataeño community should continuously be done. Specifically,

1. Develop Educational Programs and create educational initiatives that promote an understanding and appreciation of linguistic diversity among all age groups. These programs could highlight how language evolves and the importance of preserving traditional words while embracing new terms.

2. Language Preservation Efforts, implement language preservation projects targeting the older generation's vocabulary. This could involve recording and archiving traditional words and phrases, ensuring they remain a part of the linguistic heritage.

3. Encourage Intergenerational Dialogue and facilitate platforms where different age groups can engage in conversations about language. This can help bridge the gap between traditional and modern language use, fostering mutual respect and understanding.

4. Research on Social Influence, Conduct more detailed studies on how social circles and contexts influence language use, especially among middle-aged individuals. Understanding these dynamics can provide insights into how language adapts in multilingual and multicultural settings.

5. Monitor Language Simplification Trends and observe and document the trend of language simplification among younger speakers. Analyzing these changes can help in understanding the impact of globalization and technology on language evolution.

6. Promote Bilingualism, encourage bilingual education and the use of hybrid forms of language, reflecting the natural linguistic environment of the Bataeño community. This can enhance communication and cultural exchange while respecting linguistic diversity.

7. Utilize social media and leverage social media platforms to observe and influence language trends among the younger generation. Creating content that showcases the richness of the Filipino language and its evolution can engage younger audiences.

By following these recommendations, we can support the dynamic nature of the Filipino language, ensuring it remains vibrant and relevant across generations while preserving its rich heritage. By creating resources that bridge the gap between tradition and change, we can encourage the continued use and evolution of the Bataeño language for future generations.

Comparison of Miratives in Mandarin Chinese: A Preliminary Study

[1]**Jiun-Shiung Wu,** [2]**Yu-Chien Hsu**
Institute of Linguistics, National Chung Cheng University, Minhsiung, Chiayi County, Taiwan, 621

[1]Lngwujs@ccu.edu.tw, [2]AnnYCHsu@alum.ccu.edu.tw

Abstract

This paper compares sources and strength of mirativity among four miratives in Mandarin Chinese: *jìngrán*, *yuánlái*, *cái* mirative and *jiù* mirative. We argue that sources of mirativity are closely associated with strength. There are four sources: contrast with expectation, negation with strong sentiment, new information, and partial contrast with a previous proposition. And the strength of mirativity decreases in the same order. Then, we propose dynamic semantics to account for the similarity and differences of these four types of miratives.

1 Introduction

In this paper, we examine the sources of four miratives in Mandarin Chinese (for short, Chinese) and explain their variability of strength.

Delancey (1997, 2001, 2012) treats mirativity as expressing new or unexpected information, suggesting surprise. On the other hand, Aikhenvald (2002) suggests an array of mirative meanings: sudden discovery, surprise, unprepared mind of the speaker, counterexpectation and new information. Portner (2018, Sect. 3.3.4) classifies mirative (exclamative in Portner's terms) as a minor type of sentence mood

In Chinese, Tsai & Yang (2012) discuss the syntax of mirative *yuánlái* … a^0 'it turn out' and how mirativity is derived. Wu (2008) examines evaluative modal *jìngrán* 'contrary to one's expectation'. Wu (2024) explores two constructions denoting mirativity: *jiù* miratives and *cái* miratives. Examples of the four miratives are as in (1).

(1) a. Tā yuánlái shì xiǎotō a^0!
he YUANLAI be thief Prc
'It turns out that he is a thief!'
b. Tā jìngrán shì xiǎotōu!
he JINGRAN be thief
'Contrary to expectation, he is a thief!'
c. Sān tiān qián néng tōngzhī jiù
three day before DYN[1] notify JIU
āmítuófó le, bié shuō yī zhōu le!
Amitabha Prc, not say one week Prc
'It would be a blessing if a notification could be made three days before (a date), let alone one week!'
d. Yì zhōu qián néng tōngzhī cái
one week before DYN notify CAI
guài!
strange
'No way that a notification can be made one week before (a date)!'

While Tsai and Yang (2022), Wu (2008, 2024) provide detailed analysis on different constructions expressing mirativity, cross-categorial comparison has not been done. It has not been discussed how to distinguish their sources of mirativity. Moreover, variability of strength of mirativity receives little, if any, attention. In this paper, we put these two issues under examination.

This paper is organized as below. Section 2 is literature review, where Tsai & Yang (2012), Wu (2008, 2024) are reviewed. We point out that, while

[1] The abbreviations used in this paper include: CL for a classifier, DYN for a dynamic modal expression, DEON for a deontic modal expression, Prc for a particle.

the constructions discussed in these studies all express mirativity, the sources and strength of mirativity remain unclarified. In Section 3, we present our analysis and a dynamic semantic account. Section 4 concludes this paper.

2 Literature Review

In this paper, we briefly review Tsai and Yang (2012), Wu (2008, 2024),[2] and present the niche for our current study.

Tsai and Yang (2012) propose a syntactic account for *yuánlái… a*^{0} 'it turn out Prc', which expresses mirativity.[3] They suggest the following. *Yuánlái* exists under Evidential Phrase (EviP). SAP2 comes with a feature [mirative], which expresses surprise. *Yuánlái* merges with the head of SAP2. Then, Agree assigns [mirative] of the SAP2 head to *yuánlái*. See the bracketed structure below:

(2) a. [$_{SAP2}$ *a*$^0_{[mirative]}$ [$_{EviP}$ *yuánlái* [$_{MoodP}$ Mood$^0_{[indicative]}$ … [$_{IP}$ …]]]]
b. [$_{SAP2}$ *yuánlá*$_{[mirative]}$ SA2$^0_{[mirative]}$ [$_{EviP}$ t$_i$ Evi^0 [$_{MoodP}$ Mood$^0_{[indicative]}$ … [$_{IP}$ …]]]]

In (2a), *yuánlái* is inside the EviP. In (2b), it merges with SA2^0 and gets the feature [mirative] from SA2^0. This is how *yuánlái… a*^{0} gets a mirative reading.

Wu (2008) examines two evaluative modals – *guǒrán* 'as expected' and *jìngrán* 'contrary to expectation'. He proposes a modal semantics for *jìngrán*:

(3) *Jìngrán* presents a proposition which is a simple necessity of negation in *w* with respect to an evaluative conversational background.

An evaluation conversational background is a set of possible worlds where propositions are expected to be true. (3) says that *jìngrán* presents a proposition not true in this set of worlds, i.e., a proposition not expected. While Wu (2008) does not say anything about mirativity, a mirative reading arises from unexpectedness or counterexpectation.

Wu (2024) examines two mirative constructions: *jiù* and *cái* mirative. Let's look at two examples. In order to express his/her attitude of surprise toward (4a), the speaker can utter (4b) and (4c):

(4) a. Qíxiàn qián yì zhōu yào jiāo
deadline before one week DEON turn.in
zuòyè.
assignment
'Turn in your assignment one week before the deadline.'
b. Sān tiān qián néng jiāo jiù
three day before DYN turn.in JIU
āmítuófó le!
Amitabha Prc
'It would be a blessing from God if we could turn in three days before the deadline!'
c. Yì xīngqí qián néng jiāo cái
one week before DYN turn.in CAI
guài!
strange
'No way that we can turn in one week before the deadline!"

(4b) uses *jiù āmítuófó le* 'JIU Amitabha Prc' to express the speaker's surprise by proposing a more plausible time. On the other hand, (4b) spells out the speaker's surprise by directly negating the possibility of the date in (4a).

Among many things, Wu (2024) suggests that mirativity of these two constructions come from the interaction of contradiction to an expectation and strong sentiment. (4a) is an expectation. (4b) and (4c) both express something contrary to the expectation. In addition, (4a) shows strong sentiment by proposing a more likely alternative and showing the speaker's frustration with the original request. In (4b), *cái guài* 'CAI strange' itself is a strong negation. Wu (2024:7) points out that "[w]hile contradiction could lead to mirativity, contradiction plus strong sentiment guarantees mirativity."

Given the above brief review, we have a good idea of how different constructions produce a mirative reading. But, one question immediately arises: do they express exactly the same mirativity? Or, to take a step further, is there only one type of

[2] Fang (2018) discusses the mirative reading of sentential *le*. But there is evidence that mirativity is not an inherent property of sentential le. Hence, we do not review this paper. And due to space limit, we will not discuss sentential *le* at all.

[3] Please note that Tsai and Yang (2012) also discusses *zěnme*, which also denotes mirativity. Due to space limit, we will not review *zěnme* and leave the source and strength of mirativity for *zěnme* for future studies.

mirativity or are there different types of mirativity? This question is not addressed in the literature on Chinese miratives. Moreover, variability of strength of mirativity is not explored. We wish to take a preliminary look at these two issues.

3 Sources, Strength and Dynamic Semantics

While expressing mirativity, the four miratives as shown by the examples in (1) intuitively manifest subtle differences. In this section, we discuss three issues: (i) sources of mirativity, (ii) strength of mirativity, and (iii) dynamic semantics. We argue that different sources of mirativity result in different types and that sources are closely associated with strength. Finally, we propose dynamic semantics to model the similarity and differences of the four miratives under examination.

3.1 Source of Mirativity

As the review in Section 2 points out, all of *jìngrán*, *jiù* miratives and *cái* miratives show a certain type of contradiction. While Tsai & Yang (2012) do not really talk about the (compositional) semantics of *yuánlái*, Wu (2012) proposes a semantics of contrast for *yuánlái* which expresses a mirative reading: [4] it presents a proposition which was known to be not true at a past time or whose truth was unknown at a past time, but is known to be true at a later time. That is, Wu's (2012) semantics for mirative *yuánlái* shows contradiction (in terms of a proposition being known to be true at different times) as well. While these four miratives all involve contrast/contradiction, they produce contrast/contradiction in very different ways, which results in different types of mirativity. Let's see examples below.

(5) a. Tā jìngrán yào wǒmen yì-ge yuè
he JINGRAN want us one-CL month
qián jiāo kǒshìgǎo, wǒ
before turn.in draft.for.defense I
hái yǐwéi shì **yì zhōu**

qián!
before
'Contrary to expectation, he wanted us to turn in our drafts for defense one month before the deadline! I thought it was one week before!'

b. Tā jìngrán yào women yì-ge yuè
he JINGRAN want us one-CL month
qián jiāo kǒshìgǎo, wǒ
before turn.in draft.for.defense I
hái yǐwéi **bùyòng jiāo**.
still mistakenly.think no.need turn.in
'Contrary to expectation, he wanted us to turn in our drafts for defense one month before the deadline! I thought we did not have to!'

c. Tā jìngrán yào women yì-ge yuè
he JINGRAN want us one-CL month
qián jiāo kǒshìgǎo, #wǒ
before turn.in draft.for.defense I
hái yǐwéi shì yào **jiāo**
still mistakenly.think be DEON turn.in
zuòyè.
assignment
'He wanted us to turn in our drafts for defense one month before the deadline! #I thought he wanted us to turn in our assignment.'

(6) a. Tā yuánlái yào wǒmen yì-ge yuè
he YUANLAI want us one-CL month
qián jiāo kǒshìgǎo, wǒ
before turn.in draft.for.defense I
hái yǐwéi shì **yì zhōu**
still mistakenly.think be one week
qián.
before
'It turned out that he wanted us to turn in our drafts for defense one month before the deadline! I thought it was one week before!'

b. Tā yuánlái yào wǒmen yì-ge yuè
he YUANLAI want us one-CL month
qián jiāo kǒshìgǎo, wǒ
before turn.in draft.for.defense I
hái yǐwéi **bùyòng jiāo**.
still mistakenly.think no.need turn.in
'It turned out that he wanted us to turn in our drafts for defense one month before

[4] *Yuánlái* is actually ambiguous: it can present a proposition which was (known to be) true at a past time but is true at a later time, or one which was (known to be) not true at a past time or whose truth was unknown at a past time but is (known to be) true at a later time. Please refer to Wu (2012) for a detailed discussion. Please also note that Wu (2012) does not refer to *yuánlái* as a mirative, but the latter semantics presented above *does* accommodate mirativity.

the deadline! I thought we did not have to!'

c. Tā yuánlái yào wǒmen yì-ge yuè

still mistakenly.think be DEON turn.in
zuòyè.
assignment
'It turned out that he wanted us to turn in our drafts for defense one month before the deadline! I thought he wanted us to turn in our assignment.'

While *jìngrán* and *yuánlái* express mirativity by means of contradiction, (5) and (6) show a subtle difference. In (5), *jìngrán* presents an event contrary to one of the same type. In (5a), the contrasted event is to turn in one week before the deadline. In (5b), the one is not to turn in a draft at all. In (5c), the second clause (the contrasted event) is to turn in an assignment, rather than a draft for defense, and (5c) is infelicitous.

On the other hand, as the examples in (6) show, the contrasted propositions can be to turn in a draft one week before the deadline, as (6a), not to turn in a draft at all, as (6b), and to turn in an assignment, instead of a draft for defense, as (6c). And, all of (6a), (6b) and (6c) are felicitous.

If we examine (5) and (6) carefully, we can find that the difference in felicity shown in these two sets of examples lies in the following: in (5), the proposition presented by *jìngrán* and the contrasted propositions in (5a, b) are of the same type: to turn in a draft for defense, but the contrasted proposition in (5c) differs from the previous set of propositions: to turn in an assignment in (5c) vs. to turn in a draft for defense in (5a-b).

On the other hand, *yuánlái* is not sensitive to whether a contrasted event is of the same type or not. In (6), the contrasted event can be to turn in a draft for defense, as in (6a, b) or to turn in an assignment, as in (6c).

Therefore, based on the difference between (5) and (6), we argue that, in terms of mirativity, *jìngrán* and *yuánlái* differ in the sense that *jìngrán* presents a proposition contrasted with one of the same type, while *yuánlái* identifies one contrasted with another one, which can be of the same type or not of the same type.

As for *jiù* and *cái* miratives discussed in Wu (2024), they definitely contrast with a proposition of the same type. If a professor gives the following order: *yì-ge yuè qián yào jiāo kǒshìgǎo* '*do* turn in your draft for defense one month before the deadline', students can make the following responses as in (7):

(7) a. yì zhōu qián néng jiāo jiù
one week before DYN turn.in JIU
āmítuófó le!
Amitabha Prc
'It would be a blessing from God if we could turn in (our draft) one week before the deadline!'

b. yì-ge yuè néng jiāo cái guài!
one-CL month DYN turn.in cai strange
'No way that we can turn in (our draft) one month before the deadline.'

Uttering (7a), the student presents a more plausible alternative, while speaking (7b), the student directly negates the possibility of the professor's request. Regardless of whether a speaker provides a more plausible alternative or negates the original request, the speaker responds with the same type of propositions. In (7), in the utterances of the professor, (7a) and (7b), the contrasted event is to turn in a draft for defense.

Following the related literature where mirativity originates from contradiction/contrast, we furthermore classify sources of mirativity into four finer types: (i) contrast with a proposition of the same type, (ii) contrast with a proposition either of the same type or not of the same type, (iii) proposing a more plausible alternative and (iv) direct negation.

This finer classification of mirativity can explain native speakers' intuition about the subtle differences among the sentences expressing mirativity, such as those four types under discussion in this paper. Although *jìngrán*, *yuánlái*, *jiù* miratives and *cái* miratives all carry an overtone of surprise, native speakers of Chinese[5] still have the intuitive feelings that they are somehow different. Our discussion here can, at least to a certain extent, explain this difference.

[5] At least, for us and our informants, this subtle difference concerning these mirative sentences is true.

3.2 Strength of Mirativity

While it is difficult to prove, we and our informants have this intuition concerning the variability of strength of mirativity. The variability of strength can be represented, from strong to weak, as below:

(8) *jìngrán* > *cái* mirative > *yuánlái* > *jiù* mirative

For the variability of strength for *jìngrán* and *yuánlái*, we argue that the variability lies in the distinction between expectation and realization. As pointed out by many studies, e.g., Wu (2008), *jìngrán* is suggested to involve expectation.

On the other hand, *yuánlái* has an epistemic reading. For example, when someone utters *tā yuánlái shì jǐngchá* 'it turned out that he was a police officer', the most likely scenario is: the speaker did not know he was a police officer and came to realize, later, that he was a police officer. To put it differently, while *yuánlái* shows contradiction and/or contrast, it involves realization, i.e., new knowledge or new information, rather than expectation.

Expectation is a strong sentiment, and as a result, contrast to an expectation is also a strong sentiment. New knowledge can result in surprise, but surprise is not an inherent property of new knowledge. This is why *jìngrán* expresses stronger mirativity than *yuánlái*.

Neither *cái* miratives nor *jiù* miratives involve expectation. But, *cái* miratives inherently express strong sentiment. In addition to *cái guài* 'CAI strange', *cái* miratives include *cái yǒu guǐ* 'CAI have ghost', *cái bù kěnnéng* 'CAI impossible', *cái bùyòng xiǎng* 'CAI no need to think', etc. All of these phrases describe a degree next to impossibility and are inherently of strong sentiment, as argued in Wu (2024). Surprise resulted from contrast with an expectation denotes strong sentiment. *Cái* miratives ranks the second on the scale of strength of mirativity because, while not involving expectation, it describes next to impossibility, though not absolute impossibility. Next to impossibility is a sentiment less strong than an expectation and absolute impossibility.

Jiù miratives are weakest in terms of the scale of strength of mirativity because they are used to offer a more plausible alternative. By means of providing a more likely alternative, the speaker does not completely reject the original request, but compromises to a certain degree by suggesting something more doable for him.

To put it a different way, a *jiù* mirative does not completely contrast with or contradict to a previous request. Instead, it complies partially. This is why a *jiù* mirative gets the weakest mirativity among the four miratives under discussion in this paper.

Since *jìngrán* ranks the highest on the scale of strength of mirativity, a *cái* mirative ranks the second and a *jiù* mirative ranks the lowest , *yuánlái* will have to rank the third.

To sum up, in this section, we present a scale of strength of mirativity. We argue that contrast to an expectation is the strongest. Next to impossibility ranks the second. New information ranks the third. Compromising by suggesting an alternative ranks the lowest.

3.3 Dynamic Semantics

There are some formal analyses of the semantics of miratives, e.g., Rett (2008, 2009, 2011), Rett & Murray (2013), etc. In order to explain the semantics of *wh*-exlcamatives, which Rett (2009) uses to refer to mirative, Rett (2009:610) proposes a degree semantics:

(9) DEGREE E-FORCE ($\mathscr{D}_{\langle d, \langle s, t \rangle\rangle}$) is expressively correct in context *C* iff $\mathscr{D}$ is salient in *C*, and $\exists d,\ d > s$ [the speaker in *C* is surprised that $\lambda w\ \mathscr{D}(d)(w)$].

(9) essentially says the following: one's utterance of a *wh*-exclamative is valid under the following conditions. First, this *wh*-exclamative contains a degree reading, which is salient in the current context. Second, the speaker is surprised that a particular degree is true of the degree reading. And, third, the degree is greater than a contextually specified standard *s*.

Rett and Murray (2013) examine mirative evidentials and propose a dynamic semantics for mirative as follows:

(10) a. Hawk won-*hoo'o*.

b.

at-issue prop.	$p = \lambda w$. hawk won in w
not-at-issue prop.	$E \models p$
illocutionary relation	Propose to add p to CG $e_s \in \text{TARGET}(e_l) \rightarrow p \notin E_i^{t(e_l)}$

(10b) is the dynamic semantics of mirative suffix *-hoo'o*. In the context of mirrativity, the salient *E* is the speaker's set of expectations. $e_s \in \text{TARGET}(e_l)$ stands for a recency restriction, i.e. the utterance of the event denoted by *p* must immediately follow the *Hawk won* event. And, if this is true, then *p* is not in *E*, i.e. *p* is not expected.

However, since Rett (2008, 2009, 2011), Rett and Murray (2013) do not talk about variability of sources and strength of mirativity, naturally their semantics cannot take care of what we discuss in this paper.

In Section 3.2, we argue that types (sources) of mirativity are closely related to strength of mirativity in Chinese. The four types/sources in the order of strength are: counter-expectation, direct negation with strong sentiment, new information, and partial contrast by proposing a more plausible alternative.

We attempt to propose a dynamic semantics, which is capable of distinguishing the four types of sources and hence the variability of strength.

First, we define the interpretation of discourse $\mathscr{D}$ and ADD, which adds a proposition into the components of $\mathscr{D}$. What is proposed in (11) stands for the knowledge of a speaker of a mirative.

(11) a. The interpretation of discourse, $\mathscr{D}$, is a tuple <*CG*, *E*>, where *CG* (= common ground) and *E* (= expectation) are sets of propositions. That is, $\mathscr{D}$ = <*CG*, *E*>.
b. *p* is a proposition. ADD *p* to *CG* iff CG $\cup\{p\}$. And likewise for *E*.

In (11a), we define the interpretation of discourse as a tuple of two sets. *CG*, common ground, is where shared knowledge in a discourse is stored, e.g., Stalnaker (2002). As a discourse progresses, participants ADD new propositions into *CG*. *CG* is a mechanism very common in dynamic approaches to semantics.

And, due to the significant role expectation plays in distinguishing the sources and strength of mirativity, we argue that, in addition to CG, the interpretation of discourse requires *E* (expectation), as well.

Given this dynamic semantics schema, we can model the four sources of mirativity. In all of (12-15), the (a) clause represents the interpretation of discourse before a mirative sentence comes in, while the (b) clause stands for the operation of the corresponding mirative to the interpretation of discourse.

(12) *jìngrán*(*p*)
a. <*CG* = {}, *E* = {¬*p*}>
b. ADD *p* to *CG*.

For *jìngrán*, *E* contains a proposition ¬*p*. And, *jìngrán* ADD *p* to *CG*. Naturally, a contradiction arises and a mirative reading is produced. What is more, because an expectation carries strong sentiment, this is why *E* needs to be listed, independent of *CG*.

(13) *cái* mirative(*q*)
a. <*CG* = {*p*}, *E* = {}>
b. ADD *p* to *CG*, where *q* iff ¬*p* and *q* carries strong sentiment.

A *cái* mirative does not have an expectation, and therefore *E* is an empty set. In addition, a *cái* mirative presents a negative proposition which carries strong sentiment. This (negative) proposition is added into *CG*. Because *q* is contrasted with/contradictory to *p*, a mirative reading is yielded.

(14) *yuánlái*(*p*)
a. <*CG* ={}, *E*= {}>
b. ADD *p* to *CG*.

Yuánlái does not have an expectation as well. What (14b) shows is the following. Before the *yuánlái* sentence comes into the discourse, the *CG* is empty and so is *E*. An empty CG means that there is no previous knowledge about any proposition,[6]

[6] One might ask how our theory distinguish the start of a discourse and *yuánlái* since in both cases *CG* is empty. Please note that, as we point out, (11) represent the knowledge of a speaker of a mirative. Mirative *yuánlái*

including *p*. When a *yuánlái* sentence comes in, *p* is added to *CG*. This operation means that a new realization about *p* comes into the set of shared beliefs. This new information yields a mirative reading.

(15) *jiù* mirative(*q*)
a. <*CG* = {*p*}, *E* = {}>
b. ADD *q* to *CG*, where *q* is partially contrasted with *p*.

For a *jiù* mirative, the *CG* contains a proposition *p*, which is a request already existing in the discourse. A *jiù* mirative provides a more plausible alternative, which is partially contrasted with *p*. This contrast, while partial, produces a mirative reading.

Moreover, (13) and (15) capture a very important similarity between a *cái* mirative and a *jiù* mirative: they are both used as a response to a previous proposition. In (13) and (15), *CG* is not empty, which models this similarity.

To sum up, in this section, we propose a dynamic semantics, which can model and explain the sources and variability of strength of mirativity in Chinese. The interpretation of discourse $\mathscr{D}$ is a tuple <*CG*, *E*>. For *jìngrán*, *E* contains a proposition, while *CG* is empty. For *yuánlái*, both *CG* and *E* are empty. For *cái* and *jiù* miratives, *CG* contains a proposition, but *E* is empty. *Jìngrán* introduces a proposition into the discourse, which contradicts with the proposition in *E*. A *cái* mirative introduces a proposition with strong sentiment, which negates the proposition in *CG*, whereas a *jiù* mirative presents a proposition into the discourse, which partially contrasts the one in *CG*.

4 Conclusion

In this paper we discuss the sources and strength of mirativity for four miratives in Chinese: *jìngrán*, *yuánlái*, *cái* miratives and *jiù* miratives. We argue the following. First, the subtle differences of mirativity of these four miratives are associated with sources of mirativity: contrast with expection, new information, direct negation with strong sentiment and partial contrast by proposing a more plausible alternative.

In terms of strength of mirativity, because expectation is very strong sentiment, contrast with expectation is strong as well and ranks the first. Direct negation with strong sentiment ranks the second because of next to impossibility, rather than absolute impossibility. New information comes the third. Partial contrast by proposing a plausible alternative comes the last because it actually complies partially but does not contrast or contradict completely.

We propose a dynamic semantics to capture the similarity and differences of these four miratives. The interpretation of discourse $\mathscr{D}$ is a tuple <*CG*, *E*>, that is, common ground and expectation, both of which are sets of propositions. For *jìngrán*, CG is empty but *E* contains a proposition ¬*p*. *Jìngrán* introduces p into *CG*. A contradiction arises and a mirative reading is derived. For *yuánlái*, *CG* and *E* are both empty. *Yuánlái* adds *p* into CG. Because CG is originally empty and then *p* is added into CG, *yuánlái* presents new information, which yields a mirative reading. For a *jiù* mirative and a *cái* mirative, CG contains a proposition *p*, which these two types of miratives respond to, and *E* is empty. A *cái* mirative introduces a proposition into *CG*, which directly negates, with strong sentiment, the existing proposition, while a *jiù* mirative adds a proposition into *CG*, which partially contrasts with the existing proposition. Contrast/contradiction arises and a mirative interpretation is produced.

Identity or Competency? Exploring the Impact of Demographic and Professional Factors on English Faculty Competencies

Bernadette D. Bagalay
Associate Professor II, Isabela State University-San Mateo Campus
bernadette.d.bagalay@isu.edu.ph

Abstract

Grasping the factors that affect teacher competence is vital for developing programs that improve teaching effectiveness. Using a descriptive design, this study investigates the influence of demographic and professional variables on the competencies of English faculty in a higher education institution using a descriptive research design. Participants included department heads, English faculty, and students, totaling 250 individuals. Faculty self-assessed, while department heads and students evaluated faculty using a validated questionnaire with a four-point scale. Analysis of Variance (ANOVA) and t-tests revealed no significant competency differences by age, educational attainment, or field of specialization. However, significant differences were noted by sex, with female faculty showing higher competencies in instruction, Teaching English as a Foreign Language (TEFL) theory knowledge, and assessment skills. Teaching experience impacted instructional competence, and attendance at professional development trainings affected TEFL knowledge. The findings suggest tailored professional development and policy adjustments based on these factors to enhance teaching effectiveness and improve English language instruction quality.

1 Introduction

The quality of English language instruction is essential in shaping students' communication skills and overall academic success. Teacher competence, encompassing a blend of knowledge, skills, and attitudes, plays a crucial role in this process. Understanding the factors that influence teacher competence is essential for developing targeted professional development programs and educational policies that enhance teaching effectiveness.

Competence refers to the adequacy of ability to do a task in accordance to proper qualifications and standards. It is the level of integration of knowledge, skills, and attitudes (Hero et al., 2017) and it is indispensable in assuming responsibilities and liabilities in a field. In the field of education, competence is an essential aspect for the effective teaching and learning process to take place.

According to the framework proposed by Cooper (2010), competence encompasses a combination of theoretical understanding of learning processes, attitudes that encourage learning and foster positive relationships, subject-specific expertise, and a set of teaching skills. These elements equip teachers to make informed and effective professional decisions.

This suggests that teachers must be well-versed in these areas to excel in instructional decision-making. Achieving mastery, therefore, requires thorough proficiency in these four key areas of competence and the capacity to expertly apply the associated knowledge, attitudes, and skills to each instructional choice.

In a study on childhood education, Larsson (2010) identified four primary categories that shape teachers' and researchers' views on educational competence. These categories—pedagogical knowledge, pedagogical intentions, pedagogical considerations, and pedagogical assets—emphasize various dimensions of expertise essential for effective teaching. Larsson's use of the term "pedagogical" as a qualifier stresses the connection of each dimension to the educational context, underscoring how they collectively contribute to effective practice in specific teaching domains, such as English instruction. Each dimension encompasses distinct sub-components, adding depth to the understanding of competence in education by focusing on the knowledge, motives, contextual decision-making, and resources that support student learning outcomes.

This framework offers a comprehensive view of the competencies needed to create meaningful and

responsive educational experiences across specialized fields.

On one hand, Moriera et al. (2022) found a divergence in priorities between students and teachers. Students placed the greatest value on instructors' personal skills and qualities, while teachers emphasized the importance of curriculum design and instructional expertise. However, the study also revealed a significant gap in the areas of cultural competence and specialized skills for addressing diversity and fostering inclusivity in the higher education classroom, indicating that these competencies are largely underdeveloped.

On the other hand, various demographic and professional factors —such as age, sex, educational attainment, field of specialization, years of teaching experience, and the number of professional development trainings —significantly impact teacher competence (Olayvar, 2022; Bibi and Khurshid, 2021; Krumsvik et al., 2016; Darling-Hammond, 2000). For instance, Batuigas et al. (2022) emphasize that ongoing professional development is vital for teachers to adapt to new educational challenges and improve their instructional practices.

Similarly, content knowledge, pedagogical skills, (Ramos, 2021) and pedagogical-psychological teaching knowledge (Hollenstein and Brühwiler, 2024) are important in effective teaching. The effectiveness of teachers' instructional strategies likewise exerts a substantial impact on 21st century pedagogical practices (Shafiee and Ghani, 2022).

Studies have also shown that teachers' educational backgrounds and specializations can influence their teaching efficacy. Teachers with advanced degrees and specialized training in English are often better equipped to address the diverse needs of their students (Cochran-Smith and Zeichner, 2005).

Moreover, professional experience and continuous training are crucial in keeping teachers updated with the latest pedagogical strategies and educational technologies (Krumsvik et al., 2016; Garet et al., 2001; Catalano, 2020) that promote student skills and lead to successful teaching and learning (Ventista and Brown, 2023).

Despite the importance of these factors, there remains a gap in research regarding their specific impact on the competencies of English faculty. This study seeks to address this gap by examining the competencies of English faculty at a university. By investigating how demographic and professional factors influence teacher competence, this research aims to identify patterns and disparities that can inform the development of professional development initiatives and educational policies.

This study aims to answer critical questions: Are there significant differences in the competencies of English faculty when grouped according to profile variables? What are the implications of these differences for professional development and educational policy? By answering these questions, this research contributes to the ongoing efforts to improve English language instruction and, ultimately, the overall quality of education.

The findings of this study also contribute to the ongoing discourse on faculty development in higher education, offering insights that can inform policy and practice aimed at enhancing the quality of English instruction. By identifying areas of strength and opportunities for improvement, this research underscores the importance of continuous professional development and the need for targeted interventions to support faculty in their instructional roles.

2 Methodology

2.1 Research Design

This study employs a descriptive research design to identify significant variables influencing the competencies of English faculty at a university, focusing on campuses offering Bachelor of Secondary Education major in English and Bachelor of Arts in English programs.

The investigation involves three respondent groups—department heads, English faculty, and students—totaling 250 participants. Each group provides unique perspectives based on their roles in English instruction. Faculty members conducted self-assessments of their competencies, while department heads and students evaluated the faculty. To ensure the reliability and validity of the collected data, the research followed rigorous ethical standards and used validated instruments.

2.2 Instrumentation

The primary instrument for data collection is a two-part, pilot-tested questionnaire. The first part collected demographic and professional profile data of the respondents, including variables such as age, sex, educational attainment, field of specialization, years of teaching experience, and

Dimensions of Competency	DF	Sum of Squares	Mean Squares	F-ratio	F-Prob.	Decision

Table 1: ANOVA results for the differences in the competencies of the English faculty when grouped according to age. The null hypothesis is accepted and the variance ratio is insignificant if p-value is higher than 0.05 level of significance.

professional development activities over the past decade. The second part consisted of a competency checklist, rated on a four-point scale, assessing various dimensions of teaching competencies: 4 – Outstanding, 3 – Very Satisfactory, 2 – Satisfactory, and 1- Unsatisfactory.

To determine the degree of competencies of the English faculty, the following scale was used based on the ratings given by the respondents: 3.5 – 4.0 Outstanding, 2.5 – 3.4 Very Satisfactory, 1.5 – 2.4 Satisfactory, 1 – 1.4 Unsatisfactory.

This study explores the impact of demographic and professional variables on these competencies, providing a comprehensive analysis through statistical methods such as the F-test and t-test. The Analysis of Variance (ANOVA) was employed to determine significant differences in competencies when grouped according to profile variables, while the t-test was utilized to assess differences in competencies based on sex.

3 Results and Discussion

The analysis of the data collected from the study provides insights into the competencies of English faculty and examines how various demographic and professional variables influence these competencies. The results are presented and discussed based on the statistical analyses performed, including F-test and t-test computations.

The following sections detail the findings related to age, sex, educational attainment, field of specialization, years of teaching experience, and the number of professional development trainings attended over the past ten years, highlighting significant and non-significant differences in faculty competencies.

The F-test computations, as shown in Table 1, indicated no significant differences in the competencies of English faculty when classified by age. ANOVA results further supported this finding, revealing no significant differences across all six competency dimensions at the 0.05 level of significance (Dimension 1: F(3,32)= 1.693, P= .188; Dimension 2: F(3,32)= .674, P= .574; Dimension 3: F(3,32)= 1.002, P=.405; Dimension 4: F(3,32)= .792, P= .508; Dimension 5: F(3,32)= .324, P= .808; Dimension 6: F(3,32)= .100, P= .953). Therefore, the null hypothesis that there are

Dimensions of Competencies	Df	Mean	Standard Deviation	t-ratio	t-prob	Decision
I. Instruction						
Male	34	3.33	.36	-2.277	.029	Reject

Female		3.71	.29			Null Hypothesis
VI. Personality and Professional						
Male	34	3.58	.38	-.916	.366	Accept
Female		3.69	.32			Null Hypothesis

Table 2: t-Test results for the differences in the competencies of the English faculty when grouped according to sex. If the p-value is lower than 0.05 level of significance, the null hypothesis is rejected and the variance ratio is significant.

no significant differences in the competencies of the English faculty based on age is accepted, indicating consistent competencies across different age groups.

This finding aligns with the quantitative results of Odanga and Aloka (2024), which similarly contrast with their qualitative insights regarding the impact of teachers' self-efficacy on classroom management.

Table 2 shows the t-test computations which revealed significant differences in the competencies of English faculty based on sex across three dimensions (Dimension 1: t(34)= -2.277, p= 0.029; Dimension 2: t(34)= -2.960, p= 0.006; Dimension 3: t(34)= -2.371, p= 0.024). This rejection of the null hypothesis suggests that male and female English faculty exhibit varying competencies in instruction, knowledge of theories, approaches, methods, and strategies of TESL/TEFL, and assessment.

This discrepancy may be linked to variations in study habits between male and female students, which could influence the development of faculty competencies. SaizAja (2021) found that female students use language learning strategies considerably more frequently than male students, suggesting a gender-based difference in approaches to language acquisition.

Further analysis indicated no significant differences in classroom management (t(34)= -1.530, p= 0. 136), guidance (t(34)= -1.011, p= 0.320), and personality and professional competencies (t(34)= -.916, p= 0.366) based on sex, underscoring similar competencies across dimensions 4, 5, and 6. These findings suggest that these competencies are primarily honed through teaching experiences rather than formal education.

Regarding educational attainment, ANOVA results in Table 3 showed no significant differences in competencies across all six dimensions (Dimension 1: F(2,33)= .768, P= 0.472; Dimension 2: F(2,33)= 1.252, P= 0.299; Dimension 3: F(2,33)= .648, P= 0.529; Dimension 4: F(2,33)= .637, P= 0.535; Dimension 5: F(2,33)= 1.246, P= 0.301; Dimension 6: F(2,33)= .593, P= 0.558). Therefore, we accept the null hypothesis that there are no significant differences in competencies based on educational attainment, indicating consistent competencies among English faculty with bachelor's, master's, and doctoral degrees.

In contrast, Matira and Ofrin's study (2024) highlighted notable differences in the skills and

Table 5: ANOVA results for the differences in the competencies of the English faculty when grouped according to number of years in teaching English.

knowledge that teachers possessed before beginning instruction. These disparities suggest that teachers enter the classroom with varying levels of preparedness, which can influence their ability to manage learning effectively from the outset.

The one-way ANOVA presented in Table 4 revealed no significant differences in competencies based on field of specialization across all six dimensions (Dimension 1: F(2,33)= 1.726, P= 0.194; Dimension 2: F(2,33)= .482, P= .622; Dimension 3: F(2,33)= .274, P= 0.762; Dimension 4: F(2,33)= .161, P= 0.852; Dimension 5: F(2,33)= .810, P= .453; Dimension 6: F(2,33)= .036, P= 0.965). Thus, the null hypothesis is accepted, indicating similar competencies across different fields of specialization among English faculty.

In contrast, ANOVA results in Table 5 demonstrated significant differences in instructional competence (Dimension 1: F(3,32)= 3.146, P= 0.038), rejecting the null hypothesis that there are no differences in instructional skills based on years of teaching English. This suggests varying competencies among faculty members based on their teaching experience. However, for the remaining dimensions (Dimension 2: F(3,32)= 2.008, P= 0.133; Dimension 3: F(3,32)= 2.840, P= .053; Dimension 4: F(3,32)= 1.648, P= 0.198; Dimension 5: F(3,32)= 1.557, P= 0.219; Dimension 6: F(3,32)= .564, P= 0.643), ANOVA results indicated no significant differences in competencies based on years of teaching English.

Thus, the null hypothesis is accepted for these dimensions, suggesting similar competencies regardless of teaching experience. Hence, the null hypothesis that there is no significant difference in the competencies of the English faculty when grouped according to number of years in teaching English is accepted particularly in the second to sixth dimensions.

These findings are consistent with Matira and Ofrin's (2024) research, which found that teaching experience substantially affects teachers' presentation skills and instructional readiness. However, it does not seem to play a significant role in shaping their professionalism or the overall learning environment.

Total	**35**	4.206				Hypothesis

Table 6: ANOVA results for the differences in the competencies of the English faculty as to number of trainings/seminars attended for the past ten years.

Lastly, ANOVA findings in Table 6 showed no significant differences in competencies based on the number of trainings/seminars attended over the past ten years, except for Dimension 2 ($F(2,33)= 4.555$, $P= 0.018$). This indicates that faculty who attended more trainings/seminars exhibited higher competencies in the knowledge of theories, approaches, methods, and strategies of TESL/TEFL compared to those who attended fewer sessions.

This is consistent with the findings of Dela Cruz and Perez (2024), who emphasize that seminars play a crucial role in enhancing teaching effectiveness, particularly for newly appointed or less experienced educators.

In summary, while demographic and professional variables such as sex and educational attainment impact certain dimensions of English faculty competencies, age, field of specialization, years of teaching experience, and the number of trainings/seminars attended do not significantly affect these competencies across various dimensions.

4 Conclusions

Based on the comprehensive analysis of English faculty competencies across various demographic and professional variables, several key conclusions can be drawn. Firstly, age does not significantly influence the competencies of English faculty, as evidenced by consistent performance across all assessed dimensions. This suggests that regardless of age, faculty members exhibit similar levels of proficiency in instructional practices, knowledge application, and assessment methodologies.

Conversely, significant differences were observed based on sex, highlighting distinct competencies between male and female faculty members in areas such as instruction, theoretical knowledge, and assessment strategies. This divergence may stem from varying study habits observed among male and female students, potentially influencing the development of teaching skills among faculty.

Educational attainment and field of specialization were found to have no significant impact on English faculty competencies across the evaluated dimensions. Whether holding bachelor's, master's,

or doctoral degrees, and irrespective of their field of specialization, faculty members demonstrated consistent levels of competence. This indicates that academic credentials and specialized training do not necessarily correlate with enhanced teaching capabilities in the context of English language instruction at the university level.

Regarding professional experience, while instructional competence exhibited variability based on years of teaching English, other dimensions such as knowledge of theories, classroom management, and professional qualities showed no significant differences. This suggests that while teaching experience may enhance certain facets of teaching effectiveness, overall competencies in foundational skills remain stable among faculty members with varying levels of experience.

Furthermore, the number of trainings and seminars attended over the past decade influenced competencies in specific dimensions, particularly in enhancing theoretical knowledge and pedagogical strategies. Faculty members who participated in more professional development activities exhibited higher levels of competency in these areas compared to their less-engaged counterparts.

In conclusion, these findings underscore the complex interplay of demographic and professional variables in shaping English faculty competencies. While age, educational background, and field of specialization show minimal impact, sex and engagement in professional development activities emerge as significant factors influencing teaching effectiveness. These insights are pivotal for designing targeted professional development initiatives and educational policies aimed at improving the quality of English language instruction in higher education settings. By understanding these dynamics, institutions can better support faculty development efforts, ultimately enhancing student learning outcomes and academic success.

5 Recommendations

Based on the findings regarding English faculty competencies, several recommendations and implications can be outlined to enhance teaching effectiveness and support faculty development initiatives. Firstly, given the significant differences identified between male and female faculty members in dimensions such as instruction and knowledge of TESL/TEFL theories, institutions should consider tailored professional development programs. These programs could address gender-specific teaching strategies and support faculty in enhancing their competencies across all dimensions.

Furthermore, because the study highlights variations in instructional competence based on years of teaching experience, institutions should implement mentorship programs where experienced faculty mentor newer educators. This would facilitate knowledge transfer and the development of effective instructional skills among less-experienced faculty members.

In light of the significant impact of professional development activities on competencies, it is recommended that higher education institutions invest in expanding opportunities for faculty to participate in seminars, workshops, and training sessions. These initiatives should be strategically designed to cover a broad spectrum of teaching competencies, including but not limited to instructional methods, classroom management, and professional ethics. By fostering a culture of continuous learning and skill enhancement, higher education institutions can empower its faculty to adapt to evolving educational landscapes and improve student learning experiences.

On one hand, institutions should ensure equitable access to resources and support for faculty development. This includes fair distribution of teaching loads, access to updated teaching materials, and encouragement for interdisciplinary collaboration to enrich instructional practices to maintain consistent competencies across different demographic and professional groups (e.g., age, educational attainment, field of specialization).

Lastly, the findings highlight the importance of ongoing research and assessment of faculty competencies to inform evidence-based policies and practices. Regular evaluation of teaching effectiveness based on demographic and professional variables ensures that institutional resources are allocated effectively towards areas where improvements are most needed. This systematic approach not only enhances teaching quality but also strengthens the university's reputation as a center of excellence in English language instruction.

Acknowledgements

The author would like to express heartfelt gratitude to all those who have supported her professional journey. Special thanks are extended to Isabela State University for the numerous opportunities it has provided for both professional and personal development. Your commitment to fostering an environment of growth and learning has been invaluable.

Analyzing the Linguistic Generalizations of Filipino Bilingual Children to Bare and Un- Form of Verbs

Jennifer A. Santos
De La Salle University, Manila, Philippines

Abstract

Language conventions are rooted in what children are exposed to in their households daily. These conventional meanings of words may or may not be the academically accurate forms that they can use in a formal setting or that other children and people can understand. In the current post-pandemic era and modern age, there are many new conventions that children learn from their parents, friends, environment, and media. This paper, in particular, delves into how conventionality affects children's grammar skills in terms of identifying the right and wrong bare and un- forms of verbs. One male (age 13) and female (age 10), were selected as participants in this study and took the 48-item grammaticality judgment test. Using a five-point face scale, they identified whether the verb form shown in a sentence is accurately used and if it has the right form. Using the linear regression statistical model, the results showed that both the participants did well in the test, wherein the female had only minimal errors and the male had more than half of the items correct. Hence, the female participant performed significantly better than the male participant. This study revealed that, amidst various changes in today's world, young bilingual children are still linguistically competent despite the effects of language conventions.

1. Introduction

The Principle of Conventionality states that, for specific words and meanings, there is a certain form that the speakers of the language are expected to use and adhere to in the language community (Clark, 2011). This phenomenon has a significant influence on the language acquisition of children as they imitate or learn words from their surroundings and through conversational settings (Clark, 2018). The conventional forms of language, both verbal and non-verbal, are what young children absorb, whether or not they are generally correct and applicable to society. As conventionality is arbitrary in nature and sometimes not acceptable to the masses, it is then important to observe how children generalize the conventional meanings and forms in their own language community with the language system of the world or other sectors of the society they go to such as in schools, churches, playgrounds, to name a few.

With conventionality playing an important role in language acquisition, it becomes more evident that this affects the knowledge and usage of grammar rules and systems the most, as well as how children interact with other people using the language they have at home (Clark, 2007). One of the earliest grammar lessons they learn at school is about verbs. When children are taught about inflected forms of verbs, they are often prone to errors due to the many different contexts and types they must consider before they decide on the form they think is the most grammatically correct (Ambridge et al., 2015). The major factor that affects their decision-making is what they know about language based on their household norms, which could either be formally accurate, acceptable, or casually informal. However, despite the inevitability of this situation among all households, this can still be addressed and resolved through spreading awareness and

informing parents about this phenomenon in order for them to help their children.

Current Situation

The generation of children today is living in a world that is facing two major changes — the post-pandemic era and modernization or proliferation of technology. Their livelihood, education, access to information and resources, and overall lifestyle have been affected by the aforementioned phenomena. In relation to the study, the post-pandemic era and modernization have also affected the conventions of language within the household and language community of the children. Moreover, as the English language is more commonly used in academic institutions and workplaces than any of the 186 languages (Borlongan, 2023) in the Philippines, it would be necessary to study the effects of conventionality on today's young generation of students in terms of English language proficiency in forms of verbs.

Scope and Delimitations

The focus of this study will be to discover and compare the linguistic proficiency and competence of bilingual children ages 10 and 13 in terms of bare and un- forms of verbs. Moreover, this study aims to identify through the results of the data-gathering tool if the participants generalize grammar rules rooted in the conventional forms of language in their household. The test given to the participants will determine the accuracy of identifying right and wrong verb forms and compare the performance between the male and female participants.

The study will not use factors such as academic ranking, socio-demographic profile, and learning environment as variables when analyzing the results. It will also not delve into the qualitative aspects, such as strategies and motivation, that may or may not affect the participants' performance before and during the commencement of the test. Lastly, since this is a pilot study, this research will not tap many participants for the data gathering.

Significance of the Study

The results of this pilot study will greatly contribute to the general knowledge about the current state of children in the post-pandemic era and modern age regarding the effects of conventionality on their linguistic competence and development. This study will be beneficial to the following people:

1. Parents – As conventional forms of meanings of words and phrases stem from the household, parents would gain insight on how to properly address their children in the house so the children would not experience difficulties in learning the formal rules and system of language in school.
2. Students – All students will be able to assess their own learning strategies upon analyzing the results of this study to avoid generalization of conventional linguistic meanings and be able to adapt well to new lessons.
3. Teachers – The results of the study will help teachers understand how students view and absorb grammar lessons, which will help them modify their teaching strategies and encourage them to know the individual profiles and needs of each of their students to know how to address their needs and learning styles.

2. Review of Related Literature

Exploring the Principle of Conventionality

One of the most common and natural ways that children acquire a language, whether it is the first or second language, is through conversational settings (Clark, 2018). They pick up and learn verbal and non-verbal cues from the participants of the conversations around them, even if they are directly involved or are just mere observers. As a result, children apply these acquired words and phrases in their own sentences, relying on how adults or other people commonly use them. This phenomenon is a pragmatic principle called the Principle of Conventionality, which is how speakers utilize conventional forms of language within a community (Clark, 2014). This is tapped by

speakers to have the assurance that the receivers will understand their message.

Children rely on the Principle of Conventionality because their main source of linguistic knowledge is the people within the household, and the same people are the target receivers of their message, too. However, the conventions within children's immediate surroundings may differ in other places or institutions. Given that conventionality is arbitrary in nature (O'Connor, 2021), what children learn inside the house may or may not be applied outside. One possible mistake that children may commit is the overgeneralization of words' formation (morphology), meanings (semantics), and structures (syntax). According to Ambridge et al. (2013), the earliest overgeneralization errors happen when a toddler applies the meaning of a particular word to another word or word group that shares some similarities in visual or conceptual aspects, such as calling all animals with tail doggie and labeling all round fruits as apple. These types of errors result from either category errors or pragmatic adaptations to a limited vocabulary bank.

Effects of Generalization on Grammar Lessons

As children grow older, the danger of committing any of the aforementioned types of errors becomes more evident as they learn new concepts in school. Verbs, for example, are a huge part of their lessons in elementary school, and children must apply the principle of conventionality to this concept very cautiously. Children's acquisition of morphologically inflected forms of verbs or nouns is prone to error because of the various contexts and types that they must consider before deciding how to make the inflections (Ambridge et al., 2015). Some rules in the inflected form of verbs do not apply to all verbs, such as when and how to add the prefix -un or which verbs are regular (can be transformed into a past tense using the suffix -ed) and which must undergo suppletion (e.g., sing into sang) (O'Grady, 2017). With the prevalence of these errors among toddlers, some studies have been conducted worldwide to discover the usual causes of such errors and how parents or teachers can help students correct them.

The study by Brebner et al. (2016) gathered 48 English–Mandarin monolingual and bilingual children in Singapore and utilized a 10-item action picture test where the children were asked to identify the proper verb and verb tense to describe each picture. The results showed that bilingual children have faster and different patterns of acquisition compared to monolingual children in terms of properly using inflectional markers -ed, -ing, -s, irregular past tense, and irregular past participle tense of verbs. In another study, Kambanaros and Grohmann (2015) compared the performance of 64 children with Specific Language Impairment (SLI) and children with Typical Language Development (TLD). Like the previous study by Brebner et al. (2016), these children from either category were tasked to identify the action portrayed in the pictures shown to test their lexical access and retrieval for single action words. The results revealed that children with SLI mainly identified general all-purpose (GAP) verbs and were unable to produce single-word, specific lexical verbs compared to the children with TLD, who were able to excel in both types of verb categories.

When faced with an unfamiliar action, children tend to extend what they know previously to the new phenomenon, whether or not the process is accurate. Childers et al. (2016) found that toddlers aged 2.5 years old can compare previous events when learning new verbs by aligning the two events. They were capable of extracting the common element across a set of three events and applying that information to labeling novel verbs they had just encountered. Aside from testing the aptitude of the children themselves, Lustigman and Clark (2019) invited adults to evaluate children's usage of verbs through a longitudinal study. Four Hebrew children were gathered as participants in the study, and they were basically recorded each week to study the development and progression of their first language acquisition. Their words were marked as either Transparent Verb Forms (clearly identifiable) or

Opaque Verb Forms (not clearly identifiable). The results showed that the adults in the household of the children participants have responses to the verb acquisition that fall under any of the four categories: (1) adults offer interpretation or confirmation of the child's utterance using the same verb lexeme, (2) adults take up the same verb lexeme in to elaborate on the topic but do not offer an interpretation, (3) adults elaborate on the same topic with a different, semantically related, verb lexeme, and (4) adults respond without mentioning the verb lexeme used by the child, or any other related verb lexeme.

Roles and Responsibilities of Adults

It is difficult, however, to monitor every single word or phrase that children may absorb from their environment. Aside from the risk of learning connotatively "bad" words, they may also make mistakes of inaccurately applying one word's meaning to another entirely different word. The role of the parents and adults in children's language acquisition and learning has been emphasized, especially in the last reviewed study by Lustigman and Clark (2019). Conventionality and overgeneralization are two factors that must be further investigated by researchers and studied by adults to lessen the mistakes that children may commit every now and then.

Considering the implications of the aforementioned studies, the surroundings and people in the immediate environment of children indeed play an important role in the honing of a child's knowledge and skills in identifying and using words, particularly verbs, which is the main focus of this present study. However, one of the things that these studies have failed to address is how children use verbs and their various forms in sentences. They were simply tasked to look at pictures and label them. This type of assessment would not measure the children's semantic knowledge in terms of appropriately using these verbs in sentences or using the proper inflections to infer the tense, aspect, or mood. Thus, this gap will be addressed in the current pilot study through the Verb Grammaticality Test by Ambridge (2012), wherein Filipino children will be gathered to assess their skills and schema in identifying proper inflected verbs used in sentences.

3. Theoretical Framework

Overgeneralization is one of the most common errors children commit when they learn a new language or grammar lessons. According to Ambridge (2012), it is one of the three main factors that affect the grammar knowledge and skills of young students. The other two factors are lack of exposure and adult influence. To elaborate further, overgeneralization happens when children apply what they know before to the new things presented to them. They tend to automatically correlate past knowledge with novel learning, which is sometimes good, and sometimes bad. Thus, Ambridge proposed three possible solutions or mechanisms to the three aforementioned concerns, namely, entrenchment, pre-emption, and formation of semantic verb classes.

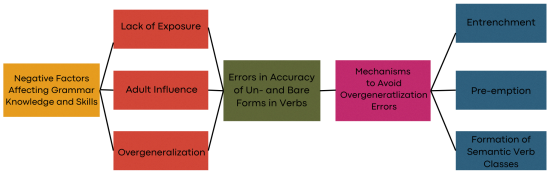

Figure 1: Theoretical Framework of the Study

Entrenchment can be done through consistent exposure to correct grammar forms of language both through visual and auditory senses. This would mean that, even at home or other places besides school, children should have daily access to accurate grammar lessons. Pre-emption, on the other hand, mostly relies on the parents' efforts, as this is done through monitoring the language utterances of children. Parents should correct statements or immediately fill in the correct form or meaning of words before the child makes the mistake or every time they are *about* to make an error. Lastly, the formation of semantic verb classes is spearheaded by teachers during class lectures and discussions. This is done by giving various examples of the same grammatical item in order to help the students fully understand how the said grammatical item is used or modified in

different contexts. These three solutions or mechanisms aim to address lack of exposure, adult influence, and overgeneralization.

4. Conceptual Framework

Since this study is focused on addressing overgeneralization, the following conceptual framework was created by the researcher based on the previous research of Ambridge (2012).

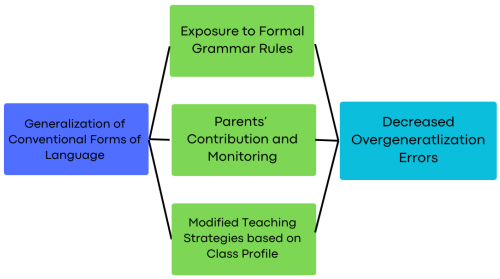

Figure 2: Conceptual Framework of the Study

In order to avoid or decrease the generalization of conventional forms of language, specifically verb forms, the researcher presents three possible solutions. The first one is exposure to formal grammar rules. This is related to the entrenchment hypothesis mentioned above. However, in this framework, there is an emphasis on the "formality" of grammar rules, which means that children should not just be exposed to general grammar rules but also to the formal ones that will be applicable to academic papers and tasks. The second one is the parents' contribution and monitoring. Aside from pre-empting their child's errors, parents should also proactively monitor their children's language development and contribute to their learning through activities, conversations, games, media consumption, and more. And third, modified teaching strategies can be done after teachers have one-on-one consultation with each of their students in order to understand their needs and skills. Combining these three solutions can help ease and decrease the overgeneralization errors committed by children.

5. Research Questions

Using Ambridge's (2000) study on children's overgeneralization tendencies and proposed mechanisms to address them, this research aims to identify if the children of today's world still have these tendencies and how they can be resolved. The purpose of this study is to answer the following questions:

1. How accurately can bilingual children identify if verbs in bare forms and un-forms presented to them are correct or not?
2. What are the differences between the male and female participants' competence in terms of identifying the accuracy of verbs in bare and un- forms?

6. Methodology

Research Design

The researcher utilized a quantitative design for the study. The research focus was embedded in the interest of discovering how accurately young bilingual children can identify if verbs in bare forms and un- forms presented to them are correct or not, as well as the differences in the performances between the male and female participants in determining the proper forms of verbs. The main objective of the researcher was to determine how well children can figure out correct and incorrect verb forms in correlation with the Principle of Conventionality influenced by today's digital age and the modern world they grew up in.

Research Setting

The data gathering took place in a school facility after all classes were finished so as not to interrupt their classes and also to have a convenient location that could accommodate all students. The assessment took place for two hours, giving the participants approximately two minutes to answer each item.

Research Participants

The participants consisted of one boy (13 years old) and one girl (10 years old). They are chosen through random convenience sampling. All participants are bilingual speakers of Filipino and English from the same community. Both participants took the training test and the actual test for a total of approximately two hours and

30 minutes. The participants' parents accompanied them throughout the procedure.

Research Instrument

The instrument used was the Verb Grammaticality Test (Ambridge, 2012). In this assessment, the participants decided which of the verbs given were prefixable with un- ("un-verbs") and which were not ("zero verbs/bare form").

Research Procedure

The Verb Grammaticality Test (Ambridge, 2012) showcased verbs presented in sentences to provide context clues, and the participants rated their accuracy or acceptability through a five-point face scale. Before the official test, a training test was conducted.

For the pre-data gathering procedure, the researcher provided a brief review of bare-form and un- form verbs with some examples before the data gathering proper. Moreover, a training test was conducted, which consisted of 7 bare-form verbs in sentences that the participants rated on a scale of 1 to 5, with 1 being "extremely acceptable" and 5 being "extremely acceptable."

For the actual data gathering, the official test consisted of 48 un- form verbs in sentences, and the children identified whether the un- form verbs were correct or not through the same five-point face scale they used during the training test.

Method of Analysis

The data was analyzed through a linear regression statistical model. The test results of the male and female participants were computed along the total average of the correct rating of the bare and un- form verbs on the five-point face scale wherein the former is the Outcome variables (x) and the latter is the Predictor variables (y).

Ethical Considerations

As the participants of this study were minors, the participants' parents were present during all the procedures. Both the children and the parents were thoroughly informed of every procedure, and they were provided with consent forms, which they signed right after the researcher explained every content in detail.

Before the data gathering, the researcher provided the participants with an informed consent form containing all of the parts of the data-gathering procedure, including whether or not they agreed with the results of their assessments being used as data for the study. The parents were also given a parental consent form that contained the data-gathering procedures in thorough detail, including whether or not they allowed their child to participate in the study. Both the parents and participants signed the forms, and they were thoroughly briefed on the contents of the said forms.

During the data gathering, the researcher did not record any video or audio recordings throughout the assessment. The test papers were the only data collected from the participants. Moreover, their parents were beside them throughout the procedure while the researcher monitored them to avoid coaching from their parents. The names of the participants were not collected; only their age and gender were used to label the data.

After the training test and official test were completed, the researcher read aloud the informed consent form and parental consent form to the participants and parents to remind them of the contents and to request their approval for the second time for reiteration purposes. The researcher also reminded them that the results of the data-gathering will not be used for anything other than the researcher's specific study.

7. Results & Discussion

Using the linear regression statistical model, the test results of each participant were computed and analyzed along with the total average of the correct rating of the bare and un- form verbs on

the five-point face scale. The test results are the outcome variables (x), and the total number of correct ratings is the predictor variables (y).

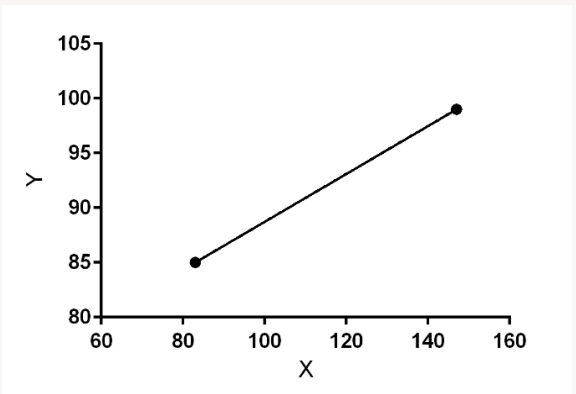

Figure 3: Male Participant Results

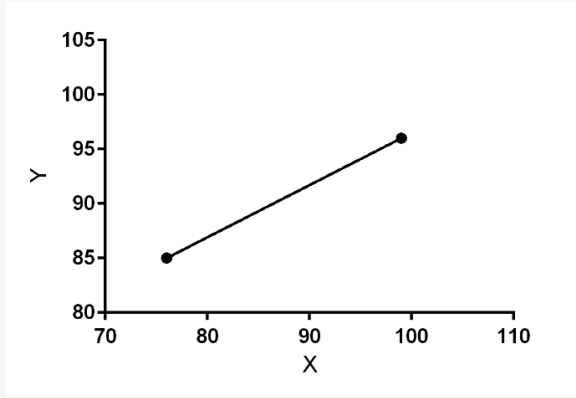

Figure 4: Female Participant Results

For Figure 3, the slope is **0.2188,** the y-intercept is **66.84,** the x-intercept is **-305.6,** and the 1/slope is **4.571.** As for Figure 4, the slope is **0.4783,** the y-intercept is **48.65,** the x-intercept is **-101.7,** and the 1/slope is **2.091.** The results will be further evaluated in detail in the Discussion part below.

Upon completing the 48-item grammaticality judgment test for bare and un- form of verbs, both male and female participants did well, as seen in the test results. The slope for the male and female children is 0.2188 and 0.4783, respectively. The overall results of both participants prove that, even as a pilot study, young bilingual children in the Philippines have a clear grasp of what an accurate bare and un-form of verb looks like.

Now, in terms of differences between the performances of the two genders, the results show that the female participant did significantly better than the male. The male participant has an error of 0.7812, while the female participant has a lower error of 0.5217. For the y and x-intercept, the combined error of the male participant is 238.76, while for the female participant, it's 53.05 only. All of the data from the analysis using the linear regression statistical model proves that the female participant comprehends the accuracy of the bare and un-forms of verbs better than the male participant.

8. Conclusion

Amidst the various changes faced during the post-pandemic era and digital world, language conventionality still does not greatly and negatively affect the linguistic skills and competencies of children. Moreover, despite English being a second language in the Philippines, young children still perform well in terms of identifying correct verb forms and applying effective strategies to adapt to new learning situations and lessons. The results of this pilot study give hope to the current generation of students, as well as their parents and teachers that despite the countless developments and innovations in today's world, children have the innate ability to adjust and thrive. This can be applied not only to grammar skills but also to holistic competencies.

Adults should be aware of how they affect and influence the children around them, whether unconsciously or proactively. Parents should try to be directly involved in their children's learning because it would be difficult for a child to be exposed to contrasting things when they are in school and at home. As for the teachers, they should modify their teaching strategies and plans to better suit the profile and needs of their students.

9. Recommendations

Future researchers could tap on more students to answer the grammaticality judgment test in order to get a more generalizable result.

Moreover, the study could also have a broader scope, such as more age range, interview questions, and involvement of parents and teachers in the data gathering process.

Address forms, politeness, and framing among multicultural students in an Indonesian university

Muhammad Jawad Yuwono and **Wulandari Santoso**
Bina Nusantara University
Jakarta, Indonesia
muhammad.yuwono001@binus.ac.id
wulandari.santoso@binus.edu

Abstract

Address forms play a crucial role in understanding sociocultural dynamics related to gender, age, status, and power relations between different individuals. A handful of studies have examined address strategies in multicultural university settings, but few have attempted to elaborate the influencing pragmatic and sociolinguistic factors at different levels of interactional frames. Utilizing surveys and interviews, this study explores how politeness is conveyed through different address forms used by students from diverse cultural backgrounds in Indonesia, and how sociolinguistic factors influence the students' address strategies across sociocultural, genre, and interpersonal frames, demonstrating their alignment with the Indonesian societal norms, formal and informal university settings, as well as variations in interpersonal relationships. Preliminary findings from this study reveals distinct politeness strategies used by students towards different groups, as well as various factors playing at different levels of framing, including gender, age, marital status, ethnicity, and linguistic identities at the sociocultural level; formal and informal domains at the genre level; and familiarity, intimacy, and power relations at the interpersonal level. Insights from this study contribute to the understanding of intercultural communication in Indonesia, and may inform multilingual educational practices and policies.

1 Introduction

Address forms or terms of address are among the most salient linguistic features associated with the sociocultural dynamics within a speech community (Kiesling, 2009). Examinations on the usage of address forms often show patterns that need to be understood in contexts, which vary widely across time and space and are influenced by various interrelated pragmatic and sociocultural factors. Different address forms may be used in formal and informal situations; at home and at work; and between those used in multilingual and monolingual settings (Formentelli, 2009; Utsumi, 2020; Soomro and Larina, 2022).

There have been a handful of address studies in non-English, bilingual, and multilingual academic contexts. Afful and Mwinlaaru (2012) found that students in Ghana refer to their lecturers differently depending on the lecturers' presence. In the presence of the lecturers, they used address forms indicating deference, while in their absence, they may use forms that symbolises resistance to powers, e.g. by calling them directly by their first names or even by nicknames shared only among the students. Soomro and Larina (2022) used both quantitative questionnaires and qualitative ethnographic methods to investigate the patterns in the address strategies among Pakistani students in multilingual university settings. They found out that hierarchical relationships play a big role in determining what kind of address forms are used by either of the students or the lecturers. They also observed that English forms such as *Sir* were mostly used towards lecturers in formal contexts, such as in classrooms and lecturers' offices, while native forms borrowed from Urdu, Sindhi etc. were used in informal contexts, such as in the cafeteria. A more recent study by Wijayanti et al. (2023) analysed addressing terms used in chats between English majors and their lecturers from several Indonesian universities, and connect them to an emerging "World English" variety in Indonesia.

While these studies have provided useful insights on address strategies among multicultural university students, they did not attempt to identify all potentially influential factors in different levels of interactional framing. In addition, the study by Wijayanti et al. (2023) only found a limited number of tokens with 13 examples of address terms. There is a need for a more comprehensive investigation into address strategies used by multicultural

students in an Indonesian university settings. The usage of English as a secondary language in education has recently gained currency in Indonesia (Tamtomo, 2015; Zein, 2020). Yet, it remains to be seen how the language is adapted to an Indonesian sociocultural context, including in terms of address strategies.

Utilizing a combination of quantitative and qualitative methods, students' choices of address were surveyed through questionnaires, and rationales for their usage were analysed thematically and interpreted in reference to the theories of politeness and interactional frames (Coupland, 2007; Holmes and Wilson, 2022). The objectives of this study are twofold: 1) to examine how politeness is conveyed through different types of address forms used by multicultural students in a multilingual Indonesian university context, and 2) to identify multiple sociolinguistic factors that influence the students' choices of address forms in three levels of interactional framing—namely sociocultural, genre, and interpersonal frames.

2 Theoretical frameworks

2.1 Address forms and address strategies in multilingual contexts

According to Dickey (1997), address forms are the words and phrases used directly by speakers regarding other participants of a conversation. These forms can be contrasted to referent forms, which are used regarding someone not part of a conversation (Dickey, 1997). Following Utsumi (2020) and Manns (2015), this study defines address forms specifically as adjunct second-person referents outside the core clauses (e.g., the word *Ma'am* in *Ma'am, I want to ask a question*). This definition provides a contrast between address forms and second-person pronouns or pronoun substitutes used as syntactic arguments, inseparable from the core clauses (Braun, 1988). In general, while the two categories may overlap, address forms are generally much more open to expansion of repertoires and take a distinctly vocative role (Formentelli, 2009).

Across languages around the world, various distinct categories of address forms can be identified, from personal names and kinship terms to honorifics, titles, and occupational terms (Soomro and Larina, 2022). In English, the category of titles includes words such as Doctor and Professor, while honorifics include words such as Sir and Madam. One word or phrase may belong to two or more categories; for example, Doctor may also be an occupational term (Formentelli, 2009). Personal names are often divided into at least two parts: 1) first name or given name, and 2) last name or surname. However, this division is not universal; for example, Indonesia does not legally distinguish between given names and surnames, and until 2022, allows people to have only one-word names (Nugraheny and Krisiandi, 2022).

Address strategies are the choices of address forms speakers use when referring to different participants of conversations (Formentelli, 2009). Variations in address strategies depend on both pragmatic factors such as politeness and formality, as well as sociolinguistic factors such as gender, age, and power relations between the conversants (Utsumi, 2020). Multilingual practices may also influence address strategies, as they expand the repertoire of forms available to the speakers. In Indonesia, multilingual speakers may utilise elements from different languages to convey their communicative purposes effectively (Tamtomo, 2015).

2.2 Politeness and interactional frames

This study adopts the notions of politeness and interactional frames to contextualise the usage of address forms by multicultural students in a multilingual Indonesian university setting. Politeness involves using specific discourse strategies to foster harmony and avoid conflict (Brown and Levinson, 1987). Positive politeness is concerned with shared attitudes and values, while negative politeness considers social distance and respects status differences. The usage of endearment terms to address other people is an example of positive politeness strategy (Holmes and Wilson, 2022). On the other hand, negative politeness involves more indirectness, as exemplified by the British English way of addressing superiors and older acquaintances with last names preceded by titles or honorifics (Wood and Kroger, 1991; Holmes and Wilson, 2022).

Interactional frames, as explained by Coupland (2007), are the different contexts of discourses in which specific identities are made apparent through the usage of linguistic features. There are three levels of framing, namely 1) sociocultural framing, 2) genre or generic framing, and 3) interpersonal framing. At the macro-level of sociocultural framing, speakers position themselves in accordance with the sociocultural values of a particular community. Linguistic features indexing identities such

Participant	Gender	Age	Languages	Background
A	Prefer not to say	25	Indonesian, English, Japanese	Javanese and Palembang Malay; raised in Jakarta
B	Male	22	Indonesian, English, Sundanese	Malay and Javanese; raised in Bandung
C	Prefer not to say	22	Indonesian, English	Tegal Javanese and Minangkabau; raised in Jakarta
D	Female	22	Indonesian, English	Chinese Indonesian; raised in Qatar and Australia
E	Male	21	Indonesian, English	Javanese; raised in Palembang and Jakarta
F	Female	20	Indonesian, English, Japanese, German	Makassarese, Manadonese, and Betawi; raised in Jakarta
G	Female	20	Indonesian, English, Korean	Chinese Indonesian; raised in Jakarta
H	Female	20	Indonesian, English	Chinese Indonesian; raised in Jakarta
I	Female	20	Indonesian, English	Manadonese and Balinese; raised in Jakarta

Table 1: List of Interviewees.

as gender, age, and ethnicity are made salient at this level. At the middle level of genre framing, speakers govern their talk in accordance with certain types of speech that are relevant to the participants of an ongoing interaction. Formality is indexed at this level (Coupland, 2007; Utsumi, 2020). Finally, at the micro-level of interpersonal framing, speakers frame their speech in accordance with the dynamics in their individual (short- and long-term) relationships to the addressees. Factors such as power differences, relational history, and intimacy are conveyed at this level (Coupland, 2007; Manns, 2015).

3 Methodology

3.1 Participants and methods of data collection

The research data was collected through questionnaires and semi-structured interviews, conducted primarily in English. The questionnaire was designed to collect quantitative data on the address forms used in academic settings. Adapting the questionnaire items in Formentelli and Hajek (2016), the first part includes four questions asking students to select the address forms they use towards 1) lecturers, 2) students of the same year of study, 3) senior students, and 4) administrative staff. Each of the questions gives a checklist of address forms (whether in isolation or combined with personal names) and includes a blank option to add more forms. The second part includes discourse completion tasks (DCTs) concerning the usage of address forms in specific situations. DCTs are open-ended fill-in-the-blanks prompts simulating real-life interactions to bring out the participants' preferred choice of forms, which may reveal patterns that are not readily apparent in simple surveys (Bruns and Kranich, 2021). A total of 3 tasks were devised, involving 1) an interaction between students and lecturers in the classroom, 2) an interaction between students during lunch break, and 3) an interaction between students and administrative staff outside class hours (see Appendix A). The questionnaire was then sent to students of English Literature study program in a university in Jakarta, Indonesia. A total of 13 participants filled the questionnaire.

Since the questionnaire resulted in a limited dataset, it is impossible to rely only on quantitative data. Following Manns (2015) and Utsumi (2020), a semi-structured interview was conducted to collect qualitative data clarifying the answers given by the participants in the questionnaires. A total of 9 participants (labeled A–I) were interviewed based on their availability (see Table 1). Each participant was asked to explain the differences in their strategies for addressing lecturers, students, and administrative staff. In particular, the inter-

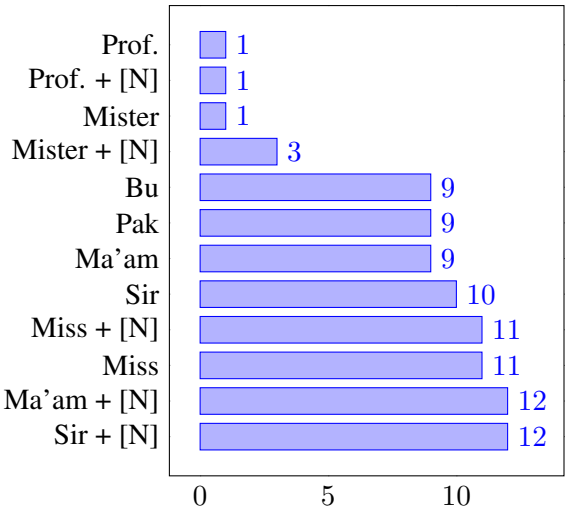

Figure 1: Frequencies of address forms chosen by student towards their lecturers.

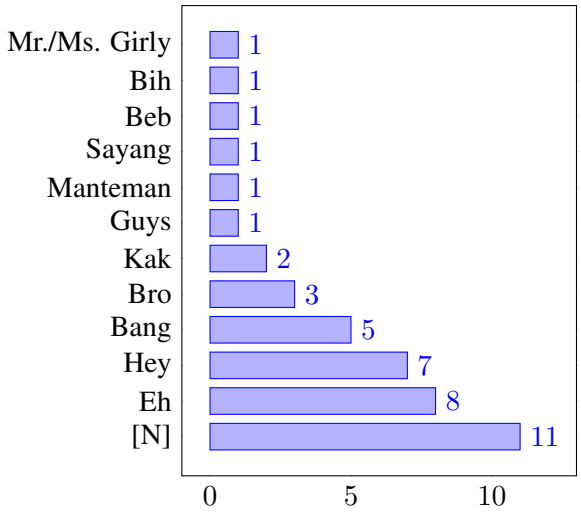

Figure 2: Frequencies of address forms chosen by students towards fellow students of the same year.

viewees were asked what specific sociolinguistic factors contribute to the variation in their address strategies, including variables such as age, gender, occupation, and marital status of the addressees.

3.2 Methods of data analysis

The procedures for this study were as follows. First, the quantitative data on the students' usage of address forms towards different groups (lecturers, fellow students, and staff) were presented in charts and analyzed by looking at their frequencies. Next, the survey results were contextualised with complementary data from the DCTs and interview excerpts. The study employed a thematic analysis method, which aims to systematically identify, organise, and discover insightful patterns within a qualitative dataset (Braun and Clarke, 2021). In particular, the data were analysed in reference to the theories of politeness and interactional frames, focusing on the politeness strategies used by students, as well as the most evident sociolinguistic factors influencing the students' address strategies at three different levels of framing.

4 Results and discussions

4.1 Address forms as politeness devices

In this section, forms used by students when addressing different groups are categorised and discussed based on how whether they are positive politeness devices indicating intimacy and solidarity, or negative politeness devices expressing social distance and deference (Holmes and Wilson, 2022).

When addressing the lecturers (Fig. 1), students overwhelmingly chose to use English honorifics such as *Sir*, *Ma'am* (the full form *Madam* is almost never used), and *Miss*, as well as Indonesian kinship terms such as *Pak* and *Bu*. All these forms were oftentimes combined with personal names—the participants made no distinction between first and last names, as is common among Indonesians. The combinations of *Sir* + [Name] and *Ma'am* + [Name] are particularly interesting, as several participants listed these combinations, but not the bare counterparts.

English honorifics as used by the students towards their lecturers can be seen as negative politeness devices indicating deference. The participants might have used honorifics to avoid directly calling the addressees (in this case, the lecturers) only by their names. Similarly, upward kinship terms such as Indonesian *Pak* 'father' and *Bu* 'mother' express a sense of social distance between the speakers and hearers, which is a characteristic of negative politeness (Holmes and Wilson, 2022). A particular attention should also be given to the usage of the term *Sir*, which according to Wijayanti et al. (2023) overlapped in usage with *Pak*, which is often appended before names. Here, the combination of *Sir* + [Name] was actually even more popular than *Mister* + [Name], which is the more typical combination among native English speakers.

When addressing fellow students of the same year (Fig. 2), 11 out of 13 participants (84.6%) reported using personal names. Other prominently listed forms include vocatives (*Hey*, *Eh*) and Indonesian kinship terms for older siblings (*Bang*,

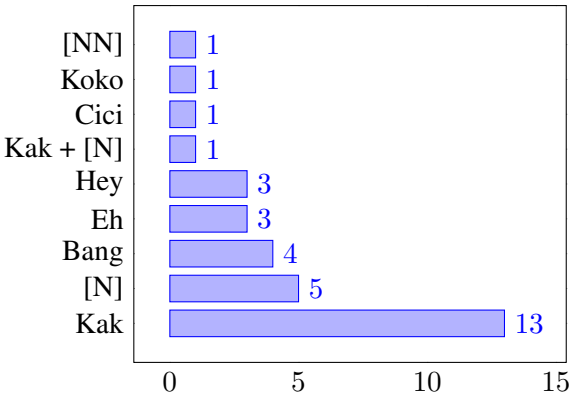

Figure 3: Frequencies of address forms chosen by students towards their seniors.

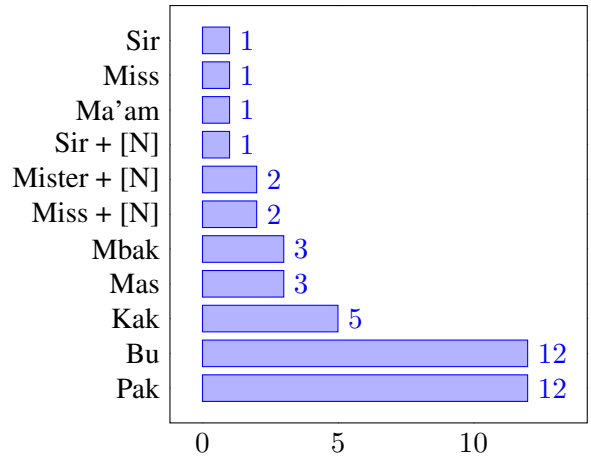

Figure 4: Frequencies of address forms chosen by students towards the campus' administrative staff.

Kak). Two participants also listed the English kinship term *Bro*. Also relatively common were endearment terms in various forms, such as *Beb*, *Bih* (both derived from English *baby*), *Sayang* (Indonesian for 'honey, sweetie'), and *Mr./Ms. Girly*. These are all terms indicating intimacy and/or familiarity, which reflect a positive politeness strategy (Holmes and Wilson, 2022). One participant also listed collective vocatives such as *guys* and *manteman* (from Indonesian *teman-teman* 'friends').

Meanwhile, in addressing their seniors (Fig. 3), all participants unanimously listed kinship terms such as *Kak* and *Bang* as one of their default address forms. These are all upward kinship terms indicating deference of the speakers towards the addressees (Holmes and Wilson, 2022). Notably, unlike the previous category, none of the participants listed any endearment terms for the seniors. Thus, it can be assumed that just as in the case with addressing lecturers, participants tended to default to negative politeness devices when interacting with senior students.

The ubiquity of bare personal names and endearment terms as address forms for students of the same year are characteristic of positive politeness strategy, as they indicate a sense of solidarity among the students (Holmes and Wilson, 2022). Bare personal names were also used to address senior students by 5 out of 13 participants (38.5%). However, at least one participant indicated in their interview that the usage was more limited towards those who they know well enough:

> [...] when I talk to seniors, my address to them depends on how close I am to them. If I don't know them well enough, I will use *Kak* because I feel like I need to be polite. If I do know them well, I will use informal addresses [...] for them [Participant F, 20]

On the other hand, while there were participants who did use upward kinship terms such as *Kak* and *Bang* with students of the same year, further inquiry through the interviews revealed that some of them used these kinship terms as familiarisers that were functionally equivalent to endearment terms:

> I usually address them with their names, but sometimes I use the other words to call them, even if they aren't older. So like, instead of being like, *eh Jawad ini gimana* ('Hey, Jawad, what should we do') [I'd] say, *bang ini gimana bang* ('Bro, what should we do') [Participant G, 20]

Last but not least, in approaching campus' administrative staff, almost all of the participants (12 out of 13, 92.3%) chose the Indonesian kinship terms *Pak* and *Bu* as the appropriate address forms, while a handful (5 out 13, 38.5%) also chose *Kak*, as well as the Javanese kinship terms *Mas* 'older brother' and *Mbak* 'older sister' (3 out of 13, 23.1% each). Only 2 participants (15.1%) chose the English forms *Mister/Miss* + [Name], with one of them also choosing the bare forms.

As in the case of students-lecturers' interactions, this preference for honorifics and kinship terms indicates a negative politeness strategy, in that it avoids addressing the interlocutors directly by their names (Holmes and Wilson, 2022). However, un-

like when they addressed lecturers, students overwhelmingly preferred native Indonesian and even Javanese address forms instead of English. This suggests that there were also other factors in play other than politeness in determining the students' address strategies, which brings us to the next subsection.

4.2 Contextualizing address forms in different levels of framing

To fully comprehend the influencing factors behind participants' strategies in deciding address forms, we need to consider the different levels of interactional frames in which they are produced (Coupland, 2007; Utsumi, 2020). This section will discuss the relevant factors in detail, with reference to the three levels of framing: sociocultural, genre, and interpersonal. Data from the discourse completion tasks and interviews will be heavily relied on to support the arguments.

At the macro-level of sociocultural framing, it is argued that gender, age, marital status, ethnic, and linguistic identities are all particularly relevant markers made salient through address forms. A significant amount of address forms examined so far are gendered, especially the honorifics and kinship terms. The very act of using address forms such as *Sir*, *Miss*, *Ma'am*, is in and of itself an act of gendering participants of interactions. Conversely, the awareness of such gendering practice also explains why a significant number of participants chose Kak over other kinship terms with similar meanings to address both senior students and administrative staff. It can be argued that this specific address form is seen as gender-neutral in Jakartan Indonesian, unlike *Bang*, *Mas*, *Mbak*, *Koko*, and *Cici*. As noted by one of the participants:

> I assume any senior students are older than I am, so to play it safe and polite, I usually use *Kak* no matter what gender. [Participant H, 20]

Data from the interviews indicates that age and marital status, both being important sociocultural markers in Indonesia, are also made salient at this level of interaction:

> It depends on how old they [the interlocutors] are compared to me and what position they hold relative to myself within a specific setting. [Participant C, 22]

> [...] I use honorifics that ha[ve] a relation with their occupation. Also, I use *Miss* to address an unmarried or younger female lecturer, while *Ma'am* is for the female lecturers that are older or married. [Participant H, 20]

The sociocultural frame also includes the indexing of ethnic identities of both the speakers and interlocutors (Manns, 2015). An example of address forms indexing the speakers' ethnic identities were the usage of *Mas* and *Mbak* towards to the campus' staff, which were limited to participant B, C, and E, all of whom were of Javanese or partial Javanese backgrounds. This concurs with observations from previous studies (Errington, 1998; Manns, 2015) that the two forms were still markedly Javanese (compared to, say, *Kak*) and were rarely used by non-Javanese. Conversely, address forms might also index interlocutors' ethnic identities, as in the case of Hokkien sibling kinship terms *Koko* and *Cici* for Chinese Indonesians.

The students' linguistic identity as speakers of Indonesian in multilingual context was often made relevant in discourses, especially among students-students' and students-staff' interactions. In the results of the DCT regarding students-staff interactions, 7 out of 13 (53.8%) responses wrote the whole sentence in Indonesian, and even a couple of those who responded in English still included Indonesian forms of address (e.g. *Excuse me,* Kak*, is the administrative desk open?*). This indicates that there the students attempted to make their linguistic identity as speakers of Indonesian clear to the addressee, which, in the scenario, was specified as a "junior male staff" behind the administrative desk.

> [...] when I talk to campus' administrative [staff], I switch to Indonesian because there's no need of me using English, because Indonesian is the standard language to use for public settings, and because if I use English, there's a chance that the staff would not understand me or there would be miscommunications. [Participant F, 20]

The variety of address terms used between different groups indicate that the participants were aware of their indexicalities. This awareness might also lead to an avoidance in using address terms that were perceived to index certain stereotypes.

One participant noted her reluctance in using *Mas* towards the staff, exactly because she was not sure if it would index the appropriate ethnic and class identity for the interlocutors:

> Technically [*Mas*] works too, but some young men in Jakarta take offense to being called that because they associate it with working-class professions or people. *Pak* works best because it's a universal honorific for all men everywhere in Indonesia and it's sufficiently formal for a situation where you do not know the other person [Participant F, 20]

Moving on to the second level of genre framing, it is argued that the use of address forms by the participants indexes at least two primary domains: formal and informal. Within formal domains, there is also lecture as a specific genre of discourse. Formality is defined by Utsumi (2020) as discourses that are public, respectful, but not intimate. One of the participants interviewed clearly made a distinction between the two:

> [...] lecturers and admin are addressed more formally that is suiting of their position. For friends, because it is more casual and familiar there is no need for formalities. [Participant A, 25]

Students-lecturers and students-staff interactions in classrooms and offices are strictly formal because they both involve public and respectful discourses, despite the obvious differences in the types and languages of address forms used. In fact, the differences are irrelevant, as there are direct parallels in the degree of formality between the English forms used to address lecturers and the Indonesian forms used to address staff. *Sir* and *Mister* can be thought of as equivalent to *Pak*, *Miss* and *Ma'am* equivalent to *Bu*, and so on. This is a strong example of how sociocultural markers of ethnic and linguistic identities that are salient at the macro-level can be made non-salient at another level (Coupland, 2007; Manns, 2015; Utsumi, 2020).

One form that can be considered indicative of informality is *Bang*, which, in Jakarta, is primarily used among speakers of Betawi and Colloquial Jakartan Indonesian. We can see this in the way a handful of participants used *Kak* to address staff, but none of them reported *Bang* for the same use, despite the parallelism between the two (both being upward sibling kinship terms). This contrasts with how participants addressed fellow students, especially seniors, with both forms. In other words, *Bang* seems to index the intimate aspect of informality, which is not supposed to be present in formal situations (Utsumi, 2020).

Within the formal domain, a particular genre is identified, which is that of the lectures, done in the university classrooms with English as the primary language of instruction. Students participating in the discourse during lectures selected address forms that reflect the polite and formal characteristic of the genre. Crucially, the genre distinguishes itself from other formal contexts by the usage of English address forms:

> [...] because we are in Eng[lish] Lit[erature] classes, we usually use *Sir/Ma'am/Miss* instead of *Pak/Bu*. [Participant G, 20]

The usage of English address forms in this formal genre of lectures findings may seem to concur with findings from Soomro and Larina (2022), who observe that English forms tended to be used in formal situations, while native forms were mostly reserved for informal situations. However, participants of this study also used native forms in formal interactions outside the classroom, especially with campus' staff. Thus, in the case of this study, the most relevant factor influencing the students' choice of English forms (as opposed to the native forms) is their participation in English academic lectures, not the formality of the situations *per se*.

At last, there is the micro-level of interpersonal framing, in which the degree of intimacy, familiarity, and personal relationships influence the usage of address forms. Interpersonal framing is best used to analyse the usage of address forms in informal situations (Utsumi, 2020), such as in the discourse between students, whether those from the same or different years of study. As mentioned above, it seems that the participants distinguish between seniors they know well, who are addressed directly by bare personal names, and those more distant, who are addressed with honorifics. Similarly, the usage of familiarisers and endearment terms might depend on the participants' interpersonal relationship with the addressees.

In one of the DCTs, the participant had to complete an interaction in which a student asks their fellow classmate taking a lunch break to bring some food for them as well. An exceptional pattern not found in the close-ended questionnaire emerged

here: the lack of *any* adjunct address terms in 3 out of 13 responses (23.1%). This can be analysed as part of the negative politeness strategy of avoidance. But in the context of interpersonal framing, the lack of address terms here can also be seen as avoiding formalities imposed by formal address terms at the genre level. Thus, the omission of address terms here can perhaps be considered a marker of casualness (Ton, 2018).

While both students-lecturers and students-staff interactions are both perceived as formal matters within the genre level, the findings from this study indicate the differences in the participants' power relations *vis a vis* lecturers and administrative staff. With lecturers, students preferred to use upwards kinship terms indicating parental relationships, such as *Pak* and *Bu*. Meanwhile, when referring to staff, students' invariably also used upwards kinship terms indicating siblings relationships, such as *Kak* and *Mas*. The divide in the use of kinship terms might reflect the interpersonal relationship hierarchy between lecturers and staff as perceived by the participants.

5 Conclusion

This study explores the nuanced usage of address forms among multicultural students in an Indonesian higher educational setting. Underpinned by the theories of politeness strategies and interactional frames, the study reveals that politeness strategies are manifested through the students' variations in address forms towards different groups. It also shows multiple factors playing at different levels of framing, including gender, age, marital status, ethnicity, and linguistic identities at the sociocultural level; formal and informal domains at the genre level; and familiarity, intimacy, and power relations at the interpersonal level. These findings offer insights on intercultural communication among university students in Indonesia, and may inform practices and policies in regards to the emerging use of English in multilingual educational context.

This study reports preliminary findings obtained from questionnaires and interviews with a limited sample size. More data is needed to verify the characterization of address strategies used by multicultural students in polyglossic university context. Further research could employ direct observation to reveal patterns that might not emerge due to the constraints of questionnaires and DCTs.

A Appendix: Discourse completion tasks

A.1 Situation 1

A student (S) attends a university lecture conducted in English by a female professor (P) and wants to ask a question.

S: _____

P: Alright, thanks for the question. Anyone else?

A.2 Situation 2

Student A is going out to the cafeteria for lunch, and Student B asks him to bring some for her, too.

A: I'm going to the cafeteria to get some lunch.

B: _____

A: No problem, I'll be back in a bit.

A.3 Situation 3

Student C appears on the campus' administrative desk and asks a junior male staff whether it is still open.

C: _____

Automatic Extraction of Relationships among Motivations, Emotions and Actions from Natural Language Texts

Fei Yang
CogBeauty Lab, China
yftadyz@163.com

Abstract

We propose a new graph-based framework to reveal relationships among motivations, emotions and actions explicitly given natural language texts. A directed acyclic graph is designed to describe human's nature. Nurture beliefs are incorporated to connect outside events and the human's nature graph. No annotation resources are required due to the power of large language models. Totally 92,990 relationship graphs are extracted from food reviews, of which 63% make logical sense. We make further analysis to investigate error types for optimization direction in future research.

1 Introduction

In daily life, different motivations drive humans to produce different behaviors, and at the same time, the satisfaction of motivations leads to different emotions. Understanding relationships among motivations, emotions, and subsequent actions has drawn a lot of attentions in the research community. One prevailing practice is, given an event text, annotators generate description texts of its motivations, emotions, and subsequent actions (Rashkin et al., 2018; Sap et al., 2019; Ghosal et al., 2022). Or annotators mark motivations, emotions, and actions on its contexts (Poria et al., 2021; Mostafazadeh et al., 2020; Gui et al., 2018). Then deep learning models are trained over the generated or labeled datasets, which encode the relationships into the models' parameters. One drawback of this paradigm is, it fails to reveal relationships explicitly, providing not much help in understanding human intelligence, although these black-box models perform well in real applications. Another drawback is, it heavily relies on human resources and workflow designs for annotation.

In this work, we propose a framework to explicitly handle relationships among motivations, emotions and actions, which automatically generates directed acyclic graphs (MEA-DAG) given natural language texts. By drawing on findings from cognitive science, a Nature Design graph is built manually, which reveals human's inside nature, being formed through thousands of years of genetic evolution. Our framework also incorporates Nurture Belief, learned from developmental experiences. Nurture Belief plays a key role in connecting outside world events and Nature Design. Figure 1 shows the Nature Design graph and a MEA-DAG example. Large language model (LLM) is used to extract and improve the quality of Nurture Belief. Therefore no annotation resources are required in our framework, and efforts are put on prompt engineering instead of annotation workflow design.

To reduce the complexity of the problem, only the motivation of human's need for food (Maslow, 1943) is focused. We divide this motivation into two types: positive and negative, which correspond to food need being met and not met respectively. From review texts of Amazon Fine Foods Reviews (McAuley and Leskovec, 2013), totally 92,990 MEA-DAGs are extracted out and 63% of them make logical sense. Error analysis is implemented to investigate the error types and find future research directions. All codes and data are released publicly. [1]

2 Related Work

Event2Mind (Rashkin et al., 2018) asks annotators to provide short textual descriptions of motivations and emotional reactions given an event. The collected texts serve as the training set of a encoder-decoder model, which predicts motivation and emotion over a new event. ATOMIC (Sap et al., 2019) extends the annotation dimensions, and trains a encoder-decoder model for inference. In (Ghosal et al., 2022), given an event in a dialogue, annotators answer five dimensions: cause, subsequent

(a) (b)

Figure 1: (a) Nature Design. This graph reveals the interactive mechanism among motivations, emotions and actions in human's nature. (b) An MEA-DAG example. Events are extracted by ASER from a review and presented in green color. The activated nodes of Nature Design are in red color. Other nodes are omitted. Nurture Belief participates in linking events to corresponding nodes, and presented in the MEA-DAG as well. For instance, "it seriously makes perfect meatballs", has a connection with `#food` by the belief tuple ("meatball", `#food`).

event, prerequisite, motivation, and emotional reaction for tuning transformer-based models. Instead of generating artificial answers, other researchers choose to mark key information directly on the contexts of events. Poria et al. (2021) annotates the cause of emotions manually at phrase level in two conversation datasets, and transformer models are fine-tuned for inference. Gui et al. (2018) annotates the cause of emotions from emotional context, and then a convolution kernel-based model is learned. In (Mostafazadeh et al., 2020), given a sentence and its context, ten dimensions including motivation, emotion, other implicit causes, and its effect are annotated by crowdsourcing. They then train a encoder-decoder model to infer both specific statements and general rules for new scenarios. All these methods code the relationship among motivations, emotions and actions into parameters of their models in a black-box style. Therefore, they contribute very little to the understanding of this relationship, although their models could do excellent inference on new scenarios.

3 Methods

Our framework consists of four phases: (1) loading Nature Design and Nurture Belief, (2) perceiving states, (3) forward transmitting, and (4) taking actions, which are shown in Figure 2. It mimics human brain's cognition process. First of all, a brain stores innate evolutional design and acquired developmental experiences. Next, suppose an event occurs around, the brain perceives this event, then neutrons send signals along axons and dendrites, and finally an action is taken by invoking body parts. Afterwards, the brain perceives feedback from the action, which forms a closed loop of cognition, providing abilities to (1) form new knowledge about this world, and (2) guide next action based on all existed knowledge in the brain. The feedback loop is not covered in this work and left for future research.

3.1 Loading Nature Design and Nurture Belief

Nature Design starts from `#past_experience`, whose behavioral outcomes drive emotions and feelings. Emotions and feelings are involuntary, which serve as passive states, reflecting patterns of physiological activities (Panksepp, 2004). After perceiving these passive states, we infer whether human's need of food is satisfied or not. Positive feelings or emotions mean the need is satisfied while negatives mean the opposite, which are shown as directed links in Figure 1 (a). Positive actions are driven to strengthen being able to continuously meet the need when it's satisfied. Negative ac-

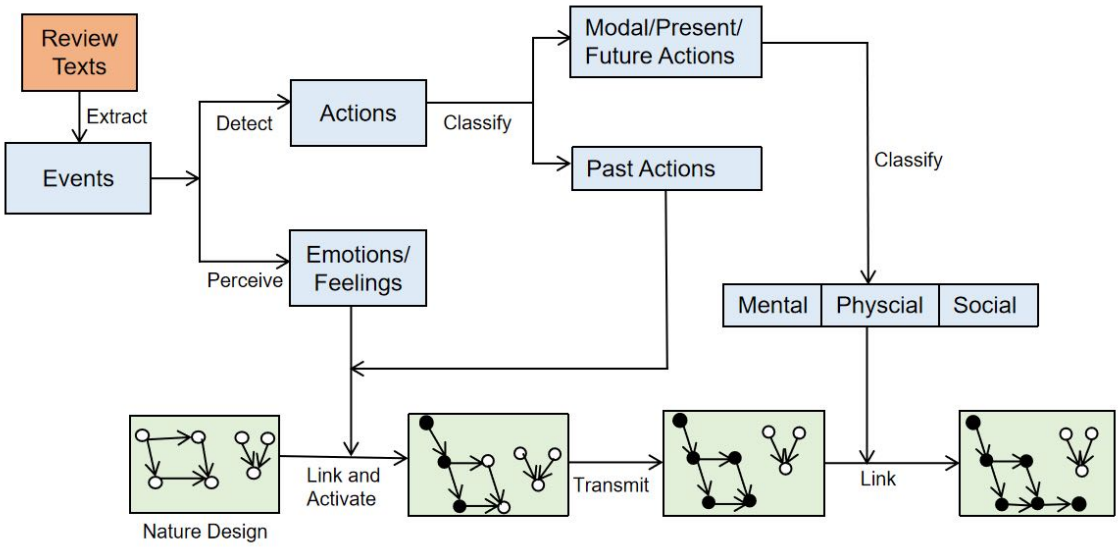

Figure 2: Framework of computing a MEA-DAG. It inputs the text of a food review (top left corner) and outputs a graph (bottom right corner). The green line at the bottom shows the evolution of a MEA-DAG in different processing stages, which imitates human brain's cognition process.

tions are driven to prevent it from happening again when human's need is dissatisfied. All actions are further broken down into three types: `Mental`, `Physical` and `Social`. Nodes of Nature Design are regarded as innate, different from learned experience (Izard, 1992; Deci and Ryan, 2000). Node definitions are summarized in Table 1. We admit that actions are not only determined by motivations, but also biologically, culturally, and situationally determined as well (Maslow, 1958). We ignore these factors and explore them in future research.

Nurture Belief includes three parts: food entities, experience feelings and emotions. They connect real world descriptions to abstractive concepts, stored as a set of tuples {("word", `node`)}. For instance, "cheerful" describes a positive emotion, which is stored as ("cheerful", `#emo_pos`). When an event is linked to a node, the related Nurture Belief tuples are presented in its MEA-DAG as well.

Food Entities. WordNet (Miller, 1995) provides an ability to link concrete entities to abstract categories. We start from the word "food" and find all its hyponyms. The hyponyms with food-unrelated senses are removed to improve accuracy. Totally 1,842 tuples of ("word", `#food`) are collected.

Experience Feelings. SentiWordNet (Baccianella et al., 2010) provides positive, negative and neutral feeling scores at sense level. By setting `PosScore`>0.6 and `NegScore`>0.6, positive and negative senses are extracted out respectively. Adjectives with only positive senses are classified as `#experience_feeling_pos`, and negative-senses only are classified as `#experience_feeling_neg`. GLM-4 (GLM et al., 2024), an open-source LLM,

- Emotion Classification Prompt

> Judge if the INPUT word is describing positive/negative emotion. Answer in English. Explain your reasoning then state the answer. Return =True= or =False=.

Figure 3: Prompt engineering. We rely on LLM to accelerate the establishment of Nurture Belief, and no longer rely on manual labeling resources.

Table 1: Explanation of nodes in Nature Design.

Node	Explanation
#food	Food entities, e.g. bread, apple.
#experience_feeling_pos	Positive feelings, e.g. delicious, easy.
#experience_feeling_neg	Negative feelings, e.g. bitter, hard.
#emo_pos	Positive emotions, e.g. happy, cheerful.
#emo_neg	Negative emotions, e.g. sad, angry.
#need_food_pos	Human's need of food is satisfied.
#need_food_neg	Human's need of food is dissatisfied.
#past_experience	Actions that take place in the past and result in a change of need state, e.g. bought, searched. It's the root node of Nature Design.
#action_pos	Actions that are driven to strengthen being able to continuously meet the need.
#action_neg	Actions that are driven to prevent it from happening again when human's need is dissatisfied.
#mental_action	Actions that happen inside human beings, not visible, e.g. analyze, versify.
#physical_action	Actions that happen outside human beings and are visible, e.g. wash, peel.
#social_action	Actions that are directed at others, e.g. denounce, rent.

is used over the negative adjectives to filter out bad cases. We list the prompt in Figure 3. Totally 1,415 positive tuples and 1,239 negative tuples are collected.

Emotions. Shaver et al. (1987) identify 135 base words which belong to six primary emotion classes: `Anger`, `Fear`, `Joy`, `Love`, `Sadness`, and `Surprise`. Synonyms of the base words are searched manually as extension words [2]. Extension words are classified as the same emotion class as their corresponding base words. We only keep adjectives and verbs. The base and extension words which belong to `Joy` and `Love` are classified as `#emo_pos`, and words from `Anger`, `Fear` and `Sad` are `#emo_neg`. GLM-4 is used to filter out bad cases, and its prompt is listed in Figure 3. Totally 1,425 positives tuples and 1,946 negatives tuples are collected.

[2]Synonym Website: https://www.merriam-webster.com/thesaurus

3.2 Perceiving States

ASER (Zhang et al., 2022, 2020) is used to extract events from the text of a food review. By resorting to POS tagging [3] and dependency parsing, we detect the following keyword combinations in an event: (1) food entity + feeling state, (2) food entity + emotion state, (3) "I/We" + emotion state, and (4) emotional action. These combinations indicate mental states about food. Keywords link and activate corresponding nodes in Nature Design, like "meatball" and "perfect" in Figure 1 (b). If "not" appears in an event, then feeling and emotion keywords would link and activate opposite nodes. For instance, in the event "I am not happy", "happy" is linked to `#emo_neg` rather than `#emo_pos`.

3.3 Forward Transmitting

Links in a MEA-DAG indicate the direction of signal transmission. The node pointed by a link is tail node, and the node on the other side is head node. Activated nodes in 3.2 send out signals along links to tail nodes, which is a forward transmitting process. For example, in Figure 1 (a), when the node `#emo_pos` is activated, as head node, it sends out a signal which activates its tail node `#need_food_pos`, and then `#action_pos` is activated by its head node `#need_food_pos`.

3.4 Taking Actions

Action events are detected according to patterns listed in Table 2. Only events that have first-person subject "I/We" are considered. Next a `Past` event is determined by checking if the POS tagging of its verb is `VBD` or `VBN`, which is then linked to and activates the node `#past_experience`. Other events, `Modal/Present/Future`, are further classified into three types: `Mental`, `Physical` and `Social` by GLM-4. Definitions and prompts are listed in Figure 3. Events of each type are linked to the following activated nodes respectively, `#mental_action`, `#physical_action` or `#social_action`.

4 Evaluation

4.1 Error Analysis

Totally 92,990 valid MEA-DAGs are extracted out from 568,454 reviews. A valid MEA-DAG is defined as only `#need_food_pos` or

[3]Penn Treebank POS tags. Check more details in https://www.ling.upenn.edu/courses/Fall_2003/ling001/penn_treebank_pos.html

Table 2: Action event patterns. Only first-person subject patterns are considered. We refer to the ASER pattern writing format.

Pattern	Example
I/We -nsubj-v_1	"I freeze"
I/We -nsubj-v_1-dobj-n_2	"I slice the loaf"
I/We -nsubj-v_1-xcomp-a	"I feel hungry"
I/We -nsubj-(v_1-iobj-n_2)-dobj-n_3	"I give this product 5 star"
I/We -nsubj-v_1-xcomp-a_1-cop-be	"I expect to be served"
I/We -nsubj-v_1-xcomp-n_2-cop-be	"I want to be a gourmet"
I/We -nsubj-v_1-xcomp-v_2-dobj-n_2	"I wait to pay the product"
I/We -nsubj-v_1-xcomp-v_2	"I want to cook"
I/We -nsubj-v_1-nmod-n_2-case-p_1	"I go into the kitchen"
(I/We -nsubj-v_1-dobj-n_2)-nmod-n_3-case-p_1	"I push the pizza into the oven"

`#need_food_neg` is activated. From valid MEA-DAGs, 100 samples are randomly chosen as a test set for manual evaluation of correctness. A MEA-DAG is incorrect if the revealed relationship is not logically making sense. During the evaluation, seven types of errors are found, whose distribution is shown in Table 3. Totally 42 errors are detected and 37 samples having at least one error. Event Linking Loss and ASER Extraction Loss are the top two error types on the test set. In this section, we discuss why each error type occurs and possible solutions to improve it. Detailed MEA-DAG examples of each error type are appended in Appendix A.

Event Linking Loss. A MEA-DAG fails to incorporate critical information of events, making the revealed relationship not logically complete. The reasons lie in the coarseness of Nature Design, capturing very limited concepts. The limited number of patterns for linking events and nodes also leads to this loss. Besides adding more nodes and patterns, one interesting direction of improvement is to equip the algorithm with learning ability, being able to automatically build new nodes and links when it perceives new events and their outcomes.

ASER Extraction Loss. ASER fails in extracting out critical events from review texts, breaking the logic completeness. This happens due to the limited patterns of event-extractions by ASER. For instance, "I do not know how I could say whether or not the cat food is tasty" would be extracted as one event, "the cat food is tasty", missing key phrases "do not know" and "whether or not". It's necessary to find a method of understanding a sentence as a whole.

Wrong Subsequent Action. An action event should not be linked to the children of `#action_pos` or `#action_neg`, as it's not driven by human's need. For example, in the event "I consider myself a pro when it comes to popcorn", the reason of being a pro is not triggered by one specific satisfaction of food-related need, but the rich experience of eating popcorn. This kind of error happens due to lack of deep semantic understanding of an event. Adding more temporal nodes to Nature Design could help to improve the accuracy.

Word Sense Ambiguity. A word is linked to a wrong node due to sense ambiguity. For example, in "you are going to get a light coffee", "light" is incorrectly linked to `#emo_pos`, as "light" here describes the flavor of coffee. Our methods have no ability to determine which sense of a word should be used in an event. A possible cure might be that MEA-DAGs are built for each sense of a word, and then MEA-DAG merging is implemented between sense and context. A proper sense could be merged smoothly into the context.

Wrong Belief. A word is wrongly linked to emotional or feeling nodes in Nurture Belief. For instance, the words "different" and "raw" are incorrectly connected to `#experience_feeling_pos`. This happens as SentiWordNet has classification errors, which could not be thoroughly filtered out by LLM. This type of error brings up an interesting research topic: automatic error-correction mechanism. In the course of human development, numerous beliefs are established about this world, some of which are false. Through subsequent experiences, they consistently reinforce correct beliefs and fix wrong beliefs. This mechanism should work perfectly for this kind of error.

Wrong Past Action. Although an action event happens in the past, they are actually driven by how well the food need is met. For instance, "I had to take one star off" is triggered by the dissatisfaction of need. Judging a past action only by tense is not enough. Adding more temporal nodes to Nature Design could help this situation.

Negation Loss. Events are linked to wrong nodes due to failure of capturing negation. "It just failed to deliver" expresses a negative meaning of action, which is hard to capture unless the semantic meaning of "fail" is incorporated in Nature Design. One solution is adding a layer of nodes which is

		Test		Short-Test		Long-Test	
		Count	Percent	Count	Percent	Count	Percent
Sample	Incorrect	37	37.0%	14	29.8%	23	43.4%
	Total	100	100.0%	47	100.0%	53	100.0%
Error	Event Linking Loss	9	21.4%	3	20.0%	6	22.2%
	ASER Extraction Loss	7	16.7%	2	13.3%	5	18.5%
	Wrong Subsequent Action	6	14.3%	1	6.7%	5	18.5%
	Word Sense Ambiguity	6	14.3%	3	20.0%	3	11.1%
	Wrong Belief	6	14.3%	4	26.7%	2	7.4%
	Wrong Past Action	5	11.9%	1	6.7%	4	14.8%
	Negation Loss	3	7.1%	1	6.7%	2	7.4%
	Total	42	100.0%	15	100.0%	27	100.0%

Table 3: Accuracy and error types with count and percentage distribution. We present the results for the test set, the short-test set (sentence number < 5) and the long-test set (sentence number $\geq$ 5).

specifically responsible for dealing with negation and other logic operations.

4.2 Review Length Effect

Depending on whether the number of sentences contained in a review is less than 5, the test set is splitted into a short-test set and a long-test set. By comparing the error differences between the short-test and the long-test, we investigate the effect of review length on accuracy.

Table 3 shows the comparison result. Incorrectness rate of the short-test set is 29.8%, while the long-test set has 43.4%, which indicates that our methods are not well-suited for processing lengthy reviews. Top three error types of the short-test are Wrong Belief, Word Sense Ambiguity and Event Linking Loss, while the long-test are Event Linking Loss, ASER Extraction Loss and Wrong Subsequent Action. From the shift of top three errors, we find that the main bottlenecks of processing long reviews lie in lack of rich nodes and links in Nature Design, as well as lack of comprehensive and in-depth understanding of a sentence.

5 Conclusion

We compute MEA-DAGs to understand the relationships among motivations, emotions and actions from natural language texts. Nature Design is novelly introduced to imitate human's nature, and Nurture Belief connects outside world and human's nature. Our methods are white-box and don't rely on huge annotation resources. Error analysis is implemented to identify the main problems and find possible directions for further optimization.

A Error Examples

A.1 Event Linking Loss

Figure 4 shows two examples whose MEA-DAGs lose critical information of events, resulting that the revealed relationship is not complete in logic sense.

A.2 ASER Extraction Loss

Figure 5 presents two examples in which ASER couldn't extract critical events from review texts. As a result, the generated MEA-DAG is incomplete.

A.3 Wrong Subsequent Action

Figure 6 presents two examples in which action events are wrongly linked to the children nodes of `#action_pos`. If the contexts and timeline of events are considered, they should be linked to `#past_experience`.

A.4 Word Sense Ambiguity

Figure 7 presents two examples in which words are wrongly linked to feeling or emotion nodes, as our methods have no ability to determine the sense of a word given its context.

A.5 Wrong Belief

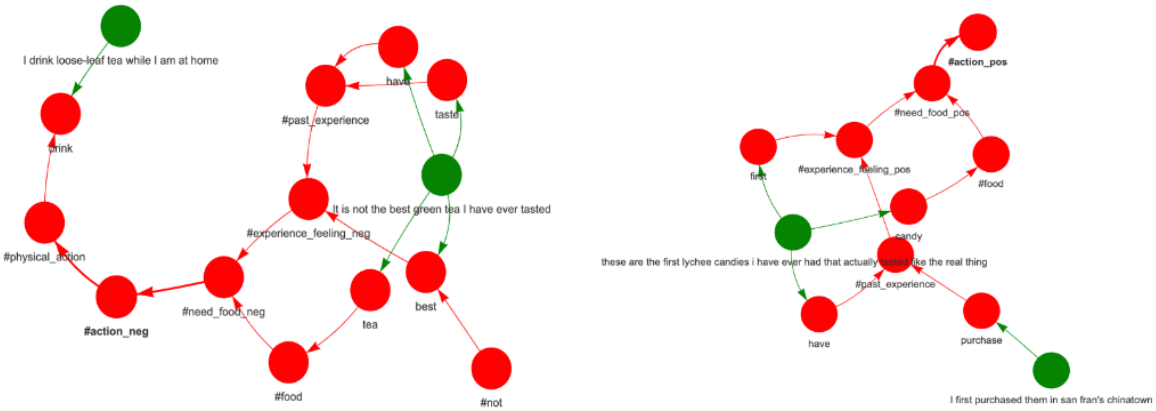
Figure 8 presents two examples in which events are linked to incorrect nodes due to errors in Nurture Belief.

A.6 Wrong Past Action

Figure 9 presents two examples in which events are wrongly linked to `#past_experience`, as they are not factors that affect whether the need is met. In fact, they are the result of food need not being met.

A.7 Negation Loss

Figure 10 presents two examples in which events are wrongly linked to `#emo_pos`, as the negation expressions "don't", "whether or not" and "doesn't" are not captured by our methods.



Review (Id=366473): "I drink loose-leaf tea while I am at home, but bags are more convenient when I'm at work, so I drink this. It's not the best green tea I've ever tasted, but it's inexpensive (especially via Subscribe & Save) and has a good brand reputation. If you're a casual fan of green tea, this will do nicely."

(a)

Review (Id=265316): "These are fabulous. I first purchased them in san fran's chinatown. Having grown up eating lots of fresh lychees, these are the first lychee candies I've ever had that actually tasted like the real thing."

(b)

Figure 4: Events extracted by ASER are in blue color. We use a green font background to highlight the events incorporated in MEA-DAG. (a): Critical events "bags are more convenient when I'm at work", "it's inexpensive" are not included in MEA-DAG. (b): Critical event "these are fabulous" are not included in MEA-DAG.

- Review (Id=438568): "I used to buy the GREEN TEA WITH GINSING and it was very good but then they stopped selling it and replaced it with GREEN TEA WITH GINSING & HONEY. Way too sweet. And the diet kind had that funny taste. I'm so glad I found this one. It tastes wonderful. AND HAS 0 CALORIES & it's way cheaper then the jugs in the stores. It's very simple to mix & it stays mixed. GREAT PRODUCT."

(a)

- Review (Id=552272): "We were very pleased with the quality of these blueberries, and would definitely purchase them again. I would also recommend them to anyone looking for chocolate covered blueberries. Every bit as good as some of the others on the market, and the cost is more reasonable."

(b)

Figure 5: Texts in blue color are the events extracted by ASER. (a): Critical events "the diet kind had that funny taste", "it's way cheaper then the jugs in the stores" and "it's very simple to mix & it stays mixed" are not captured by ASER. (b): Critical events "would definitely purchase them again", "I would also recommend them" and "the cost is more reasonable" are not captured by ASER.

- Review (Id=112029): "I love the Pumpkin Spice K-Cup. I typically drink bold and extra bold coffees - and the Pumpkin Spice doesn't qualify as either. But it smells just like pumpkin pie. and tastes pretty close to it as well. One thing I found out though is to definitely add some kind of sweetener (whether it be artifical sweetener or sugar). I always drink coffee with just cream. and when I did so with the Pumpkin Spice, I really didn't think much of it. …"

(a)

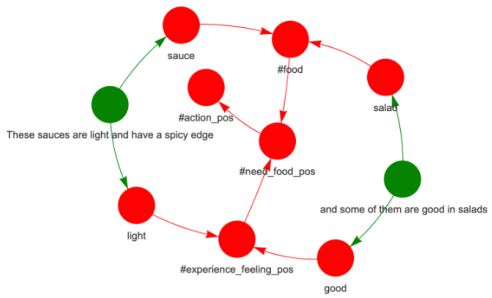
- Review (Id=6993): "I was very pleased with these disposable k-cups. I read other peoples comments that the lids are hard to get on. I found that true at first until I just used one finger and pressed them on in the center. I heard a click and they were ready to go. I will order a larger amount next time to save on shipping. The hot chocolate K-cups prefilled are terrible, but these filled with your own chocolate mix are very good."

(b)

Figure 6: Examples with Wrong Subsequent Action error. We use a green font background to highlight the wrong events. (a): "I typically drink bold extra bold coffee" is linked to `#physical_action`. However, it's not driven by `#need_food_pos`, as the word "typical" indicates that it's a habitual action. (b): "I read other peoples comments that the lids are hard to get on" is linked to `#mental_action`. However, it should be linked to `#past_experience`. Considering its context, "read" in this event is in the past tense, representing an action that occurred in the past.

- Review (Id=567786): "This hot chocolate is great am so glad I doubled the order, you can not miss with this. Now I have quick hot chocolate for the kids and grandkids."

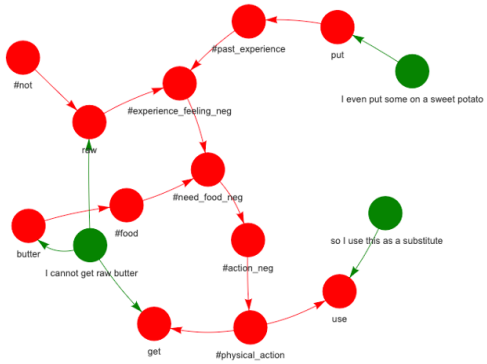
(a)



- Review (Id=73971): "These sauces are light and have a spicy edge. They mix well with meats, Mexican food, veggies, and some of them are good in salads. They are liquid, so blend well with other foods. Jalapeno is the lightest, Spicy Ranchero is like the original Taco Bell Hot Sauce Flavor the most. It goes well as a salad dressing if applied sparingly. The Chipotle one is the most mellow one, all with a bite. I will definitely buy again. Taco Bell has outdone themselves. "

(b)

Figure 7: Examples with Word Sense Ambiguity error. We use a green font background to highlight the wrong events. (a): In the event "I have quick hot chocolate for the kids and grandkids", "hot" is an objective description of food, not bearing an positive emotion or feeling sense. (b): In the event "these sauces are light and have a spicy edge", "light" is wrongly linked to `#experience_feeling_pos`, as it describes sauce taste, not a feeling.



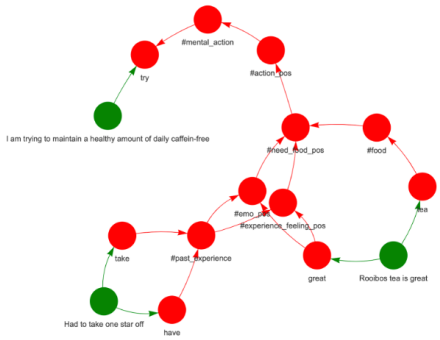
- Review (Id=2717): "I first had this popcorn at my 84 year old cousin's home. I thought it was so tender and delicious, and I wanted to buy some for myself. I found it on Amazon.com believe it or not. Anyway, I ordered 6 pounds of it. All 6 pounds are now gone. This popcorn is REALLY good. It is different than other popcorns I have eaten because the kernels are small and very delicate. I consider myself a pro when it comes to popcorn because I have eaten it every night since I was a little girl. I usually eat my popcorn 1 kernel at a time, but since the kernels are so small, I ate it by the handful. My only complaint is that it does cost a lot to have it shipped. I wish I could find it locally so I would not have to pay for the shipping costs. If you like popcorn, I highly recommend it."

(a)

- Review (Id=11657): "Great to make popcorn with. I even put some on a sweet potato, I cannot get raw butter, so I use this as a substitute."

(b)

Figure 8: Examples with Wrong Belief error. We use a green font background to highlight the wrong events. (a): The word "different" is incorrectly linked to `#experience_feeling_pos`. (b): The word "raw" is incorrectly linked to `#experience_feeling_pos`.



- Review (Id=265043): "I'm trying to maintain a healthy amount of daily caffein-free, sugar-free liquid intake, but plain water gets a bit boring after a while. Rooibos tea is great: fragrant, convenient, and it's even supposed to be anti-oxidant. The only problem is that the packaging of this product is ridiculously annoying. The plastic is very difficult to peel. I had to struggle with it for like 5 minutes, even with the help with my swiss army knife. Had to take one star off."

(a)

- Review (Id=179467): "This tea is really tasty. I wasn't even a tea person until tasting this, and once I did, I was hooked. The flavor is light and super-refreshing but you can still taste and smell the mint. The only reason why I took off one star is because I tend to like things that taste strongly, and this one is a little bit delicate for me. To remedy that, I either steep it with hibiscus or black tea, or I steep it at double strength and all is well. Putting it with honey and stevia also tastes great, and makes me feel better when I have colds. I love this tea."

(b)

Figure 9: Examples with Wrong Past Action error. We use a green font background to highlight the wrong events. (a): The event "Had to take one star off" happened due to dissatisfaction with food. Therefore, it should be linked to `#physical_action`. (b): The event "The only reason why I took off one star " is driven by dissatisfaction with food, not a factor that affects whether the need is met.

- Review (Id=369849): "I don't know how I could say whether or not the cat food is tasty, but my kitty seems to like it. My vet recommends this particular brand of food, so that's good enough for me."

(a)

- Review (Id=489837): "I was hesitant to buy this because it costs a fortune and venison and fish sounded pretty unappetizing. But I was desperate, because I have a 16 year old dog who's always been a picky eater but had now lost a dangerous amount of weight because of a heart condition. The pet store said this was the tastiest thing they had in stock and they couldn't keep it on their shelves, so despite its $4/can price tag, I decided to try it. The food looks gross. It has strange-looking pieces in it (tripe, some exotic part of the venison or blue mussel.), and it doesn't smell like something I would want to eat, either. But my dog cannot get enough of it. She gobbles it up and begs for more. She's gained back the weight she lost, and feeding her is no longer an excruciating, hour long process of coaxing and pleading. Unlike some cheaper canned foods I've tried, it does not give her digestive problems. If you have a picky eater and you've tried everything, try Ziwipeak. Maybe your dog just has a sophisticated palette :-)."

(b)

Figure 10: Examples with Negation Loss error. We use a green font background to highlight the wrong events. (a): The event "I don't know how I could say whether or not the cat food is tasty" is wrongly linked to #emo_pos due to failure of capturing "not". Although "tasty" has a sense of positive emotion, "not" changes its meaning to opposite side. (b): The event "it doesn't smell like something I would want to eat" is wrongly linked to #emo_pos, as "doesn't" is not captured in the MEA-DAG.

Assigning Impression Rating Information to the 'Balanced Corpus of Contemporary Written Japanese'

Sachi Kato
Mejiro University, Japan

Masayuki Asahara
NINJAL, Japan
SOKENDAI, Japan

Abstract

This study involved the collection of information on impression ratings from the general public using short-unit verbs, long-unit independent words, and phrases as stimuli in the 'Balanced Corpus of Contemporary Written Japanese'. A six-point scale from 0 (completely disagree) to 5 (agree) was used to measure five aspects 'naturalness', 'understandability', 'obsoleteness', 'innovativeness', and 'figurativeness'. Based on the information on these impression ratings, a linear regression model of existing representative senses was constructed, and we attempted to extract typical examples by fitting them into the corpus. By combining the impression rating information provided, it is possible to extract examples such as 'obsolete metaphors' and 'innovative metaphors.' This paper presents examples of metaphor expression extraction using evaluation.

1 Introduction

In this study, we report on impression rating information assigned to the 'Balanced Corpus of Contemporary Written Japanese' (*Gendai Nihongo Kakikotoba Kikkou Ko-pasu*: hereafter 'BCCWJ') (Maekawa et al., 2014) on crowdsourcing.

'WLSP-Familiarity' (Asahara, 2019) is a word familiarity database for the 'Word List by Semantic Principles' (*Bunrui Goihyou*: 'WLSP') (The National Institute for Japanese Language, 2004) lexicon, which uses dictionary headings as stimuli and collects ratings for five perspectives: knowing, writing, reading, speaking, and listening. Word familiarity is a rating value for a word, and we encountered the issue of not knowing how the word is perceived when actually used. Moreover, it was difficult to determine the intimacy of the sense of each word, for polysemous words.

Therefore, we presented the context of the BCCWJ and collected information on impression ratings. Specifically, we collected 6-point ratings from 0 (completely disagree) to 5 (agree) for the following five perspectives: 'naturalness', 'understandability', 'obsoleteness', 'innovativeness', and 'figurativeness', for short-unit verb words, long-unit content words, and all phrase units (*Bunsetsu*) defined by the National Institute for Japanese Language and Linguistics (NINJAL). In this paper, we explain the method of collecting impression rating information and present the basic statistics of the data. In addition, we report on our attempt to extract typical examples from the corpus, by regressing the information on representative meaning based on these impression ratings.

2 Related Research

2.1 Impression Rating Information

The NTT Database Series: 'Lexical Properties of Japanese' (*Nihongo-no Goitokusei*) (NTT Communication Science Laboratories, 1999-2008) is the world's largest database that examines lexical features from a variety of perspectives, with the aim of clarifying human language functions. In addition, it contains subjective data, such as on word familiarity, orthography-type appropriateness, word accent appropriateness, kanji familiarity, complexity, as well as reading appropriateness, word mental image etc., and objective data based on the frequency of vocabulary as it appears in newspapers. Among these, the Word Familiarity Database (Heisei Era Version) (Amano and Kondo, 1998) is an advanced lexical database that collects information on the familiarity of vocabulary. Further, the Word Familiarity Database (Reiwa Era Version) was created, because it was noted that how people perceive vocabulary had evolved over the years since the first survey, and the world's largest database was made public. Moreover, the word mental image characteristic database collected information on the 'ease of sensory imagery of semantic content' for written and spoken stimuli.

NINJAL has been continuously working on the estimation of word familiarity for the WLSP (Asahara, 2019) and has published several lexical tables. However, these have not been able to clarify how people perceive the vocabulary for polysemous words. To investigate these meanings, we conducted an experimental study that assigned impression rating information to examples from IPAL dictionaries and added semantic information to it in 2021. In this study, we extend the same research design to the BCCWJ and assign impression rating information to Japanese language polysemous words.

2.2 Core Meaning, Basic Meaning, Representative Meaning, and Typical Use Cases

It is generally considered that the meanings of polysemous words as described in the dictionary are those established in the language. When describing polysemy, Seto (Seto, 2019) discussed the establishment of the core meaning, recognition of significance, clarification of significance relations, and organisation of significance. In order to recognise polysemous word semantics, recognition criteria such as correspondence with related words (Kunihiro, 1982; Momiyama, 2002) separation and integration tests for individual sense recognition (Matsumoto, 2010), and other recognition criteria have been considered.

Polysemous words are said to have some inherent meaning, which are referred to as their core meaning, basic meaning, or representative meaning. When considering derivation relations, the chronological order of appearance is considered important based on historical changes. However, as polysemantic structures are reorganised, the typical core meaning assumed by the general public today is not necessarily based on historical changes. Seto (Seto, 2019), for example, cites the following nine characteristics: (i) literalness, (ii) presupposition of other meanings, (iii) highly concrete, (iv) easy recognisability, (v) easy recallability, (vi) exemption from usage restrictions, (vii) usual starting point of meaning development, (viii) early stage of language acquisition, and (ix) frequent use.

As linguistic resources, representative senses were assigned to polysemous words in the WLSP (Yamazaki and Kashino, 2017). It is possible for experts to identify representative senses from the corpus of WLSP labels assigned to the BCCWJ; since the numbers from the WLSP are also assigned to senses in the IPAL dictionary, it is possible to identify representative senses in the latter as well. However, these certifications are made by experts, and it is possible that these differ from the judgement of ordinary readers. As mentioned earlier, the assignment of impression rating information to examples in the IPAL dictionary has made it possible to determine how ordinary readers perceive the examples that experts recognise as representative meanings with the use of linear regression. In this study, we attempted to extract representative and typical examples by applying this linear regression equation to the collected impression rating information assigned to the BCCWJ.

3 Method of Data Collection

This section describes our method of data collection.

The data were collected from the BCCWJ-WLSP (books, newspapers, magazines) (Kato et al., 2018), that contains word sense information based on short units, and the BCCWJ-SPR2 (books, textbooks) that contains information on reading time.

The former, BCCWJ-WLSP, assigns word senses based on the WLSP to short-unit autonomous words (about 330,000 words) in a part of the BCCWJ core data sample of books, newspapers, and magazines. To contrast the word sense information based on the WLSP with the impression rating information, we collected the rating values of 20 people per case for short unit verbs and verbal nouns + *suru* (to do) on a trial basis, from 5th April to 3rd May 2021. Additionally, for long unit independent words, data from 10 people per example were collected, between 17th November and 6th December 2021.

The latter, BCCWJ-SPR2, collects reading time data from BCCWJ core data books and Japanese language textbook samples, using the phrase-by-phrase self-paced reading method. To explain reading time behaviour with respect to rating information, 10 people per example were studied for this sample on a phrase-by-phrase basis, from 17th November to 6th December 2021.

Figure 1 shows the screen for collecting rating information. The example sentences are displayed in units of one at the top of the screen, and the expressions to be judged are indicated by brackets.

The ratings were based on a six-point scale from 0 (completely disagree) to 5 (agree) for five aspects-'naturalness', 'understandability', 'obsoleteness',

Figure 1: Screen of Crowdsourcing

'innovativeness', and 'figurativeness'. Participants of the experiment (aged 20 years or older and having a Yahoo! Japan Crowdsourcing account) were each given an honorarium of 1 yen worth of reward points per answer. Moreover, participants who answered the same question more than once were prevented from answering at any time, in more than 90% of the cases.

4 Data Summary Statistics

Figures 2, 3, and 4 show the histograms of the average ratings for each expression of the short-unit verbs and long-unit content words of BCCWJ-WLSP, and the long unit sentence clauses of BCCWJ-SPR2, respectively. All the samples had been published in books, newspapers, magazines and textbooks, and as such, were presumed to be quite natural and easy for readers to understand. These were published between 2001 and 2005, and the overall trend was neither old nor new. In addition, figurativeness tended to be low.

5 Estimation of Typical Use Cases Based on Rating Information

The same rating information had already been assigned to IPAL dictionary examples, whose basic (representative) meaning information is as per the WLSP word senses. In this study, typical use cases were quantified as a degree of representative meaning and regressed using a generalised linear mixed model with the following equation, based on the IPAL dictionary rating from 5 to 1, wherein impression ratings are fixed effects and examples are random effects. This is an attempt to redefine the core sense property of Seto (Seto, 2019) in the Table 2 as a combination of impression rating information, and estimate the basic and representative meaning, as well as typical usage from the combination of the impression ratings of the general public.

$$\begin{aligned}\texttt{Representativeness (Verb)} &\sim \texttt{Naturalness} \\ &+ \texttt{Understandability} + \texttt{Obsoleteness} \\ &+ \texttt{Innovativeness} + \texttt{Figurativeness} \\ &+ (1|\texttt{Example}) \quad (1)\end{aligned}$$

The estimated fixed effect estimates are shown in Table 3. In relation to the core meaning properties of Seto in Table 2, we assumed that obsoleteness was (+) [(i) literalness, (vii) usual starting point of meaning development] and innovativeness was (-) [ii) presupposition of other meanings, (ix) frequent use] but the estimates obtained were coefficients of (-) for obsoleteness and (+) for innovativeness.

The following paragraphs will attempt to extract more representative 'typical use cases' based on the rating results of short-unit verbs. Specifically, the following linear regression equation obtained in the same study is applied:

$$\begin{aligned}\texttt{Estimated Representativeness (Verb)} &:= 0.012 \times \texttt{Naturalness} \\ &+ 0.033 \times \texttt{Understandability} \\ &- 0.015 \times \texttt{Obsoleteness} \\ &+ 0.018 \times \texttt{Innovativeness} \\ &- 0.024 \times \texttt{Figurativeness} + 1.965 \quad (2)\end{aligned}$$

Table 4 shows the average (macro-average) rating of the polysemous short unit verb *kakaru* (to hang, approach; lemma ID: 6016 in UniDic) by WLSP. The highest number of examples were found in '.16 Relation-Time' with 27, and the degree of typicality was high at 2.114. In contrast, '.31 Activity-Language' which has the highest degree of representativeness, means 'to receive a

Target	Unit	Sentences	Data Points	Date

Table 3: GLMM results on IPAL dictionary representative meaning

phone call', but there was only one example of its use. The frequency of phone call use has decreased in recent years, and as the number of examples of this usage is expected to further decrease, the degree of representativeness may eventually diminish.

Table 5 shows the highest and lowest representative senses of *kakaru*. The most representative examples were '.11 Relation-Class' and '.16 Relation-Time'. The less representative examples were '.3370 Activity-Life-Leisure' (a term in the Go boardgame), '.1502 Relation-Effect-Initiation' (*hajimeru* (to begin)), and '.1513 Relation-Effect-Fixation, Tilt, Tumble.' (*ooikabusaru* (to cover)). Interestingly, the representative meaning of PM29_00003 example 'it (hair) [*{kaka} -ta*] ([cover] -ed) shoulder tip' (.1513 Relation-Effect-Fixation, Tilt, Tumble), which is by nature a lexical word meaning without metaphorical sense, is low. Meanwhile, the highly abstract '.1110 Relation-Class-Relation', '.1600 Relation-Time-Time', and '.3730 Activity-Economy-Price and Cost' had high representativeness; moreover, they tended to have low figurativeness, even though they were figurative expressions

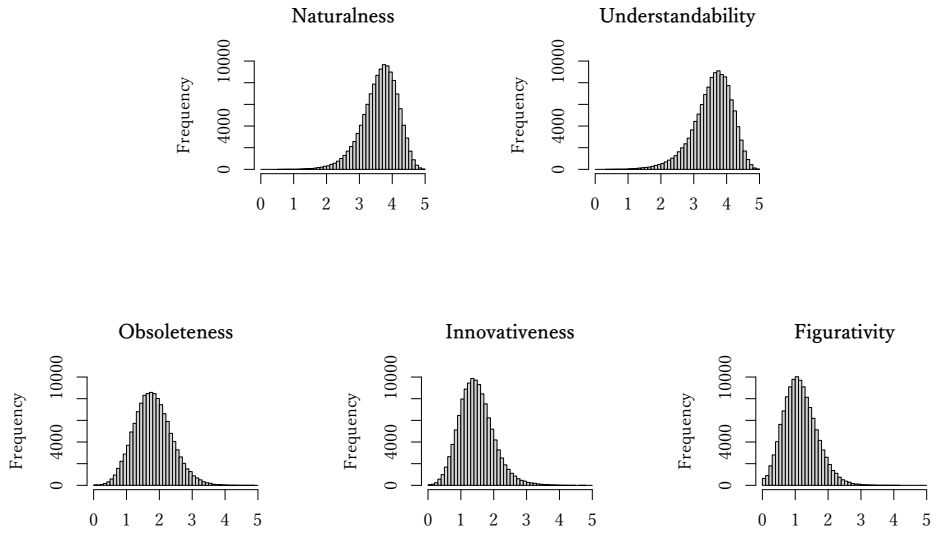

Figure 3: Distribution(BCCWJ-WLSP:LUW:bin 0.10)

originally.

6 Figurative Expression Extraction

In this study, an attempt is made to extract metaphorical expressions using Figurativity ratings from data annotated with impression assessment information. Specifically, we extract 275 instances from the PB (Books) data of the Base-phrase based Corpus (BCCWJ-SPR2) with Figurativity ratings of 3.0 or higher. Subsequently, we further investigate expressions with high Obsoleteness ratings (Obsolete Figurative Expressions) and those with high Innovativeness ratings (Innovative Figurative Expressions).

6.1 Obsolete Figurative Expressions

In the following, we will demonstrate cases with high levels of Obsoleteness.

(1) 『【転石】 苔を つけず。 』
‘ **rolling.stone** moss without.attaching. ’
[Obsoletness: 3.9, Figurativity: 3.2] ‘A rolling stone gathers no moss.’

(1) is originally an old English proverb, and a figurative expression where ‘rolling stone’ is metaphorically to describe a person or individual.

(2) 八月に 【はいると】 海は ほんの少し
August **entering** sea slightly
機嫌を 悪くする 時が ある。
mood worsen time exist.
[Obsoleteness: 3.8, Figurativity: 3.3] ‘In August, the sea tends to be slightly moody.’

The figurative expression in (2) lies in the spatial representation (’entering’) of ’August,’ where the concept of ’August’ is represented as an abstract space. This representation involves associating a sense of entry or transition, typical of spatial contexts, with the commencement of the month of August. The usage of ’はいると’ (entering) to mark the onset of August is a less prevalent and somewhat archaic construction in modern Japanese, contributing to the expression’s obsoleteness.

(3) 【ほたりほたりと】 水滴が
mimetic.word water.drops
落ちている。
falling
[Obsoleteness: 3.7, Figurativity: 3.3] ‘Water drops are falling with a patter.’

In (3), the figurative expression lies in the use of ’ほたほた,’ an older mimetic word. This expression employs ’ほたりほたり,’ the derived form of ’ほたほた,’ to depict the manner in which water drops fall. ’ほたほた’ represents the manner of water drops falling, and it is the archaic form from which ’ほたりほたり’ is derived, conveying a somewhat outdated and formal depiction of the manner of water drops falling.

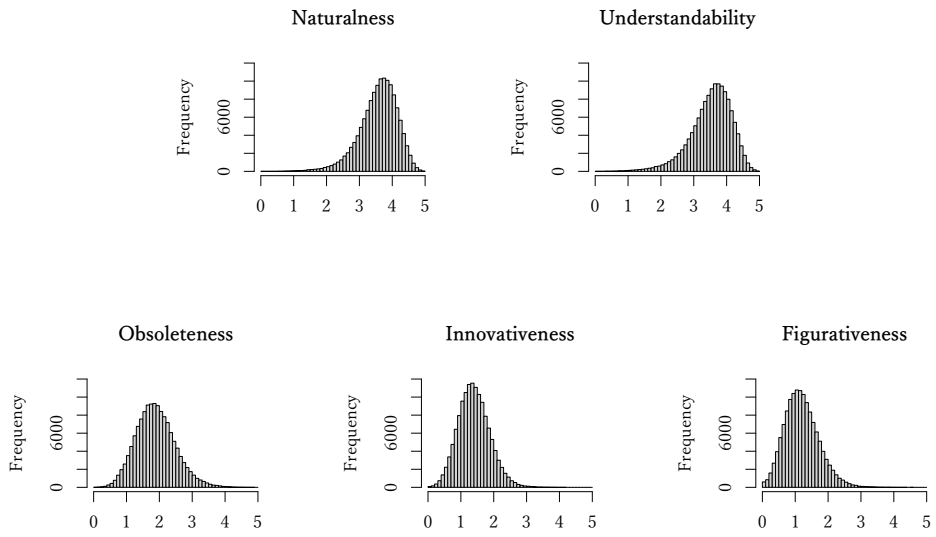

Figure 4: Distribution(BCCWJ-SPR2:phrase:bin 0.10)

6.2 Innovative Figurative Expressions

In the following, we will demonstrate cases with high levels of Innovativeness.

(4) 実際、 【「知識爆発」は】
actually, **'knowledge.explosion'**
とどまるところを 知りませんから、
stopping.point not.know.because
私たちは たいへんです。
we.are troubled.
[Innovativeness: 3.1, Figurativity 3.1] 'In fact, we don't know where the 'knowledge explosion' will stop, so we are troubled.'

The figurative expression in (4) lies in the use of '知識爆発' ('knowledge.explosion') to symbolize a rapid and uncontrolled growth of knowledge or information, akin to an explosion. The innovative aspect is reflected in the introduction of the term '知識爆発' ('knowledge.explosion'), which is not a common or standard phrase in everyday language. It represents a creative way of describing the concept of an exponential growth of knowledge or information, demonstrating originality in expression.

(5) そういう 【闇空間を】 求めてきた。
such **dark.space** sought.
[Innovativeness: 3.1, Figurativity 3.0] 'I have sought such a dark space'.

The figurative expression in (5) lies in the use of '闇空間' ('dark space') to symbolize a metaphorical space or state characterized by darkness, mystery, or the unknown. It does not refer to a literal physical space but rather represents a deeper, intangible concept related to emotions, experiences, or thoughts. The innovative aspect is seen in the creation or utilization of '闇空間' ('dark space'), a phrase that is not conventionally used in everyday language.

7 Conclusions and Future Directions

In this study, we comprehensively collected impressions that people perceive from the Japanese language using a corpus and systematically organized them into a database. Conventional language resources were primarily annotated by linguists based on standards and guidelines, focusing on annotating linguistic structures. However, aspects such as 'natural,' 'understandable,' 'obsolete,' and 'innovative' prove challenging to precisely define even by linguists. Therefore, in this study, we utilized a survey employing crowdsourcing to gather assessments from multiple individuals regarding the perspectives of 'natural,' 'understandable,' 'obsolete,' and 'innovative,' for three levels: short unit word, long unit word, and base-phrase for the parts of BCCWJ with word senses (BCCWJ-WLSP) and those with reading time (BCCWJ-SPR2).

Furthermore, for short unit verbs, we tried to extract typical examples of corpus usage by estimating the degree of representativeness, using linear regression based on the impression rating

WLSP	Na	U	O	Ne	F	Est. Repres.	Frequency

51:Nature-Matter	3.85	4.00	1.55	0.95	1.55	2.100	1
5152:Nature-Matter-Could	3.85	4.00	1.55	0.95	1.55	2.100	1

Table 4: Estimated Representativeness for WLSP article numbers of Short Unit Word *kakaru* (Lemma ID: 6016)

information obtained. By contrasting the frequency of occurrence in the corpus with the ratings of common readers, it is possible to verify how words are produced and received. In addition, the estimation of the degree of representativeness and the extraction of typical use cases contribute to the clarification of the core and basic meanings of polysemous words, as well as to the determination of grammaticality and ungrammaticality in discourse. With regard to presenting examples of usage to language learners, we believe that presenting typical examples of usage will help build language fluency. In the future, we will contrast the word meanings in the BCCWJ-WLSP to investigate whether ordinary readers perceive figurativeness in cases where a shift in meaning occurs. Furthermore, we would like to clarify expressions with various reading time from the viewpoint of impression rating information, by contrasting the reading time with the impression rating information assigned to each phrase.

We also investigated 'figurativity.' 'Figurativity' has various linguistic definitions, making annotation challenging for the general population. However, we focused on collecting figurative expressions that are understandable to the general population and conducted the survey. By combining the degree of Figurativity' with the survey results for Obsolete' or 'Innovative', we attempted to collect so-called old and stale figurative expressions, as well as novel and innovative figurative expressions. Based on the ratings, we believe we were able to obtain figurative expressions that match the desired level to some extent.

For future directions, we plan to conduct three studies.

The first study will involve a comparison between figurative expressions annotated by experts and impression ratings from the general audience. We will examine how well the general readers can recognize figurative expressions for the parts identified as figurative expressions by experts. This investigation will encompass not only metaphors but also synecdoche and metonymy, exploring the extent to which they are identifiable. Additionally, we will verify whether the figurative expressions annotated by experts are classified as obsolete or innovative.

In the second study, we will explore the relationship between figurative expressions and their impact on comprehension and interpretation. Specifically, we will investigate how the presence of figurative language influences readers' understanding and engagement with the text. Additionally, we will examine how different types of figurative expressions (e.g., metaphors, similes, idioms) affect the overall interpretation and perception of the given context.

As a third study, we will compare impression ratings with reading times in BCCWJ-SPR2 to investigate the impact of naturalness, understandability, obsoleteness, innovativeness, and figurativeness on reading time. In addition to grammatical functions, we aim to elucidate how impressions affect variations in reading time and explore their role as non-grammatical factors.

Conceptual Metaphors as Legitimization Tools in the Inaugural Speech of President Rodrigo Duterte

Mycah Amelita C. Chavez
Far Eastern University – Manila
machavez@feu.edu.ph

Abstract

Drawing upon Critical Discourse Analysis (CDA) and Cognitive Metaphor Theory (CMT), this study examined the use of metaphors as a legitimization strategy in President Rodrigo Duterte's inaugural speech. Specifically, Critical Metaphor Analysis (CMA) was employed to identify the metaphorical expressions in Duterte's speech and the conceptual metaphors that frame them. Furthermore, the rhetorical techniques associated with the metaphors were analyzed based on the legitimization strategies proposed by Reyes (2011). The analysis revealed that the conceptual metaphors used in the inaugural speech are SOCIAL PROBLEM IS A DISEASE, NATION IS A BODY, and CHANGE IS WAR. Through these metaphors, he justifies that the severe problems of the country need urgent, unorthodox solutions to move towards a better future, using legitimization strategies such as altruism, appeal to emotion, and hypothetical future. Despite the controversies during his term, Duterte's satisfaction ratings remained high, indicating public support for his policies. Hence, conceptual metaphors can be effective persuasion tools that help legitimize the policies advocated in political speeches.

1 Introduction

Language as a means of communication is a system that facilitates the conveyance of thought from one person to another. "The fundamental function of every language system is to link meaning and expression—to provide verbal expression for thought and feeling" (Finegan 2008, page 5). Particularly, language is used for persuasion of people to do something or to change their attitudes.

One venue where persuasion is widely used is in political discourse through which politicians persuade their constituents that their claims are valid (Chimbarange, Takavarasha, and Kombe 2014). Moreover, political speeches may be used to regulate society and change people's attitudes and perceptions about national issues. For instance, the inaugural speech of a president is crucial since it legitimizes their position as the head of state (Xue, Mao, and Li 2013) and serves as a medium through which the newly elected president can inform a national audience about the policies of the new government, gain a favorable public opinion, call for collective action, and rally for support from the people.

Since the inaugural speech is the first speech a president delivers as head of state, it must leave an impact on the listeners. In addition, politics involves complicated issues that may not be easily understood by the masses. Thus, metaphor is often used in political discourse to make the message clearer to the audience by comparing complex political concepts with easier and understandable ones in the frame (Burkholder and Henry 2009, as cited in Penninck 2014).

Numerous studies have been conducted to investigate how metaphor is used in political discourse. For instance, Penninck (2014) analyzed the metaphor use of American and British political leaders during the financial crises of 1929 and 2008 and observed that they mostly employed simple metaphor themes such as battle, construction, journey, and illness for the public to easily understand the crises. Similarly, Xue, Mao, and Li (2013) examined the recurring conceptual metaphors in the American presidential inaugural addresses, namely: journey, human, war, building, family, light, illness. These metaphors arouse strong emotions since the source domains are pertinent to people's daily life and experience; hence, they help the audience understand the message and serve as persuasive tools. Likewise, Guitart

Escudero's (2011) analysis of Barrack Obama's Inaugural Address illustrated that one reason for his success is the use of metaphors that mostly stem from American values and relate to the human body and natural phenomena, helping to concretize abstract concepts.

When it comes to political discourse of Philippine presidents, Navera (2012) investigated the conceptual metaphors in the speeches of post-dictatorship presidents, Corazon Aquino, Fidel Ramos, Joseph Estrada, and Gloria Macapagal Arroyo and showed that the speeches are framed with the path schema through a movement from a less favorable state to a more favorable one.

As for the speeches of Rodrigo Duterte, research mainly focuses on discourse analysis highlighting the linguistic features that reveal his ideologies. For instance, Rubic-Remorosa (2018) found that the use of various linguistic categories serves to underscore the recurring issues in his political speeches such as war on drugs, criminality, graft, and corruption and showed Duterte as a leader who would solve all the country's problems. In the same manner, a critical discourse analysis by Villanueva (2018) uncovered that Duterte used relational and material transitivity processes in his speeches to convey his identity, power, and ideologies, such as: fight against terrorism and insurgency, war on drugs, fight against corruption, strengthening of the police and military forces, and Davao as a model of change.

Although there have been studies analyzing metaphors in Philippine political discourse, there are only a few that center on Duterte's speeches. For example, Navera (2020) investigated how the war metaphor was employed in Philippine presidential speeches, especially those of Duterte, and concluded that with the use of a belligerent rhetoric framework, "… speeches are weaponized to silence critics and encourage supporters' disdain toward those who dissent and disagree with government policies" (page 77). On the other hand, Clemente (2019) explored the metaphors of sustainable development in the inaugural addresses of Ferdinand Marcos and Duterte, revealing that both presented themselves as visionary and missionary leaders through cognitive and conceptual metaphorical expressions that outline their visions for national development.

Considering that there is minimal research on the use of metaphors in the speeches of Duterte despite him being an impactful, albeit a controversial leader, there is a need for more studies that examine how the former president used conceptual metaphors to communicate and justify his policies to the Filipino people. Hence, this study attempted to analyze metaphors as legitimization tools in President Rodrigo Duterte's inaugural speech. Specifically, it sought to achieve the following objectives: to identify the metaphorical expressions in Duterte's inaugural speech, to determine the conceptual metaphors that frame these expressions, to distinguish the legitimization strategies associated with the metaphors, and to analyze how the conceptual metaphors contribute to the legitimization of his administration's policies.

2 Theoretical Framework

Critical Discourse Analysis (CDA) is an approach to analyzing written and spoken texts to reveal how language is used to represent power, dominance, and inequality (van Dijk 1997). Likewise, Fairclough (1997) defines CDA as discourse analysis that examines the relationships between discursive practices and social structures and how these practices are influenced by power relations. Discourse as a social practice implies that discursive events are shaped by social structures and vice versa (Wodak 1999). Moreover, the goals of CDA include investigating discourse practices that reflect or construct social problems, examining how ideologies can become frozen in language, and increasing awareness of how to apply these goals to instances of injustice, prejudice, and misuse of power (Bloor and Bloor, 2007).

Political speeches as discursive practices are laden with ideologies that a politician espouses. These ideologies are presented as valid through the persuasive technique of legitimization which Reyes (2011) defines as the process of justifying social actions, ideas, thoughts, or declarations with the use of strategies such as: emotions, a hypothetical future, rationality, voices of expertise, and altruism.

Political speeches also use metaphors to convey dramatic and impactful messages. Aristotle defines metaphor as a rhetorical device that gives "something a name that belongs to something

else" (Hellsten 2002, page 17). Here, metaphor is viewed as a persuasive device. Lakoff and Johnson (1980) proposed an analysis of metaphor based on target and source. The target domain and source domain consider the similarities and the interaction between the two domains, making it possible to map one domain onto another. This view suggests that metaphor is a cognitive process; thus, it "plays an important role in thought and is indispensable to both thought and language." (Penninck 2014, page 23).

As embodied in the Cognitive Metaphor Theory (CMT), the target domain is usually an abstract concept such as LIFE, and the source domain is typically a concrete concept such as JOURNEY, hence, the conceptual metaphor LIFE IS A JOURNEY. Conceptualizing LIFE as a JOURNEY enables one to map the various elements of a JOURNEY onto aspects of LIFE as shown here:

JOURNEY		LIFE
traveler	→	person leading the life
starting point	→	where the person was before reaching the goal
route	→	means
impediments	→	difficulty
guide	→	mentor
landmarks	→	progress
crossroads	→	chores or tasks
provisions	→	material resources
destination	→	goal

The correspondence between each aspect of life and journey allows one to understand life as traveling from one point to another while encountering impediments, landmarks, and crossroads with the help of a guide and surviving through provisions. In this manner, metaphors aid in mapping concepts against bodily experiences and help us make sense of the world (Sullivan 2013).

One method for examining metaphors is Critical Metaphor Analysis (CMA) which aims to "demonstrate how particular discursive practices reflect socio-political power structures" (Charteris-Black 2004, page 29) and analyze the implicit intention of the speaker and the context of the metaphor to reveal the hidden power relations within a socio-cultural context (Sudajit-apa 2017). In effect, if most people accept a particular metaphor, the power of the person who uses that metaphor will likewise be accepted and transformed into a social value (Hart 2016, as cited in Sudajit-apa 2017). Thus, CMA can provide a "particular insight into why the rhetoric of political leaders is successful" (Charteris-Black 2005, page 197).

3 Methodology

This qualitative study utilized CMA, a combination of CMT and CDA and the legitimization strategies suggested by Reyes (2011). The linguistic source is the inaugural speech of President Duterte, the transcript of which was taken from the Presidential Communications Office website.

Metaphorical expressions were first identified employing the Metaphor Identification Procedure (MIP) (Steen, et al. 2010). First, the text was read to understand the general meaning after which the lexical units were identified. The lexical meanings were lifted from Meriam-Webster Online Dictionary. Next, the contextual and contemporary meanings of each lexical unit were determined. In case a lexical unit had a contemporary meaning that was different from the contextual meaning but could still be understood when compared, it was marked as metaphorical. The metaphorical expressions were then analyzed to determine the conceptual metaphors that frame them based on CMT by identifying the target domain (abstract concept) and the source domain (concrete concept).

Finally, the relationships between the lexical meanings and conceptual metaphors were analyzed to distinguish which legitimization strategies were used - emotions, a hypothetical future, rationality, voices of expertise, or altruism. Further analysis of these strategies would show how they were used to justify Duterte's declarations and policies.

4 Results and Discussion

The following excerpts from President Duterte's inaugural speech contain metaphorical expressions which are written in boldface.

(1) *For I see these **ills as mere symptoms of a virulent social disease** that **creeps and cuts into the moral fiber of Philippine society.***

(2) *I have seen how **corruption bled the government of funds**, which were allocated for the use in **uplifting the poor from the mire** that they are in.*

(3) *These were **battle cries** articulated by me in behalf of the people hungry for genuine and meaningful change. Love of country, subordination of personal interests to the*

common good, concern and care for the helpless and the impoverished – these are among the lost and faded values that we seek to ***recover and revitalize*** *as we* ***commence our journey*** *towards a better Philippines.*

An examination of the statements reveals that the conceptual metaphors framing the president's speech are: SOCIAL PROBLEM IS A DISEASE, NATION IS A BODY, and CHANGE IS WAR.

One of the first issues discussed by the president in his speech is the condition of the country. He uses the conceptual metaphor SOCIAL PROBLEM IS A DISEASE. Such relationship is mapped as follows:

DISEASE		SOCIAL PROBLEMS
cause	→	lost and faded values
symptoms	→	corruption, criminality, illegal drugs, breakdown of law and order
effect	→	erosion of faith and trust in the government
treatment	→	government policies

Duterte claims that because the people have *"lost and faded values"* the country is suffering from a *"virulent social disease."* The use of the adjective "virulent," which means harmful or destructive, to describe *"social disease"* emphasizes the gravity of the problem. This disease manifests itself in several "symptoms." A symptom is defined as "subjective evidence of disease or physical disturbance." Duterte enumerates the evidence of the country's disease as *"corruption, criminality, illegal drugs, breakdown of law and order."* However, according to him, the root of the problem is that people have lost the values of *"love of country, subordination of personal interests to the common good, concern and care for the helpless and the impoverished."* In other words, the country is suffering because people lack nationalism, selflessness, and compassion. Moreover, because of these so-called symptoms, the people experience *"erosion of faith and trust in the government."* Thus, the problems of the country were caused by the past administration's inability to provide for the needs of the people. He reinforces this claim by saying:

(4) I see the erosion of the people's trust in our country's leaders; the erosion of faith in our judicial system; the erosion of confidence in the capacity of our public servants to make the people's lives better, safer and healthier.

According to Duterte, these problems *"need to be addressed with urgency."* Hence, to cure this disease, he says that it is essential to *"recover and revitalize"* the *"lost values and faded values."* To "recover" means "to regain or to get back to normal position or condition" while "revitalize" means "to give new life or vigor to." In a sense, the president wants the country to return to a state where people possessed the lost values of nationalism, sacrifice, and compassion. On the other hand, considering the context of SOCIAL PROBLEM IS A DISEASE, to "recover" takes on the meaning of regaining health and to "revitalize" means to give new life to a country that is suffering from a disease. Once cured, the country can move *"towards a better Philippines."* Here, the word "better" can be related to "get better" which is synonymous to recover, signifying the improvement of the country's condition. To do this, he calls on department secretaries and heads of agencies to *"reduce requirements and the processing time of all applications," "refrain from changing and bending the rules government contracts, transactions and projects,"* and *"advocate transparency in all government contracts, projects and business transactions."* Moreover, he enjoins the *"Congress and the Commission on Human Rights and all others who are similarly situated to allow us a level of governance that is consistent to our mandate."* After portraying the nation as suffering from a serious illness that urgently needs to be cured, the president proposes solutions that will improve the country's condition. The series of imperatives suggests that the country will get better only if government agencies cooperate and implement the policies of the new administration.

It is evident that using the conceptual metaphor SOCIAL PROBLEM IS A DISEASE acts as a cohesive device framing Duterte's message that change can only be achieved if the problems of the country are solved through the cooperation of the government and the people. This message is fortified by the conceptual metaphor through the legitimization strategy of "altruism." According to Reyes (2011) politicians "portray themselves...as serving their voters, and therefore they legitimize proposals as a common good that will improve the conditions of a particular community" (page 787). This is exactly what Duterte tries to achieve in comparing the nation's social problems to a disease, making it easier for the audience to

understand the many complex problems that the country is facing.

Related to SOCIAL PROBLEM IS A DISEASE is the conceptual metaphor NATION IS A BODY. The concept map is shown below:

BODY		NATION
can get sick	→	has social problems
can bleed	→	funds are sucked by corruption
can get hurt	→	beset by criminality
can get well	→	achieve progress

Just like a body, the nation can get sick and bleed, as discussed in the previous metaphor and as seen in excerpt (1). Here, the nation is presented as a body afflicted with a serious illness. Aside from the use of *"virulent"* to emphasize the gravity of the situation, the use of *"creeps and cuts"* strengthens this claim. "Creep" means "to enter or advance gradually so as to be almost unnoticed," and "cut" means "to penetrate with or as if with an edged instrument." The image portrayed by the combination of the two words is an assailant attacking someone from behind, implying that this serious problem is hurting the country unaware. Moreover, this attack affects *"the moral fiber of Philippine society."* "Moral" means "of or relating to principles of right and wrong in behavior," and "fiber" refers to "the essential structure or character." Thus, the disease that attacks the body also affects the person's capacity to distinguish right from wrong. Additionally, these social problems place the country in a bad condition and its people in low morale. To illustrate the seriousness of the problem, Duterte relates: *"I have seen how corruption bled the government of funds, which were allocated for the use in uplifting the poor from the mire that they are in."* Here, the nation is compared to a body that can bleed because of one symptom - corruption. Blood is equated to government funds which are supposed to save people from the "mire" they are in. "Mire" is defined as "heavy often deep mud or slush," or it can also be "a troublesome or intractable situation." In this case, the mire that impedes the people is poverty.

The conceptual metaphor NATION IS A BODY is used in the speech to highlight the nation's problem as well as to bring it closer to human experience. The image of a person sick, bleeding, and stuck in the mud of poverty sends a powerful message to which many Filipinos can relate. Hence, it becomes a strong justification for the policies proposed by Duterte. In this case, the strategy of legitimization used is "appeal to emotion" with emotive effects such as pity, pain, fear, and hardship. Reyes (2011) posits that the appeal to emotion enables social actors to influence the opinion of their audience through linguistic structures and rhetorical devices. Here, the usage of metaphor corroborates the findings of Xue, Mao, and Li (682) that metaphors evoke strong emotions since the source domains are relevant to people's daily life and experience; therefore, they help the audience understand the message and serve as persuasive tools.

Still another conceptual metaphor utilized in the speech is CHANGE IS WAR. Duterte emphasizes in his speech that to achieve change, a battle must be fought against the problems of society. The map that follows illustrates this comparison:

WAR		CHANGE
Participants	→	government and people versus criminals
Parts	→	problems of the country versus progress
Planning strategy	→	recovery and revitalization of lost and faded values; government policies
Initial condition	→	corruption, criminality, illegal drugs, breakdown of law and order; country is beset with problems and cannot progress
Middle condition	→	government policies
End	→	eradication of country's problems
Final state	→	peace, order, and progress
Purpose: victory	→	change

The metaphor CHANGE IS WAR is anchored on the initial condition that the country has a severe problem with the following symptoms: *"corruption, criminality, illegal drugs, and break down of law and order."* Duterte justifies this war by saying: *"There are many amongst us who advance the assessment that the problems that bedevil our country today which need to be addressed with urgency."* He starts his statement with *"there are many amongst us,"* which implies that he is not alone in thinking that the country is in peril. The use of the inclusive *"us"* involves the audience as participants in the consensus that the country's problems must be solved immediately. Moreover, the use of the word *"bedevil"* underscores the urgency of the situation. "Bedevil" means **"**to cause distress,"

and of course, a natural reaction to anything that causes distress is to eradicate it.

Since these problems conflict with the interest of the nation, which is progress, they are urgent concerns that must be addressed; therefore, war is necessary. This war involves the president, the government, and the people against the perpetrators of crime. Duterte's strategy is to *"recover and revitalize lost and faded values"* through the implementation of new policies and the cooperation of government agencies. He pleads his case through the statement: *"In this fight, I ask Congress and the Commission on Human Rights and all others who are similarly situated to allow us a level of governance that is consistent to our mandate."* The plea is introduced by *"in this fight,"* referring to eradicating the problems of society. Evidently, the president views the solution to these problems as a war that must be fought. He asks *"Congress and the Commission on Human Rights and all others who are similarly situated"* to join him in battle. However, upon closer inspection, they are not drafted to be soldiers to fight in the field, but *"to allow us* [his government] *a level of governance that is consistent to our mandate."* This request asks those mentioned to let Duterte govern according to the authority vested in him. It is understandable that he calls on Congress for cooperation since it is a law-making body that can help in implementing the new policies. However, he specifically mentions the Commission on Human Rights for another reason. Duterte admits*: "I know that there are those who do not approve of my methods of fighting criminality, the sale and use of illegal drugs and corruption."* It can be surmised that *"those who do not approve of my methods"* refers to the Commission on Human Rights since *"they say"* his *"methods of fighting criminality, the sale and use of illegal drugs and corruption... are unorthodox and verge on the illegal."* This pronouncement at the onset of Duterte's term as president is not only a plea for cooperation but also a warning to those who might try to stop him.

He further contends that *"criminality, the sale and use of illegal drugs and corruption"* are enemies that should be fought through methods that are *"unorthodox and verge on the illegal"* if necessary. He justifies these methods in excerpt (2) and the following excerpts:

(5) I have seen how illegal drugs destroyed individuals and ruined family relationships.

(6) I have seen how criminality, by means all foul, snatched from the innocent and the unsuspecting, the years and years of accumulated savings. Years of toil and then, suddenly, they are back to where they started.

Excerpt (2) indicates that corruption has a detrimental effect, especially on the poor people, as discussed in the section dealing with NATION IS A BODY. Excerpt (5) suggests that illegal drugs are harmful not only to individuals but also to families. The use of the words *"destroyed*" and *"ruined"* highlights the gravity of their effects. "Destroy" means "to ruin or to put out of existence." Using two synonymous words that pertain to destruction in one sentence when referring to a person and family relationships presents a dramatic image to the audience.

Moreover, excerpt (6) presents *"criminality"* as victimizing the innocent and the hardworking. "Criminality" in whatever method is described as "offensive to the senses" or "loathsome." It is even more loathsome when it *"snatched from the innocent and unsuspecting."* "Snatch" means "to seize or take suddenly without permission," "innocent" means "free from guilt or sin especially through lack of knowledge of evil," and "unsuspecting" means "unaware of any danger or threat." This phrase portrays people who do not deserve to be victimized by heinous crimes since they are pure, especially when they lose *"the years and years of accumulated savings."* The use of *"years and years"* to describe the accumulated savings emphasizes the amount of hard work that people put in just to save money only to be victimized by criminals.

These statements are reasons enough for the president to wage war. And if these do not convince the audience, he adds: *"Look at this from that perspective and tell me that I am wrong."* This statement is clearly a call for the audience to agree with the president based on the previous premises as well as a plea for the audience to show empathy for the victims of crimes.

Having justified that his methods are necessary in this war against criminality, Duterte goes on to say that: *"The fight will be relentless and it will be sustained."* "Relentless" means "showing or promising no abatement of severity, intensity, strength, or pace" and "sustained" means

"prolonged." Again, he puts two words with almost the same meaning in a series to warn the criminals that the government is indeed at war and will not stop the "fight" until the country's problems are eradicated. To cushion the effect of this strong statement, the president professes: *"As a lawyer and a former prosecutor, I know the limits of the power and authority of the president. I know what is legal and what is not."* By reminding the audience of his previous professions, a lawyer whose job is "to advise as to legal rights and obligations in other matters" and a prosecutor whose work is **"**to bring legal action against for redress or punishment of a crime or violation of law," Duterte assures the audience that he will not go beyond what the law mandates him as president.

The perceived end of this war is the eradication of the country's problems which will lead to peace, order, and progress. The ultimate sign of victory is change. For this reason, Duterte further justifies the war on criminality by saying:

(7) These were battle cries articulated by me in behalf of the people hungry for genuine and meaningful change. But the change, if it is to be permanent and significant, must start with us and in us. To borrow the language of F. Sionil Jose, we have become our own worst enemies. And we must have the courage and the will to change ourselves.

Duterte brings the metaphor CHANGE IS WAR closer to the audience by labeling his pronouncements as *"battle cries."* A "battle cry" is "a cry used by a body of fighters in war." However, it could also mean "a slogan used especially to rally people to a cause." The president claims that he articulates the battle cries *"in behalf of the people,"* implying that these are not his sentiments alone but also the people's. Furthermore, these people are *"hungry for genuine and meaningful change."* The use of the word "hungry" suggests that the people have been clamoring for change. Duterte describes this change as "*genuine and meaningful."* This usage signifies that if ever there was change in the past it was not sincerely experienced by the people and, therefore, insignificant. He goes on to say that change must start *"with us and in us."* The use of *"us"* communicates to the audience that they are included in the battle for change.

Of course, in a war, there are enemies; however, this time, Duterte does not refer to the country's problems but the people themselves. To be one's own enemy means the people must struggle within themselves to achieve change, but according to Duterte, this can only be achieved with courage and will. "Courage" is defined as the "mental or moral strength to venture, persevere, and withstand danger, fear, or difficulty." The people need it, especially in a war where the leader is determined to eradicate the enemy though unorthodox methods. On the other hand, "will" means "the collective desire of a group or a disposition to act according to principles or ends." Having justified that the nation is at war, Duterte calls for collective action from the people to fight with him to achieve real change.

The conceptual metaphor CHANGE IS WAR is employed in the president's address not only to remind the audience of the current state of the nation, but also to convince them that the war against the country's problems is a necessity, and drastic measures are imperative to achieve victory, which is equated with change. While he asks for cooperation from government agencies and the people, he also warns those who may try to hinder his plans. This strategy is resonant of Navera's (2020) findings that speeches may be used not only to encourage supporters to agree with the speaker but also to silence critics of the proposed policies. Furthermore, he paints a grim picture of society and relates this to people's experience by emphasizing how the innocent are usually the victims. Moreover, his use of the pronoun "us" implies that he is one with the people in the fight against the nation's problems.

As with NATION IS A BODY, he uses CHANGE IS WAR to "appeal to emotion." Reyes (2011) points out that in using emotion as a legitimization strategy, speakers use linguistic and rhetorical sources "to create two sides of a given story/event, in which speaker and audience are in the 'us-group' and the social actors depicted negatively constitute the 'them-group'" (page 785). In this case, the 'us-group' includes Duterte and the people while the 'them-group' involves those who perpetrate crimes and corruption.

Additionally, he uses "hypothetical future" to legitimize his policies by claiming that the war on criminality will bring about change – a progressive future for the country. Reyes (2011) explains that this strategy is used to exert power by promising a positive future outcome.

According to Guitart Escudero (2005) POLITICAL ACTIVITY IS A WAR is a commonly used metaphor during election time which can usually become war zones where words are weapons and rivals are enemies. However, even in inaugural speeches, "war" lexicon may still be present as in Obama´s: "…each day brings further evidence that the ways we use energy strengthen our adversaries and threaten our planet" (Guitart Escudero 2011, page 48).

In summary, the conceptual metaphors present in Duterte's inaugural speech such as SOCIAL PROBLEM IS A DISEASE, NATION IS A BODY, and CHANGE IS WAR help to frame his policies as urgent, unorthodox solutions to dire problems of the country. These conceptual metaphors function to legitimize the rhetorical mechanisms in his speeches that spell out his ideology and justification for such policies. Furthermore, Duterte's rhetorical choices, through the legitimization strategies of altruism, appeal to emotion, and hypothetical future, reinforce his identity as a leader with powerful solutions for the critical issues facing the country and help in gaining public support for his policies. This type of rhetoric is evident not only in Duterte's inaugural speech but also in his other political speeches. As Rubic-Remorosa (2018) and Villanueva's (2018) findings demonstrate, the president's speeches make use of linguistic strategies in underscoring his policies addressing the war on drugs, corruption, and criminality and depicting himself as a strong and credible leader that the people can rely on to deliver the country from its many problems.

5 Conclusion

President Duterte's inaugural speech utilizes the conceptual metaphors SOCIAL PROBLEM IS A DISEASE, NATION IS A BODY, and CHANGE IS WAR. These metaphors are used to frame his message to the Filipino people that the country is in a deplorable condition because the people have lost the values of nationalism, sacrifice and compassion. Having lost these values, the problems of the society such as criminality, illegal drugs, corruption, and breakdown of law and order emerged to make the people suffer. Furthermore, these problems are so severe that they need to be addressed with utmost urgency. The only solution is to implement policies that may be unorthodox but can help the country move forward to a brighter future.

The conceptual metaphors used in Duterte's speech facilitate the audience's understanding of the message by relating the complex issues to everyday experiences of ordinary people. He does this by using legitimization strategies such as altruism, appeal to emotion, and a hypothetical future. To convey that all the policies of the new government are made for the betterment of the country justifies even the unconventional methods that the president is known for. Moreover, using metaphors that pertain to sickness, pain, fear, hardship, and hope for a better life evoke emotions that help legitimize the government's new policies.

Duterte's use of conceptual metaphors coupled with legitimization strategies has been effective in persuading the people to support him and his policies. This is evidenced by the fact that despite the extra-judicial killings, the unfulfilled promises, the declaration of martial law in Mindanao, and other unorthodox behavior and occurrences, the president's satisfaction rating remained "very good" (Orellana 2018). The survey results showed that many people still believed that the president's policies were justified given the county's situation. Moreover, despite his declining satisfaction rating starting 2018 due to the bloodiness of his declared war on illegal drugs and his mishandling of the COVID19 pandemic, Duterte maintained a higher rating up to the end of his term compared to those of past presidents. (Ducanes, Rood, and Tigno 2023). Indeed, his popularity among the masses had a great impact on the 2022 Presidential and Vice Presidential Elections which placed Ferdinand Marcos, Jr. and Sara Duterte in power. Their landslide victory is an indication that majority of the Filipinos preferred a government that would continue Duterte's policies (Arguelles 2022).

Evidently, conceptual metaphors are effective tools of persuasion because they enable speakers to translate abstract concepts into relatable human experiences that are easily understood by the audience. They can also be used as legitimization devices that can help convince people to believe in what the speaker espouses even if it were something that they would not agree to in normal circumstances.

Based on the conclusion of this study, it is the recommended that further research be done to include the other speeches of the president to find out if the conceptual metaphors present in his inaugural speech recur in his other speeches and explore how these metaphors aided in the legitimization of Duterte's government policies.

Acknowledgements

The completion of this paper would not have been possible without the invaluable guidance of my Rhetorical Theory professor, Aileen O. Salonga, from the Department of English and Comparative Literature at the University of the Philippines. Her expertise, patience, and insightful guidance greatly contributed to the development of this research. I also wish to extend my gratitude to my home institution, Far Eastern University, for supporting my PhD studies. Lastly, I would like to thank my family for continuing to inspire me in all my endeavors.

Chinese Language in Chinese Communities: Language Shift, Maintenance, and Identity

Jessica Djolin Niti
Maria Tamarina Prawati
Bina Nusantara University / Kemanggisan, Palmerah, Jakarta Barat, 11530, Indonesia
maria.prawati@binus.edu

Abstract

Language shifts and maintenance happen in the Chinese community, which is caused by a multicultural society, especially in Jakarta. The shift of languages defines someone's identity as it is one of the features of a culture. The goals of this study are to discover the factors that cause language shift and maintenance among Madyatama University (Pseudonym) students and how the Chinese language defines their identity as Chinese people. This study is conducted on 26 students of the university, which differs into 13 females and 13 males aged 19-22 years old. The writer uses quantitative and qualitative methods and finds that the Chinese language is shifted and maintained at Madyatama University (Pseudonym), which is influenced by a multicultural society. Moreover, most of the participants agree that the ability to speak the Chinese language does not define their identity. Nevertheless, the rest of the participants agree that the Chinese language becomes their identity.

1 Introduction

Indonesia is a multicultural country, especially Jakarta, as a center of economic and business life. Therefore, various languages, dialects, ethnicities, and cultures spread in society. Chinese ethnicity is one of the races that bring their culture to Indonesia and are able to grow rapidly in society. The population of Chinese people in Jakarta in 2024 has the highest number of other countries in Indonesia, which is over 5,53% of 11.436.004 citizens (Jakarta Population 2024, n.d.). In addition, the Chinese communities are also diverse in different cultures and languages, including Hokkien, Hakka, Khek, Teochew, and others, which they use as a vernacular language (Nasution & Ayuningtyas, 2020).

During the historical story of Chinese people in Indonesia in the late 1990s, Chinese communities were treated inappropriately and discriminated against by the rules of the government (Anggraeni, 2011). As a result, most Chinese Indonesians today are unable to use and speak their language, which is the Chinese language (Werhoru & Jhon, 2018). Moreover, Werhoru and Jhon stated that ". . . instead, only assume the ethnolinguistic identity as being a native Indonesian and occasionally an English language speaker" (2018). It shows that the use of the Chinese language in Chinese communities has shifted to Indonesian and English language. However, some Chinese people still speak their language rather than other languages, which shows language maintenance (Yuliana & Yanti, 2023). The ability to speak, use, and understand Chinese languages influences the Chinese population regarding their identity. The phenomenon of language shift, maintenance, and identity also happens among Chinese communities at Madyatama University (pseudonym). Therefore, to investigate these issues, the writer asks these questions:

1. What are the factors that shift the Chinese language among Chinese communities at Madyatama University (pseudonym).?
2. What are the factors that maintain the Chinese language among Chinese communities at the?
3. How does the Chinese language define the identity of Chinese communities at the university?

2 Literature Review

A language shift is an action of acquiring a new language that causes the community to lose its first language. Baker (2001) defined language shift as "A reduction in the number of speakers of a language, a decreasing saturation of language speakers in the population, a loss in language proficiency, or decreasing use of that language in the different domain" (p. 59). It is a process where a community replaces their ethnic language with other languages, and it happens because of many factors, such as historical, political, social, and eco-

nomic factors (Grenoble, 2021). The shift of the language happens for several reasons. According to Holmes (2013), language shift typically tends toward the majority language, who might find it difficult to learn the language of a minority (as cited in Werhoru & Jhon, 2018). In addition, Farisiyah and Zamzani stated that language shifts happen not only because of the lost interest in learning the local language but also because of the parents who choose Indonesian as their vernacular language (2018). Another reason that causes language shift is the need to fit social and economic life, which makes them learn a new language to be able to communicate with other people in a new area (Putri &Setiawan, 2014). On the other hand, language maintenance is defined as a continuity of language use without being affected by other languages and becomes the key to their identity (Yuliana & Yanti, 2023). Language maintenance describes a community that maintains its native language despite numerous factors that may cause a transition to a new language (Farisiyah & Zamzani, 2018). Moreover, Baker (2000) stated that "Language maintenance usually refers to relative language stability in number and distribution of its speakers, its proficient usage by children and adults, and its retention in specific domains, such as home, school, and religion" (p. 59). Identity relates to the characteristics that differentiate one individual or organization from others (Identity, 2024). According to Zenker (2018), identity is classified based on nationality, ethnicity, race, religion, class, gender, sexual orientation, age, ability, and disability, which involves various linguistic phenomena. In addition, some philosophers agree that identity is something that the individual has and is inside them (Mahmoodi-Shahrebabaki, 2018). Language is one of the features that represent someone's identity (Baker, 2000) and is part of the culture (Dekeyser et al., 2019). However, language cannot define true identity as it is the way to communicate with other people (Karsono, 2014). The phenomenon of language shift, maintenance, and identity happens because of multiculturalism. A multicultural community comprises diverse cultural groups categorized by nationality, race, religion, and language (Suroyo et al., 2023). In a multicultural society, the individual acquires two or more languages, and it affects the use of a language, which is based on the topics, the relation between the speakers, and the context of the conversation (Nasution & Ayuningtyas, 2020). As a result, it impacts their identity and language use, which can be shifted or maintained. To support this study, the writer found several studies about language shift, maintenance, and identity, which some researchers have done. The first study was done by Eka Margianti Sagimin in 2020, titled Language Shift and Heritage Language Maintenance Among Indonesian Young Generations: A Case Study of Pamulang University Students. This study aims to find students' attempts to maintain the local language and discover some factors that cause language loss at Pamulang University using a descriptive qualitative method. From 44 participants, the researcher finds that most of the students frequently use the local language and Indonesian with their family and use Indonesian with their friends in an educational context. However, the participants show positive feedback on heritage language. The second study is titled Language Shift in Chinese-Indonesian Community by David Werhoru and Elex John in 2018. This study focuses on finding the specific factors that cause language shifts in the family, institutional, and social context, especially in Jakarta, among three Chinese Indonesian females. To collect the data, the researchers used a questionnaire and recorded an interview that took around 20 minutes for each participant. From this study, the researchers discover that language shift happens because of the lack of knowledge of the culture, the need to learn the language, the uncertainty about their ethnolinguistic identity, and the social and political history regarding the traumatic events in the past and present generations of Chinese Indonesians. The study of Chinese language shift and maintenance in Jakarta is also done by Vina Yuliana and Yanti (2023) titled Language Attitudes, Shift, and Maintenance: A Case Study of Jakartan Chinese Indonesians. The purpose of this study is to find Chinese Indonesians' language attitudes and the factors of language shift and maintenance. The researchers spread the questionnaire to 100 Chinese Indonesian people and did an in-depth interview with 9 of them. This study showed that most of the participants shifted to Indonesian and English, and only 9The last study covers language as identity, which is titled Chinese Language as an Identity Viewed by the Younger Chinese Ethnics in Indonesia by Ong Mia Farao Karsono in 2014. This study investigates the younger Chinese community in Indonesia in viewing the Chinese language as an identity. In this study, the researcher

uses qualitative and quantitative methods by spreading questionnaires to all faculties at Petra Christian University. From this study, the participants who speak and do not speak Chinese language think that the ability to speak the language cannot be considered as their identity. Instead, there are various ways to recognize Chinese people, which are their skin color, eye shape, and manner of dress. Of the previous studies that the writer reviews all discuss language shift, maintenance, and identity in one study, which becomes the reason why the writer conducts this research. Moreover, there are only a few studies that covers language identity on Chinese Indonesian. Therefore, the focus of this paper is to discover the factors that cause language shift and maintenance among the university students and how the Chinese language defines their identity as a Chinese person.

3 Methodology

To collect the data, the writer uses quantitative and qualitative methods. Google Forms was used as the medium to ask the participants several questions, which was distributed on November 8, 2023. In the first section of the form, the writer asks for basic information regarding the participant, such as name, age, and gender. The second section of the form asks about how many languages the participants speak. This section also asks about their preferences in using language that makes them comfortable. The purpose of this section is to analyze whether the Chinese language is shifting or maintaining, which is in correlation to the third section. The third section consists of questions that ask how the participants acquired or learned the Chinese language. In addition, in the last section, the writer also asks the participants' opinions on the Chinese language. The participants of this study are 26 students of Madyatama University (Pseudonym). It differs into 13 females and 13 males which aged 19-22 years old.

4 Results and Analysis

4.1 Data from the second section

From the data, the writer finds that most of the participants learn and speak two languages. The data below shows how many languages the participants can speak.

Languages	Quantity
Indonesian	1
Indonesian and English	9
Indonesian, English, and German	1
Indonesian and Chinese (Khek)	1
Indonesian, English, and Chinese	2
Indonesian, English, and Chinese (Mandarin)	3
Indonesian, English, and Chinese (Teochew)	1
Indonesian, English, and Chinese (Hokkien)	3
Indonesian, English, and Chinese (Hokkien and Khek)	1
Indonesian, English, Chinese, and Japanese	1
Indonesian, English, Chinese, and Korean	1
Indonesian, English, Chinese, and Javanese	1
Indonesian, English, Chinese (Hakka), and Belinyu	1

Table 1: Languages that the participants speak

According to how the participants acquired the languages, the writer divided it into two sections, which are native language and foreign language. Eight of the participants stated that they had learned Indonesian since they were children, which made Indonesian their native language or first language; one participant has Chinese (Hakka) as her mother tongue and one participant has Chinese (Hokkien) as her mother tongue as she has been taught and spoken the language since young. However, other participants do not explain which language is their first language clearly.

For the foreign language, most of the participants learn English from schools, movies, books, YouTube videos, TV shows, English courses, social media, and self-taught. This statement is mentioned by one of the participants:

> *"Inggris, pertama kali saya terpapar oleh bahasa inggris adalah pada saat saya mulai sekolah (TK). Disana banyak kata-kata (termasuk nama-nama, buku, dkk) yang menggunakan bahasa inggris serta terdapat pelajaran yang memba- has mengenai bahasa inggris. Disana saya mulai mengenal bahasa inggris. Pembelajaran bahasa inggris berlanjut*

pada saat saya sudah mulai masuk masa SD-SMP-SMA. Disana saya belajar bahasa inggris secara lebih mendalam di sekolah, karena memang ada mata pelajarannya. Selain itu, saya juga bela- jar melalui internet dengan cara menonton/membaca konten yang menggunakan bahasa inggris." (original version) (data 1)

"English. The first time I got exposed to English was when I started school (kindergarten). There were a lot of words (including names, books, and others) that used the English language, and there was also an English subject. Since then, I have known the English language. The learning process continued until I entered elementary school, then junior high school, and then senior high school. I learned more about the language because there was an English subject. Moreover, I also learn through the internet by watching or reading English content." (translation version) (data 1)

Another participant also learns English from her environment, which states:

"English: being in an English-medium playgroup from the age of 3 (due to learning it from a young age, I did not actively learn grammar, vocabulary, etc, but acquired and practiced it directly almost like a native speaker would)." (data 2)

The second foreign language is Chinese. The participants learn the Chinese language through schools, Chinese courses, families, friends, Summer Camp Events, Chinese drama, and Chinese movies. The following language is German, which the participant gets from private study and the Internet. Other participants also studied the Korean language using online materials and the Japanese language via games. On the other hand, the Javanese language is acquired from the participant's family. Lastly, the participant, who speaks Hakka as her first language, learned Indonesian and Belinyu when she attended public school in her hometown.

Following the languages that the participants speak, the writer compiles it based on the language that they commonly use in their family and friends.

Languages between the family	**Quantity**
Indonesian	14
Indonesian and English	5
Indonesian and Chinese	2
Indonesian and Chinese (Mandarin)	1
Indonesian and Javanese	1
Chinese (Hokkien)	1
Chinese (Hakka)	1
English	1

Table 2: Languages between the family

Based on the participants' answers, most of them use Indonesian because of the multiculturalism in the family, where Indonesian is the only language that connects them since their parents or siblings are unable to speak other languages. The participants say these statements:

"Indonesia. Cause my family is multicultural. So, may be difficult to blend the many local languages to speak for daily use." (data 3)

"Of course, Indonesia, because only the Indonesian language that all of my family understood." (data 4)

Meanwhile, other participants prefer to mix the languages to match their needs. For example, one participant mixes the languages to fit her family. Therefore, she speaks Indonesian to her mother and Chinese to her father.

"Mostly bahasa Indonesia with my mother and her family, but often use Chinese to my father and his family." (data 5)

In addition, a specific participant speaks only English language to her family because they have been exposed to Western culture.

"English, my family was highly exposed to western culture (especially from movies and music). Also, my sister is a literal gen Z (she is too exposed to YouTube and the internet to the point that English becomes her first language)." (data 6)

Languages between the friends	Quantity
Indonesian	15
Indonesian and English	10
English	1

Table 3: Languages between the friends

The participants have similar reasons for choosing those languages to interact with their friends. The reasons the participants use Indonesian are primarily because of their environment, who can only speak Indonesian, and it is more convenient for them.

> "Indonesia, because all of my friend is Indonesian people, and they must be understanding Indonesian language." (data 7)
> "Indonesia, cause Indonesia is a general language, and everybody will understand it." (data 8)
> *"Indonesia, lebih familiar."* (original version) (data 9)
> "Indonesian, it is more familiar." (translation version) (data 9)

Other participants use Indonesian and English to their friends to match their environment and globalization, which are stated in one of the participants' answers:

> "Indonesia and English. Cause I try to adjust communicate with the same local languages and the foreigners too." (data 10)
> *"Indo karna ya kita orang Indo (especially ke orang yang gabisa b.ing) dan emang karna saya SaSing dan karena emang udah kebiasa dari dulu terus en-vironment SaSing bener-bener bikin terbiasa dengan ngomong bahasa Inggris hehe."* (original version) (data 11)
> "Indonesian, because we are Indonesian people (especially to someone who can- not speak English) and because I am an English literature student, I get used to the environment, which makes me speak English more." (translation version) (data 11)
> "Indonesian with a little bit English, because middle class Indonesians, also known as the bourgeoise, tend to speak using those two languages at once be- cause of rampant globalization." (data 12)

Lastly, one participant says that he speaks English with his friend because he is more proficient in this language.

The last question in this section asks about the participants' preferences in languages that make them comfortable and express their ideas the most. From the answers, the writer finds that 11 participants answered Indonesian and English as the most comfortable languages. These languages also help them express their opinion for different purposes, which other participants agree on:

> "Both languages because I'm fluent in both of them, but they belong to different realms to me. English tends to be for friends, academia, and sharing my opinions, while Indonesian tends to be for more basic, concrete things and family (especially since my extended family consist of some people who don't speak English." (data 13)
> "If it's academic ideas then English (because in English department we make lots of paper so I'm used to English vocabulary more) but in general it can be both, depending on what I want to say but I would probably opt to mix the two." (data 14)

Nine participants answered this question in Indonesian as they thought it was the easiest way to say something, and everyone could understand this language. In addition, the participants know more about Indonesian vocabulary, and as a result, it makes them express themselves more.

> *"Indo, karena lebih tau banyak kosakata, lebih bisa mengekspresikan diri."* (original version) (data 15)
> "Indonesian, because I know Indonesian vocabulary, express myself more." (translation version) (data 15)

Five other participants answered in English because it explains their ideas accurately, which is shorter than Indonesian.

> "English, especially in terms of writing, I'd prefer using English since it sounds less cringy since English has some words

> that accurately convey an idea, while Indonesia doesn't." (data 16)
> "Obviously English, cause sometimes that in Indonesia languages too long to provide your idea, but in English you can shorten your words to speak." (data 17)

The last participant differs in the use of the language for two different purposes. She is comfortable speaking Chinese (Hokkien) with her family and Indonesian with her friends since it is the national language.

> "Hokkien at home because it has become our daily language. Bahasa Indonesia at school and public because it is the language that everyone can speak." (data 18)

According to the data that the writer collected, most of the participants were able to speak at least two languages, which are Indonesian and English. These languages are actively used with their family and friends because they are more comfortable with them and help them express their ideas since these languages are commonly used and heard in society. However, of 26 participants, 15 participants speak the Chinese language, and only 7 of them use this language actively with their family and friends.

4.2 Data from the third section

In this section, the writer asks about the participant's ability to speak the Chinese language. Of 26 participants, 15 participants were able to speak Chinese, namely Khek, Mandarin, Hakka, and Teochew. Meanwhile, the rest of the participants are not able to speak any Chinese language. The proficiency of the participants is divided into several points, which are presented in the table below. The writer uses a linear scalar from 1 to 5; 1 point means the participant is not fluent, while 5 point means the participant is fluent.

Point	**1**	**2**	**3**	**4**	**5**
Quantity	15	3	4	4	-

Table 4: Languages between the friends

Of 15 participants who speak Chinese, only 5 participants use this language in their families. Most of the participants do not use this language because no one in their family speaks Chinese languages, even though their parents come from a Chinese family. The examples can be seen from these answers:

> "I come from Indonesia, but my dad's side of the family came from Hainan and my mum's side of the family are Khek." (data 19)
> *"I think my papa speaks Khek? And Mandarin, beliau orang Aceh jadi keluarganya bicara begitu, tapi saya ga ngerti apa-apa hehe. Kalau ngumpul sukanya ngan gong."* (original version) (data 20)
> "I think my papa speaks Khek and Mandarin. He comes from Aceh; therefore, his family speaks that language. However, I do not understand anything. If there is a family gathering, I will go blank." (translation version) (data 20)

Moreover, here are their reasons for not speaking the Chinese language in their family:

> "No, because my mum and I don't speak any Chinese dialects so we wouldn't understand anything." (data 21)
> *"Ngga, mama gabisa soalnya."* (original version) (data 22)
> "No, my mom cannot speak the language." (translation version) (data 22)

Two participants speak Chinese languages with their friends. The first participant uses this language with her course friend. Other participants only speak the Chinese language to their friends who can speak the Chinese language as well.

> "Yes, with my Chinese course's friends, to recap the discussion at course, but at the university I don't." (data 23)
> "Sometimes yes. Since not all of my friends can understand Chinese, so I only speak Chinese with the people that can speak Chinese also." (data 24)

Around seven participants stated that they actually felt comfortable speaking Chinese languages. The reasons are various for each participant; for instance, a participant says that the language is homey.

> "Yes, I feel comfortable speaking the Chinese language since I grow up speaking Hakka. It makes me feel like home." (data 25)

Other participants also mentioned that even though this language is complex to learn, it is still fun.

> "Yes and no because I'm struggling to study and get the fun of it." (data 26)
> "Actually comfortable. But I have to learn again." (data 27)

Furthermore, the rest only feel comfortable if they find the right occasion.

> "Yes, but it depends on where I speak the language." (data 28)
> *"Tergantung sama siapa ngobrolnya, kalau sama keluarga nyaman-nyaman aja."* (original version) (data 29)
> "It depends on who I am talking to. If it is my family, I feel comfortable." (translation version) (data 29)

The reasons why another 19 participants do not feel comfortable is because they cannot speak the language, are not interested in learning it, do not have any friends to talk with, and this language makes them look like real Chinese people.

> "No, because I'm not fluent in Chinese and I'm also not interested to learn it furthermore." (data 30)
> "No, I'm not fluent and I don't have someone to talk Chinese with." (data 31)
> "No, because no speak Chinese in my home." (data 32)
> *"Tidak, karena terlalu cina sekali."* (original version) (data 33)
> "No, it is too Chinese." (translation version) (data 33)

Despite the difficulty, all the participants gave positive feedback toward the Chinese language. For instance, they say it is a sound, excellent, unique, and attractive language.

> "Unique, such a wonderful heritage, and attractive." (data 34)
> *"Menarik, karena memiliki karakteristik yang unik (dari penggunaan nada, tulisan, dan lainnya) dibandingkan bahasa-bahasa lain, serta terlihat seru untuk dipelajari."* (original version) (data 35)
> "Interesting because of the unique characterisctics (from the use of the tone, writing, and others) which different from other languages, looks exciting to be learned." (translation version) (data 36)

It shows that the Chinese language has been shifting to Indonesian and English at Madyatama University (Pseudonym). The factors of this issue can be seen from 11 par- ticipants who did not acquire or learn the Chinese language even though their family speak the Chi- nese language, as can be seen from data 19 – 22. Some participants also mentioned that they did not find any of their friends or family members who speak Chinese (data 31 – 32). In addition, 9 partici- pants stated that they did not want to learn Chinese languages because it is not exciting and really hard to learn. Therefore, they prefer to use Indonesian or English since everyone can understand both languages.

> "I tried to learn Mandarin by myself because my parents wanted me to, but I never became fluent because I wasn't really interested in it." (data 37)
> "Not, I'm interested in learning Chinese but it's so hard, so I gave up." (data 38)
> "No, because I'm not really that interested learning Teochew, Cantonese, or Hokkien." (data 39)

In this case, language shifting happens because of two dimensions: socio-cultural and educational. According to the data, the participants are growing up in a multicultural society where Indonesian and English are more important (data 10 – 12). It is also supported by their environment, especially in Madyatama University (Pseudonym). Most of the content that is served is written either in English or Indonesian. In addition, the participants prefer to communicate in both Indonesian and English with their friends.

At the same time, Chinese languages are also being maintained in some aspects, including education field and attitudinal. From the participants' answers, some schools teach the Chinese language, especially Mandarin, to the students. Furthermore, some participants also learned the Chinese language from their Chinese course.

> "My school has compulsory Mandarin subject." (data 40)
> "Course since junior until senior high school." (data 41)

Seven participants who speak the Chinese language actively with their family and friends also show that the Chinese language is being maintained. It happens because they are still in contact with

their family or friends who speak this language (data 23 – 24). Another reason that they maintain this language is because it makes them comfortable, which makes them feel like they are in their home (data 25 – 29).

Regardless of the lack of the ability to speak the Chinese language, most participants do not feel like they have lost their identity as Chinese people because they live in Indonesia, which has become their new identity, Indonesian people. Moreover, no rule forces them to speak or learn the Chinese language. Instead, one of the participants mentions that there is another way to show his identity. The text below shows the statements from the participants.

> "Not necessarily because I think lower rates of Chinese fluency are in themselves an aspect of the Chinese-Indonesian culture identity. Not being able to speak it or being less fluent differentiates us from other Chinese diasporas and forms part of our story." (data 42)
>
> "Nope, the language we speak doesn't define our identity. We can speak Russian or Arabic if we're Indonesian, it doesn't change the fact that we're Indonesian." (data 43)
>
> "Not really, because I live in Jakarta and not have to speak the Chinese languages." (data 44)
>
> "No, because I grew up in Indonesia and that's my identity." (data 45)
>
> *"No, ga ada yang peduliin juga."* (original version) (data 46)
>
> "No, no one cares." (translation version) (data 46)
>
> "No, because there are still other traditions that I can do to show that I am Chinese." (data 47)

However, the rest of the participants disagreed with these statements. For them, as Chinese people, they must be able to obtain the languages and the cultures because they are part of themselves, their history, and their identity.

> "Yes, since I am a Tiong Hoa. It's still a part of me." (data 47)
>
> "Yes, since language is part of who you are both ethnically and culturally. It is concurred that losing once's language is a lost of culture and a form of cultural degradation." (data 48)
>
> "Yes la, very embarrassing when Chinese people can't speak Chinese la, so stop asking because I feel embarrassed la." (data 49)
>
> *"Ya mungkin, karena kalau tidak ngomong Chinese di keluarga nanti suka dikatain bukan orang Chinese."* (original version) (data 50)
>
> "Maybe because when we do not speak Chinese in the family, people will mock us as non-Chinese people." (translation version) (data 50)
>
> *"Not really but also yes because all of our elderly can speak the language, dan kalau (semisalnya saya, atau generasi sekarang/anak-anak) tidak bisa berbahasa mandarin, seperti terasa budaya yang terbuang."* (original version) (data 51)
>
> "Not really, but also yes, because all of our elderly can speak the language, and if (for example, me or the next generation) cannot speak Mandarin, it feels like we lost the culture." (translation version) (data 51)

Conclusion

From this study, the writer concludes that language shift and maintenance of the Chinese language happens among 26 students the university. The Chinese language shifts to Indonesian and English is mainly caused by multiculturalism in the participants' social lives, whether with their family or friends. As a result, they do not obtain the Chinese language from their family, they cannot find a friend who speaks the same language, and they find that the Chinese language is too difficult to learn.

Despite the ability to speak Chinese, most participants stated that the Chinese language does not define their identity, which interestingly in accordance with Karsono's study. They mention that since they live in Indonesia, their identity is an Indonesian people, and no one will care whether they are Chinese or not. In addition, one of the participants also says that there is another way to show their identity besides speaking the Chinese language. In contrast, the rest of the participants declare that the Chinese language becomes their

identity as a Chinese person. They even say that it is embarrassing if Chinese people cannot speak the Chinese language, which means they lose their culture.

Abstract

This study examines the influence of phonotactic probabilities, phonological structures and articulatory complexity on speech production in Mandarin. By analyzing a natural spoken corpus comprising 202 hours of daily conversation in Taiwan Mandarin, which includes 2,384,567 lexical items and yields 6,272,394 tokens involving 3,852,987 consonant tokens and 2,419,407 vowel tokens, the dataset is precisely categorized into 12 syllable structure types. The study employs frequency-based probabilistic phonotactics, with probability distributions calculated using Zipf's Law and Yule's distribution, where Yule's distribution provides a better prediction for the segment distribution. Phonotactic probabilities are further determined by the bigram or biphone frequencies of phonological segments and sequences within Mandarin word types. The results reveal a departure from previous research that found a strong correlation between speech production, phonological structure and articulatory complexity, such as markedness in phones or syllable structures. Instead, Taiwan Mandarin speakers demonstrated sensitivity to frequency variations, with phonotactic probabilities independently influencing speech production, suggesting that these probabilities are encoded within speech production processes. This research contributes to the understanding of how phonotactic constraints, independent of articulatory complexity, shape speech production in Mandarin.

1 Introduction

It is generally believed that speakers can process certain sound sequences faster than others. The possible sound sequences in languages are not all equiprobable as some are more frequent than others. The increasing variety of approaches to probability in phonology indicates a growing consensus that phonological analysis needs to incorporate probability and frequency into the theoretical framework (Alderete and Finley, 2023). Therefore, phonological complexity and probabilistic constraints are essential concepts in the study of natural languages. Their strong correlation significantly influences various aspects of linguistic theory and practice. Articulatory complexity refers to the intricate features of a language's sound system, including the number and types of phonemes, syllable structures, and phonotactic rules.

A number of researchers suggested that certain sound sequences have attributed similar behavioral effects that are easier to articulate (i.e., less phonological complexity), but others attributed the patterning to varying degrees of probabilistic constraints (e.g., Jusczyk et al., 1994). Such constraints can be referred to as phonotactic probabilities where phonological phones and sound sequences are legally arranged in lexical items. For example, in English, the initial sequence [str] is allowable whereas the sequence [stn] does not form a legal arrangement. Or, in Mandarin, the initial sequence [kwa] is permissible while the sequence [kja] or [kwn] is not. In addition, the single phone unit in the above phone sequences

does not distribute evenly. The glide [w] or [j] occurs more frequently than the consonant [k] in Mandarin due to the fact that glides have a wider distribution (i.e., syllable-initially, syllable-medially, and syllable-finally) than the true consonant [k] (syllable-initially exclusively) (Wan, 2022).

In experiments by Goldrick and Larson (2008), English speakers were sensitive to variations in frequency, demonstrating that phonotactic probabilities are encoded by speech production processes. These novel phonotactic constraints were found to be correlated with the phonotactic probability of specific phonological structures. However, other research has shown a highly correlated association between speech production and phonological structure and articulatory complexity such as markedness in phones or syllable structure (e.g., Jakobson, 1941/1968; Romani and Calabrese, 1998). Evidence from these studies presents a limited number of structures that have yielded mixed and uncertain findings.

Further studies have found that phonotactic probabilities exhibit a strong correlation with neighborhood density, which refers to the number of lexical items that share phonological similarity with a target (e.g., Goldrick and Rapp, 2007; Vitevitch et al., 2004). These effects manifest at separate and independent levels within the spoken production system. In this study, we aim to compute frequency-based probabilistic phonotactics in Mandarin syllables by categorizing a spoken dataset into 12 syllable structure types via Biphone/Phone or Bigram/Gram frequencies (i.e., segment-to-segment co-occurrence probability of sounds within the lexical items; Vitevitch and Luce, 2004), with tone omitted from the calculation. In addition, the effects of phonotactic probabilities and likelihood will be measured across the different syllable structure types.

2 Methodology

The spoken data used in the study that has been collected over decades were drawn from Wan et al. (2024) involving 202 hours of daily conversation in Taiwan Mandarin involving 2,384,567 lexical items. The topics of the recorded spoken content that were recorded in a naturalistic setting varied from lecture notes, class discussions, interviews, presentations, conversations of daily lives, etc., among multiple speakers in Taiwan.

Sound files collected after 2020 were transcribed into the International Phonetic Alphabet (IPA) via Chinese characters using a Speech-to-Text (STT) system. This system was developed using the pyTranscriber application (https://github.com/raryelcostasouza/pyTranscriber) in the Phonetics and Psycholinguistics Laboratory. Transcribing a 60-minute audio file into Chinese characters took approximately 80 seconds. However, the accuracy of the transcription varied significantly, depending on factors such as voice quality, background noise, speaker gender, age, and speech speed. The accuracy rate ranged between 70% and 90%, depending on the combination of these factors. The output of the STT system was then manually checked for accuracy. Subsequently, the entire transcript was automatically segmented by the CKIP parser (Ma and Chen, 2003) and POS tagged by the CKIP tagger from the Chinese Knowledge and Information Processing group (CKIP, 1998). The parsed and tagged transcription was also manually reviewed according to the word segmentation and POS tagging criteria of the Academia Sinica Corpus (CKIP, 1998), which are commonly applied in corpora such as the Linguistic Data Consortium (Ma and Huang, 2006) and the Peking University corpus (Huang et al, 2008).

It is important to note that the spoken data samples collected in this study were analyzed based on the frequency of occurrence across various topics recorded in naturalistic settings. Word counts are up to date and are not derived from movie subtitles. The following (1) and (2) shows

$$F_r = \frac{a}{r^b} \quad (1)$$

the formula for calculating the frequency distribution and probability in Mandarin.

Formula (1) represents the mathematical expression of Zipf's law (Zipf, 1949). It describes the frequency distribution of words or other linguistic units, where the frequency of the most common unit (such as a word or phoneme) is inversely proportional to its rank in the entire corpus. In other words, the highest-ranking word or phoneme has the greatest frequency, the second-ranking unit has approximately half the frequency of the first, and this pattern continues accordingly. In the function, r represents the rank of an item, and Fr is its frequency. a is a constant, typically

representing the frequency of the highest-ranked item; b is a constant that describes the inverse

$$F_r = \frac{a}{r^b} C^r \quad (2)$$

relationship between frequency and rank.

Equation (2), Yule equation (Yule, 1924), is similar to Zipf's Law. However, the Yule equation incorporates an additional exponent, *Cr*, which accounts for the dominance of a few highly frequent distributions. Specifically, Yule's distribution is a discrete probability distribution used to model the frequency of particular distributions, reflecting the underlying processes, whereas Zipf's Law focuses on rank-order distributions. Both Zipf's Law and the Yule equation have demonstrated a relatively high degree of fit in past research concerning sound distribution (e.g. Kłosowski, 2017; Tambovtsev and Martindale, 2007). Therefore, this study employs these two formulas to examine the phonetic distribution within the dataset.

Using a corpus-based and data-driven analysis to investigate the probability of sound frequency represents a recent trend in speech communication, language learning and psycholinguistic experiments (Wan et. al., 2024; Hsieh and Wan, to appear; Chien and Wan, 2023; Wan, 2021). Therefore, the questions to be investigated involve the following:

- What is the distribution pattern of speech tokens in Mandarin? Will consonants, vowels or glides be distributed evenly?
- Are the behavioral effects of certain sound sequences due to lower or higher phonological complexity, or do they result from varying degrees of probabilistic constraints?
- How do phonotactic probabilities influence the legality of sound sequences in Mandarin? How do they impact and are encoded by speech production processes? What is the relationship between phonotactic probabilities and articulatory complexity? How do phonotactic probabilities correlate with phonological structures and articulatory complexity, such as markedness in phones or syllable structures?
- How can frequency-based probabilistic phonotactics in Mandarin be computed and analyzed? How will these effects be measured in the study?

3 Results and Discussions

Token counts and probability of sound frequency using a log 10 frequency distribution were extracted from 202 hours of daily conversation involving consonants (N= 3,852,987 tokens) and vowels (N=2,419,407 tokens) in Taiwan Mandarin, as shown in Table 1 and Table 2.

Consonants are distinguished by three primary parameters involving place of articulation, manner of articulation and voicing (voiced vs. voiceless). One of the key distinctive features in Mandarin is the use of aspiration to differentiate six minimal pairs: [p/pʰ, t/tʰ, k/kʰ, ʈʂ/ʈʂʰ, ts/tsʰ, tɕ/tɕʰ]. In each pair, the first consonant is unaspirated, while the second is aspirated. Aspiration in Mandarin is a significant phonological feature, where the presence or absence of a burst of breath below following the consonant can change the meaning of a word entirely. In addition, three series of affricates and fricatives, including voiced, voiceless unaspirated, and voiceless aspirated features, [ʐ̬, ʈʂ, ʈʂʰ, ʂ], [ts, tsʰ, s] and [tɕ, tɕʰ, ɕ], occur in consonant inventory. The inclusion of voiced fricatives such as [ʐ̬] is relatively rare in Mandarin, with most of the fricatives and affricates being voiceless. The log frequency analysis shows that the distribution pattern of the single phone units in Taiwan Mandarin is uneven. For example, the glide [w] or [j] occurs more frequently than the consonant [k] in Mandarin due to their wider distribution (i.e., syllable-initially, syllable-medially, and syllable-finally) compared to the consonant [k], which occurs exclusively in syllable-initially position. This results in a highly structured and distinctive phonological system that does not correspond to traditional markedness in phones.

A major distinction among Mandarin vowels involves differences in tongue height, anterior-posterior tongue position, and lip rounding. Consistent with previous findings, all the single vowel units are not distributed evenly. The following bar chart illustrates the rank order of frequency for each single phone unit.

	Bilabial	Labio-dental	Dental	Retroflex	Palatal	Velar
Plosive (Unaspirated)	p 97 191 (4.99)		t 252 633 (5.40)			k 137 394 (5.14)
Plosive (Aspirated)	p^h 16 720 (4.22)		t^h 90 879 (4.96)			k^h 49 864 (4.70)
Fricative		f 36 249 (4.56)	s 36 913 (4.57)	ʂ / ʐ 210 908 / 49 284 (5.32) / (4.69)	ɕ 104 968 (5.02)	x 136 644 (5.14)
Affricate (Unaspirated)			ts 75 612 (4.88)	tʂ 124 869 (5.10)	tɕ 152 966 (5.18)	
Affricate (Aspirated)			ts^h 19 220 (4.28)	$tʂ^h$ 39 001 (4.59)	$tɕ^h$ 58 030 (4.76)	
Nasal	m 108 959 (5.04)		n 495 299 (5.69)			ŋ 247 892 (5.39)

Open (Low)			a 634 190 (5.80)		

Table 2: Mandarin vowel phones.

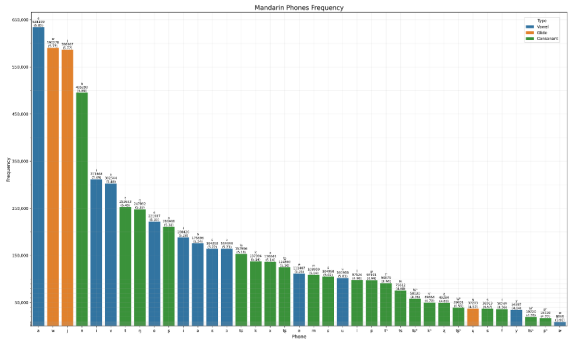

Figure 1: Mandarin phone frequency.

In this figure, the bars contain three colors: blue representing vowels, orange representing glides, and green representing consonants. It is clearly seen that the vowel [a] occurs most frequently in daily conversation in Taiwan Mandarin, followed by the glides [w] and [j], with the nasal [n] being the next most common sound. The least common vowel is the retroflex vowel [ɚ], and the least common consonant is [pʰ], followed by [tsʰ]. This distribution partially reflects the syllable structure of Mandarin, where CGVX can occur; X can be either the nasal [n] or the glides [j, w]. The glides can occur word-initially, word-medially after true consonants, and word-finally, while the nasal [n] can occur both word-initially and word-finally. Since Taiwan Mandarin does not use Erhua syllables, the retroflex vowel [ɚ] is rarely used and is commonly replaced by the vowel [ɤ]. The following shows the distribution according to two statistical quantifier measurements.

Figure 2 illustrates the phone frequency distribution of Mandarin on a log-log scale. The figure presents spoken data points alongside fitted curves using two models that include Zipf and Yule.

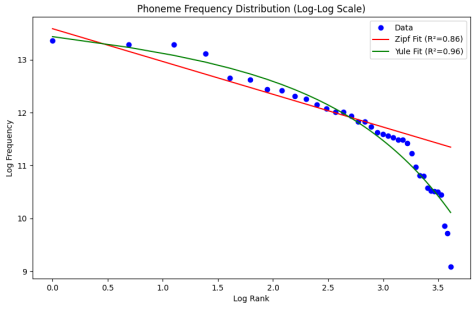

Figure 2: Mandarin phone frequency distribution (log-log scale) with Zipf and Yule fit curves.

The blue dots represent the empirical phone frequency data, while the red and green lines correspond to the Zipf and Yule fits, respectively. Compared to these two models, the Zipf fit, with a correlation coefficient (R) of 0.86, initially follows the data but diverges as the rank increases, suggesting that this model may not fully capture the distribution of less frequent phones. In contrast, the Yule fit, with an R value of 0.96, aligns closely with the data across the entire range, providing a more accurate representation of the phone frequency distribution. The higher R value of the Yule fit signifies a stronger correlation and better explanation for the observed data. Therefore, at this stage, the Yule model appears to be more suitable for representing this distribution.

Mandarin is analyzed as having a range of possible phonetic (i.e., surface) syllables: V, CV, GV, VG, VN, CVG, CVN, CGV, GVG, GVN, CGVG, and CGVN. The maximal syllable is CGVX, with C a [+consonantal] segment, G a glide, V the nucleus vowel, and X either a nasal of a glide (i.e., Wan 1999). The samples of types and token frequencies of a syllable structure, CGVN, in Mandarin are shown in Table 3.

Table 3: Samples of CGVN in IPA and token frequencies.

$$PhonProb_{[\text{ɕjaŋ}]} = \frac{1}{n}\sum_{i=1}^{n}\frac{log(freq(S_i))}{log(freq(P_i))} = \frac{1}{3}\sum_{i=1}^{3}\frac{log(freq(S_i))}{log(freq(P_i))} =$$
$$\left[\frac{Sum\ of\ log\ frequencies\ of\ words\ with\ [\text{ɕ}j]\ inintial\ biphone\ position}{Sum\ of\ log\ frequencies\ of\ words\ with\ any\ biphone\ in\ intial\ biphone\ position} + \right.$$
$$\frac{Sum\ of\ log\ frequencies\ of\ words\ with\ [ja]\ in\ second\ biphone\ position}{Sum\ of\ log\ frequencies\ of\ words\ with\ any\ biphone\ in\ second\ biphone\ position} +$$
$$\left.\frac{Sum\ of\ log\ frequencies\ of\ words\ with\ [\text{aŋ}]\ in\ third\ biphone\ position}{Sum\ of\ log\ frequencies\ of\ words\ with\ any\ biphone\ in\ third\ biphone\ position}\right]/3 =$$
$$\left[\frac{log(freq(\text{ɕjaŋ}))+log(freq(\text{ɕjɛn}))+\cdots}{log(freq(\text{ɕjaŋ}))+log(freq(\text{ɕjɛn}))+log(freq(\text{tɕjaŋ}))+log(freq(mjɛn))+log(freq(pjɛn))+\cdots} + \right.$$
$$\frac{log(freq(\text{ɕjaŋ}))+log(freq(\text{tɕjaŋ}))+log(freq(ljaŋ))+log\left(freq(\text{tɕ}^{h}jaŋ)\right)+\cdots}{log(freq(\text{ɕjaŋ}))+log(freq(\text{ɕjɛn}))+log(freq(\text{tɕjaŋ}))+log(freq(mjɛn))+log(freq(pjɛn))+\cdots} +$$
$$\left.\frac{og(freq(\text{ɕjaŋ}))+log(freq(\text{tɕjaŋ}))+log(freq(ljaŋ)+log(freq(\text{tɕ}^{h}jaŋ))+log(freq(kwaŋ))+log(freq(\text{tʂwaŋ}))+log(freq(k^{h}waŋ))+\cdots}{log(freq(\text{ɕjaŋ}))+log(freq(\text{ɕjɛn}))+log(freq(\text{tɕjaŋ}))+log(freq(mjɛn))+log(freq(pjɛn))+\cdots.}\right]/$$
$$3 = \left[\frac{log(18031)+log(14461)+\cdots}{log(18031)+log(14461)+log(11453)+log(10427)+log(9907)+\cdots} + \right.$$
$$\frac{log(18031)+log(11453)+log(5760)+log(1337)+\cdots}{log(18031)+log(14461)+log(11453)+log(10427)+log(9907)+\cdots} +$$
$$\left.\frac{log(18031)+log(11453)+log(5760)+log(1337)+log(1226)+log(1171)+log(1045)+\cdots}{log(18031)+log(14461)+log(11453)+log(10427)+log(9907)+\cdots}\right]/3 = \left[\frac{26.18886307683207}{1225.5136668570954} + \right.$$
$$\left.\frac{59.79234887458323}{911.7019871418528} + \frac{34.658475044915086}{263.65257960492846}\right]/3 = 0.07280267170780302 \quad (3)$$

Table 3 includes only tokens of CGVN syllables, although Mandarin features additional tokens with various syllable structures in the spoken dataset for CGVX syllables, showing all possible sound sequences and their token frequencies in Mandarin (note that tone is excluded from this study). Formulas (3) and (4) demonstrate the calculation of bigram/biphone phonotactic probability in Mandarin, using the CGVN syllable [ɕjaŋ] as an example, which yields a probability value of 0.073.

$$PhonPrab_{[\text{ɕjaŋ}]} = 0.07280267170780302 \cong 0.073 \quad (4)$$

Formula (3) and (4) demonstrates the calculation of the phonotactic probability for [ɕjaŋ]. In [ɕjaŋ], there are three biphones: the initial biphone [ɕj], the second biphone [ja], and the third biphone [aŋ]. The formula calculates the average positional probability of these three biphones. For the first biphone position, it sums the log10 frequencies of all words beginning with [ɕj] (e.g., [ɕjaŋ], [ɕjɛn], and others) and divides this by the sum of the log frequencies for words containing the first biphone sequence. For the second biphone position, it sums the log10 frequencies of all words containing [ja] in the second position (e.g., [ɕjaŋ], [tɕjaŋ], [ljaŋ], [tɕ^{h}jaŋ], and others) and divides this by the sum of the log frequencies for words containing the second biphone sequence. For the third biphone position, it sums the log10 frequencies of all words containing [aŋ] in the position (e.g., [ɕjaŋ], [tɕjaŋ], [ljaŋ], [tɕ^{h}jaŋ], [kwaŋ], [tʂwaŋ], [k^{h}waŋ], and others) and divides this by the sum of the log frequencies for words containing the third biphone sequence. Finally, the average of these ratios is calculated, resulting in a phonotactic probability of 0.07280267170780302, which can be approximated to 0.073.

In this model, the phonotactic probability is calculated for a given syllable using the token frequencies and a dataset of word types that involve different syllable structures. Initially, the syllable is segmented into a series of bigrams, which represent pairs of adjacent units. Subsequently, for each position within the syllable, the model computes two sums involving one for the logarithm of the same bigram occurring at the position and another for the logarithm of the frequency of all bigrams at that position. The phonotactic probability of the syllable is determined by summing the ratio of these two sums for each bigram in the syllable and dividing by the total number of bigrams in the syllable. This ratio reflects the relative frequency of each bigram in its specific position, as shown below. When a syllable contains only a single vowel, its phonotactic probability is calculated as the ratio of the vowel's logarithmic frequency to the total logarithmic frequency of all single sound syllables.

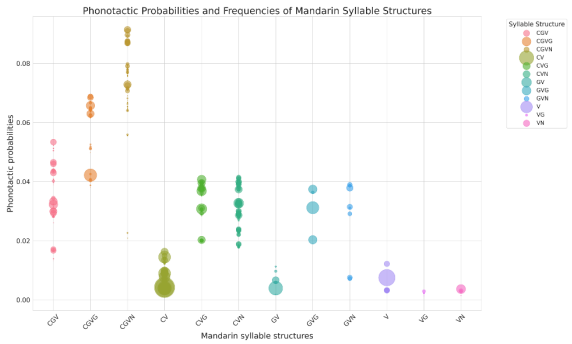

Figure 3: Distribution of phonotactic probabilities across Mandarin syllable structures.

In this figure, the x-axis displays all possible Mandarin syllable structures, including combinations of consonants (C), vowels (V), glides (G), and nasals (N) in legal sound sequences. The y-axis illustrates the phonotactic probabilities, reflecting the likelihood of each syllable structure occurring in Mandarin. Each colored dot corresponds to a specific syllable structure, with the size of the dot indicating its relative frequency or prevalence within the language. Larger dots signify more common syllable structures, while smaller dots represent less frequent ones. Among the structures with four legal sound units, CGVN exhibits the highest phonotactic probability, with a cluster of large dots in the 0.09-0.10 range, followed by CGVG. This is evident based on the formula, where the inclusion of four sound sequences can generate a higher probability (i.e., N+1). In contrast, the CV structure, despite having lower phonotactic probabilities, indicates the most frequent syllable structure in Taiwan Mandarin. The VG structure displays the lowest probabilities and small dot sizes, highlighting its relative rarity in Taiwan Mandarin.

In conclusion, the distribution pattern of speech tokens in Mandarin reveals an uneven distribution of segments, reflecting the legitimate structures within Mandarin syllables. The study suggests that the performance or behavior effects of certain sound sequences are primarily influenced by probabilistic constraints rather than articulatory complexity, such as markedness. Taiwan Mandarin speakers demonstrate sensitivity to frequency variations, with phonotactic probabilities playing a crucial role in shaping speech production, independent of articulatory complexity. These probabilities influence the legality of sound sequences by determining the likelihood of specific phonological segments and sequences within word types. The study further indicates that phonotactic probabilities are encoded within speech production processes and operate independently from traditional measures of phonological/articulatory complexity. While previous research emphasized a strong correlation between speech production and articulatory complexity, this study finds that phonotactic probabilities have a distinct and independent impact. The analysis of frequency-based probabilistic phonotactics in Mandarin, computed using Zipf's Law and Yule's distribution, highlights the importance of these probabilistic constraints in influencing speech production, as evidenced by the examination of a natural spoken corpus of daily conversations.

In this study, we examine the phonotactic probability distribution calculated in a given Mandarin syllable using the token frequencies and a dataset of word types involving different syllable structures. Type and token frequencies in the current spoken data confirm the studies found in English where the possible sound sequences are not all equiprobable as some are more frequent than others. More importantly, certain sound sequences are related to probabilistic constraints and do not fall in the articulatory complexity since the CV-type structure is supposed to be the easiest pattern at a more flexible range, whereas its phonotactic probability is the lowest. The study suggests that phonotactic constraints in Mandarin disassociate articulatory complexity and phonotactic probabilities influence speech production regardless of the markedness complexity. The spoken samples via data computation confirm an emerging agreement within the field that phonological theories need to consider phonotactic probabilities.

4 Limitations

A limitation of the current study is that the Levenshtein edit distance needs to be measured to further calculate neighborhood density. Neighborhood density refers to the number of words that sound similar to a target word. Words with a sparse neighborhood are generally recognized more quickly and accurately, while those with a dense neighborhood may be recognized more slowly and less accurately. Future research should investigate neighborhood density in Mandarin, focusing on how sound-similar words are stored in the mental lexicon.

Acknowledgments

We sincerely appreciate the valuable and constructive comments from the three anonymous reviewers and the editor, which have significantly improved this manuscript. We are also grateful to the audience who attended the conference. All remaining errors in the analysis and interpretation are solely our own. This research was supported in part by the National Science and Technology Council in Taiwan (MOST 111-2410-H-004-091) to the first author.

Cross-Linguistic Variances of Dependency Distances in Multi-Lingual Parallel Corpus

Masanori Oya
School of Global Japanese Studies
Meiji University
masanori_oya2019@meiji.ac.jp

Abstract

This study investigates whether there are differences in the variances of dependency distances of all dependency types across different languages, and also whether there are differences in the variances of dependency distances of core dependency types (nominal subjects, objects, and obliques) across different languages. Statistical tests using a multi-lingual parallel corpus data indicate that there are significant cross-linguistic differences in the variances of dependency distances of different dependency types, yet some language pairs do not show statistically significant differences.

1 Background

The theoretical background of this study is *Dependency Grammar* (*DG*) (Tesnière 1959). In the framework of DG, every word in a sentence depends on another word in the same sentence, and the main verb of the sentence depends on nothing. For example, in the sentence *David read 30 articles for his term paper*, the noun *David* depends on the verb *read* as the subject; the verb *read* depends on no other words in this sentence; the numeral *30* depends on the noun *articles*; the noun *articles* depends on the verb *read* as its object, etc. These dependencies are categorized into different *types*. For example, in the framework of *Universal Dependencies* (UD) (Zeman et al. 2017), the dependency between the noun *David* and the verb *read* is *nsubj* (nominal subject), between the verb *read* and the noun *article* is *obj* (direct object), etc.

Dependency distance (DD) is the number of words from a word in a sentence to the word which depends on the word. For example, in the example sentence above, the DD between the noun *David* and the verb *read* is one; the DD between the numeral *30* and the noun *article* is two; the DD between the noun *article* and the verb *read* is two.

DD attracts many researchers' attention as one of the measures for syntactic complexity (Gibson, 1998, 2000; Gildea and Temperley, 2010; Grodner and Gibson, 2005; Li and Yan, 2021; Liu, 2007, 2008; Liu et al., 2017). Some researchers have argued for the idea that DD represents a certain aspect of the universal properties of natural languages (Ouyang and Jiang, 2018; Ouyang, Jiang and Liu 2022; Wang and Liu 2017; Yang and Li 2019, among others). It is also argued that there is a cross-linguistic preference for shorter DDs due to the limit of short-term memory (*Dependency-Distance Minimization*) (Gibson 2000; Gildea and Temperley 2010; Temperley 2007, 2008, among others).

One of the most unique research programs related to DDs is curve-fitting of the frequency distributions of DDs. Previous studies have discovered that the frequency distribution of DDs can fit well with the right truncated modified Zipf-Alekseev Distribution (ZAD) (Jiang and Liu, 2015; Liu, 2009; Ouyang and Jiang, 2018). Frequency distributions of DDs across different languages also fit well with ZAD, and cross-linguistic variations are represented by different settings of the two parameters of ZAD (Niu, Wang and Liu 2023).

Even though we cannot deny the fact that fitting of the frequency distributions of DDs across languages provides us with a unique and promising field of investigation, it is also certain that there can be cross-linguistic differences among these frequency distributions of DDs which are also of linguistic value. Provided that different settings of the two parameters of ZAD

can indicate cross-linguistic differences of how well they fit with ZAD, it is difficult to interpret these parameters. For example, what does it mean when the parameter a of Language A is larger than that of Language B, and vice versa? In addition to this, it can be assumed that frequency distributions of dependency distances of different *dependency types* are different from each other, yet this assumption cannot be tested by curve-fitting of the frequency distribution of all the dependency distances of one language, and we may need to investigate the behaviors of dependencies of different dependency types in different languages, in order to understand them deeper than now.

2 This study

This study aims to statistically test whether there are differences in the variances of DDs for all dependency types across different languages, as well as for specific dependency types. These tests are expected to confirm that the variances of DDs exhibit significant cross-linguistic differences and that differences in dependency types will be reflected in the variances of DDs. The results of these tests will deepen our understanding of DDs. The research questions of this study are as follows:

1. Are variances of DDs of all the dependency types different across different languages?
2. Are variances of DDs of some dependency types different across different languages?

2.1 Data

The data used in this study come from the *Parallel Universal Dependencies Treebanks* 2.7 (PUD). The details of PUD are available at the Web page of the shared task on Multilingual Parsing from Raw Text to Universal Dependencies in CoNLL 2017 (http://universaldependencies.org/conll17/).

This study covers all the 21 languages in PUD: Arabic, Chinese, Czech, English, Finnish, French, Galician, Hindi, Icelandic, Indonesian, Italian, Japanese, Korean, Polish, Portuguese, Russian, Spanish, Swedish, Thai, and Turkish. Each language in PUD has 1,000 sentences, translated from English sentences, and they have been annotated with morphological and syntactic tags which were provided by Google. They are further converted into *Universal Dependencies* (UD) (Zeman et al. 2017). The details of UD are available at its website (https://universaldependencies.org/).

The fact that the sentences in PUD are translation pairs across languages allows us to regard the syntactic differences (including differences in DDs) across them as being controlled in terms of their meanings.

2.2 Methodology

For each language in the PUD, 1,000 dependencies were randomly selected. Each of these dependencies has a unique DD. This random selection was repeated for all 21 languages in the PUD, resulting in 21 sets of 1,000 DDs (Set 1). Next, for each language in the PUD, the dependencies typed as *nsubj* (nominal subjects), *obj* (direct objects), and *obl* (noun phrases in the oblique case) were extracted, and these extractions were repeated for all 21 languages. This study focuses on these *core* dependency types because they represent the core arguments of predicates, and thus are expected to exhibit the central features of their behavior. Then, we have 21 sets of DDs typed as *nsubj* (Set 2), 21 sets of DDs typed as *obj* (Set 3), and 21 sets of DDs typed as *obl* (Set 4). The sizes of these sets vary across languages. The distribution of DDs is not expected to be normal, so non-parametric statistical tests should be conducted. Therefore, a Kruskal-Wallis test, one of such non-parametric tests, was conducted on each of the sets (Set 1, 2, 3, and 4) independently, using the web application *js-STAR XR+ release 2.1.2 j*, to examine whether their variances are statistically significantly different across the 21 languages.

2.3 Results

Tables 1, 2, 3, and 4 summarize the descriptive statistics of Sets 1, 2, 3, and 4, respectively. Across these sets, the majority of the means do not exceed four, and the medians and the modes are either one or two, indicating that these languages prefer short DDs, and across the three dependency types *nsubj*, *obj*, and *obl*, suggesting the effect of Dependency-Distance Minimization (Gibson 2000; Gildea and Temperley 2010; Temperley 2007, 2008, among others).

Table 2: Descriptive statistics of the DDs of the dependency type *nsubj* in 21 languages of PUD (Set 2); Med.; median: Mod.; mode: ar; Arabic: cs; Czech: de; German: en; English: fi; Finnish: fr; French: gl; Galician: hi; Hindi: id; Indonesian: is; Icelandic: it; Italian: ja; Japanese: ko; Korean: pl; Polish: pt; Portuguese: ru; Russian: sv; Swedish: th; Thai: tr; Turkish: zh; Chinese.

The Kruskal-Wallis test on Set 1 indicated a significant difference of means among them (H = 183.04, $p < .01$). Steel-Dwass tests were conducted to test pairwise comparisons between all the possible language pairs ($n = (21*21-21)/2 = 210$), and 56 pairs were found to be significantly different (about 26% of all the possible language pairs). This means that the majority of the language pairs show similar variances of DDs of all dependency types.

Among the Germanic languages in the PUD (English, German, Icelandic, and Swedish), significantly different pairs are German and Icelandic, and German and Swedish. All the possible pairs of Romance languages in PUD (French, Galician, Italian, Portuguese, and Spanish) are not significantly different. All the possible pairs of Slavic languages in PUD (Czech, Polish, and Russian) are also not significantly different. Variances of several language pairs are not significantly different even though they do not belong to the same language branch or are not used in geographically adjacent areas (e.g., Arabic and Japanese, German and Hindi, Icelandic and Indonesian, Italian and Korean).

Word-order patterns seem to be related to the results of the tests. The variances of Japanese and of Turkish (both are SOV languages) are significantly different from those of 19 other languages except for Arabic (a VSO language); Hindi and Korean (both SOV languages) are significantly different from all the other 20 languages.

The Kruskal-Wallis test on Set 2 showed that there was a significant difference of means among them (H = 4633.55, $p < .01$), and Steel-Dwass tests for all the possible language pairs show that 108 pairs (about 51% of all the possible language pairs) were significantly different. All 6 pairs of Germanic languages in PUD are significantly different, while all 10 pairs of Romance languages in PUD are not significantly different. As for Slavic languages in PUD, only the pair

Table 4: Descriptive statistics of the DDs of the dependency type *obl* in 21 languages of PUD (Set 4); Med.; median: Mod.; mode: ar; Arabic: cs; Czech: de; German: en; English: fi; Finnish: fr; French: gl; Galician: hi; Hindi: id; Indonesian: is; Icelandic: it; Italian: ja; Japanese: ko; Korean: pl; Polish: pt; Portuguese: ru; Russian: sv; Swedish: th; Thai: tr; Turkish: zh; Chinese.

Czech and Polish is not significantly different. Like the test results on Set 1, several language pairs are not significantly different even though they do not belong to the same language branch and they are used in geographically distant areas.

The Kruskal-Wallis test on Set 3 showed that there was a significant difference of means among them ($H = 3972.53$, $p < .01$). Steel-Dwass tests were conducted to test pairwise comparisons, and it was found that 158 pairs were significantly different (about 75% of all the possible language pairs). The four Romance languages in PUD are not significantly different among themselves; only the pair of French and Spanish is significantly different. The three Slavic languages in PUD are not significantly different among themselves. The four Germanic languages in PUD are significantly different among themselves; only the pair of English and Swedish is not significantly different.

The Kruskal-Wallis test on Set 4 showed that there was a significant difference in means among them ($H = 2675.99$, $p < .01$). Steel-Dwass tests were conducted to test pairwise comparisons, and it was found that 149 pairs were significantly different. Several language pairs are not significantly different even though they do not belong to the same language branch. Results are divided within Germanic languages in PUD: Of the possible six pairs, three of them are significantly different (German vs. English, English vs Icelandic, and English vs. Swedish), while three others are not (German vs. Islandic, German vs. Swedish, and Islandic vs. Swedish). Of the possible 10 pairs of Romance languages in PUD, only two pairs are significantly different (French vs. Spanish, Galician vs. Spanish).

3 Discussion

These results described above suggest that Romance languages seem to share similar properties in terms of the variances of dependency distances, yet the variances of

dependency distances of other languages do not suggest any correlation between which language branch they belong to and the variance of dependency distances.

The result that the majority of the language pairs show similar variances of DDs of all the dependency types does not seem to contradict the results of the previous studies on curve-fitting of the frequency distributions of DDs with ZAD. However, the tests of the variances of DDs of different dependency types show noteworthy differences across the languages in the corpus data. These results would not be captured appropriately only by curve fitting of frequency distributions of DDs of all dependency types with ZAD.

We may deepen our understanding of their distributions by testing the variances of the DDs of each of all the other dependency types, to ascertain which dependency types show more cross-linguistic variations than other dependency types.

In addition to this, we may curve-fit with ZAD the frequency distributions of the DDs of not only the core dependency types, but also each of other types, in the same corpus data, to ascertain how well they fit with ZAD. By doing this, we may have some insight into how we can interpret the settings of the parameters of ZAD across different languages and different dependency types, which will be one of the questions of future research.

4 Conclusion

This study attempted to test statistically whether there are differences in the variances of dependency distances of all dependency types across different languages, and also whether there are differences in the variances of dependency distances of core dependency types across languages. The statistical test results indicated that there are significant cross-linguistic differences in the variances of dependency distances in the languages in a multi-lingual parallel corpus. Further studies are required for a better understanding of cross-linguistic variation of dependency distances, while also focusing on their similarities.

"Say What?" Influence of Perceived Self-Confidence in English of Senior High School Students on their Willingness to Communicate in English

Mark Joseph B. Zapanta, MA

Pateros Catholic School, Pateros, Metro Manila, Philippines
mark.j.zapanta@gmail.com

Abstract

English Proficiency is one key factor that enables the development of individuals' confidence to communicate in English with other people. Although, it should be noted that proficiency or confidence in English is not a predictor to willingness to communicate in the said language. Thus, this study is conducted to further explore the connection between the self-perceived confidence in English of Senior High School students and their willingness to engage in English communication inside the classroom. Additionally, the study aims to determine the factors that the participants deem instrumental to their willingness to communicate. Results reveal that while the participants consider themselves confident in English and are usually willing to communicate inside the classroom, there is only a moderate positive relationship between the two variables. This may be attributed to hesitation due to fear of committing mistakes when speaking in class. Additional data reveal that the factors that participants consider instrumental to their willingness to communicate include the strategy and skills of the teacher, their motivation to learn and use English for purposes of self-improvement. Recommendations include the conduct of further studies involving English language competency and willingness to communicate and implementation of programs for teacher development.

1 Introduction

For the past three years (2020 – 2023), the Philippines has been recognized as one of the Asian countries with high levels of English proficiency, second only to Singapore. In the global context, the Philippines continues to place high in proficiency levels, even seeing a drastic jump from rank 27 in 2020 to 18 in 2021. Since then, the rank has seen a slight drop to 22 in 2022 and a mild rise to rank 20 in 2023. [1]

This information is indicative that Filipinos are considered proficient in the English language. However, while this may be true, it should be noted that individuals proficient in a target language (in this case, English) do not necessarily use the language to communicate despite having the opportunity to do so (Haidara, 2016; Katsaris, 2019). It is important to recognize that the communicative competence of individuals is not only based on their knowledge of the language and its technical components but also on how effectively they use this said language in communication (Celce-Murcia, 2007).

In the school setting, oral communication is a key factor that helps determine how actively engaged the students are in discussions. This reflects their abilities to share their ideas, opinions and insights, and experiences related to a particular topic or lesson being discussed. Thus, it is vital to determine up to what extent the students are willing to communicate in English with people inside and outside the classroom and determine the factors

[1] English Proficiency Index: https://www.ef.com/wwen/epi/

contributing to their willingness to use English when communicating.

2 Literature Review

2.1 Willingness to Communicate

Willingness to communicate (WTC) is a person's ability to initiate and engage in communication with other people (McCroskey, 1997 in Zarrinabadi & Tanbakooei, 2016). In line with the discussion of Zarrinabadi and Tanbakooei (2016) which states that willingness to communicate (WTC) in L2 is considered as a character trait and various situational constructs, Katsaris (2019) explains that a learner's WTC using the target language (English) is dependent on the individual's personality, the environment he is part of, and the communicative context of the situation the individual is in.

It is important to take note that WTC is influenced by various factors (Hashimoto, 2022; Lemana, Casamorin, Aguilar, Paladin, Laureano, & Frediles, 2023; MacIntyre Baker, Clément, & Conrod, 2001; Muqorrobin, Bindarti, & Sundari, 2022; Zarrinabadi & Tanbakooei, 2016). This is further emphasized in Macintyre, Dörnyei, Clément, and Noels' (1998) model where different variables influencing WTC are identified. This model shows various variables and potential influences on an individual's WTC in L2.

The model consists of six layers, each representing various structures. The first three layers (I, II, & III) focus on different situation-specific influences. These are flexible in nature and are dependent on the specific context in which an individual acts. The lower three layers IV, V, & VI) are assumed as stable, consistent, and enduring influences on the development of an individual's willingness to communicate. It is worth noting that each layer in the model is interrelated, with the lower layers serving as the platform which serves as the basis for the upper three layers.

2.2 The Role of Environment and Communicative Situations

The lowest layer in MacIntyre's model highlights how different variables associated with social and individual context influence an individual's willingness to communicate. These social contexts may be related to the environment or the communicative situation that individuals are part of (MacIntyre, 2020). It is important to note that exposure to various communicative situations where English is used helps to reinforce in the learners the development of their ability to use English in speaking (Briones, Lleve, Maroto, Sevillano, Villegas, 2023; Zapanta, 2024). Additionally, Menggo, Suparwa, and Astawa (2019), highlighted how lack of support from parents, friends, and immediate circles causes inhibition in the achievement of communicative competence, thus, affecting how willing they are to communicate. This emphasizes the importance of meaningful interaction and support coming from the members of the family, members, friends, and other members of the environment that the learner is a part of (MacIntyre et al, 2001).

The learning environment (Başöz & Erten, 2019; Hashimoto, 2002) is also considered a factor in an individual's WTC. This is further proven by Osboe and Hirschel (2007) who found that being in small groups tends to be more effective in motivating students to speak as compared to having them speak in front of a bigger class. Başöz & Erten (2019) and Matuzas (2021) support this in stating that having smaller class sizes enables teachers to give more opportunities to students for them to speak more when engaging in authentic speaking activities. This allows for positive reinforcement of the students' WTC.

Apart from the class size, having a relaxed classroom atmosphere where the participants feel secure and free from experiencing the fear of being compared with other members of the class helps in the reinforcement of a positive attitude, promoting an environment conducive in strengthening the WTC of students. This is based on the premise that being in a stress-free environment enables students to communicate freely using the target language (Başöz & Erten, 2019; Katsarsis, 2019; Kayaoğlu & Sağlamel, 2013; Matuzas, 2021; Riasati, 2012; Yashima, 2019).

Equally important to take into consideration is the role of teachers in the success or failure of an individual to effectively use English in communicating (Başöz & Erten, 2019; Genelza, Lapined, Suarez, Alvez, Cabrera, & Sabandal, 2022; Kayaoğlu & Sağlamel, 2013; Salayo & Amarles, 2020; Tridinanti, 2018; Zarinabadi, 2014). Juhana (2012) underscored the importance of teachers becoming aware of the factors that may either hinder or motivate them to speak English in class. Matuzas (2021), on the other hand, emphasized the need for teachers to become aware

of the competency levels and skills of the students to help them provide appropriate tasks suitable to the students' abilities.

Furthermore, the teacher's strategy (Juhana, 2012; Kayaoğlu & Sağlamel, 2013; Osboe & Hirschel, 2007; Zarrinabadi, 2014) and the various speaking activities provided to the students are also recognized as variables influencing the students' WTC. It should be noted that giving relevant activities to students which allow them to speak English contributes to their WTC (Alieto & Torres, 2019; Başöz & Erten, 2019; MacIntyre et al, 2001). In addition, the type of tasks given to the students influences their WTC (Matuzas, 2021; Riasati, 2012), with pair and group tasks being preferred more than individual tasks as these types of tasks allow for more interaction amongst the members of the class.

Zarrinabadi and Tanbakooei (2016) explain that the WTC of a person in certain situations depends on the individual's trait and the variables relevant to that situational context. This is highlighted in the model's fifth layer, focusing on the Affective-cognitive context that includes social situation (MacIntyre et al, 2001) and communicative competence (Celce-Murcia, 2007). Several variables associated with social situations such as the purpose of the communication, the attitude and the traits of the participants, the communicative setting (MacIntyre et al, 2001; Zarrinabadi & Tanbakooei, 2016), as well as the topic being discussed (Alangsab & Lambenicio, 2022; Başöz & Erten, 2019; Genelza et al, 2022), and the speaker's proficiency level (Kayaoğlu & Sağlamel, 2013; Muqorrobin et al, 2022; Zarrinabadi & Tanbakooei, 2016) affect the degree of self-confidence and WTC of an individual. It is important to note that self-confidence, deemed as the interplay between a person's perceived competence in communication and low levels of anxiety, is considered instrumental to a person's WTC (Yashima et al, 2004).

2.3 Motivation, Self-Confidence, and Anxiety as Influential Factors to WTC

Also included in the model are various motivational propensities. Motivation has been recognized as a variable that influences individuals to use a target language to engage in communication (Aoyama, & Takahashi, 2020; Briones et al, 2023; Hashimoto, 2002; Zapanta, 2024; Zarrinabadi & Tanbakooei, 2016). Alieto and Torres (2019) further discuss that students are more motivated to learn English if they see it as a means to help in their future undertakings. An individual's motivation to learn English may be attributed to the desire to improve his/her skills in English through acquisition of words and expressions that help in the improvement of their ability to use English to communicate (MacIntyre, 2007; Salayo & Amarles, 2020), or a result of positive interpersonal communication experiences which lead to more interest in intercultural communication (Yashima, Zenuk-Nishide, & Shimizu, 2004).

MacIntyre (2007) placed emphasis on motivation and language anxiety as factors affecting the WTC of a person. Moreover Khoiriyah (2014), found a significant relationship between the speaking achievement of the students and their attitude and motivation. Additionally, having high levels of motivation towards learning a specific target language is connected to having low levels of anxiety (Yashima, 2019), leading to its frequent use in communication. Lao (2020) further confirmed this in her study when she found that learners motivated to learn and improve their skills in the English language tend to use English more frequently. Multiple studies have also confirmed that motivation to learn English is a key factor in affecting the person's WTC (Alangsab & Lambenicio, 2022; Hashimoto, 2002; Lao, 2020; Lemana et al, 2023). It is based on this premise that teachers also need to help build in their students the motivation necessary for them to improve their oral English proficiency (Lemana et al, 2023).

Self-confidence is a crucial aspect to spoken communication (Briones et al, 2023). This is further supported by Ghafar (2023) who found a significant relationship between the self-confidence of an individual and his ability to engage in English communication. Thus, it should be noted that a lack of self-confidence is a factor hindering an individual's motivation to express ideas in front of people using a target language (Briones et al, 2023; Muqorrobin et al, 2022; Riasati, 2012). Furthermore, Naidah (2019) states that learners who struggle with speaking English lack the self-confidence needed. Therefore, it can be stated that learners who have higher perception in their English competence are seen to have more willingness to communicate using the target language (Yashima et al, 2004; Yashima, 2019).

It is vital to develop the motivation necessary for individuals to gain confidence needed to speak

since self-confidence is seen as a factor that influences the willingness of a person to communicate (Aoyama & Takahashi, 2020; Dadulla, 2023). Individuals who have higher motivation levels tend to exhibit higher levels of perceived competence, influencing their self-confidence, and eventually, their WTC (Hashimoto, 2002; Lemana et al (2023); MacIntyre, 2020). In the same vein, Tridinanti (2018) discovered a moderate correlation between a person's self-confidence and his speaking performance, further emphasizing that individuals who exhibit higher levels of self-confidence have the tendency to show higher levels of speaking performance. Moreover, Zhou, Xi, and Lochtman (2020) discovered that the WTC of a person correlates with his/her overall competence in L2, further stating that higher levels of competence in English leads to more engagement in English communications.

Apart from motivation, there are other variables affecting the self-confidence of a person, hindering them from speaking English (Muqorrobin et al, 2022). It is important to understand the complex process involved when learning a second or foreign language due to the influence from multiple factors. One of these factors is anxiety toward learning and using English (Kruk, 2021). Language anxiety is seen as a prominent psychological factor that affects an individual's self-confidence, which also affects their WTC (Dewi & Wilany, 2022; Kruk, 2021; Lemana et al, 2023; Zhou et al, 2020).

Language anxiety develops due to negative experience encountered by an individual in relation to using a target language (Genelza et al, 2022). This is supported by findings stating that individuals who possess high English proficiency levels do not necessarily use the language to communicate due to anxiety and lack of self-confidence (Haidara, 2016; Osboe and Hirschel; 2007). Other causes of anxiety include having a feeling of inferiority when speaking with other people who are better speakers of English (Haidara, 2016), fear of making possible mistakes when speaking (Alangsab & Lambenicio, 2022; Dewi & Wilany, 2022; Haidara, 2016; Juhana, 2012; Kayaoğlu & Sağlamel, 2013), fear of how others would see them when they speak English (Haidara, 2016; Kayaoğlu & Sağlamel, 2013; Listyaningrum, 2017), and hesitation to speak using the target language due to shyness or nervousness (Başöz & Erten, 2019; Juhana, 2012; Nadiah, 2019).

3 Research Problem Statement and Questions

The model presented by MacIntyre et al (1998) clearly discusses a variety of variables that are influential to a person's WTC which are subdivided into multiple layers, each focusing on specific areas and how the variables in each layer contribute to the development and improvement of a person's WTC. However, this study focuses on determining the extent of influence of the students' perceived confidence in English to their willingness to communicate in English. This study aims to assess Senior High School students' confidence levels regarding their ability to use English and determine the extent of influence or connection it has on their willingness to Communicate in English.

Specifically, this seeks to answer the following:

1. How do the participants evaluate their confidence levels in English?
2. How willing are the participants to communicate in English inside the classroom?
3. What factors do the participants consider most influential to their willingness to communicate in English?
4. Is there a significant relationship between the participants' confidence levels in English and their willingness to communicate in English?

4 Methodology

4.1 Research Design

The study is descriptive quantitative research. More specifically, this research follows a correlational research design which aims to determine the degree of association between two distinct variables (Creswell, 2012). In this study, the variables being measured are the Self-confidence of the participants towards using the English language and their Willingness to communicate in English.

4.2 Research Locale and Participants

The study involved Senior High School students at Pateros Catholic School, a private non-sectarian parochial school located in Pateros, Metro Manila.

A total of 380 participants were selected from Grades 11 and 12 levels. Through stratified random sampling, the sections per level to be part of the study were determined. Once the sections have been identified, the students in each section are asked to answer the online evaluation form.

4.3 Research Instrument

To gain objective data from the participants, the participants were asked to answer an online evaluation form. The evaluation form is divided into three categories aligned with the identified targets and objectives of the study: determining their willingness to communicate using English, the participants' self-evaluation of their confidence in using English, and the factors that they deem instrumental towards their confidence in the English language. Each category uses a 4-point Likert scale with indicators reflecting various situations that the participants will evaluate based on what is applicable to them.

To identify the various situations for each category, various instruments from multiple sources were adopted: In determining the willingness to communicate using English, the instrument designed by MacIntyre et al (2001) was used. In determining the self-confidence of the participants towards the use of the English language, the instrument designed by Alieto and Torres (2019) was adopted, albeit with minor changes to contextualize the instrument in line with the objectives of the study, and the instrument used by Lemana et al (2023) served as the basis for determining the factors that the participants deemed influential or instrumental in their confidence to use English.

To validate the instrument, the online questionnaire was initially administered to 44 senior high school students from the same school who were not included in the research sample. Using Cronbach's alpha, the scales yielded the following scores:

- Confidence in using English = 0.883 (acceptable)
- Willingness to speak = 0.837 (acceptable)
- Influential Factors: Environment = 0.821 (acceptable)
- Influential Factors: Anxiety = 0.898 (acceptable)
- Influential Factors: Motivation = 0.888 (acceptable)

4.4 Data Gathering and Analysis

Data gathering was done during English classes at the school's ICT lab to help monitor and facilitate the proper answering of the evaluation forms.

After the students answered the online evaluation forms, the responses were downloaded for proper tallying and interpretation of data. To determine the participants' overall self-perceived confidence levels towards the use of English and their willingness to communicate in English, as well as the factors that the participants deem influential on their confidence to use the English language, weighted mean rating and interpretation was used.

Spearman Rho was used to determine the correlation between the participants' self-perceived confidence in their English language ability and their willingness to communicate inside the classroom. Spearman Rho is the statistical treatment used in determining the correlation coefficient of ordinal variables (Jackson, 2008). This was used since both the confidence levels of the participants and their level of willingness to communicate are considered ordinal variables

5 Results and Discussions

5.1 Participants' Confidence in English

The confidence levels of the participants in terms of the use of English is shown in Table 1. Indicated in the table are various situations reflecting use of the English language.

Based on the data presented, the participants see themselves to be very confident when it comes to comprehending English conversations as evidenced by a mean rating of **3.42** (very confident); additionally, results show that in terms of using English when engaging in casual conversations and academic discussions, the participants consider themselves to be confident in both aspects as reflected by a mean rating of **3.12** and **2.82** respectively. Overall, it can be stated that the participants consider themselves to be

Indicators	Mean	Rank	Interpretation
Engage in formal conversations using English.	2.68	5	confident
Engage in informal/casual conversations using English.	3.12	2	confident
Engage in academic discussion using English.	2.82	3	confident
Communicate and share ideas in English clearly and correctly.	2.67	6	confident
Fluently recite in class using English.	2.55	7	confident
Deliver and discuss reports using English.	2.74	4	confident
Deliver solo performances in front of a large audience like declamation, public speaking, etc.	2.08	8	moderately confident
Understand the details of English conversations.	3.42	1	very confident
Weighted Mean Rating	**2.76**		**Confident**

Interpretation scale:

- ***1.00-1.74****: not confident*
- ***1.75-2.49:*** *moderately confident*
- ***2.50-3.24****: confident*
- ***3:25-4.00:*** *very confident*

Table 1: Self-Perceived Confidence in English

confident in their English language skills as reflected by a weighted mean rating of **2.76**

5.2 Willingness of the Participants to Communicate in English

Table 2 reflects the willingness of the participants to communicate in various situations inside the class.

Based on a mean rating of **3.51**, data shows that participants are almost always willing to communicate in English when interacting with teachers and other people. This suggests that the students can engage in basic English communication. Similarly, the participants

Indicators	Mean	Rank	Interpretation
Reciting/ Answering in class discussions	2.83	5	usually willing
Asking questions for clarifications from the teacher	2.81	6.5	usually willing
Reporting/ Discussing a topic in front of a class	2.63	8	usually willing
Giving instructions to groupmates during group tasks	2.81	6.5	usually willing
Greeting the teachers/ people you meet	3.51	1	almost always willing
Share an idea/ opinion/ suggestion about a topic to your classmates	2.98	3	usually willing
Share an experience or personal story to a friend	2.94	4	usually willing
Discuss answers with your seatmate during pair work	3.08	2	usually willing
Weighted Mean Rating	**2.95**		**Usually willing**

Interpretation scale:

- ***1.00-1.74****: almost never willing*
- ***1.75-2.49:*** *sometimes willing*
- ***2.50-3.24****: usually willing*
- ***3:25-4.00:*** *almost always willing*

Table 2: Willingness to Communicate in English

consider themselves usually willing to communicate in English when discussing answers with their seatmates during pair work activities conducted inside the classroom. This is reflected by the mean rating of **3.08**, which is further supported by the participants' willingness to communicate when sharing ideas or opinions with classmates, which garnered a mean rating of **2.98,** indicating that during the given situation, the participants are usually willing to communicate.

Overall, when it comes to willingness to communicate in English inside the classroom, the

participants consider themselves usually willing to communicate in English as reflected by the weighted mean rating of **2.95**.

Indicators	Mean	Rank	Interpretation
The remarks/comments I receive from my teachers when I speak English.	3.02	4.5	moderate extent
The comments that my classmates give me when I speak English.	2.87	7	moderate extent
The strategies that my teacher uses in English class discussions.	3.27	1	to a great extent
The number of students in the class affects my confidence to speak.	3.02	4.5	moderate extent
The speaking activities provided by the teacher to the students.	3.04	3	moderate extent
Having more opportunities to use English to speak in class.	2.93	6	moderate extent
My teacher's English communication skills influence me to speak English.	3.26	2	to a great extent
Weighted Mean Rating	**3.06**		**Moderate extent**

Interpretation scale:

- ***1.00-1.74****: not at all*
- ***1.75-2.49:*** *limited extent*
- ***2.50-3.24****: moderate extent*
- ***3:25-4.00:*** *to a great extent*

Table 3: The Role of the Teacher and the Learning Environment

5.3 Factors Considered Influential to the Participants' Willingness to Communicate in English

In determining different factors that participants deemed influential to their WTC in English, three major factors were considered: The Role of the Teacher and the Learning Environment, Anxiety and other Psychological Factors, and Motivation to Learn/ Use the Language. The following results are presented based on the data gathered.

5.3.1 The Role of the Teacher and the Learning Environment

Table 3 contains data that shows how the roles of the teacher and the learning environment are deemed influential to the willingness of the participants to communicate.

Based on the data presented, the factor the students consider most influential to their WTC is the strategies used by the teacher inside the classroom as indicated by a mean rating of **3.27** (to a great extent); this is followed by the English communication skills of the teacher with a rating of **3.26** (to a great extent), supporting the findings of Juhana (2012), Kayaoğlu and Sağlamel (2013), Osboe and Hirschel (2007), and Zarrinabadi (2014) which highlights how the strategy of the teacher is an important influence to the students' participation and communication in class.

Much like in the findings of Alieto & Torres (2019), Başöz and Erten (2019), and MacIntyre et al (2001), the speaking activities provided by the teacher is also seen as a factor that influences the participants to communicate in class, with a mean rating of **3.04** (moderate extent). Overall, the results reveal that the participants consider the teacher's role and the learning environment to have moderate influence on their willingness to communicate, as evidenced by the weighted mean rating of **3.06**.

5.3.2 The Role of Anxiety and other Social Factors

Regarding the psychological factors that serve as hindrances to the willingness of the participants to communicate, Table 4 shows that while most of the indicators are considered by the participants to affect their willingness to communicate in English to a moderate extent, a mean rating of **3.25** (to a great extent) suggests that the students consider reported feeling nervous when committing a mistake when speaking a major factor that affects their willingness to communicate.

Following this is the hesitation to speak English due to fear of committing mistakes (**3.17**; moderate extent) and feeling conscious of the facial expressions or reactions of other people whenever they speak English represented by a mean rating of **3.14** (moderate extent). These results confirm the findings of Alangsab and Lambenicio (2022),

Indicators	Mean	Rank	Interpretation
I am afraid of making mistakes when speaking English.	3.17	2	moderate extent
I am afraid of being looked down upon by other students who speak English better than I do.	3.00	4	moderate extent
I become nervous when I realize I made a mistake when speaking.	3.25	1	to a great extent
I am conscious about the facial expressions or reactions of other people whenever I speak English.	3.14	3	moderate extent
I am afraid of being called by my teacher to recite in class.	2.89	7	moderate extent
I always think that other students speak better English than I do.	2.94	6	moderate extent
I want to speak English, but I feel shy to do so because I feel that I am not that good in English.	2.81	8	moderate extent
I always care about other people's opinions about me when I speak English.	2.98	5	moderate extent
I am afraid of making mistakes when speaking English.	3.17	2	moderate extent
Weighted Mean Rating	**3.02**		**Moderate extent**

Interpretation scale:

- ***1.00-1.74****: not at all*
- ***1.75-2.49:*** *limited extent*
- ***2.50-3.24****: moderate extent*
- ***3:25-4.00:*** *to a great extent*

Table 4: Role of Anxiety and other Psychological Factors

Dewi and Wilany (2022), Haidara (2016), Juhana (2012) and Kayaoğlu and Sağlamel (2013), who indicated that hesitation as a result of fear of committing possible mistakes or errors is seen as a factor that causes anxiety in the learners, which hiders them from communicating in English.

Overall, a weighted mean rating of **3.02** indicates that the participants evaluated the various instances to be moderately influential to their willingness to use English in communication.

5.3.3 The Role of Motivation

Table 5 shows how the students evaluate the various instances that motivate them to use English in communication.

The data presented shows that seeing English as a means to promote self-improvement and preparation for their future careers influences them to be more willing to use English when communicating. This is proven by a mean rating of **3.63** (to a great extent); this coincides with the findings of Alieto and Torres (2019) who also determined that their participants see learning English as a way to prepare them for the future. mean rating of **3.63** (to a great extent)

The data also reflects that participants are motivated to speak English with other people as they consider it a way to improve their knowledge of English (**3.46;** to a great extent), and that they are motivated to speak English because they see it as means to improve their skills in oral communication (**3.39**; to a great extent). These findings further support Salayo and Amarles (2020) who stated that the motivation to learn English may be because of the desire to improve one's English skills.

Overall, the participants consider the various instances that motivate them to communicate in English to impact their willingness to communicate. This is indicated in the weighted mean **3.25**, which means that the said instances influence their willingness to communicate up to a great extent. This further confirms the premise the positive influence that motivation has on an individuals' WTC (Alangsab & Lambenicio, 2022; Hashimoto, 2002; Lao, 2020; Lemana et al, 2023).

Indicators	Mean	Rank	Interpretatio
Speaking English makes me feel confident about myself.	2.91	6	moderate extent
Speaking English helps me express myself more effectively.	2.84	7	moderate extent
Speaking English helps me communicate with people who speak English.	3.27	4	to a great extent
I want to learn to speak English to improve myself for my future career.	3.63	1	to a great extent
Speaking English helps me become a more effective student.	3.23	5	moderate extent
Speaking English helps me to improve my oral communication skills.	3.39	3	to a great extent
Speaking English with other people helps improve my English language knowledge.	3.46	2	to a great extent
Speaking English makes me feel confident about myself.	2.91	6	moderate extent

Table 5: Role of Motivation

Interpretation scale:

- ***1.00-1.74****: not at all*
- ***1.75-2.49:*** *limited extent*
- ***2.50-3.24****: moderate extent*
- ***3:25-4.00:*** *to a great extent*

5.4 The Significant Relationship between the Student's Confidence Levels in English and their Willingness to Communicate

The data in Table 6 shows a moderate positive correlation between the confidence levels of the participants regarding their English skills and their willingness to communicate in English. This is indicated by a correlation coefficient value of **0.600.** This suggests that the participants' confidence in English is not a strong indicator of their willingness to communicate in English, thus supporting the premise discussed by Haidara (2016) and Katsaris (2019) stating that individuals who consider themselves proficient in English do not necessarily communicate using the language even when given the chance or opportunity.

			English	WTC
Spearman's rho	English	Correlation coefficient	1.000	**.600****
		Sig. (2-tailed)		.000
		N	380	380
	WTC	Correlation coefficient	**.600****	1.000
		Sig. (2-tailed)	.000	
		N	380	380

*****. Correlation is significant at the 0.01 level (2-tailed).***

Table 6: Correlation Between Confidence in English and Willingness to Communicate

6 Conclusions

The results presented showed the participants' evaluation of their confidence in English, their willingness to communicate, and the factors that they deem instrumental or influential to their willingness to communicate. The study also aimed at determining the significant relationship between the confidence levels of the participants towards the English language and their willingness to communicate.

Results reveal that the participants consider themselves to be confident in their ability to use English. In terms of their willingness to communicate, the participants are usually willing to communicate in English in different situations that entail them to communicate in English, suggesting the presence of hesitation to communicate in English as further proven by Spearman Rho results which revealed a moderate positive correlation between the two given variables.

As mentioned, the results indicated that while the participants consider themselves confident in their English language ability, they are hesitant to use English when communicating inside the classroom. This hesitation may be due to various psychological factors that the participants deem influential in their willingness to communicate. Some of these factors include feeling nervous when they have committed a mistake while speaking English, feeling afraid to speak English for fear of making potential mistakes, and feeling anxious of the would-be reactions of other members of the class when they speak English.

Additionally, other factors that the participants deem instrumental to their willingness to communicate include having the necessary motivation in learning and speaking the language for self-improvement and preparation for their future careers. Inside the classroom, they also consider the teaching strategies and activities provided by the teacher, as well as the teacher's communication skills instrumental in their willingness to communicate.

7 Recommendations

The research focused on determining the connection between the participants' perceived confidence towards the English language and their willingness to communicate in English. However, the study is limited to the willingness of the participants to communicate through spoken discourse. Therefore, it is recommended that a study that aims to determine the confidence towards the English language and willingness to communicate via written discourse be conducted to determine possible similarities or differences.

Since the study involves data based on the perceived confidence of the students toward the English language, it is important to take note of the possibility of bias as the responses rely heavily on the personal interpretation and evaluation of the participants leading to either overestimation or underestimation of their English proficiency skills. It is, therefore, recommended that a study focusing on the English Competency Levels conducted through standardized tests and its influence on willingness to communicate be conducted to further confirm the findings of this study or determine possible alternative findings aligned with the research conducted.

Results show that teachers play a vital role in influencing the willingness of the students to communicate, particularly the teacher's communication skills as well as the teaching strategies used, and the learning activities provided for the students. It also emphasizes the importance of ensuring students are in a learning environment that is conducive to learning and free from factors that cause anxiety.

These findings place emphasis on the importance of providing relevant teacher training workshops and seminars that focus on the following:

1. The improvement of the English communication skills of the teachers across different subject areas.

2. For English teachers, mastery of CLT (Communicative Language Teaching) Approach to help students further improve their English skills which they use to communicate in different interactive activities (Richards & Rodgers, 2001).

3. Familiarization with different teaching strategies such as Problem-based learning (Aslan, 2021), which provides an inclusive learning environment promoting collaboration and communication amongst students through interactive and meaningful learning activities. This enables students to apply critical and analytical thinking skills while also having the opportunity to communicate with other members of the class.

4. Effective integration of technological tools to help further motivate the students to actively participate in class discussions.

As mentioned, the study also shows how the strategies and skills of the teacher and learning environment are deemed influential by the students to their overall willingness to communicate, however, the study itself is limited to only including the teaching strategies and skills in general and excludes a more detailed analysis of the various strategies used.

Thus, it is recommended that a study that explores the relationship between certain teaching strategies of the teacher as well as the different classroom learning environments and the willingness of the students to communicate be conducted to have a clearer understanding of how these variables are connected.

Acknowledgments

This research would not be complete if not for the support of Pateros Catholic School – Senior High School Department, headed by the Principal, Mr. Alvin A. Altarejos, who gave the approval and permission for the research to be conducted. Many thanks also to the Grade 11 and 12 student participants who actively participated in the data gathering process.

The researcher would also like to express his utmost gratitude to the Grade 11 Level Coordinator, Mrs. Ana Adriatico-Rosales, who helped in the facilitation of the data gathering from Grade 11 students and to the STEM Coordinator, Mrs. Maridol Perez-Galvez, who assisted in the use of the ICT rooms used for the data gathering process.

The researcher is also grateful to his partner, Mr. Anthony V. Peñaflorida, whose patience and understanding served as support for the researcher during the writing process of this paper.

Above all, to the Almighty One who has granted strength and dedication to the researcher to accomplish this academic task.

Exploring Sibilant Merge Patterns for Speaker Profiling in Taiwan

Yu-Leng Lin[1,*], Bruce Xiao Wang[2]

* Lngyllin@ccu.edu.tw

Abstract

This study investigates the evolving linguistic landscape of Taiwan by analyzing the phonetic distinction between alveolar and retroflex sibilants in spontaneous Taiwanese Mandarin speech among speakers from northern and southern Taiwan. Analyzing 2,256 tokens, the study found that place of articulation was the only significant factor influencing center of gravity values, with gender, region, and Min proficiency showing no significant effects. Contrary to earlier studies, this research reveals that contemporary speakers, particularly the younger generation, consistently maintain distinct phonetic contrasts. The findings have implications for forensic phonetics, emphasizing the importance of regional and generational variations in spontaneous speech for speaker identification.

1 Introduction

Taiwan Mandarin (TM) exhibits a unique phonological feature: significant variability in the articulation of alveolar and retroflex sibilants. In standard Mandarin, the phonemic contrasts between alveolars /s ts tsʰ/ and retroflexes /ʂ tʂ tʂʰ/[1] play a crucial role in phonological identity. This distinction, however, is highly speaker-dependent, showing significant variation across individuals and regions. The merging and/or merger-in-process between alveolar and retroflexes in TM have long been reported and argued in previous studies (Ing, 1984; Kubler, 1985; Lee-Kim & Yun-Chieh, 2022; Steffen Chung, 2006).

1.1 Taiwan Southern Min influence on sibilant merging

Early work attributed this merging trend largely to Taiwan Southern Min (TSM) influence. Studies by Ing, 1984 and Kubler, 1985 claimed that this sibilant merging might arise from language contact with Taiwan Southern Min (TSM) which lacks retroflex, where speakers with higher TSM proficiency are more likely to have merged alveolar and retroflex fricatives than those who have lower TSM proficiency.

However, later studies rejected this claim (Chuang et al., 2019; Lee-Kim & Yun-Chieh, 2022) where they found that TSM proficiency does not necessarily lead to higher degree of sibilant merging. Nevertheless, previous studies consistently reported substantial between-speaker variation in the realization of retroflex, ranging from palato-alveolar to dental/apical.

The current study investigates the sibilant merging in TM, focusing on variations across different regions (i.e., north/south of Taiwan) and genders at both group and individual levels. Unlike other commonly adopted methods, which often involve reading tasks in controlled lab settings, this study used a map-based Q&A approach to encourage spontaneous speech, allowing sibilants of interest to appear naturally in participant responses. Through this approach, the current study aims to contribute to forensic applications within Taiwan, providing insights into how individual and group levels in sibilant

[1] We acknowledge that the retroflexes in Mandarin may not align precisely with the traditional articulatory definition, where in the back of the tongue tip contacts postalveolar region. Nevertheless, for consistency with prior studies, we employ these terminologies herein.

merging may serve as distinguishing features in phonetic analysis.

A particular focus is on the hypothesis proposed by early studies (Ing, 1984; Kubler, 1985), which suggests that speakers with higher proficiency in TSM are more likely to merge alveolar and retroflex sibilants than those with lower TSM proficiency. This hypothesis highlighted the potential influence of bilingualism and cross-linguistic interaction on phonological processes in TM. However, subsequent research has challenged this view. Chuang, Sun, Fon, and Baayen (2019) and Lee-Kim and Chou (2022) found that TSM proficiency does not necessarily correlate with a higher degree of sibilant merging, suggesting that the factors influencing this phonetic variation are more complex and may involve other sociolinguistic or individual differences. Despite the differing interpretations, these studies consistently report substantial between-speaker variation in the realization of retroflexes, with realizations ranging from retroflex or post-alveolar/palato-alveolar to dental or apical articulations.

1.2 Implications for forensic phonetics and speaker profiling

Understanding these phonetic nuances is not only theoretically significant but also has applied value in forensic phonetics. Forensic phonetics is a specialized field that focuses on the analysis of speech and voice patterns to aid in legal investigations for various purposes (Jessen, 2007, 2008; Rose, 2002). Forensic phonetics provides valuable tools for such analyses, particularly through speaker profiling. Speaker profiling (Schilling & Marsters, 2015) involves estimating a speaker's gender, regional accent, socioeconomic status, educational background, and other characteristics based on their speech patterns, particularly when only a recording of the offender is available. The goal is to assist law enforcement agencies in narrowing down the origin of the questioned speaker. There are broadly two approaches to speaker profiling. The first is the human-centered phonetic approach, which includes acoustic and auditory analysis (Cambier-Langeveld, 2010). The second is the automated method, which uses an automatic system (Brown, Franco-Pedroso, & González-Rodríguez, 2021). Among these, the phonetic approach is the most widely used. In the context of sibilant merging in TM, the variability among TM speakers presents both challenges and opportunities for forensic experts. On one hand, the lack of consistent phonemic contrasts complicates the task of speaker profiling, as traditional phonetic markers may not be reliably present. On the other hand, the unique patterns of sibilant merging within an individual's speech could serve as valuable idiosyncratic features for speaker profiling, especially when traditional phonetic markers are ambiguous or absent.

The current study investigates the phenomenon of sibilant merging in TM, focusing on variations across different regions and gender at both group and individual levels. By analyzing these variables, the study aims to uncover patterns that could be potentially used for speaker profiling in relation to region and gender factors in Taiwan. The findings are expected to contribute to the field of forensic phonetics by providing insights into how regional and gender-based differences in sibilant merging might inform speaker profiling processes. Ultimately, this research underscores the importance of understanding phonetic variation in TM not only as a linguistic phenomenon but also as a critical tool in forensic casework, where the ability to accurately profile speakers can have profound implications for justice and legal outcomes.

The paper is organized as follows. Section 2 outlines the methodology. Section 3 presents results and discussion. Section 4 concludes with an overall discussion and considers the implications for future research.

2 Method

2.1 Participants

Twenty participants, aged 18 to 35, were recruited from National Chung Cheng University in Taiwan. They were evenly divided by gender and region, with 5 males and 5 females from both northern and southern Taiwan. Northern Taiwan was defined as Taipei, Taoyuan, Kinlong, Hsinchu, or Miaoli, while southern Taiwan included Chiayi, Tainan, Kaohsiung, or Pingtung. All participants had lived in their respective regions until the age of 18. The average age of the participants was 23.71 years (SD = 3.36).

All twenty participants reported exposure to Min between infancy and nine years of age. In addition, they all spoke English as a second language, having begun learning it between the ages of 2 and 12. To assess the influence of TSM, participants rated their listening and speaking proficiency in TSM using a seven-point Likert scale, where 1 indicated that participants barely knew the language and 7 represented native-level proficiency. TM and English language proficiency self-rated by participants are shown in Table 1.

2.2 Mandarin production task

To elicit the most natural language data, the experiment was designed in a Q&A format. Participants were shown a printed map of the Taipei MRT and were asked questions such as, "How many stops are there between station A and station B?" and "How do you travel from point A to point B?" Because the names of MRT stops did not include [ts] and [tʂʰ], additional questions were asked to elicit target words containing these sibilants. This approach encouraged participants to focus on finding the correct answers, leading them to pay less attention to their speech. The target words elicited for the production experiment are listed in Table 2. The consonants consisted of voiceless coronal fricatives and affricates, specifically alveolars /s ts tsʰ/ and retroflexes /ʂ tʂ tʂʰ/. These consonants were placed in the syllable-initial position of the first syllable, followed by the nuclei [i], [a], [o], [u], and [ɨ], with or without coda consonants.

		F	M
N	TM listening	7.00 (±0.00)	7.00 (±0.00)
	TM speaking	6.80 (±0.45)	7.00 (±0.00)
	TSM listening	3.60 (±1.52)	4.60 (±2.19)
	TSM speaking	3.20 (±1.10)	4.20 (±2.39)
	English listening	4.60 (±1.14)	5.20 (±0.84)
	English speaking	4.20 (±1.30)	4.80 (±0.84)
S	TM listening	6.80 (±0.45)	7.00 (±0.00)
	TM speaking	6.80 (±0.45)	6.80 (±0.45)
	TSM listening	5.20 (±0.84)	4.80 (±1.10)
	TSM speaking	3.80 (±2.28)	4.20 (±1.92)
	English listening	4.00 (±0.71)	4.60 (±1.67)
	English speaking	3.00 (±1.22)	4.20 (±1.92)

Table 1: Mean language proficiency ratings and standard deviation (in brackets) on a seven-point scale (1= barely know, 7 = native-level).

2.3 Procedure

Before the formal experiment began, the experimenter briefly introduced the participants to the different MRT lines and the cardinal directions (north, south, east, west) on the map, and then proceeded with the questions. Participants were instructed to give detailed answers without looking at the written questions and to use the full names of MRT lines and stations, avoiding abbreviations such as "red line." A total of 59 questions were asked, but only those containing alveolars and retroflexes were analyzed. The number of keywords with alveolars and retroflexes was balanced, with five keywords featuring alveolars in the initial syllable and five featuring retroflexes. Each keyword was elicited at least ten times. The Q&A session lasted approximately 25 to 40 minutes, and each participant received monetary compensation for their time.

2.4 Acoustic and statistical analysis

1st syllable consonant	PoA	IPA	English gloss
[ts]	alveolar	[**ts**uei] [tɕɪn]	"nearest"
[tsʰ]	alveolar	[tɕʰɨ] [tʂɑŋ]	"Qizhang MRT station"
[s]	alveolar	[san] [tʂʊŋ]	"Sanchong MRT station"
[tʂ]	retroflex	[tʂɨ] [ʂan]	"Zhishan MRT station"
[tʂʰ]	retroflex	[tʂʰɨ] [fan]	"eat"
[ʂ]	retroflex	[ʂɨ] [pʰaɪ]	"Shipai MRT station"

Table 2: Sample elicited words.

This study analyzed the Center of Gravity (CoG) of specific keywords. The data, collected from a TM production task, were recorded at a 44.1 kHz sampling rate and preprocessed by filtering out frequencies below 500 Hz (using a pass Hann band filter with a 500 Hz lower limit and 22050 Hz upper limit in Praat (Boersma & Weenink, 2024; version 6.4.16). The annotated sound files marked the onset of frication at the first

appearance of white noise above 1000 Hz in the spectrogram and the end at the beginning of the following vowel (Li, 2008). For spectral analysis, a 23.2 ms Hamming window was applied to the midpoint of the frication. Measurement values were extracted using a custom-written Praat script, with two measurements taken: one spectral moment of the frication noise and the CoG.

A total of 3440 tokens were collected from participants' responses to 59 questions. However, only the keywords containing retroflex ([ʂ, tʂ, tʂʰ]) and dental ([s, ts, tsʰ]) sibilants were analyzed. In total, 2256 tokens from twenty participants were

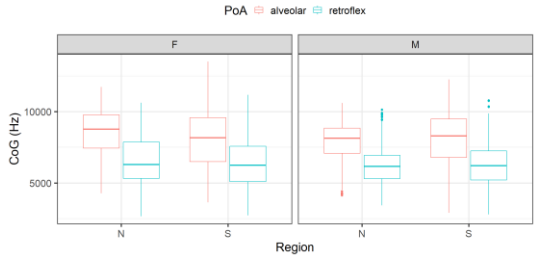

Figure 1. Interaction between PoA, region and gender (N: North, S: South).

included in the analysis. A linear mixed-effects model was used, implemented in the *lme4* package (Bates, Mächler, Bolker, & Walker, 2015) in R version 4.4.1 (R Core Team, 2024).

The independent variables in the study included place of articulation (PoA: alveolars vs. retroflexes), region (Southern Taiwan vs. Northern Taiwan), gender (male vs. female), and Min proficiency (measured on a Likert scale from 1 to 7). A linear mixed-effects model was applied to the data, with PoA, region, and gender as fixed effects, and word and speaker as random effects. Further, we conducted *Pearson's* correlation test to investigate if speakers with higher TSM proficiency would have higher degree of alveolar-retroflex merging, namely, a lower difference in the CoG values.

3 Results and discussion

The linear mixed-effects model analysis revealed that none of the fixed effects, except for PoA, had a significant impact on the center of gravity (CoG) values. Specifically, the results indicate that alveolars and retroflexes remained distinct and separable based on their CoG values ($p < .01$). However, there were no significant differences in CoG values between male and female participants or between speakers from northern and southern Taiwan. See Figure 1.

These results contrast with earlier findings (Ing, 1984; Kubler, 1985), potentially due to differences in the participant groups. The current participants belong to a younger generation characterized by increased mobility, facilitated by improved inter-city transportation in Taiwan and the widespread promotion of Mandarin. In earlier studies, participants typically acquired TSM as their first language and only began learning TM in elementary school. In contrast, the present generation receives a more diversified language education. TSM is just one of several domestic languages offered in elementary schools, alongside Hakka, indigenous languages, Mindong, and Taiwan Sign Language. However, these languages are taught for only one hour per week, and not all students choose to study TSM. As a result, participants in the current study had less exposure to TSM compared to earlier cohorts. The hypothesis that higher proficiency in TSM correlates with a greater likelihood of merging alveolars and retroflexes assumes that TSM is the dominant language, with TM playing a secondary role. In such cases, greater TSM proficiency would be expected to reduce the acoustic differences—such as in the CoG values—between alveolars and retroflexes in TM. However, the participants in the present study experience a reversed linguistic environment: TM is now the dominant language, while TSM is less prominent. This linguistic shift likely contributes to the maintenance of the contrast between alveolars and retroflexes in TM. It is plausible that these participants, who are proficient in TM, TSM, and English, are better equipped to preserve the distinction between these sounds rather than merging them. This interpretation is further supported by the data presented in Figure 2. The figure demonstrates that participants with higher Min proficiency were more likely to maintain a clear distinction between alveolars and retroflexes, although the correlation is low (*Pearson's r* = .08).

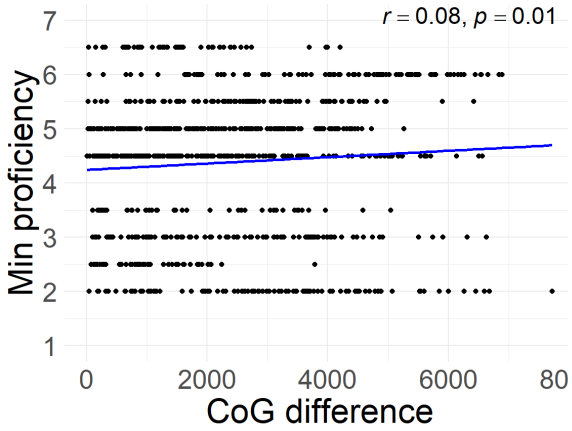

Figure 2. Correlation between Min proficiency and CoG difference.

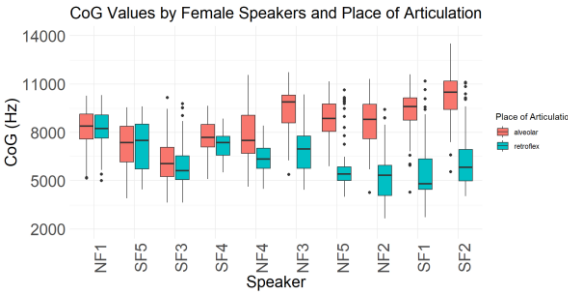
Examining individual speakers reveals findings that support the argument by Lee-Kim and Chou (2022) that an ongoing sound change is occurring in the younger generation, where the variation between alveolar and retroflex sibilants spans a continuum—from complete merger to distinct contrasts. Although there was no significant main effect of gender, Figures 3 and 4 suggest that females exhibited greater variation in their sibilant production compared to males. Specifically, the range in CoG values between alveolars and retroflexes was -100–3900 Hz for females, while for males, the range was narrower, at 700–2400 Hz. This suggests that females generally maintained a more pronounced separation between the two contrasts, with a total range difference of 4000 Hz for females, compared to 1700 Hz for males. This finding aligns with Labov's sociolinguistic claim that women tend to favor and maintain more prestigious linguistic forms, particularly those that preserve phonological contrasts (Labov, 2001).



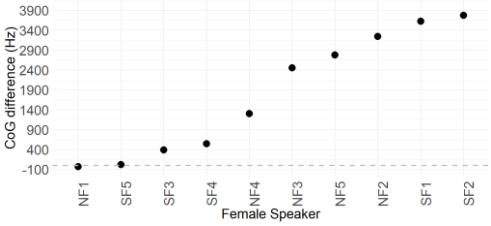


Figure 3. CoG difference of PoA produced by females.

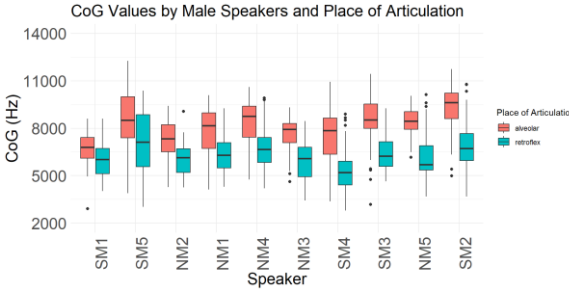

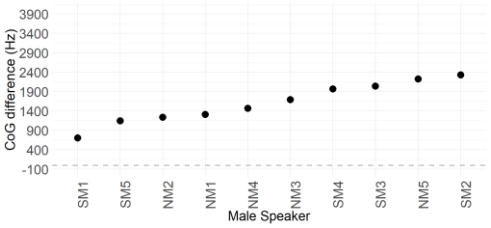

Figure 4. CoG difference of PoA produced by males.

Contrary to earlier studies (Ing, 1984; Kubler, 1985), southerners in this study appeared to maintain a more pronounced separation between alveolars and retroflexes, with a total range difference of 4000 Hz, while northerners exhibited a smaller range difference of 3400 Hz (see Figures 5 and 6). This may be linked to our earlier argument that individuals proficient in TM, TSM, and English are better equipped to preserve distinctions between these sounds rather than merging them. Further supporting this interpretation, Table 1 shows that southerners demonstrated higher Min proficiency, with TSM listening scores of 5.00 and TSM speaking scores of 4.00, whereas northerners scored 4.10 in listening and 3.70 in speaking[2].

[2] According to Lee-Kim and Chou (2022), scores higher than 5 are considered fluent, while those below 3 are considered weak. In the current study, southerners' TSM listening scores fall into the fluent category.

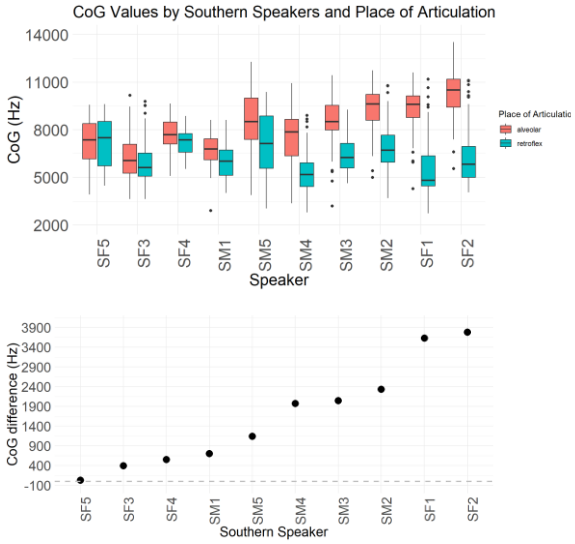

Figure 5. CoG difference of PoA produced by southerners.

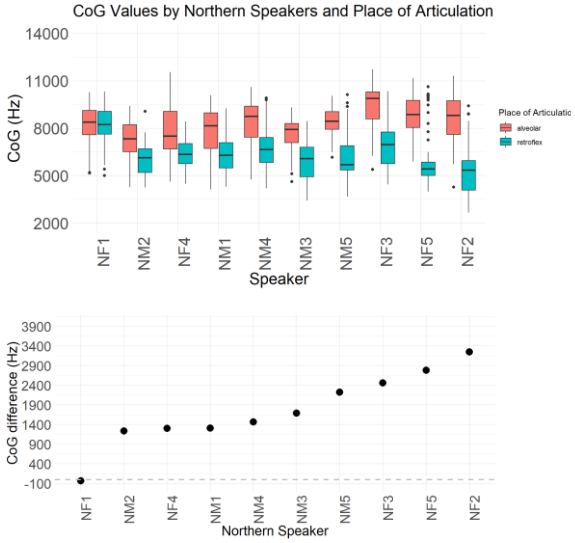

Figure 6. CoG difference of PoA produced by northerners.

4 Implications and discussion

This study sheds light on the evolving linguistic landscape of Taiwan by examining the phonetic distinction between alveolar and retroflex sibilants in TM among speakers from northern and southern Taiwan. Through analyzing 2256 tokens containing retroflex and dental sibilants, the study reveals that PoA was the only significant factor influencing CoG values, while gender, region, and Min proficiency did not produce significant effects. The participants, regardless of background, consistently maintained distinct phonetic contrasts between alveolars and retroflexes.

The results reflect a broader phenomenon of language change. As Lee-Kim and Chou (2022) suggest, ongoing sound changes in younger generations indicate that variation between alveolar and retroflex sibilants now spans a continuum—from complete merger to clear contrasts. This study's findings align with this idea, highlighting that even in a shifting linguistic environment, contrasts are maintained, though the degree of separation can vary.

Gender also plays a nuanced role in this evolving linguistic landscape. Although there was no significant main effect of gender, female participants exhibited greater variation in their sibilant production. The wider range in CoG values observed among females suggests that they are more likely to preserve contrasts than males. This observation echoes Labov's (2001) claim that women prefer and maintain more prestigious linguistic forms, reinforcing the idea that sociolinguistic factors intersect with phonetic variation.

Regional differences in phonetic behavior further emphasize the dynamic nature of language change. In contrast to earlier studies, which suggested greater phonetic merging in southern Taiwan, this study found that southern speakers maintained a more pronounced separation between alveolars and retroflexes. This may be linked to higher language proficiency among southern participants, who demonstrated greater proficiency in TSM and TM. These findings point to the complex and adaptive nature of language use across different generations, regions, and linguistic experiences in Taiwan.

In terms of speaker profiling for forensic applications, the merging patterns of alveolar and retroflex sibilants might not serve as a reliable indicator for distinguishing regional accents. Traditionally, southern speakers are more likely to exhibit a merged accent compared to northern speakers. However, this was not observed in our analysis. This discrepancy is likely due to the shifting linguistic landscape of sibilant merging in Taiwan, influenced by changes in language policy and increased mobility. While phonemic contrasts might not always align with traditional expectations, the unique patterns of sibilant articulation could still provide valuable, individualized markers for forensic experts. As linguistic behavior evolves in Taiwan, understanding these nuances becomes crucial for

accurate speaker profiling. This research not only contributes to the linguistic field but also underscores the practical applications of phonetic analysis in legal contexts, where subtle speech patterns may aid in delivering justice.

Abstract

In this paper, we present RydeeNLP, an innovative approach to Japanese language learning that leverages lexical simplification and adaptive translation techniques. Our approach introduces a novel difficulty scale encompassing elementary, middle, and high school levels, allowing for more precise and tailored language instruction. By using this scale, we have developed a comprehensive difficulty dictionary that categorizes Japanese words according to their complexity. From this dictionary, we further derived a paraphrase dictionary that maps words of similar meanings but different difficulty levels, providing learners with more nuanced vocabulary options. In addition to these resources, we expanded traditional translation models–often limited to noun replacements–to include verbs and adjectives, thereby offering a more holistic translation experience. We also designed a fine-tuned translation model that adapts output based on user-specified difficulty levels, producing translations that align with the learner's proficiency. The combination of these innovations offers a more effective and customizable solution for Japanese language acquisition compared to previous models.

1 Introduction

The popularity of Japanese language learning has surged in recent years, both in the United States and worldwide. Driven by cultural interests, business needs, and global connectivity, more learners are striving to achieve proficiency in Japanese. Despite this growing interest, learners face significant challenges, particularly when preparing for standardized Japanese tests like the Japanese Language Proficiency Test (JLPT). These tests often emphasize rote memorization and fail to adapt to the varying levels of vocabulary and grammar proficiency among students. Existing research has attempted to address these issues. For example, Kajiwara et al. (2020) explored lexical simplification techniques to make Japanese texts more accessible, while Poncelas and Htun (2022) worked on controlling simplification levels. However, these approaches have limitations, such as restricted vocabulary lists that do not cover the full breadth of the Japanese language, resulting in incomplete or overly simplified learning resources.

In response to these challenges, we propose a novel approach that focuses on enhancing Japanese learning and translation efficiency through a comprehensive lexical simplification model. Our design offers three main contributions: (1) A school-level classifier and expanded dictionaries that consider a broader range of words beyond the limited length list, addressing the vocabulary coverage issue; (2) A fine-tuning translation model designed to adapt to various school levels, delivering clear and understandable sentences tailored to the user's knowledge level; and (3) A word-swapping model that ensures accurate and contextually appropriate vocabulary replacement, even in complex Japanese sentences. These innovations not only address the limitations of previous research but also provide a more tailored and effective solution for learners at different stages of their Japanese language journey.

The remainder of this paper is structured as follows: Section 2 provides an overview of related work, highlighting the existing challenges in Japanese lexical simplification and translation. Section 3 details the datasets we used for the project. Section 4 describes the development of school-level classifier model, difficulty and paraphrase dictionary, and our translation models, including both fine-tuning and word-swapping approaches. In Section 5, we present the results of our experiments, including a comparison of BLEU scores for different models and a discussion of their implications. Section 6 outlines future development directions and potential improvements to enhance the effectiveness of our approach further. And finally, we conclude the paper in Section 7.

2 Background

Our research focuses on developing dictionaries and translation methodologies that build upon prior studies in the field of Japanese language learning. Previous studies have categorized vocabulary using various labels, such as JLPT levels and the Japanese Educational Vocabulary dictionary, which classifies words into six levels based on the input of five Japanese teachers (Sunakawa et al., 2012). However, for our research, we chose to use school or textbook levels–elementary, middle, and high school–as our categorical labels. The public textbook dataset we utilized includes approximately 50,000 words, which is significantly larger than other datasets like the JLPT dataset (Poncelas and Htun, 2022) (15,000 words), and the Japanese Educational Vocabulary dictionary Sunakawa et al. (18,000 words). This extensive dataset provides a broader range of language resources, enhancing the scope of our research compared to previous studies.

From this comprehensive school-level dataset, we developed a classifier capable of predicting the difficulty of words and categorizing them into three school levels. This classifier extends the selection of words beyond those explicitly listed in the textbook dataset, inspired by the methodologies of Hading et al. and Kajiwara et al.. Additionally, we created two types of dictionaries: a difficulty dictionary and a paraphrase dictionary. These efforts are influenced by the research conducted by (Kajiwara et al., 2020) and (Hading et al., 2016).

To construct the difficulty dictionary, we applied our classifier model to predict the school level of words within a large Japanese corpus. Concurrently, we developed a paraphrase dictionary, which groups words with the same meaning but different difficulty levels. According to Kajiwara et al., there are three primary approaches to building a paraphrase dictionary: dictionary-based, parallel corpora, and distributional similarity methods. Our approach combines dictionary-based and distributional similarity methods. By utilizing the thesaurus published by the National Institute for Japanese Language and Linguistics (NINJAL) to include semantically similar words, and integrating our classifier model with the difficulty dictionary, we were able to create an extensive paraphrase dictionary. This comprehensive resource enables the development of a more versatile translation model that goes beyond predefined word lists.

For the translation process, we trained two types of translation models. The first model was developed by fine-tuning an existing English-Japanese translation model, inspired by Poncelas and Htun. The use of tags added to source sentences to control the output of neural machine translation (NMT) models has been explored across different domains (Chu et al., 2017) and languages (Johnson et al., 2017). In our model, tags indicating the school level were added at the beginning of the English input, allowing the model to learn the relationship between words and school levels during the fine-tuning process.

The second model utilizes a pragmatic word swapping approach. This model generates a single Japanese translation according to a user-specified school-level tag, and words beyond the user's specified level are swapped to ensure that all words in the sentence are easier than the chosen difficulty level. Through these translation models, we aim to expand Japanese translation resources and develop a word-level translation model that aligns more closely with users' vocabulary knowledge. The methodologies and resources employed in our research are compared in Table 1.

3 Datasets

The construction of the difficulty dictionary in this study leverages a diverse set of high-quality datasets, carefully curated from multiple authoritative sources. These include a textbook corpus across all subjects, the Balanced Corpus of Contemporary Written Japanese (BCCWJ) for a comprehensive representation of modern written Japanese, and the JA-wiki corpus for extensive lexical coverage derived from online encyclopedic content. Additionally, we incorporated the Asahi Newspaper Word Vector dataset to capture contemporary usage patterns and the Bunrui Goi Hyo Database, a well-regarded Japanese thesaurus, to enhance semantic richness. To ensure the adaptability of our models across different contexts, we also utilized the SNOW T-23 parallel corpus for aligned bilingual data and complemented our resources with a web-scraped dataset to cover emerging trends and colloquialisms. This multifaceted approach ensures a robust and versatile foundation for the development of our lexical simplification tools, enabling more nuanced and context-sensitive applications.

3.1 Existing Datasets

The Textbook Dataset (NINJAL, 2011), provided by the National Institute for Japanese Language and

Table 1: Literature Comparison

Linguistics (NINJAL), includes textbooks from the 2005 school year across elementary, middle, and high school levels. This dataset provides detailed word frequency data across various educational levels and subjects, and the words in this dataset includes elementary level: 13k, middle school: 12k, and high school: 23k. For our purposes, words appearing at multiple educational levels were categorized according to the lowest level at which they first appeared, allowing us to establish a baseline vocabulary progression for school-level classifiers.

3.1.1 BCCWJ, JA-wiki, and Asahi Newspaper Word Vector

To supplement the Textbook Dataset, we incorporated additional resources: the Balanced Corpus of Contemporary Written Japanese (NINJAL, 2013b) (BCCWJ), JA-wiki (Wikimedia Foundation, 2024), and Asahi Newspaper Word Vectors (Asahi Shimbun Company and Retrieva, Inc., 2017). These datasets provide a broad spectrum of contemporary written Japanese across different genres, helping to capture a diverse range of vocabulary and usage. Word frequencies from BCCWJ and JA-wiki, along with 300-dimensional vectors from the Asahi Newspaper dataset, were employed as features in the word difficulty prediction model, ensuring a robust representation of Japanese language usage.

3.1.2 Bunrui Goi Hyo Database (Japanese Thesaurus)

The Bunrui Goi Hyo Database (NINJAL, 2004) serves as a comprehensive thesaurus, offering valuable insights into word meanings and synonyms. This information is crucial for building a paraphrase dictionary later.

3.1.3 SNOW T23

The SNOW T23 corpus (Katsuta and Yamamoto, 2018), consisting of 35,000 English-Japanese parallel sentences, provides data on sentence simplification, which helps evaluate our translation and simplification models.

3.2 Scraped Web Dataset

A significant contribution of our research is the creation of a Scraped Web Dataset, specifically curated to capture vocabulary tailored to different educational levels as presented on various online platforms. Unlike existing datasets that are limited to predefined contexts or formats, this dataset dynamically encompasses a wide range of educational materials available on the web, reflecting contemporary language use and emerging trends in Japanese education.

As shown in Figure 1, to construct this dataset, we systematically scraped websites designed for students at various school levels, capturing a diverse collection of words and phrases. By classifying words based on the lowest educational level at which they appear, similar to our methodology for the Textbook Dataset, we ensured consistency while greatly expanding the lexical database. This dataset allows for more granular control over the vocabulary selection process in our difficulty prediction models, ensuring they are relevant, current, and directly applicable to the learners' needs.

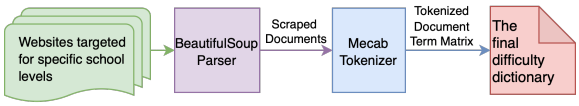

Figure 1: Web Scrapping Process

4 Design

4.1 Overview

In this section, we present the design of our system, which includes five main components: (1) a word difficulty classifier, (2) a difficulty dictionary, and (3) a paraphrase dictionary. These components work together to create (4) a translation model fine-tuned for specific complexity levels and (5) a word-swapping model that adjusts word difficulty according to user specifications. Each component is carefully designed to address the challenges of Japanese language learning and provide tailored resources for learners.

Features
Word Frequency in BCCWJ corpus
Word Frequency in JA-wiki corpus
Part of speech
Goshu (classification of Japanese words by their origin as Japanese, Chinese or Western)
300-dimension Vector Dependency-Based Word Embeddings from Asahi Newspaper Word Vector

Table 2: Features of the School-level Classifier

4.2 Word Difficulty Classifier

Our word difficulty classifier is a crucial component designed to categorize words into three school-level labels. The classifier leverages five features, as detailed in Table 2, to accurately predict the difficulty level of a given word.

The classifier employs the MeCab library, a Japanese morphological analysis tool, to obtain detailed information such as part of speech and Goshu. The choice of using the mecab-ipadic-NEologd dictionary allows for a more extensive collection of contemporary words, enhancing the classifier's performance. An example of morphological analysis using MeCab is shown in Figure 2.

Figure 2: Morphological analysis using MeCab

In developing the classifier, we tested various machine learning models, including Support Vector Machine (SVM), Naive Bayes, Random Forest, Multilayer Perceptrons (MLP), Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), and Long Short-Term Memory networks (LSTM). Table 3 summarizes the parameters used for these models.

4.3 Difficulty Dictionary

The difficulty dictionary is constructed using a combination of curated and created datasets: a textbook dataset, a web-scraped dataset, and words extracted from BCCWJ, JA-Wiki, and Asahi Newspaper Word Vector. The dictionary categorizes 149,000 entries by school level, significantly surpassing the size of previous dictionaries and providing a more comprehensive resource for assessing word difficulty.

For a word to be included in the classifier, it must appear in these datasets, ensuring consistency and accuracy across our models.

4.4 Paraphrase Dictionary

The paraphrase dictionary is a key component designed to enable nuanced translations by mapping words with similar meanings across different difficulty levels. This allows users to tailor translations according to the desired proficiency level, enhancing the adaptability and educational value of the translations.

Words in the paraphrase dictionary are grouped based on combinations of difficulty levels, such as `(high, elementary)`, `(high, middle)`, and `(middle, elementary)`. This classification helps users select appropriate vocabulary that aligns with specific learning goals.

To construct the paraphrase dictionary, we first identified groups of semantically similar words across different levels using the difficulty dictionary. For words that are not present in the difficulty dictionary but appear in the BCCWJ, JA-wiki, and Asahi Newspaper Word Vector datasets, we employed a classifier to predict their corresponding school grade level.

To determine the most appropriate paraphrases, we calculated the cosine similarity between a higher-level target word and each lower-level word in the group. This metric allowed us to identify pairs of words with the highest semantic similarity, ensuring that the replacements are contextually appropriate and meaningful.

For example, consider a group of words with meanings related to "important" (e.g., [大切, 大事, 重い, 肝要, 肝心, 肝心かなめ, 緊要, 喫緊, 重要, 枢要, 主要], as shown in Table 4). To find the most similar elementary-level word to 肝要 (vital), which is classified at the high school level, we calculated the cosine similarity between 肝要 and four elementary-level words ([大切, 大事, 重い,

重要]). The pair with the highest cosine similarity score was (肝要, 大事) with a score of 0.608, indicating that 大事 (important) is the best match for substituting 肝要 while maintaining the intended meaning (see Table 5). This systematic approach ensures that the paraphrase dictionary is both comprehensive and precise, providing users with reliable word substitutions that are sensitive to varying proficiency levels.

words-group	words
High	肝要　緊要　喫緊　枢要
Middle	肝心　肝心かなめ　主要
Elementary	大切　大事　重い　重要

Table 4: Words and Their Groups Example

Target Word (High)	Elementary words	Cosine Similarity
肝要 **(vital)**	大切 (crucial)	0.55890274
	大事 (important)	**0.60757375**
	重い (important)	0.22134371
	重要 (significant)	0.48181933

Table 5: Cosine Similarity between the Target and Elementary Words

The paraphrase dictionary contains 103k word combinations. The outcome of dictionaries is summarized in Table 6.

Name	Label	Number of Words
Difficulty Dictionary	Elementary	33k
	Middle	16k
	High	100k
Paraphrase Dictionary	High - Elementary	58k
	High - Middle	30k
	Middle - Elementary	15k

Table 6: Word Count Breakdown of Dictionary Dictionary and Paraphrase Dictionary

4.5 Translation Model with Fine-Tuning

Our translation model is designed to produce translations that are tailored to specific complexity levels by incorporating school-level tags into the input sentences. This model is built on the fugumt-en-ja architecture, a transformer-based Sequence-to-Sequence model derived from Marian MT, which has been adapted for English-to-Japanese translation. The fugumt-en-ja model comprises six layers in both the encoder and decoder, providing robust performance for our targeted translation tasks.

To achieve translations suitable for different proficiency levels, we integrate special tokens into the input sentences. This approach, inspired by prior work in domain adaptation and multilingual translation (Chu et al.; Johnson et al.), allows us to control the difficulty level of the output. For Japanese, Poncelas and Htun have demonstrated that adding difficulty tags effectively enhances the precision of translation models by aligning vocabulary complexity with desired learner levels.

The fine-tuning process of the translation model involves the following steps:

Replace Words into Dictionary Form: We use MeCab to process each sentence and extract the dictionary forms of all words. This standardization step is crucial for consistent tagging and processing.

Add School-Level Tags to Each Sentence: Each word's school level is determined by referencing a predefined difficulty dictionary. The overall level of a sentence is set by the highest school level present among its words. We then construct a token in the format Ln based on the sentence's school level n (e.g., $L0$ for elementary, $L1$ for middle school, and $L2$ for high school). By incorporating these tokens, the model learns to associate input tags with corresponding vocabulary levels, enabling controlled output generation during the decoding process.

Expand the English Source-Side Sentence: The English source sentence is expanded by prepending the appropriate school-level token (e.g., $L2$, $w1$, $w2$, ...), ensuring the model aligns the input with the desired complexity level.

Fine-Tune the FuguMT Model: The FuguMT model is fine-tuned using the preprocessed input sentences with embedded school-level tags, optimizing its performance for generating translations that match specified difficulty levels.

To create a balanced training dataset for fine-tuning, we utilized multiple corpora as shown in Table 7, ensuring a diverse and representative sample of text. After classifying sentences by their difficulty levels, we curated datasets to avoid label imbalances, resulting in approximately 0.25 million sentences for each level. This careful balancing ensures that the model learns effectively across all difficulty levels.

4.6 Word Swapping Model

The Word Swapping Model is a second translation model designed to adjust word difficulty levels in translations based on user-specified preferences, using a unified Japanese translation as a starting

Name	Data Size
The Multitarget TED Talks Task (MTTT)	158k
English-Japanese Translation Alignment Data	118k
The Kyoto Free Translation Task	218k
Japanese-English Subtitle Corpus	314k
Tanaka Corpus	148k
Bilingual Corpus of Laws and Regulations	186k
JParaCrawl	200k

Table 7: Datasets used for fine-tuning

point. This model allows for dynamic adaptation of vocabulary to match the desired complexity level, enhancing the educational utility of translations.

A significant challenge in developing this model lies in the complexity of Japanese grammar, particularly in verb conjugations. Japanese verbs undergo various forms of conjugation influenced by their row (gyō, 行) in the syllabary and specific conjugation patterns. Understanding these patterns is essential for accurately modifying words to match different difficulty levels without compromising grammatical correctness.

In Japanese syllabary tables, gyō refers to horizontal rows of kana organized by their initial consonant sounds. Each row is named after its first syllable, as illustrated in Table 8.

	あ (a)	い (i)	う (u)	え (e)	お (o)
あ行 (a-gyō)	あ (a)	い (i)	う (u)	え (e)	お (o)
か行 (ka-gyō)	か (ka)	き (ki)	く (ku)	け (ke)	こ (ko)
さ行 (sa-gyō)	さ (sa)	し (shi)	す (su)	せ (se)	そ (so)
た行 (ta-gyō)	た (ta)	ち (chi)	つ (tsu)	て (te)	と (to)
な行 (na-gyō)	な (na)	に (ni)	ぬ (nu)	ね (ne)	の (no)
は行 (ha-gyō)	は (ha)	ひ (hi)	ふ (fu)	へ (he)	ほ (ho)
ま行 (ma-gyō)	ま (ma)	み (mi)	む (mu)	め (me)	も (mo)
や行 (ya-gyō)	や (ya)	-	ゆ (yu)	-	よ (yo)
ら行 (ra-gyō)	ら (ra)	り (ri)	る (ru)	れ (re)	ろ (ro)
わ行 (wa-gyō)	わ (wa)	-	-	-	を (wo)
ん行 (n-gyō)	ん (n)	-	-	-	-

Table 8: Gojūon (Japanese Syllabary) Table

Japanese verbs are categorized into five main conjugation patterns: (1) **Five-Class Conjugation (五段活用)**, (2) **Upper Ichidan Conjugation (上一段活用)**, (3) **Lower Ichidan Conjugation (下一段活用)**, (4) **K-Verbs Irregular Conjugation (カ行変格活用)**, (5) **S-Verbs Irregular Conjugation (サ行変格活用)**.

Each pattern can transform verbs into six different forms depending on the context, including: (1) **irrealis (未然形)**, (2) **continuative (連用形)**, (3) **conclusive (終止形)**, (4) **attributive (連体形)**, (5) **hypothetical (仮定系)**, (6) **imperative (命令形)**.

Additionally, verbs may undergo special euphonic changes (音便, onbin) in certain forms of the Five-Class Conjugation, such as: **I-Sound Euphony (イ音便)**, **Promotive Euphony (促音便)**, **N-Sound Euphony (撥音便)**.

Another complexity comes from the three types of characters in Japanese: Hiragana (ひらがな), Katakana (カタカナ), and Kanji (漢字). Verbs primarily consist of Kanji and Hiragana. To replace higher-level verbs with simpler ones effectively, we first convert the Hiragana part of the verb to the Roman alphabet, apply the necessary conjugations, and then convert it back to Hiragana. This approach allows for precise management of complex verb conjugations in Japanese. A similar process is employed for adjectives, while noun transformation involves directly swapping one noun for another. Table 9 summarizes this process.

To accurately manage these complexities in word swapping, our model uses the MeCab library to analyze and retrieve detailed grammatical information about each word, focusing on how to modify words while maintaining grammatical accuracy.

Name	POS	Words/Forms that Follow
未然形 Imperfective Form	verb, adjective	～ない (nai), ～う (u),～よう (you)
連用形 Continuative Form	verb, adjective	～ます (masu), ～た (ta)
終止形 Conclusive Form	verb, adjective	Period
連体形 Attributive Form	verb, adjective	Noun
仮定形 Hypothetical Form	verb, adjective	If statement
命令形 Imperative Form	verb	Period

Table 9: Forms Validation of Conjugation Types

The word swapping model follows a structured process to ensure that translations are both natural and contextually appropriate. This process is detailed step-by-step in Algorithm 1. As illustrated in Figure 3, consider the original English sentence, "Treat a sprained foot." Without the word-swapping model, the Japanese translation would be "捻挫した足を治療する," which is classified as high-school level difficulty based on our dataset (Step 1). However, after applying the 8-step word swapping model, the translation is transformed into "くじいた足を治す," which simplifies the language by using more Hiragana and less Kanji, thereby adjusting the difficulty to the elementary school level.

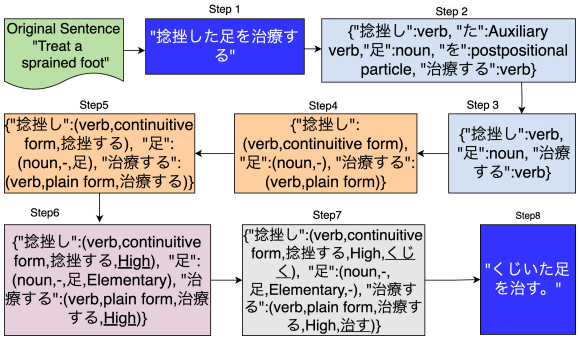

Figure 3: Word Swapping Process

Algorithm 1 Word Swapping Algorithm

Input: Sentence S, Difficulty Level L
Output: Modified Sentence S'
Step 1: Generate Unified Translation
$T \leftarrow FuguMT(S)$
Step 2: Tokenization and POS Tagging
$D \leftarrow MeCab(T)$ {Dictionary D pairs words with their POS}
Step 3: Retrieve Target Words
$W \leftarrow \{w \in D : POS(w) \in \{noun, verb, adjective\}\}$ {Exclude proper nouns}
Step 4: Conjugation Form Recording
for each word $w \in W$ **do**
    $Conj(w) \leftarrow MeCab(w)$
end for
Step 5: Infinitive Form Conversion
for each word $w \in W$ **do**
    $w \leftarrow Infinitive(w)$
end for
Step 6: Identify Upper-Level Words
$W_{upper} \leftarrow \{w \in W : Level(w) > L\}$
Step 7: Word Swapping Based on Difficulty Level
for each word $w \in W_{upper}$ **do**
    $w' \leftarrow ParaphraseDict(w, L)$ {Find simpler word w'}
    if w' **is not found then**
        $w' \leftarrow FindAlternative(w, L)$ {Use Word Vector and Classifier}
    end if
    $w' \leftarrow Conjugate(w', Conj(w))$ {Restore original conjugation}
end for
Step 8: Construct Modified Sentence
$S' \leftarrow Reconstruct(T, W_{upper})$
Return S'

5 Evaluation

5.1 Model Accuracy Performance

The performance of the classifier models was evaluated based on accuracy and the distribution of classifications across different school levels. Figure 4 shows the accuracy results for various models. The Multilayer Perceptrons (MLP) model was selected as the optimal classifier for this study due to its high accuracy and balanced classification distribution.

While the Random Forest classifier achieved the highest accuracy, it tended to classify an excessive number of words as high school level, leading to a significant class imbalance (Figure 5). This imbalance could result in a biased difficulty dictionary, adversely affecting the overall model performance and translation quality. In contrast, the MLP model provided a more balanced distribution across elementary, middle, and high school levels, making it more suitable for generating comprehensive and evenly distributed dictionaries.

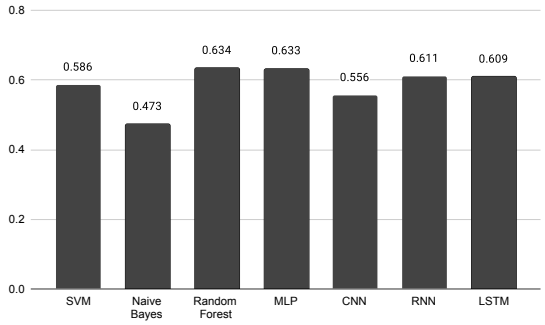

Figure 4: Classifier Accuracy

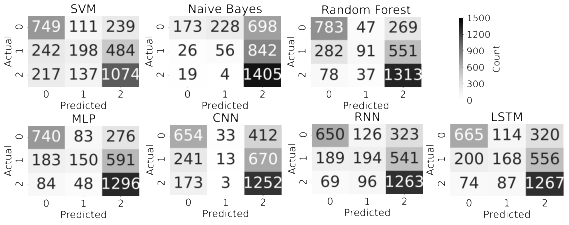

Figure 5: confusion matrix of each model

5.2 Model Latency Test

We also evaluated the latency of each model to understand the computational efficiency of word difficulty evaluation. Figure 6 presents the latency test outcomes, measured in milliseconds per word. Except for the Support Vector Machine (SVM) and Convolutional Neural Network (CNN) models, all models completed the difficulty evaluation in under 1.0 ms per word, demonstrating high speed and suitability for real-time applications. The tests were conducted on a machine configured with an N2-standard-8 instance, 32GB of RAM, and four vCPUs. These results suggest that the MLP model not only offers balanced accuracy but also performs efficiently, making it a strong candidate for practical deployment.

5.3 Translation Models

The quality of the translation models was assessed using the BLEU score, a standard metric for evaluating machine translation quality. The BLEU scores for various models are summarized in Table 11. As a benchmark, we sampled 5000 sentences from the SNOW T23 Parallel Corpus.

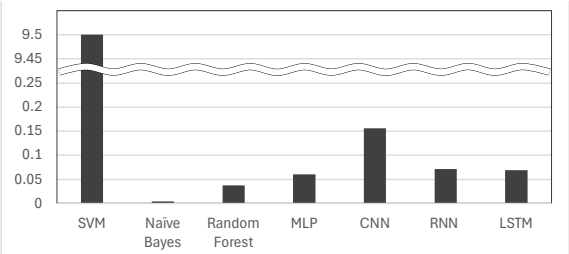

Figure 6: Model Inference Latency (ms/word)

Parameter	Setting
Training dataset in variable lengths	0.2M, 0.4M, 0.75M (full-dataset)
Epochs	1, 2, 4
Learning rate	2e-5, 5e-5

Table 10: Fine-tuning Parameters

The plain Fugu-MT model achieved a BLEU score of 0.191, serving as a baseline for comparison. Fine-tuned models, optimized with various training dataset lengths and epochs (see Table 10), produced lower BLEU scores, with the best-performing models achieving scores of 0.156 for elementary, 0.158 for middle, and 0.159 for high school levels. This decline in BLEU scores suggests that fine-tuning on specific difficulty levels, while improving vocabulary adaptation, may reduce overall translation fluency due to frequent word substitutions.

Interestingly, the word-swapping model consistently outperformed the fine-tuning models across all school levels, indicating that this approach maintains a better balance between preserving translation fluency and adapting vocabulary complexity. Although the BLEU scores of our models are lower than those reported by Poncelas and Htun, this discrepancy is expected because our model considers all words in a sentence, not just those on a limited list like the JLPT. As a result, our model swaps words more frequently, which can naturally lead to a lower BLEU score but provides more comprehensive vocabulary adaptation.

Model	Elementary	Middle	High
Fugu-MT	0.191	-	-
Word-Swapping	0.170	0.176	0.178
Fine-tune[0.2M, 1Epoch]	0.137	0.138	0.139
Fine-tune[0.2M, 2Epoch]	0.137	0.139	0.140
Fine-tune[0.2M, 4Epoch]	0.140	0.144	0.145
Fine-tune[0.4M, 1Epoch]	0.153	0.156	0.158
Fine-tune[0.4M, 2Epoch]	0.155	0.156	0.158
Fine-tune[0.4M, 4Epoch]	0.156	0.158	0.159
Fine-tune[0.75M, 1Epoch]	0.128	0.134	0.137
Fine-tune[0.75M, 2Epoch]	0.132	0.135	0.139
Fine-tune[0.75M, 4Epoch]	0.134	0.138	0.144

Table 11: The BLEU Scores

6 Future Development

To advance our Japanese lexicon simplification and translation methods, several areas need focused development. Enhancing the accuracy of the word-level classifier is a key priority. Refining this classifier with additional training data and advanced techniques could improve its ability to capture nuanced differences in school levels. Improving lower BLEU scores in fine-tuning translation models is also a significant component for the future. By exploring various architectures and hyperparameters, model performance and alignment with desired accuracy may be improved. The word-swapping approach must adopt a more consistent strategy to resolve complicated Japanese grammar, such as prefix issues. The complexity of Japanese grammatical structures and exceptions complicates the production of error-free sentences using the word-swapping model. If the fine-tuning model's performance improves, it is likely to become the more practical choice due to the fine-tuning model's better handling of Japanese grammar.

7 Conclusion

Our approach to simplifying the Japanese lexicon through the creation of difficulty and paraphrase dictionaries, along with a word-level classifier, demonstrates significant potential. The expanded vocabulary coverage should be beneficial for various Japanese translation tasks. The exploration of translation methods—fine-tuning and word-swapping—highlights both benefits and challenges. Although the fine-tuning method currently yields a slightly lower BLEU score, it offers a sophisticated means of learning vocabulary difficulty relationships. Conversely, the word-swapping method, while more direct, presents complexities in ensuring grammatical correctness. Future developments should focus on refining these methods, expanding resources, and exploring hybrid solutions to enhance translation accuracy and usability.

Tupleised co-occurrence measures vs LLM word embeddings for corpus linguistics: The case of English light verb construction detection

Ryan Ka Yau Lai
University of California, Santa Barbara
kayaulai@ucsb.edu

Abstract

This paper examines how word embeddings from large language models (LLMs) can be leveraged for corpus-linguistic studies of co-occurrence. Specifically, I examine whether Phrase-BERT (Wang et al. 2021) representations contain information about co-occurrence properties of English verbs and nouns, such as token frequency, attraction, productivity and dispersion, and if so, how Phrase-BERT can be used alongside such measures in corpus-linguistic analyses. I find that (a) Phrase-BERT representations partially encode information from co-occurrence statistics, (b) Phrase-BERT by itself predicts quite well whether a verb-noun combination is a light verb construction, but predictions are further improved by corpus statistics and semantic information, (c) Phrase-BERT's predictions as to whether something is an LVC can be partially explained through corpus statistics.

1 Introduction

Co-occurrence is at the heart of both corpus and computational linguistics. Both fields are interested in exploring forms that regularly co-occur with each other to form *collocations* or *multi-word expressions*. Both began studying co-occurrence with similar methods: counting co-occurrence between pairs of forms, computing statistics for measuring the salience of co-occurrence, and choosing the highest-scoring pairs (Dras & Johnson 1996, Evert 2005, Tan et al. 2006 etc.).

Yet the two traditions have parted ways. Modern computational linguistics treats the extraction of multi-word expressions as a sequence labelling problem (e.g. Waszczuk et al. 2019, Taslimipoor & Rohanian 2018): Given a sequence of tokens in a corpus, how can we label the beginning and end of multi-word expressions? The methodology has moved beyond statistics to using pre-trained large language models (LLMs), which calculate the probabilities of strings of tokens using very large corpora.

Meanwhile, corpus linguistics has further developed the traditional method. Rather than a single co-occurrence statistic (such as PMI or G^2), recent work suggests that co-occurrence properties are better captured by suites of statistics that operationalise different aspects of distribution with different psycholinguistic interpretations (e.g. Gries 2022a, 2024, van Hoey 2023). This movement towards multi-dimensionality is called *tuplelisation*: it involves gathering combinations, or *tuples*, of corpus statistics. Crucial to this development is the realisation that correlation between statistics comprising the tuples should be minimised, and the introduction of tools to do so (Gries 2022b, 2022c).

Nevertheless, the versatility and accuracy of black-box language models remain attractive for corpus linguists. For example, while a linguist cannot obtain accurate co-occurrence statistics for a pair of words involving a word that did not occur in the corpus, this is unproblematic if we use word embeddings (vector-space representations) based on LLMs: word vectors are trained on much larger corpora and, in their modern incarnations, can handle unseen words, since word embeddings are creating by combining embeddings of subwords: fragments of words determined by a tokeniser.

Given the strengths of LLM word embeddings, one may ask how to integrate them into the corpus linguist's workflow without sacrificing the linguistic interpretability desired in theoretical

corpus-linguistic work, and how it make it work alongside traditional corpus-linguistic methods. Extensive work has demonstrated that LLM word embeddings encode all types of linguistic information, from word classes (Belinkov et al. 2018) to agreement and anaphora (Lin et al. 2019), named entities and semantic roles (Tenney et al. 2019), syntactic structures (Jawahar et al. 2019) and, crucially for this paper, constructional information (Tayyar Madabushi et al. 2020), including filler-slot attraction (Thrush et al. 2020). This suggests that LLM behaviour can be pinned down to aid corpus-based investigations of language use, including co-occurrence.

This paper tackles this question through the case study of association between verbs and their objects in English, particular as regards the identification of *light verb constructions*, combinations of a semantically light verb with a semantically heavy lexical noun, as such constructions are particularly relevant to corpus-based lexicography and constructicography. LLM-based word embeddings are taken from Phrase-BERT (Wang et al. 2021).

Specific research questions of this paper are:

1. To what extent do Phrase-BERT embeddings of verb-object sequences encode co-occurrence information between the verb and the head noun of the object?
2. Do tupleised co-occurrence statistics encode any information useful for identifying light verb constructions *not* already present in Phrase-BERT?
3. Can tupleised co-occurrence statistics, along with semantic and syntactic information, be used to interpret *how* Phrase-BERT predicts whether a verb-object sequence is a light verb construction?

Section 2 gives the background information to this paper. Section 3 describes the nature of the datasets used. Section 4 shows that Phrase-BERT embeddings can partially predict tupleised co-occurrence statistics calculated from the British National Corpus (BNC; Leech 1992). Section 5 examines the detection of light verb constructions. It demonstrates that corpus statistics are still useful when used alongside Phrase-BERT embeddings for LVC detection. It also shows how tupleised corpus statistics can help interpret the behaviour of a Phrase-BERT-based model of light verb detection.

2 Background

2.1 Covarying collexeme analysis

The linguistic phenomenon studied in this paper is combinations of verbs and objects within a specific construction type in English: active, transitive clauses. Thus, it can be regarded as a covarying collexeme analysis (Stefanowitsch & Gries 2005): We are looking at the co-occurrence of items within two constructional slots of a construction.

2.2 Tupleised co-occurrence statistics

The corpus statistics used in this paper are mostly based on Gries (2022a). Most of the measures are calculated using values from the following contingency table, where *n* stands for noun (i.e. the object), *v* stands for verb, and ¬ means 'not':

	n	$\neg n$	Totals
v	$f(n, v)$	$f(\neg n, v)$	$f(v)$
$\neg v$	$f(n, \neg v)$	$f(\neg n, \neg v)$	$f(\neg v)$
Totals	$f(n)$	$f(\neg n)$	N

For example, if *n* is 'look' and *v* is 'take', then $f(n, v)$ is the number of tokens of verb-object combinations with *take* as verb and *look* as object; $f(\neg n, v)$ is the number of tokens of verb-object combinations where the verb is *take* and the object is not *look*; $f(\neg v)$ is the number of verb-object combinations where the verb is not *take*; and so on. From these numbers, estimated probabilities can be calculated: For example, $p(\neg n, v) = f(\neg n, v)/N$ is the estimated probability that a verb-object combination has *take* as verb and an object other than *look*, and $p(v|n) = f(v|n)/f(n)$ is the estimated probability that the verb is *take* given that the object is *look*.

Eight corpus statistics will be considered in this paper. Firstly, *token frequency* is simply $f(n, v)$.

The second and third statistics are measures of *unidirectional association*, i.e. how much is the noun attracted to the verb, and the verb to the noun? For the attraction of the verb to the noun, this is calculated using the Kullback-Leibler divergence (KLD) between the distribution of the verb given the noun and the unconditional distribution of the verb. The more dissimilar these two distributions are, the more highly the verb is attracted to or repelled from the noun:

$$KLD(v|n) = p(v|n)\log_2\frac{p(v|n)}{p(v)} + p(\neg v|n)\log_2\frac{p(\neg v|n)}{p(\neg v)}$$

Following Gries (2022a), this value is then normalised to fall between 0 and 1, with 0 being the lowest attraction and 1 being the highest attraction by applying the exponential function to -1 times the KLD and then subtracting the result from 1. In cases of repulsion, i.e. $p(v|n) < p(v)$, a negative sign is added in front of the negative KLD, so the final quantity ranges from -1 to 1. The formula for this value is as follows:

$$KLD_{norm}(v|n) = \text{sgn}\big(p(v|n) - p(v)\big) \times (1 - e^{-KLD_{v \to n}})$$

The attraction of the noun to the verb is calculated similarly, just with *n* and *v* swapped in the formula. For example, in the construction *play truant*, *play* is highly attracted to *truant* (high verb-to-noun attraction), but *truant* is not highly attracted to *play* (low noun-to-verb attraction), since if we know the noun is *truant*, the verb much more likely to be *play* than most other nouns; but if we know the verb is *play*, it is very hard to guess the noun is *truant*.

The next four statistics all measure productivity: The degree to which verbs can combine with a variety of nouns, and vice versa. The fourth and fifth statistics are the type frequencies: the number of noun types that accompany each verb, denoted tf_v, and the number of verb types that co-occur with each noun, denoted tf_n. I take the logged values of both, i.e. $\log(tf_v)$ and $\log(tf_n)$.

The sixth and seventh statistics are entropy, which measures how unpredictable the noun is given the verb, and vice versa. Unlike type frequency, this measure also takes into account the relative prevalence of different collocates. For example, if one noun co-occurs with a single verb 99% of the time and 99 other verbs the remaining 1% of the time, its entropy would be nearly 0 even though the type frequency is 100. Unlike the conventional formula for entropy, the entropy used in this paper is normalised, following Gries (2022a), such that it cannot exceed 1. For the entropy of the verb given the noun, the entropy is normalised by the frequency of the noun:

$$H_{norm}(v|n) = \frac{-\sum_v p(v|n) \log_2 p(v|n)}{\log_2 f(n)}$$

The entropy of the verb given the noun is similarly calculated by swapping *v* and *n* in the formula.

The eighth and final statistic is DP_{nofreq} (Gries 2022c). This calculates how evenly distributed the verb-object combination is within the corpus. The first step in calculating this value is to get the raw dispersion statistic *DP*. To do this, we first calculate the proportion of instances of a verb-object combination, say *take* + *look*, that comes from each document in the corpus. We then calculate the proportion of verb-object combinations in general that comes from each document in the corpus. We then find the Manhattan distance between the two vectors of proportions. Next, we estimate the minimum and maximum values of DP given the token frequency of *take* + *look*. Finally, we calculate DP_{nofreq} by calculating its position within the range of possible values: the minimum value is 0, the maximum value is 1, and if the DP value is halfway between the minimum and maximum, then DP_{norm} is .5, and so on. Details of calculation are in Gries (2022c).

2.3 Light verb constructions

The particular application of corpus statistics and Phrase-BERT in this paper will be focused on the identification of light verb constructions (LVCs). A light verb construction is a grammatical construction consisting of a semantically light verb that contributes little to no predicational information and a lexical item, generally a nominal, which contributes the bulk of the information about the event or state being described. In English, a typical light verb construction consists of a verb followed by an indefinite object such as *take a peek* or *do backflips*. This paper will consider exclusively those LVCs that contain a noun.

Light verb constructions are studied in both corpus linguistics and NLP. They are a type of multi-word expression of great interest in both applied and theoretical linguistics: They are a common source of L2 errors because of their idiosyncratic properties (e.g. which verbs are paired with which nominals) (García Salido 2016), and their cognitive representation is a constant topic of interest, e.g. in English, they have the form of verb-object constructions, yet in some ways function like intransitive predicates (e.g. Wittenberg & Piñango 2011). It also has applications in NLP tasks like event extraction and information retrieval (Vincze et al. 2013), since the noun in an LVC should be treated as part of the predicate, rather than a participant in the event. Thus, extracting LVCs from corpora has many applications, such as for compiling computer- and/or human-readable glossaries of LVCs within

a domain, for studying the grammatical properties of LVCs in L1 and L2 production, etc.

2.4 Phrase-BERT

As mentioned above, this paper uses Phrase-BERT (Wang et al. 2021) to classify constructions as LVCs. The main advantage of Phrase-BERT is that unlike most BERT-based approaches to calculating phrasal similarity, it is trained on collections of paraphrases such that phrases with similar meaning but no words in common will have similar embeddings, whereas words with overlapping words but very different meanings will have different embeddings. Thus, Phrase-BERT does not rely heavily on lexical overlap between phrases, and can better capture similarity between phrases that do not necessarily share words. As LVCs are a highly abstract category mostly characterised by how meaning is distributed in different parts of the construction, using Phrase-BERT can potentially make it easier to detect LVCs even if their component words do not appear in LVCs in the training data, and avoid mistakenly classifying non-LVCs as LVCs just because they share words with LVCs. This may be especially useful for detecting LVCs in L2 production, which may have less lexical overlap with LVCs in L1 data, but still share the semantic properties of LVCs.

2.5 Related work

To date, LLMs' most common uses in corpus linguistics are (a) using word embeddings to measure semantic similarity, which predates LLMs (Desagulier 2019, Tiun et al. 2020, etc.) and (b) using outputs generated from LLMs for automatic annotation (e.g. Weissweiler et al. 2024, Yu et al. 2024). Though this paper also uses LLMs to produce annotations, it uses word embeddings originating from LLM representations as predictors, rather than using LLM-generated output directly.

Concerning co-occurrence specifically, Uchida (2024) found that ChatGPT produces a collocation list that has 42.8% overlap with the list of collocations in the Corpus of Contemporary American English (COCA) created by selecting all collocations with mutual information (a bidirectional association measure) over 1, suggesting that ChatGPT's weights may encode some knowledge about co-occurrence of words (though the collocations may have also come from memorising collocation lists and dictionaries in the training data, rather than actually analysing co-occurrence between words).

In computational linguistics, Kanclerz & Piasecki (2022) has reintegrated statistical measures into MWE labelling; their approach, however, only uses bidirectional association measures to create lists of non-MWEs for negative training data. Thus, their co-occurrence statistics are not tupleised, and word embeddings and co-occurrence statistics are used at two different stages of their system for different purposes; they were not directly compared. To my knowledge, no work has attempted to compare word embeddings from LLMs to tupleised co-occurrence statistics.

3 Data

Three data sources were used for this study. Firstly, I took the verb-object constructions from the British National Corpus annotated by Tu & Roth (2011). This dataset includes the verbs *make*, *get*, *do*, *have*, *take*, *give*; around half were annotated as LVCs and half as non-LVCs. Secondly, I took annotations of OntoNotes 4.0 (Weischedel et al. 2011) from the latest version of PropBank (Bonial et al. 2014), which annotates for LVCs and other verb-object combinations. These two datasets were combined; to make the two comparable, the surrounding context of the LVCs, i.e. words before the verb or after the object, were discarded. Instances where the noun precedes the verb were also ignored. Dependency parses of the LVCs were used to extract the presence of dependencies like articles (*a*, *an*, etc.). An LLM-based disambiguation model (Wahle et al. 2021) was used to find the WordNet synset corresponding to the noun. The lexical file of the synset was then used as a semantic feature, dividing the nouns into categories like 'artifact', 'cognition', 'process', 'substance', 'animal', etc., similar to one of the features in Tu & Roth (2011). This dataset will be referred to as the LVC dataset.

For calculation of corpus statistics related to verb-noun constructions, the entire BNC was parsed using spaCy (Honnibal & Montani 2017) and all verb-direct object pairs were extracted. The eight statistics were then calculated. This dataset will be referred to as the VN dataset. Details of the construction of the datasets are in Appendix A.

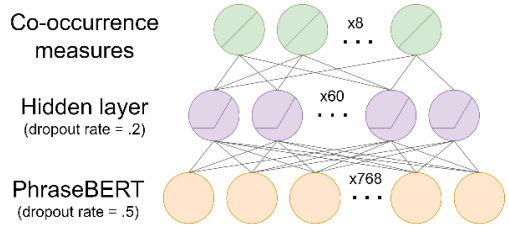

Figure 1: Architecture of the model used in Experiment 1.

4 Experiment 1: Predicting co-occurrence statistics from Phrase-BERT embeddings

The first experiment investigates whether information contained in corpus statistics is represented in Phrase-BERT in some form. This was done by attempting to predict corpus statistics from Phrase-BERT embeddings. If Phrase-BERT embeddings do contain information on association, entropy, etc., then these measures should be predictable from Phrase-BERT representations.

4.1 Methodology

A neural network (Figure 1) was used to predict co-occurrence statistics from Phrase-BERT embeddings. The model architecture consisted of an input layer containing all Phrase-BERT embeddings with dropout rate .5, a hidden layer of 60 units with ReLU activation and dropout rate .2, and finally eight output units with linear activation. The co-occurrence measures were centred and scaled before modelling, and a training-dev-test split of 8-1-1 was used. The model was implemented in Keras (Chollet et al. 2015).

4.2 Results & discussion

Figure 2 plots the predicted values from the neural network against the actual corpus statistics. As can be seen from the graph, although there are considerable deviations between the predicted and actual values of the co-occurrence statistics, the embeddings do have substantial predictive power overall. The mean squared error (calculated on the normalised corpus statistics) in the test set was .521. Were a curvilinear activation function employed, some of the predictions may be even more accurate. Moreover, it should be noted that some of the noise may come from noise in the co-occurrence statistics themselves, rather than in the ability of the embeddings to predict co-occurrence

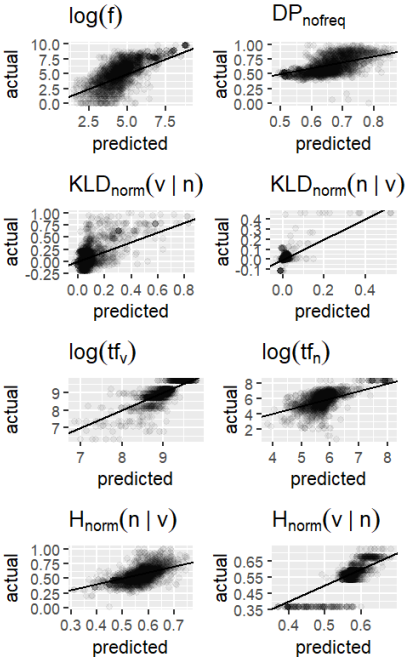

Figure 2: Predicted values of the corpus statistics using Phrase-BERT embeddings and actual values of the eight corpus statistics as calculated using the BNC. Only the test set is shown. Dots on the diagonal line have exactly equal actual and predicted values. The actual and predicted values are presented in their original scales, rather than the normalised version used in modelling.

patterns. In sum, embeddings seem to encode some, though not necessarily all, of the information available in co-occurrence statistics.

5 Experiment 2: Relative contribution of BERT and co-occurrence statistics to light verb prediction

Since Experiment 1 found that word embeddings do encode information relevant to co-occurrence, one question is whether problems traditionally faced by corpus linguists that call for co-occurrence statistics can be solved by using word embeddings alone, or if co-occurrence measures still contain independent information that matter. In

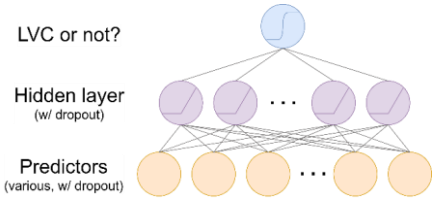

Figure 3: Architecture of the model used in Experiment 2.

this section, we will consider the particular problem of extracting light verb constructions from a corpus. Imagine, for example, that we would like to teach light verb constructions in an L2 language instruction setting, and would like locate all light verb constructions in a set of level-appropriate texts to determine which readings would best serve the purpose. Would Phrase-BERT alone suffice to complete the job, or do we need traditional sources of information like co-occurrence statistics?

To answer this question, in this section, I aim to predict whether a phrase is a light verb construction from Phrase-BERT embeddings, corpus statistics, and both. If Phrase-BERT embeddings perform similar to or better than corpus statistics, and using both does not constitute an improvement over Phrase-BERT alone, then Phrase-BERT already contains all the useful information contained in the corpus statistics. If, on the other hand, using both sources of information is better than using Phrase-BERT alone, then this implies that corpus statistics contain useful information for LVC prediction that is not encoded in Phrase-BERT. I also run versions of these three models that add WordNet lexical files, dependency syntax information, or both, to see if any advantage of adding corpus statistics can be eliminated when semantic and/or syntactic information is added.

5.1 Methodology

The model trained in this section aims to predict whether a phrase is a light verb construction, based on the LVC dataset. Different combinations of predictors were used: I trained models using Phrase-BERT only, co-occurrence statistics only, or both, with syntactic information, semantic information, or both. Note that although both the corpus statistics and the Tu & Roth light verb judgements used the BNC, the Tu & Roth judgements were not involved in the calculation of corpus statistics, so there is no information leak.

The model architecture (Figure 3) consisted of an input layer containing the various variables, a hidden layer, and a sigmoid output layer for the choice between LVC vs non-LVC. Class weights were proportional to the reciprocal of the sample size of each class. Decision thresholds were tuned to maximise F1 using a grid search between 0 and 1 (exclusive) and a step size of .01. Grid search was used to determine the number of hidden layer units and dropout rates; all combinations of the values in Table 1 were tried, and for each combination of variables, I took the hyperparameter combination that resulted in the highest F1 in the validation set. As with Experiment 1, scaled and centred corpus statistics were used, and the training-dev-test split was 8-1-1.

Model	*P*	*R*	*F1*	*AUC*
BERT	0.937	0.970	0.953	0.955
STAT	0.910	0.935	0.922	0.835
BERT + STAT	0.950	0.964	**0.957**	**0.958**
BERT + SYN	0.951	0.958	0.954	0.952
STAT + SYN	0.898	0.969	0.932	0.846
BERT + STAT + SYN	0.953	0.960	0.956	**0.958**
BERT + SEM	0.946	0.961	0.953	0.949
STAT + SEM	0.901	0.961	0.930	0.870
BERT + STAT + SEM	0.940	**0.972**	0.956	0.955
BERT + SYN + SEM	**0.955**	0.948	0.952	0.954
STAT + SYN + SEM	0.915	0.955	0.935	0.890
BERT + STAT + SYN + SEM	0.951	0.958	0.955	0.956

Table 2: Results of Experiment 2 based on the test set. P = precision, R = recall, F1 = F1-value, AUC = area under the curve, BERT = Phrase-BERT embeddings, STAT = co-occurrence statistics, SEM = WordNet lexical files, SYN = noun modifiers' presence.

5.2 Results

Precision, recall, F1 and AUC values of all the models trained were shown in Table 2. Phrase-BERT alone performs substantially better than corpus statistics on all metrics. Yet when we combine both, the resulting model does better on all metrics but recall compared to the model with BERT alone. This pattern (adding statistics improves most metrics) largely persists even after adding syntactic dependencies and/or semantic categories to the model, though the model with just BERT and statistics remains the best model in terms of F1. Thus, co-occurrence statistics contain useful information beyond what is encoded in Phrase-BERT, syntactic dependencies on the noun, and WordNet lexical files.

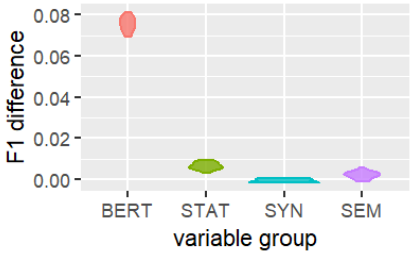

Figure 5: Permutation variable importance of the four variable groups, as calculated by drop in F1 after shuffling the relevant variable group.

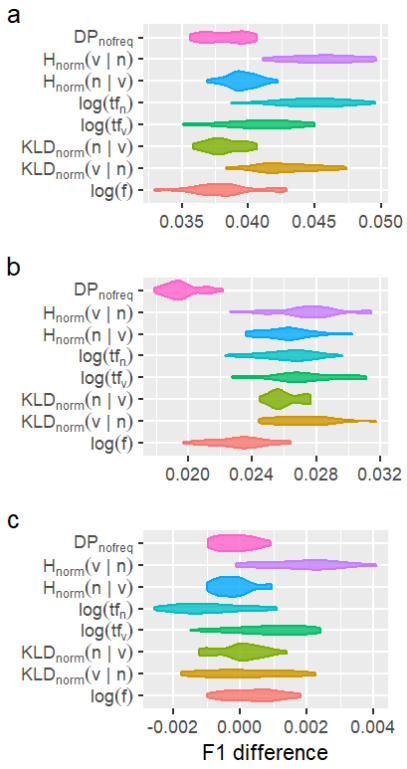

Figure 4: Permutation variable importance of the tupelised co-occurrence statistics in (a) the STAT model, (b) the STAT + SYN + SEM model, (c) the BERT + STAT + SYN + SEM model. Note that the x-axis is different in each graph, with the scale of the x-axis in (c) much smaller than (a) and (b).

5.3 Discussion

To examine how important corpus statistics were, I used a permutation variable importance approach on the maximal model. I randomly shuffled the values of each of all four groups of variables, and examined the impacts on the F1 in the test set. I did this reordering 20 times per variable group. As seen in Figure 5, the biggest drop in F1 by far came from reordering BERT, but reordering corpus statistics still resulted in a rather more substantial drop in performance than the semantic or syntactic variables. This suggests that corpus statistics have a small, but still substantial contribution towards the predictive power of the model.

But which statistics exactly are still important in this full model, i.e. are not captured by Phrase-BERT or by the syntactic and semantic properties? I repeated the permutation variable importance process, but this time shuffling each statistic independently, for three models: (a) statistics only, (b) statistics with syntax and semantics, (c) statistics with BERT, syntax and semantics (Figure 4). Going from model (a) to (b), there is a drop in all of the variables' importance, but all of them still matter, so semantics and syntax only capture a small part of the useful information from co-occurrence statistics. Unsurprisingly, once BERT is added, all the statistics' importance drop drastically, though $H_{norm}(v|n)$ remains important.

To further examine how exactly co-occurrence statistics contribute to better predictions in qualitative linguistics terms, I qualitatively compared the predictions of the full model (c) with the model with everything but co-occurrence statistics (hereafter the no-stats model). I looked at cases in which one model got something wrong that the other got right.

Firstly, I looked at cases of phrases labelled as non-LVCs in the original dataset but one of the two models judge as an LVC. These cases are especially important as the two models differ substantially in precision. Phrases that were classified as false positives in the full model and true negatives in the no-stats model often seem to be mislabelled in the original data or edge cases, e.g. *take effect* or *do some work* (many similar phrases were counted as LVCs in the data). On the other hand, if we look at the opposite situation – phrases that were false positives in the no-stats model but true negatives in the full model – there were fewer apparently mislabelled items. Instead, many were clear non-LVCs where the verb is seemingly light (and is light in many other contexts), but in the specific phrase retains the non-light lexical meaning, e.g. *made a profound impression* (where the verb indicates the subject is actually creating something) or *get credit* (where the subject metaphorically receives something). In these cases, the useful contribution from corpus statistics likely comes from the ability to relate the noun to the verb rather than considering them separately. For example, *get* is a frequent verb often appearing in LVCs and *credit* is an abstract noun, which are often associated with LVCs. So looking at *get* and *credit*

separately, one may be tempted to classify this as an LVC. But the noun is not strongly attracted to the verb (z-score of $KLD_{norm}(n|v) = -.21$). Out of the 815 input variables, the most negative Shapley value is $KLD_{norm}(n|v)$ (Shapley value = -0.03), suggesting that it was a major factor that pushed the maximal model to treat this phrase as non-LVC. This suggests such information was not encoded as well in Phrase-BERT alone.

I then examined cases where phrases labelled as LVCs in the original dataset were classified as non-LVCs by one of the two models. Very few phrases were false negatives in the full model but true positives in the no-stats model. There were no clear patterns in phrases that were false negatives in the no-stats model but true positives in the full model, except that they sometimes have less frequent nouns, like *booking* (seen once training data) or *injection* (seen twice). This is unsurprising given that the models are close in terms of recall.

Of course, these results do not imply that corpus statistics are always needed on top of Phrase-BERT for LVC classification. I did not consider the context surrounding the LVCs, so I do not know whether Phrase-BERT better captures surrounding contextual information than corpus statistics like previous and next word entropy (Zhào et al. 2016). Moreover, the workflow for my system requires the user to first locate candidate verb-object combinations, rather than getting a list of LVCs from a raw text corpus; statistics may be hard to use in this situation. Still, the results suggest that corpus statistics remain relevant in at least *some* situations relevant to the corpus linguist.

5.4 Follow-up experiment

Since Experiment 2 found that much of the useful information in corpus statistics is found in Phrase-BERT, one may ask *how* Phrase-BERT uses this implicit co-occurrence information to make predictions about LVC membership. To do this, I used the syntactic, semantic predictors and co-occurrence statistics to predict the behaviour of the BERT-only model. Again, a neural network with a single ReLU hidden layer of 15 units was used, with the same dropout rates as Experiment 1. The output layer has linear activation, and predicts the estimated probability from the BERT-only model, with a logit transformation applied to the probability so that it can be any real number.

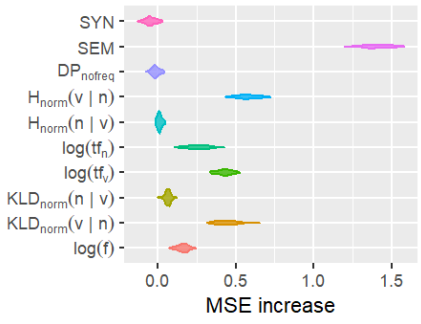

Figure 7: Permutation variable importance of the statistics in the follow-up experiment, as calculated by drop in F1 after shuffling the relevant variable group.

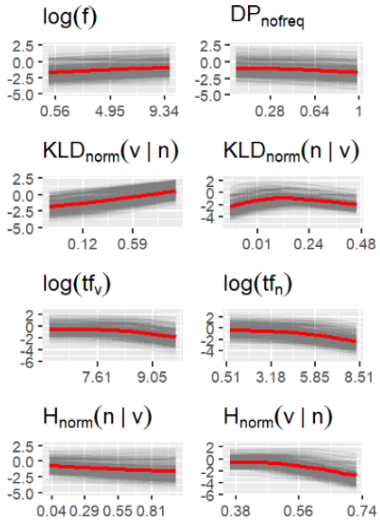

Figure 6: Partial dependency plots of the six statistics in the test set. Note that these are based on z-scores, not original values.

Permutation variable importance (Figure 7) shows that WordNet semantic information is the most important, and as before, $KLD_{norm}(v|n)$, $H_{norm}(v|n)$ and the type frequencies stand out as the most important predictors based on co-occurrence statistics. To see the exact way in which statistical information encoded in Phrase-BERT is used to predict light verb construction status, partial dependency plots of the relationship between the statistics and the prediction of the BERT-only model are shown in Figure 6. The strongest relationships are: $KLD_{norm}(v|n)$ (i.e. the verb's attraction to the noun) is positively associated with LVC status, while $KLD_{norm}(n|v)$ is positively associated for very low values but negatively associated elsewhere. These results can be interpreted as Phrase-BERT having learnt that in LVCs, the verbs are generally strongly attracted to the noun, and the nouns are somewhat, but not very, attracted to the verb. The productivity of the noun with respect to the range verbs it combines with, as

measured by type frequency and entropy, is also negatively associated with LVC status.

These results may be compared to those obtained for Tibetan LVCs in Lai (in press). However, there are several important differences between the two studies. Firstly, in this paper, noun-verb combinations are investigated regardless of frequency, whereas in Lai (in press), only combinations with the highest frequency were taken. Secondly, in this study, only verbs that appear in at least one LVC are considered, whereas Lai (in press) makes no such restriction.

The relationship between $KLD_{norm}(v|n)$ and $KLD_{norm}(n|v)$ and LVC status is mostly in accord with the Tibetan findings. The initial positive relationship between $KLD_{norm}(n|v)$ and LVC status found here is absent from the Tibetan study, likely because low-frequency noun-verb combinations were not considered there. Lower entropy of the verb slot given the noun $H_{\text{norm}}(v|n)$ and type frequency of the noun $\log(tf_n)$ being associated with LVC status is also consistent with the Tibetan findings. In the Tibetan study, higher values of $H_{\text{norm}}(n|v)$ and $\log(tf_v)$ were visually found to be associated with LVC status (though the statistical test was insignificant), contrary to the weak negative association found here. This small difference, however, does not necessarily indicate a typological difference, as it can likely be attributed to the fact that the present study excludes verbs that never appear in LVCs: such verbs were likely absent from LVCs precisely because they appear with fewer nouns, and their inclusion would have tipped the scales the other way.

6 Conclusion

In this study, we showed that a considerable amount of information in co-occurrence statistics is encoded in Phrase-BERT, though not all. We saw that tupleised corpus statistics only do slightly worse than Phrase-BERT at predicting whether a verb-object combination is an LVC, and moreover, the statistics have an independent contribution to LVC detection beyond information also encoded in Phrase-BERT, mostly coming from $H_{norm}(v|n)$, the normalised entropy of the verb slot for each noun. Finally, corpus statistics can be used to partially interpret how Phrase-BERT identifies LVCs. Indeed, the patterns found through this analysis largely accord with findings in Lai (in press) for Tibetan, showing that the power and robustness of tupleised corpus statistics for LVC detection crosslinguistically. Importantly, this would not be possible in a traditional single-statistic approach, which would not capture e.g. the fact that noun-to-verb attraction is mostly *negatively* associated with LVC status but verb-to-noun attraction is *positively* associated.

Thus, tupleised corpus statistics can aid in interpreting black-box systems and improving the performance of such systems when added as additional predictors. Tupleisation contributes to the lasting relevance of co-occurrence statistics for corpus linguists in the age of LLMs.

A Details of data extraction

To create the LVC dataset, Tu & Roth's data was used as-is, with no modifications except replacing the underscores with spaces. To extract non-LVC verb-object combinations from PropBank, I looked for verbs (`pos = V`), and then looked for an `ARG1` whose constituency tree representation starts with `(NP` in the corresponding proposition. To extract LVC verb-object combinations, I looked for verbs again, but this time looked for a word labelled `ARGM-PRR` which indicates it is the head of a light verb nominal. If this is not immediately adjacent to the verb, then the closest word to the `ARGM-PRR` whose constituency tree representation starts with `(NP` is considered the start of the light verb nominal. Otherwise, the word itself is considered the entirety of the light verb nominal.

Phrase-BERT representations of the examples of the LVC dataset were computed for the string of words starting with the verb and ending in the light verb nominal, including anything in between, such as indirect object pronouns (e.g. *throw* ***them*** *a curveball*).

The object nominals were dependency-parsed and dependents on the object were extracted, including *a*, *the*, *no*, *some*, *any*, *good*, *this*, *little*, *more*, *great* and *first*. The syntax features used in this paper are simply Boolean features indicating the presence of these words.

The WordNet lexical files were based on the head of the object alone. I used `nltk` to get the synsets corresponding to the head, and then used Wahle et al.'s model to find the most appropriate meaning given the LVC instance. A sample input is as follows:

```
question: which description
describes the word " explanation "
best in the following context? \
descriptions:[ " a statement that
makes something comprehensible by
describing the relevant structure
or operation or circumstances etc.
", " thought that makes something
comprehensible ", or " the act of
explaining; making something plain
or intelligible " ]
context: gave us an " explanation
" .
```

I then took the lexical file of the synset whose definition was deemed most appropriate.

To create the VN dataset, sentences were first extracted from the HTML version of the BNC. Then I used spaCy to dependency-parse and lemmatise everything in the corpus. Direct objects (`dobj`) and passive subjects (`nsubj:pass`) were extracted from the corpus along with their verbal heads. Statistics were then calculated based on extracted verb-object combinations.

Case Particle Omission in Nominative-Accusative Dependency in Japanese

Abstract

This paper defends Marantz's (1991) dependent case theory through the study of case particle omission in Japanese. We show that case particle omission is not merely an instance of a morpho-syntactic or morpho-phonological process, but it instead applies in tandem with syntax-phonology and syntax-semantics conditions imposed on C. The study also supports the full phasal transfer/spell-out model (Bošković 2016; Saito 2017a,b, 2020), where CP, rather than TP, and *v*P, rather than VP, are phasal spell-out domains in Japanese.

1 Introduction

Whether Japanese employs the abstract Case system is an important and widely discussed issue among researchers. Advocates of the abstract Case theory claim that Case is licensed by certain functional categories in the designated structural configurations (Tada 1992; Koizumi 1995; Ura 2000 a.o.). In contrast, Saito (2014, 2016) argues that the language has no φ-feature agreement and that Case itself plays a role in determining labels for syntactic constituents. Another view, which we support in the current study, is presented in the framework of morphological case theory (Marantz 1991). There, case does not play a role in the syntax, and case features are instead inserted and licensed at the Morphological Structure (MS) on the PF side. Aoyagi (2004, 2006) posits Marantz's case dependency system, proposing that case features are already present in the syntax but become interpretable by being phoneticized at the MS/PF.

This study examines case particle omission, as exemplified in (1), to provide insight into case theory.

(1) Taroo*(-ga) kuruma(-o) kat-ta.[1]
Taro(-Nom) car(-Acc) buy-Past
'Taro bought a car.'

It is well known that case particles in Japanese are omittable in colloquial speech. However, a case particle is often said to be omittable only when an NP is adjacent to a verb (Saito 1983, cf. Kuroda 1988). Thus, the nominative marker *-ga* often resists omission, while the accusative marker *-o* tends to be more easily omitted (Kuno 1973).

However, Masunaga (1988) points out that the subject/object asymmetry is lost when a sentence-final particle (SFP) like *yo* is added. She claims this addition can de-focus an NP and instead focus a verb, thereby enabling case particle omission, as shown in (2).

[1] Abbreviations used in this paper are as follows: Acc = accusative, Gen = genitive, Nom = nominative, SFP = Sentence Final Particle

(2) Burondo-no otokonoko(-ga) Taroo(-o)
blond-Gen boy(-Nom) Taro(-Acc)
nagut-ta yo.
hit-Past SFP
'A blond boy hit Taro.'
(adapted from Masunaga 1988: 148)

In what follows, we explore the conditions in which case particle omission is allowed. Through such an exploration, we observe that realization of the accusative *-o* depends on the presence of the nominative *-ga*, which supports the dependent case theory.

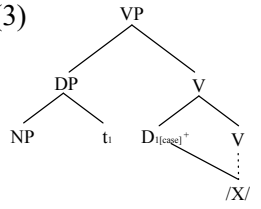
The organization of this paper is as follows. In Section 2, we review several previous works on case particle omission, taking up Aoyagi (2004, 2006), Endo & Maeda (2020), and Fukuda & Furukawa (2023), pointing out the issues found in each analysis. In Section 3, we examine data on case particle omission and propose our own version based on dependent case theory, a hybrid of Baker (2015) and Aoyagi (2004, 2006). We further claim that both case assignment and omission work in tandem with independently motivated constraints imposed by the syntax-phonology and syntax-semantics sides. Section 4 further examines case particle omission in other constructions and extends our proposal. Section 5 concludes this paper.

2 Case particle omission in Japanese: Previous studies

2.1 Aoyagi (2004, 2006)

In Section 1, we saw that the accusative marker *-o* is generally more omittable than the nominative marker *-ga*. Aoyagi (2006) captures this fact by utilizing D-to-V incorporation within the framework of Marantz's (1991) morphological case theory. Aoyagi (2004, 2006) refines Marantz's theory by proposing that a morphological [case] feature on the D head of a DP is licensed by being phoneticized. For Aoyagi, case particle omission is an instance of feature phoneticization by a verb in terms of D-to-V incorporation, as illustrated in (3).

(3)



X = V's phonetic form
(adopted from Aoyagi 2006: 106)

While Aoyagi's incorporation analysis can well accommodate the *-o* omission, the *-ga* omission, as seen in (2), is left unexplained.

In Section 2.2, we look at the work of Endo & Maeda (2020), who attempt to explain the *-ga* omission in point.

2.2 Endo & Maeda (2020)

Based on Masunaga's (1988) observation of *-ga* omission in the presence of an SFP, Endo & Maeda (2020) propose that case particle omission is an instance of truncation, which applies to the outmost layer of an NP (i.e. where a case particle appears) to be placed at the CP-peripheral position. They claim that the presence of an SFP forces an entire TP (IP for them) to move to a CP-peripheral position—more precisely, to the Spec of a Speech-Act Phrase for discourse-related reasons. This enables the outmost layer of an NP to be truncated; as a result, the NP appears without a case particle.

While their truncation analysis can now account for *-ga* omission, the mechanism of *-o* omission becomes unclear, as pointed out by Fukuda & Furukawa (2023). Let us now see how Fukuda & Furukawa accommodate case particle omission.

2.3 Fukuda & Furukawa (2023)

Fukuda & Furukawa (2023) propose a PF externalization condition tied to a semantic requirement. They argue that the case particle of a focused NP must be phoneticized, while non-focused NPs can appear without case particles.[2] Fukuda & Furukawa adopt Miyagawa's (2022) framework of SFPs. They assume that an SFP can be adjoined either to a *v* or CommitP, a domain above CP.

When it is attached to a *v*, either the whole VP or V can be focused.[3] In both cases, the subject NP is outside of the focus domain, and *-ga* can, therefore, be omitted. In addition, when only V is focused, *-o* can also be omitted. When an SFP is attached to a

[2] Fukuda (2022) has proposed a PF-externalization condition on a focused NP, focusing on the data from the Kumamoto dialect and multiple nominative constructions in Standard Japanese. We refer to his analysis in note 6.

[3] Fukuda & Furukawa (2023) adopt Miyagawa's (2010, 2017) feature-inheritance system, positing a [focus] feature on either *v* or C, which we do not go into details here.

CommitP, the entire TP is focused; consequently, none of the NPs can appear without case particles. Fukuda & Furukawa point out that (4) has two interpretations:

(4) Burondo-no otokonoko-φ Taroo-o
blond-Gen boy Taro-Acc
nagut-ta yo.
hit-Past SFP.
'A blond boy hit Taro.'
(adapted from Masunaga 1988: 148)

In one interpretation, the verb is focused. In this case, *-ga* can be dropped without any problems because the subject NP is not focused. Moreover, under this interpretation, *-o* can also be dropped, resulting in particle omission from both NPs. The other interpretation is that the entire VP is focused. Fukuda & Furukawa claim that in the VP-focused case, the object is inside the focus domain, and *-o* cannot be omitted, while *-ga* can be omitted because the subject is outside of the focus.

Although Fukuda & Furukawa ban case particle omission of an NP inside a focus domain in (4), *-o* can be dropped even under the VP-focus interpretation, contrary to their prediction. Suppose (5) is preceded by a question such as, "What did the blond boy do?". The VP can obtain a focus interpretation.

(5) Burondo-no otokonoko-φ Taroo-φ
blond-Gen boy Taro
nagut-ta yo.
hit-Past SFP.
'A blond boy hit Taro.'

Thus, while we admit that focus plays an important role in case particle omission, we explore an alternative account in Section 3.

3 A closer examination of case particle omission

3.1 Further data and generalizations

Although both *-ga* and *-o* can, in principle, be omitted, the omission does not occur freely. To see this restriction, suppose that (7a-d) is uttered after (6).[4]

(6) Saikin nanika at-ta?
recently something happen-Past
'What's new?'

(7) a. Taroo-ga/*wa kuruma-o kat-ta yo.
Taro-Nom/Top car-Acc buy-Past SFP
b. Taro-ga kuruma-φ kat-ta yo.
Taro-Nom car-φ buy-Past SFP
c. */??Taro-φ kuruma-o kat-ta yo.
Taro car-Acc buy-Past SFP
d. (?)Taro-φ kuruma-φ kat-ta yo.
Taro car-φ buy-Past SFP
'Taro bought a car.'

(6) introduces the following sentence as new information. In (7a), the subject must be marked with the nominative *-ga*; the topic marker *-wa* is incompatible. In (7b), *-o* is omitted. While *-wa* is known to be more omittable than *-ga* (Kuno 1973), (7a) ensures that what is omitted in (7c) and (7d) is *-ga* and not *-wa*. We find a clear contrast between (7c) and (7d), although it might be subject to some speakers' variation. Crucially, *-ga* is only omittable if *-o* is also omitted.[5] Put another way, we can make the first generalization in (8).

(8) *Generalization I*
The case particle *-o* can only be licensed in the presence of *-ga*.

None of the previous analyses reviewed in Section 2 can account for (8). Fukuda & Furukawa (2023), for example, cannot attribute the contrast between (7c) and (7d) to the placement of focus on a particle-less NP because the entire sentence is inside the sentential focus domain; thus, none of the NPs may appear without a case particle.

In addition, an SFP is necessary for case particle omission, especially for the omission of *-ga*.

[4] We are grateful to Tomokazu Takehisa for pointing out that a new-information-inducing question like (6) needs to be presented in order to see the *ga*-omission instead of the *wa*-omission.

[5] Aoyagi (2006: 118) points out that the same pattern holds in the Kansai dialect, although his examples do not require an SFP. We leave this parametric variation for future work.

(9) Saikin nanika at-ta?[6]
recently something happen-Past
'What's new?'

(10) a. Taroo-ga/*wa kuruma-o kat-ta.
Taro-Nom/Top car-Acc buy-Past
b. Taro-ga kuruma-φ kat-ta.
Taro-Nom car-φ buy-Past
c. *Taro-φ kuruma-o kat-ta.
Taro car-Acc buy-Past
d. ??/*Taro-φ kuruma-φ kat-ta.
Taro car-φ buy-Past
'Taro bought a car.'

The pattern here conforms to what has been observed in earlier works. (10c) is equally or nearly as bad as (7c), but (10d) is no longer acceptable without an SFP. Because *-o* is dropped in (10b), we take it that the ungrammaticality of (10d) is caused by the omission of *-ga*, which we state in (11).

(11) *Generalization II*[7]
Without an SFP, *-ga* resists omission.

We now present an analysis of our generalizations.

3.2 Analysis: Case particle omission via the dependent case assignment theory

We argue that Generalization I in (8) is captured within the framework of the dependent case theory (Marantz 1991). Marantz (1991: 245) proposes that "case morphemes are added to stems at MS [(Morphological Structure)] according to the morphological requirements of particular languages." Marantz assumes that a noun bears a case affix, and this case affix, N+CASE, looks for case features such as [nom], [acc], etc., which a noun then acquires according to its structural configuration and the disjunctive case hierarchy.

(12) *Case realization disjunctive hierarchy*
a. Lexically governed case
b. Dependent case
c. Unmarked case
d. Default case
(adapted from Marantz 1991: 247)

According to Marantz, the more specific rule wins over the more general rule in (12). Thus, the precedence goes from the top of the list to the bottom. What is relevant for us is the dependent case and default case, which we assume are the accusative *-o* and the nominative *-ga* (Aoyagi 2004, 2006). As for the structural configuration, although Marantz defines the domain for case assignment in terms of government, we adopt Baker's (2015) updated version of the spell-out domain for dependent case.

(13) If there are two distinct NPs in the same spell out domain such that NP1 c-commands NP2, then value the case feature of NP2 as accusative unless NP1 has already been marked for case. (Baker 2015: 48)

Baker (2015) claims that case assignment is implemented upon spell-out, whereby the assigned case feature is phonologically realized at PF.

As for the *-ga* assignment, we follow Aoyagi (2004, 2006) and assume that it is a default case assigned to any NP to which none of the more specific rules in (12a-c) apply, as shown in (14).[8]

(14) *-ga* is a default case assigned to any NP not marked for case.

In addition, we assume the syntax-phonology conditions in (15) and the syntax-semantics conditions in (16).

---

[6] Fukuda (2022: 163) elucidates the neutral interpretation of the thematic subject in the multiple nominative subject constructions by using the adverb *saikin* 'nowadays'.

(i) Kumamoto-ga saikin suikabatake-ga ooi.
K.-Nom nowadays watermelon-fields-Nom many
'Nowadays, Kumamoto has a lot of watermelon fields.'

As for the focused interpretation of the thematic subject, Fukuda (2022: 163) elucidates it by introducing the appropriate question-answer pair.

We get to the multiple *-ga* constructions in Section 4.

[7] (11) can also explain that case drop is not permitted with an embedded subject because SFPs can only be licensed in a root clause (cf. Endo & Maeda 2020).

(i) John-wa dareka*(-ga)/Masao*(-ga)
John-Top someone(-Nom)/Masao(-Nom)
Hanako(-o) tazune-te kita-toki
Hanako(-Acc) visit-TE came-when
soko-ni inak-at-ta.
there-at not-be-Past
'John was not there when somebody/Masao came to visit.'
(adapted from Kuroda 1988:114)

[8] Baker (2015) claims that Japanese is a marked nominative language instead of an accusative language, where the nominative case is assigned as a marked case, which we do not adopt in this study.

(15) *Conditions for Syntax-Phonology*
a. Edge (X) must be phonetically overt.
b. Edge (X) includes both X (the head) and the specifier of X.
(adapted from Collins 2007: 3)

(16) *Conditions for Syntax-Semantics*
a. CP is a discourse domain whose head is associated with a [topic/focus] feature (cf. Miyagawa 2010).
b. At least one element must enter the discourse domain to establish a [topic/focus] relation imposed by C. (cf. Miyagawa 2010; Nishioka 2018)

Departing from Collins (2007), we do not assume that (15) "applies in a minimal way so that either the head or the specifier, *but not both,* are spelled out overtly" (Collins 2007: 3, emphasis added). We instead assume that either the head or the specifier of Edge (X) must be phonologically overt.

As for Generalization II in (11), we take it to mean that an SFP plays an important role in satisfying the edge condition (cf. Collins 2007; Richards 2023) in (15). More specifically, we suggest that an SFP is a C-element, which makes the edge (i.e. the C head) phonologically overt.

Furthermore, we take case particle omission to be a product of the morphological operation called *obliteration* (Arregi & Nevins 2007, 2012). Obliteration removes the entire terminal node responsible for a case feature (Kasai 2024; cf. Tagawa 2023), which we assume is a K(ase) head (Travis & Lamontagne 1992; Fukuda 1993 a.o.). We further assume that obliteration is applied in the morphological component (MS) after syntax (Arregi & Nevins 2007, 2012; Tagawa 2023; Kasai 2024).

However, we take it that timing plays an important role in obliteration, assuming that it is applied at MS but *before* the case feature is assigned or phoneticized at MS. This means that case features are *not* assigned upon spell-out but are inserted and interpreted at MS according to the syntactic configuration of the spell-out domain in (13), and in reference to the case realization hierarchy in (12).[9]

Based on these premises, we assume (17a, b).

(17) a. *v*P and CP are phases.
b. What is spelled out/transferred is a phase itself and not a complement of a phase (Bošković 2016; Saito 2017a,b, 2020).

(17a) is the standard assumption about phases, but (17b) differs from the popular view that a complement of a phase (TP/VP) is a spell-out domain (Chomsky 2001 and his succeeding works). Following Saito's works, we assume that *v*P, not TP, is spelled out upon completion of CP when φ-feature agreement between T and a subject NP via feature inheritance from C-to-T (Chomsky 2008) is absent. While transfer of a root CP domain is not explored in Saito, we assume that a CP is also spelled out/transferred upon completion along with its head and complement (Obata 2010).

Now that we have some tools to form the basis of our analysis, let us propose (18).

(18) *Conditions for K-Obliteration*
a. A K(ase) head can be obliterated for free only if the associated KP is inside a *v*P domain.
b. A K head cannot be obliterated if it is inside a CP domain.

(18a) ensures that both subject and object KPs can appear with or without a case particle as long as they are inside *v*P upon spell-out. However, (18b) states that if a KP is outside of *v*P and is instead in the CP domain, K cannot be obliterated. This means that a KP inside a discourse domain must appear with a case particle, in line with Fukuda & Furukawa's (2023) observation.[10] We also assume that obliteration must apply *all at once* at *v*P. To put it more precisely, obliteration cannot apply after a case feature is assigned.

Finally, we propose the conditions in (19).

(19) *Conditions on Dependent Case Assignment*
A KP can be assigned a dependent case only when it is dependent on another KP.

(19) ensures that an object KP cannot be assigned a dependent case if a subject's K head is obliterated. We believe this is a natural assumption because it is precisely the K head that is responsible for a

[9] Baker (2015) in fact takes this position as seeing spell-out as "the process of transducing a syntactic representation into a PF representation" (Baker 2015: 230). Although he assumes that case assignment happens upon spell-out, spell-out in this view is compatible with the current study.

[10] We will argue shortly that (18a,b) in fact follows from an independent corollary and a principle.

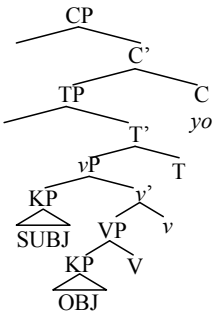
morphological case assignment/realization; an object KP depends on another KP, not another NP. In this precise sense, a KP cannot undergo K obliteration after case feature assignment.

Bearing these assumptions in mind, let us return to our examples in (7), repeated below as (20).

(20) a. Taroo-ga/*wa kuruma-o kat-ta yo.
Taro-Nom/Top car-Acc buy-Past SFP
b. Taro-ga kuruma-φ kat-ta yo.
c. */??Taro-φ kuruma-o kat-ta yo.
d. (?)Taro-φ kuruma-φ kat-ta yo.
'Taro bought a car.'

Under our analysis, (20a) results when neither the subject nor object KP undergoes obliteration, with both KPs inside a *v*P at MS/PF, as shown in (21).

(21)



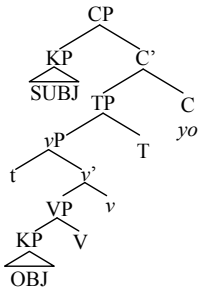
In this configuration, on the syntax/phonology side, the edge externalization condition in (15) is satisfied because the SFP *yo* occupies the C head. On the morphology/phonology side, due to the disjunctive case hierarchy in (12) and the c-commanding configuration for dependent case in (13), the object KP is assigned a dependent case because it is c-commanded by the subject KP. As for the subject KP, it is assigned the default case *-ga* (Aoyagi 2004, 2006). As for the syntax/semantics side, when both KPs are inside *v*P, the syntax/semantics condition in (16) requires at least one topic/focus element in CP. We claim that in this configuration, an event argument, which Nishioka (2018) calls a *s(tage)-pro*, occupies a CP spec, by which the sentence gets a neutral interpretation.[11]

(22) [$_{CP}$ s-pro [$_{C'}$ [$_{TP}$ [$_{vP}$ [$_{KP}$ Taro-ga] [$_{v'}$ [$_{VP}$ [$_{KP}$ kuruma-o] bought]*v*]]T] SFP]]

That is, (20a), when associated with its structure in (22), is interpreted as a recent event and not about, for example, Taro's action (cf. Nishioka 2018).

Another option for (20a) is for the subject KP to enter a CP domain, while the dependent case is assigned to the object KP. For this to happen, the subject needs to move out of *v*P, as shown in (23).

(23)



The subject's movement should not be a problem since we assume that *v*P is transferred upon completion of CP. Thus, the subject moves out of a *v*P into a CP domain (Oseki & Miyamoto 2018) in the narrow syntax, while the dependent case is successfully assigned to the object KP at MS. We claim that the dependent case assignment is possible because the object KP can depend on the copy of the moved subject KP.

If the subject KP moves out of the *v*P-domain to enter the CP-domain in (20a), the sentence yields a different semantic interpretation. Now that the subject KP is in the discourse domain, it becomes the focus/topic of the sentence (i.e. the sentence is interpreted as being about Taro's action).

Crucially, we argue that the subject KP in (23) cannot undergo obliteration after its movement to CP. But suppose it does. In that case, the moved subject (i.e. NP) and its copy (i.e. KP) are not identical. In other words, the chain of movement is not uniform. On a related point, Takahashi (1994) proposes a condition on adjunction called *The Uniformity Corollary on Adjunction (UCA)*, which bans adjunction to a non-uniform chain (Takahashi 1994: 25). In our case, obliteration cannot be applied to a sub-part of a chain because it would otherwise create a non-uniform chain. Thus, on the assumption that the corollary in point is also applied in MS, (18a,b) can now be subsumed to this corollary.

[11] While Nishioka (2018) posits s-pro in Spec, TP, we assume that s-pro is in Spec, CP because C is associated with a focus/topic feature in our analysis.

On another related point, Fox & Pesetsky (2005a,b) propose a condition on spell-out called *Order Preservation*, which requires that "*information about linearization, once established at the end of a given Spell-out domain*, *is never deleted in the course of a derivation* (Fox & Pesetsky 2005b: 6, emphasis in original).[12] They claim that spell-out only *adds* information and does not *delete* it. In this view, (18a,b) can also be reduced to this property of spell-out in that obliteration of a sub-part of a chain is banned because information about linearization in each spell-out domain, *v*P and CP, would not be identical. This is because the phonological content in each domain would be different due to partial obliteration.

There is another option for (20a): both the subject and object KPs have moved to a CP domain, being spelled out at the CP phase. In this scenario, both the subject and object are focused (i.e. the sentence is about Taro's action against a car), which is compatible with Fukuda & Furukawa's (2023) observation that focused NPs must appear with a case particle.

Let us now turn to (20b), where the subject is case-marked, but the object's case is dropped. This case is also straightforward because when both the subject and object KPs are in the *v*P spell-out domain, the object's K head can be freely obliterated due to (18a), and the subject KP can be assigned the default case *-ga* because of (12).

(24) [$_{CP}$ s-pro[$_{C'}$[$_{TP}$ [$_{vP}$[$_{KP}$ Taro-ga][$_{v'}$[$_{VP}$ [$_{NP}$ kuruma] kat]*v*]]-ta] SFP]] default case K obliteration

As was the case with (22), when both KPs are inside *v*P, the s-pro occupies the Spec, CP to satisfy the topic/focus requirement in (16), and the sentence obtains a neutral interpretation.

Alternatively, in (20b) the subject KP can move to a CP domain and be spelled out at CP, whereas the object is spelled out at the *v*P phase. Unlike (20a), since the dependent case need not be assigned to the object because its K head is obliterated, the subject can enter the CP domain with no problem. In this case, the subject KP fulfills the topic/focus requirement in (16b). As a result, the sentence is interpreted as Taro's action because the subject gets a focus/topic interpretation.

In contrast to (20a), the case-less object NP in (20b) does not have an option of moving to a CP domain. This is because K obliteration is applied at MS, which means that the relevant NP never has a chance to move in the narrow syntax. Consequently, the object cannot have a topic/focus interpretation in (20b), again, in conformity with Fukuda & Furukawa's observation.

Let us now turn to our crucial, unacceptable example in (20c), where the subject's case particle is dropped, while the object is case-marked. We argue that this is excluded because the object KP can never be assigned a case in this configuration. That is, the object KP cannot depend on the subject for case because our dependent case assignment condition in (19) requires the presence of another KP that c-commands the object KP. However, the K head of the subject in (20c) is obliterated, as shown in (25).

(25) *[$_{CP}$ s-pro [$_{C'}$[$_{TP}$[$_{vP}$ [$_{NP}$ Taro] [$_{VP}$[$_{KP}$ kuruma-o] bought]]T] SFP]] *not a KP *dependent *o*

Finally, (20d), where the case particles of both the subject KP and object KP are dropped, is obtained because the K head of both KPs can be obliterated for free as long as they stay inside *v*P in the narrow syntax and are spelled out at the *v*P domain.

(26) [$_{CP}$ s-pro [$_{C'}$ [$_{TP}$ [$_{vP}$ [$_{NP}$ Taro] [$_{VP}$[$_{NP}$ kuruma] bought]]T]SFP]] K obliteration K obliteration

As for the interpretation, as with (22) and (24), the topic/focus requirement is satisfied by the s-pro, which brings about the neutral interpretation. Crucially, the subject and object NPs cannot move to CP to get the topic/focus interpretation because both NPs have undergone K obliteration. This in turn suggests that an NP inside a CP domain must appear as a KP with a case particle.[13]

[12] See also Ke (2022), who argues for a full phase transfer with edge effects, which he claims is independently guaranteed by Fox & Pesetsky (2005a,b). See also Baker (2015) to support Fox and Pesetsky's view in relation to the role of spell-out.

[13] It seems that in (20d) the subject can have a topic/focus interpretation as long as the case-less NP is followed by a phonological pause. We tentatively speculate that leaving a pause can stress an NP, which can then become a topic/focus. The same observation can be held in (20c): it is acceptable only if the subject NP is followed by a pause, acting as a topic/focus. We conjecture that the NP in point is somehow base-generated in the CP domain like a "bare-topic" (Taguchi 2009; Takita 2014), as exemplified in (i).

4 Further predictions and implications: A study of the multiple *ga* construction

The proposed analysis can also account for the distribution of multiple -*ga* marked subjects in (27).

(27) a. Kagosima to Miyazaki-ga
Kagoshima and Miyazaki-Nom
syootyuu-ga umai (yo).
shochu-Nom tasty SFP
b. Kagosima to Miyazaki-ga
syootyuu-φ umai (yo).
c. Kagosima to Miyazaki-φ
syootyuu-ga umai *(yo).
d. Kagosima to Miyazaki-φ
syootyuu-φ umai *(yo).
'Kagoshima and Miyazaki have good shochu.'
(adapted from Fukuda & Furukawa 2023: 76)

Fukuda & Furukawa observe that the -*ga* omission from the major subject in (27c) and from both subjects in (27d) is possible when an SFP is present. They argue that the case particle omission in (27b,c) reflects non-focus interpretations of the thematic subject and the major subject, respectively. Based on the observation that the major subject must obtain the exhaustive-listing interpretation (Kuno 1973) without an SFP, while the thematic subject receives a neutral interpretation, they argue that the case particle of the major subject cannot be dropped when an SFP is absent because the subject must of necessity be focused. However, when an SFP is present, they claim that it is possible for just the verb to be focused. In that case, neither major nor thematic subjects need to be focused; consequently, (27b-d) all become possible.

We observe that (27a) and (27b) can also have a neutral interpretation. For example, suppose that two people are talking about good places to eat in Japan (e.g. "Hokkaido has good salmon, while Ishikawa has good crabs."). The conversation continues as follows:

(28) A. Osake-wa doo?
liquor-Top what about
'What about liquor?'
B. a. Kagosima to Miyazaki-ga
Kagoshima and Miyazaki-Nom
syootyuu-ga umai yo.
shochu-Nom tasty SFP
b. Kagosima to Miyazaki-ga
syootyuu-φ umai yo.
c. Kagosima to Miyazaki-φ
syootyuu-ga umai yo.
d. Kagosima to Miyazaki-φ
syootyuu-φ umai yo.
'Kagoshima and Miyazaki have good shochu.'

All (28Ba-d) are acceptable answers to (28A), but an SFP is necessary. Our analysis can account for this by positing the structure in (29).

(29) [$_{CP}$ s-pro [$_{C'}$ [$_{TP}$ [$_{vP}$ [$_{KP}$ Kagoshima and Miyazaki-ga] [$_{vP}$ [$_{KP}$ syootyuu-ga] [$_{v'}$ tasty *v*]]] T] SFP]]

In (29), the SFP satisfies the edge condition in (15), and thereby both major and thematic subjects can stay inside the *v*P domain. Thus, the K head of either KP can undergo obliteration for free because our analysis allows for obliteration as long as the target KP is spelled out at a *v*P domain. If, however, K is not obliterated and both KPs are spelled out in the same domain, we need to explain how the thematic subject avoids obtaining dependent case -*o* from the major subject, yielding (30), for example.

(30) *[$_{CP}$ s-pro [$_{C'}$ [$_{TP}$ [$_{vP}$ [$_{KP}$ Kagoshima and Miyazaki-ga] [$_{vP}$ **[$_{KP}$ syootyuu-o]** [$_{v'}$ tasty *v*]]] T] SFP]] *dependent -*o*

Given that the major subject is not theta-marked, we argue that (30) is excluded due to Aoyagi's (2004, 2006) (counter-)visibility condition in (31).

(i) Ano hon-φ, Taro-ga Δ kat-ta yo.
That book Taro-Nom buy-Past SFP
(lit.) 'That book, Taro bought Δ.'
(adapted from Takita 2014: 142)

Takita analyzes the boxed NP in (i) as a bare-topic and argues that it is an instance of Hanging Topics (Cinque 1977 a.o.). In fact, we find some similarities between our case and bare topic/hanging topic constructions. For example, both bare topics (Taguchi 2009, Takita 2014) and case particle-less subjects (Kuroda 1988) are restricted to root clauses (see Taguchi 2009, Takita 2014, and Kuroda 1988 for relevant examples).

(31) **The (counter-) visibility condition**
Only DPs that are theta marked are visible for dependent case assignment. (Aoyagi 2004: 7)

The ungrammaticality of (27c,d) without an SFP can also be accommodated because without an SFP, at least one element, most naturally the major subject, must enter the discourse domain to satisfy the topic/focus requirement imposed by C. Once the major subject is inside the CP domain, its case cannot be dropped because of the condition on K obliteration in (18), in line with Fukuda & Furukawa's (2023) phonological externalization of a focus element.

Interestingly, when (28Bb-d) are introduced by a multiple wh-question like (32A), (28Bc,d) are no longer eligible as an answer, as shown in (32Bb,c).

(32) A. Nihon-wa dono tiiki-ga
Japan-Top which area -Nom
nani-ga oisii-ka osie-te.
what -Nom tasty-Q tell-TE
lit. 'Tell me what tastes good in which area of Japan.'

B. a. Kagosima to Miyazaki-ga
Kagoshima and Miyazaki-Nom
syootyuu-φ umai yo.
shochu-Nom tasty SFP

b. ??/*Kagosima to Miyazaki-φ
syootyuu-ga umai yo.

c. ??/*Kagosima to Miyazaki-φ
syootyuu-φ umai yo.
'Kagoshima and Miyazaki have good shochu.'

While the thematic subject can appear without a case particle (=32Ba), when the case particle of a major subject is omitted, the sentence becomes bad. We suggest that the unacceptability of (32Bb,c) arises because the higher wh-phrase of a multiple wh-question must be exhaustively listed (Comorovsky 1989) or D-linked (Comorovsky 1996). Framing it in the current analysis forces the major subject to enter the CP domain, which prevents K obliteration. Consequently, (32Bb,c) are both unacceptable. The observation conforms to Fukuda's (2022) and Fukuda & Furukawa's (2023) observations in that focused elements cannot drop their case particles. Yet, our observation is slightly different from theirs in that exhaustivity is only relevant to the higher NP, forced with D-linking.

5 Conclusion

We presented an analysis for case particle omission in support of the dependent case theory advocated by Marantz (1991) and updated by Baker (2015). Along the lines of Marantz's (1991) case realization disjunctive hierarchy applied to Japanese case realization (Aoyagi 2004, 2006), together with Baker's domain-sensitive case assignment upon spell-out, we explored an analysis where a case particle omission is an instance of obliteration that can apply freely within the *v*P spell-out domain.

We proposed that case particle omission interacts with the independently motivated edge externalization condition (cf. Collins 2007; Richards 2023) and with the topic/focus condition imposed on the CP domain.

We then extended our analysis to the multiple subject constructions in Japanese, confirming that the major subject and the thematic subject can in principle be spelled out within the same *v*P domain. Alternatively, the major subject can be spelled out at the CP domain, while the thematic subject is spelled out at the *v*P domain. Either way, the timing of the case assignment and the applicability of K obliteration are determined according to this information. We also observed that the sentence structure is in conformity with its interpretation.

Thus, we concluded that case particle omission is not just a morpho-phonological phenomenon but is, in fact, in agreement with the semantics as well as with the syntax-phonology. One remaining issue is how the current study can be extended to other languages as well as to other linguistic phenomena, which we continue to explore for further study.

Semantics Outperforms Prosody in Emotional Speech Processing: Evidence from a Complex Stroop Experiment

Abstract

Semantic and prosodic cues both play crucial roles in conveying feelings and emotions in speech communication. Previous studies on the salience effects in emotional speech processing have shown inconsistent results. Most past research has focused on two simple categories of emotion. In this study, we investigated the perceptual saliency of the two cues in Mandarin using semantics-prosody Stroop tasks involving seven basic emotions: happiness, sadness, anger, fear, disgust, surprise, and neutrality. The results, based on 36 normal Chinese adults, demonstrated a semantic salience effect. This suggests that individuals may rely more on semantic cues when integrating emotional speech across different channels in more complex and challenging situations.

1 Introduction

Emotion is an integral part of human language communication. To understand the emotion of speakers, various cues are integrated. In the auditory modality, semantics and prosody are two crucial channels. Semantic cues refer to the emotional meanings inherent in the speech contents, while prosodic cues include phonetic features such as duration, pitch, and intensity. Both cues play a role in emotion processing, but they can express the same or different states at the same time. Saying "I'm very happy!" with an angry tone of voice is one example. In this instance, there is a disagreement between the two information channels. People might rely more on one of the two cues for verbal emotion processing.

The inequality among channels of information mentioned above, commonly referred to as the sensory dominance or salience effect (Colavita, 1974). Stroop task is frequently used to investigate the salience effect of different channels. A typical Stroop test utilizes color words and word colors as two perceptually congruent (e.g. word "red" in red) or incongruent (e.g. word "red" in blue) dimensions. Participants are instructed to identify one dimension while ignoring the other (Stroop, 1935). Congruency effects indicate the semantic correspondence between the two dimensions, while task effects reveal the asymmetry of the two channels. The presence, magnitude, and direction of Stroop effects are modulated by both dimensional relatedness and imbalance (Melara & Algom, 2003).

The Stroop-like paradigm has been adapted to investigated channels in emotion processing. Participants are often asked to focus on the emotion of one channel while disregarding information from the other. Such research has gained consensus regarding the congruency effect in emotion processing, that is, congruent stimuli elicit faster and more accurate responses. (Barnhart et al., 2018; Lin et al., 2020; Pell, 2005; Schirmer et al., 2005; Schwartz & Pell, 2012;). However, findings regarding the sensory dominance effect of communication channels are mixed. Some researchers found a processing saliency of the semantic meaning over prosody(Kitayama & Ishii, 2002; Pell et al., 2011), while others claimed the predominance of prosodic cues (Ben-David et al., 2016; Filippi et al., 2017; Kim & Sumner, 2017; Lin et al., 2020).

The discrepancies regarding the perceptual salience of prosodic and semantic channels may stem from cultural backgrounds and experimental settings (Lin et al., 2020). Studies have reported a greater emphasis on semantic salience in Western cultures (Grimshaw, 1998; Kitayama & Ishii, 2002; Pell et al., 2011), while prosody appears to take precedence among participants from Asian countries (Ishii et al., 2003; Lin et al., 2020; Liu et al., 2015). Additionally, experimental settings including stimulus，number of choices, and task

difficulty also affects the channel and modality salience effect (Lin et al., 2020).

The inconsistencies in previous studies highlight the need for further investigation into the dominance effects of prosody and semantics. Firstly, more studies have focused on subjects from Western cultural contexts, with only a few studies have addressing tonal languages such as Chinese (Lin et al., 2020; Lin et al., 2021; Xiao &Liu, 2024). Secondly, the stimulus settings in many studies might be too simple. Some studies utilized binary choices of positive and negative emotions, employing positive or negative prosody to express corresponding words (Schirmer and Kotz, 2003; Sutton et al., 2007). Others have used two discrete emotion categories, such as happy and sad prosody to convey synonymous words of "happy" and "sad" (Lin et al., 2020; Filippi et al., 2017). The simplicity might create the imbalance of difficulty between semantic and prosodic tasks, as binary judgments based on semantic information from sound are often more challenging than those based on prosody. In natural conversation, people normally make decisions from a much richer array of emotional categories.

This study aims to investigate the salience of prosody or semantics in Emotional Speech Processing. In this study, we used a Stroop paradigm featuring a broader range of emotions to investigate the emotional speech perception of Mandarin native speakers based on semantic and prosodic cues. Referring to Ekman's basic emotion categories (Ekman, 1992), we selected seven emotion categories (neutral, happy, sad, angry, fearful, disgust, surprise) for the stimuli. 36 subjects were required to choose from seven options during the prosodic and semantic tasks. The accuracy rates and response times of the two tasks in both conditions will be recorded and compared. According to a previous study (Lin et al., 2020), Mandarin native speakers rely more on prosodic cue.

It is expected that the present study will contribute to the research objectives from two perspectives. Firstly, the study of Mandarin speakers may add information to explorations in high-context culture. Secondly, the complex experimental design can examine the process of emotion integration in scenarios that are closer to real-life situations.

2 Method

2.1 Participates

Thirty-six subjects (18 women and 18 men) completed all experimental tasks. Women had a mean age of 25.3 years (*SD* = 1.7), and men were also on average 25.3 years old (*SD* = 1.5). All participants were all native Mandarin speakers and postgraduate students. They all had normal or corrected-to-normal vision and were without any history of speech, language, hearing impairment or any neurological problem. The experiment was approved by the Institutional Review Board (IRB). Subjects completed written informed consent prior to inclusion in the experiment and were financially compensated for their time. The PolyU Institutional Review Board (IRB) approved of the ethics for this study (HSEARS20240818003).

2.2 Stimuli

The stimuli comprised 328 different sounds of disyllabic spoken words in Mandarin Chinese, representing seven types of emotions (including happy, sad, angry, fearful, disgust, surprise and neutral) in semantic contents and prosody simultaneously. Specifically, the stimuli were selected from a sound set consisting of 84 different semantic words across the seven emotional categories, each spoken with seven types of emotional prosody (see Table A1 in appendix A for examples of words corresponding to the seven emotions). Thus, the emotions of the two auditory channels in each stimulus could be congruent or incongruent. There were 76 congruent stimuli and 252 incongruent stimuli. (see Table A2 in appendix A for details of stimulus types) Each stimulus differed from the others in at least one of the two channels.

Semantic channel: The disyllabic words were sourced from the Affective Lexicon Ontology (Xu et al., 2008), which is an opensource database that categorizes words according to Ekman's 6 basic emotion categories (Ekman, 1992) and rates their emotional intensity. Words of 7 emotional groups were matched based on word frequency, utilizing the SUBTLEX-CH-WF (Cai & Brysbaert, 2010), which is derived from movie subtitles and thus reflects everyday spoken language effectively. Additionally, the semantics of the words were tested and evaluated by 15 native Mandarin speakers through an online task. In a forced-choice task with seven emotional categories, each

category reached an accuracy rate exceeding 90%. In a word familiarity rating task, each word received an average familiarity score greater than 4 on a five-point scale (1=not familiar, 5=very familiar).

Prosodic channel: The words were produced in 7 types of emotional prosody by a professional broadcaster (male, age:30) who achieved the highest level on the Standard Mandarin Chinese Test. All sounds were tested and screened by five native Mandarin speakers who did not participate in Stroop experiments. For the 328 stimuli involved in this experiment, the accuracy of the prosody for each emotional category was above 92% in the forced-choice task with seven choices (ignoring the meaning of words). The average confidence level of the emotion for each stimulus was above 5.9 in 7 points scales.

To ensure the naturalness of the stimuli, we did not alter any of the original properties of the sounds. The statistics of the acoustic properties of the different emotions can be found in Table A3 in appendix A. Although there were differences in acoustic parameters between emotional types, all categories were covered in the experimental task in both the congruent and incongruent conditions to control the interference.

2.3 Procedure

In the experiment, subjects were asked to finish two Stroop tasks (a prosodic task and a semantic task) separated by 12 to 60 hours. The order of two tasks was balanced between subjects to avoid familiarity effect. In prosodic task, they needed to choose the emotion conveyed by prosody of the sounds from seven choices as quickly and accurately as possible while ignoring the semantics. In semantic tasks, the requirements reversed.

Each task included a practice session with 49 trials of unrepeated stimuli (7×7) before the formal test session. Participants were required to achieve 80% accuracy within a 5-second reaction time to ensure they could understand and follow the instructions. During the task, the location of the keys for the options remained constant but was randomized between subjects. The practice session also helped them become familiar with the key locations. There was no significant difference in the number of practice sessions for the two tasks (prosodic vs. semantic: 1.58 vs. 1.22). In the formal session, there were 420 trials divided equally into 14 blocks. 210 stimuli with incongruent emotional prosody and semantics were played once, while 70 congruent stimuli were repeated 3 times to equalize the number of stimuli in two conditions. The order of stimuli was completely randomized.

Each trial began with a fixation cross for 1000 ms, followed by a visual notice “Listen carefully!” (in Mandarin and English) displayed for 1000 ms to attract subjects’ attention. Stimulus would then be presented binaurally over headphones, with the options and requirements displayed on the screen simultaneously. Subjects were required to push the keys on a keyboard (fixed position for each emotion) as quickly as possible while maintaining accuracy to select the emotion conveyed in the attended channel. We recorded accuracy and response time from stimulus onset.

The experiment was conducted in a sound-insulated room with subjects seated in a comfortable chair approximately 70 cm from the monitor. The experimental program was written by E-Prime (version 3.0.3.80; Psychology Software Tools, 2012). Auditory stimuli were presented binaurally at 70 dB SPL through Audio-Technica headphones. Detailed instructions were included in the program before practice and formal sessions.

2.4 Statistical Analyses

Linear mixed-effects models were performed to analyze the data using R (Version 4.3.3; R Core Team, 2024) with the lme4 package (Bates et al., 2015). We focus on three variables separately: Accuracy (ACC), Response Time (RT), and Speed-Accuracy Tradeoff (SAT). Among the various methods of calculating the SAT, we used the Balanced Integration Score (BIS) proposed by Liesefeld et al. (2015), which integrates speed and accuracy with equal weights (Liesefeld & Janczyk, 2019).

Considering that RT data exhibits positive skewness, we performed a log transformation to RT data. The BIS data showed a clear left-skewed distribution, so we used Box-Cox transformation (Box & Cox, 1964; Sakia, 1992) to achieve a normally distributed BIS data.

In the linear mixed-effects models, ACC, the logarithm of RT, and transformed BIS were respectively entered as dependent variables. Congruency (congruent vs. incongruent) and task (semantic vs. prosodic) were entered as fixed factors, with congruent condition in prosodic task set as the default level. Subjects and items were entered as random intercepts. Tukey’s post hoc

Parameter	Any effect	Estimate	SE	*t*-value	*p*-value
Task	No	-0.007	0.004	-1.755	0.079
Congruency	Yes	-0.029	0.011	-2.600	0.0098**
Task× Congruency	Yes	0.019	0.006	3.371	<0.001***
Prosody - Semantics (Congruent)		0.007	0.004	1.662	0.344

Table 2: Linear mixed-effects model with the logarithm of RT as the dependent variable.

tests using the lsmeans package (Lenth, 2016) were conducted when there was a significant effect. The full models for ACC, RT and BIS analyses are represented as follows:

$$ACC = \beta_0 + \beta_1 \times Task + \beta_2 \times Congruency + \beta_3 \times Task \times Congruency + b_{items} + b_{subjects} + \varepsilon_{ij} \quad (1)$$

$$RT_{(log)} = \beta_0 + \beta_1 \times Task + \beta_2 \times Congruency + \beta_3 \times Task \times Congruency + b_{items} + b_{subjects} + \varepsilon_{ij} \quad (2)$$

$$BIS_{(transformed)} = \beta_0 + \beta_1 \times Task + \beta_2 \times Congruency + \beta_3 \times Task \times Congruency + b_{subjects} + \varepsilon_{ij} \quad (3)$$

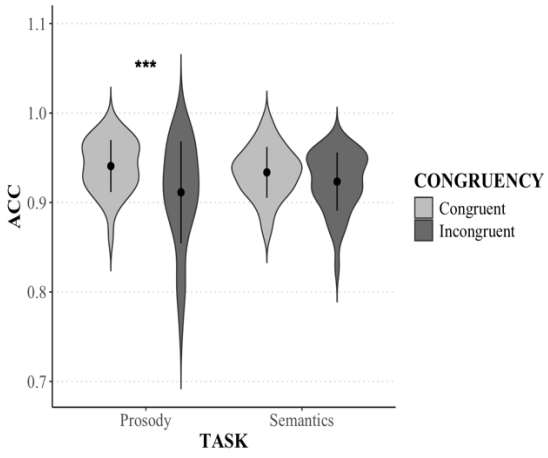

Figure 1: Accuracy in the two tasks and two congruence conditions.

3 Results

The results of the linear mixed-effects models for ACC, RT and BIS are shown in Table1, Table 2 and Table 3 respectively.

3.1 Accuracy

Overall, the participants responded with high accuracy (M = 92.7%, SD = 2.7%). Figure 1 illustrates the accuracy data for the congruent and incongruent conditions in the two tasks, which are normally distributed according to the *Kolmogorov-Smirnov* test.

Linear mixed-effects analyses showed no main effect of task, $\chi^2(1) = 3.08$, p >0.05. The main effect of congruency condition ($\chi^2(1) = 6.76$, p =0.009) was significant. Congruent stimuli elicited more (2.0% ± 2.8%) accurate responses than incongruent ones (β_2 = -0.029, SE = 0.011, t = -2.6, p <0.01). There was an interaction effect between task and congruency($\chi^2(1) = 11.36$, $\beta_3 = 0.019$, $SE = 0.006$, t =3.371, p <0.001).

Post hoc tests showed significantly higher accuracy for the semantic task in the incongruent condition (t=-2.853, p=0.023). The difference between the two conditions was significant in the prosodic task (t=6.96, p <0.001) but did not arise in

Parameter	Any effect	Estimate	SE	t-value	p-value
Task	No	-2.901	1.565	-1.853	0.067
Congruency	Yes	-7.301	1.565	-4.664	<0.001***
Task× Congruency	No	3.594	2.214	1.610	0.110
Prosody - Semantics (Congruent)		2.901	2.38	1.219	0.616
Prosody - Semantics (Incongruent)		-0.663	2.38	-0.279	0.992
Congruent - Incongruent (Prosody)		7.301	2.38	3.069	0.014*
Congruent - Incongruent (Semantics)		3.373	2.38	1.571	0.399

Table 3: Linear mixed-effects model with the transformed BIS as the dependent variable.

the semantic task (t = 2.445, p =0.069). This suggested that the conflicting information from semantics reduces correctness more than prosody.

3.2 Reaction Time

In analysis of RT data, incorrect responses and responses over 2 SDs from the mean were excluded (Baayen & Milin, 2010; Lin et al., 2020), which respectively accounted for 7.3% and 4% of the overall data set. Reaction time data in the two tasks and conditions are displayed in Figure 2. Reported mixed-effects analyses in Table 2 were conducted based on the logarithm of RT.

Analyses on the logarithm transformed reaction time showed main effects of task ($\chi^2(1) = 64.28$, $p < 0.001$), congruency (χ^2 (1) = 38.63, $p < 0.001$), and a significant interaction (χ^2 (1) = 12.26, $p < 0.001$). Participants responded 49 ± 228 ms faster to the prosody task than to the semantic task (β_1 = 0.038, SE = 0.005, t = 8.017, $p < 0.001$), and 132 ± 72 ms faster to the congruent stimuli (β_2 = 0.084, SE = 0.014, t = 6.215, $p < 0.001$).

Post hoc tests found that the response was faster in congruent condition for any task (prosodic task: t = -14.58, $p < 0.001$; semantic task: t = -10.47, p <0.001). Significant difference between tasks existed in the congruent condition (t = -6.74, $p < 0.001$), but disappeared in the incongruent condition (t = -2.52, p = 0.057). This suggests that the difference between the tasks narrowed after being disturbed by inconsistent messages. Further, it is likely that there was greater negative interference from semantics than prosody in the incongruent condition

3.3 Speed-Accuracy Tradeoff

We used the BIS as a parameter for the SAT, whose larger value indicates that the subject did better (Liesefeld & Janczyk, 2019). Reported analyses in Table 3 were based on the transformed BIS using Box-Cox transformation (Box & Cox, 1964).

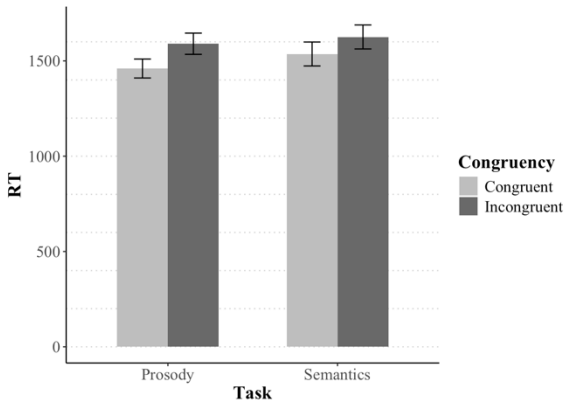

Figure 2: Reaction time in the two tasks and two congruence conditions.

Analyses only showed a main effect of congruency (χ^2 (1) = 21.75, $p < 0.001$). Participants responded better in congruent condition (β_2 = -7.3, SE = 1.57, t = -4.66, $p < 0.001$). Task effects were not significant (χ^2 (1) = 3.43, p = 0.064) and there was no interaction (χ^2 (1) = 2.59, p = 0.107). In the posttest, worse performance in the incongruent condition than congruent only occurred in the prosodic task (t = -3.07, p = 0.014), suggesting a significant role for semantic interference.

4 Discussion

To be clear, we summarize the results of the statistical analysis in Table 4. Combining the three parameters, the main effect of congruency remained significant, indicating that two channels with congruent information perform faster and more effectively than incongruent ones. This is not surprising, as people are more frequently exposed to congruent affective information conveyed by both channels in daily life (Nygaard & Queen, 2008).

We were particularly interested in the predominance effects of prosody and semantics. Our results showed that only the RT exhibited a main effect of the task, with prosody being

Parameter	Significant effect in LMM	*Post hoc test*	
		Prosody vs Semantics	**Congruent vs Incongruent**
ACC	Congruency, Task× Congruency	Better semantic task in incongruent condition	Better in congruent condition only in prosodic task
RT	Task, Congruency, Task× Congruency	Faster prosodic task in congruent condition	Faster in congruent condition
SAT(BIS)	Congruency	NS differences	Better in congruent condition only in prosodic task

Table 4: Summary for results of statistical analysis.

recognized significantly faster than semantics. However, this alone might be insufficient to prove that prosody plays a more important role in the identification process. This result might stem from the fact that prosodic signals are acquired earlier than semantic signals. Subjects need to finish listening to a disyllabic word before making a judgment about its semantics. This possibility was also reported in the study by Lin et al.(2020). Additionally, we found an interaction effect where the prosodic task was significantly faster only in the congruent condition. This might suggest a difference in the interference caused by inconsistent information from various channels. Further, semantic passages may cause greater latency, thereby negating the advantage of the faster speed of the prosodic task.

In the conflict condition, semantic interference was greater than that of prosodic interference. Results from both the ACC and SAT analyses support this conclusion. A significantly poorer performance in the conflict condition was observed only in the prosodic task. When judging semantics, no significant difference was found between the congruent and incongruent conditions. We might therefore conclude that there is a semantic salience effect in the emotional word processing.

We also confirmed the predominance of semantics by analyzing the incorrect responses. We counted the incorrect options that matched the emotion of the misleading channel in both tasks for each participant (i.e., in prosodic task, participants selected angry for a word “angry” spoken sadly). The proportions of matched incorrect options (P_{MIO}) among all incorrect options were calculated. A larger P_{MIO} indicates a stronger salience effect from the misleading channel. Using a paired t-test, we found the P_{MIO} in the prosodic task (P_{MIO_P} = 17.4%± 8.8%) was significantly larger than that in semantic task (P_{MIO_S} =11.4% ± 6.8%), with $t\ (35) = 2.675$, $p = 0.011$. Incorrect responses in the prosodic tasks are more influenced by semantics than vice versa.

Our results did not show prosody salience effect during emotional speech processing in Mandarin speakers, which differs from the findings of Lin et al. (2020). They used only two emotions, and prosody performed better than semantics. This suggests that changes in complexity due to the number of emotion categories might influence the strategies people use for emotional speech processing, leading to a shift in cue dominance. For example, in the study by Grimshaw (1998), stimuli involved words “mad” “sad” “glad”, “fad” expressed by four emotions (angry, sad, happy, and neutral). Increased reaction time and decreased accuracy in inconsistent conditions were observed only in the prosodic task. In other words, this indicated a semantic dominance effect.

The study suggests that the contrast in task difficulty might have an influence on the Stroop effect which cannot be ignored. In the two-choice task, participants could quickly establish the relationship between the acoustic features (e.g., pitch) of prosody and emotions, enabling them to respond without fully listening to the stimulus. The acoustic features of the semantic cues were more complex, and there were fewer repeated features to help subjects establish patterns. This imbalance in difficulty might affect their strategies in the task, leading to faster responses in prosodic task. In our study, the complexity of the options increased the difficulty level of the prosodic task, thereby equalizing the difficulties of the two tasks. After the experiment, subjects were asked to rate the difficulty of the two tasks using a 5-point scale (1=very simple, 5=very hard). There was no significant difference between the prosodic (2.78) and semantic (2.47) tasks. The increased difficulty also weakened the ceiling effect. In this context, the results of the study may be more robust.

This study has some limitations. Firstly, it has not clearly delineated how variations in complexity

specifically influence the cues relied upon by native Mandarin speakers. Complexity can be affected both by the number of emotional categories involved in the task and by controlling the number of channels. Future research will explore this issue by changing more variables. Secondly, this study only utilized male speakers. Future investigations will include female speakers to provide a more comprehensive examination of gender differences and identity recognition in emotional perception processing. Lastly, as this study is purely behavioral, it has certain limitations. We will consider employing more brain imaging techniques for further exploration.

5 Conclusion

This study explored the salience effect of prosody and semantics in speech emotion processing through a complex stroop experiment. It was found that semantic information was more salient than prosody cues, evidenced by the greater influence of semantic information on prosodic judgments. Task difficulty was better controlled in this study, which may have yielded more robust results. Complex tasks are more relevant to real life than previous studies, therefore this study informs natural emotional speech processing and provides reference for exploring neural basis of emotional recognition with potential clinical applications.

Abstract

This study explores phonological rhythm in Thai through the speech cycling (SC) paradigm. Six native Thai speakers, with and without musical training, produced phrases synchronized to external rhythmic cues. We measured the alignment of stressed syllables within a phrase repetition cycle (PRC) and analyzed the distribution of these alignments. The results revealed that Thai speakers consistently aligned stressed syllables at specific ratios, such as 1/3, 1/2, and 2/3 of the PRC. The study also found differences based on musical training, with trained participants showing more refined rhythmic patterns, suggesting a complex interplay of both universal and experience-based rhythmic constraints.

1 Introduction

The study of speech rhythm is a primary area of investigation in both the phonological and phonetic literature where the question has been approached from a variety of angles (*cf.* Turk & Shattuck-Hufnagel, 2013 for an in-depth review). Speech rhythm has predominantly been examined through the lens of cross-linguistic comparisons of so-called speech rhythm "metrics" in search of different rhythmic classes across languages. This approach that has yielded varied results, as will be discussed in detail in the next section (*cf*. Arvaniti, 2012; Bertinetto, 1989).

However, alternative approaches to the study of speech rhythm have been developed. Of specific interest here are attempts at grounding speech rhythm in more general cognitive constraints on speech production and perception (*cf*. Cummins & Port, 1998; Franich, 2021; Port, 2003; Tilsen, 2009).

In this paper, we follow this second family of approaches and conduct an experimental investigation of phonological rhythm in Thai using the "speech cycling" paradigm, an experimental task where participants have to produce words at specific points, known as phases, of a larger phrase cycle in accordance with an external rhythmic cue (Cummins & Port, 1998; Tajima & Port, 2003).

In the remainder of this introduction, we first introduce previous research on speech rhythm based on the rhythm class hypothesis and the challenges this approach has encountered. Subsequently, we introduce the speech cycling paradigm as way to overcome some of these limitations and to ground speech rhythm in more general cognitive mechanisms. Finally, we outline the suitability of Thai rhythm as a good case study given the dearth of experimental work on the topic and previous conflicting findings.

1.1 The rhythm class hypothesis

The notion that languages belong to different rhythmic classes, based on isochrony at the syllable ("syllable timing") or stress-interval levels ("stress timing"), was influentially proposed by Pike (1945) and Abercrombie (1990). However, experimental work probing isochrony failed to observe it (Arvaniti, 2009; Bertinetto, 1985; Dauer, 1983; Fletcher, 2010). The view of rhythm as isochrony was abandoned and a new notion of rhythm based on a complex interplay of language-specific phonological and syntactic properties emerged (Bertinetto, 1989; Dauer, 1983, 1987; Fletcher, 2010).

In the 1990s, following the work of Ramus and colleagues (Ramus et al., 1999), a renewed interest towards metrics that could help establishing rhythmic classes arose, e.g., (Bertinetto & Bertini, 2010; Dellwo, 2006; Grabe & Low, 2002). Such metrics mostly measure durations and include the proportion of vocalic intervals (%V), the standard deviation of consonantal and vocalic intervals (ΔC, ΔV) and their variation coefficients (varcoΔC,

varcoΔV). Other metrics also include vocalic and intervocalic raw and normalized pairwise variability indices *(nPVI*, *rPVI*). Despite this renewed interest in rhythmic classes, a variety of problems with the proposed rhythmic metrics emerged (Arvaniti, 2009; Kohler, 2009).

First, the classification of languages with "unknown" or "mixed" rhythmic typologies turned out to be far from straightforward. For instance, Thai was classified as stress-timed using PVIs, but as syllable-timed using %V and ΔC (Grabe & Low, 2002). Second, it was also pointed out that the new metrics were highly sensitive to segmental materials (Arvaniti, 2009; Fletcher, 2010; Mairano & Romano, 2011). Third, a large crosslinguistic study demonstrated that rhythmic differences across languages – attributable to rhythmic classes – and confounds – like elicitation task and segmental composition – have comparable effects on rhythm metrics (Arvaniti, 2012).

Due to the challenges of studying speech rhythm using rhythm metrics applied to elicited or natural speech, several scholars have recommended a shift in focus. Instead of concentrating solely on timing properties, as captured by traditional rhythm metrics, they suggest examining higher-level patterns in grouping and prominence both in speech production and in listeners' perception (Arvaniti, 2009; Kohler, 2009).

An experimental paradigm, called "speech cycling" (Chung & Arvaniti, 2013; Cummins & Port, 1998; Franich, 2021; Tajima & Port, 2003; Tilsen, 2009; Zawaydeh et al., 2002), has been developed exactly as a mean to uncover constraints on prominence and grouping patterns and their relationship to speech rhythm.

1.2 The speech cycling paradigm

The "speech cycling" paradigm – henceforth SC – was first developed by Cummins and Port (1998). SC is a rhythmic task where participants produce words at specific points, known as phases, of a larger phrase cycle; they do so by entraining to an external rhythmic cue.

SC involves entraining the initial and final words of a short phrase – for example "*beg for a dime*" – to high (H) and low (L) metronome beats. While the H-L interval duration remains constant across trials, the duration of two successive H–H, called the phrase repetition cycle (PRC), is systematically manipulated. The final stressed syllable thus needs to be aligned at different phase – e.g., 0.3, 0.5, and 0.75 – of the PRC, Figure 1.

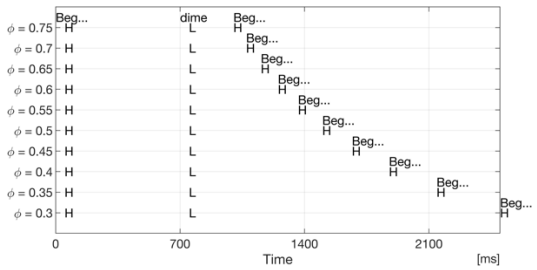

Figure 1: Illustration of word entrainment to H and L tones for different phases and duration of the PRC for the phrase "*beg for a dime*"

Thus, in SC, participants are exposed to a uniform rhythmic continuum of possible phases for the final stressed word within the larger phrases cycle. Thus, SC experiments can be used to probe whether a rhythmic continuum can be faithfully reproduced by participants or whether the continuum is warped into a small number of discrete categories, Figure 2.

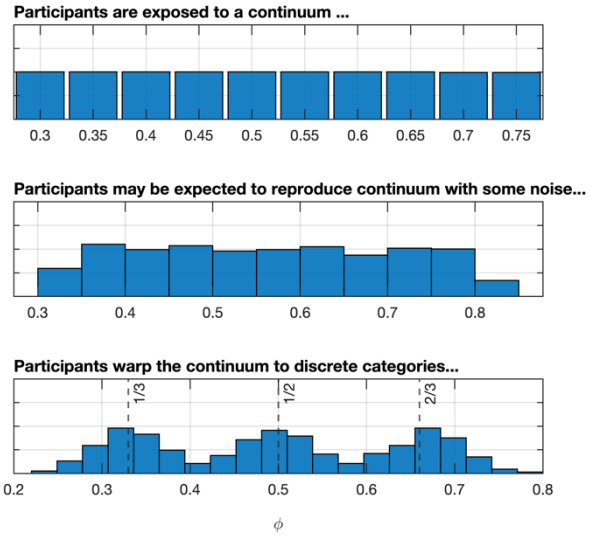

Figure 2: Logic of Speech Cycling experiment, see text for more details.

Cummins and Port (1998) found that American English (AE) speakers have a strong tendency to warp the rhythmic continuum intro three categories. Specifically, they produce stressed syllable at the harmonic series or its multiples (1/3, 1/2, 2/3) of the PRC, Figure 2. Cummins and Port (1998) demonstrated that these values of the PRC also exhibit lowest variance and can, thus, conceptualized as "attractors" in the potential landscape of a dynamical system. Thus, Cummins and Port (1998) and Port (2003) related the

rhythmic warping they observed to the relative initiation of a new foot relative to PRC and conceptualized the process as a system of coupled oscillators. From this perspective, the different attractors they observed can also be translated into low-dimensional phonological representations. Specifically, the attractors were taken to reflect the initiation of a new trochaic metrical foot in AE.

An attractor at 1/3 is taken to reflect the metrical grouping [*beg for a*][*dime*][-], the only possible grouping where stress on the final syllables appears at 1/3 of the PRC. Similarly, the attractor an ½ represents the grouping [beg for a][dime]; and an attractor at 2/3 represents a grouping [beg][for a][dime]. These patterns exhaust the rhythmic possibilities of English speakers and reveal the organization of prominence and grouping in this language. SC allows us to understand that the impression of AE rhythm being driven by stressed syllables may arise in part from phonological properties (e.g., vowel reduction etc.) but, crucially, also from the strong constraints that exist on the distributions of stressed syllables within phrases. If the distribution is highly constrained, repetition of similar pattern will naturally arise resulting in "rhythmic" patterns.

A final important discovery of Cummins and Port (1998) was that the rhythmic warping observed in SC is identical for both rhythmically naïve participants, as well as rhythmically trained participants, e.g., professional musicians. These finding suggest that the constraints observed in speech cycling reside above experience, possibly being cognitive in nature.

Since the original study on AE, SC has been applied to other languages, to show that constraints exists on the production foot-initial syllables in Japanese like (Tajima & Port, 2003); stressed syllables in Arabic (Zawaydeh et al., 2002); accentual-phrase initial syllables in Korean (Chung & Arvaniti, 2013); and foot-initial syllable in Medumba (Franich, 2021). More work on AE (Tilsen, 2009) has also tried to further develop the conceptualization of rhythm observed in SC as a system of coupled oscillators by taking into account the initiation of articulatory gestures and their variability.

Despite the interest attracted by this paradigm, many aspects of SC remain underexplored. No work has investigated further the role of rhythmical/musical training on speakers' behavior during SC. Additionally, the number of languages investigated with speech cycling remains scarce. For instance, no Asian tonal language or prominence-final, so–called iambic, language has been investigated. Modelling work using dynamical systems outside of English is also lacking. With these issues in mind, we introduce the case study to which we applied the SC paradigm.

1.3 The case study: Thai Rhythm

There are several aspects that make Thai a good case study to investigate rhythm using SC.

First, the rhythmic class of Thai is debated. Thai has been described as both syllable timed (Pantupong, 1973; Suntornsawet, 2022) and stress-timed/mixed (Luangthongkum, 1978). Rhythm metrics have not settled the matter. The rhythmic classification depends on the metric used (Grabe & Low, 2002).

Second, if Thai really is as stress timed as some report (Mairano & Romano, 2011), it is quite different from AE in view of its tonal nature, simple phonotactics and, above all, iambic rhythm. In iambic rhythms, the nature of the foot type is driven by durational cues, naturally forming groupings with longer final prominent elements. In line with the iambic nature of Thai, duration has been often reported to be the primary cue to stress in Thai (Nitisaroj, 2004; Potisuk et al., 1996). This is opposed to trochaic systems where grouping is more intensity based (Hayes, 1995). Thus, probing the behavior of Thai speakers compared to AE speakers is of great interest.

Third, while prominence is uncontroversially final in Thai (Bee, 1975; Bennett, 1994), the grouping around prominent syllables is debated. Some assume cretic structures [–◡–] (Bee, 1975), while others have shown experimental evidence for anapests [◡◡–] (Gandour et al., 1992). Fourth, Thai rhythm has been hypothesize to display a high degree of individual variation (Luangthongkum, 1978).

1.4 Research Questions and Predictions

In view of the issues outlined in the previous sections, we focus on three research questions concerning Thai rhythm probed using the SC paradigm. These are:

1) Do Thai speakers exhibit rhythmic constraints in their production of stressed syllables within phrases, similar to AE speakers?

2) Taking individual music experience into account, are there differences in these behaviors based on rhythmic/musical training?

3) If rhythmic constraints are manifested, does this behavior betray the signatures of an underlying dynamical system?

We put forth the following predictions. For 1), given the warping of rhythmic continua in various languages, we expect to observe it in Thai too. However, in view of iambic nature of Thai, we also expect final prominence and different grouping compared to trochaic languages, like AE.

For 2), we expect, based on previous work on AE (Cummins & Port, 1998), a similar behavior for participants regardless of their musical/rhythmic background. For 3), under the assumption that speech cycling rhythm can be understood in terms of attractors in a dynamical system of coupled oscillators, we expect the attractors to display low variance, in line with previous work on AE (Cummins & Port, 1998; Tilsen, 2009).

2 Methodology

2.1 Participants, Materials, and Procedures

Participants. We recruited six native Thai speakers with (M) and without musical background (NM). All M participants obtained at least a bachelor's degree in music, while NM had no formal musical training. None of them disclosed any speech or hearing impairment. The presently limited number of participants is due to the demographics of interest, professional musician and musically naïve speakers, and the long experimental duration requiring approximately 2.5–3 h for a full session.

Speech materials. Following previous work on SC, we used ten short phrases with identical prosodic structure "N_1 jù: Prep(osition) N_2" ("N_1 is in/on N_2"). Following (Cummins & Port, 1998), all words in the sentence were monosyllabic and all N_1 and N_2 nouns started with a voiced stop onset to facilitate p-center location. Since *jù:* and *Prep* are function words, they are produced as unstressed.

Procedures. Inside a recording studio, participants sat in front of a computer monitor running a custom GUI used to run the experiment and record audio. Participants were instructed to produce a sentence displayed on the screen and align the first word to a H tone and the last word to a L tone. The H and L tones were generated using a pure tone at 1200 Hz (H) and 600 Hz (L). Tones lasted 50 ms, with 10 ms fade in and out. The H-L interval was kept constant at 700 ms, while the time from the L to a following H was varied so that the H-L interval covers the range 0.3 and 0.75 of the H-to-H PRC, in .05 steps yielding 10 phase values, Figure 3.

In each trial, a random phrase and phase were selected. Participants were instructed to listen to four pairs tones to prepare. Then, participants repeated target sentences ten times aligned with the tones and another ten without the tones while trying to maintain the same phase. We obtained a total of 100 trials (10 unique sentences x 10 phases) per participant and 18- repetition per trial for a total of ~10800 tokens.

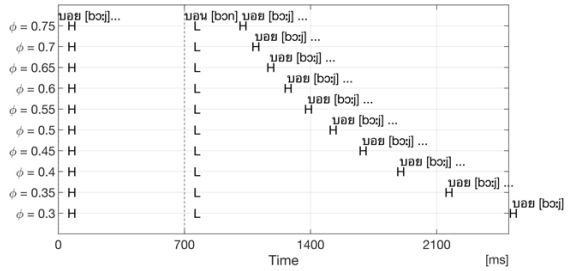

Figure 3: Illustration of rhythmic continuum for stressed syllable alignment in the PRC.

2.2 Data Processing

Following previous work on SC, the main dependent variable we extracted is where the onset of the final stressed word occurs within the phrases in terms of proportion of the phrase. This is also known as observed phase (φ), Figure 4. As a concrete example of a phrase, we calculated the location of the final word p-center (e.g., บอน [bɔ:n] in บอยอยู่ในบอน [bɔ:j jù: naj bɔ:n]) relative to the PRC, which starts and ends with the initial stresseed word of each sentence repetition (e.g., บอย [bɔ:j] in บอยอยู่ในบอน… บอยอยู่ในบอน… [bɔ:j jù: naj bɔ:n…bɔ:j jù: naj bɔ:n]), Figure 3. Note that the measure is not based on the external rhythmic cue but on participants' productions.

Following the original experiment (Cummins & Port, 1998) and much previous work in the rhythm literature, word onset is not defined as a segmental boundary, but rather as the p-center associated with each word, an event where people perceive prominence and align finger tipping corresponding to maximal change in energy of the signal amplitude envelope.

P-centers were algorithmically located as the midpoint of local rises in the amplitude envelope as

follow. To obtain a smooth amplitude envelope that preserves maximally the vocalic energy for each trial, we first down sampled the audio by a factor of 4 to have a frequency of 11025 Hz. We then filtered the signal using a passband first-order Butterworth filter with cutoff frequencies at [700, 1300] Hz. The resulting signal was rectified by taking its absolute value. This procedure was followed by a second round of filtering using a lowpass first-order Butterworth filter with a cutoff frequency of 10 Hz. Finally, we smoothed the amplitude envelope twice using a moving average filter based on 5 samples. To locate the midpoint of rises we started by finding local peaks in the amplitude envelope, rescaled between 0 and 1. We then located the minimum preceding each peak as the closest zero crossing in the gradient of the envelope. Finally, the p-center of each syllable was identified as the midpoint between each minimum and peak, Figure 4.

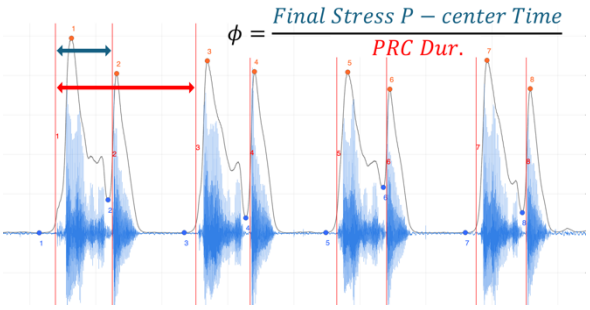

Figure 4: Example of automatic p-center extraction of initial and final syllables for four repetitions and calculation of observed phase (φ). Blue lines mark waveform, gray lines the rectified smoothed amplitude envelope and red line mark detect p-centers between minima (blue dots) and maxima (orange dots).

The phase of each repetition in a trial was calculated as the time of the p-center of the stressed final word divided by the total duration of the PRC spanning the lag between initial p-centers of successive repetitions, Figure 4. Based on a visual display of the amplitude envelope, the locations of peaks, minima, the p-centers were inspected and manually corrected when necessary. Note that, unlike previous work (Cummins & Port, 1998), we did not take the median of all repetitions in a trial, as this could reduce variability and statistical power. Instead, we used all repetitions in all trials. Following previous work (Cummins & Port, 1998), we collapsed repetitions with and without metronome tones, as we observed no significant effects after preliminary testing.

2.3 Data Analysis

Following (Cummins & Port, 1998), we tested the existence of rhythmic constraints in Thai using Gaussian Mixture Models (GMMs) to model the phase distribution both pooling data across subjects and within each subject separately, we tested up to six mixtures and chose their optimal number using the Bayesian Information Criterion (BIC).

To test possible differences between M and NM participants, we obtained bootstrapped 95% confidence intervals for the median of observed phases as a function of target phases. We also fit nested linear mixed-effect regression models to test whether target phase, musical experience, and their interaction are significant predictors of observed phase. All models had by-subjects random intercepts and slopes for musical experience and target phase. Target phase was z-score normalized.

To test whether observed phase is lower at some target phases, separately by subject, we obtained 95% confidence intervals for median values of the interquartile ranges (IQR) and we also fit smoothing splines to the IQR values.

3 Results

3.1 Rhythmic warping: data pooled across all participants

By fitting GMM to observed p-center phase across all participants, we found that Thai speakers warp the rhythmic continuum they are exposed to, Figure 2, into a small number of categories of possible stress locations, Figure 5. These are best modelled with five Gaussian mixtures (μ = .35, .42, .52, .62, .64) capturing three evident modes that gravitate around 1/3, 1/2, and 2/3 of the PRC, Figure 5. In this respect, Thai speaker closely mirror the behavior reported for other languages, like AE.

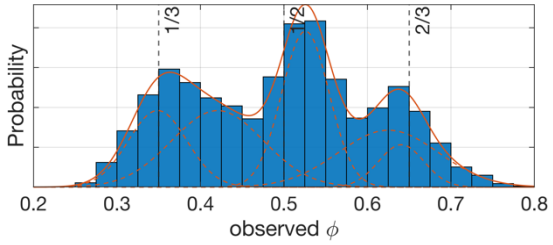

Figure 5: GMM fit to observed relative phases across all participants.

3.2 Rhythmic warping: the role of musical training

Unlike what has been reported for AE, we observed marked differences among participants with and without musical training. A clear difference between M and NM is that they differ in the number of modes displayed in their observed phase. M participants display 3 modes roughly at .33, .5, and .66. NM participants display only 2 modes: .34-.38 and .46-.56, Figure 6.

The rationale for this difference is that M participants can better imitate the phases where the W_1–W_3 group occupies 2/3 (.66) of the phrase repetition cycle. This is illustrated by the 95% CI of the median distance from target phases that is almost invariably < .1 for M and > .1 for NM, when φ > .66, Figure 7.

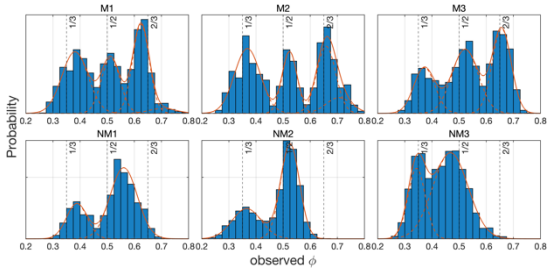

Figure 6: GMM of observed relative phases by participant (top: M, bottom: NM).

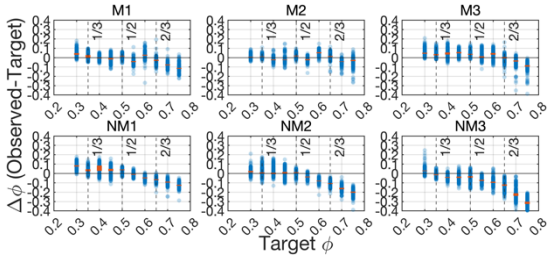

Figure 7: Distribution of distances from target phases with overlaid bootstrapped 95% CI for the median

The different behavior of M and NM is confirmed by fitting LME regressions to their observed phases. The model that best fits the data includes an interaction between target phase and musical experience ($\chi_{(1)}$=13.78, p < .001). The model fit, Figure 8, shows that observed phase increases with target phase, indicating that participants correctly perform the task. Intercept for .5 phase is 0.53 (95% CI [0.52–0.55], p < .0001). Observed phase increases by .11 (95% CI [0.10 –0.13], p < .0001) per .15 increase in target phase, indicating a close match. Lack of musical experience is associated with a lower intercept (−0.04 95% CI [−0.08 −0.001], p = .04) indicating that there the match of target phases is less accurate even at .5 target phase for NM participants. NM participants struggle more to match target phases as target phase increases, as reflected in a negative interaction between lack of musical experience and target phase (−0.05 95% CI [−0.072 −0.032], p < .0001).

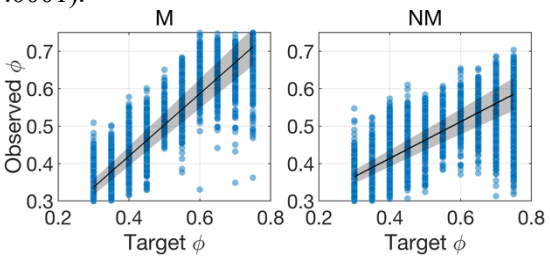

Figure 8: Model fit of observed phase as a function of target phase for M (left) and NM (right).

3.3 Rhythmic warping: dynamical systems' signatures

Finally, we studied variability based on bootstrapped 95% CI of the median IQR obtained using all repetition in a trial. From this analysis, the dynamical signature of lower variance in and around integer ratios (1/3, 1/2, and, to a lesser extent, 2/3) of the PRC also emerges, Figure 9 Top. This fact is reflected in the "dips" in the smoothing spline fits, Figure 9 Bottom. Low variability around ~.33 is evident for M1, M2, M3, NM1, and NM3. Low variability around ~.5 is exhibited by all participants. Finally, low variability around ~.66 is less clear, but seems present for M1, M2, and NM1.

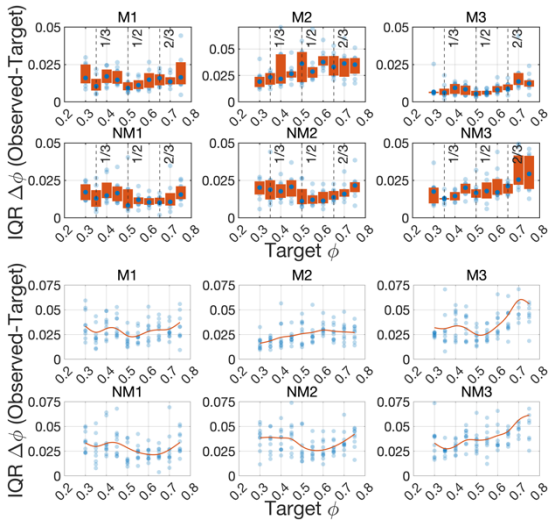

Figure 9: Top: Distribution of distances from target phases IQRs with overlaid bootstrapped 95% CI for the median. Bottom: smoothing splines fit to the same data.

4 Discussion and Conclusion

We now return to our research questions. The first question we investigated is whether Thai speakers exhibit rhythmic constraints in their production of stressed syllables. The GMM modeling strongly suggests that they do, as Thai speakers are highly constrained in their placement of final stressed syllables within a phrase. When exposed to a continuum of possible alignments for stressed syllables within a phrase, Thai speakers, with or without musical experience, cannot fully reproduce that continuum. To the contrary, they warp it into a small number of alignment categories that tend to divide the PRC into simple integer ratios such as 1/3, 1/2, 2/3. This finding replicates previous work on languages like AE, cited in the introduction. Our findings allow us to further substantiate the claim that the impression of rhythmicity in speech may come from higher level constraints on production and perception. These constraints dictate a small number of possibilities for the placement of prominent events, like stressed syllables. This limited range of possibilities for the placement of prominent events, in turn, can give rise to an impression of rhythmicity. This impression of rhythmicity arises simply from the fact that only a limited number of patterns is available, and, thus, the patterns end up being repeated, leading to an impression of periodicity and rhythmicity.

The second question we investigated is whether there are individual differences in rhythmic warping behaviors based on rhythmic/musical training. Recall that previous work on AE (Cummins & Port, 1998) found no differences between participants that do and do not have such training. This finding was taken as evidence for the cognitive and universal nature of the constraints at play in production/perception.

However, our combined evince from GMM fitted by–participant and linear mixed effect regression shows that a clear difference exists between participants with and without musical training in Thai, unlike in AE. Thai participants with a musical background display a low (1/3), mid (1/2), and high attractor (2/3), while participants without a musical background display only the first two attractors. This is an important aspect that may have been overlooked in previous work, as it shows that rhythmic constraints are not purely cognitive in nature, but they also stem from linguistic experiences – as shown by the difference between AE and Thai – and by individual experience – as shown by the difference between participants with and without musical training.

We now briefly discuss how the differences in performance between Thai and AE speakers may be related to the phonological properties of the two languages. Unlike English varieties, Thai is a language where rhythm is iambic and prominent elements are group final (Bee, 1975; Bennett, 1994). Thus, for example, the grouping of a phrase would be [ˈbɔːj] [jùː naj ˈbɔːn] vs. [ˈbeg for a] [ˈdime] in English (Cummins & Port, 1998). Note that this grouping with final prominence is expected in Thai not only on the grounds of phonological analyses, but also of Thai traditional music grouping.

Keeping in mind this background, we can attempt to relate the attractors we observed to low dimensional phonological analyses. For attractors at l/3 and 1/2 of the PRC, participants produced two stress groups [ˈbɔːj] [jùː naj ˈbɔːn] with final prominence and considerably shorter W_2 and W_3 compared to W_1 and W_4, that is [–] [∪∪–]. The only difference between attractors at l/3 and 1/2 is the presence of a silent beat in the 1/3 case [–] [∪∪–] [ ] (Cummins & Port, 1998).

However, a different strategy must be adopted when an attractor is displayed at 2/3 of the PRC. Specifically, three stress groups are needed and, in AE, this requires introducing a stress on words that are normally unstressed like *for*, *i.e.*, [ˈbeg] [ˈfor a] [ˈdime] (Cummins & Port, 1998). In Thai, speakers also need to produce three stress group, as, e.g., [ˈbɔːj] [jùː ˈnaj] [ˈbɔːn] [–] [∪–] [–] on normally unstressed words. This is exactly what M participants do and NM participants fail to do.

We believe that a potential reason for this failure is that Thai speakers tend to normally create trisyllabic stress groups constituted by a single anapestic foot in faster speech ([∪∪–]). A grouping where most of the duration is concentrated on the final prominent syllable. However, this strategy is incompatible with introducing stress on either of the preceding two words, as is necessary for the final stressed syllable to appear at 2/3 of the PRC.

Our hypothesis is based on previous phonological and experimental work. For Thai speakers, a tendency towards polysyllabic stress groups ending in a longer prominent syllable has been reported in the phonological literature (Rudaravanija, 1965) and also experimentally confirmed (Nitisaroj, 2004; Potisuk et al., 1996).

Moreover, syllable durations that are in line with anapestic rhythm ([⏑⏑–]) have been reported as the routine realization of trisyllabic compounds and phrases (Gandour et al., 1992).

In sum, NM participants display only patterns that seem in line with what has been observed in non-rhythmic Thai speech. M participants, on the other hand, can produce other less common patterns. In our opinion, the difficulties manifested by speakers without musical training in producing a rhythm compatible with an attractor at 2/3 of the PRC could be an additional manifestation of the strongly iambic rhythm of Thai. A property that sets this language apart from other languages like AE and that makes Thai run contrary to a more "isosyllabic" or syllable-timed rhythm often observed at high speech rates (Arvaniti, 2012).

The final question we have investigated is whether the rhythmic constraints we reported may betray the signatures of an underlying dynamical system of coupled oscillator that could be used as a way to conceptualize the observed rhythmic patterns, as hypothesized in recent work (Nam et al., 2008; O'Dell & Nieminen, 1999; Tilsen, 2009).

To test this question, we supplemented GMM models with analyses of variability. Our analyses of variability at different phase values using both bootstrapping of IQRs and spline smoothing confirms previous findings of lower variability around the centers of the categories in which the rhythmic continuum of stress placement is warped by participants.

The combined findings of a warping of the rhythmic continuum into a small number of more stable categories and the lower variability of said categories are compatible with previous suggestions, (e.g., Port, 2003), that, in SC, rhythm can be generated by two coupled oscillators of different frequencies for the stress groups (or metrical foot) and the phrase. These oscillators evolve according to a potential function representing the phase of the slower PRC when a new stress group is initiated (Port, 2003).

For reasons of space we refrain from presenting a full discussion of a coupled oscillator model of speech cycling in Thai. Yet we wish to point out that we have developed a computational implementation of the dynamical system proposed in previous work and, by further parametrizing a previous proposal (Port, 2003), we found that it qualitatively mirrors well our data pooled across participants, Figure 10.

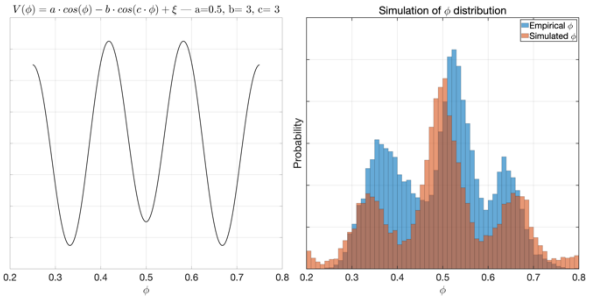

Figure 10: Left: potential function of phase dynamics. Right: stochastic dynamical system model simulation vs empirical data.

As shown in Figure 10, this dynamical system correctly captures macroscopic properties of the constraints observed on the placements of stressed syllables in Thai. That is to say, it captures a strong tendency for stressed syllables to be produced around 1/3, 1/2, and 2/3 of the phrase.

In addition, tuning the parameters a, b, and c of the model in the equation in Figure 10 allows us to generate cross-linguistic and cross-individual variation. Minimal changes to these parameters can, for example, generate behaviors where only two attractors are present, as we have observed for some of participants with no rhythmic training, e.g., NM3 in Figure 6, as illustrated in Figure 11.

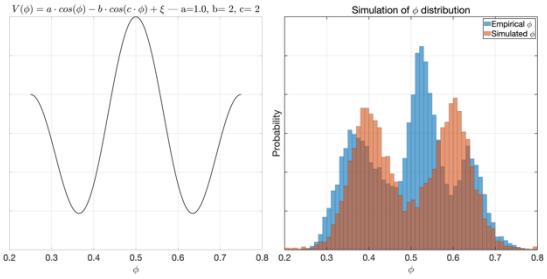

Figure 11: Left: potential function of phase dynamics. Right: model simulation vs empirical data.

We can thus think of said parameter modulations as a capturing how rhythm is the result of a universal laws (the dynamical system potential) and parameters that may be modulated by a variety of factors such as linguistic background (for instance being a speaker of English or Thai) or individual experiences (for instance having musical training, auditory acuity, previous experience with rhythmic tasks, *etc*).

To conclude, this study shows that Thai speakers exhibit rhythmic constraints in speech, aligning stressed syllables at simple ratios integer like 1/3, 1/2, and 2/3 of a phrase. This finding indicates that

universal cognitive processes can give origin to the impression of rhythm in speech because the number of available patterns is limited, thus repetition becomes the norm. Importantly, musical training can loosen these constraints. Musically trained speakers show more distinct rhythmic patterns than speakers without such training. This second finding suggests that, while some rhythmic constraints are universal, others are shaped by individual experience. Finally, our findings also reveal how Thai's iambic, prominence-final rhythm interacts with these constraints, with non-musically trained speakers reflecting natural speech patterns more closely. We have proposed that this dual nature of constraint on speech rhythm can elegantly be capture by a dynamical system. In this system, the potential function reflects universal tendencies that are further modulated by parameter modulations capturing individual experience.

Thus, our results support a view of speech rhythm as the manifestation of a complex interplay between cognitive mechanisms and individual experience that shape speech behavior in language- and individual-specific ways.

Abstract

In this paper, we present a token-by-token whole-spectrum approach using deep learning to investigate sound change, focusing on the understudied phenomenon of Khmer velar coda palatalization. By applying deep learning classification models to Mel spectrograms, our approach confirms that Khmer is undergoing velar palatalization. The model also reveals significant inter-speaker variation within the same linguistic community, with different speakers at different stages of the sound change. Additionally, our method, using Grad-CAM, identifies specific acoustic features associated with this phonological shift. Our findings highlight the potential of deep learning techniques to enhance our understanding of sound change.

1 Introduction

A fundamental area in the study of phonology and phonetics deals with the study of how the sound inventories of a language evolve over time. This continuous process of sound change represents one of the most pervasive and characterizing properties shared by all human languages and it has been investigated since the 18^{th} century (*cf.* Garrett and Johnson 2013 and references therein).

Sound changes are traditionally considered the endpoint of low-level phonetic changes that gradually diffuse through lexical items and a population of speakers until they affect the total number of phonological contrasts by changing their phonetic realization or by increasing (via splits) or decreasing their number (via mergers). An outstanding issue in linguistic theory remains developing viable models that can render justice to the complexity of this process (*cf.* Harrington et al. 2018 and references therein).

Two important prerequisites stand in the way of developing appropriate models of sound change.

First, sound changes often involve a variety of acoustic (and articulatory) dimensions that are relevant to the production and perception of speech. In other words, to appropriately characterize sound change, we must be able to probe, describe, and quantify variation beyond a small number of low-dimensional phonetic parameters that are often examined in experimental phonetic and phonological studies, e.g., duration, vowel formants, fundamental frequency *etc.* (for examples of this approach *cf.* Gubian et al. 2015, Puggaard-Rode 2022).

Second, given the increased attention paid in linguistic theory to exemplar and episodic models of lexical access and speech production/perception and their relationship to sound variation and change (Pierrehumbert et al. 2002, Johnson 2007, Goldrick and Cole 2023, Blevins and Wedel 2009), we need to develop models that enable us to quantify variation of interest on an episodic or token-by-token basis.

In this paper, we present an approach that offers promising solutions to tackle the two issues outlined above and, thus, can help in developing comprehensive descriptions and models of sound change. Specifically, we present a deep-learning approach that (i) enables us to quantify multidimensional phonetic and phonological variation relevant to sound change by applying deep-learning classification to (Mel)-spectrograms and (ii) allows us to quantify the degrees of change associated with individual exemplars of a phonological category.

We apply this method to the phenomenon of palatalization in Khmer (ISO-693-3; khm), an Austroasiatic language and the official language of Cambodia.

1.1 The case study: Khmer velar palatalization

Khmer has a phonological contrast between velar and palatal nasal and stop consonants in the onset position. However, the status of this contrast in coda position remains debatable. According to descriptions in Khmer grammar books and dictionaries (e.g., Huffman, 1970; Filippi and Vicheth,

2016), velar codas /k/ and /ŋ/ undergo palatalization following front vowels, such as /iː/, /eː/, /ei/, /ɛː/, and /ae/, and are subsequently realized as palatal consonants [c] and [ɲ]. Furthermore, Khmer orthography only attests non-palatal coda following long front vowels. This suggests that palatal codas were not originally present, but developed over time through diachronic palatalization of velar codas in this environment.

Khmer palatalization is of great interest for three reasons.

First, no experimental investigations of the phenomenon exist. This constitutes a noteworthy empirical gap, given that palatalization phenomena *following* front vowels are relatively rare (being mostly known from Germanic, *cf.* Hall 2022) compared to palatalization of consonants *preceding* front vowels.

Secondly, although this palatalization is often described in the literature as a completed sound change, anecdotal evidence suggests that Khmer speakers may not fully perceive a merger between palatal and velar sounds in this context. This raises the possibility that the change may, in fact, *not* be fully complete. Some speakers may produce fully velar consonants, while others produce fully palatal consonants. Additionally, speakers might produce fronted velar consonants due to co-articulation with preceding front vowels. Consequently, the status of this phenomenon—as either an ongoing or completed sound change—remains uncertain and requires further investigation.

Third, the distinction between velar and palatalized velars, is well-defined articulatory in terms of tongue body contact with the different points of the palate, yet, the acoustic manifestations of this articulatory underpinnings are notoriously elusive (Keating and Lahiri, 1993; Ladefoged and Maddieson, 1996; Ladefoged and Johnson, 2014).

1.2 Research questions

With the issues outlined above in mind, we investigate Khmer palatalization with a token-by-token whole-spectrum approach that leverages deep learning.

First, we trained convolutional neural network models to classify Mel spectrograms of phonologically contrastive velar and palatal nasals in non-front vowels environment.

Subsequently, the trained models were then used to investigate Khmer palatalization of velar consonants. Specifically, they were used to predict the probability that a certain velar token is realized as palatal in front-vowel environments. This approach allows us to situate individual tokens from individual speakers on a velar to palatal continuum based on the whole Mel spectrogram.

Equipped with these models, we investigated the following three research questions.

(i) Do we observe a degree of palatalization of velar stop after front vowels in Khmer as reported in grammar and dictionaries?

(ii) Do we observe complete neutralization of velars to palatals after front vowels in Khmer or do we observe a cline of realizations; possibly, differing across individuals within a community?

(iii) Finally, can an investigation of the inner workings of said models help to shed light on the spectral features that are likely to underlie the (eroding) distinction between velar and palatal stops in Khmer?

2 Methodology

2.1 Participants and data collection

The recordings were collected from five native speakers of Khmer: two from Phnom Penh and three from Takhmao, a city near Phnom Penh. There are two male and three female participants. Their ages are in the range of 20-30 years old ($\mu = 23.8, \sigma = 3.83$). Speakers from both cities speak the Phnom Penh variety reported to have final velar palatalization (Filippi and Vicheth, 2016). All participants were literate in Standard Khmer.

The target words consisted of monosyllabic or minor disyllabic words with final palatal and velar nasals, preceded by both front and non-front vowels. We divided the target words into two groups: one containing true velar and palatal nasals, and the other containing palatalized velar nasals.

For the true velar and palatal dataset, the target words included those with velar /ŋ/ and palatal /ɲ/ nasals following non-front vowels /a/, /iə/, /uə/, and /ou/. In this environment, velar consonants are not expected to undergo palatalization. We prioritized minimal pairs between velar and palatal codas. There were 16 unique target words (2 codas $\times$ 4 vowels $\times$ 2 unique words per template). Participants were asked to produce each target word 20 times, resulting in a total of 320 tokens per speaker.

For the palatalized velar dataset, the target words included those with a velar nasal following front vowels /iː/, /eː/, /ei/, /ɛː/, and /ae/, which are environments for velar palatalization. There were 10 unique target words (5 vowels × 2 unique words per template), with each word repeated 10 times, resulting in 100 tokens per speaker. An example of the different types of words used in the wordlist is shown in Table 1. All target words were embedded in a carrier sentence: [niʔ.jɨj tʰaː _____ tɒː tiət] "Speak the word _____. Next.".

Palatal	Velar	Palatalized
baɲ 'to shoot'	baŋ 'to cover'	wɛːŋ 'to be long'

Table 1: An example of the wordlist

For the true velar and palatal dataset, the target words were presented to participants embedded in a carrier sentence in Khmer orthography. Participants were instructed to read the entire sentence aloud. For the palatalized velar dataset, to avoid the influence of the orthography on the final consonant, we included trials where participants were presented with pictures representing the target words, in addition to the trials with orthographic presentation. It is worth noting that we did not observe any difference between picture and orthography stimuli. Thus, we analyzed the tokens from both picture and orthography stimuli together in this paper.

The recordings were conducted using the SpeechRecorder software (Draxler and Jänsch, 2004). The audio signal was captured directly to a laptop computer at a sampling rate of 44.1 kHz through a head-mounted unidirectional microphone. The recordings were done in a closed space with minimal noise.

2.2 Data preparation

The recordings were force-aligned using the MAUS language-independent model (Schiel, 1999). Subsequently, the TextGrids generated by MAUS were manually corrected using Praat (Boersma and Weenink, 2020) by a phonetically trained native speaker of Khmer. The manual correction focused on the segmentation of the nasal finals to ensure that no trace of the vowel was included in the nasal coda segment, as the acoustic signals during the nasal closures were used as input for the classification model. An example of the segmentation is illustrated in Figure 1.

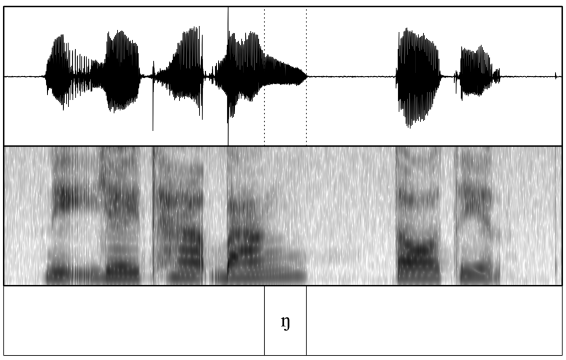

Figure 1: A segmentation example from Praat of word with velar nasal coda

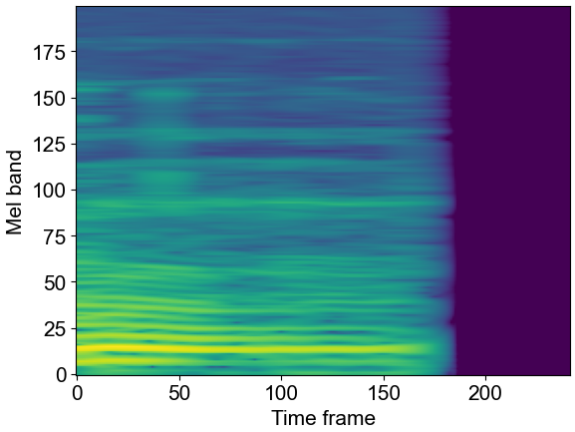

Figure 2: Mel-spectrogram example of one nasal token input. The dark shade part exhibits the zero-padded region.

To capture the multidimensionality of the acoustic signal, we extracted spectral information from the audio signal during the nasal closure using the Mel spectrogram method. The window size was set to 50 ms with a 1 ms time step, and the Mel filter bank was set to 200 Mel bands, ranging from a minimum frequency of 1 Hz to a maximum frequency of 22.05 kHz. To create a consistent input size required by the model, all tokens shorter than the maximum duration were symmetrically padded with zeros preceding and following the audio signal. Figure 2 illustrates an example of the resulting Mel spectrograms, showcasing the intensity of spectral components over time and frequency. The resulting Mel spectrograms were used as the input to the classification models.

2.3 Baseline model training and testings

To account for inter-speaker variation, separate deep learning models were trained using each individual participant's data, following the method-

ology of Liu and Xu (2023). As a result, we developed five baseline models, corresponding to the number of participants recorded for this study.

Each model is a deep learning classification model to classify the place of articulation of the coda based on spectral information. A convolutional neural network (CNN)-based model was implemented, with the best-performing model used as the baseline model. The model architecture is adapted from Doshi (2021) and its schematization is illustrated in Figure 3. The architecture consisted of four convolutional layers.

The input for the baseline model was the Mel spectrograms from the true velar and palatal datasets. The dataset was split into training, validation, and test sets in a 40:30:30 proportion, resulting in 128:96:96 tokens per model.

The model was trained using PyTorch in Python, with the Adam optimizer and a learning rate of 0.001. Binary cross-entropy loss was used to calculate the loss based on the probability values for both classes. The training process lasted for 150 epochs, and the best model was selected based on the lowest loss value on the validation set. The best-performing model was then used to classify the testing data to confirm its ability to accurately classify true velar and palatal codas.

In addition to the classification results, we also extracted a prediction probability representing the degree of palatalization on a scale from 0 (velar) to 1 (palatal). To achieve this, the sigmoid function was employed as the activation function applied to the output layer. The sigmoid function can be calculated using the following formula:

$$\sigma(x) = \frac{1}{1 + e^{-x}} \quad (1)$$

The baseline model, trained on true velar and palatal codas, was then used to classify the palatalized velars based on their Mel spectrograms. The degree of palatalization was quantified by the sigmoid function as described above. We interpreted values closer to 0 as indicating that the palatalized velars are more velar-like, while values closer to 1 suggest that they are more palatal-like.

3 Results

3.1 Classification of true velar and palatal

The model trained on true velar and palatal codas successfully classified these true velar and palatal codas with 100% accuracy across all models for all participants. To further evaluate the performance of our model, we also extracted the probability outputs. The histograms of the probabilities from the model of all participants are illustrated in Figure 4.

The distributions for all speakers are clearly divided between the two classes. All tokens of each class were classified with extreme probabilities, either 0 or 1, with no tokens showing intermediate probability values. Specifically, all velar nasal tokens had values closer to zero, while palatal nasals had values closer to one. This provided strong evidence that the model effectively categorizes tokens based on their place of articulation and further confirmed that velar and palatal codas are contrastive in a non-front vowel environment.

3.2 Classification of palatalized velars

When the classification models were applied to palatalized velar tokens, two distinct patterns of classification emerged, as summarized in Table 2. Notably, there were no effects of gender or place of origin, Phnom Penh or Takhmao, on the pattern displayed by the speakers.

Participants	Palatalization pattern
SP3, SP4	Categorical
SP1, SP2, SP5	Gradient

Table 2: Summary speaker groups of the two types of sound change patterns.

For one group of speakers, SP3 and SP4, the models classified the majority of the palatalized velar tokens as palatal nasals /ɲ/ (> 90%), as shown in Table 3. This suggests that, for these speakers, velar nasals following front vowels undergo a categorical shift to palatal nasals. The histograms of the probability distribution for SP3 and SP4, shown in Figure 5, also reflect this categorical shift, with the majority of tokens clustering around the probability value of 1, indicating ubiquitous classification as palatals.

For the other group of speakers, SP1, SP2, and SP5, the models classified approximately half (50% - 70%) of the palatalized velars as palatals, with a slightly higher number of tokens categorized as palatals than velars. Notably, SP5 exhibited a larger proportion of palatal classifications compared to the other participants, with 67% of all tokens classified as palatal. In the histograms for SP1, SP2, and SP5, although two small peaks are observed at both

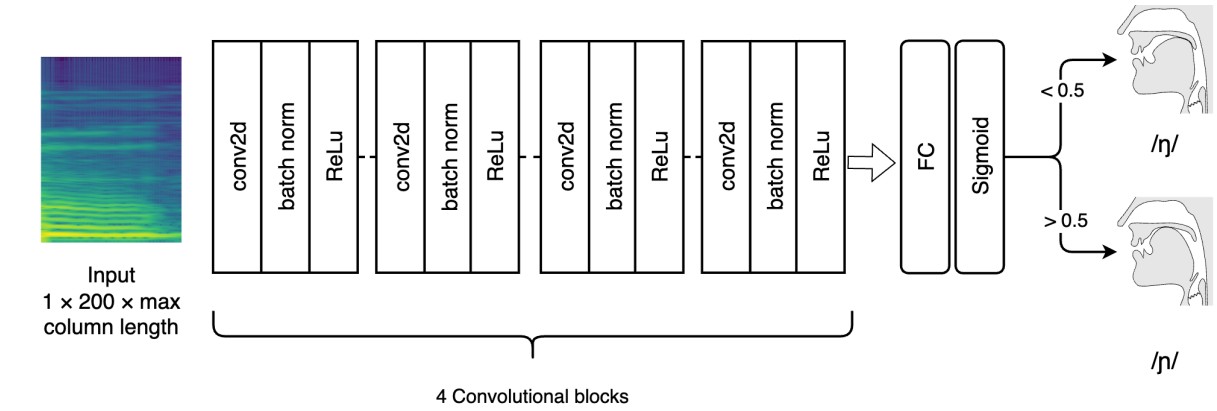

Figure 3: Audio classification model architecture.

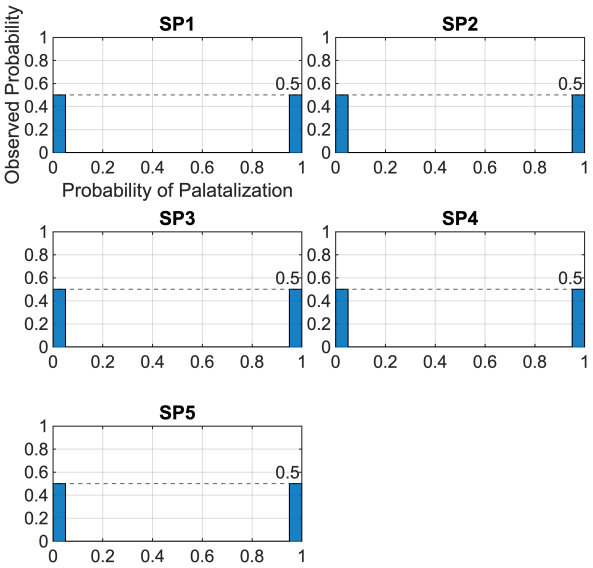

Figure 4: Histogram for true velar and palatal probability distribution of each participant.

ends of the distribution, the probability distribution is not as categorical. Mid-range probability values between 0 and 1 are sparsely distributed.

We may interpret these findings as suggesting that velar palatalization for this group of speakers is not a completely categorical process, but a gradient process. In other words, the contrast between velar and palatal nasals is not entirely neutralized in the front vowel environment: although some tokens may merge with true palatals, the majority of palatalized velars are not fully realized as palatals. These tokens might be realized as sounds intermediate between velars and palatals, likely due to the co-articulation effects of front vowels and velar codas where the tongue body position is intermediate between velar and palatal positions in the vocal tract.

Participant	/ŋ/	/ɲ/
SP1	47%	53%
SP2	47%	53%
SP3	7%	93%
SP4	2%	98%
SP5	33%	67%

Table 3: Palatalized velar class distribution of each participant.

3.3 Gradient-weighted Class Activation Mapping (GradCAM)

Given the model's strong performance in classifying true palatal and true velar nasals, this section investigates the acoustic features used by the models to distinguish between these two places of articulation. Previous acoustic studies have shown that this contrast is primarily signaled by differences in the transition of adjacent vowel formants, which are highly dependent on the vowel quality. For example, the formant transition from high front vowels to velar codas differs from that of low back vowels to velar codas (Ladefoged and Johnson, 2014). However, our findings in Section 3.1 demonstrate that the models accurately recognized the true place of articulation for the two nasal consonants using only the acoustic information from the nasal closure itself, without relying on vowel transitions. This suggests that the contrast between velars and palatals is also present within the acoustic signal of the consonants themselves.

To explore the spectral features that the models used to differentiate between the two places of articulation, we applied Gradient-weighted Class Activation Mapping (Grad-CAM) (Selvaraju et al., 2017) to the model classifications of true velars and true palatals as discussed in Section 3.1. Grad-

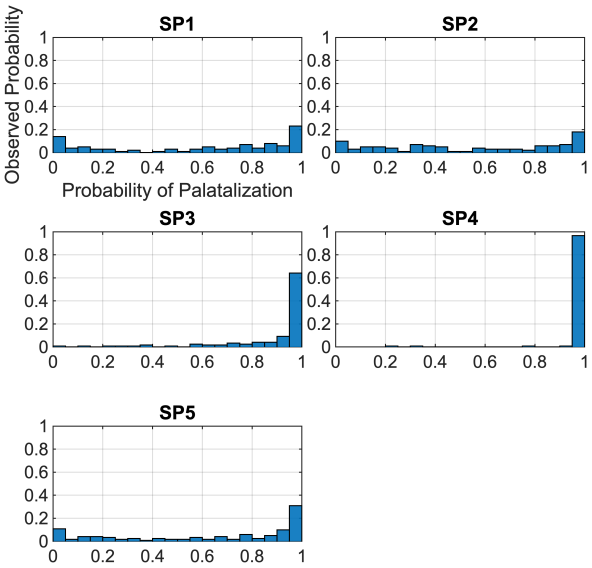

Figure 5: Histogram for palatalized velar probability distribution of each speaker.

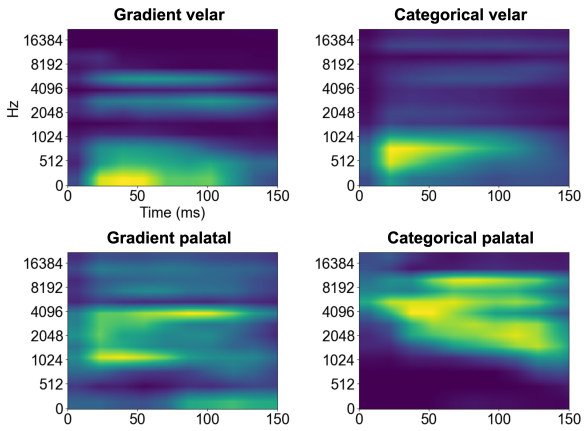

Figure 6: Grad-CAM class activation heat maps showing average weights for velar tokens (top) and palatal tokens (bottom) from SP2 exhibiting a gradient pattern (left) and SP4 exhibiting a categorical pattern (right).

CAM enables us to pinpoint specific regions within the input that the model focused on during its classification, thereby revealing the spectral features that distinguish velar and palatal nasals. In this section, we present results from two participants who exemplify the distinct realization patterns of palatalized velar outlined in Section 3.2.

The results of the Grad-CAM analysis are shown in Figure 6. The heat maps depict the average activation weights in the Mel spectrograms that the models used to classify true velars (top) and true palatals (bottom). Lighter colors indicate regions where the model assigned greater importance during classification. Notably, we observed several straight lines spanning the entire duration of the Mel spectrograms across all heat maps. This pattern suggests that the spectral features distinguishing velar and palatal nasals are consistent throughout the nasal closure interval, rather than being tied to specific temporal moments.

The distinguishing features appear to be on the spectral dimension. Specifically, it is likely that these straight lines on the heat maps represent anti-formants, with the distinguishing feature for velar and palatal nasals being the frequency ranges where the anti-formants are located.

For the velar tokens (top of Figure 6), the models focused on the lower frequency range. Although this pattern is consistent across both speakers, the specific frequency ranges where the model concentrated differ. For the speaker with the gradient distribution (SP2; top left of Figure 6), the model concentrated most heavily in the lower frequency range, particularly the 0-250 Hz range, with some areas of lower weights distributed in the 250-1024 Hz range, around 3000 Hz, and 6000 Hz. In comparison, for the speaker with the categorical distribution (SP4; top right of Figure 6), the model's focus was heaviest around 512 Hz, with additional areas of lower weights in regions comparable to those seen in the velar tokens produced by the speaker with the gradient distribution.

For the palatal tokens (bottom), the model's focus shifted to the higher frequency range. For the speaker with the gradient distribution (SP2; bottom left), the model concentrated the heaviest weight on two regions: around the 1024 Hz and 4096 Hz frequencies, with lower weights distributed across all frequency ranges. On the other hand, for the speaker with the categorical distribution (SP4; bottom right), the model's focus clustered in the higher frequency range, above 4000 Hz, with the heaviest weight lying between 8192 Hz and 16384 Hz.

There seems to be a tendency that if the main feature found for a velar is higher, as in the case of the speaker with categorical distribution, the corresponding feature for the palatal would also be higher.

In sum, based on the Grad-CAM results, we hypothesize that the distinction between velar and palatal nasals is present in the spectral domain, specifically in the location of anti-formants across different frequency ranges. However, there is still no clear evidence explaining why the two types of speakers, based on their production of palatalized

velars, differ in their production of true velars and true palatals as well. Further work is needed to fully elucidate this matter.

4 Discussion and Conclusion

Returning to our research questions, we first asked whether velar consonants in Khmer exhibit a certain degree of palatalization when they appear after front vowels, a process that has been reported as categorical in grammars and dictionaries. Our deep learning analyses confirm that a model trained on phonologically contrastive velar and palatal consonants classifies a large number of velar tokens as palatal in the environment following front vowels. This finding confirms an ongoing palatalization sound change in Khmer.

Additionally, we asked whether this sound change is completed and categorical or whether we observed a cline of velar to palatal realizations. To address this question, we have applied a method that allows us to quantify the degree of palatalization on token-by-token and subject-by-subject basis relying on the entire Mel spectrogram in view of known difficulties in characterizing place of articulation differences, especially for velar vs. palatal nasals. Our findings suggest that the process is an ongoing sound change as the realization of palatalized velars is not always identical to that of palatals. Interestingly, within the same speaker community, we observe that, for some speakers, the sound change is completed and palatalized velars are basically indistinguishable from phonological palatals. These findings resonate with the notion that sound change gradually diffuses through a community of speakers that propagate change via their interactions, in line with recent episodic approaches to sound change that rely on agent-based simulation (e.g., Harrington et al., 2018).

Finally, we also asked whether we can probe the inner workings of our model to relate our whole-spectrum analysis to low-dimensional phonetic features. Using Grad-CAM, we were able to hypothesize that the models are able to identify the place of articulation of Khmer consonants on the basis of a subset of frequency ranges in the spectrum that are broadly compatible with so-called anti-formants, as is known from the phonetics literature.

Beyond the empirical contribution of elucidating important details of a previously unstudied sound change, Khmer coda palatalization, we believe that this work also offers a first step towards an important methodological contribution. As noted in the introduction, recent works on sound change have emphasized the importance of the multidimensional richness of the acoustic signal and the role of episodic instantiations of these signals in influencing changes that affect the phonological categories of a language. In this paper, we have proposed a method that leverages deep learning and the entire Mel-spectrogram as a way to tackle these issues and quantify ongoing sound-change. The approach we have developed is able to probe, describe, and quantify the nature of a sound change and observe its distribution within a small sample of a linguistic community of interest. Additionally, we have offered preliminary ideas to bridge the gap between high-dimensional whole-spectrum analyses and more-traditional phonetic analyses.

The approach we have developed – we believe – is widely applicable to a variety of sound changes and is of interest to scholars working on the topic. This is because our approach offers a way to quantify where each episodic instantiation of a phonological category resides in a phonetic continuum between two phonological categories that may be drifting toward each other. This is of course a problem that is familiar from many types of sound changes, e.g., palatalization, lenition, changes in vowel quality *etc*. Our method, thus, constitutes an addition that can supplement the toolkit of experimental phonologists and phoneticians working on sound change.

To conclude, in this paper we have developed a token-by-token whole-spectrum approach that leverages deep learning. We have applied this method to a previously understudied case of sound change, Khmer coda palatalization. Our method has confirmed that the language is undergoing sound change, as hypothesized in previous work. Strikingly, different speakers within the same linguistic community seem to lie on different points along the path toward the completion of this sound change. Finally, we were able to relate the change in question to specific acoustic characteristics that are notoriously difficult to pinpoint. Thus, it is our hope that the findings and methods presented in this paper will offer a small further step towards a better understanding of a core property of human languages: the continuous evolution of their sound inventories.

Abstract

This study investigates the role of visual feedback on Mandarin speakers learning Cantonese tones using a high-variability perceptual learning paradigm. Thirty Mandarin speakers participated in a two-day experiment, completing pre-tests, training, post-tests, and generalization tests. Explicit (tone letters) and implicit (tone numbers) information related to tones were provided during training. Participants' eye movements were recorded during training. The testing results showed that the identification of Cantonese tones by Mandarin speakers improved significantly, demonstrating the effectiveness of the training procedure incorporating visual feedback. Eye-tracking data revealed that participants spent the most time fixating on tone letters, and their attention to these letters increased as the training progressed. These findings highlight the importance of explicit visual information in auditory perceptual learning of tones. The impact of Mandarin tone experience on learning Cantonese tones was also discussed.

1 Introduction

Different languages utilize acoustic cues differently. In tonal languages, lexical tones serve to differentiate the meanings of words. It is thus essential for learners to learn to correctly identify the tones from different categories to understand the meaning of words. However, mastering novel lexical tone categories has been found challenging not only for nontonal speakers who have little tone experience but also for tonal speakers whose acoustic features of the native tones differ from that of the novel tonal language (So & Best, 2010; Francis et al., 2008; Hao, 2012). Taking Mandarin and Cantonese for example, there are four lexical tones in Mandarin (high level tone T55, high rising tone T35, low falling-rising tone T214, and high falling tone T51) but six tones in Cantonese (high level tone T55, high rising tone T25, middle level T33, low falling tone T21, low rising tone T23, and low level toneT22). Peng (2006) displayed the distributions of Mandarin and Cantonese tones in a two-dimension coordinate where the x-axis was pitch slope while the y-axis was pitch height, showing that the tone balloons for Mandarin tones were compact and discretely distributed yet there were overlaps among balloons for Cantonese tones. Such acoustic features have led to difficulties for Mandarin speakers to perceive Cantonese tones (Zhang et al., 2016).

The effectiveness of perceptual learning paradigm in tonal learning has been widely recognized (Wang et al., 1999; Chandrasekaran et al., 2010; Francis et al., 2008). In recent years there has been an increasing number of studies focusing on the role of multimodal information in auditory perceptual learning, in which visual information plays an important role. According to the dual-coding theory (Paovoi, 1986) and the cognitive theory of multimedia learning (Mayer, 2001), the mental representation of speech sounds would become more robust if information is presented through both auditory and visual channels, contributing to better learning outcomes. In terms of tone learning, many previous studies have found that various kinds of visual information can facilitate learner's ability to perceive the tones correctly, such as real pitch contours of the tone (Liu et al., 2011), static or dynamic pitch changes (Wei et al., 2022; Godfroid et al., 2017; Zhen et al., 2019), hand gestures (Morett et al., 2022; Morett &

Chang, 2015; Baills et al., 2019), numbers (Liu et al., 2011; Godfroid et al., 2017) and colors (Godfroid et al., 2017). The visual facilitation mentioned above can be divided into two kinds, one is the explicit information that gives a direct indication of the pitch height or direction of the tone such as pitch contour, arrows, etc.; and the other is implicit information that does not cue the pitch-acoustic change of the tone but only provides a way to label it, such as a number or a color. Although a few studies have compared the learning effects under different visual information aids (Godfroid et al., 2017), it is still unclear which type of information, namely, explicit or implicit, learners would prefer when both are provided for them to opt for.

Another frequently studied but unresolved issue is the potential impact of native tone experience on learning new tonal languages. Previous studies on Mandarin learners' perception of Cantonese tones have reached some consensus: after training, T55 and T21 in Cantonese are better distinguished, while the two level tones (T22 and T33) are very difficult to identify (Francis et al., 2008; Zhang et al., 2008; Chang et al., 2017; Jongman et al., 2017). However, there is disagreement regarding the specific tone confusion patterns. Zhang et al. (2016) found that Mandarin speakers' tone confusion primarily occurs bidirectionally between tones sharing a similar pitch contour, such as T22-T33 (the two level tones) and T23-T25 (both rising tones), with little confusion among other tones. In contrast, Francis et al. (2008) found additional confusions mainly induced by pitch height, including misidentifying T22 as T21 more frequently than as T33 and confusing T23 and T21 bidirectionally. These two confusion patterns represent different influences of native language experience. The former suggests that confusion occurs only along the pitch height dimension, indicating that pitch contour might be a more dominant cue to suppress confusion. In contrast, the latter suggests that confusion exists along both the pitch height and pitch contour dimensions.

Learning Cantonese tones by Mandarin speakers provides an opportunity to explore both visual preferences and the influence of native language on nonnative tone acquisition. Mandarin speakers are well experienced in learning Mandarin tones with the aids of both explicit symbols and implicit numbers. Starting as early as the first grade of elementary school, Mandarin speakers have been systematically taught Pinyin, the phonetic symbols for Chinese characters, in which tones are named by 1 to 4 and are depicted by contour markers above the vowels. For instance, “mā”, “má”, “mǎ”, “mà” indicate syllable “ma” with tone 1 to 4. Such extensive experience in using both explicit and implicit cues may lead Mandarin speakers to have a balanced preference for explicit and implicit visual information when learning Cantonese tones. Additionally, examining the confusion patterns in Cantonese tone perception by Mandarin speakers adds insights into how native tone language speakers learn nonnative tones and the influence of their native language on this process.

In this study, we adopt the high-variability perceptual learning paradigm that provides visual feedback to train Mandarin speakers to learn Cantonese tones. Specifically, we provide both explicit and implicit visual information related to tones, and we are mainly concerned with the following two questions: 1) whether Mandarin speakers prefer implicit or explicit information when they acquire new tones in another language (i.e., Cantonese), and 2) How does their native tonal language background influence their acquisition of Cantonese tones?

2 Methodology

Participants

30 native Mandarin speakers (17 female, mean age = 24.3 yrs, SD = 2.13) were recruited to participate in the experiment. All of them are college students in Hong Kong, with no self-reported visual, hearing, or cognitive impairment. One male participant was left-handed. The participants resided in Hong Kong for an average period of 9.2 months (SD = 6.10) and none of them had previous knowledge of Cantonese. All participants signed written consent before the experiment. The experiment protocol was approved by the Human Subjects Ethics Sub-committee of The Hong Kong Polytechnic University.

Stimuli

Stimuli of this study were 24 Cantonese monosyllables deriving from 4 carrier syllables (/fɐn/, /fu/, /ji/, and /sɛ/) × 6 Cantonese tones (T55, T25, T33, T21, T25, and T22). All monosyllabic stimuli involved were real words in Cantonese. Four native Cantonese speakers (2 females) were recruited to pronounce each word three times in a

sound-attenuated booth, rendering three tokens for a word from one speaker. One token of each word from two speakers (one male and one female), was chosen as the standard sound across pretest, training, and posttest for each subject. In the generalization test, all three tokens per word, produced by the other two speakers, were utilized as stimuli to investigate the generalization of training effects derived from limited exposure to standard phonetic cues onto novel materials. All stimuli were normalized to 450ms in duration and 70 dB in intensity using Praat (Boersma & Weenink, 2024).

Experiment Procedure

The whole experiment lasted for two consecutive days and included two sessions of Cantonese tone training and three sessions of testing with one conducted before the training (i.e., pre-test) and two after the training (i.e., post-test and generalization test). Each session of the experiment used a block design, with blocks divided by male and female speakers, and the order of the blocks was counterbalanced. The training program adopted the perceptual learning paradigm and high variability phonetic training, with participants' eye movements being tracked throughout using an SR Research EyeLink 1000 Plus sampling at 1000 Hz. In testing phrases, tone identification task was used to evaluate participants perceptual accuracy of the target words. In day 1, participants completed the pre-test and first training. In day 2, they received the second training and attended the post- and generalization test immediately.

The training procedure started with a context where the sounds and corresponding Chinese character of the syllable /sɛ/ were presented sequentially with the six Cantonese tones. Then the formal training trials began, with syllables /fɐn/, /fu/ and /ji/ being the target stimuli. In each trial, participants were presented with a fixation cross (500ms), a monosyllabic stimulus (450ms), followed by a response screen with six options covering all Cantone six tone categories. Participants then made a response based on their perception by pressing the number keys from 1 to 6 on the keyboard. After that, a blue or red cross appeared on the screen to indicate the correctness of their choice, with blue denoting correctness and red denoting errors. Subsequently, a correct information display regarding the heard sound appeared, presenting four types of information for three seconds (i.e., the four Areas of Interests, AOIs): 1) tone number, numbers from 1 to 6 which indicate the Cantonese tone categories; 2) tone letter, consisting of a vertical bar representing the range of possible pitch heights and a branching bar representing the onset and offset of pitch heights of a tone (Chao, 1930); 3) character of the target sound and 4) English meaning of the target sound. The locations of AOIs were counterbalanced and pseudo-randomized. Before the training commenced, participants were briefed on the meanings of each type of information. Participants were instructed that they could freely choose their learning strategy. The two training sessions took about 1 hour, consisting of 288 trials (3 carrier syllables × 6 tones × 4 repetitions × 2 speakers × 2 training sessions) in total.

The procedure for the tone identification task in the three tests was very similar to the training process, with the main difference being that no feedback or information was provided. Next trial was proceeded automatically after detecting a choice. In each test, there were 108 trials, resulting from 3 carrier syllables × 6 tones × 3 repetitions × 2 speakers.

3 Results

Results for tone identification

Figure 1 illustrates the accuracy of the tone identification task in pre-test, post-test and generalization test. Accuracy results were submitted to a two-way repeated measures analysis of variance (ANOVA) with *Test* (pre-, post- and generalization test), and *Tone* as the with-in subject factors. Necessary post-hoc analyses were conducted through Tukey method for comparing families of multiple estimates. There were significant main effects of *Test* (F (2,58) = 215.2, p < 0.001). Post-hoc analysis showed that the accuracy of both post-test (72.1%) and generalization test were significantly higher than that of pretest (27.5%), ps < 0.001. Accuracy of post-test was significantly higher than that of generalization test (p = 0.04). These results showed that participants' perception of Cantonese tones was greatly improved after training and the ability to identify tones was generalized to untrained sounds to a certain degree. The main effect of *Tone* was also significant (F (5, 154) = 85.64, p < 0.001). T55 is the easiest tone to be identified with the highest overall accuracy of 79.8%. Next is T21

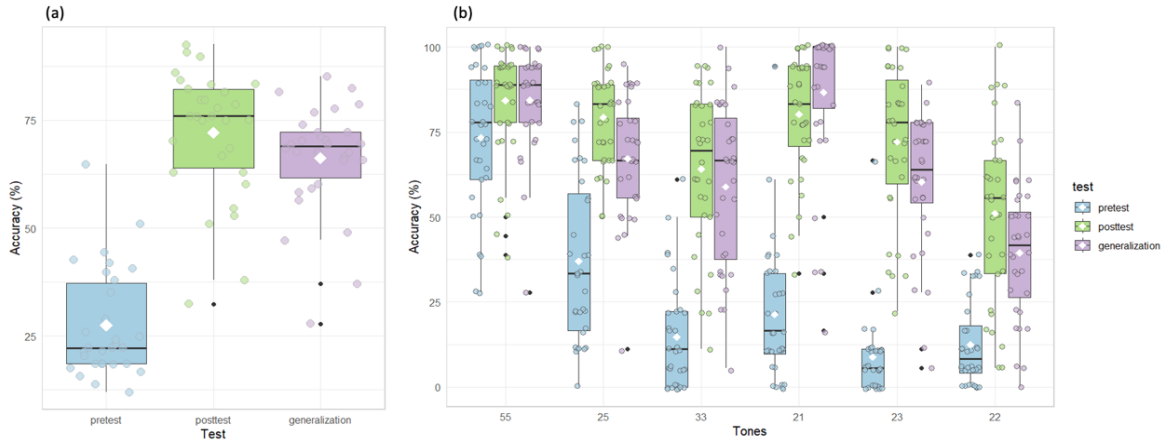

Figure 1. The accuracy of tone identification task in pre-test, post-test and generalization test. (a) shows the overall accuracy, (b) shows the accuracy of 6 Cantonese tones in three tests. The white rhombus indicates the mean value.

(a)

	R55	R25	R33	R21	R23	R22
T55	83.9%	0.9%	11.3%	0.4%	0.9%	2.6%
T25	0.0%	79.6%	0.2%	2.0%	18.1%	0.0%
T33	23.9%	0.4%	63.7%	0.7%	1.5%	9.8%
T21	0.0%	0.9%	2.6%	81.7%	3.9%	10.9%
T23	0.2%	21.7%	1.5%	2.8%	72.2%	1.7%
T22	4.3%	0.7%	39.1%	2.4%	2.0%	51.5%

(b)

	R55	R25	R33	R21	R23	R22
T55	83.3%	0.7%	11.3%	0.0%	0.9%	3.7%
T25	0.4%	67.3%	0.6%	2.2%	28.9%	0.6%
T33	21.1%	0.9%	58.9%	0.4%	2.0%	16.7%
T21	0.2%	1.9%	0.4%	88.0%	3.7%	5.9%
T23	0.6%	30.6%	2.0%	4.1%	60.6%	2.2%
T22	9.3%	0.2%	48.3%	1.1%	1.7%	39.4%

Table 1. Confusion matrix of tone identification for (a) post-test and (b) generalization test. The letter T stands for the target responses and the letter R refers to the responses given by the participants.

(63.6%) and T21 (61.2%), followed by T23 (47.0%) and T33 (45.9%), and the most difficult tone to identify is T22, with the lowest accuracy of 34.0%.

The interaction between *Test* and *Tone* (F (10, 290) = 18.58, $p < 0.001$) was also significant, suggesting that participants' ability to correctly identify tones improved differently depending on the specific tone. Specifically, apart from T55 which consistently maintained a high accuracy rate with no significant changes across the three tests, the recognition accuracy of the other five lexical tones in the post-test and generalization test was significantly higher than in the pre-test ($ps < 0.001$) with no difference between the post-test and generalization test ($ps > 0.19$). In the post-test, there were no significant differences in accuracy rates among T55, T25, T21, and T23. In comparison, the accuracy rates for T22 and T33 were significantly lower ($ps < 0.01$). By the time of the generalization test, T55 and T21 exhibited the highest accuracy rates, significantly surpassing T25, T33, and T23 ($ps < 0.01$), with T22 showing

significantly lower accuracy compared to all other tones (ps < 0.01).

Examination of confusion in post- and generalization tests (Table 1) provides some qualitative context for interpreting tone identification accuracy results. In both tests, T55 was also highly accurate and was only occasionally misidentified as T33 (11.3% in both tests). For T33, the mid-level tone, is consistently misidentified as T55 (23.9% and 21.1% in pre-test and generalization test) and T22 (9.8% and 16.7% respectively) across both tests. The low-level tone (T22) was the hardest one to identify across both tests. It was frequently misidentified as T33 in both tests (39.1% and 48.3% respectively) and occasionally misidentified as T55 in generalization test (9.3%). The high-rising tone (T25) and the low-rising Tone (T23) were mostly confused with each other, with a notably increasing confusion from the post-test to the generalization test (T25 misidentified as T23: from 18.1% to 28.9%; T23 misidentified as T25: from 21.7% to 30.6%). The only falling tone (T21) was maintained high accuracy with minimal confusion.

Results of fixation duration during training

To learn more about how participants allocate their attention to the four types of information during training, we analyzed the fixation duration of the participants within the 3-second time window of information display. One participant's data was identified as outlier and was excluded from the analysis. Figure 2 illustrates participants' average fixation duration. A Kruskal-Wallis rank sum test

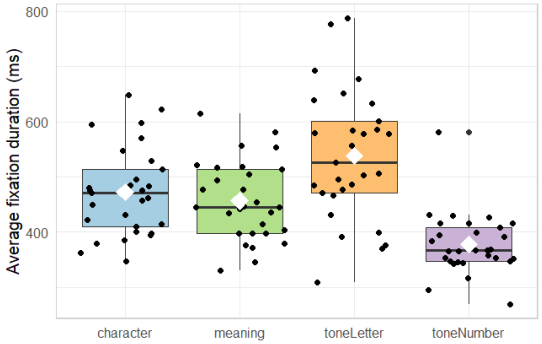

Figure 2. Average fixation duration of participants looking at the four AOIs during training.

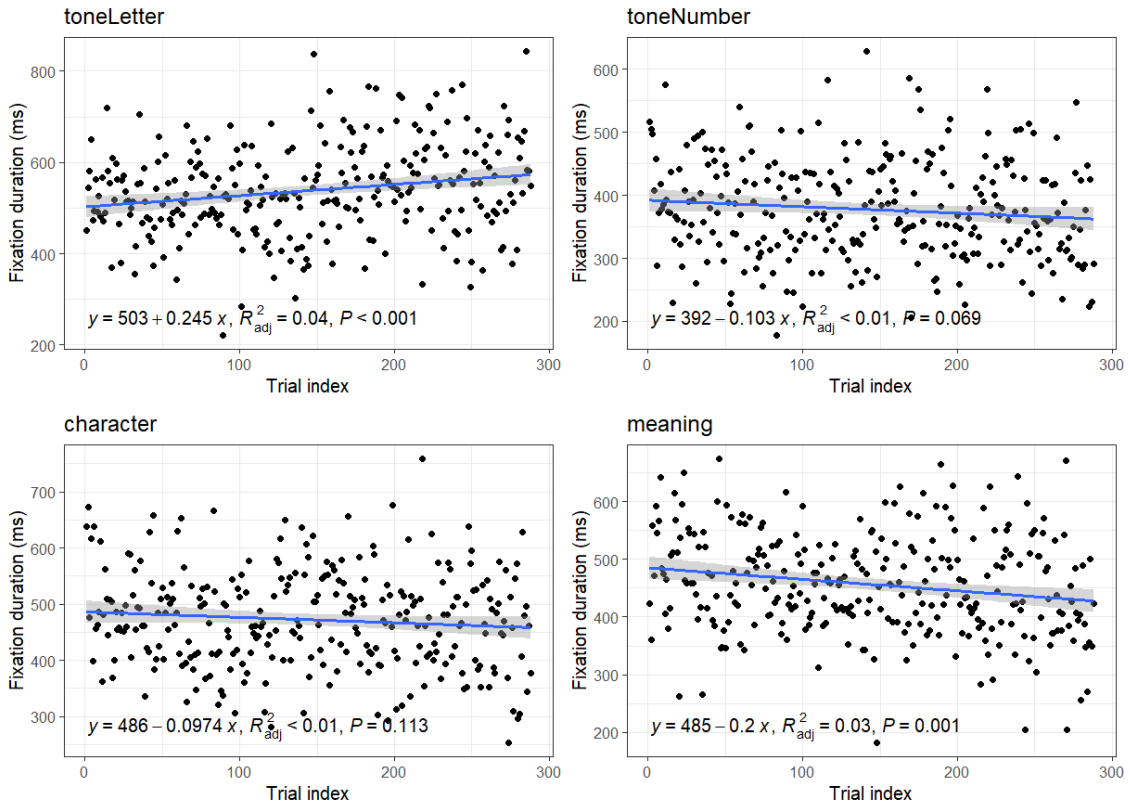

Figure 3. The changes in participants' fixation durations on the four types of information over the course of training sessions. Top left panel: Tone letter; top right panel: Tone number; bottom left panel: Chinese character; bottom right panel: English meaning.

was conducted to determine if there were statistically significant differences in average fixation duration across different AOIs. The results showed a significant difference between AOIs ($\chi^2(3) = 39.85$, $p < 0.001$), indicating that participants paid unequal attention to different information. To further investigate these differences, pairwise comparisons were performed using the Wilcoxon rank sum exact test with Bonferroni correction for multiple comparisons. The fixation duration of tone letter was significantly higher than that of meaning ($p = 0.04$) and tone number ($p < 0.001$). No significant difference was found between fixation duration of character and that of meaning ($p = 1$). Tone number got the least attention during training ($ps < 0.01$) when compared with other three types of information.

Figure 3 illustrates the fixation patterns of participants towards four AOIs during training. As can be seen, participants' attention to the tone letter significantly increased with the increasing number of trials ($\beta = 0.245$, $t(286) = 3.54$, $p < 0.001$), indicating that their reliance on the tone letter enhanced as the training progressed. Participants' attention to meaning significantly decreased along with the increase in trials ($\beta = -0.2$, $t(286) = -3.30$, $p = 0.001$), while that to character and number remained relatively stable, showing no significant changes.

4 Discussion

In this study, we trained Mandarin speakers to learn Cantonese tones, while recording their eye movements during the training process. The results showed a significant improvement in participants' perception accuracy on Cantonese tones produced by trained and new speakers, indicating the high-variability training program that provided feedback and visual indication effectively sharpened the perception of nonnative tone in learners from tonal language backgrounds. However, such learning and generalization effects were not equally manifested across all six tones, as participants, who achieved significantly higher accuracy in identifying T55 and T21, were relatively prone to mutual confusion between T25 and T23, as well as between T33 and T22. Additionally, the eye-tracking results revealed that participants had different preferences for different types of visual information, they tended to focus more on tone letters which reflected the pitch contour of tones but less on numbers that are also frequently used in Mandarin to refer to tone categories.

Mandarin speakers' preference for explicit visual information when learning nonnative tones

Contrary to our prediction that Mandarin speakers might have balanced preference for tone letters and numbers, we found that when given the freedom to choose their learning strategies and allocate their attention, Mandarin speakers spontaneously paid the most attention to the tone letters and the least attention to tone numbers. These results suggest that when Mandarin speakers were newly exposed to nonnative tones, they preferred to draw on explicit rather than implicit visual information to help reinforce the phonetic features of the tones and aid speech perception.

A possible reason for this behavior is that, since the explicit tone letters directly depict the acoustic features of tones, Mandarin learners may find it easier to guide top-down attention to enhance the integration of auditory and visual cues. In contrast, the implicit tone numbers offer limited pitch information, which might cause extra cognitive load to establish a correspondence between each number and a specific tone. Given that Cantonese has two more tones than Mandarin, this task becomes even more challenging. Besides, due to the robust correspondence between numbers (1 to 4) and Mandarin tones (T1[55], T2[35], T3[214], and T4[51]) in Mandarin speakers' memory, there might be interference with the establishment of new tonal categories through numbers, which could lead Mandarin speakers to avoid relying on numbers to learn new tones.

However, it's essential to note that due to the relatively short training duration in this study (approximately 1 hour), the observed attention patterns may only represent learners' initial exposure to a new tone system. It remains an open question whether learners will allocate more attention to other cues as training time increases.

The influence of L1 tones on the acquisition of nonnative tones

Our findings are consistent with previous studies (Francis et al., 2008; Zhang et al., 2016), showing that T55 and T21 are the easiest tones for Mandarin speakers to identify and are seldom confused with other tones. T22 is the most difficult, while T23,

T25 and T33 are intermediate in difficulty yet easily confused with other tones. Our confusion pattern aligns with that of Zhang et al. (2016), with confusion occurring mainly between T22 and T33 (the two level tones), and T23 and T25 (the two rising tones).

Mandarin speakers, who are sensitive to pitch slope, encounter greater confusion in distinguishing tones sharing similar pitch directions but varying pitch heights. As a result, even though the pitch difference between T22 and T21 is numerically smaller than that between T23 and T25, participants rarely confused them since T21 is a falling tone. This may be because changes in pitch slope are easier for Mandarin speakers to perceive and learn than pitch height, which may be influenced by the perception of tones in the native Chinese language. As described earlier, the pitch difference between the four tones of Mandarin is large, and a more notable feature is that each tone has a distinctive pitch contour, therefore Mandarin subjects might rely more on the pitch contour when perceiving tones. This view is supported by Chandrasekaran et al. (2007), in which they compared the differences in the acoustic dimensions (pitch height or pitch contour) that native Chinese speakers and native English speakers primarily relied on when perceiving Mandarin tones and found that for pitch contour was much more important for Mandarin-speaking subjects.

5 Limitation

The relatively short nature of the training procedure remains a limitation of the current study, which may capture long-term learning outcomes to an limited extent. To address this problem, we are now conducting a new experiment with an extended training procedure in order to better assess the retention of the training effect.

6 Conclusion

We trained Mandarin speakers to learn Cantonese tones through perceptual learning paradigm with visual feedback provided. Mandarin speakers' ability to identify Cantonese tones improved significantly after training, demonstrating the effectiveness of visual information in auditory tone learning. Mandarin speakers spontaneously gave the most attention to the tone letter – the explicit visual information during the training process. Our results emphasized the importance of explicit visual information in auditory perceptual learning.

Abstract

Talk show, a type of media discourse, blend casual conversation with institutional dialogue. This study investigates the addressing performance by the host towards male and female guests. Due to the widespread popularity and rapid dissemination of information, talk shows have been a significant form of media discourse. Addressing is particularly important in the talk show, particularly in the conversation where there are multi-party interactions to determine the next speaker. Previous studies have found asymmetrical addressing forms for different gender groups. Males tend to have wider selection of addressing forms while females have relatively limited choices, indicating the power difference in the society (Lakoff, 1975; Kramer, 1975). The phenomena seem be more obvious in Chinese society, where is deeply rooted in the patriarchal hierarchy (Pan, 1995; Blum, 1997).

By applying the T/V model proposed by Brown and Gilman (1960) in the Chinese contexts, it is observed that the addressing practice in the talk show in Chinese context reflects broader culture norms. The results indicate asymmetrical addressing practice towards male and female guests. Particularly, male guests tend to be addressed with titles while females are more often addressed by their first or full names. Although subtle gender bias is observed in the addressing practice, there is also a tendency towards gender equity, as indicated by the frequency of the 'T' form. The study underscores the importance of context in corpus-based research and highlights how language use can reflect gendered social structures, particularly in Mandarin Chinese, which lacks grammatical gender marking.

1 Introduction

Addressing is the product of communication that exist only in interaction. The study of addressing provides significant insights of power dynamics, intimacy relations and gender differences (Wolfson and Manes, 1979; Wierzbicka, 1991; McConnell-Ginet, 2020). Different from *referring*, which simply identities the person mentioned in the utterance, *addressing* assigns specific labels to the addressee, placing them into certain categories. *Direct addressing*, also named *vocative*, is term of direct address to call persons (Chao, 1956). In the study of addressing, researchers examine how males and females use different addressing forms in different contexts (e.g., Wolfson and Manes (1979); Tang (2015); Naaman et al. (2022)). However, how people of different genders are addressed has received relatively less attention. Additionally, most existing studies focus on written genres or spoken genres of two-person interactions. In contrast, multi-party conversations in media discourse receive less attention, partially due to the complexity of identifying the next speakers as well as the the difficulty of obtaining data.

Language is a reflection of culture, and addressing terms mirror the deeply rooted patriarchal hierarchy in Chinese society. Despite the deeply ingrained traditional cultures being hard to eradicate immediately, the tendency towards gender equality is inevitable, as evident by the decreasing trend of gender-marking in occupation such as 女医生 nv3yi1sheng1 (female doctor), 女侦探 nv3zhen1tan4 (female detective) (Su et al., 2021).

2 Literature review

2.1 Addressing forms and gender

According to Gumperz (1972), the terms we use to address others (e.g., nicknames, first name, title) do not change the nature of the message as a form of address but significantly affect how people are perceived and treated in social contexts. A wide range of English and Chinese addressing options have been identified by scholars such as Chao (1956),

Leech (1999) and McConnell-Ginet (2020), providing valuable insights for the analysis of vocatives. These types encompass a range of forms that are available for addressing people of close relationships or people of different hierarchical structures. These addressing options can be used for direct addressing - *vocatives* which serves one of the following three communicative functions: 1) getting the attention of the addressee, 2) identifying someone as the intended recipient of the message in multi-party conversations, and 3) maintaining or emphasizing the relationship between speaker and addressee (Leech, 1999, p108-109).

Applying the model of addressing proposed by Brown and Ford (1961), a lot of existing studies such as Lakoff (1975), Kramer (1975), Pan (1995), and Weatherall (1996) observe the asymmetrical usage when addressing males and females in both written and spoken sources. The results indicate that men have a broader selection of addressing, reflecting their perceived power and dominance, while women have a more limited choice due to their societal powerlessness and marginalization. As a result, women are more frequently addressed by endearing terms or terms giving emphasis on their youthfulness and immaturity. Asymmetrical usage of forms of addressing are observed in two-person conversations in different contexts such as in service encounter (Wolfson and Manes, 1979), workplace (Pan, 1995), film dialogues (Formentelli, 2014), and academia (Zhou and Larina, 2024). Using corpus-based method, Baker (2010)'s corpus-based analysis observed a higher usage of male title (Mr.) than female titles but in a decreasing tendency across time. Naaman et al. (2022) also observed that patients do not make difference when addressing males and female physicians. These studies reinforce the tendency towards gender equality. Does it mean the gender bias has disappeared? As previously mentioned, addressing are different in various contexts. It is essential to investigate addressing within specific context. In some settings, gender bias and stereotypes still persist, while in others, there is no significant difference. Nevertheless, the tendency of gender equality cannot be neglect and our study aim to explore the current situation in the Chinese context.

2.2 Pronouns beyond power and solidarity

The T/V binary distinction model of pronoun system proposed by psychologists Roger Brown and Albert Gilman (1960) has provided profound impact on the social dimensions of pronoun usage. T (from the Latin *tu*) is used to represent the 'familiar or intimate' pronoun, while V (from the Latin *vos*) represents the 'formal or polite' pronoun in any language. The authors typically focus on the semantic differences of pronouns of French, German and Italian where they have two singular pronouns for address. Apart from the nonreciprocal T and V, the other addressing terms such as proper names and titles that mentioned by Brown and Gilman (1960, p266) open floor for more discussion on more forms that can express power asymmetry in equalitarian societies. McConnell-Ginet (2003, 2020) further extended and elaborated the polysemy of the T/V binary model in the context of American English. For instance, *sir* can show mutual respect as well as deference from a relatively lower hierarchy. The corresponding T and V for second-person pronouns in Chinese are 你 ni3 (informal you) and 您 nin3 (formal you), the former is the informal form, while the later is the deferential form. Given that T and V are not gender marked in Mandarin Chinese, except for the third person singular forms, it would be applicable to consider the the usage in particular contexts. Previous study on e-commerce live streaming discourse found that males and female use pronouns differently (Yang and Wang, 2022). Particularly, males sellers use more 你(ni3) while female sellers use more 您(nin2), indicating males and females have different strategies to promote successful selling. However, the question of whether males or females are addressed with a variety of pronouns have not yet been thoroughly explored. The usage of T/V pronominal forms of address highlights the importance of cultural and social influences on linguistic choices. A recent case study of T/V pronominal forms of address in Chinese and Russian classroom interaction by Zhou and Larina (2024) observed that the power distance and social distance determines the inter-culture difference in using T/V pronominal forms of address. Particularly, the T form of address to teacher emphasizes closeness rather than distance in Chinese, which is influenced by the familial connection in traditional Chinese culture.

2.3 Addressing in Chinese culture

Language has a significant impact on shaping our world. It is clear that those who have the power to create the symbols and define their meanings hold a privileged and highly advantageous position

(Spender, 1998). In the patriarchal order culture such as Chinese, this potential has been realized. For Chinese men, names have a transformative power that binds them as individuals to a recognized collectivity. Influenced by the philosophical systems of Taoism and Confucianism, there is a tension between the concept of the unique individual and the idea of the person connected to society. Traditionally, women are associated with men, as seen in the way women are addressed within the constellation of male names for a marriaged women (e.g., Lee's wife) or address women within the limits of kinship terminology (e.g., second daughter). As Watson (1986) observed in his study in a village in China, peasant women are neither fully individualised nor fully recognized as persons.

Traditionally, Chinese shows avoid pronouns partially because of the relative semantic emptiness (McConnell-Ginet, 2020) to categorize a person or group. Similar situations also observe in pronoun usage in Korean and Japanese where people tend to avoid using pronouns in general and use nominal address term (Park, 2010). However, the usage of pronouns denote pragmatic functions. First of all, the notion of connection building is reflected on the use of pronoun 'we' (我们). The inclusive and exclusive use of 'we' define explicitly and publicly social groups. Therefore, it is a strong means to establish and reinforce social identities (Hausendorf and Kesselheim, 2002). Emphasizing family-centered cultural values of the Chinese society, pronoun 'we' is evident to be used in academia to construct the collective identities (Ren and Chen, 2019). The use of addressing is influenced by Chinese culture. Although Chinese is a language that lacks of gender agreement and linguistic gender markers, linguistic sexism can permeate a language through various forms in vocabulary such as gendered-marking occupation (Tso, 2014) and defining women in terms of their personal appearance or sexual attributes (Baker, 2010). Traditionally, most professions are considered to be male dominance. Women who enter these masculine professions requires explicit and marked feminine modifier with the affix 女 nv3(female) (Farris, 1988; Su et al., 2021). For example, the gendered marking of 女医生 nv3yi1sheng1 (female doctor) is common, while 男医生 nan2yi1sheng1 (male doctor) is rare.

3 Methodology and research questions

The data are drawn from naturally occurring multi-party cross-gender conversations; i.e, the transcript of the talk show in Mandarin Chinese whose participants are invited to be guest speakers (experts and laypeople) to sharing their opinions under the institutional control of the host, who manages the topic and agenda. The data are therefore representative of multi-party conversations of different power relations. For comparative insights, the vocatives used by host to address male guests and female guests in cross-gender conversations (n=115) are analyzed (Table 1). Text analysis software *Sketch Engine* (Kilgarriff et al., 2014) was used to descriptive analysis of the use of different types of vocatives in different gender groups as linguistic feature across transcript text files. Using the Corpus Query Language (CQL) search tool in *Sketch Engine*, the names of the speakers serve as keywords for the search. This allows for the rapid identification of utterances containing addressing terms, which are then manually categorized to determine whether they are directed towards males or females. If multiple vocatives are used in the same line of utterance, the first referential form will be considered.

Table 1: Statistics in cross-gender conversation for analysis

Role&Gender	Tokens	Words
Host	169,289	145,573
Female guests	154,406	132,775
Male guests	147,175	126,557
Total	470,870	404,905

This study aims to enhance our understand of current address practice in Chinese context and to investigate whether cultural influences on addressing people of gender groups have evolved or remained constant. The research questions in this study are as follows:

RQ1: Do TV talk show host address male guests and female guests differently?

RQ2: How does the addressing reflect different power relations between participants in the talk show?

RQ3: Can the language used to describe female guests and male guests in talk show be understood as being biased against women?

4 Findings

4.1 Distribution of gendered addressing terms

Overall, there are six types of addressing forms occurring in the talk show in our data, namely FL (first name + last name), FN (first name), kinterm + N, TFLN (titles with full name), TLN (title with last name) and LN (last name only). It is found that three types show statistically differences. Table 2 summarizes the frequency of addressing made by host for male guests and female guests. Overall, more addressing forms are used to address female guests than male guests. There are total 211 addressing forms observed in the cross-gender conversations in the talk show. 64.5% (n=136) are used to address female guests while only 35.5% (n=75) are used to address male guests. Following McConnell-Ginet (2020) taxonomy of addressing forms, we observed that both the addressing forms included on the list as well as additional ones off the list are used in the talk show. The hosts uses significantly more FL (first name + last name) and FN (first name) to address female guests (e.g., 幼婷you4ting2) while these two addressing forms are infrequent for male guests. In contrast, the host uses significantly more forms with titles, last name with title, to address male guests (e.g., 许老师xu3lao3shi1 *teacher Xu*) (χ^2=95.696, df=5, p value=.000). It is found that 51 (83.6%) instances of TLN (title with last name) are used to address male guests, compared to only 10 (16.4%) for female guests. These titles include both gender-marked terms such as 先生 xian1sheng1 (Mr.) and gender-neutral terms such as 老师 lao3shi1 (teacher), 导演 dao3yan3 (film director), 教授 jiao4shou4 (professor), 主席 zhu3xi2 (chairman), 主任 zhu3ren4 (director). In addition, there is far less usage of kinship terms (e.g., 哥 ge1 (older brother)) in the talk show and the result does not show significant difference.

Table 2: Addressing option * addresser gender crosstabulation

Addressing option	Female guests	Male guests	Total
FL	29	4	33
FN	88	13	101
Kinterm + N	3	4	7
TFLN	6	2	8
TLN	10	51	61
LN	0	1	1
Total	136	75	211

Example 1:

a.三人行必有我师，每次都跟王领导学到格言...
When three walk together, one can be my teacher, Every time, I learn a maxim from Leader Wang."
b.今天王蒙老师还给我们隆重举荐一位女领导，我们今天来有了女领导徐坤大作家
Today, Teacher Wang Meng also formally recommended a female leader to us. Today, we welcomed the renowned female writer, Xu Kun.

4.2 Gendered addressing terms and their collocations

The results in Table 3 and Table 4 reveal some gender similarities and differences in the collocates that are associated with either group in addressing practice. While it is suggested that pronouns should be avoided as they can indicate a lack of respect and relative semantic emptiness (Blum, 1997; McConnell-Ginet, 2020), Liu (2009) notes that the co-occurrence of address nouns and the use of address pronouns reinforces and complements each other in the service encounter discourse for establishing close relationship. The co-occurrences of addressing terms and pronouns is also observed in the talk show which explicitly mark the addressee. It is observed that while '你' ni3 (informal second pronoun 'you') and 我们 wo3men2 (first person plural) are neutral, '你知道' ni3zhi1dao4 (you know), '你看' ni3kan4 (you see) and '咱们' zan2men2 (we/us) tend to be used more for female guests while the deferential second person pronoun 'you' (您) has more usage with male guests.

Example 2
a. informal 'you' to address female guest
李艾你是学什么的?
LI Ai, what is your major?

b. deferential 'you' to address female guest
李玫瑾老师，我们又把你盼来了，今天我特别把我们的重量级嘉宾陈丹青请来跟您切磋切磋，互相请教请教。
Professor LI Meijing, we have eagerly awaited your return. We especially invite the key figure CHEN Danqing to exchange opinion and learn from each other.

c. informal 'you' to address male guest
许老师你觉得最近日本这什么情况?
Teacher Xu, what do you think about the recent situation in Japan?

Table 3: Words located among the top20 collocates of female guests' addressing

	Collocate	Freq	Coll. freq.	logDice
1	你	49	393	11.5273
2	人行	14	29	11.3155

d. deferential 'you' to address male guest
陶老师您见多识广。
Teacher Tao, you are well-informed.

Example 3
a. inclusive-we
除了查老师，要给大家介绍我的老朋友，中国国家地理杂志的李拴科，咱们的地球专家。
Besides Teacher Zha, I would like to introduce my old friend, LI Shuanke from National Geographic Magazine of China, our/us earth expert.

b. exlusive-we
这个幼婷可以给我们介绍一下。
Youting can introduce this for us.

Example 4
李艾真是越来越年轻了。
LI Ai is truly looking younger and younger.

Further qualitative analysis of the utterances with pronouns reveals notable gender differences. Females are frequently prompted to perform actions such as elaboration on the host's request for a future act (给我们讲讲 *please tell us*) or answering a question (你回答一下马老的问题 *please answer the question raised by teacher Ma.*). In contrast, males are commonly encouraged to engage by stating facts (您见多识广 *You are well-informed*) and sharing opinions (你觉得最近日本这什么情况? *What do you think about the recent situation in Japan?*). These differences may imply that the stereotyping of women as submissive seems to maintain. Moreover, some linguistic forms underscore the sexism. Women are more likely to receive compliments on their appearance, whereas men are more often to be mentioned by what they do. For instance, in Example 3b and Example 4, female guests are introduced at the beginning of the talk show with comments on her attractiveness. Conversely, male guest is introduced with a focus on his occupations and achievements of being an earth expert (地球专家) in Example 3a.

Example 5
今天来了一位很有气质，很有风华的这么一位女士，而且还是咱们许老师的，不是老情人，老熟人，老相好，而且她就是了解了她的事迹之后更让我感觉到文学这条道路是多么的难，因为李兰妮女士现在是深圳作协主席，她深圳作协主席吧文学道路是这么样的难，她不但得了严重的抑郁症，而且还得了严重的癌症，现在叫做带癌生存。
Today, we have a very elegant and charming lady with us, who is also not an old lover but an old

acquaintance, an old friend of Teacher Xu. After learning about her story, I feel even more strongly about how difficult the literary path is. Ms. LI Lanni is now the chairperson of the Shenzhen Writers' Association. This literary journey is so challenging that she not only suffered from severe depression but also from serious cancer. Now, she is living with cancer.

In the Example 5 above, the female guest is initially addressed with the social title 李兰妮女士 (Ms. LI Lanni). She is identified by her relationship with another guest and acknowledged by her professional achievement as the chairperson of the Writers Association in Shenzhen. Dion and Schuller (1990) found that women in managerial roles who used the title 'Ms.' were rated higher on traits like competence, leadership skills and overall masculinity, compared to their counterparts addressed as 'Miss' or 'Mrs.' in the late 1980s. However, she is also referred to by the illness she suffers from, which undermines her image as a competent chairperson. Additionally, she is mentioned again in relation to the male guest where she is teased not as a romantic partner, but as an old acquaintance and close friend.

From the use of vocatives with titles, it is observed that certain forms are already gender-marked such as 女士 nv3shi4 (Ms.), 先生 xian1sheng1 (Mr.), 爷 ye2 (sir). However, for some addressing forms that can be used for both genders, the prefix 女 nv3 (female) is added before occupational titles. For instance, 女领导 nv3ling3dao3(female leader) in Example 1b. These patterns underscore the subtle gendered bias present in addressing practice.

5 Discussion

5.1 Pronouns beyond power and solidarity

Addressing options are not rigid, members of particular Communities of Practice (CofP) often develop their own practices that may not align with established model (McConnell-Ginet, 2003). In the talk show, the host differentiates vocatives using pronominal forms to subtly convey his stance and strategies towards male and female guests. According to T/V binary model proposed by Brown and Gilman (1960)'s, the pronominal forms of T/V languages highlight the roles of power and solidarity in address practices. However, the T/V forms are polysemous (Tannen, 1994; McConnell-Ginet, 2003) with the V form expressing respect or deference and the T form being either friendly or condescending. Therefore, addressing practice are perceived differently in different contexts and cultures.

In Chinese, the equivalent of the 'T' form in second-person pronouns is 你 while the more fomal 'V' form is 您. As presented in Table 3 and Table 4, the results indicate that the 'T' form 你 has higher frequency than the 'V' form, indicating the tendency of 'T' form towards gender equity (Baker, 2010). Although the traditional avoidance of pronouns in China stems from their potential to be perceived as insulting and impudent within the strict hierarchy, the occurrence of pronouns in talk show can serve as function of indicator of recipient in multi-party conversations. Additionally, the second-person address form can place the interlocutor at the centre of an experience, fostering a sense of involvement, as compared to pronoun *I* (Vásquez, 2014). For instance, 叶檀你觉得是吗? (YE Tan, what do you think?) illustrates the use of the pronoun *you* co-occurs with addressing form of FL *YE Tan* to seek an opinion. Another example is 陶老师您见多识广。(Teacher Tao, you are knowledgeable and experienced.), which uses the formal form of pronoun *you* to praise the recipient, Teacher Tao.

Apart from the polysemy of pronoun 'you', the use of *we* also carries ambiguous connotations. While the prototypical use of *we* indicates a collective discursive identity of membership categorization and signify closeness, Camiciottoli (2014) observe that the referent of the first-person plural pronoun *we* may include or exclude the addressees. Levinson (1983, p69) refers to this as 'we-inclusive-of-addressee' (Example 3a) and 'we-exclusive-of-addressee' (Example 3b). These inclusive and exclusive use of pronoun *we* have been observed to be associated with politeness, solidarity and persuasion. In the multi-party conversation in the talk show, the use of 'we' explicitly and publicly defines social groups and introduces the relationships to the audience. Both inclusive and exclusive meaning are observed. For instance, 咱们 zan2men2, another form of 'we', has an inclusive meaning that demonstrates solidarity or serves as a performative utterance to introduce the male guest in Example 3a. However, Example 3b excludes the addressee, Youting, to invite and persuade her politely to share opinion, while '我们' wo3men2 (we) refers to the listeners.

5.2 Women's place in the talk show

Although females are given more power in the talk show as they have equal opportunities and have the same roles for opinion sharing as male guests, the cross-gender conversations in the talk show in our analysis does not seem to put females at an advantage place. Female guest's disadvantage is observed in the asymmetrical distribution of vocatives used by the host. According to Brown and Ford (1961), there are three possible patterns if we only considered FN and TLN: 1) the reciprocal change of FN, 2) the reciprocal exchange of TLN, and 3) the non-reciprocal pattern in which one person uses FN and the other TLN. Because of the discursive constraints of the conventionalized beginning of the talk show, the introduction of the guest speakers are always conducted by the show host and may or may not follow by the reciprocal addressing by the guests. For instance, after the host 窦文涛 introduces the guests, they usually start discussion immediately. This is partially due to the situational constraints such as time restrictions and agenda restrictions. When host conducts performative utterances at the beginning of the episode to introduce both guests, it is evident that host address guests in mutual FN or TLN forms. In terms of the non-reciprocal form of TLN and FN. Females are always addressed in FN.

Although female guests can be addressed by title in Example 5, additional information about the health issue of the female guest is brought up by the physically weakness of '身残志坚' (physically disabled but strong willed) compared to male guest. In addition, the multi-party combination in this talk show seem to provide females marginally weaker position. Although participants take up specific roles in multi-party conversations, male solidarity is particularly observable symmetrical conversations where involve equal number of participants (Berrier, 1997), not mentioning the cross-gender conversations in the talk show of our current analysis consisting of two males and only one females. Additionally, while the categories of participants involve diverse social status and background, the categories of participants' gender is limited since there is no female to female conversations in this talk show.

The complexity of talk show is even more challenging when participants of different genders are involved. In *Behind the Headline with Wentao*, when both experts and lay people of different gender groups are present as show guests, much of the programm's focus has to do with the interchange between them. The interchange of show guests thus become an issue of interchange of different gender. As observed in the results in our analysis, the choice of vocative form for females are FN which may be used to infer information about the perceived relative lower status and solidarity in social relationships (Brown and Ford, 1961; Wolfson and Manes, 1979; Manes and Wolfson, 1981). The frequency of the FN particularly for female guests may had potential for communicating sexism. In the talk show, the personal experience and common sense knowledge have considerable status and increasingly appear as a form of knowledge in the talk show (Ilie, 2006), the use of FN for female guests may indicate their relatively lacking of experience and knowledge compared to male guests. The choice of addressing may also be the requirement of programme effect, aiming to create confrontational and contrasting atmosphere.

6 Conclusion

In this study, we investigated the addressing performance employed by the host in a Mandarin Chinese talk show. Unlike news interviews, which are typically characterized by a structured, institutional dialogue, talk shows function as public fora that allow for a blend of formal and casual conversations. This unique setting provides a rich context for analysing spontaneous language use, especially in question-answer sequences. While most existing studies focus on dyadic conversations involving only two participants, our research addresses the complexities of multi-party interactions. The talk show format, with its three participants (the host and two guests), offers a valuable source for understanding how addressing terms are used in more dynamic and fluid conversation settings. The host, who assumes a controlling role in the talk show, predominantly uses addressing terms to manage the flow of conversations. To illustrate the host's addressing performance more effectively, we selected cross-gender conversations featuring an equal number of male and female guests. This choice allows us to observe potential gender differences in the use of addressing terms within a balanced and controlled setting. Although there are many different types of addressing terms, their selection of is not random (Ervin-Tripp, 1969). Our analysis found no overtly negative views about women in the lan-

guage used by the host. However, nire subtile evidence of gender bias emerged through both qualitative and quantitative analysis. The choices of address forms serve as indicators of how language use can reflect sexist attitudes (Weatherall, 1996). Specifically, the host tended to use more full names (FL) and first name (FN) when addressing female guests, while male guests were more frequently addressed with titlesm such as title plus last name (TLN) and title plus full name (TFLN). These findings suggest that addressing practices in the current data set are affected by traditional Chinese culture. Chinese cultural naming influence how we perceive and perform addressing practice (Hagström, 2012). The study of address terms gives us considerable insight into the ways in which gender and person are constructed in Chinese society, which is greatly influenced by two philosophical systems of Taoism and Confucianism. As a result, it is unsurprising that more formal address terms with titles are predominantly used for men, reflecting their relatively higher status in the societal hierarchy. Conversely, the frequent use of first names and full names for women signals their comparatively lower status and power in the social order.

The present study reinforces the importance of context in a corpus-based approach when examining addressing practices. Analyzing address forms within their specific social and cultural contexts provides valuable insights into the construction of gender and personhood in Chinese society. This is particularly significant in a language like Mandarin Chinese, which lacks grammatical gender marking. Our findings underscore how a corpus-based analysis can reveal subtle, yet pervasive, patterns of gendered language use that might otherwise go unnoticed.

Abstract

Personality is a stable trait, but it may be influenced by the language in use, as bilingual speakers may internalize different experiences and values when acquiring these languages. This study investigated the effect of language on neuroticism in Chinese-English bilinguals using a multi-method approach combining self-report questionnaires, behavioral data-based assessments, and electroencephalography (EEG) recordings. Thirty Chinese-English bilingual students completed the Big Five Inventory (BFI) in both languages, responded to questions, and underwent EEG recording during the tasks. The results showed no significant differences in neuroticism scores between the Chinese and English versions of the BFI. However, behavioral data analysis using artificial intelligence (AI) revealed higher neuroticism scores in Chinese responses than in English. EEG analysis indicated differences between languages in the theta and alpha bands during the writing phase. These findings suggest that language may have a more pronounced effect on the implicit expression of personality traits, as reflected in language use and neural activity patterns, but not explicit self-reports. This study contributes to the understanding of the complex relationship between language and personality in bilinguals and highlights the potential of AI-based methods for personality prediction through text analysis.

1 Introduction

Personality is usually considered a relatively stable structure that maintains consistent qualities and behaviors over time and across different situations (Boeree, 2006). However, the concept of personality stability intersects interestingly with the Sapir-Whorf theory's proposition that language influences personality. This theory, based on the preliminary concepts of Edward Sapir (1921) and Benjamin Lee Whorf (1956) and further developed by Roger Brown and Eric Lenneberg, argues that there is a deterministic or influential relationship between language and thought. Within this theoretical framework, two hypotheses are distinguished: the strong hypothesis posits that language shapes and defines one's way of thinking, whereas the weak hypothesis views language as a factor that influences thought (R. Brown, 1976; R. W. Brown & Lenneberg, 1954; Bugelski, 1970). Although the strong hypothesis of Sapir-Whorf and Wittgenstein's arguments has largely failed to gain recognition in the field of psycholinguistics (Ahearn, 2021; Pinker, 2015), the influence indicated by the weak hypothesis has been confirmed in multiple research areas, including studies on the perception of color (Athanasopoulos, 2009; Winawer et al., 2007), space (Majid et al., 2004), time (Boroditsky, 2001; Casasanto, 2008), and new vocabulary (Barner et al., 2009).

Learning a new language involves adopting a different way of thinking, as language potentially influences identity, cognition, and personality. This idea challenges the notion that personality is stable, suggesting that language can dynamically influence thoughts, perceptions, and interactions. Further exploration of language and personality relationships is warranted to understand this complex dynamic.

1.1 Culture Frame Shifting (CFS)

Culture Frame Shifting is a compelling theoretical explanation for the phenomenon of personality change when using different languages. CFS refers to the shift in values and attributions of bicultural individuals (people who have internalized two cultures) when exposed to different cultural stimuli (Y. Hong et al., 2000). Some studies have suggested that CFS can affect personality traits

(Ramírez-Esparza et al., 2006; Rezapour & Zanjirani, 2020), emotional expressions, attribution styles (Kreitler, 2018), and cognitive processes related to cultural evolution (Gabora et al., 2008; Gabora & Smith, 2018). Regarding bicultural individuals, specific cultural symbols can trigger cultural values and attributes. For example, a series of studies have shown that when Chinese-American bicultural individuals are exposed to American icons (e.g., the White House & Lincoln), their American cultural knowledge network is activated; when exposed to Chinese icons (e.g., the Forbidden City & Confucius), their Chinese cultural knowledge network is also activated (Y. Y. Hong et al., 1997; Kemmelmeier & Winter, 2008). Moreover, in attribution tasks, participants placed less emphasis on external social factors when primed with American culture than with Chinese culture (Y. Hong et al., 2000).

Bilinguals exhibit different personality traits when using different languages, suggesting that language activates specific cultural frameworks (Ramírez-Esparza et al., 2006; Rezapour & Zanjirani, 2020). Ronzani's (2023) study on bilingual students confirms this, showing cultural frame switching (CFS) affects personality and leads to adaptation to the second language's culture. Participants' English proficiency also influenced self-descriptions, with only one Canadian resident describing himself as "polite." To adapt, they imitate local behavioral and linguistic patterns in the media. The degree of bicultural identity integration (BII) moderates the impact of CFS (Benet-Martínez et al., 2002). However, Bender et al. (2022) found similar response patterns in bicultural and monocultural participants, indicating that the CFS mechanisms may be more complex.

1.2 Measurement of Personality

In the field of personality assessment, self-report questionnaires are mainstream tools that consist of multiple statements or words for self-reflection. Participants were asked to rate their level of agreement with these descriptions in order to assess their personality traits. The Big Five framework is the most widely used and extensively applied personality measurement model, encompassing the following five dimensions: agreeableness, conscientiousness, neuroticism, openness, and extraversion. Currently, various tools are available to assess the Big Five dimensions, with representative ones including NEO-Personality-Inventory Revised (NEO-PI-R) (Costa & McCrae, 2008), the NEO Five Factor Inventory (NEO-FFI) (McCrae & Costa, 2004), and the Big-Five Inventory (BFI) (John, 1990; John & Srivastava, 1999). Among them, the BFI is concise, easy to understand, has broad applicability and cross-cultural validity, and is supported by numerous studies. So far, self-report questionnaires remain the most used method for personality assessment. However, owing to the subjectivity of self-reports, the results of self-report questionnaires may be influenced by social desirability.

With technological advancements, it is now possible to gain insights into individuals' personality traits by analyzing their behavioral data. For example, personal text messaging characteristics or social media behavior can be used to predict the Big Five personality traits. Gjermunds et al.'s (2020) meta-analysis provides strong evidence of the effectiveness of this analytical approach, confirming moderate correlations between the Big Five traits and text analysis indicators across multiple studies. This highlights the robustness of the relationship between language use and personality and supports the potential use of various computational methods, such as latent semantic analysis (LSA) (Kwantes et al., 2016), artificial neural networks (ANN) (Suhartono et al., 2017; Yoong et al., 2017), and transformer models (Vasquez & Ochoa-Luna, 2021) in personality analysis through text. However, although this research method can reduce participants' direct involvement to a certain extent and lower the possibility of data fabrication, such an analysis often requires a large amount of data to train language models, which is time-consuming and labor-intensive. Moreover, data fabrication may still exist, as individuals may shape an image inconsistent with their true selves when sending text messages or on social media platforms because of social expectations, personal desires, or other reasons.

To avoid social desirability bias, physiological and biological indicators such as EEG provide more reliable personality measures, as neural data are difficult to manipulate. Compared with other physiological methods (fMRI), EEG has the advantages of low cost and high portability, with a more stable relationship to personality. For example, neuroticism is reflected in higher left hemisphere activation (Bono & Vey, 2007). Studies have decoded personality traits, particularly

agreeableness, from resting-state EEG frequency powers (Jach et al., 2020). Predicting extraversion, agreeableness, and conscientiousness was better when using positive emotional stimuli, whereas neuroticism was better classified from negative emotions (Zhao et al., 2018; Li et al., 2020). Overall, EEG shows promise for reliable and objective personality assessments.

1.3 Current Study

Neuroticism is a fundamental personality trait characterized by emotional instability, anxiety, moodiness, and negative emotionality. It is highly relevant to mental health and well-being, as higher levels of neuroticism are associated with a greater risk of developing various psychological disorders, including depression and anxiety (Lahey, 2009). Focusing on neuroticism allows for a deeper understanding of how language influences the expression of personality traits that are closely linked to mental health outcomes. By examining neuroticism specifically, this study aims to shed light on the potential impact of language on emotional regulation and psychological well-being in bilingual individuals.

The present study aims to address two key research gaps in the literature on language and personality: (1) investigating the language effect on neuroticism using text responses and EEG and (2) identifying neuroticism with an artificial intelligence (AI) model. Therefore, we employ a multi-method approach that combines self-report questionnaires, behavioral data-based assessment, and EEG recordings to examine the influence of language on personality, specifically neuroticism, among Chinese-English bilinguals. We hypothesize that language will influence the personality expression of second language users, as reflected in their language use (e.g., the degree to which personality-related vocabulary is used in different language contexts) and EEG responses (e.g., the contrast of neural activity patterns associated with neuroticism traits when using different languages). To test these hypotheses, we recruited thirty Chinese-English bilinguals from the Hong Kong Polytechnic University to participate in questionnaire assessments, behavioral experiments, and EEG experiments.

The findings of this study are expected to contribute to our understanding of the complex interplay between language, culture, and personality, and to inform the development of culturally sensitive approaches to personality assessment and intervention.

2 Method

2.1 Participants

Thirty Chinese-English bilingual students (9 male, 21 female) from the Hong Kong Polytechnic University, aged between 19 and 30 years, were recruited to participate in this study. Participants were randomly assigned to either the behavioral experiment group (3 males, 14 females) or the EEG experiment group (6 males, 7 females). All participants were native Chinese speakers who had taken a standardized English proficiency test (IELTS 6 or TOEFL 80). The mean age of the participants was 23.73 years (SD = 2.41), and the mean age of English acquisition was 6.77 years (SD = 2.63). All participants were right-handed, as assessed by the Edinburgh Handedness Inventory (Oldfield, 1971), and had no psychological or neurological disorders. Participants also had normal or corrected-to-normal vision. The study protocol was approved by the Human Subjects Ethics Sub-committee of the Hong Kong Polytechnic University.

2.2 Materials

Big Five Inventory. The Big Five Inventory (BFI) (John, 1990) is a 44-item self-report questionnaire that assesses the five dimensions of personality: agreeableness, conscientiousness, neuroticism, openness, and extraversion. Participants rated their agreement with self-descriptive statements using a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). In this study, both the English and Chinese versions of the BFI were used. The English BFI has demonstrated good psychometric properties, with alpha reliabilities ranging from 0.75 to 0.90 and test-retest reliabilities ranging from 0.80 to 0.90. The Chinese BFI has also shown good reliability, with alpha reliabilities ranging from 0.79 to 0.87, and an average test-retest reliability of 0.84 (Li & Chung, 2020). The internal consistency between the Chinese and English versions of the BFI was found to be satisfactory.

Stimuli. Sixteen scenario questions were used as stimuli in this study, with eight texts in each language (Chinese and English). Among these, two questions were neutral and six were related to neuroticism, covering the six dimensions of

neuroticism: anxiety, angry-hostility, depression, self-consciousness, impulsiveness, and vulnerability (Vittersø & Nilsen, 2002). To avoid bias, no emotional leading was included in any of the questions, and all questions were concluded with an open-ended prompt asking participants how they felt and what they would do in the given situation.

Each Chinese scenario contained approximately 150 words, whereas each English scenario contained approximately 80 words. This setting aimed to equalize reading time across languages. It is worth noting that there were no content differences between the Chinese and English scenarios, only language differences. See sample scenarios in the Appendix A.

2.3 Procedure

The study employed a scenario-reading and response task divided into Chinese and English sessions. To minimize sequence bias, participants were required to complete the experiment twice, with half starting with the Chinese session and the other half starting with the English session. There was a 4 to 10 days interval between sessions to avoid the influence of the previous session's content. The experimental procedure is illustrated in Figure 1.

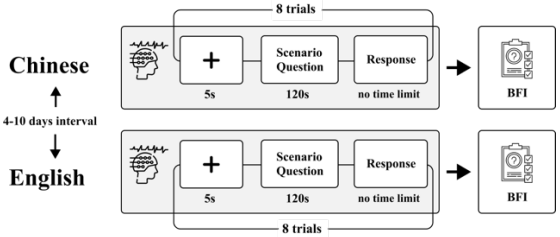

Figure 1: The experimental procedure. BFI: Big Five Inventory.

Each experiment consisted of eight trials. In each trial, participants saw a fixation cross (+) for 5,000 ms, followed by a scenario question presented in font size 36, Calibri font for English, and Microsoft YaHei for Chinese. The scenario question was displayed until the participant pressed the space bar to indicate that they had finished reading and were ready to proceed. The maximum duration for reading was 120 seconds. Then, the prompt "Please put in your thoughts..." appeared on the screen and participants were instructed to input their responses using the same language as the scenario question. Chinese responses were suggested to be around 70-80 characters, and English responses were 30-40 words, although this was not a strict requirement. Participants were encouraged to share their genuine reactions and actions, rather than what they thought they should do or what they expected.

After the experimenter explained the details, the participants voluntarily signed an informed consent form. Then, participants were fitted with an EEG cap, which took 40 minutes. The experiment was conducted in a soundproof room with two computers in front of the participant: Computer A was connected to the EEG recording system and presented the scenario questions, while Computer B, using a Python GUI, collected their responses. Participants then conducted a practice trial with a scenario that was not included in the formal experiment to familiarize themselves with the procedure. The presentation of stimuli and collection of behavioral responses were programmed using E-Prime. The order of the trials was randomized. After the experiment, participants were asked to fill out a Big Five Inventory questionnaire, covering four dimensions other than neuroticism, to prevent them from discerning the purpose of the experiment.

2.4 Analysis

BFI Analysis. Only eight items associated with neuroticism were calculated from the 44-item questionnaire (Items 4, 9, 14, 19, 24, 29, 34, and 39). Items 4, 14, 19, 29, and 39 were scored directly (e.g., a response of 5-strongly agree was allocated 5 points), whereas items 9, 24, and 34 were reverse-scored (e.g., a response of 5-strongly agree was allocated 1 point). The analysis employed raw scores rather than standardized scores. Upon aggregating these scores, a between-subjects t-test was conducted to examine potential differences in participants' scores when responding to the questionnaire in the Chinese versus English versions.

Behavioral Analysis. In this study, we used artificial intelligence (AI) models to analyze the participants' behavioral data. We employed the GPT-4 model, a state-of-the-art language model developed by OpenAI, known for its powerful natural language understanding and generation capabilities (OpenAI, 2023). GPT-4 is trained on a diverse range of internet text and leverages transfer learning. This allows the model to effectively analyze and score text responses in both Chinese and English.

We established an API interface to connect to the gpt-4-0125-preview server and designed a prompt that divided the degree of neuroticism into five levels, increasing in severity from 1 to 5. Next, we let the AI model read each participant's responses to the senario questions and assign scores based on the level of neuroticism reflected in their answers (Table 1). To reduce the arbitrariness of AI scoring, we ran the prompt twice in both Chinese and English, meaning that for each answer (480 in total), we obtained four scores (SD < 0.96). We used the average of these four scores for subsequent calculations. In addition, we used the scores of responses to situational questions labeled as "neutral" as a reference to assess the accuracy of AI scoring. The results showed that only three responses were assigned a score of 2, while the rest were scored as 1 (indicating minimal neuroticism in the text), suggesting that the scores provided by the AI are highly accurate. It is worth mentioning that the AI did not assign a score of 5 (indicating extremely high neuroticism in the text) to any response. Through further testing, we found that AI only assigns a score of 5 when extreme words such as "suicide" or "die" appear in the text.

Responses	**Score**
I will feel so happy and surprised. So I will share this news with my best friend first, then I will check my timetable and make a plan. I will push myself to do things faster and seize the chance to see my idol!	1
Firstly, I think it is very common that people meet new individuals and begin their new exploration in their life. Therefore, personally, I felt happy for them if they have their more wonderful life. Because I will have mine as well in the future. Secondly, I will like the post they presented in the social media and wish them have a good time. Meanwhile, I will remember all the unforgetable things between us even though they or I have new friends in the future.	1
I feel very embrassed and guse that my colleague's polite smile is fake and they must mock me secretly. I will try my best to claim down and aviod other's sightline.	4
I feel so angry, he is cheating us! I don't believe professor believed him, because he cannot individually complete most of the tasks. I have to do some actions, I will find the evidence to prove my hard work.	4

Table 1: Neuroticism scores of examples responses scored by AI

NOTE: Score: average of four scores; Examples responses based on different scenario questions.

EEG Analysis. EEG data were analyzed using EEGLAB in MATLAB. Continuous EEG was preprocessed using the following steps: First, the sampling rate was downsampled to 100 Hz. The lowered sampling rate speeds up the data preprocessing and may not affect the result of the current analysis, as we focus on the spectrum between 1 and 50 Hz, for example, delta to gamma band. DC offset was removed. A high-pass filter of 1 Hz was applied to the continuous data. Bad channels were detected and replaced using spherical interpolation. ICA was applied to the EEG to identify non-brain signals. The independent component was automatically examined using the ICALabel function, and any component with a greater than 80% possibility of being a non-brain signal was removed from the data. After artifact correction, the continuous data were epoched to -1 to 10 s long ERPs relative to the onset of each reading and writing phase. These single-trial ERPs were entered into the spectrum power analysis, where the 1–50 Hz spectrum power of each trial was calculated relative to the pre-onset baseline for each channel.

Only the spectrum power of the Cz electrode was considered in the current report, as Cz is the most frequently studied channel in EEG studies. In future research, more electrodes will be considered with cluster-based multiple comparison corrections. Five frequency bands were selected for further analysis: delta (1-4 Hz), theta (4-8 Hz), alpha (8-12 Hz), beta (12 – 30 Hz), and gamma bands (30-50 Hz) (Kumar & Bhuvaneswari, 2012). The spectral power of each frequency band was averaged across trials for the reading and writing phases separately in the two language sessions.

The frequency band average spectrum power was then entered into a three-way within-subject ANOVA to explore any differences between the two languages. The task phase (two levels: reading and writing), language in use (two levels: Chinese and English), and Frequency Bands (five levels: Delta, Theta, Alpha, Beta, and Gamma) served as within-subject factors. The Greenhouse-Geisser correction method was used when the assumption of sphericity was violated. A post-hoc analysis was applied when there was a significant main effect or interaction among the factors.

3 Results

3.1 BFI Results

The data reported here were collected from 30 participants, including 30 Chinese BFI questionnaires and 30 English BFI questionnaires. The analysis results showed that the neuroticism scores of the Chinese version of the questionnaire (M = 23.37, SD = 5.97) were higher than those of the English version (M = 22.70, SD = 5.73) (Figure 2), but the paired t-test results ($t(29) = 0.83$, $p = 0.41 > 0.05$) indicated that the difference between the two versions was not statistically significant, suggesting that the effect of language version on neuroticism scores was minimal. In addition, the correlation between the neuroticism scores of the participants' Chinese and English versions was compared ($r = 0.72$), pointing out that there was a high degree of consistency in measuring neuroticism dimensions across language versions.

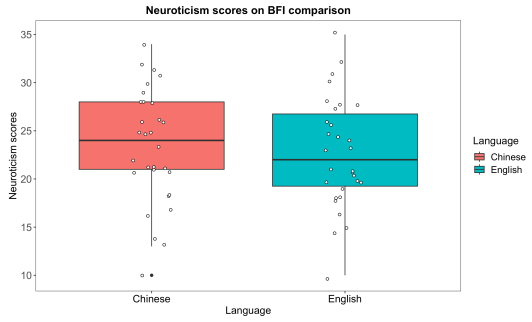

Figure 2: Boxplot of neuroticism scores from Chinese-English bilinguals on the BFI in both Chinese (orange) and English (blue) versions. No significant differences were observed between the languages.

3.2 Behavioral Results

The neuroticism scores assigned by AI of participants' responses using the Chinese and English were compared. The results showed that the neuroticism score of the Chinese (M = 2.315, SD = 0.405) was higher than that of the English (M = 2.196, SD = 0.403) (Figure 3). Through paired t-test analysis, we found that this difference was statistically significant ($t(29) = 2.125$, $p = 0.042$), indicating that there was a significant difference between the Chinese and English when participants processed responses to the scenario questions.

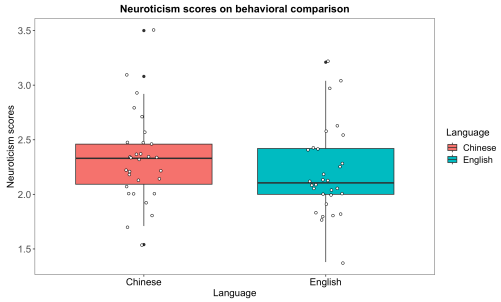

Figure 3: Boxplot of neuroticism scores from Chinese-English bilinguals on the behavioral results in both Chinese (orange) and English (blue) versions. Significant differences were observed between the languages.

However, for neuroticism scores, correlations between AI scores and BFI scores were not significant (Pearson's $r = 0.25$, $p = 0.171$ for Chinese language; $r = 0.10$, $p = 0.591$ for English language), implying that AI scores were not effective in predicting participants' personality traits. The results suggest that although the AI model is statistically different in its assessment of neuroticism scores across language, its validity as a personality predictor still needs to be improved.

3.3 EEG Results

The within-subject ANOVA revealed a main effect of Frequency Bands ($F(1.67, 20.09) = 348.99$, $ges = 0.894$, $p < 0.001$) and an interaction among language, frequency bands, and task phase ($F(2.40, 28.8) = 3.47$, $ges = 0.002$, $p = 0.037$). No other significant main effects or interactions were found (see Table 1 in the Appendix B). The main effect of the frequency bands was mainly contributed by the gradual lowering of the spectrum power from the delta to gamma bands. This trend is commonly seen in the spectrum power analysis of EEG, as a higher bandwidth tends to convey a lower power.

The Post hoc analysis of the three-way interaction revealed that only the writing phase of the tasks showed a language difference in the theta ($t = -2.258$, $p = 0.043$) and alpha ($t = -3.343$, $p = 0.006$) bands. No other frequency bands showed significant spectrum power differences between the languages during the writing task phase. No language difference was revealed in the reading phase on any frequency band (Table 2).

FB	Phase	Language	Power (dB)	SD

NOTE: FB: frequency band; Phase: task phase; SD: standard deviation.

4 Discussion

The findings provide some interesting insights into the complex connections and interactions between language and personality.

The results of BFI analysis showed that there was no significant difference in neuroticism scores in the Chinese and English versions of the questionnaire ($p > 0.05$), and the correlation between the two was high ($r = 0.72$), indicating that language had little influence on the BFI neuroticism scores and the neuroticism measurements were highly consistent across different language versions. This supports previous research that BFI has cross-cultural validity and that self-reported personality traits tend to remain stable across language contexts (John & Srivastava, 1999). However, participants are likely to changing their responses based on perceived social expectations or personal desires, so self-report questionnaires may be affected by social expectation bias (Gjermunds et al., 2020).

Contrary to the results of BFI, the behavior data analysis based on AI scores showed that there was a significant difference in neuroticism scores ($p = 0.042$) when participants responded to scenario questions in both Chinese and English. Participants showed higher levels of neuroticism in the Chinese responses compared to the English responses. This finding is consistent with the cultural frame Shift (CFS) theory, which suggests that language can serve as a powerful clue to activate specific cultural frames and influence personality expression (Ramírez-Esparza et al., 2006; Rezapour & Zanjirani, 2020). The difference in neuroticism scores between the two languages may be due to the adaptation of subjects to the second language culture (Ronzani, 2023). The low correlation between the AI's neuroticism score and the BFI score reveals the limitations of using AI-model text analysis for personality prediction. Although AI-model scoring methods can reduce subjectivity and social bias in assessments compared to humans, their validity and credibility as predictors of personality still need to be improved.

EEG analysis showed that participants showed differences between different languages only in the writing phase and showed differences in the use of Chinese and English in the theta band ($t = -2.258$, $p = 0.043$) and the alpha band (-3.343, $p = 0.006$). This finding is consistent with the results of the two previous analyses of this study, in which there were no personality differences in the perception phase

(BFI analysis) and only in the expression phase (typed response analysis) were personality differences observed. Higher theta and alpha power in English writing conditions may reflect the increased cognitive load and attention demands associated with using a second language (Kumar & Bhuvaneswari, 2012). However, it is important to note that the current EEG analysis is limited to the Cz channel, which may influence the conclusions reached to some extent.

The differences between BFI results and behavioral with EEG results suggest that language may have a more pronounced effect on the implicit expression of personality traits. This finding is consistent with previous research in which, with the same BFI questionnaire in English and in Spanish, the results for English-speakers and Spanish-speakers differed from the results for English-Spanish bilinguals, with significant differences in neuroticism scores for the former, but not for the latter (Ramírez-Esparza et al., 2006). Language use and neural activity can measure personality without participants being fully aware of it, revealing more implicit aspects of personality (Jach et al., 2020; Li et al., 2020). The implicit expression of personality through language use may be influenced by the activation of specific cultural frameworks associated with each language (Y. Hong et al., 2000).

The findings suggest that language may influence the implicit expression of personality traits, as reflected in language use and neural activity patterns, even if explicit self-reports remain stable across languages.

However, the study has limitations. Firstly, the small sample size (n=30) may limit generalizability, requiring larger, more diverse samples in future. Secondly, we focused only on native Chinese-English bilinguals, the results may be affected by language proficiency, necessitating extension to native English-Chinese bilinguals and other multilinguals to investigate language's influence on personality expression. Third, although we attempted to use BERT models for text-based personality prediction. The limited training data leading to overfitting, so the existing GPT-4-0125-preview model was used instead. In addition, we did not compare the AI-assigned neuroticism scores with ratings from human experts. In future research, we plan to include human expert ratings to evaluate the validity of AI-based personality assessments.

5 Conclusion

This study innovatively combined multiple research methods, including self-report questionnaires, scenario question reading and response task, and EEG recordings, to investigate the influence of language on neuroticism in Chinese-English bilinguals. The findings suggest that language may have a greater impact on the implicit expression of personality traits (e.g., responses to scenario questions and neural activity patterns) compared to explicit self-reports. This finding is consistent with previous research that language use and neural activity can measure implicit aspects of personality that individuals may not be fully aware of. It is also consistent with cultural frame shifting (CFS) theory, demonstrating that language is a powerful cue to activate specific cultural frames and influence personality expression.

It is worth noting that this study explored the use of AI models to predict neuroticism through text in behavioral data analysis. Although the validity and credibility of this approach still need improvement, it provides new ways for future research on language and personality. Future studies should investigate the impact of language on other dimensions of personality using larger and more diverse samples and continue to develop and refine AI-based personality prediction methods.

Appendix A. Sample scenarios used in the experiment

Scenarios	Property
It's been a few weeks since you last saw your friends, so you decide to organize a weekend gathering, hoping to reconnect and strengthen your friendships. You carefully plan the details of the event, including each person's favorite food and drinks, and even prepare some interactive games to ensure a lively atmosphere. After sending out the invitations, most of your friends reply quickly, but one friend you are particularly looking forward to seeing hasn't responded. At this moment, how do you feel? What would you do?	Neuroticism
After finishing your classes for the day, you step out of the building and see the sun slowly setting on the horizon. A friend messages you on WeChat, asking if you're free to try a newly opened restaurant tonight. You quickly go through your pending assignments and scheduled plans in your mind and realize that there's nothing particularly urgent for the evening. You gladly accept your friend's invitation, deciding to spend a pleasant evening with a few close friends and temporarily put aside the pressures of your studies. At this moment, how do you feel? What would you do?	Neutral

Effect of Rap Music Context on Lexical Tone Normalization

Abstract

This study explores the role of rap music in lexical tone normalization among Mandarin speakers, addressing a gap in existing research that primarily focuses on speech contexts. While previous studies suggest that tone normalization is largely speech-specific, rap music, which combines elements of both speech and music, may provide unique insights. We examined the effects of rap, cello, and drum contexts compared to typical speech contexts. Our findings reveal that rap music, unlike purely instrumental music, elicited tone normalization effects similar to those of speech. This suggests that the pitch information in rap music may activate cognitive mechanisms akin to those used in speech processing.

The presence of human voices in rap creates a frame of reference, enabling listeners to normalize tones based on contextual pitch information. This challenges the notion that lexical tone normalization is exclusive to speech, highlighting the potential for speech-like elements in music to influence auditory perception. Our research underscores the importance of vocal elements in tone normalization and suggests that rhythm alone is not a critical factor.

Future research should investigate other speech-like materials and include participants with diverse linguistic and musical backgrounds to deepen our understanding of these mechanisms. By expanding the scope of contexts and participant diversity, we aim to further elucidate the cognitive processes underlying tone normalization and its broader implications for language education, rehabilitation, and AI technologies.

1 Introduction

1.1 Research Background

Speech normalization focuses on how phonologically identical utterances can exhibit significant acoustic variation among different speakers, yet listeners still recognize words across these variations. This phenomenon has been thoroughly investigated in vowel perception, where the "frame of reference" theory is pivotal. This theory suggests that listeners utilize contextual cues to form a cognitive framework, aiding in the accurate interpretation of vowel sounds. Ladefoged and Broadbent (1957) showed that vowels assessed within a precursor phrase with altered vowel formant frequencies were perceived differently compared to those in a phrase with lower formant frequencies. This concept has been reinforced by numerous studies (Ainsworth, 1974; Dechovitz, 1977; Nearey, 1978, 1989; Remez et al., 1987; Johnson, 1990).

Similarly, lexical tone normalization, another aspect of speech normalization, refers to the process by which individuals interpret tone information in various perceptual environments. Leather (1983) observed normalization effects with Mandarin tones, indicating that the pitch range of a contextual utterance affects the perception of test tones with varying F0 values.

Many studies have explored how context influences the perception of level tones in Cantonese (Francis, 2006; Wong & Diehl, 2003; Zhang, 2012). There are also some studies using Mandarin as subjects (Chen, F. & Peng, G., 2016). These studies indicate that target tones are often perceived as lower when the contextual pitch is higher, and vice versa. Zhang et al. (2012) found a disparity in the perception of Cantonese level tones between speech and non-speech contexts. Musical context, as an important non-speech context, has also been partially studied (Zhang et al., 2013; Tao

and Peng, 2020). These studies indicate that musical context does not have the same effect on tone perception as speech context.

Previous research suggests that lexical tone normalization is largely speech-specific, influenced mainly by speech context rather than non-speech or music contexts. These findings imply that music and speech contexts activate different cognitive mechanisms in processing tonal information. However, these conclusions are primarily based on typical musical styles, overlooking special genres like rap music, which shares some acoustic features with speech. To better understand the role of contexts that blend music and speech in lexical tone normalization, it is essential to examine rap music. If rap music does not evoke tonal normalization, it would support the idea that normalization is specific to speech. On the other hand, if rap music does evoke tonal normalization, it would suggest that contexts with speech-like elements can also trigger this process. Furthermore, as rap combines elements of both language and music, it does not necessarily imply that language and music share common cognitive features.

Rap is defined as a style of popular music, developed by African Americans in New York in the 1970s, where words are spoken rhythmically and often in rhyming sentences over an instrumental backing. [1] As a genre of hip-hop music, rap features strong rhythm and a lack of melody. Therefore, we believe that rap occupies a space between speech and music, potentially playing a unique role in the normalization of lexical tones among Mandarin speakers.

Previous research suggests that lexical tone normalization is largely speech-specific, influenced mainly by speech rather than non-speech contexts. However, these conclusions often overlook genres like rap music, which shares acoustic features with speech. This study aims to explore whether rap music can evoke lexical tone normalization, challenging the speech-specific hypothesis. By examining rap, cello, and drum contexts, we seek to understand the role of different contexts in Mandarin tone normalization. This exploration is crucial for determining whether elements of rap music can bridge the gap between speech and non-speech contexts.

This research fills a gap in the study of rap contexts in lexical tone normalization, providing new insights into the speech-specific hypothesis. By focusing on Mandarin, we aim to offer additional evidence in a field where results from Cantonese and Mandarin have sometimes conflicted. This study contributes to a deeper understanding of how different auditory contexts influence tone perception, potentially reshaping theories of speech processing.

The findings have implications for tone language education, particularly Mandarin teaching. They could inform speech and music-related rehabilitation therapies, offering new strategies for auditory training and cognitive rehabilitation. Additionally, the study's insights can advance AI technologies, such as speech-to-text systems and voice recognition, by improving algorithms that process tonal languages. Understanding how different contexts affect tone normalization can enhance language learning tools and improve AI's speech processing capabilities, making technology more accessible and effective for tone language speakers.

Furthermore, this research could impact the development of educational curricula by integrating musical elements into language teaching, thereby enriching the learning experience. In therapeutic settings, the findings might lead to innovative approaches that utilize musical contexts to aid in speech recovery and cognitive development. The potential applications of this research extend to various fields, highlighting its broad relevance and utility.

Our primary question is whether the rap context can facilitate the normalization of Tone 1 and Tone 2 in Mandarin. We hypothesize that rap, as a unique non-speech context, may trigger tone normalization processes distinct from those in speech and instrumental music contexts. By comparing these contexts, we aim to determine whether vocal form has a different contrastive context effect than instrumental music. This investigation will provide insights into the cognitive processes underlying tone perception and

[1] The Oxford English Dictionary defines "Rap" as "a style of popular music (developed by New York Blacks in the 1970s) in which words (usually improvised) are spoken rhythmically and often in rhyming sentences over an instrumental backing". In the online version of the Encyclopedia Britannica, Rap is defined as "the competitive use of rhyming lines spoken over an ever-more-challenging rhythmic base".

the potential for cross-modal influences between music and language.

In conclusion, this study explores the boundary between music and language, providing evidence for speech normalization. By examining contexts that combine elements of both, we aim to uncover whether lexical tone normalization involves a unique frame of reference, similar to vowel perception. This exploration is crucial for understanding the broader cognitive mechanisms underlying speech perception and normalization. Ultimately, the research seeks to bridge gaps in current knowledge, offering a comprehensive view of how diverse auditory contexts influence language processing. Through this work, we hope to contribute to the ongoing dialogue in linguistics and cognitive science, paving the way for future studies that further unravel the complexities of human auditory perception.

2 Methodology

We utilized a similar experimental design and stimuli as in previous research (Tao et al., 2021). Below is a brief overview of the stimuli preparation and experimental procedure; for more detailed information, refer to (Zhang et al., 2013; Zhang et al., 2017).

2.1 Participants

The study involved 24 native Mandarin speakers [12 females, average age (mean±SD) = 23.5±2.2], all of whom were right-handed and had no hearing impairments. This number was determined to ensure the four context type conditions were counterbalanced among participants. According to Peng et al. (2010), tone inventories can influence categorical perception without context. Therefore, participants were selected exclusively from Northern China, speaking only Mandarin and no other dialects. None had formal musical training or professional experience in music. All participants provided written consent prior to the study, which was approved by the Human Subjects Ethics Sub-committee of The Hong Kong Polytechnic University.

2.2 Stimuli

Stimuli of this study comprised targets and contexts across four conditions: rap, cello, drum, and speech. These were designed to explore the effects of different rhythmic and melodic contexts on lexical tone normalization, categorized into two main groups: vocal and instrumental, each with distinct characteristics.

In the vocal group, the rap and speech contexts were produced by four native Mandarin speakers (two males and two females), each with over five years of amateur rap experience and approximately seven hours of weekly exposure to rap music. The content for both speech and rap contexts consisted of a six-syllable meaningful sentence: "下面你会听到 (Below you will hear)" and "现在我说的是 (Now what I say is)." The rap context was derived from a track by Chinese rapper Pharaoh, specifically the song "百变酒精," chosen for its strong rhythmic elements and clear articulation, ensuring it was representative of Chinese rap music. The rap materials were recorded with a speaker performing alongside a background music (BGM) track, with only the vocal component recorded. This approach aimed to make the rap material accessible while retaining distinctive rap characteristics. In contrast, the speech context maintained a natural conversational rhythm, typical of spontaneous speech, with variations in tempo and intonation.

Meanwhile, the instrumental group consisted of cello and drum contexts, both purely instrumental and devoid of vocal elements. These contexts were designed to match the pitch and rhythm of the rap context, providing a basis for comparison. The cello context emphasized melodic continuity, with musical notes aligned to the pitch of each syllable in the rap context, and its rhythm was consistent with the rap context, following the pattern: "X X X X | X X". The drum context utilized the sound of a woodfish to represent rhythmically strong instruments and featured strong, syncopated beats with complex rhythmic patterns, creating a rhythmically dominant context compared to the more melodic cello context.

The selection of these four sound types aimed to isolate the effects of rhythm and melody on lexical tone normalization. By comparing the rhythmically strong drum and rap contexts with the rhythmically weaker cello and speech contexts, we sought to determine whether rhythm alone could account for any observed effects. The instrumental group allowed us to examine the impact of rhythm without vocal influence, while the vocal group provided insight into the role of vocal melody and rhythm.

The Mandarin syllable /i/ was chosen as the target syllable, derived from natural recordings by the same speakers. An 11-step tone continuum was constructed, ranging from Mandarin Tone 1 (high-level tone) to Tone 2 (mid-rising tone). In Mandarin, /i/ with a high-level tone means "clothes" (coded as stimulus Number 1), while with a mid-rising tone, it means "aunt" (coded as stimulus Number 11). After recording the sentences, the F0 trajectories were adjusted by three semitones to create F0-lowered and F0-raised contexts. The music contexts were similarly produced. All targets were set to an intensity of 55 dB and a duration of 450 ms, while all contexts were adjusted to an intensity of 55 dB and a duration of 1000 ms.

2.3 Experiment Procedure

Participants attended a practice block, four experimental blocks, and a subjective choice block. The practice block consisted of two repetitions and two phrases with two tones, totaling eight trials. This block included only one talker (different from the four talkers in the subsequent experimental blocks) and one context (speech). It was designed to familiarize participants with the experimental procedure. The study comprised four experimental blocks, each representing a distinct context condition: cello, drum, rap, and speech. These conditions were systematically counterbalanced among participants to ensure each appeared equally across different positions. Each participant was randomly assigned to one of several counterbalancing sequences, ensuring that each context condition appeared in each position an equal number of times. The subjective choice block was a judgment task where participants decided whether the heard sound belonged to rap or speech.

The experimental blocks were designed as tone identification tasks. Participants were asked to judge the target syllable after attentively listening to the preceding context. Specifically, participants were instructed to focus on the entire utterance and press "1" for Tone 1 or "2" for Tone 2 using their right hand. During each trial (see Fig. 1), a forward mask (+) was displayed for 500 ms, followed by the context stimulus played through inserted earphones. After hearing the context and a jittering silence (ranging from 300 ms to 500 ms), the target syllable was presented, ranging from Mandarin Tone 1 to Tone 2. Participants then identified the target tone.

To mitigate order effects, participants pressed the corresponding keys when a question mark appeared 500 ms after the target onset, remaining for up to 1500 ms. Reaction times were not analyzed, as they did not provide meaningful insights into psycholinguistic properties. The focus was on participants' tone judgments, aligning with standard research procedures.

Each context condition included two F0 frequency shifts, two content types from four speakers, and 11 target steps, totaling 176 trials per condition. The experimental blocks were counterbalanced to avoid order effects.

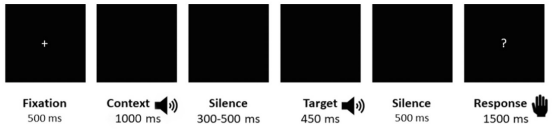

Figure 1: The trial procedure of the Mandarin word identification task.

2.4 Analysis

In line with previous studies (Chen, et al., 2016; Tao, et al., 2021; Zhang et al., 2023), we analyzed the Tone 2 identification rate to assess lexical tone normalization.

For the tone identification task, we performed a Probit analysis of the recognition responses to calculate the position and boundary width of the category boundaries (Finney, 1971), comparing between different types of contexts.

We performed one-way repeated measures ANOVAs on identification rates (IR) with Context as the main factor, followed by three-way repeated measures ANOVAs on Tone 2 identification rates. Two main factors were Context (cello, drum, rap, speech) and F0 shift of context frequency (low, high).

3 Results

The data analysis procedure largely followed previous research (e.g., Chen, et al., 2016; Tao, et al., 2021; Zhang et al., 2023).

For each stimulus, the identification score was calculated as the percentage of responses where participants identified the stimulus as either 'Tone 1' or 'Tone 2'. Figure 2 shows the average percentage of Tone 2 responses under two F0 shift conditions (high vs. low) across four contexts. The red line indicates responses to target stimuli in the

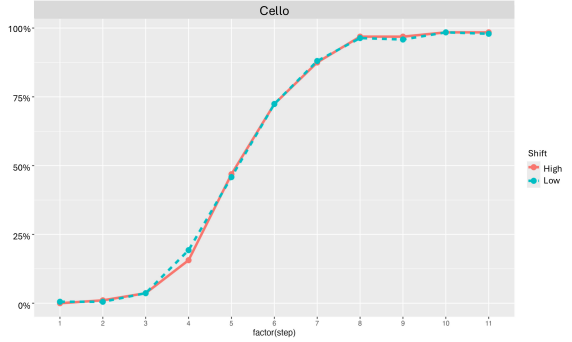
high-F0 context, while the green line represents those in the low-F0 context.

Consistent with previous studies, the results in Figure 2 were reanalyzed using Probit analysis to provide a clearer understanding of the data and to estimate the identification boundaries and shifts based on the preceding context (Chen & Peng, 2016). The boundary of categorical tone perception was defined as the onset F0 of the target stimuli corresponding to 50% on the lines. Detailed results are presented in Table 1 and Figure 3.

A repeated measures ANOVA was conducted to examine the categorical boundary, considering context type (cello, drum, rap, speech) and context frequency shifts (high, low) as within-subject factors. The analysis indicated a significant main effect of context type, $F(3, 188) = 14.139$, $p < 0.05$, while no significant effect was found for context frequency, $F(1, 46) = 0.432$, $p = 0.730$.

In a separate analysis, another repeated measures ANOVA was performed with the same factors. This time, a significant main effect of context frequency was observed, $F(3, 188) = 14.954$, $p < 0.01$, but no significant effect for context type, $F(1, 46) = 0.493$, $p = 0.688$.

Post hoc analyses were conducted for each context type individually. In the speech condition, variations in context frequency (high vs. low) significantly affected the results, $F(1, 46) = 15.195$, $p < 0.01$, leading to an approximate 1.016 shift in categorical boundary positions (refer to Table 1). Similarly, the rap condition showed a significant effect, $F(1, 46) = 13.338$, $p < 0.01$, with a boundary shift of approximately 1.012 (see Table 1). However, no significant effects were found for the cello condition, $F(1, 46) = 0.001$, $p = 0.977$, or the drum condition, $F(1, 46) = 0.002$, $p = 0.967$. These results suggest that the primary effects were driven by the speech and rap contexts, likely due to the perception of ambiguous tone stimuli in the middle range of the continuum (see Fig. 2, stimuli No. 5 to No. 7).



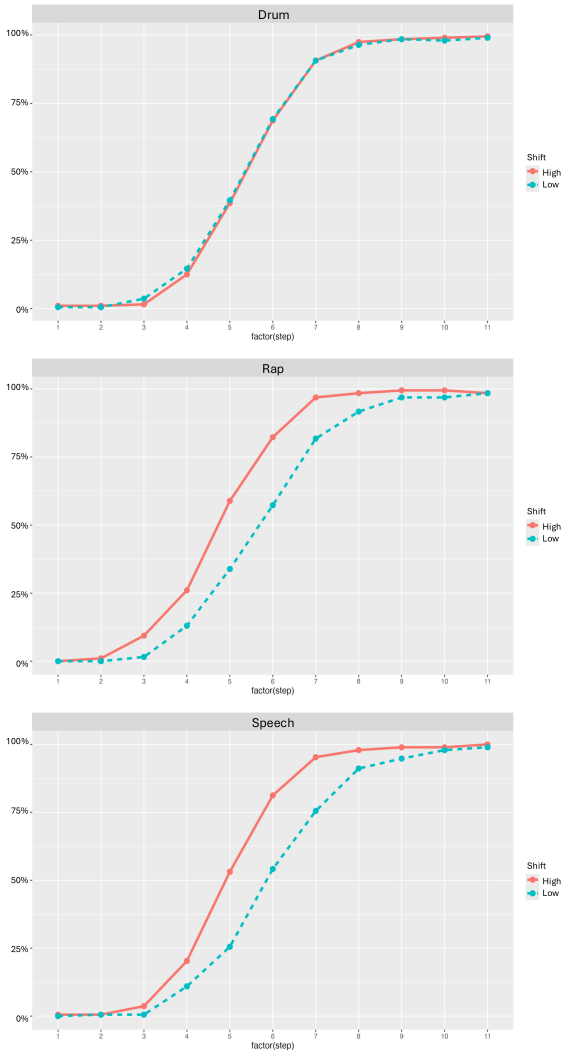


Figure 2 Average Tone 2 Response by Step and Shift for Each Context (from top to bottom: Cello, Drum, Rap and Speech)

Contexts	High	Low	Difference
Cello	5.357	5.349	0.008
Drum	5.429	5.419	0.009
Rap	4.805	5.817	1.012
Speech	5.012	6.028	1.016

Table 1 Derived categorical boundary positions for each type of context with high and low mean F0.

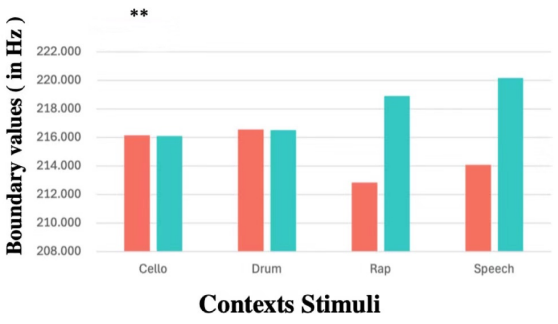

Figure 3 Category boundary values of each context types and frequencies. Red bars represent higher mean F0 context; blue bars represent lower mean F0 context. Higher category boundary values indicate more Tone 2 responses. **: $p < 0.01$.

4 Discussion

Our study reveals that typical instrumental music, such as cello and drum, does not induce lexical tone normalization. This finding aligns with previous research using piano as a musical stimulus (Tao et al., 2021), suggesting that instrumental music lacks the necessary elements for this process. Therefore, it appears that the absence of human vocal elements in instrumental music may be a critical factor. This absence might prevent listeners from accessing the pitch cues essential for normalization.

When considering rhythm, it is important to note that drum and rap are rhythmically strong, while cello and speech are rhythmically weak. Despite this classification, rhythm does not appear to significantly impact lexical tone normalization. Instead, rap and speech, despite their rhythmic differences, exhibit similar effects. This indicates that rhythm is not a critical factor in lexical tone normalization, suggesting that other elements may play a more significant role. The consistency of effects across different rhythmic contexts implies that the mechanism underlying tone normalization is robust to rhythmic variations.

Furthermore, the ability of rap music to induce lexical tone normalization challenges the notion that this process is exclusive to speech. This suggests that normalization may not be solely attributable to speech-like elocution but can also be triggered by rap, a distinct musical genre. Consequently, the shared elements between rap and speech might be key factors in this process. It is possible that these shared elements include pitch information and other vocal characteristics inherent in human speech. This finding opens new avenues for exploring how different types of vocalizations can influence cognitive processes related to language.

Moreover, the lack of significant effects from instrumental contexts highlights the importance of human vocal elements. The presence of vocal elements, regardless of classification as music or speech, seems necessary for lexical tone normalization. This reliance on human voices, particularly pitch information, suggests a mechanism similar to vowel perception, where vocal characteristics establish a frame of reference. Thus, it is crucial to explore what specific elements in human voices contribute to this process. Understanding these elements could provide insights into how the brain processes complex auditory information.

Additionally, the absence of normalization in instrumental contexts may be due to differences from speech. In our experiment, the cello context was created by adjusting the average pitch of each word, which may have been perceived as distracting. Participants might have subjectively excluded these contexts during the task. Therefore, future experiments will explore whether including complete frequency information can induce normalization by better replicating tonal direction and ensuring participant focus. By refining the experimental design, we aim to determine whether more naturalistic instrumental stimuli can elicit normalization effects.

In light of these findings, it is evident that lexical tone normalization may not be limited to speech alone. We aim to identify the key factors involved, hypothesizing that these exist in the common elements between rap and speech stimuli. Future research will explore diverse rap genres and incorporate EEG experiments to distinguish the roles of speech information and human voice elements. This approach will help clarify the components that induce lexical tone normalization and explore the mechanism from multiple perspectives. By employing advanced neuroimaging techniques, we can gain a deeper understanding of the neural correlates of this phenomenon.

However, one limitation of our study is the relatively small number of participants (24 native Mandarin listeners), which may impact the generalizability of our findings. While our results suggest that lexical tone normalization is not exclusive to speech, the limited sample size means that these findings should be interpreted with caution. The small participant pool may not fully capture the diversity of perceptual abilities and linguistic backgrounds present in the broader population. Consequently, this limitation prevents us from definitively challenging the speech-specific hypothesis of lexical tone normalization. Future studies with larger and more diverse participant groups are necessary to validate our

findings and provide a more comprehensive understanding of the mechanisms involved.

Furthermore, we plan to use professional rappers and recruit participants with varied linguistic and musical backgrounds. Previous studies indicate that musical ability affects tone normalization (Zhang et al., 2023). Including Cantonese speakers or Mandarin-Cantonese bilinguals may provide further insights into perceptual abilities and their influence on results. This diversity in participants will allow us to examine how different backgrounds impact the perception of pitch information and contribute to lexical tone normalization. By considering individual differences, we can better understand the variability in normalization effects across populations.

In conclusion, our study expands the understanding of lexical tone normalization, suggesting it may be influenced by factors beyond speech. By identifying the shared elements between rap and speech, we can better understand the underlying mechanisms. This research has significant implications for future studies, as it highlights the need to explore various sound contexts and their potential to induce lexical tone normalization. Through continued investigation, we aim to uncover the fundamental reasons behind this phenomenon and its broader applications. Ultimately, this work contributes to a more comprehensive understanding of how humans process complex auditory stimuli and adapt to diverse linguistic environments.

Building on these findings, we propose a talker-specific hypothesis. The study found that neither of the instrumental music contexts (cello and drum) significantly affected lexical tone normalization, whereas speech contexts did, supporting the speech-specific hypothesis. Interestingly, rap contexts produced effects similar to speech, suggesting that rap functions more like speech than instrumental music in lexical tone normalization. This finding challenges the speech-specific hypothesis by demonstrating that rap music can induce lexical tone normalization in listeners similarly to typical speech.

Therefore, we suggest that the critical factor may not be speech per se, but rather the presence of human-produced vocal sounds. This implies that different types of vocalizations, under certain conditions, can trigger lexical tone normalization. It may be necessary for listeners to subjectively recognize and interpret the sounds as human-produced. We aim to further investigate the mechanisms and conditions under which this occurs, proposing that the talker-specific hypothesis could provide a broader framework for understanding these effects. Future research will focus on exploring the underlying processes and constraints of this hypothesis, contributing to a deeper understanding of auditory processing and linguistic adaptation.

5 Conclusion

The study found that neither of the instrumental music contexts (cello and drum) significantly affected lexical tone normalization, whereas speech contexts did, supporting the speech-specific hypothesis.

Interestingly, rap contexts produced effects similar to speech, suggesting that rap functions more like speech than instrumental music in lexical tone normalization. This finding challenges the speech-specific hypothesis by demonstrating that rap music can induce lexical tone normalization in listeners similarly to typical speech.

The lack of significant effects from instrumental music, contrasted with the effects from contexts containing human voices, implies that lexical tone normalization may depend on the presence of human vocal elements, particularly pitch information. Additionally, the similar effects observed across different rhythm types suggest that tone normalization may not be sensitive to variations in rhythm.

Instrumental music contexts did not yield significant effects, whereas materials containing human voices did. This suggests that lexical tone normalization may rely on the presence of human voices, especially the pitch information within those voices.

A type of rap music context can induce lexical tone normalization in listeners similarly to typical speech. This finding may conflict with the speech-specific hypothesis.

Japanese *kana*-questions as non-intrusive questions

Hitomi Hirayama
Keio University / Kanagawa, Japan
hhirayam@keio.jp

Abstract

This study analyzes *kana*-questions in Japanese. Specifically, they are analyzed as non-intrusive questions (Farkas, 2022) observed in Romanian. However, *kana*-questions have unique features that allow interactions with the intonation contours. This study discusses how we can obtain a variety of interpretations of *kana*-questions using the table model of the discourse and the interaction of discourse effects. *Kana*-questions are also compared to *daroo*-questions in Japanese and *wohl*-questions in German. This paper reveals that *kana*-questions should be analyzed as non-intrusive rather than just entertaining modality or conjectural questions.

1 Introduction

In Japanese, it is possible to construct various types of interrogative sentences using sentence-final particles. Their use varies depending on the context, and some have been analyzed as biased questions in the literature (Ito and Oshima, 2014; Sudo, 2013). This paper explores a different type of question, which consists of a sentence radical plus a combination of particles *ka* and *na*, which I call *kana*-questions (henceforth *kana*-Qs) in this paper.[1]

Kana-Qs can appear in polar and constituent questions with rising and falling intonation,[2] as shown in (1-2).

(1) a. Taroo-wa kuru ka na ↓
Taro-TOP come Q na
'I wonder if Taro will come.'

b. Taroo-wa kuru ka na ↑
Taro-TOP come Q na
'Do you think Taro will come?'

(2) a. Dare-ga kuru ka na ↓
who-GA come Q na
'Who would come, I wonder.'

b. Dare-ga kuru ka na ↑
who-GA come Q na
'Who do you think would come?'

I argue that these *kana*-Qs are manifestations of non-canonical questions in Japanese. In particular, they are non-intrusive questions, such as *oare*-interrogatives in Romanian (Farkas, 2022): As a discourse effect marker, *kana* contributes to weakening the *Addressee compliance* assumption. This paper also aims to analyze the interaction between *kana* and other discourse effect markers.

The rest of the paper is structured as follows. Section 2 provides the background of this question type and the framework used in the analysis. Various interpretations of *kana*-Qs are also illustrated. Section 3 provides an analysis of *kana*-Qs, comparing them with Romanian non-intrusive questions. In particular, I argue that falling intonation modifies the anchor of discourse commitment. Section 4 discusses the derivations of the special interpretations of *kana*-Qs and compares them with similar questions in Japanese and German. Section 5 presents concluding remarks.

2 Background

This section provides a basic background on *kana*-Qs and the framework used in the analysis. The first section adds some more data points for the analysis. The second section introduces the discourse model of Farkas and Bruce (2010).

[1] Here *kana* is treated as a chunk of particles. Whether the effects could be reduced to the composition of each particle is a topic for future research.

[2] The rising intonation, shown by ↑ in the example, involves a falling intonation at the beginning of *na* and rising intonation (i.e., ↘↗). The falling intonation, shown by ↓ has the opposite pattern (i.e., ↗↘). Although this paper only discusses these two intonation contours, there can be other variations. I leave the exact characteristics of the intonation contours compatible with *kana*-Qs for a future research.

2.1 Properties of *kana*-Qs

In Japanese linguistics, *kana*-Qs are categorized as one of *questions with a doubt* (*utagai-no gimonbun* in Japanese) and are argued not to have the function of posing a question to an addressee (Nihongo Kizyutu Bunpo Kenkyukai, 2003). This unique characteristic is manifested in the fact that *kana*-Qs are often used as self-addressing questions. Furthermore, this type of *kana*-Q often accompanies a falling intonation. When such a *kana*-Q is uttered, there is no need for an addressee or an answer. With rising intonation, however, a *kana*-Q is degraded as a self-addressing question. This is reflected in the translation of (1) and (2). With falling intonations, it is more like an assertion with *I wonder*. In contrast, with rising intonations, it could be a bonafide question, and it is possible for the addressee to answer the question if they can.

In addition to the usage illustrated above, *kana*-Qs have a variety of interpretations, such as criticism (Nakanishi, 2015), as in (3). The cluster *kana* also interacts with other expressions, and with outer negation (Sudo, 2013; Ito and Oshima, 2014), *kana*-Qs can express the speaker's desire (Takanashi, 2022), as shown in (4). Different intonation contours give them different connotations or acceptability.

(3) Anata-ni sonna kenri-ga aru ka na ↓/↑
you-DAT such right-NOM exist Q na
'You have such a right? (I believe you don't.)'

(4) Ashita hare nai ka na ↓/$^{??}$ ↑
tomorrow sunny NEG Q na
'I hope it will be sunny tomorrow.'

For example, in (3), both rising and falling intonations can be used, and in either case, the question is understood as a rhetorical question and not an information-seeking one. The tone of criticism differs depending on the intonation. With a rising intonation, the criticism has an "inflaming" effect, which is not evident with a falling intonation.

Conversely, a rising intonation sounds infelicitous in (4). Note that as an expression of the speaker's desire, *nai* in (4) cannot be interpreted as real negation. This is not a self-addressed question, by which the speaker asks themselves a question. Rather, as the English translation indicates, with *nai kana*, the speaker expresses their desire that the weather will be nice the next day. With this interpretation, only the falling intonation is compatible. With rising intonation, the sentence could be felicitous as a question in which *nai* is interpreted as predicate negation. In other words, with rising intonation, (4) is interpreted as "Do you think it will not be sunny tomorrow?"

Even though some interpretations brought about by *kana* are not like questions but similar to assertions, semantically speaking, they are still questions. In Japanese, *sonnani* 'very' is a weak Negative Polarity Item (NPI) that can be licensed in an interrogative sentence (Matsui, 2011). Even with a falling intonation or an assertive interpretation, *kana*-Qs can accompany *sonnani*, as shown in (5).

(5) Sono eega, sonnani omosiori ka na ↑/↓
that movie very interesting Q na
'Do you think that movie is very interesting? / I wonder if that movie is very interesting.'

With a falling intonation, it is possible to interpret the sentence sarcastically, where the speaker does not believe that the movie is interesting. In other words, this can be interpreted as a rhetorical question. This shows that the falling intonation does not change the semantics of the sentence given by the question particle *ka*.

2.2 Discourse model

I use the table model of Farkas and Bruce (2010) to explain the discourse effects of *kana*-Qs. This section introduces their model using an unmarked polar question. For the sake of simplicity, let us assume that there are only two discourse participants, A and B, where A is the speaker (who utters questions) and B is the addressee. Table 1 shows the output discourse after A utters a polar question with a sentence radical, p. For example, when p is *Taro will come*, Table 1 shows the status of discourse after A says, "Will Taro come?"

A	**Table**	B
DC_A:	$\{\boldsymbol{p}, \neg p\}$	DC_B:
Common Ground: s_1	ps:{$\mathsf{DC}_B \cup \{p\}$, $\mathsf{DC}_B \cup \{\neg p\}$}	

Table 1: Context structure after a polar question is uttered by A

In Table 1, DC_X refers to the discourse commitment of a discourse participant, X. In this case, both discourse participants make no commitment, so both DC_A and DC_B are empty. Table in the middle of Table 1 is where a set of propositions

under discussion is placed. When a polar question is asked, what is under discussion is whether p or $\neg p$. Consequently, a set of the two propositions are placed there. Common ground is the knowledge shared by all the discourse participants. In this case, s_1 does not include whether p or $\neg p$. Projected Set (ps) shows the future discourse move, modeled as a list of the addressee's DC by default, following Meriçli (2016). In this case, we have $\{\mathsf{DC}_B \cup \{p\}, \mathsf{DC}_B \cup \{\neg p\}\}$: Since A asks B a polar question, *Will Taro come?* B is supposed to answer the question by adding p or $\neg p$ to their discourse commitment at that time.

3 Analysis

I analyze *kana*-Qs as non-intrusive questions following Farkas (2022). That is, the *kana* particle as a whole contributes to weakening one of the default assumptions about the question acts: *Addressee compliance*. In other words, *kana* signals that the speaker does not assume that the addressee will provide the information sought in the question. The difference between Japanese *kana*-Qs and *oare* questions lies in the use of intonation contours. In this section, I first introduce *oare* questions in Romanian and the analysis by Farkas (2022). Then, an analysis of Japanese *kana*-Qs is provided based on her analysis.

3.1 *Oare* questions in Romanian

Similarly to *kana*, the Romanian particle *oare* can occur optionally in both constituent and polar questions, as shown in (6) (Farkas, 2022, 295).[3]

(6) a. (Oare) ce a spus Amalia?
oare what has said Amalia
'What did Amalia say, I wonder.'

b. (Oare) e acasă Amalia?
oare is home Amalia
'Is Amalia home, (I wonder).'

The English translation by *I wonder* is approximate, as so are the English translations of *kana*-Qs. In (6), *oare* is optional; however, in some contexts, *oare* questions are infelicitous. Such cases are 'interrogation' contexts, where addressees must resolve the issue, as exemplified in (7).

(7) *Context: Policeman to drive he stopped*
Oare cu ce viteză ai mers?
oare with what speed have gone.2SG
'What was your speed, I wonder.'

The behavior of *oare* is explained by regarding it as a discourse effect modifier. Farkas (2022) argues that *oare* weakens the addressee's compliance, which is one of the default discourse effects that accompany question acts, as defined in (8).

(8) *Addressee's compliance*
The speaker assumes that the addressee will provide this information in the immediate future of the conversation as a result of the speaker's speech act.
[Farkas (2022, 297)]

In interrogation contexts, the addressee's compliance cannot be weakened because of the conflict between the assumption and context. Consequently, the infelicity of (7) with *oare* is explained.

In the table model, the discourse effect realized by *oare* is reflected in the projected set (ps), as shown in Table 2. The addition is s_1. This means that there is a possibility that the common ground will remain unchanged in future discourse.

A	**Table**	B
DC_A:	$\{\boldsymbol{p}, \neg p\}$	DC_B:
Common Ground: s_1	ps: $\{\mathsf{DC}_B \cup \{p\}, \mathsf{DC}_B \cup \{\neg p\}, s_1\}$	

Table 2: Context structure after an *oare*-question is uttered by A

In other words, this question act leaves the possibility that the addressee does not give an answer to the question. Note that it is also possible for the addressee to answer the question if they want, which is the case with Romanian. It is acceptable to use an *oare* interrogative with *What do you think*, which explicitly asks the addressee for a possible answer.

3.2 *Kana*-Qs in Japanese as a non-intrusive question

In this section, I analyze *kana*-Qs as a non-intrusive questions following Farkas (2022). First, I illustrate one crucial difference between *oare*-questions and *kana*-Qs that need to be captured in the analysis: the intonation contour. Then, I add the necessary components to the discourse table model to handle the difference.

[3] Unlike *kana*, which appears only in the sentence-final position, the syntactic position of *oare* has more freedom. I will not discuss these differences in this study in detail.

3.2.1 Intonation Contour

In the Introduction and in Section 2.1, I showed that *kana*-Qs are compatible with both falling and rising intonations. Differences in intonation can also lead to interpretable differences as well. However, in Romanian, *oare* is incompatible with falling intonation, as shown in (9), where a period is intended to indicate a falling intonation.

(9) * (Oare) e acasă Amalia.
oare is home Amalia
'Amalia is home, (I wonder).'

Intonation primarily distinguishes declaratives and polar interrogatives (Farkas, 2022, 299) in Romanian. Consequently, the example in (9) indicates that *oare* cannot be used in declaratives.

Intonation also functions to distinguish declaratives and interrogatives in Japanese. However, as shown in the example with *sonnani* (5), falling intonation does not necessarily indicate that the sentence is semantically declarative. As a result, it is necessary to understand the intonation's contribution to the question act and add it to our analysis.

3.2.2 *Kana*-Qs with rising intonation

I begin by laying out the analysis of *kana*-Qs with rising intonation. *Kana*-Qs with rising intonation can be analyzed in a similar way as *oare*-questions. In other words, their discourse effects are identical to those shown in Table 2. Remember that *oare*-questions can weaken the addressee's compliance, which question acts assume by default. As a result, in the interrogation context, it is infelicitous (7). The same effect can be obtained in *kana*-Qs with rising intonation.

(10) *Context: Policeman to driver he stopped*

Anata-wa nan-kiro dasiteta ka
you-TOP what-kilometer speed Q
na ↑
na

'(Intended:) How fast do you think you drove?'

In this context, the driver must provide a true answer to the police officer. Therefore, in a normal context, a police officer would not ask questions in this manner. However, it is not entirely impossible for a police officer to ask this question. If they believe that the driver will not give an answer and want to challenge them in a mean way, treating the driver like a child, a *kana*-Q with rising intonation sounds fine. In fact, it is easy to imagine a pediatrician asking a *kana*-Q with the rising intonation of a crying child, as shown in (11).

(11) Kyoo-wa doko-ga itai ka na ↑
today-TOP where-NOM hurt Q na
'Where do you feel the pain?'

Asking the same question this way of an adult patient is infelicitous. This effect is explained by the effect of weakening the addressee's compliance. When a patient is a young child, even if apparently a doctor is talking to them, it is often the case that they do not expect the child to give them a satisfactory answer. Instead, their parents are expected to answer the doctor's question. In a context where the discourse participant is expected to have the full capacity to answer, signaling that the speaker is weakening the addressee's compliance is unnecessary.

3.2.3 *Kana*-Qs with falling intonation

Now, let us turn to *kana*-Qs with falling intonations. As shown in the Introduction, with falling intonation, *kana*-Qs function as self-addressed questions. I propose that this effect can be captured by arguing that falling intonation's contribution is modifying the discourse commitment anchor in the projected set. Specifically, falling intonation changes the anchor from the addressee to the speaker, as shown in Table 3.

A	**Table**	B
DC_A:	$\{\boldsymbol{p}, \neg p\}$	DC_B:
Common Ground: s_1	ps: $\{\mathsf{DC}_A \cup \{p\}, \mathsf{DC}_A \cup \{\neg p\}, s_1\}$	

Table 3: Context structure after a *kana*-polar question is uttered by A with falling intonation

Other than the project set, the output table is identical to that shown in Table 2. This change amounts to mean that the next move is the speaker's answering p, $\neg p$, or doing nothing. With falling intonation, it is the speaker who is responsible for the next move, but because of the discourse effects of *kana*, they also have the freedom not to give an answer. In fact, the *kana*-Q with a falling intonation is compatible with any move in the projected set, as shown in (12a-c).

(12) Will Taro come + *kana* ↓ ...
a. Un, zettai kuru
yes, for sure will come

'Yes, he will come for sure.' $=p$

b. Iiya, zettai konai
no for sure come.NEG
'Nah, he won't come for sure.' $=\neg p$

c. Maa, doodemo ii ya
well whatever good
'Well, never mind.' $= s_1$

When the speaker provides an answer to a question, depending on the answer, the question as a whole can be interpreted as a rhetorical question. The speaker also has the option not to resolve the issue further, just ignoring what is put on the Table (12c).

Note that, even when *kana*-Qs accompany falling intonations, if there is a discourse participant around the speaker, they can also answer the question. This is not necessarily expected by the speaker and could be achieved by virtue of the cooperativeness of the addressee. When the speaker chooses not to resolve the issue, the addressee can interpret this as an invitation to participate in determining the answer.

4 Discussion

In this section, first, I first illustrate how the proposed analysis of *kana*-Qs leads to the interpretations shown in Section 2.1. Then, I compare *kana* with similar questions in Japanese and German.

4.1 Interpretation of *kana*-Qs

In Section 3, we discussed how *kana*-Qs are used as rhetorical questions or self-addressed questions, where the speaker knows the answer to the question, or there are no discourse participants other than the speaker. How is it possible to obtain an inflammatory effect or interpret a speaker's desires? I argue that the former can be derived from the discourse effects of this special question, and the latter from the interaction between *kana* and outer negation.

4.1.1 "Inflaming" effect

When *kana*-Qs accompany rising intonation, the question sometimes has an "inflaming" effect, as seen in (3). Another example is provided in (13).

(13) kore zenbu tabe-rareru ka na ↑
this all eat-able Q na
'Do you think you can eat this up all?'

If the intonation in (13) is a falling intonation, there is no inflaming effect. It is possible that the speaker is worried about whether they (the speaker and their peers) could eat up everything. However, rising intonation is more likely to have an inflaming effect, in which the speaker challenges the addressee.

I argue that the effect is the result of weakened addressee's compliance. Remember that with canonical question acts, we assume that the addressee will provide the true answer to the question. However, as non-canonical questions, namely non-intrusive ones, *kana*-Qs weaken the assumption and allow the addressee not to say anything. What motivates the speaker to weaken the assumption even though they perform questioning acts?

Answering questions amounts to making a commitment to some proposition. For example, taking up the example (13), if the addressee (=B) says *yes* B makes a commitment that B can finish the dishes. Saying *no* indicates commitment to the negation of the proposition. Assume a context in which if B cannot finish the dishes, they have to pay a fine for that, and the portion of the dishes is very large. In this context, B may not want to commit immediately. B might not have enough confidence, but simultaneously, might not want to acknowledge that the portion is too large for them to handle. If the speaker imagines that B would be in such a situation, they could use *kana*-Qs with rising intonation to indicate that B has the option of being silent. From the addressee's side, *kana*-Qs with a rising intonation sound like the speaker assumes that B cannot make an immediate commitment, which could be understood as B being challenged by the speaker. Consequently, B can become inflamed by the question.

4.1.2 *Nai ka na* as speaker's desire

Kana-Qs can be used to express desire as seen in (4), repeated here as (14). Two components require an explanation. The first is the interaction between *nai* and *kana*. The other is infelicity with the rising intonation.

(14) Ashita hare nai ka na ↓/$^{??}$ ↑
tomorrow sunny NEG Q na
'I hope it will be sunny tomorrow.'

As mentioned in Section 2.1, when the whole sentence is understood as a desire, *nai* is interpreted as an outer negation. With an inner negation or predicate negation interpretation, the entire question retains the question interpretation. If we add *zenzen* 'at all,' which needs to occur with a

negation, as shown in (15), it does not convey the speaker's desire.

(15) Ashita zenzen hare nai ka na ↓/↑
tomorrow at all sunny NEG Q na
'I wonder if it won't be sunny at all tomorrow./Do you think it won't be sunny at all tomorrow?'

It should be noted that the addressee has the option of answering (15) but not (14). (14) is similar to *daroo*-Qs discussed in Section 4.2.1, in that the addressee cannot react to the utterance by saying, *Why do you ask such a thing?* In other words, (14) cannot be a matrix question.

To understand the contribution of outer negation, let us review its functions. (16) summarizes the functions of outer negation in Japanese.

(16) a. It is located outside of the proposition (i.e., it cannot license an NPI)
b. It conveys that the speaker's positive private bias toward the prejacent (Sudo, 2013; Ito and Oshima, 2014; Hirayama, 2018)

Used with rising intonation, outer negation signals that the speaker has a private bias and the sentence radical is true. Here, private bias means that the bias is not available to other discourse participants. If we add this effect to our discourse table, we get Table 4.

A	**Table**	B
DC_A:	$\{\boldsymbol{p}, \neg p\}$	DC_B:
PB_A: p		PB_B
Common Ground: s_1	ps: $\{\mathsf{DC}_A \cup \{p\}, \mathsf{DC}_A \cup \{\neg p\}, s_1\}$	

Table 4: Context structure after A utters (14)

In the middle of the table, we have a new row that indicates the private bias of discourse participant (PB_X). The table indicates that the speaker A has a bias that p is true. Simultaneously, due to the contribution of *kana*, A also indicates that they have an option not to pursue the issue further. Combining this private bias and weakening compliance to answer the question, *nai kana* questions as a whole indicate that the speaker signals that they hope the sentence radical is true but leave the possibility that the issue is not settled in either way.

Let us now turn to the infelicity brought about by the combination of rising intonation and *nai kana*. As discussed in Section 3.2.2, with rising intonation as a default, the project set refers to the DC of the addressees (B). B can ignore the question because of *kana*. However, outer negation signals a speaker's private bias. Here, there is a conflict among intonation, the discourse effects of outer negation, and *kana*. The speaker wants to indicate their bias, but at the same time, they give the addressee freedom to ignore the issue. If the speaker wants to see whether B agrees that their private bias matches the truth in the world, they could have simply used outer negation questions without weakening the addressee's compliance. In summary, referring to the addressee's private bias and granting the freedom not to do anything while expressing the speaker's private bias creates a conflict between the discourse effects of outer negation and *kana*.

4.2 Comparison with similar questions

I analyzed *kana*-Qs as non-intrusive questions such as *oare*-questions. In this section, *kana*-Qs are compared with similar questions in Japanese and German to gain a deeper understanding of non-canonical questions.

4.2.1 *Daroo*-Qs

Daroo is a sentence-final auxiliary in Japanese. When used with the question marker *ka* and falling intonation, as shown in (17), the whole question could be understood as a self-addressed question (Hara, 2023) (henceforth *daroo*-Qs). *Daroo*-Qs can be either a polar or constituent question.

(17) a. Taroo-wa kuru daroo ka * ↑ / ↓
Taro-TOP come Q
'I wonder if Taro will come.'
b. Dare-ga kuru daroo ka * ↑ / ↓
who-NOM come Q
'I wonder who will come.'

Daroo-Qs are similar to *kana*-Qs in that they have self-addressed interpretations. In other words, unlike canonical questions, they do not seem to have an addressee's compliance assumption. In fact, *daroo*-Qs cannot be used in interrogation contexts like *kana*-Qs, as we observed in (7).

However, detailed comparison reveals that they are very different. The first crucial difference is that *daroo+ka* does not allow rising intonation at all. It renders ungrammaticality rather than infelicity.[4]

[4]Hara (2023) analyzes this infelicity comes from type-mismatch.

Another difference is that *daroo*-Qs are more speaker-oriented than *kana*-Qs are. Both *kana*-Qs and *daroo*-Qs have *I wonder* translation, but while *kana*-Qs can be matrix questions, *daroo*-Qs indicate that the speaker entertains multiple possibilities (Hara, 2023). As observed by Uegaki and Roelofsen (2018), *daroo*-Qs cannot be matrix questions. When a speaker utters (17), nobody can say anything like *Why do you ask me such a question?* By contrast, a discourse participant can challenge *kana*-Qs in an appropriate context. In summary, while *kana*-Qs weaken the addressee's compliance, *daroo*-Qs do not have such an assumption to begin with.

4.2.2 German *wohl*-Qs as a conjectural question

Farkas (2022) compares an *oare*-question with a *wohl*-question in German discussed in Eckardt (2020). In German, when a particle *wohl* is used and also the verb is placed in the sentence-final position, it is possible that the question does not request an answer from an addressee, unlike a canonical question.[5] As a result, the English translation of a *wohl*-question is similar to the *oare*-question in Romanian and has *I wonder*.

(18) Wo wohl der Shulüssel ist?
where wohl the key is
'Where might the key be, I wonder.'
[Eckardt (2020, 2)]

In Eckardt (2020), *wohl*-questions are analyzed as conjectural questions, which ask for answers entailed by the pooled knowledge of discourse participants. Farkas (2022) argues that conjectural questions are similar to non-intrusive ones but not identical. One striking difference is that conjectural questions weaken the addressees' competence assumptions rather than their compliance. *Wohl*-questions are infelicitous when the speaker believes that the addressee knows the answer to the question. For example, the question (18) is infelicitous when a child utters it to their mother, believing she would give an answer.

On the other hand, the *oare*-question can be felicitously used in a context where the speaker believes that the addressee knows the answer. The example (19) is a conversation on the phone, and the addressee is present in the context. Moreover, the addressee should know if they are still thinking of the speaker of (19), and the speaker believes so.

(19) Paul, oare te mai gânde sti la mine?
Paul, oare you still think.2 at me
'Paul, are you still thinking of me, I wonder.'
[Farkas (2022, 322)]

The Japanese *kana*-Q is acceptable in the same situation, as shown in (20).

(20) Taroo, anata-wa mada watashi-no koto
Taro you-TOP still me-GEN matter
kangaeteiru ka na ↓
thinking Q na
'Taro, are you still thinking of me, I wonder.'

Furthermore, when a question has an ironic connotation, the speaker often believes that the addressee knows the answer. For example, (3), repeated here as (21), can be used in a context in which the speaker believes that the addressee acknowledges that they do not have rights under discussion. This question could be followed by an utterance such as *'You know you don't, right?'*.

(21) Anata-ni sonna kenri-ga aru ka na ↓/↑
you-DAT such right-NOM exist Q na
'You have such a right? (I believe you don't.)'

Overall, analyzing *kana*-Qs as non-intrusive rather than as conjectural questions is more plausible. *Kana*-Qs do not assume the weakened addressees' competence unlike *wohl*-questions in German.

5 Concluding remarks

In this paper, I argue that *kana*-Qs are a kind of non-intrusive questions, which weaken addressees' compliance. One crucial difference between *kana*-Qs and Romanian *oare*-questions is that *kana*-Qs allow for an interaction between the discourse effects of this cluster and intonation. Another difference is that *kana*-Qs can interact with other discourse particles that comprise non-canonical questions and provide more sophisticated effects for the discourse.

One immediate limit of this study is that *kana* is analyzed as a cluster rather than as a form of the combination of *ka* and *na*. *Na* itself can appear

[5] *Wohl* can appear in a question with normal word order (a verb comes in the second position), but such an interrogative sentence is different from what can be classified as a conjectural question discussed here. In this paper *wohl*-questions refer only to interrogatives with sentence-final verbs.

without *ka* in a declarative. Future research should pursue the possibility of analyzing discourse effects of *kana*-Qs by combining the effect of the question particle *ka* and the sentence-final *na*. In order to do so, it would be necessary to analyze *na* in declaratives or other sentence types.

Another next step is to conduct deeper cross-linguistic research on this topic. As shown in Section 4.2, not only does Japanese have similar but also different non-canonical questions, but other languages, such as German, have a rich inventory of non-canonical questions. What default assumptions in questioning acts can be weakened using tools such as discourse particles in natural languages? Are there other methods to achieve the same goals in the absence of such tools? For what purpose do we weaken or waive the default assumptions when performing speech acts? More extensive cross-linguistics comparisons are required to answer these questions.

Mental Representation of Mandarin Tone 3: an Integrated Phonetic and Phonological Reflection

Ye Yanyuan, Peng Gang
The Hong Kong Polytechnic University

Abstract

The phonetic description and phonological analysis of Mandarin Tone 3 has been a complex issue that attracted divergent views. To better understand this tone, the current study has computed the mental representation of Tone 3 by adopting the reverse-correlation paradigm. Thirty participants (15 males, mean age = 21.94 ± 2.4 years) were recruited to compare and judge which of the two randomly generated stimuli sounded more like Tone 3. Analyses on the interaction between participants' response and the manipulated random contour in perception of this tone has indicated that mental representation of Mandarin Tone 3 reflected some of the phonological representations (i.e., the [+low] feature) as well as preserving the phonetic characteristics (i.e., contourisity, dynamic and static portions, and duration-dependency). This method has offered possibilities to better understand the nature of linguistic elements in an integrated way.

1 Introduction

For citation forms in the Mandarin tonal system, Tone 3 is uniquely characterized as the only concave tone. Traditionally, it has been described as having a low-falling pitch at the beginning, followed by a rising pitch towards the end of the contour, and is thus analyzed as 214 on a five-scale system where numerical sequences represent pitch values, as proposed by Chao (1965, 2013).

However, Tone 3 exhibits significant variance in its phonetic realization, especially in continuous speech, where the final rising portion may be omitted, resulting in a low-falling tone (Ho, 1976; Howie, 1974; Zhu, 2012). Additionally, the pitch contour of Tone 3 varies with different syllable durations. The concave contour is predominantly observed in longer syllables, while shorter syllables tend to exhibit low-falling variants (Howie, 1974; Nordenhake & Svantesson, 1983; Yang et al., 2017).

In the auditory domain, perceptual tasks on lexical tones have shown that Tone 3 exhibits considerable within-category variation compared to the other three tones. Despite occupying a relatively large perceptual space, the highest identification rate for Tone 3 is reported for the low-falling contour, even when stimuli are presented in isolation, as shown in Figure 1 (Peng et al., 2012). Additionally, low-level tones, although less frequently observed in production, could also be perceived as Tone 3 (Whalen & Xu, 2009). The effect of syllable duration on tone identification has also been observed, with longer durations eliciting more Tone 3 responses rather than Tone 2 (Blicher et al., 1990).

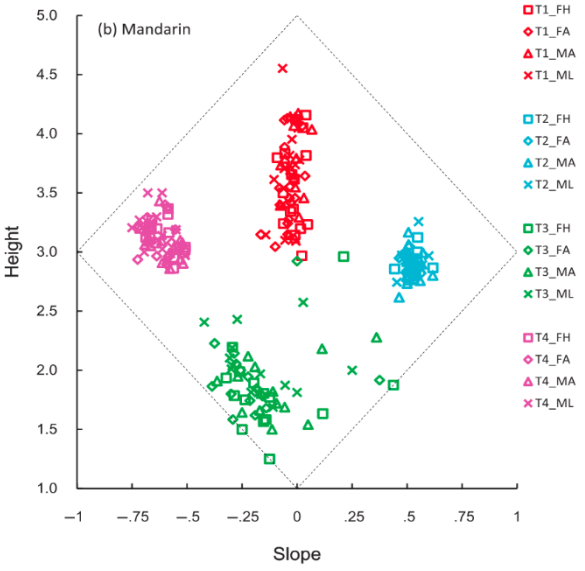

Figure 1 Two-dimensional plot (height and slope) of perceptual center of gravity for the Mandarin tone system, sourced from Peng, et al. (2012).

Phonologically, Tone 3 is generally described as having a [+low] feature, starting from early generative phonology using single-tier analysis. Milliken (1989, as cited in Duanmu, 2007) argued that the L/Low feature is crucial for Tone 3, with the final rising (H/High) being a floating feature. Duanmu, (2007) suggested that only the L feature should be considered, with the rising portion being a product of the disyllabic foot, which should be excluded. Despite their differences, both analyses emphasized the significance of the [+Low] feature and avoided focusing on the pitch shape. In multi-tiered representations, Yip (1980) proposed that the phonological representation of Tone 3 should not only focus on the [-upper] register, which she agreed is the most important aspect, but also include the contour feature, represented as LL, indicating a level and unchanging pitch direction (Bao, 1999). The view that Mandarin Tone 3 is a low-level tone was also supported by Shi & Ran (2011). These studies emphasized the dominance of the register in analyzing Tone 3, but also acknowledged the importance of the contour or pitch direction, although their views on the pitch shape varied.

The discrepancies between phonetic and phonological analyses, as well as within each domain, have reflected different understandings of Tone 3, leading to difficulties in experimental design. Based on their divergent understandings, even experiments addressing the same issue of Tone 3 have used different stimuli. For example, studies considering Tone 3 as a concave tone tended to manipulate the turning point of the pitch contour (Liu, 2004), those viewing it as low-falling focused on the pitch slope, and those treating Tone 3 as a low-level tone examined the effect of the register (Chen et al., 2010; Wang et al., 2014). These differing criteria for stimulus selection have resulted in varied outcomes, which in turn hindered the better understanding of Tone 3.

To better describe, analyze, and understand Tone 3 (as well as other tones), the reverse-correlation paradigm, a new data-driven method, was adopted in the current study. This paradigm focuses on how top-down representations are used to process incoming stimuli and can estimate the mental representations of categories based on participants' response patterns to randomly varying information (Brinkman et al., 2019). Initially applied in the visual domain, this paradigm has been adapted to auditory research with the development of the CLEESE toolbox (Burred et al., 2019). CLEESE is a Python-based toolbox that enables random and numerous manipulations of pitch on the same base audio. Several studies have begun using this novel method in auditory perception. Wang et al. (2022) found that the mental representation of typically developing children is similar but less variable than that of children with autism spectrum disorder by generating speech, complex tone, and song stimuli with randomly manipulated pitch contours.

The current study explores the mental representation of Mandarin tones through this novel paradigm, examining the relationship between phonetic realizations, phonological analyses, and mental representations under the case of Tone 3 description. The reverse-correlation paradigm will be applied to compute the mental representations. The study also seeks to examine the effect of duration on the mental representation of the tone. Thus, long and short stimuli will be generated, and their induced patterns will be compared. As the primary cue of lexical tones is fundamental frequency (f0), which becomes the main parameter used to manipulate tone variation, we also aim to determine whether listeners' pitch sensitivity affects the mental representation of the tone. Therefore, a pitch-judgment task will be conducted to examine the ability to discriminate pitch height, and the correlation between pitch sensitivity and mental representation will be analyzed. These efforts aim to better describe and understand Mandarin Tone 3, thereby investigating the nature of speech.

2 Methods

2.1 Participants

Thirty native Mandarin speakers (15 males, mean age = 21.94 ± 2.4 years) were recruited for this study. All participants were right-handed and had no background in music, linguistics, or psychology. None reported any hearing or mental health issues.

2.2 Stimuli

The Mandarin monosyllable *yi* /i/ with Tone 3 was produced by a female native Mandarin speaker who was born and grew in Beijing. A recording sample without creaky voice was selected, as this phonation type, although common observed in Tone 3 production, can disrupt the continuity of the extracted f0 contour. The pitch contour of the chosen sample was flattened to 188 Hz and

normalized to 80 dB. To investigate the effect of the duration of syllable, the sample was adjusted to 250 ms for the short condition and 450 ms for the long condition, creating the base stimuli. Then, pitch-shifting manipulation using Gaussian pitch noise was applied to these stimuli by sampling pitch values at 7 equal and successive time points, using a normal distribution (SD = 180 cents) in the CLEESE toolbox, following Burred et al. (2019). CLEESE is a Python-based toolbox used to generate variations of sound with randomly manipulated pitch contours while maintaining constant amplitude and duration, as shown in Figure 2.

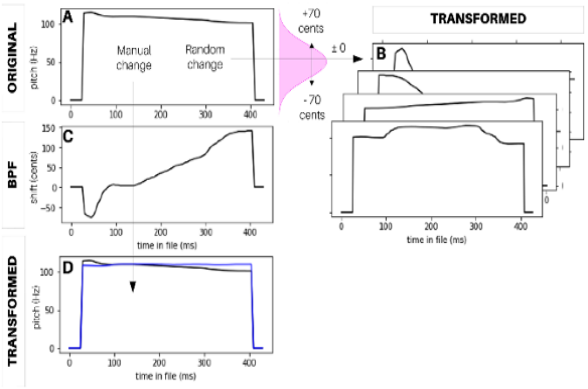

Figure 2 Examples of pitch manipulations created with CLEESE, sourced from Burred et al. (2019).

We optimized the algorithm by adding a condition that the manipulated pitch contour must change gradually, rather than abruptly or with large fluctuations, as restricted by human vocalization. After piloting the quality and naturalness of the generated syllables and the duration of the task, 200 pairs for the long condition and 200 pairs for the short condition were generated, resulting in 800 pitch variations in total.

The stimuli for the pitch-judgment task were generated as pure tones in Praat (Boersma & Weenink, 2009) with f0 set to be level and ranging from 440 to 452 Hz, resulting in 12 stimuli in total. The duration was set to 1 second and the intensity to 80 dB.

2.3 Procedure

The experiment was conducted via Gorilla, an online platform validated for effective remote experimentation (Anwyl-Irvine et al., 2020). Participants were instructed to complete two tasks: the word-comparison task and the pitch-judgment task. For the first task, aimed at computing the mental representation of Tone 3, participants were asked to choose which syllable sounded more like the word *yi3* ("以") from two stimuli randomly generated by CLEESE. There were two separate blocks for long and short durations, with the order of these blocks counterbalanced across participants.

For the pitch-judgment task, participants listened to two pure tones with pitch differences ranging from 1 Hz to 12 Hz and judged whether the second stimulus sounded higher, lower, or the same in pitch compared to the first one.

2.4 Analysis

The auditory classification image for each participant was generated using the CLEESE toolbox by averaging the differences reflected in each choice made by the participants, as described in Burred et al. (2019). To analyze the overall contouring pattern, a one-way ANOVA was conducted to compare the normalized pitch in Tone 3's mental representation at each timepoint of the pitch contour, determining whether the mental representation of Tone 3 is a level tone. Subsequently, a linear mixed-effects model was constructed to examine the effects of duration of the syllable (long vs. short) and listeners' pitch sensitivity on the normalized pitch at each timepoint using the *lme4* package in R (Bates et al., 2015).

3 Results

For the overall contour of normalized pitch in the mental representation of Tone 3, the one-way ANOVA revealed a significant main effect of Timepoint ($F(2.001) = 67.16$, $p < 0.001$). Post-hoc analysis indicated that the normalized pitch of all adjacent timepoints (i.e., Timepoint 1 vs. 2; 2 vs. 3; …; 6 vs. 7) were significantly different, as shown in Figure 3. However, no significant differences

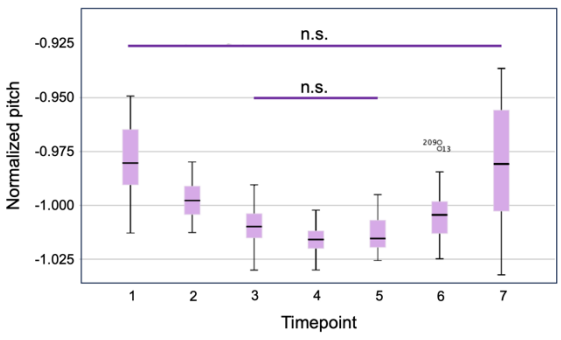

Figure 3 Normalized pitch of mental representation of Tone 3 in each timepoint

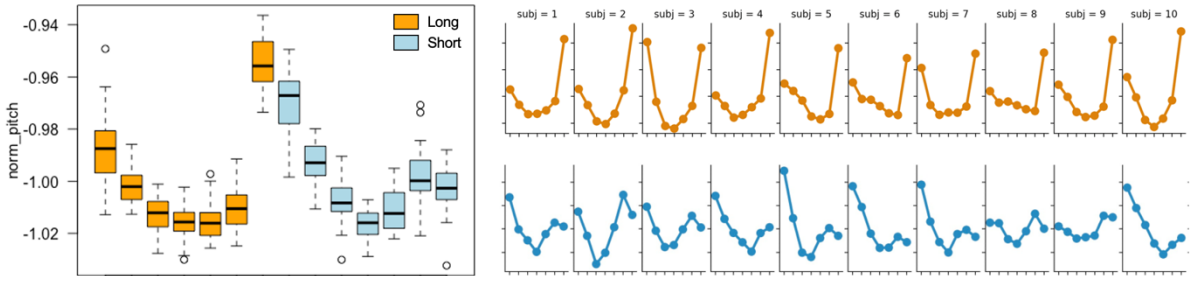

Figure 4 Mental representation of Tone 3 in long and short duration in the group (left panel) and individual level (right panel). The upper right panel (orange) shows the mental representation of long syllable from subject 1-10, the bottom right panel (blue) shows the representation of short syllable from the same subjects.

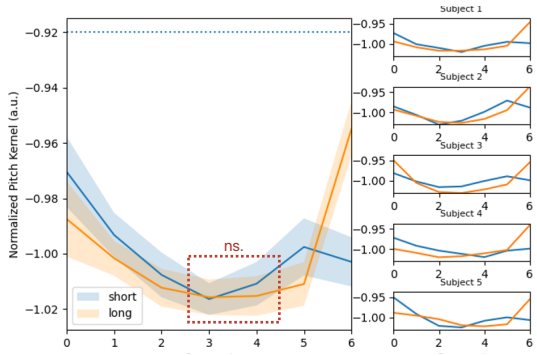

Figure 5 Classification image of Tone 3 generated by CLEESE

Time	estimate	df	*t* ratio	*p* value
T1	0.017	364	7.343	<.0001
T2	0.008	364	3.626	0.0003
T3	0.005	364	1.998	0.0465
T6	0.013	364	5.759	<.0001
T7	-0.048	364	-20.672	<.0001

Table 1 Pairwise comparison of long and short duration in each timepoint

were found between Timepoint 1 vs. 7 and Timepoint 3 vs. 5 (*p*s > 0.05).

Regarding the effects of syllable duration and listeners' pitch sensitivity, the linear mixed-effects model on the normalized pitch at each timepoint, with Duration (long vs. short) and Pitch sensitivity of listeners as fixed effects, revealed no significant fixed effect of pitch sensitivity, nor any relevant interaction effects (all *p*s > 0.05). Consequently, pitch sensitivity was removed from the model and excluded from further analysis.

A two-way repeated measures ANOVA with Duration (long vs. short) and Timepoint (1, 2, …, 7) revealed significant main effects of Duration ($F(1,29) = 30.42$, $p < 0.001$), Timepoint ($F(2.10, 60.83) = 113.90$, $p < 0.001$), and their interaction ($F(2.48, 71.86) = 117.88$, $p < 0.001$). Post-hoc analysis showed that at Timepoint 1, 2, 3, and 6, the normalized pitch of the short syllables was higher than that of the long syllables. Conversely, at Timepoint 7, the normalized pitch of the short syllable was lower than that of the long syllable (see Table 1). At Timepoints 4 and 5, the differences in normalized pitch between long and short syllables did not reach a significant level (*p*s > 0.05). The generated classification image of Tone 3 was shown in Figure 5.

4 Discussions

This study seeks to better describe and analyze Mandarin Tone 3 by adopting the reverse-correlation paradigm using CLEESE toolbox. The comparison between the computed mental representation and the phonetic descriptions and phonological analyses are conducted based on the observation of their overall shape of pitch contour and the effects elicited by duration. The [+low] pitch is the most crucial feature in the mental representation of Mandarin Tone 3, as supported by the results of both analyses. In the overall pitch contour, Timepoint 4 exhibited the lowest pitch height with the smallest variance compared to the other six timepoints. Additionally, there is a consistently low portion in the middle part of the pitch contour, regardless of the duration of syllables. Specifically, when the duration is longer, the onset of the syllable becomes lower, and the offset becomes higher than that of the shorter syllable. Notably, both long and short syllables have shared a portion that represents the lowest part of the contour.

The significance of low pitch in Tone 3's mental contour reflects its phonetic descriptions. Although there are differing views on the shape of its pitch — whether low-falling or concave — they all indicate that it should be low at one portion (Zhu et al., 2012). The crucial role of the [+low] feature also aligns with the phonological analysis of Tone

3, which emphasizes its [low] or [-upper] feature (Duanmu, 2007; Yip, 1980). Notably, the phonological view mainly emphasizes that [+low] is the most important feature, denying the role of contour in the analysis of Tone 3, which has also been addressed in the analysis of mental representation.

For the overall contour, as indicated by the result that the normalized pitch of all adjacent timepoints were significantly different, the mental representation of Mandarin Tone 3 is concave rather than level. Specifically, the normalized pitch at the first and last timepoints of the contour are the highest, while the middle part (i.e., Timepoint 4) has the lowest pitch height. Although this shape of the contour would be altered by duration, that longer syllables have a relatively lower onset and higher offset, it remains concave in both long and short syllables.

This finding contrasts with the idea that the phonological representation of Tone 3 is low-level (Yip, 1980; Shi & Ran, 2011) and shows consistency with the phonetic description. The reason that Tone 3 is phonologically analyzed as a level tone is mainly rooted in systematic rules and abstraction rather than merely focusing on the acoustic aspect. For instance, the view that Tone 3 should be considered as a level tone is based on the perspective that when level pitch is acceptable to be a phonetic variant, it could be considered the underlying form (Maddieson, 1977). The inconsistency between the mental and phonological representation may reflect the distinction of focus, such that the mental representation might be influenced and thus focuses more on the acoustic characteristics.

As indicated by the results of the current study, to figure out the characteristics of Mandarin Tone 3, [+low] is indeed crucial. But contour is inevitable in the description as well. It might not matter about the exact shape of the concave, but [+contourisity] is significant (proposed by Zhu 2012). In phonetic realization, the shape of the concave might be a result of the adjustment of gestures approaching to the [+low] target and thus would be affected by the duration of the syllable to be produced. This "Durational effect" has also been observed in the perceptual task, indicating a possible effect elicited by production (Blicher et al., 1990). In the mental representation of Tone 3, we have also observed the concave pitch in both long and short tones, meaning that the seemly irrelevant adjustment of vocalization does contribute to how we define and recognize a tone.

The larger pitch variance at the onset and offset, particularly at Timepoints 1 and 7, suggests the presence of two dynamic portions at the beginning and ending of the contour in Tone 3. Conversely, a static portion in the middle, as indicated by Timepoint 4 where pitch variance is relatively low, reflects the consistent occurrence of the low pitch in the contour.

This perspective that Tone 3 may encompass both dynamic and static portions is further supported by the involvement of varying syllable durations. Our findings indicate that longer syllables exhibit a lower onset and higher offset, whereas shorter syllables display the opposite pattern. However, there was no significant difference between long and short syllables in the middle portion of the contour. This has suggested that the change in duration does not affect the pitch in this middle portion, which remains static and is resistant to be changed. This finding is in line with Zhang & Shi (2016), who have described that there are dynamic and static portions in the pitch contour of Mandarin Tone 3 based on the large sample size of Beijing Mandarin vocalizations. The dynamic and static characteristics observed in both phonetic and mental representation of Tone 3 have reflected a correspondence between acoustic and cognitive domains.

In the mixed-effects model, we failed to observe the fixed effect of participants' pitch sensitivity or the interaction effects with other factors on their mental representation of Tone 3, suggesting that auditory sensitivity might not contribute to the pattern of the mental representation of lexical tones focusing on the same acoustic parameters.

5 Conclusions

Based on the computation and observation upon listeners response pattern to the random manipulated f0 contours in the reverse-correlation paradigm, mental representation of Mandarin Tone 3 is found to have reflected some of the phonological representations (i.e., [+low]) as well as preserving the phonetic characteristics (i.e., contourisity, dynamic and static portions, and duration-dependency). By reflecting a combination of phonetic and phonological characteristics, this method has offered possibilities to better understand the nature of linguistic elements in an integrated way.

Frequency and Congruency: A New Perspective on Motion Verb and Path Expression Co-occurrence

Yuzo Morishita
Momoyama Gakuin University
ymorishi@andrew.ac.jp

Abstract

This study re-examines the co-occurrence patterns of motion verbs and path expressions from a frequency-based perspective, complementing existing semantic-based approaches. By linking the properties of frequent verbs and GOAL, one of the notions of PATH, with the concepts of congruency and redundancy commonly found in language, I propose a new framework for explaining verb co-occurrence relations. The findings suggest a strong correlation between the individual characteristics of motion verbs and general tendencies.

1 Introduction

The notion of PATH is one of the most essential components in describing motion events. Talmy's (1985, 2000) theory of motion events classifies languages into satellite-framed and verb-framed languages based on which the elements in a clause lexicalize the notion of PATH (Talmy 1985, 2000). Satellite-framed languages include English, Estonian, and German. In these languages, as shown in the following examples, the notion of PATH is often lexicalized by elements such as prepositions, particles, or adverbs.

(1) a. Finally, he scowled and strode toward the scooter. (COCA 2005, FIC)
b. The dog trotted over and looked at us with smiling eyes. (COCA 2015, FIC)
c. I went to Istanbul in good faith. (COCA 2018, TV)
d. I'm glad we came here. (COCA 2003, NEWS)

There are some differences between researchers in the study of motion expressions. However, the notion of PATH can be divided into the following categories: SOURCE, TRAJECTORY, GOAL, DIRECTION, and DEIXIS (e.g., Talmy 2000). Regarding satellite-framed languages, a vast amount of research focuses on the relationship between these elements, which have been lexicalized as PATH, and verbs, in other words, what types of notions of PATH tend to co-occur with which verbs (e.g., Stefanowitsch and Rohde 2004, Papafragou 2010, Kopecka 2010, Guse 2022).

Furthermore, although this is not limited to motion expressions, there is an argument that languages exhibit a wide range of congruency and redundancy. It has been confirmed that there is congruency and redundancy in various areas. (Dahl 2004, Langacker 2008, Janda and Reynolds 2019). In addition, congruency and redundancy have been confirmed in various linguistic phenomena and studies have shown similar properties in motion expressions (Taremaa and Kopecka 2023). In this study, I discuss how this congruency and redundancy can also be seen in English motion expressions by exploring the relationship between verbs and satellites such as prepositions (e.g., *toward*), particles (e.g., *out*), and adverbs (e.g., *here*), that lexicalized the notion of PATH in English.

Unlike previous studies, this study includes *come* and *go*, which are unusual in English in that they do not lexicalize the manner of motion but DEIXIS. These two deictic verbs and 14 types of motion verbs are randomly selected from the Corpus of Contemporary American English (COCA). I also discuss the congruency of the meanings of these two different types of motion verbs and path expressions.

The remainder of this paper is organized as follows. Section 2 introduces previous research on the speed and granularity of the meanings of motion verbs and studies on the properties of DEIXIS in motion event descriptions. Section 3 describes the empirical method used in this study, and Section 4 presents the results. Section 5 discusses the properties seen between verbs and path expressions in motion expressions based on the results obtained

in Section 4. Section 6 summarizes this study.

2 Previous Studies

Research on motion expressions is ongoing in various languages. As mentioned above, most extant studies have focused on the relationship between motion verbs and path expressions, which has been verified using corpora and experimental methods. It has long been argued that, in motion events, humans tend to focus more on the endpoint than on the starting point when considering the notion of PATH (e.g., Ikegami 1987, Dirven and Verspoor 1998).

In the case of Estonian, a satellite-framed language, Taremma and Kopecka (2023) argued that speed of motion is essential if motion verbs are likely to co-occur with path expressions associated with GOAL. Incidentally, this is not the first study to focus on speed when studying motion expressions. Taremma and Kopeka (2022) demonstrated that verbs expressing fast movement occur more frequently than those expressing slow movements. In an Estonian corpus study, Taremma and Kopeka (2023) found that verbs expressing fast movement are more likely to co-occur with elements that lexicalize the notion of GOAL than verbs expressing slow movement. This study examines whether similar trends could be observed in other languages, that is, whether fast-moving verbs are likely to co-occur with path expressions, lexicalizing the notion of GOAL in English as it does in Estonian.

However, in English, not all motion verbs that co-occur with prepositions or particles that lexicalize the notion of PATH are manner of motion verbs. The verbs *come* and *go*, which are deictic motion verbs, are unusual because they do not lexicalize the manner of motion. However, the fact that they do not lexicalize the manner of motion implies that these verbs are neutral regarding speed.

What types of path expressions do deictic motion verbs co-occur with? At this point, congruency and redundancy emerge. By including *come* and *go* as the objects of this research, other assertions made in other studies on the relationship between motion verbs and path expressions are plausible. This study also examines the granularity of verb meanings. One study that focuses on the granularity of the meanings expressed by motion verbs is Guse's (2022) study on German. Inspired by Tutton (2013), she demonstrates that, in German, if the granularity of the meanings expressed by motion verbs is low, such verbs tend to co-occur more with path expressions, lexicalizing the notion of GOAL. Let us now consider the case of English motion verbs. The meanings expressed by *come* and *go* are very low in granularity, whereas verbs such as *swagger* express meanings of very high granularity. Therefore, it can be predicted that *come* and *go* are more likely to co-occur with elements expressing the notion of GOAL than with other verbs, and verbs such as *swagger* are less likely to co-occur with elements expressing the notion of GOAL.

3 Methods

To confirm whether the congruency and redundancy mentioned above can also be seen in the motion verbs and various path expressions in English, this study compares the following five types of manners of motion verbs listed in (2a–2e). These are in Slobin et al.'s (2014: 717) list. The two deictic motion verbs are in (2f).

(2)
a. *walk*, *run* (basic level)
b. *amble*, *stroll*, *saunter* (variety of walking - relaxed)
c. *stride*, *sashay*, *swagger* (variety of walking - normal pace)
d. *scamper*, *scurry*, *scuttle* (rapid movement)
e. *jog*, *trot*, *sprint* (variety of running)
f. *come*, *go* (deictic motion)

Some of these verbs, such as *walk* and *run*, have a low granularity of meaning, whereas others, such as *amble*, *stroll*, and *saunter*, have a high granularity of meaning. Some verbs indicate different movement speeds, such as *stride*, *sashay*, and *swagger*, which are slower, and *jog*, *trot*, and *sprint*, which are faster. Therefore, I can ascertain whether congruency and redundancy in English movement expressions can be observed by investigating which of the 14 movement verb types tend to co-occur with which path expressions. As mentioned above, I also include *come* and *go*, which lexicalize the notion of DEIXIS. I extracted 100 examples of each verb from COCA that express physical movement. From these 1,600 examples, I examine the relationship between verbs and path expressions in English.

Python was used to search for the verbs mentioned above in the text versions of the COCA files to extract examples from the corpus. For instance, in the case of *swagger*, i) I searched for all oc-

currences of *swagger*, *swaggers*, *swaggering*, and *swaggered* in the corpus, and then, ii) after randomly reordering them, iii) extracted only those examples that included a verb that expressed physical movement. Therefore, all usages that did not express physical movement were manually excluded from this study.

In addition, to avoid factors such as mood and specific constructional characteristics as much as possible, only finite-form verbs were analyzed. Therefore, the following examples were excluded from the analysis.

(3) a. **Walk** up and down the beach looking for sea life, such as snails, crabs, and starfish. (COCA 2012, WEB)
b. (...) he **would have come** back if I had a biscuit. (COCA 2013, TV)
c. In a few seconds, Paul Mahon **came striding** toward the camp. (COCA 2007, FIC)
d. A line of altar boys entered from the sacristy in the rear, **ambling** into the center aisle (...) (COCA 1996, MAG)

In this study, I collected examples until reached 100 examples of path expressions, as I was focusing on path expressions in this study. In some cases, as in the following example, multiple path expressions may appear in a single clause.

(4) a. Correctional officers sprinted out across the turf toward two men attacking a third. (COCA 2014, FIC)
b. The thought was calm, but she shuddered as the beast scampered away through the rocks. (COCA 1992, FIC)

4 Results

Using the method described in Section 3, I collected the following data. First, let me examine how often each verb occurs with each type of path expression, as shown in Table 1. Second, I checked how often each verb co-occurred with each type of notion of PATH, as shown in Table 2.

As shown in Table 2, the English data obtained for this study also show a clear co-occurrence with the notion of GOAL (e.g., Ikegami 1987, Dirven and Verspoor 1998). When the rate of co-occurrence with the path expression lexicalizing the notion of GOAL was compared with the rate of co-occurrence with the path expression lexicalizing the notion of SOURCE, a statistically significant difference was confirmed (χ^2 =91.351, df=1, p <.001). Therefore, goal bias in physical movement expressions in English was also demonstrated.

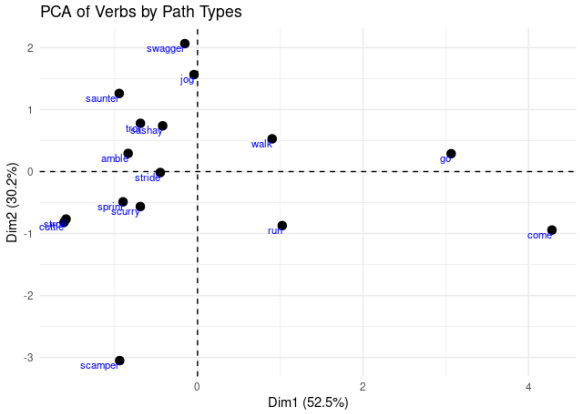

Figure 1: Results of the analysis of motion verbs using PCA

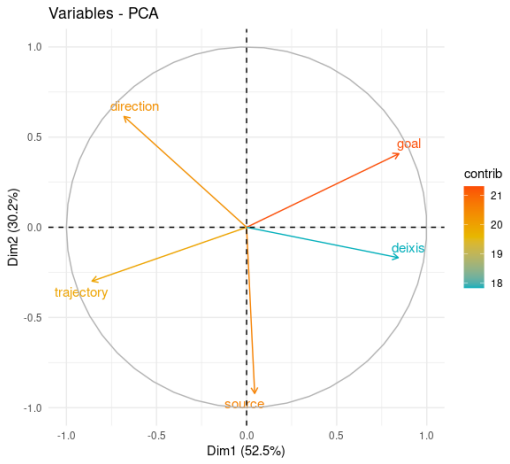

Figure 2: Contribution of each notion of PATH

Next, I examine the relationship between GOAL and SOURCE, as well as the relationship between other notions of PATH and verbs. Principal component analysis (PCA) was performed on the obtained data. The results are shown in Figures 1 and 2.

The results of this analysis grouped verbs such as *walk*, *run*, *come*, and *go*, which have high co-occurrence rates with GOAL (e.g., *into* and *to*) and directional expressions (e.g., *down* and *toward*). I notice that *run*, which expresses fast movement, is in the same group as *walk*, which expresses slow movement, as well as *come* and *go*, which are deictic motion verbs with no specification of speed. In other words, the results of this study show that the claim that verbs lexicalizing fast movements tend to co-occur with path expressions associated with

Verbs	Examples	Path expressions	The notion of PATH
walk	Ralph walked forward a couple of steps.	*forwards*	DIRECTION
...	...	...	...
sashay	Sarah sashayed to the mirror.	*to*	GOAL
sashay	(...) I sashayed through the doors into the lobby.	*through*, *into*	TRAJECTORY, GOAL
...	...	...	...
come	I come from Europe.	*from*	SOURCE
...	...	...	...
go	And he went there and (...) lost his life.	*there*	DEIXIS
...	...	...	...

Table 1: Sentences extracted from COCA that indicate physical movement

Verbs	SOURCE	TRAJECTORY	GOAL	DIRECTION	DEIXIS	$\sum$
walk	13	13	42	32	0	100
run	21	10	37	31	1	100
amble	13	20	28	39	0	100
stroll	12	34	23	31	0	100
saunter	11	15	28	46	0	100
stride	15	18	30	37	0	100
sashay	11	18	31	39	1	100
swagger	8	11	36	45	0	100
scamper	28	23	19	30	0	100
scurry	17	20	27	36	0	100
scuttle	18	23	19	40	0	100
jog	9	13	35	42	1	100
trot	13	15	29	43	0	100
sprint	19	16	24	41	0	100
come	17	1	41	23	18	100
go	15	3	51	26	5	100

Table 2: 16 motion verbs and co-occurrence path expressions

the notion of GOAL cannot be confirmed, at least for English.

However, the results support the claim made by Guse (2022) that verbs with low semantic granularity tend to co-occur with path expressions lexicalizing GOAL. From Table 2 and Figure 1, verbs with a high degree of granularity of meaning (e.g., *saunter*, *stroll*, *sashay*) tend to co-occur with path expressions associated with TRAJECTORY.

In addition, the results of this study show whether congruency or redundancy exists in motion expressions. Deictic motion verbs are more likely to co-occur with the *here* and *there* than other motion verbs. It can be seen that verbs describing the manner of movement seldom co-occur with *here* or *there*. Still, deictic motion verbs, particularly *come*, co-occur overwhelmingly with deictic path expressions.

5 General Discussion

Based on the results in the previous section, I discuss here the relationship between verb meanings and path expressions in English motion expressions, particularly the relationship between the granularity of verb meanings and path expressions and the properties of congruency and redundancy in the language.

However, before proceeding, I would like to introduce a new concept: the Weber–Fechner law. This law is not limited to language but describes a widespread property of the relationship between stimulus intensity and recognition: the perception of new stimulus changes based on the intensity of the original stimulus. Therefore, the Weber–Fechner law can also be applied to language. According to this law, a strong stimulus indicates a high frequency. In other words, if a word or expression is common and is seen or heard frequently, it will be a weak stimulus for many people, and they will hardly pay attention to it when they come into contact with it. For example, the expression *Good morning!* is an expression that few people pay attention to when they hear it. However, the *Top of the morning to you!* is an expression that most people pay attention to.

According to the Weber–Fechner law, the relationship between stimuli and recognition is expressed by the following equation:

$$\frac{\Delta f}{f} = constant \qquad (1)$$

Verbs	Frequency	Logarithm
go	3,546,732	6.55
come	1,802,158	6.26
run	465,066	5.67
walk	253,671	5.40
stroll	6,473	3.81
stride	5,493	3.74
sprint	4,170	3.62
jog	4,090	3.61
trot	4,042	3.61
scurry	2,872	3.46
scuttle	1,690	3.23
amble	1,313	3.12
saunter	1,208	3.08
scamper	1,194	3.08
sashay	317	2.50
swagger	278	2.44

Table 3: Frequency and logarithm of each motion verb in COCA

For example, this means that the intensity of a stimulus for an expression that has been heard 100 times before is the same as that of a stimulus for an expression that has been heard 1,000 and is heard ten times before.

According to the Weber–Fechner law, the granularity of a word's meaning is inversely related to its frequency. In other words, when the frequency of a word is low, the granularity of its meaning is considered high. When the frequency of a word is high, the granularity of its meaning is low. Applying the Weber–Fechner law to the granularity of meaning makes it possible to quantify the meaning of English motion verbs and consider them as objective indices. Although not limited to those expressing physical movement, the following table shows the frequency of the 16 motion verbs in COCA and the logarithms considered in this study.

I examined whether there was any correlation between the logarithm of the frequency of these verbs and the frequency with which they occur with path expressions lexicalizing GOAL. The results are shown in Figure 3.

The high correlation coefficient (r = .73) indicates that there no major problem in relating the granularity of the meaning of the motion verbs to the frequency of the words. Incidentally, Taremaa and Kopecka (2022) also pointed out that high-frequency motion verbs tend to co-occur with path expressions that lexicalize the notion of GOAL.

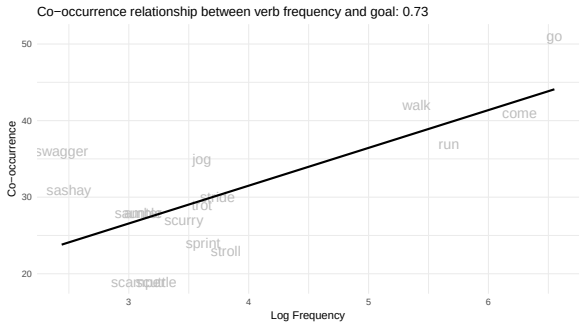

Figure 3: Frequency of each motion verb and co-occurrence with GOAL

Why are words with high frequency, that is, words with a low granularity of meaning, more likely to co-occur with path expressions that lexicalize GOAL? This is due to our tendency to focus on the endpoints of movement when recognizing motion events (Dirven and Verspoor 1998). When people or objects move, we tend to focus on the endpoint rather than the starting point. This was demonstrated by Lukusta and Landau (2005) through psychological experiments. In other words, for us, the default PATH in motion event is the notion of GOAL rather than the notion of SOURCE.

When applying the Weber–Fechner law, the granularity of meaning of these default path expressions is low. In other words, for the proposed concepts of SOURCE, TRAJECTORY, GOAL, DIRECTION, and DEIXIS, the default concept of GOAL can be considered the path concept with the lowest granularity of meaning. Therefore, from the viewpoint of congruency and redundancy, it is reasonable that *come*, *go*, and *walk*, which have the lowest granularity of meaning among motion verbs, co-occur with path expressions associated with GOAL, which has the lowest granularity of meaning among the PATH concepts.

I would also like to mention the unique properties of venitive deictic motion verbs based on the data obtained in this study, referring to studies of the deictic motion verbs in other languages. For instance, Matsumoto et al. (2017) used an experimental approach to investigate interesting properties of venitive deictic motion verbs in English, Japanese, and Thai. They reported that these verbs are more likely to be used when interacting with the speaker rather than only moving in the speaker's direction (cf. Enfield 2003). This property of these verbs was not sufficiently described by Fillmore (1971). It is interesting that such interactional behavior plays an important role when the movement in the speaker's direction is expressed by a verb but not by prepositional phrases such as *toward(s) me*.

This study confirms that *come* and *go* are more likely to co-occur with deictic path expressions such as *here* and *there* than with verbs that lexicalize manner of motion. In particular, I found that *here* often co-occurs with venitive deictic motion verb, *come*. How many instances in my study did *come* co-occur with prepositional phrases, such as *toward(s) me*? There is only one such example, as shown in (5).

(5) Across the field a cat **was coming** toward me and so I picked up a big 7 or 8 foot long stick and made myself as big as I could.
(COCA 2012, WEB)

This study shows that congruency is crucial for English motion expressions. It implies that verbs with similar properties and path expressions tend to co-occur. Applying this to the fact that the verb *come* and the prepositional phrase *toward(s) me* are difficult to co-occur suggests that the unique properties are lexicalized in *here* and cannot be paraphrased to other prepositional phrases.

6 Conclusions

This study was inspired by the recent research on motion verbs that has focused on the semantic properties of verbs. By reconsidering these properties in terms of frequency, I was able to provide a new perspective on motion verbs and path expressions. In particular, by linking the properties of frequent verbs and the default GOAL in the notion of PATH with the properties of congruency and redundancy, which are common in language, this study provides a plausible explanation for the co-occurrence relationship of verbs.

The notion of GOAL, the default in our cognition of motion events, is the one to which our attention is strongly directed and often stated. Stefanowitsch and Rohde (2004) also pointed out that *escape* is more likely to co-occur with SOURCE. Nevertheless, among the motion verbs considered in this study, *scamper* is more likely to co-occur with SOURCE than with GOAL, as the following example shows.

Among the motion verbs in this study, *scamper* is more likely to co-occur with path expressions lexicalizing SOURCE than GOAL, per the following example.

(6) a. He **scampers** out of the room, impatient now for the completion of our evening ritual. (COCA, 2009 FIC)
b. Bunny **scampered** out of the pool in her bikini. (COCA 2010, FIC)

While it is essential to focus on such individual cases and clarify the characteristics of each verb, it is also necessary to define language's general properties and tendencies. Although this study is limited to a survey of only 16 intransitive motion verbs, it revealed at least a critical trend in English motion events description.

This study has two limitations. The first is the number of verbs investigated. English has a vast number of motion verbs. For example, Levin (1993: 265–266) lists more than 100 verbs in English. However, the number of verbs expressing physical movement is not very large. For example, the verb *goosestep*, listed by Levin (1993: 265), has only three hits even in COCA, a corpus containing over 100 million words. However, a close examination of the properties of as many words as possible could identify facts that were not revealed in this study.

Furthermore, the fact that the deictic motion verbs *come* and *go* are likely to co-occur with path expressions such as *here* and *there* and that there is congruency in English motion expressions suggest that it may be necessary to analyze their co-occurrence with pronouns.

The Entailment Relationship Between Transparent Perceptual Reports and Opaque Infinitival Complements: An Approach Without Possible Worlds

Yu Tomita
Leipzig University / Leipzig, Germany
ytomita@uni-leipzig.de

Abstract

This paper proposes a solution to the problem that remains in Tomita (2019). I propose an approach that resembles Hobbs (1985), updated in Hobbs (2003b). His idea is that all predicates take arguments in the *Platonic (or Meinongian) universe*, which consists of everything (every object and eventuality) that possibly exists, regardless of whether it exists in the actual world. This study aims to refine their approach by constructing a semantic system without possible worlds. Then, I discuss the remaining problems and truth-makers.

1 Introduction

This paper proposes a way to solve a problem in the entailment relationship between embedded and matrix clauses, discussing a combination of perceptual reports and infinitival complements as crucial examples. The example (1a) is called a perceptual report and is not problematic in event semantics (see, e.g., Higginbotham, 1983). When (1a) is true, it is entailed that *Mary left*. In general cases of infinitival complements, however, the sentence usually does not necessarily entail the content in its infinitival complement, as shown in (1b).

(1) a. John saw Mary leave. $\hookrightarrow$ Mary left.
b. John forbade Mary to leave. $\not\hookrightarrow$ Mary left.

First, I will review two approaches: (i) the non-existing eventuality approach (Hobbs, 1985; Parsons, 1991), where an infinitival complement serves as an argument to perception verbs, and (ii) quantificational event semantics (Champollion, 2015), where a sentence has a GQ type over events, and in an opaque context, entailment relations wreak havoc. However, since both approaches in (i) are non-compositional, the event-quantification problem was not considered.

Here, I use the term *truth-makers* covering such objects for truth-making. In other words, I define truth-makers as something in semantics that verifies (or falsifies) the truth of statements. According to Fine (2017), a major class of these truth-making objects can be divided with different properties. One is *worldly*, and the others are *stately*. The former, a set of possible worlds, and the latter, a set of eventualities (events and states), work almost similarly.

The remaining roadmap of the paper consists of the following sections. In Section 2, I review possible worlds from the perspective of *Truth-Maker semantics* (Fine, 2017) and compare them with the event(ualitie)s that Hobbs (1985, 2003b) proposed, considering the entailment relationships between perceptual reports and infinitival complements. I argue that possible worlds are unnecessary for analyzing infinitival complements. In Section 3, I introduce a formalism called Outer Quantificational Event semantics (Tomita, 2019), modifying some notations. Then, I will highlight the problem in Tomita (2019) in Section 4 and propose a modification by embedding an additional restriction in perceptual verbs in Section 5. This predicts different existential entailments between the matrix and embedded clauses. In the final section, I discuss the limitations of the proposed analysis and future work on other truth-makers.

2 Backgrounds

Here, I define truth-makers as something in semantics that verifies (or falsifies) the truth of statements, following Fine (2017, p.557).

> On the objectual approach[...], the *truth-conditions are objects*, rather than clauses, which stand in a relation of truth-making to the statements they make true.

According to Fine (2017), various kinds of *truth makers* inhabit this field. The summary of these truth-makers is presented below:

(2) a. *worldly truth-making objects* (= possible worlds)
b. *stately truth-making objects* (verifiers)
i. exact verifier (events and states): wholly relevant to the statement
ii. inexact verifier (situations): partially relevant to the statement
iii. loose verifier: no requirement of relevance

From this perspective, I regard worlds, events, and situations as instances of truth-makers: their coverages overlap. Note that Fine (2017) calls exact truth-making objects *states*. Still, it seems to have similarities to *situations* in linguistics, while Hobbs (2003a) calls all stately truth-making objects *events*. Here, I tentatively use the term *eventualities* to cover all stately exact verifiers in (2b), focusing on the difference between **possible worlds** (2a) and **eventualities**, and making no distinction among stately truth-making objects (in Fine's sense).

2.1 Possible world semantics

These properties characterize the possible worlds:

(3) a. **Completeness:** If one possible world is given, it can settle (verify or falsify) any propositions.
b. **Accessibility relation:** Some possible world is reachable from another one close enough to it.

Here, I describe the possible worlds as a class of objectual verifiers, each of which completely verifies any proposition and is connected with some accessibility relationship. I think of possible worlds as semantic (and mathematical) tools of truth-making. It is widely accepted that they are necessary for analyzing modals, conditionals, and *de re/ de dicto* distinction. In possible-world semantics, propositions denote a set of possible worlds or, equivalently, characteristic functions of worlds to truth values, as shown in (4).

(4) a. $[\![\text{Brutus stabbed Caesar}]\!] = \{w \mid \text{Brutus stabbed Caesar in } w\}$
b. $[\![\text{Brutus stabbed Caesar}]\!](w) =$ 1 iff Brutus stabbed Caesar in w

2.2 Difference between Eventualities and Possible Worlds

Here, I compare some properties of possible worlds and eventualities. Fine (2017) pointed out that the possible worlds can, unlike other truth-makers, settle the truth value of any propositions; if one possible world is given, it can verify that any statement is true or false. In other words, the possible world can settle any proposition and play the roles of both a verifier and a falsifier. In contrast, eventualities do not always settle all propositions.

In addition to Fine's claim on completeness, possible worlds are usually characterized by a directed graph structure representing the accessibility relationships among them. Compared with a partial order, typically common in events and situations, the graph structure is stronger since any partial order can be written as a directed graph, but not vice versa. There is a dilemma of cardinality. If you assume an infinite number of possible worlds in natural language semantics, you should also consider an infinite number of accessibility relations among them, strengthening my argument. However, if you try to reduce the cardinality of possible worlds, Fine's argument will become more serious. See also Tomita (2019); Tancredi and Sharvit (2022) for critical remarks on the possible-world approach.

In summary, even if possible worlds are descriptively adequate, they still carry inevitable shortcomings: (i) they are too strong, and (ii) they sometimes fail to describe the meaning. Therefore, possible worlds should be considered *too massive truth-makers*.

2.3 Opaque infinitival complements

Opaque object readings such as one in *John seeks a unicorn* provide empirical support in favor of possible-world semantics (Montague, 1970). However, in recent years, few semantic studies such as Moltmann (2020) and Tancredi and Sharvit (2022) analyzed attitude verbs and their complements without possible worlds. Each of them appealed to other truth-makers, such as the *attitudinal objects* and the *judge parameter*, respectively. Here, I will focus on the difference between the transparent and opaque reading of infinitival clauses.

In addition, Tomita (2019) proposed Outer-Quantificational Event Semantics, which is based on Champollion's (2015) quantificational event semantics, arguing that an entailment problem in infinitival complements can be solved without possible worlds. He embedded **E!**(x) into the thematic-relation head [**theme**] that corresponds to the verb *see* and always entails the actual existence of the object for the seeing event. In the next

section, I will lay out some formalism along the lines of Tomita (2019), modifying some notational conventions.

3 Formalism

Here, I describe the ideas in Hobbs (1985, 2003b) that accepted the Platonic universe as the quantification domain. To allow quantification over the Platonic universe as its domain, a non-standard formalism called *first-order free logic* is introduced, which adds the special predicate over the Platonic universe **E!**(x) that is true if and only if x actually exists.

3.1 Mathematical tools and notational conventions

Here, I use λ-calculus, adding some constants for natural language semantics. Only e (entity), v (eventuality), and t (truth value) are atomic types. The Greek letters ρ, τ, σ are type variables. Due to space limitations, I define logical constants of type $\langle \sigma t, \langle \sigma t, \sigma t \rangle \rangle$ over one-place predicates A and B of type σt. Instead of some standard binary operators, namely, conjunction ($\&$) and implication ($\rightarrow$) symbols, $[_e A \wedge B]$ and $[_e A \supset B]$ are used:

$$[_e A \wedge B] \equiv (\lambda e.[A(e) \& B(e)])$$
$$[_e A \supset B] \equiv (\lambda e.[A(e) \rightarrow B(e)])$$

Since the conjunction is associative, I write $(\lambda e.[A_0(e) \& \ldots \& A_n(e)])$ as $[_e A_0 \wedge \ldots \wedge A_n]$.[1]

3.2 Outer and inner quantifiers

In our formalism, quantifiers are divided into two pairs: One's domain covers the Platonic universe, which contains all entities and eventualities. In contrast, the other's domain covers a subset that only consists of something that exists actually or some eventuality that occurs actually. I define these quantifiers as higher-order lambda terms of type $\langle \sigma t, t \rangle$ (on the typed lambda calculus, see, e.g., Unger (2010)) in (5);

(5) Outer quantifiers:
   a. Existential (particular) quantifier: $\Sigma(\lambda x.M)$
   b. Universal quantifier: $\Pi(\lambda x.M)$

where M is of type t and σ is a type variable ranging over entities and eventualities. In (5), each quantifier binds to every occurrence of the free variable x in M. In particular, $\Sigma(\lambda e.[A_0(e) \& \ldots \& A_n(e)]) \equiv \Sigma[_e A_0 \wedge \ldots \wedge A_n]$.

Inner quantifiers such as $\exists x.M (= \exists(\lambda x.M))$ and $\forall x.M (= \forall(\lambda x.M))$ are defined with respect to the outer ones.

(6) Inner quantifiers
   a. Existential (particular) quantifier: $\exists(\lambda x.M) := \Sigma[_x \textbf{E!} \wedge (\lambda x.M)]$
   b. Universal quantifier: $\forall(\lambda x.M) := \Pi[_x \textbf{E!} \supset (\lambda x.M)]$

As shown in (6), each of the inner quantifiers is defined with each of the outer counterparts and **E!**.

3.3 Outer-quantificational event semantics

Our steps proceed in almost the same way as Coppock and Champollion (2019). In their framework, verbal denotations lexically contain the existential quantification of events. Thus, they are predicates of type $\langle vt, t \rangle$.

Along the line proposed by Tomita (2019), I incorporate first-order free logic into Champollion's Quantificational Event Semantics, as in (7).

(7) Type $\langle vt, t \rangle$ expressions (to be revised):
   a. $[\![$(to) leave$]\!] \rightsquigarrow \lambda f.\Sigma[_e \textbf{leaving} \wedge f)]$
   b. $[\![$forbid$]\!] \rightsquigarrow \lambda f.\Sigma[_e \textbf{forbidding} \wedge f]$
   c. $[\![$(to) see$]\!] \rightsquigarrow \lambda f.\Sigma[_e \textbf{seeing} \wedge f]$

where f stands for a variable of type vt. Thematic relations such as [agent] and [theme] are separated from verbal denotations, as shown in (8).

(8) Type $\langle e \cup v, \langle \langle vt, t \rangle, \langle vt, t \rangle \rangle \rangle$ expressions:

$$[\![\text{[agent]}]\!] \rightsquigarrow \lambda x \lambda N \lambda f.N[_e x : \textbf{ag} \wedge f]$$
$$[\![\text{[theme]}]\!] \rightsquigarrow \lambda x \lambda N \lambda f.N[_e x : \textbf{th} \wedge f]$$
$$[\![\text{[experiencer]}]\!] \rightsquigarrow \lambda x \lambda N \lambda f.N[_e x : \textbf{ex} \wedge f]$$

where $x : \mathbf{r}$ is abbreviation for $\lambda e.(x = \mathbf{r}(e))$ of type vt, and $\mathbf{r}$ stands for some thematic-role function, such as **ag(ent)**, **th(eme)**, **ex(periencer)**. They are the functions of the set of eventualities to the set of everything, namely, the Platonic universe. In other words, these functions assign each eventuality to something in the Platonic universe. Here is an example calculation for the sentence *Brutus stabbed Caesar*.

(9) a. $[\![\text{[agent]}]\!]([\![\text{Brutus}]\!])$
   $\Rightarrow \lambda N \lambda f.N[_e \textbf{b} : \textbf{ag} \wedge f]$

[1] Though these notations are similar to those in Icard and Moss (2023), I additionally use brackets with a subscript variable $[_e \ldots]$ for the sake of readability.

b. $[\![\text{[theme]}]\!]([\![\text{Caesar}]\!])$
$\Rightarrow \lambda N\lambda f.N[_e\mathbf{c}:\mathbf{th} \wedge f]$

c. $(9b)([\![\text{stab}]\!])$
$\Rightarrow \lambda f.\Sigma[_e\mathbf{stabbing} \wedge \mathbf{c}:\mathbf{th} \wedge f]$

d. $(9a)((9c))$
$\Rightarrow \lambda f.\Sigma[_e\mathbf{stabbing} \wedge \mathbf{c}:\mathbf{th} \wedge \mathbf{b}:\mathbf{ag} \wedge f]$

The first two steps (9a) and (9b) show that each verbal argument is combined with a thematic-relation head. Then, in the subsequent two steps, they each take the verbal denotation as their "arguments in λ-calculus". Instead of the original sentential closure in Champollion (2015), Tomita (2019) adopt **E!**. Figure 1 shows the derivation steps in the sentence. With the sentential closure **E!** of type vt, the corresponding neo-Davidsonian logical form $\exists e.[\mathbf{stabbing}(e) \wedge \mathbf{th}(e) = \mathbf{c} \wedge \mathbf{ag}(e) = \mathbf{b}]$ is obtained.

4 Problem in Tomita (2019)

Tomita (2019) proposed that **E!** is applied to the eventuality in the matrix clause but not to the one in the embedded clauses because the embedded infinitival clause is treated as an argument of the matrix verb.

Because the sentence (1b) implies $\Sigma[_{e'}\mathbf{leaving} \wedge \mathbf{m}:\mathbf{ag}]$, which does not commit to the actual existence of any leaving eventuality, this is compatible with any situation whether Mary left or not. However, according to my old proposal, the denotation for (1a) does not entail *Mary left*. Therefore, in Tomita (2019), I argued that complements of perceptual verbs denote the following expression.

(10) $[\![\text{XP} + \text{[}\mathbf{theme}\text{]}]\!] \rightsquigarrow$
$\lambda N\lambda f.[[\![\text{XP}]\!](\lambda x.[N(\lambda e.\mathbf{th}(e) =$
$x \wedge \mathbf{E!}(x) \wedge f(e))])]$

Then, the sentence (1a) commits to the existence of the event *Mary left* since **E!** applies to the embedded event.

However, some problems remain against his proposal. First, when a thematic-relation head contains the existence predicate **E!**, it can combine non-perceptual verbs such as *forbade* in (1b) that have a different entailment relationship. Second, since (11) entails neither *John saw Mary leave* nor *Mary left*, his proposal cannot predict the correct entailment.

(11) Paul forbade John to see Mary leave.

In the next section, I propose an alternative to this problem.

5 Proposal: Percolation of the Existence Property

Here, I consider the problem of entailment in infinitival complements. Intuitively, if an event of seeing occurs, it implies that something or some eventuality seen in that event also exists or occurs. I describe this intuition as a lambda term of type vt, such that $\lambda e.[\mathbf{E!}(e) \rightarrow \mathbf{E!}(\mathbf{th}(e))] \equiv [_e\mathbf{E!} \supset (\mathbf{E!} \circ \mathbf{th})]$. As mentioned in the previous sections, **th** is a function of a set of eventualities to something in the Platonic universe, and thus $\mathbf{E!} \circ \mathbf{th} \equiv \lambda e.\mathbf{E!}(\mathbf{th}(e))$. The proposed denotation of the verb *see* is now revised as (12), which implies that if some event of seeing exists in the actual world, its theme (internal argument) also exists.

(12) Type $\langle vt, t\rangle$ expression (perceptual verbs):
$[\![\text{(to) see}]\!] \rightsquigarrow \lambda f.\Sigma[_e\mathbf{seeing} \wedge (\mathbf{E!} \supset$
$(\mathbf{E!} \circ \mathbf{th})) \wedge f]$

Unlike my old proposal in (10), thematic-relation heads do not contain such existential predicates as shown in (13).

(13) Type $\langle v, \langle\langle vt, t\rangle, \langle vt, t\rangle\rangle\rangle$ expression:
$[\![\text{[theme]}]\!] \rightsquigarrow \lambda e'\lambda N\lambda f.N[_e e':\mathbf{th} \wedge f]$

In Coppock and Champollion (2019), Hendriks' (1993) raising rule is applied to some thematic-relation heads due to the type mismatch between them and quantifiers of type $\langle et, t\rangle$. For example, (13) is shifted to the following expression:

(14) Type $\langle\langle vt, t\rangle, \langle\langle vt, t\rangle, \langle vt, t\rangle\rangle\rangle$ expression:
$[\![\text{[theme]}]\!] \rightsquigarrow \lambda M\lambda N\lambda f.M(\lambda e'.N[_e e':$
$\mathbf{th} \wedge f])$

where $\vec{a}$ is a null sequence, $\tau = \sigma = t$, and $\langle\vec{c}, \sigma\rangle = \langle\langle vt, t\rangle, \langle vt, \sigma\rangle\rangle = \langle\langle vt, t\rangle, \langle vt, t\rangle\rangle$. The details of this rule are shown in Coppock and Champollion (2019), Hendriks (1993), and the Appendix in this paper. (14) takes a GQ-type eventuality for the verb *see*. The logical form corresponds to *(to) see Mary leave* is calculated in (15). The infinitival complements are of the GQ-type over events $\langle vt, t\rangle$.

(15) (Infinitival) VP: to see Mary leave

a. $(14)([\![\text{Mary leave}]\!]) \Rightarrow$
$\lambda N\lambda f.\Sigma[_{e'}\mathbf{leaving} \wedge \mathbf{m}:$
$\mathbf{ag} \wedge (\lambda e'.N[_e e':\mathbf{th} \wedge f]))$

b. $(15a)(12) \Rightarrow \lambda f.\Sigma[_{e'}\mathbf{leaving} \wedge \mathbf{m}:$
$\mathbf{ag} \wedge (\lambda e'.\Sigma[_e\mathbf{seeing} \wedge (\mathbf{E!} \supset$
$(\mathbf{E!} \circ \mathbf{th})) \wedge e':\mathbf{th} \wedge f])]$

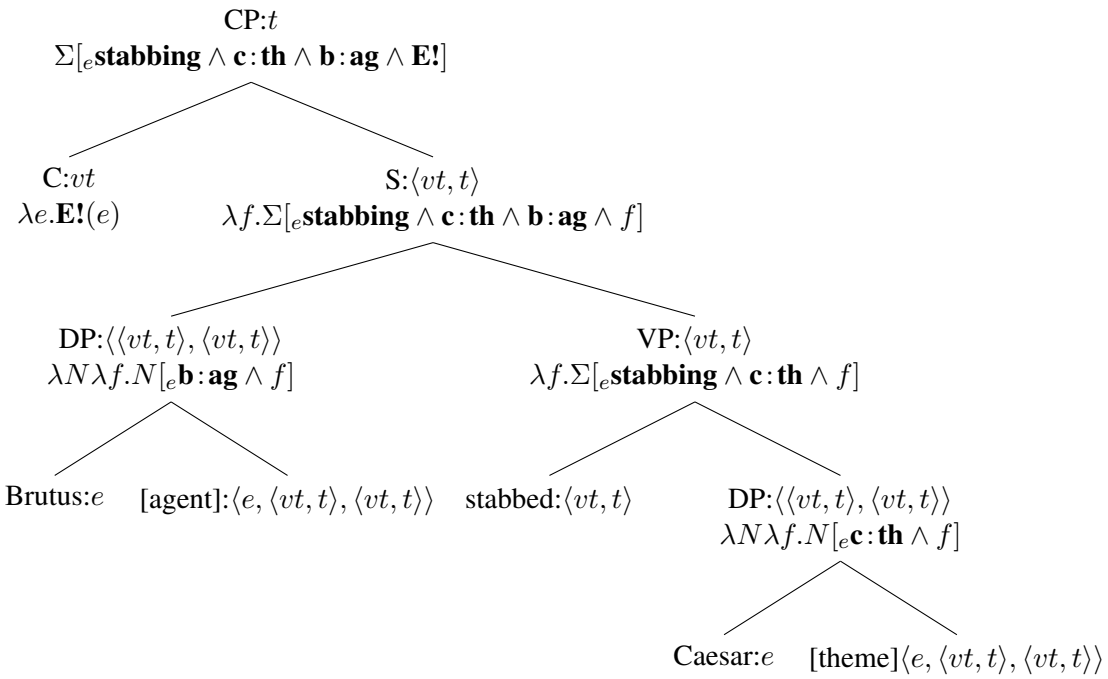

Figure 1: Derivation tree of *Brutus stabbed Caesar*

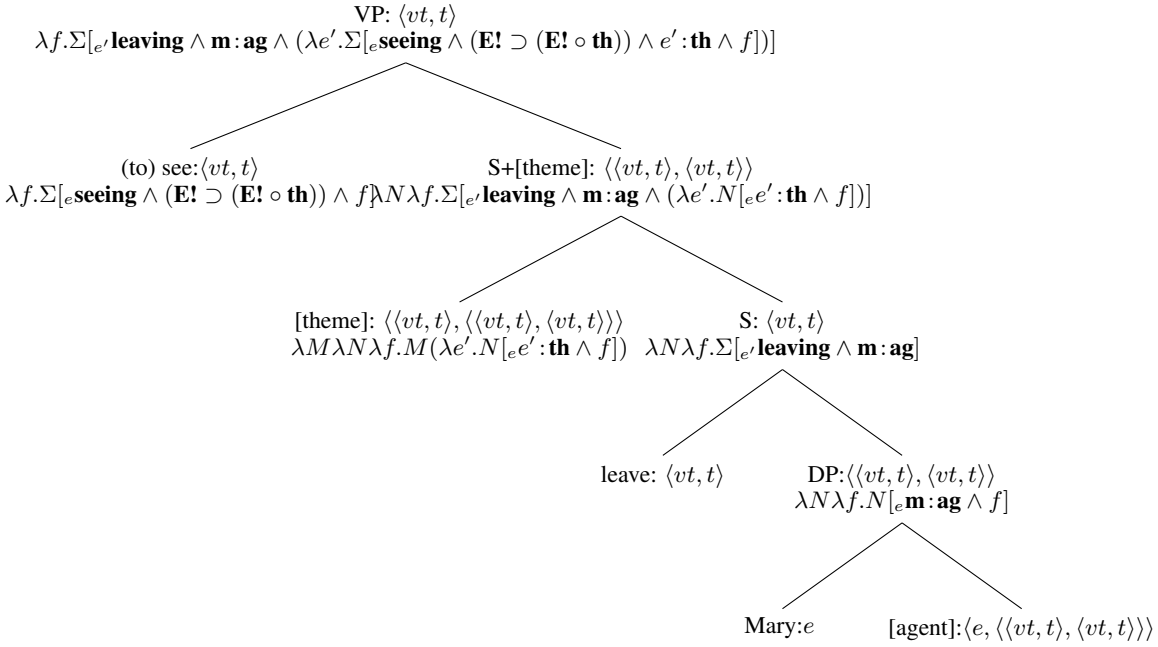

Figure 2: Derivation tree of *VP: (to) see Mary leave*

Figure 2 shows the corresponding derivation tree.

Unlike the previous proposal in (10), this does not entail *Mary left* unless the existential closure is given. If (15b) is given as a VP of the perceptual report *John saw Mary leave*, then the logical form contains $\mathbf{E!}(e) \supset (\mathbf{E!}(\mathbf{th}(e))$ and $\mathbf{E!}(e)$, which indicates that $\mathbf{th}(e) = e'$ also actually exists ($\mathbf{E!}(e')$), which results in a transparent reading. In contrast, when (15b) is given as a VP of infinitival complements in *Paul forbade John to see Mary leave*, this does not entail *Mary left* since the existence of the event in the matrix clause does not percolate to the events in the embedded clause, resulting in an opaque infinitival reading.

6 Discussion

Until this section, I argued that there is no need to use possible worlds to analyze some infinitival complements. However, there are some limitations and necessary future work. I will now discuss them and some related work.

6.1 Limitations

I further investigate which types of truth-makers are necessary for the other problems shown below.

Here are both transparent and opaque examples.

(16) a. Ralph saw Ortcutt to be a spy
b. Ralph saw ORTCUTT not to be a spy

In the above example, ORTCUTT (semantically focused proper name) in (16b) is a bit different from the non-focused one (16a) in that ORTCUTT in (16b) can designate a different person other than Ortcutt in (16a); see, e.g., Schwarzschild (1999). The same problems can be found in opaque infinitivals.

(17) a. Ralph considered the man in the brown hat to be a spy.
b. Ralph considered the man seen on the beach not to be a spy.

In both sentences in (17), *the man* can denote the same entity in context. However, both sentences can have different values (see, e.g., Quine, 1956). As like Tancredi and Sharvit (2022), the judge-parameter should be taken into consideration, which typically varies between an evaluator and a speaker according to the evaluator; none of which is introduced as a kind of stately truth-makers in Fine (2017). I do not address whether such truth-makers can be classified as different or be reduced to more general truth-makers. My current conjecture is that such truth-making tools are still necessary for semantics and can be incorporated into my proposal since these truth-makers play a completely different role from truth-making objects.

6.2 Related work

In the proposed framework, the existential quantifier in an infinitival complement always takes scope over the matrix clause, regardless of its syntactic position. From the syntactic point of view, the infinitival is extraposed and takes scope over some constituents in an upper clause. See also Higginbotham (1983, Sec. 2) for the related discussion. Similar discussions can be found in recent work on finite relative clauses; see, e.g., Koval (2019) and papers cited therein. As stated in the first two sections of this paper, possible worlds are required to analyze these embedded clauses. However, as shown in this proposal, when useful (but unusual) tools are admitted, it may become possible to reveal semantic phenomena without possible worlds.

Acknowledgements

This work is based on a talk in the semantics colloquium course of the CYCLOP program in the Department of Linguistics at Leipzig University. I thank the audience and Barbara Stiebels for allowing me to discuss my ongoing work. I also appreciate Hitomi Hirayama's helpful comments and am grateful to the anonymous reviewers.

Appnedix: Generalized Raising Rule

Here, I modify Hendriks' raising rule to allow thematic-relation heads to take an argument of type $\langle et, \sigma \rangle$. If an expression denotes M of type $\langle \vec{a}, \langle b, \langle \vec{c}, \tau \rangle \rangle \rangle$ where $\vec{a}$ and $\vec{c}$ are possibly null sequences of any types, then this also denotes the following term:

(18) Type $\langle \vec{a}, \langle \langle b\tau, \sigma \rangle, \langle \vec{c}, \sigma \rangle \rangle \rangle$ expression: $\lambda \vec{x} \lambda v \lambda \vec{y}.[v(\lambda z.[M(\vec{x})(z)(\vec{y})])]$

If this rule is applied to the thematic-relation head, it can take any argument of type $\langle et, \sigma \rangle$, such as the wh-phrase in the framework proposed in Unger (2010).

Comparing Gender Bias in Lexical Semantics and World Knowledge: Deep-learning Models Pre-trained on Historical Corpus

Abstract

This study investigates the impact of continued pre-training transformer-based deep learning models on historical corpus, focusing on BERT, RoBERTa, XLNet, and GPT-2. By extracting word representations from different layers, we compute gender bias embedding scores and analyze their correlation with human bias scores and real-world occupation participation differences. Our results show that BERT, an encoder-only model, achieves the most substantial improvement in capturing human-like lexical semantics and world knowledge, outperforming traditional static word vectors like Word2Vec. Continued pre-training on historical data significantly enhances BERT's performance, especially in the lower-middle layers. When historical human biases are difficult to quantify due to data scarcity, continued pre-training BERT on historical corpora and averaging lexical representations up to the 6th layer provides an accurate reflection of gender-related historical biases and world knowledge.

1 Introduction

The core idea of distributional semantics models (DSMs) is that the context of a word usage can be used to explore its semantics (Harris 1954; Firth 1957). With the rapid advances in deep learning, models based on deep transformer networks (Vaswani et al., 2017) have achieved remarkable performance in many empirical tasks, such as answering questions and engaging in dialogues (Rajpurkar et al. 2016; Adiwardana et al. 2020). Despite this success, how these models acquire and encode linguistic information remains unclear (Avetisyan and Broneske, 2023). These models may reflect human-like gender biases at the semantic level of certain words like humans. However, there is little research on how these biases and semantic information are encoded by the models, and deep-learning-based representations have not engaged rigorously enough with semantic theory. It is still difficult to differentiate whether the model has genuinely progressed in modeling semantics or merely increased its ability to memorize corpus statistics (Pavlick, 2022).

Moreover, deep learning models are typically pre-trained on large contemporary corpora, and it is uncertain whether continued pre-training on historical corpora can help the models learn more human-like semantics and world knowledge related to gender of historical times (Qiu and Xu, 2022). Given that continued pre-training can be computationally expensive, it is necessary to determine which model achieves the most human-like word representation (Vulić et al., 2020). This includes traditional DSMs like Word2Vec (Mikolov et al., 2013), encoder-only models like BERT (Devlin et al., 2018) and RoBERTa (Liu et al., 2019), or decoder-only models like GPT-2 (Radford, 2019) and XLNet (Yang, et al., 2019).

By probing into the gender biases learned by these models from continued pre-training process, it is possible to study historical societal perceptions of gender bias that may be difficult to measure directly. This research makes several significant contributions: 1. Advancing research in historical sociolinguistics and cognitive bias by bridging the gap between sociolinguistics and deep-learning techniques. 2. Highlights the important role of historical corpora as a treasure trove for studying biases throughout history, allowing researchers to reconstruct historical societal attitudes and analyze biases in a more nuanced and precise manner. 3. Enabling historical bias research in data-scarce environments by demonstrating that models can learn biases from period-specific corpora, enabling historical bias research in contexts where direct data on societal attitudes may be scarce or non-existent. It opens new avenues for studying historical biases in diverse cultural and linguistic contexts.

2 Related Work

For lexical representations, traditional distributional semantics models (DSMs) include count-based methods like TF-IDF (Jones, 1973) and prediction-based methods such as Word2Vec (Mikolov et al., 2013), GloVe (Pennington et al., 2014), and FastText (Bojanowski et al., 2017). These models produce a single word vector, potentially overlooking semantic differences across different contexts (McLevey et al., 2022).

In contrast, deep learning models aim to obtain sentence representations for real-life applications, with word representations emerging as a byproduct (Pavlick, 2022). Models include BERT (Devlin et al., 2018) and GPT-2/3 (Radford et al., 2019; Brown et al., 2020), which have been extensively studied for their semantic representation capabilities.

Contextualized embeddings have been shown to surpass traditional static word embeddings in capturing word semantics and identifying diachronic semantic shifts. Peters et al. (2018) and Radford et al. (2019) demonstrated that contextualized token embeddings encode word senses even without explicit training. Giulianelli et al. (2020) and Hu et al. (2019) developed contextualized embeddings for historical contexts, examining changes in word meanings over time. However, these studies often rely on models pre-trained on modern corpora, which may bias results towards contemporary language use (Qiu and Xu, 2022).

To address this, Hamilton et al. (2016) created HistWords, Word2Vec embeddings trained on historical corpora, to study semantic changes over 100 years of American history (Garg et al., 2018). Yet few works have extended this approach to contextualized language models. Vulić et al. (2020) compared contextualized word embeddings like BERT with traditional static DSMs like FastText, finding that contextualized embeddings generally outperform static ones. Gu et al. (2022) applied lexical semantics in embeddings for practical tasks. Nair et al. (2020) showed that contextualized embeddings have a higher correlation with human judgments. Yet Yenicelik et al. (2020) found that BERT embeddings' organization is "not purely determined by semantics." For world knowledge, previous studies have indicated that climate variations in language and world knowledge are closely linked (Huang and Dong, 2020; Dong and Huang, 2021). However, research comparing grounding and reference is notably absent (Pavlick, 2022). Some studies have explored multimodal variants (Sun et al., 2019; Radford et al., 2021), but they lack the semantic analysis depth of text-only models (Bender and Koller, 2020).

Gender bias is a critical topic across disciplines, with language analysis traditionally used to study it qualitatively (Holmes and Meyerhoff, 2004; Coates, 2015). Gender issues can be studied through machine learning techniques (Lu et al., 2022). If deep learning models can be continue pre-trained to better reflect human-like gender-related bias and world knowledge, they could become powerful tools for sociological and linguistic studies.

Inspired by previous works, this study aims to determine which model—BERT (Devlin et al., 2018), RoBERTa (Liu et al., 2019), GPT-2 (Radford, 2019), or XLNet (Yang, et al., 2019) benefits the most from continued pre-training on historical corpora in terms of capturing more human-like gender-related attitudes, uncover how lexical semantics and world knowledge are encoded across model layers, and evaluate whether these models provide better human-like lexical representations compared to traditional static DSMs. By leveraging deep learning techniques, this research goes beyond previous traditional DSMs studies to explore the distribution of gender-related semantics and world knowledge within deep-learning model architectures, offering new insights into the intersection of language and society.

3 Methodology

The scarcity of historical quantitative data on gender bias in sociolinguistic research underscores the significance of this study. By using word representation as a quantitative tool, we aim to measure biases in historical societal changes. This study employs the 1990 Corpus of Historical American English (COHA) (Davis, 2010) for continued pre-training of BERT (Devlin et al., 2018), RoBERTa (Liu et al., 2019), GPT-2 (Radford, 2019), and XL-Net (Yang et al., 2019).

For lexical semantics, we use the gender rating survey on different adjectives by Williams and Best as a benchmark (1990). For world knowledge, we use 1990 US demographic data on gender occupation participation (Ruggles et al., 2015) to validate the accuracy in the world knowledge dimension. We extract the corresponding word representations from the continue pre-trained models

and conduct linear regression analysis to identify the model that best reflects historical gender bias and gender-related world knowledge. Additionally, we aim to determine the best method for extracting gender-related word representations. The flowchart of the experiment can be seen in Figure 1:

3.1 Model Size

Previous empirical studies (Hu et al., 2020; Warstadt et al., 2020; Radford et al., 2019; Zhang et al., 2021) have shown that larger models tend to improve task performance and capture semantic information more effectively. Therefore, to compare the semantic representation capabilities of different models, it is essential that the models are comparable in size and are pre-trained on the same corpus. This research selects four transformer-based models of comparable sizes: encoder-only models BERT Base (Devlin et al., 2018) and RoBERTa Base (Liu et al., 2019), and decoder-only models GPT-2 small (Radford, 2019), and XLNet Base (Yang et al., 2019).

3.2 Layer Selection

Peters et al. (2018) and Tenney et al. (2019) found that lower hidden layers of BERT-based models tend to capture more syntactic information, while higher layers capture more abstract semantic information. This study plans to extract word representations from different layers of the models to explore the general distribution of semantic information and determine which specific layer best reflects human-like word representation.

3.3 Training Method

The choice between continued pre-training and fine-tuning is crucial. Fine-tuning a pre-trained model tends to yield better results for specific tasks (Wang et al., 2019). However, fine-tuning can alter the parameters of the higher hidden layers, potentially losing some linguistic information (Liu et al., 2019; Merchant et al., 2020; Mosbach et al., 2020). Since this study does not focus on any specific downstream task but aims to explore the general semantic representation of words in the context of a specific historical period, continued pre-training on historical data is more suitable and will be conducted here.

3.4 Evaluation

In terms of evaluation, NLP methods can be broadly divided into three categories (Pavlick, 2022): Extrinsic Task-Based Evaluation, Targeted Task-Based Evaluations (Linzen and Broni, 2020), and Representational or Probing Evaluation (Belinkov and Glass, 2019). This study aligns with the third category, as it investigates the model's understanding of semantic structure by extracting and analyzing word representations. By probing these representations, we aim to reveal how effectively the model captures underlying semantic patterns, including gender biases present in the data.

4 Experimental Settings

4.1 Pre-processing

This experiment selects the Corpus of Historical American English (COHA) (Davis, 2010) as the dataset due to its relatively large and balanced historical corpus. COHA contains over 475 million words from various genres, including fiction, nonfiction, newspapers, and magazines, spanning from the 1820s to the 2010s. Given the lack of systematic quantitative data on stereotypes in social science, this study utilizes the historical survey on gender stereotypes from 1990 (Williams and Best), so texts from 1990-1999 in COHA are selected as the training corpus for subsequent experiments. This subset contains 30,622,378 words and 2,374,121 sentences, with an average sentence length of 13 words.

For data processing, all text in COHA is converted to lowercase, and all punctuation marks are removed. Abbreviations are appropriately handled. The study uses the model's default tokenizer. Another important step is addressing possible mismatches between COHA and the tokenizer. For example, in COHA, words like "don't" are separated into "do" and "n't," which may cause issues during tokenization(Qiu and Xu, 2022). These are substituted back into their original forms. As suggested by Gulordava and Baroni (2011), lemmatization has little effect on the detection of semantic change, so it is not performed in the pre-processing process.

4.2 Continued Pre-training on Models and Representation Extraction

This study aims to continue pre-training BERT, RoBERTa, GPT-2, and XLNet using the COHA (1990) corpus and compare the results with a traditional Word2Vec model trained from scratch. The training starts from the last checkpoint of the original base models, following the official guidelines of

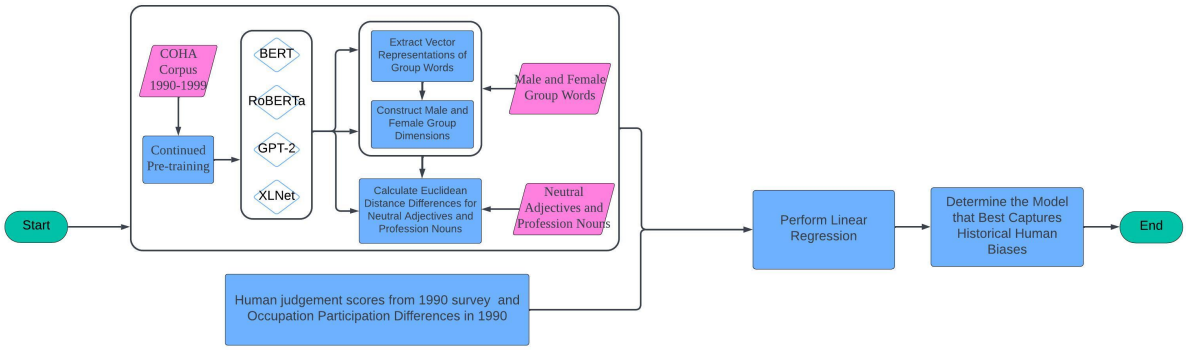

Figure 1: Flowchart of Continued Pre-training and Extraction of Gender-related Word Representation

Hugging Face. Since the average sentence length in the 1990s COHA is just 13 words, much shorter than the default 512, this research follows Qiu and Xu (2022) and limits the maximum sequence length to 128.

To thoroughly train the models, the number of epochs is set to be 300. However, if the loss becomes stable for a long time or the evaluation score stabilizes or starts to drop, early stopping will be applied. This research saves every checkpoint at the end of each epoch to analyze the dynamic changes in word representations. All training processes are completed on Alibaba Cloud using NVIDIA A10 cards with 24GB memory. The output models are stored in Alibaba Cloud OSS buckets.

For Word2Vec training, this research follows Hamilton et al. (2016). The symmetric context window size is set to 4 (on each side) with embeddings of size 300. The Word2Vec model is trained using the CBOW method with a smoothing parameter of 0.75. The negative sample prior is set to log(5), and the context is simply the same vocabulary as the target words.

Details of the models and configurations used are shown in Table 1 and Tale 2, which provides the necessary information to train the models using the openly available source code.

Model	Word2Vec
Parameters	Vocabulary Size*300
Embedding Size	300
Window Size	4
Smoothing Parameter	0.75
Negative Sample Prior	log(5)
sg	0

Table 1: Descriptions and Hyper-parameters of Word2Vec Training

This study aims to explore the semantic representation of words as a more "abstract" concept, rather than their representation in specific sentence contexts. Traditional static word embedding methods intuitively use distributional semantics to represent words, but deep learning models may differ from static word vectors. Firstly, words may be tokenized into sub-word tokens, which are influenced by the context and position within the sentence (Mickus et al., 2019). However, research by Vulić et al. (2020) demonstrates that pre-trained encoders still retain lexical semantics despite various contexts. This research adopts Vulić et al. (2020)'s unsupervised word-level representation strategies and configurations to probe the lexical semantics of words related to gender.

Model	BERT-Base	RoBERTa-Base

Table 2: Descriptions and Hyperparameters of Deep-learning Model Training

For all models used in this research—BERT Base (Devlin et al., 2018), RoBERTa Base (Liu

et al., 2019), GPT-2 Small (Radford et al., 2019), and XLNet Base(Yang et al., 2019)—each word representation is extracted in isolation without any external context. Special tokens [CLS] and [SEP] are excluded from sub-word embedding averaging. Two strategies are used for comparison: one is to extract only the representations from layer Ln, and the other is to average representations over all layers up to the n-th layer (including Ln).

4.3 Evaluation Metrics

This study utilizes historical survey data and objective records as benchmarks to evaluate the models' abilities to capture lexical semantics and reflect world knowledge.

To assess lexical semantics, we draw on the survey conducted by Williams and Best (1990), which measured people's perceptions of gender stereotypes using a list of adjectives. Participants provided scores indicating whether each adjective was perceived as more feminine or more masculine. For our study, we retained only the adjectives that appear in the Word2Vec vocabulary. The complete list of adjectives and their corresponding human-elicited scores are provided in the appendix.

For evaluating world knowledge, we use data from the 1990 U.S. Census (Ruggles et al., 2015) to calculate the gender disparity in occupational participation. This data serves as the "ground truth" or "objective metric" for societal gender roles at that time, reflecting historical realities. The full occupational participation data, broken down by gender, is also included in the appendix.

Building on the approach of Garg et al. (2018), we have constructed two "gender" dimensions: one for female-associated terms (e.g., "she," "her") and another for male-associated terms (e.g., "he," "his"). These lists, along with the lists of adjectives and occupations, are also available in the appendix. Words from the adjective and occupation lists are referred to as "neutral words" in this study.

To measure the association strength between neutral words and gender groups, we first create "gender group vectors" by averaging the vectors of words within the female and male groups. We then compute the Euclidean Distance between each neutral word's vector and the gender group vectors. This allows us to determine the relative norm distance of each neutral word concerning the male and female groups, from which the gender embedding bias of each word from each model is calculated. The bias score is defined as follows:

$$\text{Bias Score} = \|\vec{\mathbf{v}}_{\text{neutral}} - \vec{\mathbf{v}}_{\text{female}}\|_2 - \|\vec{\mathbf{v}}_{\text{neutral}} - \vec{\mathbf{v}}_{\text{male}}\|_2$$

The neutral vector represents the vector of a neutral word, and female and male vector denote the average vectors for the female and male groups respectively.

To measure embedding bias against historical data, this research follows Garg et al. (2018) that Ordinary Least Squares (OLS) linear regression analysis is conducted between the survey (or census) data and the gender embedding bias scores from the models to examine the correlation between the model's gender bias and the gender stereotypes as reflected in human.

R^2 (coefficient of determination) is used as an evaluation metric in this context because it quantifies the proportion of variance in the human survey data or census data that can be explained by the model's embedding biases (Montgomery et al., 2021). A higher R^2 value indicates a stronger correlation between the embedding bias captured by the models and the actual societal biases reflected in human data. The OLS linear regression analysis is conducted using the Python library statsmodels, which provides a robust framework for such statistical evaluations. This method allows us to precisely quantify the alignment between model-inferred biases and historical human biases, thus providing an objective measure of model performance.

5 Results and Discussion

5.1 Distribution of Gender-related Lexical Semantics and World Knowledge in Proto-models

To investigate the distribution and fundamental state of lexical semantics and world knowledge of gender-related words in different deep learning models, word representations for each neutral adjective and occupation noun were extracted from each layer of the original open-source models. The gender bias embedding score for each word in these models was calculated, followed by an analysis of the correlation strength between the model's gender bias scores, human bias scores, and occupation participation differences. The R^2 values from the OLS (Ordinary Least Squares) analysis for each layer across different models are presented in the line charts in Figure 2:

Figure 2 presents the R^2 values comparing the word representation bias scores of neutral adjectives at each layer of various proto-models with

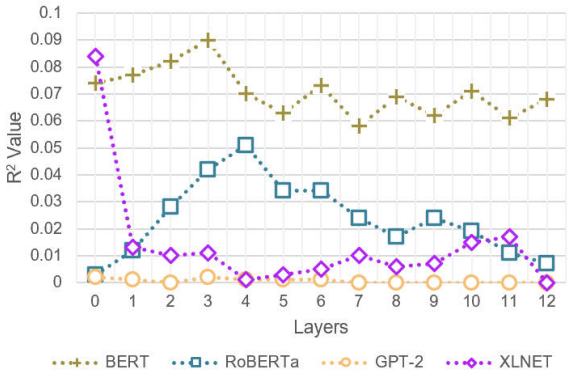

Figure 2: Lexical Semantic Representation of Adjectives in Each Layer of the Original Models (The R^2 value for Word2Vec is 0.099)

human bias scores obtained from the survey. Our analysis indicates that deep learning models, when used without fine-tuning or continued pretraining, do not perform adequately in analyzing diachronic semantic distributions. Specifically, the R^2 values for each layer of all deep learning models fell short of those obtained from traditional Word2Vec embeddings. Among the models evaluated, the original BERT model outperformed the others, followed by RoBERTa, XLNet, and GPT-2. Additionally, Figure 2 suggests that encoder-only models generally outperform decoder models in this task.

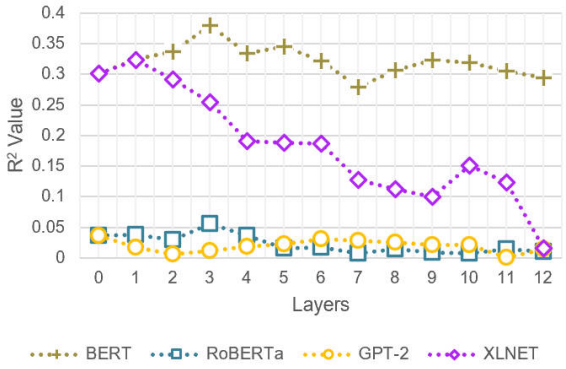

Figure 3: World Knowledge Representation of Occupation Nouns in Each Layer of the Original Models (The R^2 value for Word2Vec is 0.284)

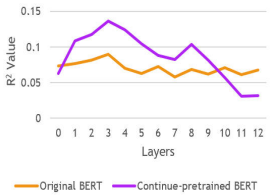
Figure 3 illustrates the R^2 values between the word representation bias scores for occupation nouns at each layer of proto-models and the gender occupation participation data from official census. The results show that the performance of proto-models remains unsatisfactory when compared to the ground truth of gender occupation participation. Among the models, only BERT and XLNet exhibit slightly better performance.

Despite the presence of semantic information in each layer of deep learning models, this information tends to be dispersed across all layers. Generally, the core lexical semantics of words are predominantly concentrated in the lower-middle layers of most models.

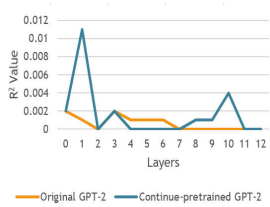
5.2 Effects of Continued Pre-training on Historical Corpus on Deep-learning Models

After continued pretraining of the afore-mentioned models using the 1990s COHA corpus, we extracted word representations from each layer of the trained models to assess their alignment with human similarity judgments and census data. We also evaluated whether the gender-related semantic representation abilities of the models were enhanced compared to their original versions.

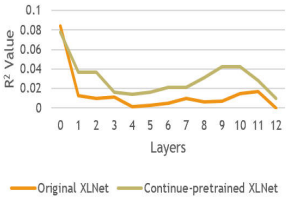


(a) R^2 Values of Adjectives for BERT

(b) R^2 Values of Adjectives for RoBERTa



(c) R^2 Values of Adjectives for GPT-2

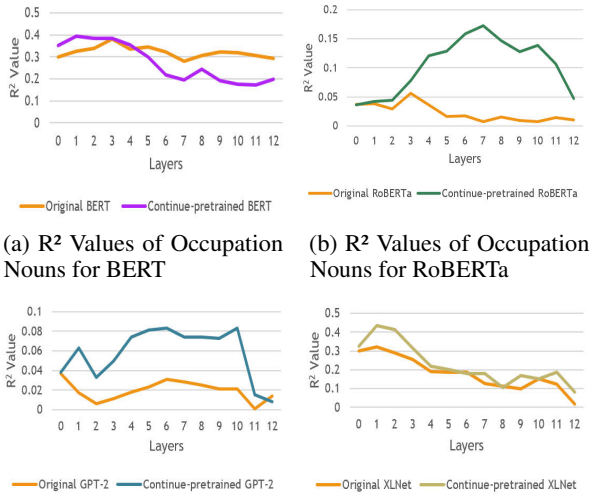


(d) R^2 Values of Adjectives for XLNet

Figure 4: Summary of R^2 Values of Adjectives of Each Layer from BERT, RoBERTa, GPT-2 and XLNet (before and after Continued Pretraining)

Figure 4 summarizes the R^2 values comparing adjectives' word representations from BERT, RoBERTa, GPT-2, and XLNet to human-elicited survey scores, evaluated across each model layer before and after continued pretraining on historical data. The results demonstrate that continued pretraining on a historical corpus generally enhances the models' ability to represent gender-related semantics, aligning them more closely with human judgments. Notably, BERT shows the most significant improvement in capturing nuanced gender associations, particularly in the lower-middle layers. RoBERTa and XLNet also exhibit enhanced perfor-

mance, though the gains are less consistent across all layers. GPT-2 shows the least improvement, reflecting the challenges faced by decoder-only architectures in modeling fine-grained gender biases. Overall, these findings underscore the importance of continued pretraining on domain-specific corpora to enrich the models' semantic representations and better reflect the complexities of human language understanding.



(a) R² Values of Occupation Nouns for BERT

(b) R² Values of Occupation Nouns for RoBERTa

(c) R² Values of Occupation Nouns for GPT-2

(d) R² Values of Occupation Nouns for XLNet

Figure 5: Summary of R² Values of Occupation Nouns of Each Layer from BERT, RoBERTa, GPT-2 and XLNet (before and after Continued Pretraining)

Figure 5 summarizes the R² values comparing occupation nouns' word representations from BERT, RoBERTa, GPT-2, and XLNet to real-world occupation participation differences across each model layer, both before and after continued pretraining on historical data. The results reveal that pretraining on a historical corpus also significantly enhances the models' ability to capture gender-related world knowledge. This improvement is especially evident in the lower-middle layers. BERT, in particular, show marked gains in representing gendered associations related to occupation nouns, indicating that the model benefit from integrating historical context to develop a deeper understanding of how gender roles have been encoded in language over time. Overall, these findings highlight the potential of continued pretraining on specific corpora to strengthen the semantic representation capabilities of deep-learning models, especially in areas that reflect societal attitudes and biases.

5.3 Comparison of Models' Human-Likeness in Lexical Semantics and World Knowledge

To determine which type of model best represents human-like semantic representations, we extract word vectors from each trained model and evaluate their correlation with human similarity judgments and census data. Two strategies are employed for word vector extraction: the first involves using only the representations from layer Ln, and the second is averaging representations across all layers up to the n-th layer (including Ln). Figure 6 presents the results for adjectives using only the representations from layer Ln, while Figure 7 shows the results for occupation nouns only the representations from layer Ln.

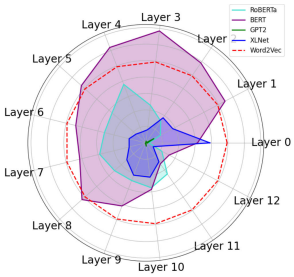


Figure 6: R² Values of Adjectives in Single Layers

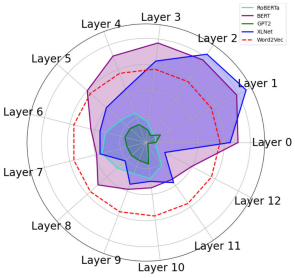

Figure 7: R² Values of Occupation Nouns in Single Layers

As shown in Figure 6 and Figure 7, after continued pretraining on historical data, only the lexical representations from layers 1-5 of BERT surpassed those of Word2Vec for both adjectives and occupation nouns. In contrast, individual layers from other models did not surpass Word2Vec. Additionally, the trend observed indicates that type-level lexical information is more concentrated in the lower layers, approximately layers 1-5.

Figure 8 and Figure 9 present the results for adjectives and occupation nouns by averaging representations across all layers up to the n-th layer (including Ln).

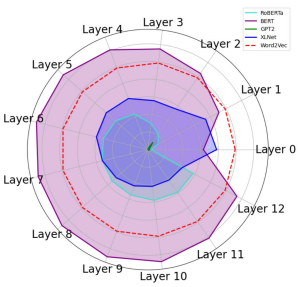

Figure 8: Average Layers of Adjectives Representation

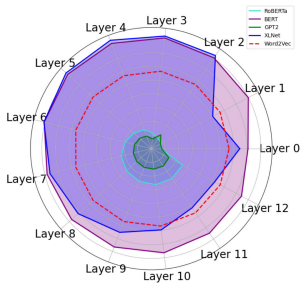

Figure 9: Average Layers of Occupation Representation

Since the original BERT and XLNet models already outperform Word2Vec in terms of world knowledge for occupation nouns, it is expected that these models continue to surpass Word2Vec even after training. However, the distribution of information in BERT and XLNet has shifted from being relatively uniform to being more concentrated in the lower layers, with information primarily concentrated in layers 0-6. In contrast, GPT-2 and RoBERTa perform relatively poorly and do not exceed Word2Vec.

The results indicate that only BERT achieved notably positive outcomes, demonstrating the best correlation with human annotations. According to Vulić et al. (2020), the performance of individual layers can be task and language dependent, while averaging across all layers might sometimes reduce performance, averaging across the bottom-most layers is generally beneficial. For this study, which aims to reflect historical human gender bias more accurately, averaging up to the 6th layer (inclusive) is recommended.

To verify the stability of these results, we further analyzed R^2 values using 10 different random seeds to check whether they remained consistent. Figure 10 shows the Mean Absolute Deviation (MAD) error of R^2 values for each layer. The R^2 values are generally stable, with the standard deviation for the average 6th layer result being approximately 0.01, indicating that the training is relatively robust and stable.

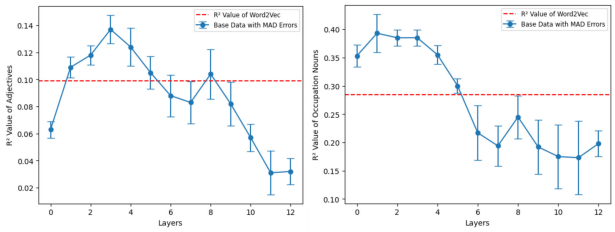

Figure 10: R^2 Values with Adjectives and Occupation Nouns of MAD Errors from Random Seed Training Models

6 Conclusion

These findings demonstrate that continued pre-training on historical data is effective for historical semantic analysis, particularly for examining historical gender bias. Our findings reveal that gender-related type-level semantic information is primarily concentrated in the lower-middle layers of deep-learning models, with an optimal strategy being to average representations up to the 6th layer. This approach allows for a more accurate reflection of historical human biases, as evidenced by BERT's performance, which outperformed both static word embeddings like Word2Vec and other transformer-based models in generating human-like semantic representations.

Overall, while each layer of a deep-learning model contributes to capturing different aspects of semantic information, type-level lexical information is predominantly concentrated in the lower-middle layers. The optimal performance of specific layer can vary based on the language and task, however, averaging representations across all layers up to a certain point generally proves to be a more robust approach.

6.1 Significance and Implications

This study has several key implications. First, it shows that continued pre-training on historical corpora can enhance deep learning models' ability to represent gender biases in ways that align with human understanding, supporting sociocultural research.

Second, the findings highlight the strengths of models like BERT in capturing linguistic nuances that simpler models, like Word2Vec, might miss. This study offers practical guidance for optimizing model design and application across linguistic tasks.

Lastly, it demonstrates that deep-learning models can reveal hidden patterns of bias even in data-scarce environments, enhancing historical analysis.

6.2 Limitations and Future Directions

The study focuses on a specific period (the 1990s) and one type of bias (gender-related). Future research could explore other time periods, biases, and cultural settings to broaden our understanding.

Additionally, the study did not examine other fine-tuning strategies or larger models. Future work could investigate domain-specific fine-tuning strategies and assess if larger models provide more precise representations of historical biases.

6.3 Summary

In summary, our research suggests that deep-learning models pre-trained on historical data are powerful tools for semantic analysis. By understanding how these models distribute information across layers, researchers can better explore the evolution of language and bias. This work lays the groundwork for refining model training tech-

niques, expanding linguistic corpora, and uncovering deeper insights into the relationship between language, culture, and society.

A Appendix

A: Group Words

Man Words: he, son, his, him, father, man, boy, himself, male, brother, sons, fathers, men, boys, males, brothers, uncle, uncles, nephew, nephews

Woman Words: she, daughter, hers, her, mother, woman, girl, herself, female, sister, daughters, mothers, women, girls, females, sisters, aunt, aunts, niece, nieces

B: Neutral Words

Occupations: bookbinder, waitstaff, laborer, sailor, technician, porter, chemist, electrician, inspector, salesperson, secretary, plumber, doctor, mechanic, instructor, carpenter, upholsterer, shoemaker, bartender, chiropractor, nutritionist, pharmacist, administrator, surgeon, geologist, teacher, painter, soldier, photographer, attendant, economist, janitor, clergy, peddler, auctioneer, artist, dentist, driver, dancer, cashier, cook, sheriff,

nurse, compositor, author, lawyer, conductor, manager, postmaster, dietitian, architect, gardener, optometrist, housekeeper, sales, accountant, molder, draftsperson, clerical, typesetter, musician, plasterer, machinist, newsperson, pilot, baker, weaver, therapist, entertainer, police, jeweler, boilermaker, bailiff, operator, surveyor, psychologist, professor, engineer, judge, proprietor, librarian, broker, millwright, welder, designer, lumberjack, toolmaker, setter, huckster, clerk, smith, athlete, tailor, scientist, mathematician, farmer, veterinarian, official, statistician, physician, conservationist, cabinetmaker, guard, doorkeeper, mason, physicist

Adjectives: active, adaptable, adventurous, affected, affectionate, aggressive, alert, aloof, ambitious, anxious, apathetic, appreciative, argumentative, arrogant, artistic, assertive, attractive, autocratic, awkward, bitter, blustery, boastful, bossy, calm, capable, careless, cautious, changeable, charming, cheerful, civilized, clever, coarse, cold, commonplace, complaining, complicated, conceited, confident, confused, conscientious, conservative, considerate, contented, conventional, cool, cooperative, courageous, cowardly, cruel, curious, cynical, daring, deceitful, defensive, deliberate, demanding, dependable, dependent, despondent, determined, dignified, discreet, disorderly, dissatisfied, distrustful, dominant, dreamy, dull, effeminate, efficient, egotistical, emotional, energetic, enterprising, enthusiastic, evasive, excitable, fearful, feminine, fickle, flirtatious, foolish, forceful, foresighted, forgetful, forgiving, formal, frank, friendly, frivolous, fussy, generous, gentle, gloomy, greedy, handsome, hasty, headstrong, healthy, helpful, honest, hostile, humorous, hurried, idealistic, imaginative, immature, impatient, impulsive, independent, indifferent, individualistic, industrious, infantile, informal, ingenious, inhibited, initiative, insightful, intelligent, intolerant, inventive, irresponsible, irritable, jolly, kind, lazy, leisurely, logical, loud, loyal, mannerly, masculine, mature, meek, methodical, mild, mischievous, moderate, modest, moody, nagging, natural, nervous, noisy, obliging, obnoxious, opinionated, opportunistic, optimistic, organized, original, outgoing, outspoken, painstaking, patient, peaceable, peculiar, persevering, persistent, pessimistic, pleasant, poised, polished, practical, praising, precise, prejudiced, preoccupied, progressive, prudish, quarrelsome, queer, quick, quiet, quitting, rational, realistic, reasonable, rebellious, reckless, reflective, relaxed, reliable, resentful, reserved, resourceful, responsible, restless, retiring, rigid, robust, rude, sarcastic, selfish, sensitive, sentimental, serious, severe, sexy, shallow, shiftless, shrewd, shy, silent, simple, sincere, slipshod, slow, sly, smug, snobbish, sociable, sophisticated, spendthrift, spineless, spontaneous, spunky, stable, steady, stern, stingy, stolid, strong, stubborn, submissive, suggestible, sulky, superstitious, suspicious, sympathetic, tactful, tactless, talkative, temperamental, tense, thankless, thorough, thoughtful, thrifty, timid, tolerant, touchy, tough, trusting, unaffected, unambitious, unassuming, unconventional, undependable, understanding, unemotional, unfriendly, uninhibited, unintelligent, unkind, unrealistic, unscrupulous, unselfish, unstable, vindictive, versatile, warm, wary, weak, whiny, wholesome, wise, withdrawn, witty, worrying, zany

Polarity Questions in Cebuano

Christine Jane Aquino
University of the East-Caloocan
De La Salle University
christinejane.aquino@ue.edu.ph

Abstract

Interlocutors utilize polarity questions in daily conversations to ascertain whether the proposition uttered is true or false. Despite its crucial role in communication, this has not received much attention in research, and Tanangkingsing's (2009) existing Cebuano references grammar. The current study addresses this gap by investigating how Cebuanos form and answer polar questions, such as the yes or no, existential, and confirmatory or tag questions, based on the conversations with five Cebuano native speakers and their group chat messages. The results show that yes-no questions and declarative sentences may have similar structures but differ in intonation. Such questions may be presented with the particle *"ba."* In addition, it can be answered using the double negative and double positive structures but not the negative-positive and positive-negative structures. The same is true for existential questions – they may follow the same structure of declarative sentences but differ in intonation. They may also appear with the particle *"ba"* in negative and positive existential questions. Similar to the yes-no question, the positive existential questions can be answered using the double negative (that starts with *"wa,"* but not *"di"* or *"dili")* and double positive structures. However, Cebuanos do not answer them using the negative-positive and positive-negative structures. Meanwhile, they answer the negative existential questions using the double negative and positive-negative structures. On rare occasions, they answer it using the negative-positive structure, which can be formed with the interjection *"uy."* Further, the Cebuanos employ *"noh"* and *"di ba('t)"* in their confirmatory or tag questions. They usually place *"noh"* after the preposition and *"di ba('t)"* in either position. Although di can be a short form of the word *"dili,"* the latter cannot be utilized in this type of question; it is only used in dichotomous questions. While this study provides a basic description of how to form and answer polarity questions in Cebuano, it is worth noting that the results should be taken cautiously as these may vary depending on the context of the message, the common ground of the interlocutors, and prosody that contributes to the meaning of the message.

1 Introduction

Cebuano is a major Austronesian language belonging to the Bisayan language family under the Central Philippine of Malayo-Polynesian (Eberhard et al., 2024). Approximately 28.9 million people in the Philippines (NSO, 2020) speak this language. It is primarily used in Central Visayas, Eastern Negros, parts of Eastern Visayas, and much of Mindanao. As it is one of the most widely spoken languages in the Philippines, a wide array of topics on its grammar have been covered, which significantly contributed to the understanding of Austronesian languages.

One of the earliest studies on Cebuano is that of Bell (1976), which provided an in-depth examination of the structure and behavior of Cebuano subjects within transformational and relational grammar frameworks. The study examined the structure and behavior of Cebuano subjects within the transformational and relational grammar frameworks. The study presented the views of the previous investigators on the said topic. It also provided assumptions on the initial and final subjects in relational grammar. It discussed the rules for the initial and final subjects. It further demonstrated how the analysis could be extended to data from causative constructions and several ascension rules. The findings can help

advance understanding of Cebuano syntax within the two frameworks.

Sityar (2000) explored the topic and the y indefinite arguments in Cebuano, which are referential opposites. Sityar analyzed this using a structural account inspired by discourse configurational language analyses. Analyzing the syntactic and semantic properties of these and their discourse functions provided insights into the grammar and structure of the Cebuano language.

Additionally, Wolff (2001) wrote a paper highlighting Cebuano's history, origin, orthography, introductory phonology, morphology, and syntax. This work offers a broad and detailed description of the essential features of Cebuano, which serves as a fundamental reference for scholars studying it.

Years later, Tanangkingsing and Huang (2007) studied passive construction and offered a different view than previous studies exploring the same topic. They provided a detailed analysis of the syntactic and semantic properties of Cebuano passives and their discourse functions and pragmatic implications, which delivers new insights or interpretations that can better improve the understanding of Cebuano grammar.

This was followed by the development of Tanangkingsing's (2013) functional reference grammar of Cebuano, which significantly contributed to Cebuano grammar comprehension.

Further research in Cebuano language includes Caroro et al.'s (2020) work, which delved into the orthographic word parsing in Cebuano. The study also contributed to the field by identifying the grammar rules for hyphenated words, which helped enhance the understanding of Cebuano-Visayan discourse. This also provided implications for computational linguistics in developing language processing tools for Cebuano.

Tan-de Ramos (2021) analyzed the multidimensionality of pronominals in written discourse a year later. The study did a textual analysis to ascertain the position of pronouns in the clauses of the texts. The results show how Cebuano pronominals interact dynamically with the immediate morphological elements. The study may contribute to understanding Cebuano grammar and offer insights into the cultural and sociolinguistic aspects that influence pronoun choice in the discourse.

Finally, Tanangkingsing (2022) studied the pragmatic functions of *unsa* and the enclitics that co-occur with it in a five 30-minute spoken discourse. The study demonstrated how this word functions as an interrogative pronoun, placeholder, and stance marker. The findings shed light on the multifunctionality of *unsa* and offer insights into how the speakers strategically convey meaning and manage discourse using linguistic elements.

While these foundational studies have greatly extended the understanding of Cebuano's grammatical structure and usage, they have focused mainly on syntax, discourse functions, and distinct grammatical phenomena. Despite these contributions, a vital facet of daily conversation in Cebuano, polarity questions, has not acquired the same level of scrutiny. Polarity questions, which include yes-no, existential, and confirmatory (tag) questions, play a key role in determining the truth value of propositions and guiding everyday interactions (König & Siemund, 2007).

Studying polarity questions in Cebuano is essential for several causes. First, it provides a better understanding of its syntactic and semantic structures. Second, it uncovers how Cebuanos manage discourse, convey meaning, and interact socially. Research on similar types of questions in other languages, such as Schachter and Otanes' (1972) work on Tagalog, stresses the more expansive linguistic importance of these forms. For example, Tagalog polarity questions use specific particles like *"noh"* and *"ba,"* added to the negator *"hindi,"* which also appears in Cebuano, suggesting possible shared features among Philippine languages. However, despite their value, polarity questions in Cebuano have not been examined, even in extensive works like Tanangkingsing's (2009) reference grammar.

This study addresses this gap by examining Cebuano's structure and usage of polarity questions. By analyzing authentic dialogues among native speakers, the research presents how yes-no, existential, and confirmatory questions are formed and answered. The findings extend existing knowledge of Cebuano grammar and offer helpful insights into the pragmatic points of language use, benefiting both linguists and language learners.

2 Methodology

2.1 Research Design

The current study relies on conversations as its data to determine and describe the patterns in how Cebuanos form and answer polarity questions. The

qualitative research approach captures this research purpose. Qualitative research features a broad analysis of data, which can disclose inherent themes, meanings, patterns, and objectives that the quantitative approach might fail to notice (Clarke et al., 2019). In particular, the descriptive research design further embodies the goals of this study. A descriptive research design provides a comprehensive, precise, and systemic description of phenomena (Leedy & Ormrod, 2023). This research design only describes the observed phenomenon and does not ascertain the relationships between variables. Hence, the study employs a qualitative research approach and descriptive research design as they catch the intended methods of the study to answer the following research question:

1. How do Cebuanos form and answer polar questions, such as the yes or no, existential, and confirmatory or tag questions?

2.2 Corpus

This study employs a corpus, a casual written conversation of five Cebuano native speakers in a group chat in a messaging app. The data only covers the messages from the group chat in the last quarter of 2023 (October-December), with more or less 450 minutes of conversation. These five group chat members are siblings, all females, ages 40, 48, 50, 54, and 56.

2.3 Data Gathering Procedure

2.3.1 Securing Informed Consent Forms

The researcher secures informed consent forms from the members of the group chat. The form includes the researcher's information, title, and purpose for the study. Moreover, the form discusses the risks, benefits, confidentiality, anonymity, and voluntary participation.

2.3.2 Sorting, Tabulating, and Grouping

The researcher transfers the downloaded data from the messaging app to Microsoft Word. The questions in the conversation are identified by using the find tool in the software and inputting the question mark. The questions found are copied and pasted in a separate file, together with the surrounding sentences, which the researcher interprets as responses to the questions appearing before them in the conversation. The questions and responses were then grouped as yes or no, existential, and confirmatory or tag based on Schacter and Otanes' (1972) description of these questions in their Tagalog Reference Grammar. The data was then grouped to identify patterns and themes quickly.

2.3.3 Data Handling, Retention, and Disposal

The researcher abides by the Data Privacy Act of 2012, ethical guidelines, and legal requirements to safeguard the informants' privacy. Moreover, the researcher collects, organizes, and keeps data carefully to guarantee its accuracy and confidentiality. Further, the researcher ensures that the data gathered from the participants is only used for this study alone.

The data is saved in a password-protected folder for a year. This will be deleted upon the completion of the study.

2.4. Data Analysis Procedure

The data analysis is guided by Schacter and Otanes' (1972) description of yes or no, existential, and confirmatory or tag questions. The researcher analyzes the data manually to identify the themes and patterns in how Cebuanos form and answer the identified types of polar questions. Their structures are compared to the construction of declarative sentences. The common particles, interjections, and (non)existential words employed when constructing and answering such polar questions are also identified. Subsequently, the results were counterchecked by conducting an in-person conversation with one of the members of the group chat from which the data was taken.

3 Results and Discussion

3.1 Yes-No

Consistent with Schacter and Otanes' (1972) discussion of yes-no questions in Tagalog, the results show that yes-no questions (1) and declarative sentences (2) in Cebuano may have similar structures but differ in intonation. Such questions may be presented with the particle *"ba,"* as in:

(1) *Manlakaw (ba) ta?*
Will go out PAR ABS.1pi
'Are we going out?'

(2) *Manlakaw ta.*
Will go out ABS.1pi
'We will go out.'

These insights into language structure and semantics explain how intonation and specific linguistic particles, such as *"ba"* in Cebuano, play pivotal roles in delineating questions from statements despite their syntactical similarities. The particle *"ba"* signals that the sentence is a question, a common trait in various Philippine languages (Reid, 1970), which is also observed in studies on Austronesian languages (Blust, 2013). Essentially, *"ba"* in Cebuano fits into the regional pattern seen in languages across this region.

The same phenomenon is observed in Indonesian, an Austronesian language like Cebuano and Tagalog, where yes-no questions and declarative sentences can be formed similarly and are distinguished only by intonation (Sneddon et al., 2012). This phenomenon may suggest a possible historical and linguistic relationship that can be further explored with other languages.

When examining how Cebuanos respond to this type of question, the research highlights two distinct patterns to express their thoughts clearly: the double negative (3) and double positive (4) structures, as in:

(3) *Di(li). Di(li) ta manlakaw.*
NEG NEG ABS.1pi will go out
'We will not go out.'

(4) *O. Manlakaw ta.*
Yes will go out ABS.1pi
'Yes. We will go out.'

But not the negative-positive (5) and positive-negative (6) structures, as in:

(5) *Di(li). Manlakaw ta.*
NEG will go out ABS.1pi
'No. We will go out.'

(6) *O. Di(li) ta manlakaw.*
Yes. NEG ABS.1pi will go out
'Yes. We will not go out.'

This observation highlights how people consistently use double positive or negative language structures instead of mixing them to keep their communication logical and clear. This insight is consistent with Krifka's (2013) study, which found consistency is critical to ensuring clarity and understanding when answering questions. This concept is similar to the rule of polarity agreement in the German language (König & Siemund, 2007), where speakers stick to either a yes or no response without mixing the two to avoid confusion. This preference for clear, straightforward answers can be traced back to a natural tendency in human cognition to avoid ambiguity and misunderstanding in conversations (Geurts, 2003).

3.2 Existential

Still congruous with Schacter and Otanes' (1972) discussion of existential questions in Tagalog, positive existential questions in Cebuano (7) also follow the same structure of declarative sentences (8) but differ in intonation. They may also appear with the particle *"ba,"* as in:

(7) *Naa (ba) kay kwarta?*
EXI PAR ABS.2s money
'Do you have money?'

(8) *Naa kay kwarta.*
EXI ABS.2s money
'You have money.'

The same is true with the negative existential questions (9) and its equivalent declarative sentence (10), as in:

(9) *Wa (ba) kay kwarta?*
EXI.NEG PAR ABS.2s money
'Do you not have money?'

(10) *Wa kay kwarta.*
EXI.NEG ABS.2s money
'You do not have money.'

Extending the same observation from yes-no questions to existential questions further strengthens the importance of the particle *"ba"* and intonation in distinguishing yes-no questions from statements in Cebuano. The change in intonation to signal interrogativity is also consistent in the Indonesian language (Sneddon et al., 2010) and Javanese (Ogloblin, 2005). This observation emphasizes the potential for a cross-linguistic analysis that could reveal universal patterns or principles governing question formation, which may deepen the understanding of human language processing and its cognitive underpinnings.

Similar to the yes-no question, Cebuanos answer the positive existential questions using the double negative structure that starts with *"wa"* (11) and double positive structure (12), as in:

(11) *Wa. Wa koy kwarta.*
EXI.NEG EXI.NEG ABS.1s money
'I do not have. I do not have money.'

(12) *Naa. Naa koy kwarta.*
EXI EXI ABS.1s money
'I have. I have money.'

but they do not answer this using the double negative structure (13) that starts with *"di"* or *"dili,"* as in:

(13) *Di(li). Wa koy kwarta.*
NEG EXI.NEG ABS.1s money
'No. I do not have money.'

This is logical as the translation of *"di"* is no or not, which may be more appropriate for yes-no questions than existential ones.

Also, they do not answer it using the negative-positive (14) and positive-negative (15) structures, as in:

(14) *Wa. Naa koy kwarta.*
EXI.NEG EXI ABS.1s money
'None. I have money.'

(15) *Naa. Wa koy kwarta.*
EXI EXI.NEG ABS.1s money
'I have. I do not have money.'

Meanwhile, they answer the negative existential questions using the double negative (16) and positive-negative (17) structures, as in:

(16) *Wa. Wa koy kwarta.*
EXI.NEG EXI.NEG ABS.1s money
'None. I do not have money.'

(17) *O. Wa koy kwarta.*
Yes EXI.NEG ABS.1s money
'Yes. I do not have money.'

The identical patterns in the way Cebuanos answer yes-no and existential questions demonstrate their desire to keep the communication rational and unambiguous. This observation further supports Krifka's (2013) study, which can be a natural in human cognition to avoid ambiguity in messages (Geurts, 2003).

On rare occasions, they answer the negative existential question using the negative-positive structure (18) and can be formed with the interjection *"uy,"* as in:

(18) *Dili (uy). Naa koy kwarta.*
NEG hey EXI. ABS.1s money
'Hey, no. I have money.'

The response pattern using interjection *"uy"* suggests an emotional or emphatic nuance. This indicates feeling surprised, which may make the person answer with strong negation of the statement mentioned. The same observation is seen in other Philippine languages, where interjections are used to express disbelief or reinforce assertions (Reid, 1993). This is also observed in other Austronesian languages like Malay and Indonesian, where interjections like *"loh"* and *"kan"* depict mild surprise or emphasis (Gil, 2002). This suggests a broader regional pattern where interjections are integral in managing interpersonal dynamics and conversational flow.

3.3 Confirmatory or Tag

Cebuanos employ *"noh"* and *"di ba('t)"* in the confirmatory or tag questions. They usually place *"noh?"* at the end (19), as in:

(19) *Ulit sya, noh?*
Gluttonous ABS.3s PAR
'(S)he is gluttonous, right?'

And di ba('t) in either position (20, 21), as in:

(20) *Di ba('t) ulit sya?*
NEG PAR gluttonous ABS.3s
'Isn't (s)he gluttonous?'

(21) *Ulit sya, di ba?*
Gluttonous ABS.3s NEG PAR
'(S)he is gluttonous, isn't (s)he?'

This is the same with Tagalog construction of confirmatory or tag questions in which they follow different formulas (Schacter & Otanes, 1972) – *"ano"* can be placed after the proposition while *"di ba"* in either position.

Although *"di"* can be a short form of the word *"dili,"* the latter cannot be utilized in confirmatory or tag questions, as in:

(22) *Ulit sya, dili ba?*
Gluttonous ABS.3s NEG PAR
'(S)he is gluttonous, isn't (s)he?'

Instead, *"dili"* can be used in dichotomous questions, as in:

(23) *Ulit sya? Dili?*
Gluttonous ABS.3s NEG
'Is (s)he gluttonous or not?'

(24) *Ulit sya o Dili?*
Gluttonous ABS.3s or NEG
'Is (s)he gluttonous or not?'

Despite the fact that *"di"* is a short form of *"dili,"* which translates to no or not in English, the findings show that their usage differs depending on the question type. The data shows that *"dili"* is not usually used for confirmatory or tag questions as *"noh"* and *"di ba"* are more appropriate. The data further shows that *"dili"* is more appropriate for dichotomous questions that have two contrasting options as seen in examples (23) and (24). This shows an added layer of complexity in the usage of Cebuano words negative marker, *"dili."*

4 Conclusion

The current study extends Tanangkingsing's (2009) functional reference grammar of Cebuano by providing additional descriptions of how Cebuanos form and answer polarity questions, such as the yes or no, existential, and confirmatory or tag questions.

These findings can help linguists and researchers better understand Cebuano's grammatical structures and rules, contributing to the language's overall knowledge. The results also shed light on the pragmatic aspects of Cebuano language use, which can inform language learners outside of the culture. Finally, this may help teachers design better language learning materials for the Mother Tongue Based-Multilingual Education (MTB-MLE) curriculum and strategies for learners of Cebuano as a second language.

Although this provides a basic description of how to form and answer polarity questions in Cebuano, it is worth noting that the results should be taken cautiously as these may vary depending on the context of the message, the common ground of the interlocutors, and prosody that contributes to the meaning of the message.

Future researchers can include more discourse types in the corpus and investigate whether the initial findings in this study will be consistent despite the different contexts.

Acknowledgments

I would like to express my deepest gratitude to the informants of this study who graciously allowed access to their group chat, enabling the documentation and analysis of their mother tongue.

Furthermore, I am profoundly grateful to Dr. Shirley Dita for her invaluable encouragement and for motivating us to investigate polarity questions across various languages.

Decomposing Directional Serial Verb Constructions in Mandarin：A Preliminary Study

Wu, Tong
Guangdong University of Foreign Studies
salai84@foxmail.com

Abstract

This study investigates directional constructions in Mandarin Chinese from inner aspect perspective by focusing on decomposing complex adjacent directional serial verb constructions and their variants. Past studies have often categorized them as directional complement or verb compounds. A major analysis treats serial verb constructions by internal argument sharing approach, though lacking clear motivation. Some other influential analysis adopts Ramchand's (2008) First Phase Syntax, propose various pre-assumptions to account for linear order or situation type (cf. Hu 2022, Chen 2023). Embracing Sybesma (1999)'s view of aspectual projection s between vP and VP, this study posits that adjacent directional serial verb constructions (pre-object type) reside in inner aspect while split directional serial verb constructions (post-object type) do not. This work extends the hypothesis to directionals and enhances the idea that Aktionsart in Mandarin emerges not solely from the lexicon, but significantly from syntactic structures. This work also assist in sub-categorization of Mandarin directional constructions.

Keywords: directionals, serial verb construction, inner aspect, situation types

1 Introduction

"Directional verb compounds" (see Li and Thompson,1989) or "directional constructions" (V+(V_1V_2), e.g. *ban chu lai* 'transport exit come' = 'bring out (towards the speaker)) in Mandarin Chinese exhibit two key characteristics. First, these constructions have multiple verbs in a single surface string. Second, they present high flexibility in surface as directionals can either be pre-object (adjacent to the matrix verb) or post-object (split from the matrix verb).

To provide fundamental concepts, we'd better start with the three verb classes:

Matrix Verbs (V_m): An open class involving displacement or manner verbs, including transitive verbs like *ban* 'transport', *reng* 'throw' and intransitive verbs such as *pao* 'run', *pa* 'climb'.

V_1: The directional/manner type of verbs (a closed class of 6 to 8 words, e.g. *jin* 'in')

V_2: The deictic/orientational type of verbs (closed class of *lai* 'come' and *qu* 'go')

Directional Serial Verb Constructions (DSVCs) can be further separated into simple and complex constructions. DSVCs also allow being categorized by object

positioning relative to V_1 and V_2. This study starts from simple versus complex DSVCs, and delves into the variations within these categories.

(1) Simple directional constructions
Zhangsan na jin/lai le ta de diannao.
3SG carry in/come PERF his computer
'Zhangsan has carried his computer inside.'

In this pattern, either V_1 or V_2 co-occur with a manner verb in a clause. Complexity arises in terms of post-object conditions. While V_2 can appear after the object, V_1 cannot unless it is combined with V_2 or with a directional complement.

(2) a. Zhangsan na le ta de diannao *jin/lai.
3SG carry PERF his computer *in/come
'Zhangsan has carried his computer inside.'
b. Zhangsan na le ta de diannao jin wu
3SG carry PERF his computer into room
'Zhangsan has carried his computer into the room.'

In the complex directional constructions, V_m co-occurs with both V_1 and V_2, giving rise to three paradigms:

(3) Adjacent complex directional construction - 1
Zhangsan na chu lai le ta de diannao.
3SG take out come PERF his computer
'Zhangsan has taken out his computer.'

(4) Adjacent complex directional construction - 2[1]
Zhangsan na chu le ta de diannao lai.
3SG take out PERF his computer come
'Zhangsan has taken out his computer.'

(5) Split complex directional construction-2
Zhangsan na le ta de diannao chu lai.
3SG take PERF his computer out come
'Zhangsan has taken out his computer.'

This paper focuses on decomposing the adjacent structures through Inner Aspect Approach and will further argue that split structures and adjacent structures are two different configurations. In the second part, we will go through some mainstream discussions. Section 3 presents the data, tests and generalizations while section 4 provides a detailed analysis of adjacent structures through an inner aspect approach.

2 Literature review

Recent analyses have different calls towards DSVCs. Paul (2022) distinguishes complex constructions from simple constructions, proposing that simple constructions are verb compounds. Following Collins' (1997) sense, she believes that complex directional constructions are genuine object sharing serial verb constructions (hereafter SVCs):

(6) $[_{Asp0}\ V_1\text{-}V_2\text{-}V_3\text{-}Asp^0[_{vP1}[_{v1}\ \sout{V_1}\sout{V_2}\sout{V_3}\ v_1[_{VP1}\ O[_{V1}\ \sout{V_1}\ [_{vP2}\ [_{v2}\ v_2[_{VP2}\ pro_i[_{V2}\ \sout{V_2}[_{VP3}\ pro_i[_{V3}\ \sout{V_3}]]]]]]]]]]$

(In her proposal, "V_1" stands for the "V" in my proposal, module V_2 and V_3)To derive the flexible surface forms, she claims that V_2 can either choose to move up independently or along with V_3 without providing a clear rationale for this optionality.

Some other researchers adopt a constructivist approach based on Ramchand's (2008) First Phase Syntax. Both Hu (2022) and Chen (2023) treat V_1

[1] Some researchers (Hu 2022, Chen 2023) refer this variant as split construction. I hold different opinion and believe that its linguistic property is more similar to adjacent construction. This will be further proved in section 3. Here, I name it as adjacent complex directional construction for there is a directional morpheme adjacent to the matrix verb.

and V_2 in complex constructions as V_1-V_2 compound. Hu argues that the directional items merge as Root and take different categories in different syntactic positions. His analysis of complex adjacent DSVCs is as follows:

(7) [$_{vP}$ Agent [$_{v}$ *v*-[V_1-V_2] [$_{PpathP}$ Theme[$_{Ppath}$ ~~V_1-V_2~~]]]]

While Hu's proposal provides great insights into Chinese Root property, it does not adequately address situation type distinctions.

Chen (2023) reorders Ramchand's subevent hierarchy, analyzing adjacent DSVCs as resultatives, distinct from split DSVCs and proposes the following analysis:

(8) [$_{InitP}$ S[$_{Init}$ V-V_1-V_2[$_{ProcP}$ O[$_{Proc}$ ~~V–V_1-V_2~~[$_{ResP}$ O[$_{Res}$ ~~V_1-V_2~~]]]]]

Chen's analysis, however, provides limited explanation of the adapted structural assumptions and stipulations of constraints.

This paper aligns with Paul (2022)'s idea that V_1 and V_2 in complex constructions are not compounds ans supports Chen's (2023) argument that adjacent DSVCs are resultatives. Moreover, this paper proposes that both simple and complex adjacent constructions belong to the same configuration while split constructions belong to another. Building on the Inner Aspect Hypothesis, the study further decomposes adjacent DSVCs.

3 Linguistic data

In this part, I will provide three pieces of linguistic evidence to present the semantic and syntactic differences among different variants.

3.1 Situation types

Situation type, in other words, aspectual nature of directional compounds has drawn interest from certain researchers. Starting at least back to Lu (1977) who observes the resultative effect and directional features of directional constructions in Mandarin. Different researchers have proposed their ideas on the aspect nature of directional constructions. But a unanimous agreement is that directional constructions (at least on [V_1+V_2+O] structures) carry [+telic] feature and this telicity is assumed as a part of "resultative aspect" (Kimura 1984), "perfective aspect particles" (Fang 1992), or "aktionsart marker" (Kang 2001).

This paper believes that situation type differences are a crucial point in exploring the nature of DSVCs and proposes that adjacent DSVCs are achievements while split DSVCs are accomplishments. Following Vendler (1967)'s classification, this analysis considers both achievements and accomplishments to have [+telic] feature. Accomplishments have [+durative] feature while achievements possess [-durative] feature. We apply IN-X-TIME test and FAILED-RESULT test to assess the [±telic] feature. FOR-X-TIME test and ALMOST test are applied to evaluate the [±durative] feature.

FAILED-RESULT test is known to be sensitive to [±telic] feature based on the entailment relationship.

(9) a. Zhangsan pai le [na ge changjing], ke shi mei pai xia lai.
3SG shoot PERF PRN scene but Neg shoot down come
'Zhangsan shot that scene, but (he) hasn't shot (the scene) down.'

b. *Zhangsan pai chu (lai) le [na ge changing], ke shi mei pai xia lai.
3SG shoot down (come) PERF PRN scene, but Neg shoot down come

c. *Zhangsan pai le [na ge changing] chu lai, ke shi mei pai xia lai.
3SG shoot PERF PRN scene down come, but Neg shoot down

The above comparison clearly shows that the object in example (9b) and (9c) is influenced when a V_1 follows *pai* "shoot", the result of *pai chu* "shoot out" becomes irreversible. While without the telic point, the sentence in (9a) remains grammatical even if the result is failed since it is an open-ended event.

IN-X-TIME test can also assess the telic feature in Mandarin Chinese by checking if the action can be completed within a specific time frame:

(10) a. *Zhangsan yi-xiaoshi-nei na le jufaxue-keben.
3SG in-an-hour carry PERF the syntax-textbook
b. Zhangsan yi-xiaoshi-nei na jin (lai) le jufaxue-keben.
3SG in-an-hour carry in (come) PERF syntax-textbook
'Zhangsan has carried the syntax textbook inside in an hour (and has come to the speaker's position).'
c. Zhangsan yi-xiaoshi-nei na le jufaxue-keben (jin) lai.
3SG in-an-hour carry PERF syntax-textbook (in) come.
'Zhangsan has carried the syntax textbook inside in an hour.'

Examples above show that DSVCs can occur with IN-X-TIME test while (10a) cannot. Noticeably the event structure in (10a) is activity which forms an open-ended event. This further enhances the fact that both adjacent and split structures in DSVCs have telic features.

The above tests only prove to the extent that DSVCs can either be achievements or accomplishments. Hence FOR-X-TIME test and ALMOST test are applied to evaluate the [±durative] feature.

In Mandarin, with accomplishments, the FOR-X-TIME test elicits two interpretations while with achievements it yields one interpretation only (Peck, Lin and Sun 2013). When modifying accomplishments, the formed construction can express the amount of time after the telic point is achieved; I refer to this as the result interpretation. It can also express the amount of time the process of achieving the end takes; hence is referred to as process interpretation. With achievements, only result interpretation can be offered.

(11) a. Baba duan shang (lai) wanfan wu fenzhong le.
3SG bring up (come) dinner five minutes PERF
Result reading: 'It has been five minutes since dad brought the dinner up.'
b. Baba duan shang wanfan lai wu fenzhong le.
3SG bring up dinner come five minutes PERF
Result reading: 'It has been five minutes since dad brought the dinner up.'
c. Baba duan wanfan (shang) lai wu fenzhong le.
3SG bring dinner (up) come five minutes PERF
Result reading: 'It has been five minutes since dad brought the dinner up.'
Process reading: 'Dad has been bringing up the dinner for five minutes. (he is still in the process of bringing the dinner up, the dinner is still not ready).'

The interpretation contrast between (11a) and (11c) tells us that adjacent structures present achievements feature while split structures showing accomplishments feature by possessing two readings. The interpretation in (11b) suggests that when there is a directional item adjacent to matrix verb, it shows alignment property with typical adjacent structure (10a), even with a split directional item resides after the object.

Lastly, by applying ALMOST test, achievements would entail unambiguous reading while accomplishments ambiguous readings. It is suggested that event modifier ALMOST can either elicit counterfactual interpretation or incompletive interpretation. The former refers to "almost start the event" and the latter refers to "almost completed the event". Statistics show that adjacent structures behave like achievements while split structures vice versa.

(12) a. Mama jihu ban chu (lai) le zhuozi.
3SG almost move out (come) PERF desk
Incompletive: 'Mom moved the desk and almost moved the desk out.'
b.Mama jihu ban chu le zhuozi lai.
3SG almost move out PERF desk come
Incompletive: 'Mom moved the desk and almost moved the desk out.'
c. Mama jihu ban zhuozi (chu) lai le.
3SG almost move desk (out) come PERF
Counterfactual: 'Mom almost begun moving the desk out.'
Incompletive: 'Mom moved the desk and almost moved the desk out.'

The ambiguity contrast between (12a) and (12c) further supports the generalization that adjacent structures present achievements feature while split structures showing accomplishments feature. The reading in (12b), further supports the idea that so long as some directional item α adjacent to matrix verb, it shows achievement features even with a split directional item β which resides after the object.

3.2 Thematic relationships

By examining the thematic relationship between the verb in the main clause and the object of directional construction, it is observed that different variants take different thematic relationships.

In adjacent structures, no direct thematic relationship exists between V_m and object. Rather, the "objects" function as the argument of adjacent directionals components, reflecting an affectedness relation：

(13) Nolan pai chu le Oppenheimer de chenggong yu beiju.
3SG shoot out PERF 3SG POS success CON tragedy
'Nolan has shot out Oppenheimer's success and tragedy.'

On the contrary, there is direct thematic relationship between V_m and Object in split structures:

(14) Zhangsan na keben chu lai le.
3SG take textbook out come PERF
'Zhangsan has taken the textbook out.'

The textbook here is the direct object of matrix verb, and it takes patient theta role, with or without V_1V_2.

3.3 Linear relationship with viewpoint aspects

The placement of the perfective marker *le* in relation to adjacent and split DSVCs

highlights a structural distinction. In adjacent structures, *le* can only appear after the entire directional phrase and cannot intervenes between the serial verbs (cf. Yang 2009):

(15) a. *Zhangsan duan le shang lai [yi wan tang].
3SG serve PERF up come 1-CL-soup

b. *Zhangsan duan shang le lai [yi wan tang].
3SG serve up PERF come 1-CL-soup

c. Zhangsan duan shang lai le [yi wan tang].
3SG serve up come PERF 1-CL-soup
'Zhangsan has served the soup up to the table.'

This distribution suggests that the matrix verb and the directionals components are syntactically cohesive in adjacent structures, preventing perfective aspect markers from intervening. Cartographically, this restriction also implies that the syntactic position of outer aspect occupies a projection higher than that of directional serial verbs in adjacent DSVCs.

4. A preliminary proposal

Building on the linguistic facts presented in Section 3, this study proposes that adjacent DSVCs function as resultatives. The current analysis is that adjacent and split directional constructions are two different configurations and therefore require separate syntactic analysis. In the following parts, I will first introduce Inner Aspect Hypothesis which investigates how Aktionsart plays a role in Mandarin. And then, a detailed analysis of complex adjacent structures will be provided.

4.1 Inner aspect hypothesis

Inner aspect hypothesis in Mandarin investigates "what sort of substructures events are composed of" (Verkuyl 1988). It is proposed by Sybesma (1999), developed by the spirit of Travis (2010), modified by the joint effort of Xuan (2008, 2011), Shen and Sybesma (2012), Sybesma (2015, 2017):

(16) $[_{vP}[_{v}\ v^0[_{Asp3P}[_{Asp3}\ Asp3^0[_{Asp2P}[_{Asp2}\ Asp2^0[_{Asp1P}[_{Asp1}\ Asp1^0]VP]]]]]]]$

There are three aspectual projections involved between VP and *v*P. This proposal mainly utilizes Asp2P(PhasalP) and Asp1P(TelicityP). Asp1P(TelicityP)marks the structure as telic (cf. Xuan 2008) Asp2P helps "reducing the multi-point telicity scale to a two-point scale" (Lu et al. 2019) Asp3P (RealizationP), denotes realization of the projected endpoint of the event, is occupied by perfective *le* or vice versa, is not the main issue in this proposal, yet still presented for a clearer structure of the whole inner aspect (cf. Sybesma 1999). Object is derived at [spec Asp1P]: Theta-role assignment has been considered as a Spec-Head relationship (Chomsky 1993, Xuan 2008, Travis 2010) .

4.2 The structure

Drawing on the evidence presented in Section3, this study proposes that in adjacent structures, V_1 occupies the head of Asp1P, marking the event's telic point, while the object is merged in [spec Asp1P]:

(17) Zhangsan na jin le jufaxue-keben.
3SG carry in PERF the syntax-textbook
'Zhangsan has carried the syntax textbook inside.'

[$_{vP}$ Zhangsan[$_{v}$ v^0[$_{Asp3P}$[$_{Asp3}$ *le*[$_{Asp1P}$ *jufaxue-keben*[$_{Asp1}$ *jin*] *na*]]]]]]]

Unlike the head of Asp1P which defines the telic endpoint for the event, V_2 presents different features by contributing a distinct aspectual layer. The analysis below provides three key arguments regarding semantic dependency, progressive compatibility and A-bar movement restriction to support this claim.

Semantically speaking, in (18), the object *kuzi* 'pants' cannot be directly interpreted as the object of *qu* 'go'. Namely, (18) cannot be interpreted as "There is a wearing event and the result is that the pants is went". Moreover, if V_1 is placed aside, a construction like *kuzi qu* ('pants go') is semantically uninterpretable in Mandarin. This dependency supports the hypothesis that V_2 functions to enhance the event's completion that the telic point is achieved, rather than to serve as an independent verb.

(18) Zhangsan ba kuzi chuan jing qu le.
3SG ba pants wear into go PERF
'Zhangsan has worn the pants.'

Moreover, complex adjacent structures exhibit different aspect interpretation, rendering them incompatible with progressive aspect marker:

(19) a. Zhangsan na jin lai le jufaxue-keben.
3SG carry in come -PERF syntax-textbook
'Zhangsan has carried the syntax textbook inside (and has come to the speaker's position).'
b. *Zhangsan zhengzai na jin lai jufaxue-keben.
3SG PRG carry in come the syntax-textbook

Attempts to modify complex adjacent structures with the progressive marker *zhengzai* results in ungrammaticality in (19b) while simple adjacent structures remains grammatical in (19a).

Thirdly, VV_1O structure resists operations involving A-bar movement such as passivization, topicalization, or relativization, while VV_1V_2O structures readily accommodate these. Here I illustrate this restriction through topicalization:

(20) *Diannao, Zhangsan na jin le.
Computer 3SG carry in PERF

On the contrary, VV_1V_2O structures are grammatical in these cases:

(21) Diannao, Zhangsan na jin lai le.
Computer 3SG carry in come PERF
'Zhangsan has carried the computer inside.'

However, there's a challenge from split structures since they present similar linear structure if undergo the a-bar movements stated above. Again, this similarity is presented in topicalization context:

(22) a. Zhangsan na le diannao jin lai.
3SG carry PERF computer in come
'Zhangsan has carried his computer inside.'
b. Diannao, Zhangsan na jin lai le.
Computer 3SG carry in come PERF
'Zhangsan has carried the computer inside.'

As stated in (2) VOV_1 pattern is not grammatical, hence it naturally cannot be a-bar bound which seemingly explains the ungrammaticality in (20), making independent A-bar movement test on adjacent structures impossible to be applied.

To avoid this problem, we use sentences that have asymmetrical distribution of adjacent and split variants as the example:

(23) a. Zhangsan ku chu le yan lei.
3SG cry out PERF tears
'Zhangsan cried out tears.'
b. Zhangsan ku chu lai le yanlei.
3SG cry out come PERF tears
'Zhangsan cried out tears.'
c. *Zhangsan ku le yanlei chu.
3SG cry PERF tears out
d. *Zhangsan ku le yanlei chu lai.
3SG cry PERF tears out come

(23a, b) only has adjacent configuration but not split configuration which is shown in (23c, d). Interestingly, A-bar movement is still restricted in asymmetrical cases, suggesting that adjacent structures are indeed restrained:

(24) a. *Yanlei, Zhangsan ku chu le.
Tears, 3SG cry out PERF
b. Yanlei, Zhangsan ku chu lai le.
Tears, 3SG cry out come PERF
'Tears, Zhangsan cried out.'

To sum up, the current generalization is that the object in VV_1O configuration cannot be a-bar bound but vice versa in VV_1V_2O configuration. Hence V_2 must sit in another projection to provide a landing site for the object to move. This fact further supports the assumption that V_1V_2 cannot be a compound that derives in the same syntactic position.

My preliminary analysis of this phenomenon is that spatial items (directional deictic verbs) can also serve as phasal verbs (phase complement in Chao (1968)). By carrying the semantic meaning of point of view from which a speaker perceives an event, they occupy $Asp2P^0$ to close off the event. Hence V_2 is in the head of Asp2P:

(25) [$_{vP}$Zhangsan[$_{v}$ v^0[$_{Asp3P}$[$_{Asp3}$ *le*[$_{Asp2P}$[$_{Asp2}$ *lai*[$_{Asp1P}$*jufaxue-keben*[$_{Asp1}$ *jin*]*na*]]]]]]]

Under my hypothesis, V_1 resides in Asp1P, while V_2 occupies in Asp2P. Moreover, to explain why A-bar movement is blocked when only $Asp1^0$ is occupied, we need to recall the Barrier condition (cf. Baker 1988):

Barrier (final version): For every α included in XP, XP is a barrier iff (a) and (b) hold.

a. α does not occupy an escape hatch in XP.

b. X is distinct from Y, where Y is the head of YP, and YP is the minimal maximal projection which does not exclude XP.

Based on my hypothesis, Asp2P and Asp1P are two different functional projections, satisfying principle (b), we now need to satisfy principle (a). However, since a standard spec to spec movement is used to move the object up, the object can always occupy the escape hatch. Hence certain constraints need to be developed here to block the A-bar movement of object. My preliminary analysis to this is to propose the Directional Stranding Constraint:

For directional constructions, any α that possesses [spec Asp1P] will be stranded in Asp1P, unless it is governed by some other functional projection Asp2P.

5. Conclusion

This study examines the composition of Directional Serial Verb Constructions (DSVCs) in Mandarin Chinese. Serial verb constructions have been an essential topic in linguistic research due to the complex interaction of serial verbs and their flexibility in surface structure. Focusing on the aspectual properties of DSVCs, this

analysis contributes to a clearer understanding of Mandarin event structure and offers a more precise categorization of directional constructions.

The finding extends Inner Aspect Hypothesis to directionals, supporting the discovery that situation type distinctions in Mandarin are not solely lexically computed but are also deeply embedded with syntactic layers. This framework is also in line with Roberts and Roussou's (2003) hypothesis on grammaticalization, allowing directionals to move up and be integrated to encode inner aspect values.

While the analysis presented here mainly addresses adjacent DSVCs, further research is needed to clarify the structure and constraints of split DSVCs. Based on the situation type difference and thematic difference discussed in previous sections, the current proposal hypothesizes a structural position for split constructions as follows:

(26) [$_{vP}$ S[$_{v}$ *v*[$_{VP}$ O[$_{V}$ V] GoalP]]]

It is proposed that the directionals in split constructions are Goal Phrase, bearing the intention of goal position instead of directional information, merged as the complement of the matrix verb. Future research will investigate into the nature of split DSVCs to expand this preliminary model.

Abstract

This study uses multi-dimensional analysis to explore the linguistic features of literary criticism by professional critics and common readers. We analyzed 68 linguistic features to identify patterns and differences in critical discourse. The findings show that professional critics tend to be more informational, explanatory, evidence-based, and focused, while common critics are generally less organized, more personal, and dispersed. Understanding these disparities helps bridge the gap between academic and public discourse, establishing a mutual basis for communication and positive interaction, and provides practical guidance for making literary criticism more accessible.

1 Introduction

Literary criticism has historically divided professional and common readers (Johnson, 1779; Woolf, 1953). This divide is evident not only in the perspectives and depth of criticism but also in the linguistic features and modes of expression. Common readers' online reviews have become increasingly active, creating a discourse system distinct from traditional professional criticism. Yet, there's a lack of empirical research on these linguistic differences. Studies have explored this from sociological (Koreman et al., 2024) and literary theory (Long, 2024) perspectives, but not much from a linguistic perspective using large-scale data.

This study aims to bridge this gap by analyzing discourse variation between professional and common readers in Chinese foreign literature criticism from 2008-2022, including academic abstracts and Douban book reviews. The research objectives are: 1) Build a comparative corpus of professional and user reviews. 2) Analyze 68 linguistic features to identify patterns. 3) Use factor analysis to uncover key dimensions. By conducting multi-dimensional analysis, this research seeking to address the following questions.

1. Are there differences between professional literary criticism and general literary reviews across the 5 dimensions?
2. What register variations of professional and common literary critics do the dimensional differences between the two types of reviews reflect?

2 Literature Review

2.1 Professional Readers and Common Readers

The dichotomy between professional readers and common readers remains a contentious divide, characterized by the opposition and estrangement between the two groups, resulting in a lack of interaction and communication basis. This estrangement is evidenced by a perceived alienation in literary criticism, due to an overemphasis on academic and theoretical aspects (Yin, 2020). This shift has professionalized and academized literary criticism, marginalizing the interests and concerns of ordinary readers, and making literary criticism more exclusive and less accessible (Miall & Kuiken, 1998).

Despite its objective nature of aesthetic value judgments and aesthetic appreciation as the fundamental purpose, professional critics maintain a dominant position in literary criticism. As authority figures, they exert substantial influence in the cultural field, controlling the discursive power of literary criticism (Bourdieu, 1980; Van Rees, 1989; see also Kristensen & From, 2015). From an external perspective, their institutional embeddedness grants traditional critics legitimacy and thus provides them with authority (Janssen, 1997; Verboord, 2010). Discourse delineates their territory and signal how their classifications should be compared to those of others (Tominc, 2014; Van Leeuwen, 2007). Specifically, Koreman et al. (2024) suggests that professional critics use specific strategies to reinforce their authority.

This dominance and authority of professional critics create an ongoing tension with common readers, who often approach literature differently, highlighting the need of diverse perspectives and the de-canonization of critics. Previous studies lack consensus on the precise definition of the "common reader." Johnson did not explicitly associate this group with a particular class, profession, or level of education (Kernan, 1989:232). Prior to the 18th century, literary works were predominantly aimed at "refined readers" (Engell, 1989:160), who were typically well-educated and equipped to appreciate the subtleties of literature. Over time, the notion of the ordinary reader expanded. During the Neoclassical period, ordinary readers were viewed as individuals embodying universal human traits, with their reading experiences and emotions considered central to literary criticism. According to Zhang & Yin (2022), the term "ordinary readers" encompasses both actual individuals and idealized readers, but primarily refers to a broad audience, comprising most readers who fall outside the realm of literary professionals or those engaged in literary careers.

The rise of electronic reading and online platforms has provided cultural participants not only with more options to inform common readers on the cultural products but also with places where they can voice their opinions (Beaudouin & Pasquier, 2017; Verboord, 2014). Consequently, the power balance between audiences and critics has changed and new forms of criticism have emerged (Frey, 2014; Jaakkola, 2021; Kristensen & From, 2015).

Douban Books Reviews, a popularized platform for ordinary readers, serves as a public forum for literary critics with personal aesthetic perspectives and democratic critical analyses of literary works. Over two decades, Douban's online literary criticism has evolved alongside traditional literary criticism, forming a new variant known as Douban literary criticism (Long, 2024).

2.2 Biber's Multi-dimensional Analysis

Register, as a discourse type that emerges to serve different communicative purposes, is a linguistic variety closely associated with specific usage contexts (Biber & Conrad, 2019:6; Halliday, 1978: 31). It reflects the tendency to use certain linguistic features in relation to the specific functions and themes of a text. Different disciplines construct their disciplinary cultures and knowledge through distinct discourse conventions, such as the expression of authorial stance, participation, and the organization of arguments (Hyland & Bondi, 2006). In the context of the disciplinary characteristics of academic discourse, research on the linguistic features of literary academic discourse can reveal certain unique aspects of professional literary criticism.

Biber (1988) proposed the Multi-Dimensional (MD) Analytical Approach, which combines large-scale corpora with dimensionality reduction techniques to extract register dimensions. This method deconstruction features at both macro and micro-level to examine language differences across disciplines and to describe precise language choices in specific contexts (Biber, 2006; Hardy & Römer, 2013). It provides comprehensive methodological support for

analyzing register variation and features in different types of literary criticism discourse.

In English studies, applying multi-dimensional analysis to the study of academic language features and register variation has recently become a focal point in academic writing research. For example, Gray (2013), Xu & Zhang (2023) analyze linguistic strategies in academic research articles, and the conclusions of English research articles (RAs) in linguistics using a multi-dimensional analysis (MDA) method. Abstracts are crucial for evaluating research paper quality and represent article pragmatic tendencies (Hyland, 2000: 63). Multi-dimensional analysis has been applied to humanities journal abstracts (Zhang et al., 2018; Zhao et al., 2021). These studies primarily used Nini's (2015) Multidimensional Analysis Tagger (MAT), based on Bibber's framework with 67 features. While demonstrating MDA's applicability to English academic discourse analysis, these studies also revealed limitations in preset linguistic features.

Multi-dimensional analysis in Chinese academic discourse remains limited due to technical constraints. Notable studies include Zhu (2014), Liu (2018; 2019), and Yuan (2022), who identified linguistic feature patterns across 7 dimensions in humanities and social sciences journals. These works utilized computational techniques, advancing and expanding the research scope in Chinese stylistics and language variation. However, multi-dimensional analysis has not yet been applied to Chinese foreign literature studies.

3 Methodology

3.1 Identification of Professional Readers and Common Readers

For the two kinds of reviews, the distinction between professionals and common readers might not be clear-cut, as, in recent times, "the boundaries between different types of critics (and reviewers) have blurred" (Feldman, 2021). Even though the professional readers build their authority relying on (perceived) expertise, many types of expertise are hardly unique to professional critics (Koreman et al., 2024). Many of the "amateurs" contributing online have educational credentials and specialized knowledge comparable to "professionals" (Kammer, 2015).

This study distinguishes between "professional critics" and "common critics" based on the authority of the researchers. The former refers to authorized publications that have been peer-reviewed, with critics typically holding a certain social research status. The latter concerns individuals, who contribute reviews on an individual basis without the 'institutional legitimacy and authority' of professionals, as these amateurs are not affiliated with or employed by legacy media (Kammer, 2015: 874).

3.2 Corpus Selection and Preprocessing

This research gathered and selected literary criticism data from the past fifteen years (2008-2022), with the aim of representing the voices of both "professional readers" and "common readers" to a certain extent. For professional readers, we have chosen a total of 5720 Chinese abstracts from five authoritative foreign Literary studies journals (CSSCI Index). For general readers, we have manually selected 133 classic foreign literature works out of online book reviews retrieved from the *Douban top 250 book list*. After eliminating review entries with a text length of less than 180 tokens, we have obtained a total of 4536 reviews. Using different sources for corpus data collection, ensuring that the time span is aligned and filtering the text as evenly length as possible as a compromise in the absence of more information from the comments.

In this research, we built comparative corpora: the professional reader corpus (i.e., Pro Corpus) which contains 3,239,857 tokens, and the common reader corpus (i.e., Com Corpus) which contains 3,055,063 tokens. All data are cleaned, including removing full English comments, unnecessary numbers and informal punctuation.

After the comparison of tagging toolkits, including `NLPIR-ICTCLAS`, `NLTK`, `HLT-LTP4`, and `Jieba`. `Jieba` provides the most comprehensive and abundant part-of-speech annotation system and labels, and it was used as a key reference. Word segmentation and part-of-speech tagging are performed using `Jieba`. The descriptive information of the corpus is presented on Table 1.

3.3 Selection of Linguistic Features

Due to the insufficient automatic instruments of the Chinese grammatical system with functional interpretations comparing with English, previous research has predominantly adopted a combined approach of automatic and manual annotation to construct linguistic features. For instance, Liu (2018; 2019) employed a combination of word segmentation systems and manual annotation, extracting 63 and 72 linguistic features respectively, encompassing lexical, grammatical, and rhetorical aspects.

Regarding feature selection, the study referred to the 88 Chinese features proposed by Zhu (2014), which is one of the most comprehensive Chinese feature lists accessible. Given the differences in corpus samples, features with high Variance Inflation Factor (VIF) values were eliminated based on VIF, and appropriate merging and refinement of features were conducted. Meanwhile, linguistic features crucial to register variation in literary criticism were selected, such as specific word classes, grammatical categories, and syntactic structures related to the communicative functions of the target register (Pan, 2022).

68 linguistic features were extracted, with statistics on the frequency of occurrence in each abstract and standardized frequency per 1000 tokens. These features belong to 21 categories: Tense and aspect markers, Place and time adverbials, Pronouns, Nominal forms, Expressions, Passive forms, Stative forms, Subordination features, Prepositional phrases, Adjectives and adverbs, Lexical specificity, Auxiliary, Lexical classes, Modals, Verbs and specialized verb classes, Co-ordination, Negation, Exclamation & interjection, Numerals, Quantifiers, and Onomatopoeia.

3.4 Data description

This study employed the Python statistical package to conduct an Exploratory Factor Analysis on the normalized data. First, we examine the interpretability of the variables, using `factor_analyzer` to conduct KMO and Bartlett's test, yielding a KMO value of 0.671. The Bartlett's test of sphericity was significant ($p = .000$ ($< .05$), indicating that the data are suitable for factor analysis. Factor analysis was employed to ascertain the loadings of each feature under each factor. A Kaiser Normalization with Varimax Rotation (Kaiser, 1958) is employed to calculate the factor loadings. Through a Kaiser normalization, each row of a table of loadings and cross-loadings is divided by the square root of its communality (Kock, 2014a). This has the effect of making the sum of squared values in each row add up to 1. The first 6 factors were selected to establish the

Type	Source	Document	Min Length	Max Length	Mean Length	Tokens
Pro	《外国文学》(Foreign Literature)	5720	51	605	224.03	3,239,857
	《外国文学》(Foreign Literature)					
	《外国文学评论》(Foreign Literature Review)					
	《当代外国文学》 (Contemporary Foreign Literature)					
	《外国文学》 (Foreign Literature)					
Com	Douban Online Review (Foreign Literature)	4536	181	255	313.09	3,055,063

Table 1: Description of Comparative Corpus Pro, Com. The corpora consist of professional academic abstracts and Douban book reviews from 2008 to 2022. The book reviews are based on foreign literary works from the Douban Top 250 book list.

dimension referring to the Scree Plot (Figure 1). A total of 40 language features and their loading values were obtained, accounting for 27.546% [1] of the Cumulative Variance Explained. According to Conrad & Biber (2001:39), the linguistic features of dimensions 6 and 7 in the multidimensional analysis are relatively rare, and most studies have discarded them. This study only examines the first 5 dimensions.

3.5 Factor Analysis and Dimension score calculation

Dimensional interpretation relies on salient linguistic features with communicative functions, defined by absolute loading values exceeding 0.3. The magnitude of these values correlates with the feature's importance in interpretation. Features are categorized as positive or negative based on their factor loadings, representing two directions (positive and negative) within a dimension. Dimensions may include feature sets with similar or divergent orientations, showing complementary distribution across registers. According to Conrad & Biber (2001:39), the linguistic features of dimensions 6 and 7 in the multidimensional analysis are relatively rare, and most studies have discarded them. Dimensional scores for comparative corpora validate the 5 dimensions in distinguishing between professional literary criticism and common reviews. The process involves calculating standardized score (z-scores) for linguistic features in both corpora using Python. Then compute dimensional scores for each text by summing positive loadings and subtracting negative loadings. Averaging these scores to obtain the final register dimensional score (Figure 2).

According to the standardized score of the language feature frequency data, the scores of each text in 6 dimensions are obtained by quantitative weighting of the factor loadings of each dimension. After the score is standardized, it can be quantitatively compared regardless of the length of the text.

The following analyzes and names the first 5 dimension of the humanities and social sciences register with reference to the linguistic characteristics of each dimension and the mean of the domain dimension of the discipline, combined with specific texts.

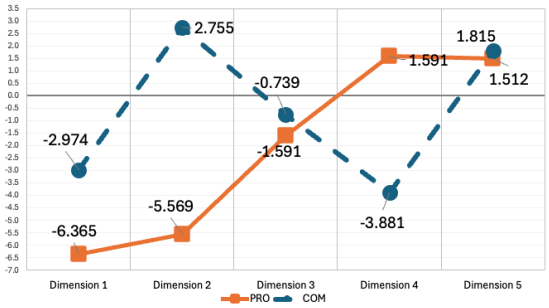

Figure 2: Dimension score of 5 dimensions

4 Dimensional analysis of texts in both registers

4.1 Personal subjective stance vs. Objective description and interpretation

The first dimension (Table 2) clusters linguistic features expressing personal perspective and emotion, including adverbs, adjectives, state words (d, a, z), and amplifiers (ap), adding descriptive and evaluative resources. Adverbs include "amplifiers", "emphatics", "downtoners", and "hedges". The first two reinforcements mark higher topic engagement (Chafe, 1982). For evaluative language, it has been emphasized in academic discourse by Hyland (2005). The structure of "是(vshi)" verb makes more concise judgments, when used with predicates, conveys sparse information and often pairs with demonstrative pronouns (rzv) to express judgments or evaluations. Brainerd (1972) grouped pronouns to explain less informative, less accurate, or less formal styles, rarely appearing in formal written texts that require clarity and formality.

In the use of personal pronouns, the first-person pronoun (rr1) appears in this dimension.

[1] The Cumulative Variance Explained in Literary content is weakly lower than in other fields of general humanities.

	Linguistic Features	Label	Loadings
POS	Total adverbs	d	0.671
	Total pronouns	r	0.596
	Amplifiers	ap	0.468
	Demonstrative pronoun	rz	0.455
	First-person pronouns	rr1	0.454
	Total other adjectives	a	0.440
	Numerals	m	0.397
	Interjection	y	0.393
	Proverb	i	0.383
	Predicate demonstrative pronoun	rzv	0.360
	Adjectives as noun and predicate attributes	z	0.328
	Concessive adverbial subordinators (although, though)	cas	0.318
	Verb "shi" as main verb	vshi	0.310
NEG	Public verbs	pv	-0.656
	Verbs functioning as noun	vn	-0.538
	Preposition	p	-0.478
	Coordinating conjunctions	cc	-0.378

Table 2: The linguistic features of the dimension 1 and factor loadings. POS and NEG represent the positive and negative linguistic features according to factor loadings respectively (similarly hereinafter).

Although some scholars argued that the use of first-person pronouns shows the author's ownership and identity posture towards academic propositions and knowledge creation (Hyland, 2012). However, in literary criticism, professional critics intend to strip away the identity of the author, that is, avoids subjective expressions, such as "我(I)", "我们(we)", "笔者(author)", "本文/拙文/拙作(this article)", etc. This separate their personal preferences from the quality of the book through reflexive reading (Chong, 2013: 274–275). On the contrary，the personal point of view (articulated, e.g. by the usage of first-person pronouns) is found in common reviews (De Jong and Burgers, 2013; Skalicky, 2013). This is consistent with what the general readership holds, a popular aesthetic "that emphasizes functional, emotional and experiential ways of evaluation (Van Venrooij and Schmutz, 2010: 397). Common readers' interpretations are based on personal feelings and life experiences, providing more emotional and personal reflection of how literary works are received and their impact on society. These characteristics reflect the readers' evaluation of texts as interactive, low information density, context-dependent, and less formal style.

The factor loadings of the negative feature groups of this dimension, such as the common verb (pv) and the function of the verb as a noun (vn), were -0.656 and -0.538, which tended to reduce the interactivity and enhance the descriptive and written. Preposition(p) contains prepositions that represent means and credentials, such as "凭借", "通过", "依照", etc., emphasizing the basis for objective statements and inferences, which helps to enhance logical coherence and persuasiveness. The positive characteristics (*pv*, vn, **p**) are indicated with different symbols.

[1]当代小说*探讨*的核心问题是文本自身的运行。戏仿是文本*言说*自我的方式之一，将重心从被表现之物转向表现过程。什维亚**通过**戏仿各种文学类型检验作家继承和创新文学遗产的能力。本文力图**通过**分析什维亚作品中的戏仿现象**来**思考书写与意义、书写与文明之间的关系。

Example [1] reflects professional literary critics' preference in descriptive and objective evaluation concepts, "moving from knowledge that is embodied or instinctive to knowledge built on rational arguments" (Chong, 2013: 273), engaging in "evidence-based reviewing" (p. 272).

The dimension score of professional literary reviews and common reader -6.365 and -2.974 respectively, with a significant difference ($p < 0.05$). This indicates more frequent co-occurrence of negative features in professional reviews, suggesting stronger objectivity. However, the overall factor loadings and dimension scores are relatively low.

Professional literary criticism is rooted in extensive literary background, theoretical knowledge, and professional analysis. Critics "invoke conceptions of art (literature) that resonate with the wider field of cultural production" (Janssen, 1997; Van Rees, 1989).

Conversely, common critics "rarely translate these discursive propositions into an argumentation which explains in a more detailed way why this specific emotion is evoked" (Koreman et al., 2024), focusing on personal emotional statements and subjective assertions. This reveals the tendencies of professional and common literary critics, in this dimension, while both texts generally employ interpretive and descriptive language features, literary studies, as an interpretive discipline (Becher, 1989), are more closely connected to aesthetic consciousness and interpretability.

4.2 Literary narrative vs. Evidence-based

	Linguistic Features	Label	Loadings
POS	total verbs	v	0.817
	verbs used as adverb	vd	0.739
	necessity modals	nm	0.394
	possibility modals	pm	0.359
	private verbs	prv	0.356
	predictive modals	prm	0.353
	directional verbs	vf	0.332
	total conjunctions	c	0.327
NEG	total nouns	n	-0.632
	name of persons	nr	-0.521
	names of persons translated based on pronunciation	nrt	-0.397

Table 3: The linguistic features of the second dimension and factor loadings.

For the second dimension, common readers focus the narrative of literary content. They situate the content in their own life and often discuss their connection with the book. This accords with the findings of previous studies (De Jong and Burgers, 2013; Skalicky, 2013; Verboord, 2014) indicating that the amateurs often refer to their own experience. This dimension includes private verbs (prv), which express the psychological activities of characters in the text. Along with event modality verbs (Cui, 2003) indicating necessity (nm), expressing possibility (pm), predicative modal words (prm), these linguistic elements collectively contribute to a dimension that reflects personal involvement, interaction and subjective expression. The presence of private verbs allows for the articulation of internal states and cognitive processes, while the various modal verbs and directional verbs facilitate the expression of attitudes, possibilities, and movement in both literal and figurative senses. The co-occurrence of these features suggests a discourse style that is more informal, personal, and narrative-driven. It contrasts with more objective, impersonal academic writing styles.

Negative features primarily focus on proper nouns such as personal names (nr), translated place names (nrt), and geographical names (ns). As Biber (1988) posits, nouns are the main carriers of referential meaning in a text, indicating a text with higher information density. It is commonly found in literary history studies, particularly in the analysis of authors' lives and works. This information provides the basis for in-depth analysis and evidence-based research.

4.3 Colloqiualism vs. Explanatory

	Linguistic Features	Label	Loadings
POS	exclamation	e	0.9716
	English Words	eng	0.9718

Table 4: The linguistic features of the dimension 3 and factor loadings.

Exclamations (e) and English Words (eng) have high factor loadings in this dimension (Table 4), representing colloquial and professional expression features respectively. Exclamations are often associated with propositional modality, expressing the speaker's attitude, stance, and even emotions (Cui, 2020), and indicating informality and orality. English Words denote specialized terminology, often used to elaborate or specify literary concepts or definitions, enhancing precision and reducing ambiguity, see [2]. These characteristics suggest that this dimension is closely linked to the different reviewer's explanatory, and colloquial narrative discourse traits respectively.

[2] 雌雄同体(androgyny)这个文学构想是伍尔夫研究,尤其是《一间自己的房间》研究中经常被提及的重要概念之一。

4.4 Textual richness vs. Monotony

In Table 5, positive features in this dimension

	Linguistic Features	Label	Loadings
POS	type token ratio	ttr	0.358
NEG	total auxiliary	u	-0.8586
	auxiliary de for the possessive case of noun	ude1	-0.7556
	auxiliary le aspect article	ule	-0.3217

Table 5: The linguistic features of the fourth dimension and factor loadings.

is type/token ratio (ttr)，which is a measure of morphological richness, and reflects the diverse usage of words with different syllables in the text (Xie, 2024; Liu，2019). Academic texts exhibit high lexical complexity, featuring numerous multi-syllabic words, particularly two to four-syllable terms. This characteristic enhances information density and semantic precision in expressing complex concepts. The elevated type/token ratio indicates rich word patterns and precise expression, aligning with the abstract nature that literary papers pay more attention to proposing and presenting the arguments (Conrad & Biber, 2001: 29). This linguistic feature enhances information density by conveying more specific and specialized content, allows for greater semantic precision and dispersion (diversity) of discourse content in expressing complex concepts.

Negative features include auxiliary words (u), the aspect marker "了" (ule), and the structural particle "的" (ude1), reflecting lexical monotony. The frequent use of "的", which expresses the modifying or restrictive relationship between attributes and head words, demonstrates vocabulary uniformity through its repetitive usage in the text.

The dimensions of professional literary criticism and general reader reviews are 1.501 and -3.881 respectively, with a significant difference ($p < 0.05$). This indicates that professional literary criticism exhibits significantly higher lexical richness and information density compared to general reader reviews.

4.5 Structural Controllability

Dimension 5 (Table 6) focuses on negation

	Linguistic Features	Label	Loadings
POS	mean word length	wl	0.9886
	negation	ngt	0.9889

Table 6: The linguistic features of the dimension 5 and factor loadings.

(ngt) and word length (wl). Negation serves functions such as emphasis, contrast, and exclusion. By modulating the information flow, it enables speakers to convey messages more effectively and control discourse structure, which makes the content more involved, and topics concentrated, as exemplified in [3].

[3] 此次的伦理转向**不是**回到 19 世纪的文学批评传统，**而是**对形式主义的反驳和对文学作为一种认知方式的重新定位。此次的复兴**也不是**道德批评的重申，**而是**伦理批评的进一步发展。

5 Conclusion

This study reveals major differences in language use between professional critics and common readers in Chinese foreign literature criticism. These disparities reflect divergent purposes, audiences, and modes of expression, while also highlighting the power dynamics and discourse constructions within the field. Observations based on MDA show that professional literary criticisms focus on extensive literary evidence, whereas common critics are often rooted in personal emotions and experiences evoked by literary narratives. The differences indicate that, although both groups employ interpretive and descriptive language features, general readers exhibit a more personalized aesthetic perspective. Their voices have become an essential part of literary criticism, influencing diverse interpretations of literary value and critical practices. This research provides a new approach to understanding literary criticism from the perspective of varying discourse, emphasizing the interplay between expert analysis and common reader engagement.

Developing a Sandhi Lexicon (SandhiLex) for Sinhala: Understanding and Formalizing Morphophonology of Sinhala Language

Chamila Liyanage and **Randil Pushpananda**

Language Technology Research Laboratory,
University of Colombo School of Computing,
Sri Lanka
{cml,rpn}@ucsc.cmb.ac.lk

Abstract

Sandhi, a grammatical feature in Sinhala inherited from Old Indo-Aryan, has been discussed in all Sinhala grammar books, beginning with *Sidat Saṅgarāva*, reportedly the first Sinhala grammar book. This paper presents a study of Sandhi in the Sinhala language and introduces a novel classification based on linguistic analysis. The study identifies three primary lexical units involved in sandhi formation and six lexical entries related to the Sandhi process. Based on this analysis, morphophonological variations in Sinhala are classified into four categories: Lexicalized Sandhi, Derivational Sandhi, Etymological Sandhi, and Affixational Sandhi. Accordingly, a Sandhi Lexicon (SandhiLex) for the Sinhala language was compiled using a semi-automatic method. The SandhiLex includes approximately 4,500 Sandhi lexemes for the Lexicalized Sandhi dataset and over 300k lexical units for the Affixational Sandhi dataset, contributing significantly to advancing research in Natural Language Processing for the Sinhala language.

1 Introduction

Sandhi refers to the process of phonological changes that occur at word boundaries. This particularly refers to the morphophonological changes occur at the point of joining two words or characters (Devadath et al., 2014). Sandhi, as a morphophonological phenomenon, is challenging in word boundary detection, leading to difficulties in many NLP tasks such as tokenization, morphological analysis, parts-of-speech tagging, and machine translation.

Sinhala, as an Indo-Aryan language, exhibits the morphophonological feature called Sandhi, making it particularly challenging for NLP tasks. Therefore, a treatment is required to address the recognition of word boundaries. Further, as this grammatical feature has been derived from Old Indo-Aryan phonology (Jain and Cardona, 2007), Sandhi has evolved into a complex grammatical phenomenon, with both historical and contemporary forms occurring in the language. Accordingly, a study of Sandhi in Sinhala is beneficial for understanding the language's phonological structure, linguistic evolution, and interaction between historical and contemporary forms. From a linguistic resource compilation perspective, De Silva (2019) notes that Sinhala is a low-resource language, requiring more language resources for many NLP tasks. However, no reported work has been carried out to develop a language resource for Sandhi in Sinhala language. Hence, this paper reports a study of Sandhi in Sinhala language and the process of developing a Sandhi lexicon for Sinhala.

Text processing tasks in agglutinative languages are not trivial for several reasons, one of which is the concatenation of multiple lexical entries into a single word. For instance, in the following example, වම් *vam* (left) and අත *ata* (hand) are two distinct words. They can be concatenated into a single word, a Sandhi: වමත *vamata* (lefthand), with only minor morphophonological changes.

e.g. වම් *vam* (left) + අත *ata* (hand)
වමත *vamata* (lefthand)

The challenge with Sandhi as a natural language phenomenon lies in the difficulty of recognizing word boundaries. For instance, පරිගණක *pariganaka* (computing), අධ්‍යයන *adhyayana* (studies) and ආයතනය *āyatanaya* (institute) are three distinct words in the Sinhala language, each corresponding to different lexical meanings. Figure 1 shows how these three Sinhala words can be arranged in four different structures while maintaining the same meaning.

As exemplified by the four lexical combinations in Figure 1, the same lexical entries can be presented in multiple ways, making it challenging to identify word boundaries and leading to several difficulties in language processing tasks. Accurately

i. පරිගණක අධ්‍යයන ආයතනය
parigaṇaka adhyayana āyatanaya

ii. පරිගණක අධ්‍යයනායතනය
parigaṇaka adhyayanāyatanaya

iii. පරිගණකාධ්‍යයන ආයතනය
parigaṇakādhyayana āyatanaya

iv. පරිගණකාධ්‍යයනායතනය
parigaṇakādhyayanāyatanaya

Figure 1: Four sequences using three lexical units to indicate the meaning 'Institute of Computer Studies'

identifying individual words within concatenated forms can enhance the effectiveness of tasks such as information retrieval, syntactic or grammatical parsing, machine translation, sentiment analysis, and linguistic annotation. Additionally, this complexity poses challenges for language learning and teaching.

Recognition of Sandhi formation can be analyzed through two primary methods: rule-based methods and machine learning methods. Despite the challenges in finding resource persons with relevant linguistic expertise, Priyanga et al. (2017) has attempted to develop a rule-based model of a Sinhala word joiner. However, the actual requirement lies in the opposite direction: recognizing word boundaries to segment Sandhi words. Although the machine learning approach would presumably be more accurate, no research has reportedly been conducted in this direction due to the lack of available datasets. Therefore, Priyanga et al. (2017) primarily focuses on implementing Sandhi rules found in the *Sidat Saṅgarāva*, a 13th-century text, without exploring modern linguistic methods that could be more beneficial. Consequently, the present research was conducted to understand Sandhi in Sinhala language and develop a Sandhi lexicon for the particular language.

2 Sandhi in Sinhala Language

Sinhala, an Indo-Aryan language, is one of the two official languages of Sri Lanka, spoken by the majority of the population, with about 20 million speakers worldwide. Sinhala has been in contact with Tamil, which belongs to the Dravidian language family, for a long time within the country. Due to colonization, Sinhala has also been influenced by Portuguese, Dutch, and English languages.

Jain and Cardona (2007) notes that Sandhi is a feature of Old Indo-Aryan (OIA) phonology. As Sinhala is an Indo-Aryan language, a sub-branch of the Indo-European language family, grammatical features of OIA have been inherited by the language. Thus, Sandhi is one of the major grammatical features discussed in every grammar book since the *Sidat Saṅgarāva*, that became a reference for all subsequent grammar books, such as Gunasekara (1891); Gunawardhana (1924); and Thilakasiri (1997).

Given the complexity of Sandhi as a grammatical phenomenon in Sinhala, it has not only been discussed as a topic in traditional grammar books but has also been the subject of separate works. Several books have been written on Sandhi, including Coperahewa (2014), a compilation of a dictionary of Sandhi words in Sinhala; Ekanayake (2016), an analysis of the Sandhi phenomenon in Sinhala, particularly with reference to Old Sinhala; and Disanayaka (1997), an analysis based on (a kind of) structural linguistics.

2.1 Classification of Sandhi

In the literature, Sandhi in the Sinhala language has been classified based on three criteria: i. morphophonological process, ii. occupying lexical units and iii. diglossic variants.

2.1.1 Morphophonological Process

The *Sidat Saṅgarāva* has classified Sandhi into nine categories based on morphophonological functions. Although the term Sandhi is now commonly used in English, it was referred to as 'Permutation' (*Pt*) in De Alwis (1852), an English translation of the *Sidat Saṅgarāva*. The 9 classes are mentioned below.

i. *Pt* by the elision of the first vowel

ii. *Pt* by the elision of the second vowel

iii. *Pt* of vowels

iv. *Pt* by substitution of vowels

v. *Pt* by substitution of consonants

vi. *Pt* by reduplication of first letter

vii. *Pt* by elision

viii. *Pt* by substitution

	Sandhi	Segmented
i.	අත්‍යන්ත *atyanta* (Absolute)	අති + අන්ත *ati* + *anta*
ii.	අභ්‍යන්තර *abhyantara* (internal)	අභි + අන්තර *abhi* + *antara*
iii.	නිරාහාර *nirāhāra* (Starving)	නිර් + ආහාර *nir* + *āhāra*
iv.	නුදුටු *nuduṭu* (unseen)	නො + දුටු *no* + *duṭu*
v.	මිනිසෙක් *minisek* (a man)	මිනිස් + එක් *minis* + *ek*
vi.	පොතේ *potē* (in the book)	පොත + ඒ *pota* + *ē*
vii.	පොතෙන් *poten* (from the book)	පොත + එන් *pota* + *en*

Table 1: Examples of lexical units for internal Sandhi

ix. *Pt* by reduplication of letters

In Gunawardhana (1924), the author analyzes the classification presented in *Sidat Saṅgarāva*. Considering the nuances of phonological processing, he offers his own analysis of Sandhi classes, expanding the nine categories found in *Sidat Saṅgarāva* to a total of fifteen classes.

As Sandhi is a common grammatical phenomenon in Indo-Aryan languages, Allen (1972) has classified Sandhi in Sanskrit into five distinct classes: i. Vowel + Vowel, ii. Vowel + Consonant, iii. Consonant + Vowel, iv. Consonant + Consonant, and v. Terminal Sandhi. For Sinhala Meegaskumbura (2020) identifies only (first) four classes, omitting the fifth class, Terminal Sandhi.

2.1.2 Occupying Lexical Units

Gunawardhana (1924) and subsequently Kumaranathunga (1937) have classified Sandhi into two categories based on the occurrence of lexical units in the Sandhi process: (i) Internal Sandhi and (ii) External Sandhi.

(i) **Internal Sandhi**

Internal Sandhi refers to morphophonemic changes that occur within a stem or when a stem is joined with an inflectional affix (Gunawardhana, 1924; Kumaranathunga, 1937). These changes can involve all types of affixes, including suffixes and prefixes (with the note that Sinhala does not use infixes). This method of Sandhi formation leads to a large set of new lexical entries in the language. While suffixes typically lead to inflections, prefixes often result in derivations, which are generally included as separate lemmas in dictionaries as depicted in Table 1.

	Sandhi	Segmented
i.	අංගෝපාංග *aṁgōpāṁga* (components)	අංග + උපාංග *aṁga* + *upāṁga* (element) + (accessories)
ii.	උත්තමායුෂ *uttamāyuṣa* (highest age)	උත්තම + ආයුෂ *uttama* + *āyuṣa* (highest) + (age)
iii.	කලායතනය *kalāyatanaya* (art institute)	කලා + ආයතනය *kalā* + *āyatanaya* (art) + (institute)
iv.	නීත්‍යනුකූල *nītyanukūla* (legal)	නීති + අනුකූල *nīti* + *anukūla* (law) + (compliant)
v.	ලේඛනාගාර *lēkhanāgāra* (archives)	ලේඛන + ආගාර *lēkhana* + *āgāra* (records) + (house)

Table 2: Examples of lexical units for external Sandhi

(ii) **External Sandhi**

External Sandhi occurs between either two stems or two words (Gunawardhana, 1924; Kumaranathunga, 1937). For instance, all the lexical entries in Table 2 are distinct words. Significantly, both the Sandhi words and their segmented components appear as separate lemmas in Sinhala dictionaries.

2.1.3 Diglossic Variants

Sandhi, as a natural language phenomenon, can occur in both spoken and written aspects of a language. In the spoken aspect of the Sinhala language, පොත් ටික *pot ṭika* (the small set of books) becomes පොට්ටික *poṭṭika*, and බත් ඵුට්ටක් *bat cuṭṭak* (a small amount of rice) becomes බච්චුට්ටක් *baccuṭṭak*, indicating morphophonological changes at the point where two morphemes join. However, Sandhi in spoken language is not of much concern, since lexical entries with these particular morphophonological changes, such as පොට්ටික *poṭṭika* or බච්චුට්ටක් *baccuṭṭak*, do not typically occur in written form. Consequently, they do not appear in text corpora and do not pose

significant challenges in Sinhala language computing tasks.

2.2 New Classification of Sandhi

As discussed in Section 1 Sandhi refers to a morphophonological process that occurs in several instances. There are three primary lexical units involved in the formation of Sandhi in Sinhala: noun lemmas, prefixes, and suffixes. However, there are six lexical entries involved in the Sandhi process in Sinhala, as illustrated below.

i. Lemma [L]
Noun lemmas are the most frequently used lexical units in the formation of Sandhi words.
e.g. වම *vama* (left), දකුණ *dakuna* (right), අත *ata* (hand)

ii. Prefix I [P1]
In the formation of Sandhi in Sinhala, prefixes can be classified into two categories, with the first category containing prefixes that generate new lemmas.
e.g. නිර් *nir*, සත් *sat*, අති *ati*

iii. Prefix II [P2]
The second category of prefixes includes those that do not generate new lemmas in the formation of Sandhi words.
e.g. නො *no*

iv. Suffixes [S]
In the agglutinative process, adding suffixes to a particular word may cause morphophonemic changes. Thus, suffixes can be recognized as one of the lexical units involved in Sinhala Sandhi formation.
e.g. ඉන් *in*, එන් *en*, එහි *ehi*

v. Unchanged Lemma [UL]
After the concatenation of lexical entries, some Sandhi words remain lemma unchanged. In other words, these Sandhi words do not appear as lemmas in dictionaries.
e.g. ඔවුනොවුන් *ovunovun* (each other), වමත *vamata* (left hand)

vi. New Lemma [NL]
After the concatenation process, certain Sandhi words acquire new meanings and appear as new lemmas in dictionaries.
e.g. අභ්‍යන්තර *abhyantara* (internal), කලායතනය *kalāyatanaya* (art institute)

Sandhi words in Sinhala are formed by combining two or more lexical units from the first four of the six lexical types mentioned above. Analysis reveals five possible types of concatenation using these categories.

- $\mathrm{L} + \mathrm{L} = \mathrm{UL}$
- $\mathrm{L} + \mathrm{L} = \mathrm{NL}$
- $\mathrm{P1} + \mathrm{L} = \mathrm{NL}$
- $\mathrm{P2} + \mathrm{L} = \mathrm{UL}$
- $\mathrm{L} + \mathrm{S} = \mathrm{UL}$

Accordingly, Sandhi can be identified as a morphophonological process that occurs in several instances. Based on these occurrences, we classify Sinhala Sandhi words into four classes:

i. Lexicalized Sandhi ($\mathrm{L}+\mathrm{L} = \mathrm{UL}$)

ii. Derivational Sandhi ($\mathrm{P1}+\mathrm{L} = \mathrm{NL}$)

iii. Etymological Sandhi ($\mathrm{L}+\mathrm{L} = \mathrm{NL}$)

iv. Affixational Sandhi ($\mathrm{P2}+\mathrm{L} = \mathrm{UL} \mid \mathrm{L}+\mathrm{S} = \mathrm{UL}$)

These four distinct categories are discussed below.

2.2.1 Category 1: Lexicalized Sandhi

The most challenging aspect of the Sandhi phenomenon is when two distinct words concatenate to create a new form in which the word boundary cannot be easily identified. For instance, දකුණු *dakuṇu* (right) and අත *ata* (hand) are two distinct words that can be concatenated to form දකුණත *dakuṇata*, a Sandhi word where the boundary between the original words is not clear. Accordingly, in this category, we treat Sandhi forms that are created from two distinct words but maintain their original meaning, where both the separate forms and the concatenated form convey the same meaning. Therefore, they should not appear in dictionaries as distinct entries for the same meaning.

2.2.2 Category 2: Derivational Sandhi

Some of the Sandhi words appear as lemmas in dictionaries, having taken on a referential meaning in their concatenated form, although the Sandhi phenomenon occurs as a result of a morphophonological process. For instance, all five lexical entries in Table 2 are included in this category, where they

are formed as a result of concatenation but have derived new lexical forms with distinct meanings. In each of these five examples, the two forms used to concatenate have distinct meanings and have derived into different forms. For instance, ලේඛන *lēkhana* (writings) and ආගාර *āgāra* (house) are two words with distinct meanings that can be concatenated to form ලේඛනාගාර *lēkhanāgāra* (archives), a new word with distinct meaning, which is thus included in dictionaries.

Further, there is another set of forms that can be included in this category, consisting of cases where one part does not occur as a distinct word in the language. For instance, in the concatenated form සමුපකාර *samupakāra* (co-operative), සං *saṁ* is not a separate word but a prefix, while උපකාර *upakāra* (help) occurs as a distinct word. The morphophonological process has applied as a result of derivation, and thus such words can also be included in this category.

2.2.3 Category 3: Etymological Sandhi

The Sandhi phenomenon can also occur in the etymology of words and in the derivation of two particular morphemes into one lexical form. For example, ප්‍රත්‍යුත්තර *pratyuttara* (Response) is a Sandhi word with ප්‍රති *prati* + උත්තර *uttara* (Answer) as two separate morphemes. Its corresponding Sinhala derived form පිළිතුරු *piḷituru* (Answer) is also split into two morphemes as පිළි *piḷi* + උතුරු *uturu*; however, the latter morpheme උතුරු *uturu* cannot be found in the language with that particular meaning. Thus, the word පිළිතුරු is split only for etymological reasoning.

Furthermore, the word කම්මල *kammala* (smithy) is considered a Sandhi word composed of two distinct words: කම් *kam* (work) and හල *hala* (shop). Although කම්මල *kammala* is derived from these two particular forms, the original lexical meanings of the two forms have disappeared, resulting in a different meaning. Thus, the Sandhi phenomenon occurs here as a result of etymological reasoning. Therefore, such words are treated under the third category.

2.2.4 Category 4: Affixational Sandhi

Internal Sandhi forms discussed in Section 2.1.2 are treated into this category, including Sandhi phenomena that occur between a lexeme and either a prefix or suffix. For instance, the lexical entries in Table 1 are examples for affixational Sandhi. Since the lexical entries in this category involve one word combined with prefix or suffix, they do not present challenges in word boundary detection and are therefore not explored in depth in this work.

	Sandhi	Segmented
i.	අන්‍යෝන්‍යාධාර *anyōnyādhāra* (mutual aid)	අන්‍යෝන්‍ය + ආධාර *anyōnya* + *ādhāra* (mutual) + (aid)
ii.	ඔවුනොවුන් *ovunovun* (each other)	ඔවුන් + ඔවුන් *ovun* + *ovun* (they) + (they)
iii.	එකිනෙක *ekineka* (one by one)	එකින් + එක *ekin* + *eka* (from one) + (one)
iv.	කුටෝපක්‍රම *kūṭōpakrama* (tricks)	කුට + උපක්‍රම *kūṭa* + *upakrama* (crafty) + (plan)
v.	පුණ්‍යෝත්සව *puṇyōtsava* (meritorious ceremony)	පුණ්‍ය + උත්සව *puṇya* + *utsava* (merit) + (ceremony)
vi.	නමැති *namæti* (named)	නම් + ඇති *nam* + *æti* (name) + (having)
vii.	නැණැස *næṇæsa* (wisdom Eye)	නැණ + ඇස *næṇa* + *æsa* (wisdom) + (eye)

Table 3: A sample set of lexemes occur in SandhiLex

3 SandhiLex Compilation

As per the study conducted on the Sinhala Sandhi system, the compilation of SandhiLex, the Sandhi lexicon for Sinhala, was conducted in several steps using both manual and semi-automatic methods. The approach used to develop the Sandhi lexicon was as follows:

i. Collecting Sandhi lexemes from Sinhala grammar books.

ii. Collecting Sandhi lexemes from Sinhala dictionaries.

iii. Extracting Sandhi lexemes from distinct word lists.

iv. Extracting sandhi lexemes for less frequent phonemic combinations

v. Preparing Affixational Sandhi dataset

Accordingly, several types of Sandhi forms were not included in the lexicon for three reasons, such as: (i) etymological Sandhi, (ii) derivational Sandhi, and (iii) those forms appear in the spoken aspect of the language, as discussed in section 2.1.3. A sample set of Sandhi words included in SandhiLex is illustrated in Table 3.

3.1 Sandhi Lexeme

As mentioned in section 2, Sinhala, as an agglutinative language, allows one form to be inflected for many unique lexical elements. Since the lexicon becomes complex when compiled with inflected forms, the core dataset of lexical items of Sandhi (which does not include inflectional Sandhi forms) was denoted only with stem-like lexical units. These units can be considered the most common forms in the compilation of the respective lexical items. Accordingly, in this initiative, Sandhi lexemes (SiLx) refer to those specific lexical elements with no inflections.

3.2 Collecting SiLx from Sinhala grammar books

One of the easier ways of collecting Sandhi words is by reviewing the literature and manually collecting the specific lexical entries, since it is more accurate method of collecting Sandhi lexemes. Further, Sandhi, as a common topic, is addressed in nearly all traditional and contemporary Sinhala grammar books. However, since these resources are only available in print, the data must be collected manually. Thus, as the first step of the initiative, we collected Sinhala Sandhi words manually from Sinhala grammar books. Among the books utilized for collecting manually the sandhi lexemes included Derivative Grammar Books: Pannasara Thero (2004); Gunawardhana (1924), traditional grammar books: Perera (1985); Thilakasiri (1997); Sumanasara (2007); Non-Traditional Prescriptive Grammar Books: Kumaranathunga (1937); De Seram and Gunawardhana (1971); Sampath (2013); and Disanayaka (1997).

3.3 Collecting SiLx from dictionaries and glossaries

Coperahewa (2014) is a dictionary compiled of Sinhala Sandhi words. This dictionary consists of around 1,600 entries, which include all types of Sandhi words, including affixational Sandhi, etymological Sandhi, and derivational Sandhi. As in traditional grammar books, the list of Sandhi words in Coperahewa (2014) includes lexical entries that are not used in contemporary Sinhala language. Furthermore, Sinhala language dictionaries such as Wijethunga (2005), Soratha Thero (1952), and Soratha Thero (1956) were also referred, and Sandhi lexemes were manually collected from these.

3.4 Extracting SiLx from a text corpus

LTRL-UCSC (2007) is a Sinhala text corpus which includes modern Sinhala novels, short stories, and critiques written by renowned Sinhala authors. It also contains news articles collected from mainstream Sinhala newspapers published between 2004 and 2010. This corpus represents contemporary Sinhala language usage across various contexts and genres, making it a balanced text corpus suitable for NLP research and development for the language.

In this initiative, we use the distinct word list from LTRL-UCSC (2007) since it includes the most frequent words in the language. Although manually collecting the particular lexical entries would be more accurate, it is a tedious task due to several reasons. Firstly, it is time-consuming, and secondly, it requires substantial human resources and a high level of linguistic and grammatical knowledge of the language. Therefore, we need efficient methods for extracting lexical entries from relevant resources. Accordingly, a list of Sandhi words was extracted and cleaned through several steps:

i. Utilizing the list of distinct words from LTRL-UCSC (2007) and filtering the words beginning with vowels.

ii. Extracting words for certain character clusters as illustrated in Table 4.

iii. Removing irrelevant words.

This method proved to be more effective.

3.5 Extracting sandhi lexemes for less frequent phonemic combinations

In the process of compiling the lexicon, this step was employed to count the phonemic combinations for which morphophonemic changes were applied. For this task, the entire dataset (only category 1) was transliterated using the ISO 15919 standard for Sinhala. This was done to simplify the

character clusters	Occurrences in the corpus	Remains in the SandhiLex
ාර්ථ *ārtha*	1009	214
ංක *ṁka*	2323	304
ක්ෂ *kṣa*	4317	396
ත්‍ය *tya*	1986	388
ාචාර *ācāra*	649	142
ාලෝක *ālōka*	125	48
ාකාර *ākāra*	1138	102
ාංග *āṁga*	557	110
පදේශ *padēśa*	165	44
න්තර *ntara*	762	136

Table 4: A sample of character clusters extracted from the distinct word list

process of counting the phonemic combinations. After reiterating the process, the phonemic combination frequencies of the final version are presented in Table 5.

As per the statistics given in Table 5, the most frequent phonemic combinations in the list are a a and a ā, which reported frequency counts of 1555 and 1276 respectively. However, none of the other combinations reach a count of 1,000 occurrences. Furthermore, out of 144 phonemic combinations, 68 of them do not appear in the list, whereas another 37 reported fewer than 5 occurrences in the list.

4 Affixational Sandhi dataset

The SiLx entries treated under category 4, which was discussed in Section 2.2.4, are included in the affixational Sandhi dataset. This dataset was compiled using LTRL-UCSC (2007) and LTRL-UCSC (2008) developed by the Language Technology Research Laboratory of the University of Colombo School of Computing, Sri Lanka. Since the data consisted of affixes along with lexemes, the number of data samples is much larger compared to the main set of data, which includes the first three categories. For instance, the dataset consists of 73,620, 18,434, 16,985, 7,520, 2,569, and 2,561 lexical entries for the suffixes උත් *ut*, ඉන් *in*, එන් *en*, එහි *ehi*, එකු *eku*, and එක් *ek* respectively.

5 Conclusion

Sandhi, as a morphophonological process, has been a topic in all grammar books. Considering the inadequacy of studies in traditional grammar books, this paper reports a new classification of Sandhi in Sinhala by classifying them according to their morphophonological processes and occurrences in the language. Accordingly, Sinhala Sandhi has been classified into four categories: Lexicalized Sandhi, Derivational Sandhi, Etymological Sandhi, and Affixational Sandhi. Based on the study, a Sandhi Lexicon (SandhiLex) for the Sinhala language was compiled, comprising around 4,500 Sandhi lexemes for Lexicalized Sandhi data and more than 300k lexical units of affixational Sandhi dataset which will contribute to the advancement of research in NLP for the Sinhala language.

Table 5: Phonemic combination frequencies in the SandhiLex

6 Limitations

Sandhi is one of the main grammatical phenomena in the Sinhala language, the morphophonemic nuances can be studied further. However, this research focused specifically on understanding Sandhi phenomena in Sinhala, recognizing its significance as a grammatical feature that affects many NLP applications. Thus, one objective of the paper was to report the process of developing a Sandhi lexicon for Sinhala. As Sandhi has been classified into several categories, the initiative was to collect Sandhi words particularly for the most significant category of Sandhi words. Further, the study was limited to analyzing Sandhi in the Sinhala language. The study can be further advanced

by analyzing the Sandhi categories in other Indo-Aryan languages as well. Additionally, the nuances of morphophonological features can be explored in greater depth in future research.

Acknowledgements

This research was financially supported by the University of Colombo School of Computing through the Research Allocation for Research and Development. The authors gratefully acknowledge Mr. Vincent Halahakone for his assistance in data collection for the Sandhi dataset and for proofreading the paper. We also thank Prof. W.M. Wijeratne for reviewing the paper and providing insightful feedback. Special thanks go to Prof. Sandagomi Coparahewa and Ms. Chanika Dayarathna for their support in finding several books required for the research. Finally, we thank all the members of the Language Technology Research Laboratory of the University of Colombo School of Computing for their various contributions in making this work a success.

Abstract

Dative alternation, a phenomenon prevalent across many languages (e.g., 'I gave the children toys' and 'I give toys to the children'), exhibits a more complex structure in Chinese compared to English. This study adopts a comparable corpus-driven statistical approach to analyze dative construction variations across different Mandarin varieties using large corpus. The findings reveal significant regional differences in word order, particularly between preverbal and postverbal structures. These contrasts are consistent with our previous observations on light verb alternation. From a pedagogical perspective, these regional variations highlight the need for teaching materials tailored to different Mandarin varieties, helping learners better understand syntactic diversity and improving their proficiency.

1 Introduction

A dative sentence describes a transfer event, commonly conveyed through verbs like 'give', 'send', or 'mail' in English. These transfer events typically involve two objects: the direct object, indicating the theme of the transfer action, and the indirect object, indicating the recipient of the transfer action. For instance, in sentence (1) 'I gave Mary a book', the direct object (the theme) is 'a book', and the indirect object (the recipient) is 'Mary'.

(1) I gave Mary a book.
Verb Recipient Them

1.1 Dative Alternation in English

Many languages in the world are found to have multiple syntactic forms for encoding the same transfer event (Bresnan and Nikitina, 2003; Margetts and Austin, 2007, among others). For example, in English, both (2a) and (2b) refer to the same event, but (2a) is a double object structure with the word order Verb Recipient Theme, and (2b) is a prepositional dative structure with the word order Verb Theme Recipient.

(2a) Susan gave the children toys.
Verb Recipient Theme
(2b) Susan gave toys to the children.
Verb Theme Recipient

Bresnan and Hay (2007) argues that the alternative constructions can be found in contexts of repetition, and they are viewed as having overlapping meanings which permit them to be used as alternative expressions or paraphrases.

More interestingly, variation differences are found to exist among different language varieties in dative alternation. Hoffman and Mukherjee (2006) demonstrate that the overall rates of the prepositional dative with 'give' are higher in Indian English than British English. Bresnan and Hay (2007) displays that New Zealand and American English differ quantitatively in the effect of animacy on dative alternation. Scholars have extended their researches on dative alternations, comparing American English, African American English, Nigerian English, Ghanaian English, British English, and Australian English. (e.g., Kendall et al., 2011; Akinlotan and Akinmade, 2020; Nyanta, 2017; Bresnan and Ford, 2010).

1.2 Dative Alternation in Chinese

Dative alternation in Chinese presents more complexity compared to English. Chinese also has the two word orders existing in English (3a, 3b),

with the order Verb Recipient Theme, and Verb Theme Recipient.

(3a) 我 送 **他** 一本书
wo *song* *ta* *yibenshu*
I gave him one book
Verb Recipient Theme
'I gave him a book.'

(3b) 我 送 一本书 给 **他**
wo *song* *yibenshu* *gei* *ta*
I gave one book to him
Verb Theme Recipient
'I gave a book to him.'

In addition to these two word orders, Chinese also allows for the recipient to precede the verb, either with (3c) or without the preverbal preposition (3d), which has the order of Recipient Verb Theme.

(3c) 他 **每人** 赠 了 一本书
ta *meiren* *zeng* *le* *yi ben shu*
he everyone send LE one book
Recipient Verb Theme
'He sent everyone a book.'

(3d) 他 向 **图书馆** 赠 书
ta *xiang* *tushuguan* *zeng* *shu*
he to library denote book
Recipient Verb Theme
'He donated books to the library.'

Furthermore, the theme can precede the dative verb, as seen in the BA construction (3e) or a topicalized sentence (3f), with the order Theme Verb Recipient.

(3e) 我 把 书 送（给） **他**
wo ba *shu* *song (gei)* *ta*
I BA book give(to) him
Theme Verb Recipient
'I gave the book to him.'

(3f) 书 送（给） **他**
shu *song(gei)* *ta*
book give(to) him
Theme Verb Recipient
'gave the book to him'

Dative alternation in Chinese is notably more intricate than in English. However, systematic empirical research on the syntactic choices of dative alternation in Chinese is rare. This attention to variation among different Chinese variants is even scarcer.

We have observed differences in the selection of ditransitive sentence structures among Mandarin variants. For instance, certain expressions found in the Taiwan corpus might be challenging for Mainland Chinese speakers to accept (e.g., example (4)).

(4) 赠 书 **纽约** **布许维克** **图书馆**
zeng shu Niuyue Buxuweike Tushuguan
Present book NewYork Brookwick Library
Verb Theme Recipient
'Present books to the Brookwick Library in New York.'

For example, example (4) from the Taiwan corpus showcases the verb-theme-recipient word order without the postverbal preposition 给 *gei* 'to'. This is very rare in Mainland corpus, but is quite common in Taiwan corpus.

Due to the lack of a systematic investigation into variations in dative alternation, this study aims to investigate whether different varieties of Mandarin vary in the probabilities of these choices, utilizing a comparable corpus-driven statistical approach.

In the context of international Chinese education, understanding regional variations in dative alternation is crucial for improving pedagogical strategies. Mandarin Chinese, spoken in Mainland China, Taiwan, Hong Kong, and Singapore, shows significant syntactic differences, which may pose challenges for learners. Investigating these variations can help design teaching materials that are sensitive to these regional differences, offering more tailored and effective instruction for learners based on the Mandarin variety they are likely to encounter.

2 Methodology

We have found that dative variation is highly common among Mandarin varieties, showing usage differences across different regions (such as Mainland China, Hong Kong, and Taiwan) and countries (such as Singapore). This study aims to explore potential variations in dative usage probabilities among Mandarin-speaking countries and regions, including Mainland China Mandarin

(MM), Hong Kong Mandarin (HM), Taiwan Mandarin (TM), and Singapore Mandarin (SM). We focus on these four regions because they represent significant centers of Mandarin-speaking populations, each with unique cultural influences that impact language use. This provides a diverse backdrop for studying linguistic variations.

The corpus we use for Mainland Mandarin, Taiwan Mandarin and Singapore Mandarin is the Annotated Chinese Gigaword corpus which was collected and available from LDC and contains over 1.1 billion Chinese words, with 700 million characters from Taiwan Central News Agency, 400 million characters from Mainland Xinhua News Agency, and 30 million Chinese characters from Singapore Lianhe Zaobao (Huang, 2009).

The Hong Kong data was collected from LIVAC (Linguistic Variation in Chinese Speech Communities) Chinese Synchronic Corpus. LIVAC is a large language database which has been cultivated over more than 20 years from more than 700 million words of modern Chinese media language in various regions, including Hong Kong. This corpus is drawn from the representative Chinese newspapers, media and news reports (Tsou and Kwong, 2015).

For data collection, we initially compiled a list of 26 verbs that could be used ditransitively, and extracted sentences containing these words. These 26 verbs were primarily sourced from previous studies and our corpus observations (He, 2008; Liu, 2006; Yao and Liu, 2010), as shown in Appendix A.

Then we process the data with the following steps:

1) Featured the ditransitive sense of the target verb e.g., we distinguish 付 *fu* for ‘to pay’ versus 付 *fu* as a family name; 丢 *diu* for ‘to lose’ and ‘to throw’; 赏 *shang* for ‘to reward’ and ‘to appreciate’;

2) Randomly extracted approximately 1000 tokens for each verb in each variety, resulting in 25,449 tokens in the Mainland Corpus, 27,055 tokens in the Taiwan Corpus, 18,530 tokens for Hong Kong Mandarin, and 19,841 tokens for Singapore Mandarin;

3) Manually selected the dative construction, with both recipient and theme overt, yielding 4,585 tokens in the Mainland Corpus, 3,755 tokens in the Taiwan corpus, 2,450 tokens in the Hong Kong corpus, and 2,941 tokens in the Singapore corpus;

4) Annotated the alternative types.

We employed a hierarchical perspective (Yao and Liu, 2010.) to annotate dative alternation, as shown in Figure 1. Initially, we delineated two primary categories: postverbal ditransitive and preverbal ditransitive. postverbal ditransitive denotes structures where both recipient and theme appear after the verb. Meanwhile, preverbal ditransitive includes constructions where either theme or recipient precedes the verb.

Within postverbal ditransitive, two distinct word orders emerged: Verb Recipient Theme, exemplified by (3a), and Verb Theme Recipient, seen in (3b). In the realm of preverbal ditransitive, we identified three word orders: Recipient Verb Theme, comprising recipient preceding the verb without a preposition, such as 3c, and adverbial prepositional structures, as in 3d. The second word order, Theme Verb Recipient, encompasses BA construction (e.g., (3e)) and topicalized sentences (e.g., (3f)). The third word order, Theme Recipient Verb, either use preverbal preposition, or in BA construction, as seen in examples below:

(5a) 纪念章 陆续 向 **老党员** 颁发
jinianzhang luxu xiang lao dangyuan banfa
‘The commemorative medals are being presented to veteran party members in succession.’

(5b) 把 那些 原则 向 **领袖** 传达
ba naxie yuanze xiang lingxiu chuanda
‘Convey those principles to the leader.’

●	Postverbal ditransitive:
	➢ Verb Recipient Theme ➢ Verb Theme Recipient
●	Preverbal ditransitive:
	➢ Adverbial prepositional structure: Recipient Verb Theme ➢ BA construction: Theme Verb Recipient ➢ Recipient before the verb (without preposition): Recipient Verb Theme ➢ Topicalized sentence: Theme Verb Recipient ➢ Adverbial prepositional structure: Theme Recipient Verb ➢ BA construction: Theme Recipient Verb

Table 1: Hierarchical categorization.

3 Data

3.1 Frequency of Dative Usage

Initially, we analyzed the frequency of ditransitive usage. Table 2 indicates that Taiwan verbs exhibit an overall ditransitive usage frequency of approximately 0.1388, while Mainland verbs demonstrate around 0.1802. The frequency of dative usage in Singapore Mandarin is 0.1482, and for Hong Kong Mandarin is 0.1322.

A Chi-square test of independence was conducted to examine the relationship between region and the frequency of using dative constructions. The test indicated a significant association between region and construction use: (X^2 (3, N = 13,731) = 252.31, $p < 0.001$). These results suggest that the frequency of using dative constructions varies significantly across regions.

	dative	all	frequency	X^2	P-value
MM	4,585	25,449	0.1802	252.31	<0.01
TM	3,755	27,055	0.1388		
HM	2,450	18,530	0.1322		
SM	2,941	19,841	0.1482		

Table 2: Ditransitive frequency comparison.

3.2 Top Ten Verbs

Secondly, we examined the top ten verbs most frequently used ditransitively in each variety, as shown in Figure 1, 2, 3 and 4.

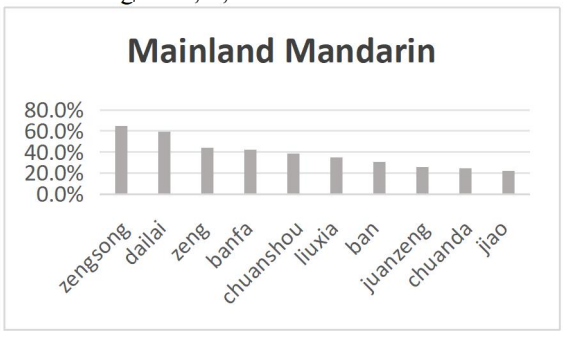

Figure 1: Top 10 Ditransitive verbs/Mainland.

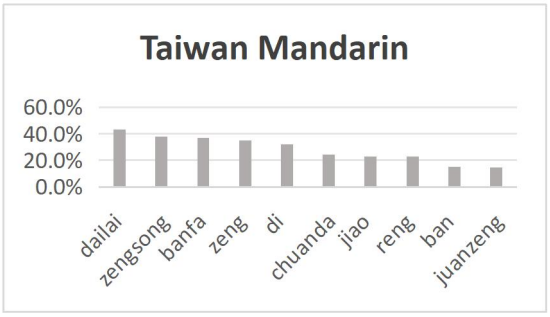

Figure 2: Top 10 Ditransitive verbs/Taiwan.

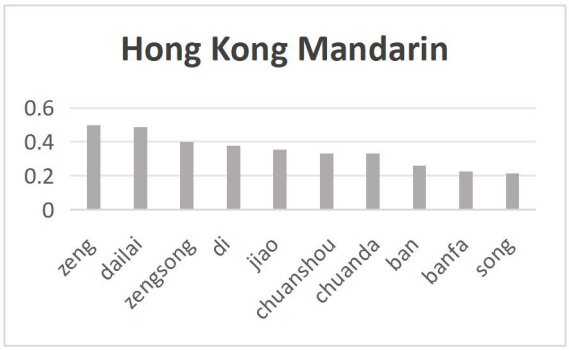

Figure 3: Top 10 Ditransitive verbs/Hong Kong.

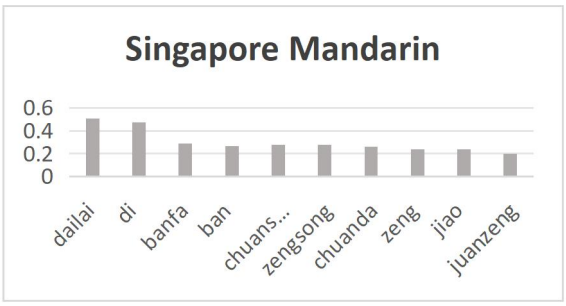

Figure 4: Top 10 Ditransitive verbs/Singapore.

Notably, the majority of these verbs are common in all the regions, with only three exceptions. In Mainland Mandarin, the unique word is 留下 *liuxia*. In Taiwan Mandarin, the unique word is 扔 *reng*, and in Hong Kong Mandarin is 送 *song*. Interestingly, we observed that for the word in Mainland Mandarin, 留下 *liuxia* prefers accompanying abstract direct objects, e.g., 留下回忆 *liuxia huiyi* 'leave memory', 留下印象 *liuxia yinxiang* 'to leave impression'. While for the unique words in Taiwan Mandarin (扔 *reng*) and Hong Kong Mandarin (送 *song*), they tend to pair with concrete direct objects, e.g., 扔茶杯 *reng chabei* 'to throw cup', 送礼物 *song liwu* 'send gift'.

3.3 Distributional Differences

3.3.1 Preverbal vs. Postverbal Variations

We first compared the differences in the frequency of preverbal and postverbal usages across regions. Figure 5 shows the distributional differences in these two orders among different regions (Normalized Ratio = dative usage/all tokens * 10,000).

Moreover, a Chi-square test of independence was conducted to examine the relationship between region and the use of preverbal and postverbal constructions. The results were significant (X^2 (3, N = 90,875) = 2420.4, p < 0.001), indicating a statistically significant association between region and construction type.

Pairwise comparisons using Holm's adjustment method revealed significant differences between all pairs of regions (adjusted p-values<0.05). This suggests that the distribution of preverbal and postverbal usage varies significantly across the regions studied.

Based on the analysis of the data, Mainland Mandarin shows a significant preference for using preverbal dative constructions, while Taiwan Mandarin favors postverbal dative constructions. In Hong Kong Mandarin and Singapore Mandarin, the frequency of preverbal constructions also exceeds that of postverbal constructions, but the difference in frequency between the two types is not as pronounced as in Mainland Mandarin.

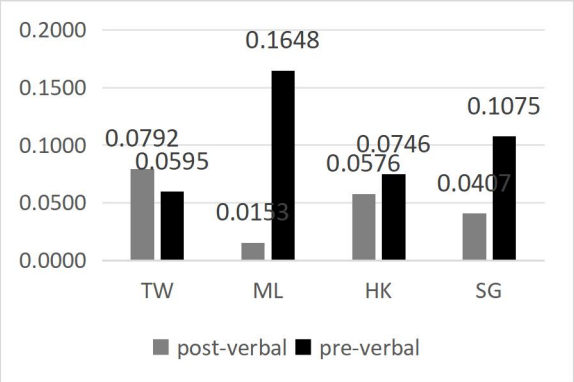

Figure 5: Pre-Post verbal contrasts.

3.3.2 Specific Category

In this section, we examine the differences within the specific categories. The Theme Recipient Verb construction involves a limited number of instances; consequently, we will exclude this category from subsequent analysis due to insufficient data for robust statistical examination.

A Chi-square test of independence was conducted to examine the relationship between regions and types. The analysis revealed a significant association between the variables (X^2 (15, N = 27,055) = 4053.6, p < 2.2e-16). This suggests that the distribution of types is not independent of the region, indicating regional differences in type usage.

We conducted pairwise comparisons using the Holm method to adjust for multiple testing, examining the proportions of eight types across four regions (TM, MM, HM, SM). The analysis revealed significant differences across most types in the various regions, with the following three exceptions: MM and SM showed no significant differences in construction with Recipient Verb Theme, while TM and MM exhibited no significant variance in BA construction with Theme Verb Recipient order and topicalized sentence with Theme Verb Recipient.

We further conduct a detailed analysis using proportions. Figure 6 illustrates the usage frequency of each type across the different regions.

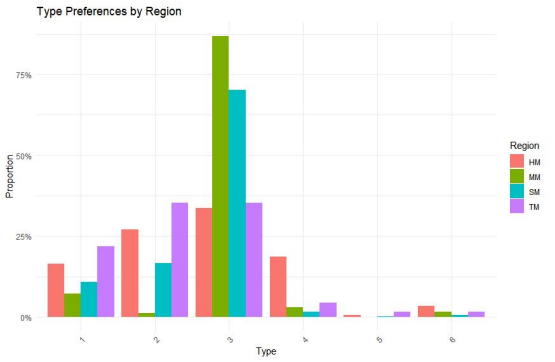

Figure 6: Type preferences by region.

As shown in the figure, among the four regions, Mainland Mandarin (MM) has the most pronounced preference for adverbial prepositional structure with Recipient Verb Theme (example (6)). Additionally, we can observe that Singapore Mandarin (SM) also shows a strong inclination towards using this type of dative construction, as shown in example (7).

(6) 给 **孩子们** 送 礼物
gei haizi men song liwu
'Give gifts to the children'
-- MM example

(7) 给 **孩子** 送 点心
gei haizi song dianxin
'Give snacks to the child'
-- SM example

Additionally, Taiwan Mandarin (TM) demonstrates a stronger preference for using constructions with the order Verb Recipient Theme and Verb Theme Recipient compared to other regions, with Hong Kong Mandarin (HM) being the next most inclined, as demonstrated in example (8a-8b) and (9a-9b) respectively.

(8a) 送 **管区 青溪 派出所** 茶叶
song guanqu Qingxi paichusuo chaye
'send tea to the Qingxi Police Station in the jurisdiction area'
-- TM example

(8b) 送 圣诞节 礼物 给 **部署 海外 的 士兵**
song Yedanjie liwu gei bushu haiwai de shibing
'send Christmas gifts to soldiers deployed overseas'
-- TM example

(9a) 送**台湾歌迷**演唱会的限量版"9+1"T 恤
song Taiwan gemi yanchanghui de xianliangban 9+1 T xu
'Give Taiwanese fans limited edition "9+1" concert T-shirts'
-- HM example

(9b) 送了一束鲜花和一包利市给**母亲**
song le yi shu xianhua he yibao lishi gei muqin
'Gave a bouquet of flowers and a red envelope to mother'
-- HM example

Notably, in Taiwan, postverbal objects can be very complicated, as observed in complex examples such as (11a and 11b), a contrast to Mainland Mandarin's tendency to use prepositional structures with more elaborate indirect objects, as seen in examples like (10).

(10) 向 **中国 常驻 联合国教科文组织 代表 张学忠** 颁发 了 昆曲 艺术 的 荣誉 称号 证书
xiang Zhongguo changzhu Lianheguo jiaokewenzuzhi daibiao Zhang Xuezhong banfa le kunqu yishu de rongyu chenghao zhengshu
'Award the honorary title and certificate for Kunqu Opera Art to Zhang Xuezhong, China's Permanent Representative to UNESCO.'
-- Mainland example

(11a) 颁发 纪念章 和 荣誉状 给 **二十三 位 党龄 三十 年 以上 的 绩优 及 资深 同志**
banfa jinianzhang he rongyuzhuang gei ershisan wei dangling sanshi nian yishang de jiyou ji zishen tongzhi
'Awarded commemorative medals and certificates of honor to 23 outstanding and senior comrades with party experience of more than 30 years.'
-- Taiwan example

(11b) 颁发 奖状 给 **任 开平 中学 参赛 学生 代表团 指导 的 两 位 饭店 师傅**
banfa jiangzhuang gei ren kaiping zhongxue cansai xuesheng daibiaotuan zhidao de liang wei fandian shifu
'Award certificates to the two hotel chefs who served as guides for the participating student delegations from Kaiping Middle School.'
-- Taiwan example

Hong Kong Mandarin shows a stronger preference for using BA construction with Theme Verb Recipient compared to other regions, as shown in example (12).

(12) 把 礼物 送 给 **听话的 孩子**
ba liwu songgei tinghua de haizi
'Give the gift to the well-behaved child'
-- HM example

The usage frequencies of Recipient Verb Theme and topicalized sentence with Theme Verb Recipient are relatively low across all regions.

Mainland Mandarin shows a very low preference for using Verb Theme Recipient structure, whereas Taiwan exhibits the highest preference, followed by Hong Kong. Notably, in Taiwan, the postverbal preposition can be omitted in the Verb Theme Recipient structure, as seen in examples (13a), (13b), and (13c). Such usage is relatively common in Taiwan, and a few instances have also been found in the Hong Kong corpus, as shown in (13d). In contrast, in Mainland Mandarin and Singapore Mandarin, no similar instances have been found; the use of the postverbal preposition 给 *gei* 'to' is compulsory in most situations in these two varieties.

(13a) 赠 车 **马尼拉**
zeng che Manila
'Give a car to Manila'
-- TM example

(13b) 赠 书 **旅奥 侨界 中文 图书室**
zeng shu lü'ao qiaojie zhongwen tushushi
'Donate books to the Chinese library of the overseas Chinese community in Austria'
-- TM example

(13c) 赠 书 **花莲 图书馆**
zeng shu hualian tushuguan
'Donate books to the Hualien Library.'
-- TM example

(13d) 付 医疗费 **黄威**
fu yiliaofei Huangwei
'Pay the medical expenses for Huang Wei'
-- HM example

In summary, Taiwan tends to favor postverbal constructions, particularly Verb Theme Recipient construction. Conversely, other regions prefer preverbal constructions, with Mainland China showing the most pronounced tendency, followed by Singapore. Hong Kong also exhibits a preference for preverbal over postverbal constructions, although this tendency is not as marked as in Mainland China and Singapore.

4 Discussion

4.1 Light Verb Variations

The contrast between preverbal and postverbal structures aligns with our observations on light verb alternation in Chinese. In examining light verb constructions, we notice that for the semantically bleached light verb (e.g., 进行/加以/做/搞/从事 *jinxing/jiayi/zuo/gao/congshi* 'to do'), predicative content mainly comes from its taken complement, the light verb itself may only contribute aspectual information, without containing any eventive information (e.g., 进行研究 *jinxing yanjiu* 'to conduct research'). Since the taken complement is often verbal, the complement itself can take another theme (whether internal or external). For example, 进行研究可行性 *jinxing yanjiu kexingxing* 'to conduct research on practicability'). However, we have observed that there are different alternative patterns to introduce the theme of the verbal object in the corpus data, as shown in Table 3.

	Description	Examples
Type 1 PP_LV_H	Prepositional structure before light verb	对可行性进行研究 *dui kexingxing jinxing yanjiu* for_practicability_proceed_research
Type 2 LV_NP_H	Theme as a modifier between light verb and complement	进行可行性研究 *jinxing kexingxing yanjiu*proceed_practicability_research
Type 3 LV_NP_DE_H	prepositional structure appears between light verb and taken complement with DE	进行（对）可行性的研究 *jinxing (dui) kexingxing de yanjiu* proceed_(for)_practicability_DE_research
Type 4 LV_PP_H	prepositional structure appears between light verb and taken complement	进行 对可行性研究 *jinxing dui kexingxing yanjiu* proceed_for_practicability_research
Type 5 LV_H_NP	Theme can directly follow light verb complement	进行研究可行性 *jinxing yanjiu kexingxing* proceed_research_practiciability

Table 3: Alternative types for light verb construction.

The results indicate that 进行 *jinxing* in Mainland Mandarin prefers alternation Type 1: such as in example (14). While in Taiwan Mandarin, 进行 *jinxing* is favored by Type 2 (as in 15)), Type 4 (as in 16)), and Type 5 (17a,17b,17c)).

We have observed significant differences in the preference of word order between Mainland and Taiwan Mandarin. For the light verb 进行 *jinxing*, the theme in Taiwan Mandarin prefers to appear after the light verb (either between the light verb and the complement or follow the complement), while the theme in Mainland Mandarin significantly prefers to appear before the light verb. This preverbal and postverbal contrast is consistent with what we have observed in the variations in dative alternations.

Type 1: PP_LV_H
(14) 对政策进行调控
dui zhengce jinxing tiaokong
'to regulate policies'
Type 2: LV_NP_H

(15) 在此地区进行森林砍伐
zai ci diqu jinxing senlin kanfa
'to log in this region'
Type 4: LV_PP_ H
(16) 进行 对 市政府工务部门质询
jinxing dui shizhengfu gongwu bumen zhixun
'To conduct an inquiry into the municipal government's public works department.'
Type 5: LV_H_NP
(17a) 进行研制高级复合材料减速板
jinxing yanzhi gaoji fuhe cailiao jianfuban
'To develop advanced composite materials for speed bumps.'
(17b) 开始进行处理教育预算
kaishi jinxing chuli jiaoyu yusuan
'To start processing the education budget.'
(17c) 进行调整自用车辆税费
jinxing tiaozheng ziyong cheliang shuifei
'To adjust the tax and fees for personal vehicles.'

4.2 Pedagogical Implications

From a pedagogical perspective, these findings have significant implications for international Chinese education. Language learners from different regions will likely encounter distinct constructions depending on the Mandarin variety they are exposed to. For instance, a learner from Taiwan might find it more intuitive to use postverbal constructions, while a Mainland learner may be more accustomed to preverbal constructions. Understanding these regional differences allows educators to better tailor their teaching strategies and materials to meet the needs of learners from diverse backgrounds. Additionally, highlighting these variations can help students appreciate the richness of Mandarin's syntactic flexibility, fostering a more nuanced understanding of the language.

5 Implications and Future Research

The regional variations in dative alternation identified in this study have important implications for both linguistic theory and language education. The observed differences in word order preferences across Mandarin varieties underscore the diversity of Mandarin usage in different regions, which is critical for understanding how language evolves and adapts in different social and cultural contexts. For international Chinese education, these findings suggest that a one-size-fits-all approach to teaching Mandarin may not be effective. Instead, tailored teaching materials and methods should be developed to address the specific syntactic structures commonly used in the regions from which the learners originate or to which they will be exposed.

Our future research will focus on exploring the typological motivations behind the syntactic variations across different Mandarin varieties. We also aim to examine the factors influencing syntactic choices, including animacy, syntactic complexity, semantic class, definiteness, pronominality, concreteness, and number. By predicting how these factors shape variation in syntactic choices, we seek to highlight the non-random nature of surface form selection.

From a pedagogical standpoint, future studies should investigate how regional syntactic differences can be integrated into teaching materials, such as textbooks, online courses, and teacher training programs. This approach will enhance learners' understanding of syntactic diversity and improve their ability to use the language flexibly in various contexts. Additionally, tools for assessing and adapting to learners' regional backgrounds could further optimize the learning experience.

The Evolving Use of WAR Metaphors in Businesswomen-focused Media Discourse

Yanlin Li[1], Jing Chen[2], Kathleen Ahrens[1], Chu-Ren Huang[1]

Abstract

Previous research has indicated that modeling language changes over time may offer insights into how concepts and ideas are understood and conceptualized within a society as it undergoes changing societal circumstances (Burgers, 2016; Burgers & Ahrens, 2020; Chen et al., 2022; Chen et al., 2023). In this study, we examine the incremental changes of metaphorical language within the WAR source domain to capture the similarities and differences of the lexical units clustered in semantic space. We also model the patterns of WAR metaphors diachronically in business media discourses (businesswomen-focused) in the three time periods: 1995-2004 as Period I which overlaps with Koller's (2004) research, 2005-2017 as Period II, and 2018-2024 as Period III, which roughly lines up with the MeToo movement that occurred during 2017. Our findings suggest that the use of WAR metaphorical keywords varies over time while the overarching metaphor of BUSINESS AS WAR persists. Additionally, we find that businesswomen's roles as out-group members remain unchanged over time. Moreover, the application of WAR metaphors evolved from conceptualizing female leadership in a military-like corporate structure to increasingly discussing women's struggles to achieve work-life balance and addressing gender inequality issues, particularly around the time of the MeToo movement. This shift indicates that while the BUSINESS IS WAR framing persisted, the specific ways in which WAR metaphors were leveraged to describe businesswomen's experiences became more varied and nuanced over time.

1. Introduction

Metaphors shape our understanding of societal issues. In the field of business communication, Koller (2004) studied how WAR metaphors shape perceptions of women in business, showing that they are often criticized for stepping outside traditional roles, by frequently associating women with "cutthroat" traits. Winter et al. (2020) further investigated perceptions of women's roles and power dynamics in the workplace. Their analysis revealed gender-specific findings that women tend to view aggression as a loss of self-control, while men see it as a means of gaining power. These studies reveal how the use of metaphor reflects societal issues during specific periods.

As society continually evolves, diachronic studies may be employed to monitor ongoing social changes reflected in the use of metaphors, enhancing our understanding of existing societal issues and topics. In recent years, communication scholars have investigated how metaphors function as frameworks for interpreting issues and how changes in metaphor use reflect shifts in the conceptualization of social topics, both theoretically and empirically (De Landtsheer, 2015; Nerghes et al., 2015; Burger, 2016; Musolff, 2017; Burgers & Ahrens, 2020; Zeng et al. 2021). Moreover, Burgers (2016) has suggested that the shifts in metaphors can be modeled in two ways using both qualitative and quantitative methods: (1) fundamental changes, which indicate transformations of metaphors' source domains; (2) incremental changes, which indicate transformation of meanings in a specific metaphor (changes in source-target mapping).

In this paper, we conduct a diachronic case study of business media discourse, specifically focusing on examining the incremental changes of WAR metaphors in content related to

businesswomen. We aim to identify 1) the distribution of WAR metaphors over time in businesswomen-focused business media discourses; 2) the shifting topics around the use of these WAR metaphors; 3) The nuanced changes in the meaning and implications of the frequently used WAR metaphorical keywords over time.

2. Incremental changes in metaphors over time

Metaphors are cross-domain mappings from a source domain (e.g., WAR) onto a target domain (e.g., BUSINESS) (Lakoff & Johnson, 1980; Lakoff, 1993). Previous studies indicated that metaphors within a particular source domain underwent variations in their mappings to the target domain, resulting in incremental changes over time. Burger (2016) defined incremental changes in metaphors as the alteration of a metaphor's meaning over time, which can occur gradually (evolutionary) or in response to a sudden event (revolutionary). In this process, the metaphor itself remains unchanged but its meaning shifts. In other words, incremental change occurs when the meaning of an existing metaphor is either renegotiated or extended through four forms: (a) the metaphor itself may evolve, for instance, "desktop metaphor used in GUI (graphical user interfaces) of personal computer undergone a change from novel to conventional (Isaacson, 2014); (b) its associated meanings can transform, such as the "toxic metaphors" used to conceptualize the specific event "finance crisis" in newspapers changed from the generic and unspecified expression such as "toxic waste" to specific expressions such as "toxic mortgages" (Nerghes et al., 2015); (c) metaphors themselves can be recontextualized in various ways. For example, "Holland," a metaphor initially used to describe a mother's experience with her son who has Down syndrome, has been adapted to represent topics in blogs where parents share their experiences with special needs children. It has also been used to designate sections in theme parks specifically designed for these children (Semino et al., 2013); or (d) established metaphors can be applied to new social issues, for example, technology companies adopt the older metaphor "ether" which described a medium that connected everything to imply the new technology functioned as a conduit for communication among all connected devices (Schaefer, 2013).

Burgers and Ahrens (2020) explored incremental semantic change by focusing on two essential dimensions of concreteness (Iliev & Axelrod, 2017): specificity and physicality of metaphors in each source domain. Their findings indicated that these metaphors are largely physical, representing abstract concepts such as TRADE through concrete entities, including objects and living beings. For instance, "enlarging our foreign trade" conceptualized trade as an unspecified PHYSICAL OBJECT. Similarly, in the LIVING BEINGS metaphor "to fight unfair trade practices", trade is conceptualized as an unspecific enemy needing to be fought. Their findings showed that the metaphors remained both highly physical and notably unspecific during the examined time period.

Zeng et al. (2021) investigated incremental changes in FREE ECONOMY metaphors. Their study found that FREE ECONOMY metaphors have slightly decreased over time. The meanings of FREE ECONOMY metaphors underwent incremental changes in JOURNEY and BUILDING metaphors). For example, in the BUILDING metaphors, Hong Kong politicians focused on "constructing a free economy" before June 29, 2003, but shifted to "completing" it after the CEPA was issued. Similarly, in the JOURNEY metaphor, officials initially highlighted an "ongoing phase" with terms like "explore" and "step" but later emphasized the final goal of "achieving full economic liberalization". These strategies illustrate how political leaders build positive self-images so as to frame their agendas to facilitate economic liberalization in Hong Kong.

In this paper, we turn our attention to the issue of whether such changes in source domains occur outside of political contexts and, if so, how these changes reflect changes in social moves in the business world. We focus on the use of WAR metaphors in business media content related to businesswomen to examine:

RQ1. To what extent do WAR metaphors undergo incremental changes in business media content related to businesswomen?

RQ2. In what ways have the societal topics (target domain) of WAR metaphors in business

media discourse related to businesswomen evolved over time?

RQ3. How have the meanings of frequently used WAR metaphorical keywords shifted within business media content focused on businesswomen over time?

3. Method

3.1 Keyword list

Ahrens et al.'s (2024) gendered metaphor study identified 50 keywords from five frequently source domains (BUILDING, COMPETITION, JOURNEY, PLANT and WAR) based on previous metaphor research (Lakoff & Johnson, 2003), dictionaries such as the Collins Cobuild metaphor dictionary (Deignan, 1995), and source domains identified in professional contexts (e.g., Charteris-Black 2004, 2006, 2011) as well as using the source domain verification methodology in Ahrens & Jiang (2020). Ahrens et al. (2024)'s experimental study on the 50 identified keywords shows that keywords associated with three source domains (BUILDING, COMPETITION, and WAR) were viewed as more masculine, while keywords associated with the source domains of JOURNEY and PLANT were viewed as more feminine.

In this study, we initially adopt the ten WAR metaphorical keyword list from Ahrens et al (2024). In addition, Ahrens et al.'s (2022) finding and discussion on evaluating the influence of metaphor in news on foreign-policy support indicates that the novel metaphors may involve near-synonyms of a conventional mapping. Thus, we include the near-synonyms (by searching strongest matches related to WAR domain from https://www.thesaurus.com/) to generate the keyword list (shown in Table 1) for our data collection.

Moreover, any possible metaphorical expressions identified during reading the texts such as "lost (ground)", "conquering", "demolished", "and ambush" which are not on the list, are also included for further verification. Verified WAR metaphors are also included in the data analysis.

3.2. The collection of word-sentence pairs

We conducted a structured search using the Business Source Complete database via EbscoHost to gather data for our analysis, including "Bloomberg Businessweek" and "BusinessWeek" (former name), to ensure article relevance. We specifically chose articles related to women in business and female entrepreneurs by using relevant keywords such as "female entrepreneurs" or "women entrepreneurs" or "female business" or "women business".

WAR keywords Ahrens et al.'s (2024)	**Near-synonym (**strongest matches) **from Thesaurus**
war	battle, bloodshed, combat, conflict, fighting, hostility, strife, strike, struggle, warfare
army	artillery, battalion, command, squad, troops
assault	aggression, incursion, invasion, offensive, onslaught, rape, strike, violation, abuse, invade, rape, shoot down, violate
battle	assault, attack, bloodshed, bombing, combat, crusade, fighting, hostility, skirmish, strife, struggle, war, warfare
combat	fight, shootout, skirmish, struggle, war, warfare
enemy	adversary, antagonist, attacker, bandit, competitor, criminal, detractor, foe, guerrilla, invader, murderer, opponent, opposition, prosecutor, rebel, rival, spy, terrorist, traitor, villain
military	army, force, navy, service, troop, naval
skirmish	battle, combat, conflict, feud, fisticuffs, fracas, scuffle, strife, tussle, WAR
weapon	ammunition, bomb, cannon, firearm, gun, knife, machete, machine gun, missile, nerve gas, pistol, revolver, rifle, shotgun, sword, tear gas
warrior	fighter, hero, soldier

Table 1. WAR source domain keywords from Ahrens et al. (2024) and their near-synonyms

We searched for these keywords in articles from 1995 to 2024. The identified keywords and their associated sentences were then exported into data files, which were divided into three distinct time periods: Period I (1995-2004)

similar to the time period prior to 2004 researched by Koller (2004), Period II (2005-2017), and Period III (2018-2024) which is the period aligning with the feminist MeToo movement. The relevant articles were saved in text files for context checking and annotation. The total corpus contains 36 articles: 18 from Period I, 11 from Period II, and 7 from Period III. Overall, the corpus contains 66,497 tokens (14,676 types). Specifically, the sub-corpus for Period I includes 31,290 tokens (6,503 types); the sub-corpus for Period II contains 22,651 tokens (4,897 types); and the sub-corpus for Period III includes 12,556 tokens (3,276 types).

3.3 Procedure

We then followed the MIPVU procedure (Steen et al., 2010) to systematically identify metaphorical language usage and remove the non-metaphorical items. Next, we verified source domain (Ahrens and Jiang, 2020) by cross-checking the identified WAR metaphorical keywords with the SUMO (Suggested Upper Merged Ontology) knowledge base and general dictionaries. This ensured that the chosen items accurately represented the WAR conceptual domain. Then, we followed the mapping principles outlined by Ahrens (2010) to identify the target domains and the associated topics for conceptual metaphor analysis. During the process, two annotators with linguistics expertise collaborated to review the initial data sets and verify the WAR source domain. In terms of the WAR source domain verification and the identification of societal topics reflected by target domains, the inter-coder reliability of two coders with linguistic experts was 88.89%. Any ambiguous cases were resolved through discussion to reach a final agreement, and non-relevant instances were removed from the dataset.

The finalized list of WAR source domain keywords and associated sentence-level examples contains 46 occurrences of keyword and sentence pairs in Period I, 23 occurrences of keyword and sentence pairs in Period II, and 12 occurrences of keyword and sentence pairs in Period III.

4. Results and discussion

4.1. The decreasing trend: WAR metaphors in businesswomen's media coverage

Our first RQ considered the extent to which WAR metaphors undergo incremental changes in business media content related to businesswomen. In our analysis of the normalized frequencies of the WAR metaphorical keywords across the three time periods (shown in Figure 1), we observed changes in the presence and prominence of various word vectors. In Period I, the words "battle" and "struggle" dominated with a normalized frequency of 130 per 1000 words, while other words related to military conflicts, such as "force," "rival," and "army," appear less frequently, ranging from 43 to 65 per 1000 words. The total 24 distinct WAR keywords presented in Period I reflect a focus on specific aspects of battle in the use of WAR metaphors in

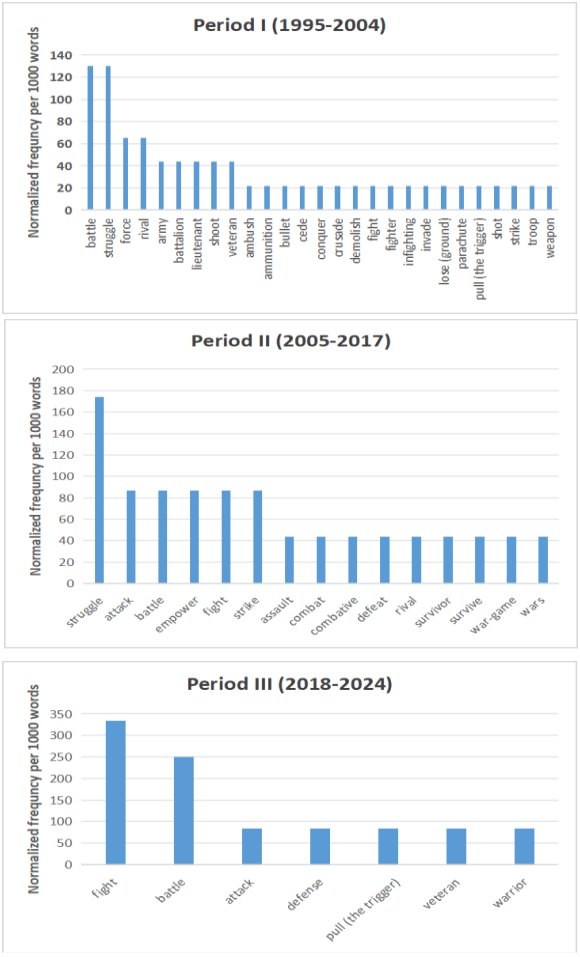

Figure 1. Normalized frequencies of the WAR metaphorical keywords across the three time periods

business media discourses related to businesswomen.

Moving to Period II, "struggle" increased to a normalized frequency of 174 per 1000 words, indicating its central role in the use of WAR metaphors during this period, while "battle" and "attack" both had a normalized frequency of 87. This period saw the introduction of some new words like “empower”, “assault” and “combat” for the use of WAR metaphors. However, some words from the previous Period I, such as "ammunition", "bullet", “weapon” and “parachute” which are specific weaponry terminologies and directly related to military and traditional combat scenarios, were noticeably absent from the use of WAR metaphors in the discourses for this period.

In Period III, "fight" emerged as the most frequent term with a normalized frequency of 333 per 1000 words, with "battle" also maintaining a strong presence at a normalized frequency of 250. Metaphorical expressions from Phase 1, such as “pull (the trigger)” and "veteran" reappeared in Period III after being absent in Period II. New WAR metaphorical keywords such as "defense" and "warrior" appeared, while others from earlier phases, such as "force" and "troop," do not appear at all.

Overall, "struggle," "battle," and "fight" were consistently present, highlighting their central role in the use of WAR metaphors within the business media discourses. The absence and re-occurrence of certain words indicated a shifting focus over time. To further explore the diachronic changes, we refer to the cluster visualization of WAR metaphors from 1995-2024 (see Figure 2) for our investigation. Keywords and their associated sentence pairs were input into the BERT (Bidirectional Encoder Representations from Transformers), an open-source machine-learning framework for word embedding (Devlin et al., 2018). This process generated vectors for the keywords, reflecting the complex semantic and syntactic relationships between the words and their contexts.

The advantage of BERT is that its pre-trained model can process language bidirectionally; in other words, it handles the surrounding context of each word at the token level. This results in more accurate and context-aware embeddings, capturing nuanced meanings effectively.

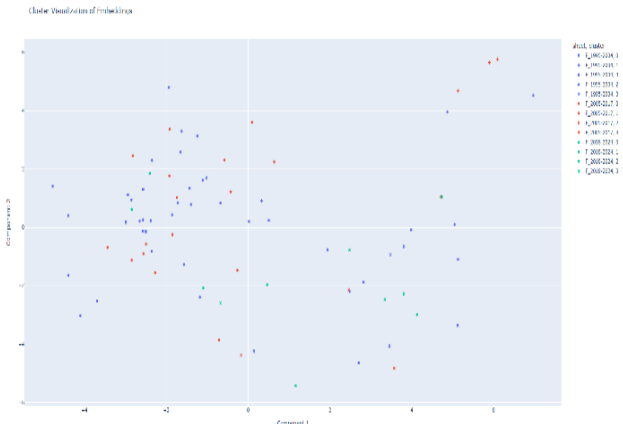

Figure 2. Cluster visualization of WAR metaphors from 1995-2024

Clustering was performed using the K-Means algorithm to group keywords based on their semantic similarities. Firstly, keywords for different periods were lemmatized to standardize different forms of the same word, and their embeddings were aggregated. The optimal number of clusters was determined using silhouette analysis, ensuring that the selected number of clusters best represented the data. The K-Means algorithm was then applied to the embeddings to assign each keyword to a cluster. Finally, the data was visualized in a 2D scatter plot using PCA for dimensionality reduction, with point colors indicating cluster membership.

The overall distribution of the word vectors reflects their relationship in semantic space in the three different time periods. In Period I, words like "ammunition" and "weapon" clustered in an area focused on military action. As time passes, the disappearance of these words shifted the distribution of semantic space towards broader themes, such as “struggle” and “survival.”

From the dispersion of vectors, we found that many words clustered together in Period I, more closely in the same direction to form a dense group indicating a more cohesive usage of WAR metaphors to portray a strong military-focus picture in the business media content. The vectors in subsequent periods tended to scatter over a wider space. The absence of certain concrete WAR keywords created a sparser vector space in Period II. However, we observed a re-cluster of vectors “fight" in Period III to form a new semantic center that highlights the new

societal topics in business media during this period.

We also observed an expansion of dimensions in the vector space from the change of WAR metaphorical words over time, with a change from the specific military terms in earlier times to experiential-oriented words such as "struggle", "survive" and "fight". This gradually spreading tendency indicates a broader social change reflecting the evolution of language use over the three time periods, indicating social transformations taking place in the use of WAR metaphors in business media discourses. One potential explanation for this shift could be a growing awareness of businesswomen's experiences under the BUSINESS AS WAR framing as an increasing number of women have pursued careers in business. The more dispersed use of WAR metaphors in later periods may suggest an attempt to highlight women's experiences, the challenges women are facing at work, and the importance of gender equality as an inclusive way for women to achieve professional success.

The following sections will delve deeper into these trends and analyze the implications of the changing use of WAR metaphors in businesswomen-focused media discourses.

4.2. Topics around the use of WAR metaphors

In response to RQ2, we analyzed the conceptual metaphors and topics structured in the three time periods. On the one hand, we found that the overarching concept of BUSINESS AS WAR remained stable under changing societal circumstances. For instance, company teams were perceived as "army", "troop" and corporate conflicts were perceived as "war" and "battle". In addition, businesswomen's roles as out-group members remained unchanged over time. On the other hand, we also observed an evolving role of language with different foci. Businesswomen are not only warriors for their work itself, but they are also battling beyond business for work-life balance and gender equality. As time changed, business media focused more attention on businesswomen's challenges in balancing their careers and personal lives, a topic that had received less discussion in the articles in the corpora in earlier periods. This shift in business media discourse signaled a broader social transformation, indicating that businesswomen have started to gain greater visibility in public.

4.2.1. Women's unchanged out-group role

Although businesswomen have gained increased public attention in the industry over the past decades, they are still viewed as out-group members by male colleagues, their companies, and the public. This perception of businesswomen as outsiders has remained unchanged over time, as we found expressions such as "aren't always comfortable ceding control to investors" and "not trusted enough to pull the trigger" as negative comments regarding businesswomen's decision-making power.

Business social media also indicated that women, as out-group members (Eubanks, 2000; Koller, 2004), were conceptualized as INVADERS/ENEMY by the "historically dominated men". This has resulted in businesswomen's extra effort to engage in a hegemonic co-option strategy so as to join male-dominated social activities in order to become in-group members in the hegemonic masculine-dominated business world.

Consequently, the persistent view of businesswomen as out-group members has resulted in more challenges for women to achieve professional success at work. Despite the growing presence of women in business, they continue to face obstacles due to this entrenched perception of them as not belonging to the industry.

4.2.2. Transferring topics: Women's battles beyond business (to balance and equality)

In businesswomen-focused media content, the use of WAR metaphors has changed over time while keeping the idea of business as a battlefield. Initially, female leadership was portrayed in a hierarchical, military-like corporate structure using specific military or weaponry terminology. Later, there was a shift towards discussing women's challenges in balancing work and personal life. In the most recent period, there has been increased focus on gender inequality, especially during the MeToo movement.

4.2.2.1 Female's leadership role in military-like corporate structure

WAR metaphors in Period I mainly clustered in the same areas, suggesting similar semantic features when depicting the overall picture of the business world under the overarching conceptual metaphor BUSINESS IS WAR, including CORPORATE AS BATTLEFIELD, TEAM AS ARMY, and the hierarchical roles in corporate which involve female leadership such as FEMALE LEADERS ARE GENERALS and FEMALE LEADERS' SUBORDINATES AS LIEUTENANTS (see Example 1).

Example 1: Stewart rarely appears on magazine covers anymore and is trying to groom some of her lieutenants as media personalities.

Compared with Period I, WAR metaphors in Period II partially overlapped with the area where most of the clustered data in Period I was located, which indicates that a portion of the WAR metaphors still reinforces the conceptual knowledge conceptualized in Period I, when business social media continued to conceptualize businesswomen's leadership under the overarching concept BUSINESS IS WAR. The following Example 2, for instance, aligned with the businesswomen's aggressive leadership, which was conceptualized in Period I.

Example 2: Combative working conditions aren't new for Barra.

In addition, media described businesswomen as FIGHTERS with a more detailed description of the strategy female leaders adopt. Example 3 conceptualizes female business leaders' competitive advantage of expanding network as WEAPON when running a business.

Example 3: A woman entrepreneur's most effective weapon is a constantly expanding network.

4.2.2.2 Women's battle for work-life balance

Moving to Period II, we also observed an evolving role of the WAR metaphors. Businesswomen were not only portrayed as warriors fighting for success in their work, but the metaphorical framing expanded to encompass their battles for work-life balance (see Example 4). In other words, businesswomen were no longer only depicted as combatants in the corporate but also as fighters for integrating work and life together in the workplace.

Example 4: It's when she turns to the fraught question of how women struggle to balance their career and kids that Sandberg reminds you she breathes the rarefied atmosphere of Planet Zuckerberg.

This shift in the use of metaphorical language indicates a growing awareness of and sensitivity to the unique experiences and priorities of businesswomen in the media. The BUSINESS AS WAR framing evolved to better reflect the broader societal and cultural struggles that women navigated as they pursued professional success.

4.2.2.3 Businesswomen's battles for gender equality

Although gender equality was mentioned in Period I, the media placed greater emphasis on gender equality in the later period. A growing number of magazine articles from Period II described businesswomen as "corporate survivors" and discussed their disputes against companies. These articles revealed the reality that "many Wall Street firms assigned women to less prestigious trading desks and divisions with the smallest bonus pool". In Period III, we see the media continue to address the issue of gender inequality, with an increasing amount of media coverage on this topic.

In fact, women's role as out-group members also appears more often to be recipients or targets of the anti-DEI (diversity, equity, inclusion) opposition rather than active participants. As Example 5 suggests, women are facing difficulties due to forces outside their control. Moreover, women are not afforded that level of trust and empowerment, as shown in Example 6.

Example 5. While Vander Marel is hopeful corporate cannabis can turn the tide on its gender problem, she acknowledges it will be difficult. "It's an uphill battle," she says. "It takes years to change boards."

Example 6. Women analysts are trusted to make suggestions but not trusted enough to pull the trigger for the portfolio," she says.

In addition, business media has devoted increased attention to women's legal disputes with companies during this period, framing

these conflicts as a FIGHT or BATTLE. This included extensive coverage of a well-known 13-year lawsuit case between a businesswoman and a Wall Street company, Goldman Sachs. which was portrayed as a “MeToo triumph”. The media's tendency to depict these legal challenges faced by businesswomen through the lens of conflict and battle suggested a social shift in how their experiences were being framed and discussed.

4.3. Incremental semantic change of frequently used WAR metaphorical keywords

To answer RQ3, we calculated the frequency of the keywords under the WAR source domain used in the three time periods (see Figure 3). The keywords “battle”, “struggle”, and “fight” are the most frequently used WAR metaphorical keywords for the three time periods. To examine the ‘frequently occurring keywords’, we adopted a cutoff cumulative percentage up to 60% as the criteria to cover the top keywords that occupy more than half of our total observations.

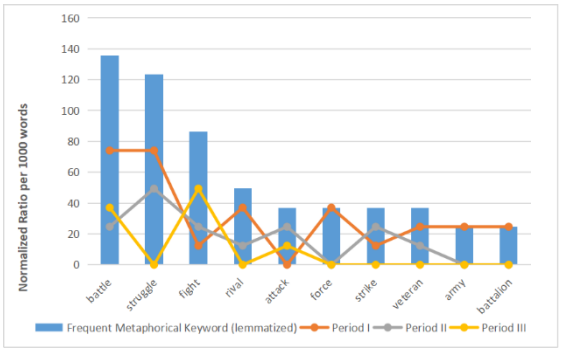

Figure 3. Distribution of the frequent WAR metaphorical keywords (cumulative percentage up to 60%) in businesswomen-focused discourses in corpora

4.3.1 Semantic changes of "battle"

Over the past decades, "battle" has been used to capture the various challenges women face in the workplace, emphasizing women’s resistance and the determination to achieve equality positively. In Period I, the word "battle" primarily symbolized corporate conflicts, particularly highlighting the struggles women encountered in reaching executive positions at work. It also framed the pursuit of gender equality as a proactive endeavor by women to overcome stereotypes. Moving towards Period II, the focus of WAR metaphors evolved to emphasize more specific challenges, portraying businesswomen's struggles as combat-like efforts to progress and succeed. During Period III, "battle" took on a more situational context, addressing gender issues in corporate environments and highlighting women’s future endeavors to overcome conflicts, as well as legal disputes with their (former) employers. Therefore, the semantic changes of “battle” framed women’s ongoing challenges in a multifaceted way over time.

4.3.2 Semantic changes of "struggle"

Throughout Periods I and II, the metaphoric meaning of "struggle" consistently reflected the conflicts and challenges faced by women in the workplace, highlighting topics such as work-life balance and the specific difficulties encountered by skilled businesswomen and entrepreneurs. As shown in Table 1, "struggle" emerged as the most frequently used WAR metaphor keyword in Phase II, playing a central role in framing discussions during this period. However, in Phase III, the absence of "struggle" indicated a shift in focus toward broader societal issues, suggesting a movement toward advocating for advancements in gender equality.

4.3.3 Semantic changes of "fight"

In Period I, the metaphorical meaning of "fight" represented a determined and sustained effort by women to achieve their goals, emphasizing personal empowerment. During Period II, the metaphorical keyword “fight” denotes more aggressive and determined confrontations against entrenched gender biases and highlights the need for businesswomen to secure financial resources at the workplace. In Phase III, "fight" expanded its reference to describe the collective efforts of women-led companies to advance equality, ongoing legal battles, and the active defense of women's rights, reflecting increasing attention to the societal issue of gender inequality. This progression illustrated a social change from individual determination to collective endeavors for women’s rights and resources.

6. Conclusion

In conclusion, our current analyses of WAR metaphors revealed the evolving use of WAR metaphors over time. The consistently

prominent keywords "struggle," "battle," and "fight" demonstrated how societal issues are related to the challenges women face across different periods. As the language shifted from specific military terminologies to more experiential terms like "struggle" and "survive," these changes reflected broader social transformations. While the persistent out-group role of businesswomen remains evident, the topics addressed have transitioned from hierarchical, military-like views of female leadership to a greater emphasis on work-life balance and gender inequality, particularly in light of movements like MeToo. This semantic evolution has shaped public understanding of women's experiences in the workplace and highlighted the increasing recognition of their struggles beyond traditional business confines. In terms of limitations, this is a small-scale case study that needs future research to explore a broader and more diverse range of texts from business media to gain deeper insights into the evolving role of metaphors related to women in business.

Abstract

This paper examines the application of the ISO-TimeML framework for semantic annotation of time and events in Vietnamese texts. A case study is presented to explore temporal entity annotation by analyzing various types of event and temporal information in Vietnamese. Additionally, all attributes represented within ISO-TimeML for event entities are analyzed, considering their applicability to the Vietnamese language. Our model's results are highly promising when compared to the performance of large language models and existing temporal extraction models for Vietnamese.

1 Introduction

One of the essential tasks in natural language processing is to comprehend temporal and event information associated with natural language expressions. Until now, there are only a few works on temporal and event expressions for Vietnamese as in (Lambert et al., 2012), (Tran et al., 2012) and especially in (Strötgen et al., 2014), where the authors proposed to build a small annotated corpus of Vietnamese article with temporal expressions as part of general named entities. However, there have been no published systematic study on the semantic annotation of events and temporal expressions for Vietnamese. In the framework of our project, we are interested in the annotation of temporal information in Vietnamese documents, using a standardized universal scheme for the sake of interoperability and consistency.

Several efforts had been made to develop TimeML (Pustejovsky et al., 2003), a specification language for representing and encoding events, temporal entities and relations in documents. This markup language is then integrated in the semantic annotation framework (SemAF-Time) of the ISO TC37/SC4 project for language resource management under the name of ISO-TimeML (Pustejovsky et al., 2010).

This paper introduces our work on the application of the annotation framework ISO-TimeML to the semantic annotation of Vietnamese texts. The paper is organized as follows. Section 2 presents a brief overview of ISO-TimeML.Section 3 explores events and temporal entities in Vietnamese in relation to the ISO-TimeML annotation scheme, examining various language-specific phenomena of Vietnamese. Section 4 presents our experiments in generating ISO-TimeML formatted event and temporal expressions for Vietnamese, by combining rules and dependency syntax. Conclusions and future works are found in Section 5.

2 ISO-TimeML

As mentioned above, ISO-TimeML is a XML-based markup language specified in the ISO SemAF-Time standard of semantic annotation framework for temporal information. This standard involves the annotation of all expressions having temporal import, including temporal expressions and eventualities. The specification of ISO-TimeML is composed of an abstract syntax of annotations, a concrete syntax in XML, and a semantics of ISO-TimeML. This paper focuses more on the abstract syntax of ISO-TimeML.

The ISO-TimeML standards include annotation schemes for entities corresponding to times and events on one hand, and relationships between these entities on the other hand. Stand-off annotation is employed in ISO-TimeML to mitigate the shortcomings of in-line labeling, especially when entities are discontinuous.

Assuming that all times and events are re-

ferred to as intervals, ISO-TimeML takes into account three aspects of the semantic description of an interval entity:

- Order: The position of the interval relative to others;
- Measure: The size of the interval;
- Quantity: The number of intervals.

Order and measure are annotated as entity links, while quantity involves the quantification annotation schema QuantML (Bunt et al., 2022).

2.1 Time Entities

In ISO-TimeML, temporal expressions are marked up with the <TIMEX3> tag with four main types: date, time, duration and set, as shown in Table 1 with examples in English.

Table 1: Time's types and examples in English.

Type	Explanation	Value Examples
date	Calendar time	John left between ***Monday*** and ***Wednesday***
time	A time of the day, even in a very indefinite way	Mr. Smith left ***ten minutes to three***
duration	Explicit durations	Mr. Smith stayed ***2 months*** in Boston
set	Set of times.	John swims ***twice a week.***

Each time entity also has an binary attribute (temporalFunction) specifying if the time is not absolutely determined. For example, this attribute for *January 31* has a positive value, while it has a negative value for *Januray 31, 2024*.

2.2 Event Entities

Events are marked up with the <EVENT> tag with several attributes.

The class attribute contains 7 values: state, reporting, perception, aspectual, I-action, I-state, occurrence. A summary of these classes is shown in the Appendix (Table 5) (Saurí et al., 2006).

In addition to class attribute, event entities are also annotated with syntactic-semantic information, including part-of-speech, tense, aspect, verb form, modality, mood, and polarity.

2.3 Entity Links

Temporal expressions and events are linked together by four types of link tags (ISO, 2012): temporal links (TLINK - temporal relationship between events, times or between an event and a time), aspectual links (ALINK - relationship between an aspectual event and its argument event) and subordinating links (SLINK - relations between two events), measure links (MLINK - relation between events and duration).

2.4 ISO-TimeML Development and Implementation

The ISO semantic annotation schema are still far from complete. Recently many papers on the development and improvement of annotation schema have been published. For example, (Lee, 2015) about MLINK, (Zymla, 2018) on annotation scheme for tense/aspect, (Silvano et al., 2021) on designing multi-layer semantic annotation scheme based on ISO standards, (Yahiaoui and Atanassova, 2022) on temporal information in scientific papers.

Several temporal resources have been developed for English and other languages such as Italian (Caselli et al., 2011), French (Bittar et al., 2011), Chinese (Li et al., 2014), multilingual (Strötgen et al., 2014), etc..

For Vietnamese, the Association for Vietnamese Language and Speech Processing (VLSP) has developed and published various syntactically annotated corpora in the framework of VLSP 2020, 2021, 2022 and 2023 workshops [1]. Our ongoing project on the semantic annotation of Vietnamese document aims to develop a gold sembank for the VLSP community. To facilitate the compatibility of language resources, the annotation scheme will be developed in accordance with the established standards designed for this purpose.

The next section examines the application of the ISO-TimeML scheme to Vietnamese and discusses language-specific phenomena of Vietnamese related to event and temporal information.

[1] https://vlsp.org.vn/conferences

3 Application of ISO-TimeML to Vietnamese

To analyze the applicability of the ISO-TimeML annotation framework to Vietnamese, this paper focuses on the exploration of time and event entities in Vietnamese. Subsection 3.1 introduces different temporal expressions in Vietnamese for each temporal type. Subsection 3.2 investigates various attributes of event entities in ISO-TimeML and their equivalent representation in Vietnamese.

3.1 Time Entities in Vietnamese

In Vietnamese, representing time may involve various word types and phrases. However, it mainly consists of nouns and nominal phrases.

The following sections show regular examples of Vietnamese time entities belonging to four main types of time entities specified in ISO-TimeML as listed in Table 1.

3.1.1 Date

Date entities consist of temporal expressions describing a calendar time. Here are some Vietnamese examples:

- Thứ Sáu (Friday)
- ngày 1-10-2023 (October 1, 2023)
- mùa hè năm nay (this year's summer)
- tuần trước (last week)

Amongst the examples above, the weekday may be ambiguous because thứ sáu also means "the sixth". So if one says ngày thứ sáu, both "Friday" and "the sixth day" make sense. This applies to all weekdays from Monday to Saturday (only Sunday is not equivalent to a order number).

3.1.2 Time

The examples below illustrate time entities referring to a time of the day.

- 9 giờ sáng ngày thứ Sáu (9 a.m Friday)
- buổi sáng hôm qua (yesterday's morning)
- tối qua (last evening).

We would like to bring attention to the annotation of some temporal expressions that demonstrates the benefit of using stand-off annotation. For example, given the phrase từ 2 đến 3 giờ (literally "from 2 to 3 o'clock"), two time entities need to be annotated: 2 giờ (o'clock) and 3 giờ (o'clock). However, 2 and giờ are not consecutive in the sentence. Stand-off annotation proves valuable in this case.

3.1.3 Duration

Below are some temporal phrases describing explicit duration.

- 2 tháng (2 months)
- 24 giờ (24 hours)
- cả đêm hôm qua (all last night)

3.1.4 Set

These last examples of time entities correspond to expressions describing a set of times.

- hai lần một tuần (twice a week)
- mỗi 2 ngày (every 2 days)

In summary, the annotation of time entities in Vietnamese doesn't differ much from other languages like English. The links between time entities for representing time ordering are similar.

3.2 Event Entities in Vietnamese

For event entities, ISO-TimeML offers various attributes, namely class, type, part-of-speech, tense, aspect, verb form, modality, mood, and polarity. Event class, as described in Table 5, type, modality, and polarity can be considered as universal. Therefore, this research will concentrate on the five remaining attributes and discuss the application of these specified attributes to Vietnamese event expressions.

3.2.1 Part-of-speech

As specified in ISO-TimeML, in Vietnamese, event entities also include verbs, nominalizations, adjectives, predicative clauses, or prepositional phrases.

From a comparative perspective, we would pay attention to the cases of phrasal verbs and nominalizations.

In Vietnamese, a predicate can be composed of a verb and another word of different parts-of-speech. In many cases, the composition involves a verb and a preposition or another verb indicating the orientation of the action. In those

cases, we can choose to mark only the head verb.

In many other cases, the predicate is composed of a verb corresponding to an action and another verb or an adjective determining the result of that action. For example, the English sentence "I hit the window" can be translated into the following sentence:

Tôi (I) đập (hit) cái kính (the glass),

while the translation of the sentence "I broke the window" is

Tôi (I) đập (hit) vỡ (broken) cái kính (the glass).

For these cases, the verb compound can be annotated as two separate events:

"Tôi (I) đập (hit) kính (glass)"

and

"kính (glass) vỡ (broke)".

As for nominalizations, recall that Vietnamese words are morphologically invariant. Instead, classifier nouns, such as cái, sự, việc, cuộc are added before verbal or adjectival predicate to form noun phrases. For example: sự (classifier meaning fact) cố gắng (try) meaning efforts, and cái (classifier for things) ăn (eat) meaning *foods*. Therefore, when annotating events expressed by means of nominalizations, it is necessary to focus on the main verb and record the classifier noun.

3.2.2 Tense, Aspect, Vform and Mood

These four attributes are typical for the specification of verbs in Indo-European languages. However, Vietnamese is a monosyllabic language which is morphologically invariant. This means that considering only the main predicate would not yield equivalent values for all the attributes mentioned above.

While the Vform attribute value is none for all events in Vietnamese, the tense, the aspect and the mood attribute can be specified in two ways: use of temporal adverbs or of temporal expressions.

For example, the adverb đang (i.e. in progress) can be used to express an event in present or present continuous tense. However, if we use a temporal expression like Bây giờ (i.e. now), the meaning of a sentence remains unchanged if the adverb đang is omitted in that sentence. The two sentences

1. Bây giờ (now), tôi (I) sống (live) ở (in) Hà Nội (Hanoi)

   and

2. Bây giờ (now), tôi (I) đang (*in progress*) sống (live) ở (in) Hà Nội (Hanoi)

share similar meanings:

Now I am living in Hanoi.

The use of temporal expressions are illustrated in the following examples.

- For the past tense, commonly used words include trước (before), qua (past), such as: Hôm qua (yesterday), hôm trước (the day before), 3 hôm trước (3 days ago), 2 tuần trước (2 weeks ago).

  For example: Hôm qua (yesterday), tôi (I) đi (go) Hà Nội (Hanoi)" is understood in the past tense because of using hôm qua, instead of using adverb.

- For the present tense, typically used words include nay (today), này (now). For example: "Hôm nay (today), lúc này (at this moment).

- For the future tense, words like mai (tomorrow), sau (then) are commonly used. For example: ngày mai (tomorrow), hôm sau (the next day), tuần sau (next week).

Temporal expressions can be sometimes ambiguous, as shown in the following sentence:
Tôi (I) định làm (do) bài tập (homework) trong (in) 10 phút (minutes) nữa (later).

This sentence can be understood in two ways

1. *I'm doing homework and will finish in 10 minutes*,

2. *After 10 minutes, I will do my homework.*

It is interesting to note that the same temporal adverbial phrase trong 10 phút nữa (in the next 10 minutes) doesn't cause ambiguity in the following sentence:
Tôi (I) định đi (go) làm (work) trong (in) 10 phút (minutes) nữa (later)
with the only possible understanding:
From now until 10 minutes later, I will go to work,
without specifying the exact time.

The difference comes from the perception of the two main verbs: "to do" and "to go".

Finally, it is important to remember that in many cases, neither temporal adverbs nor temporal expressions can be found in a sentence.

In such instances, that single sentence is underspecified regarding tense or aspect attributes. These attribute values can be determined using information expressed in the discourse annotation.

4 Experiments

To generate event and time expressions for Vietnamese, the workflow is described specifically in Figure 1.

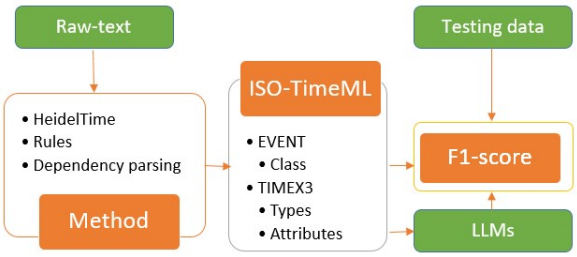

Figure 1: Workflow for generating ISO-TimeML annotation for Vietnamese.

As mentioned earlier, our model will focus on extracting <EVENT></EVENT> and <TIMEX3></TIMEX3> tags for Vietnamese text.

To identify events, we concentrate on the main occurrences and utilize dependency parsing to extract the primary verbs and adjectives from the sentence. Then, the similarity of Vietnamese verbs to each class is evaluated based on the definitions provided for each class in English.

For temporal expressions, we selected HeidelTime[2] as the base model, and then refined and added necessary rules for Vietnamese. Next, our data will be processed using dependency parsing (Linh et al., 2020). All spans labeled *obl:tmod* (time-related label in dependency syntax) will be used to extract time expressions. At the same time, experiments will be conducted to craft prompts for several large language models, such as GPT-4[3] and Gemini[4], to generate ISO-TimeML for Vietnamese. Afterwards, the results of these models are described, followed by some discussions.

4.1 Dataset

The data used in our experiments is derived from the VLSP-NER 2021 dataset (Linh et al., 2022). Since this dataset includes time tags for Vietnamese, all sentences containing these time tags are extracted. Then, our proposed process is applied to this extracted data. Additionally, we manually annotate 112 Vietnamese sentences, which are used as test data.

4.2 Metrics

The systems are evaluated using an adjusted scoring method. This involves calculating precision, recall, and F1 for each attribute by considering the number of event and temporal expressions with the correct attribute, the total number of event and temporal expressions in the gold standard, and the total number of event and temporal expressions in the system's output (Chang and Manning, 2012). The revised attribute scores based on the following formulas:

$$P_{att} = \#Correct_{att}/\#Mention_{resp}$$

$$R_{att} = \#Correct_{att}/\#Mention_{gold}$$

$$F_{1att} = 2 * P_{att} * R_{att}/(P_{att} + R_{att})$$

This formula will then be applied to each type of ISO-TimeML tag (<EVENT></EVENT>, <TIMEX3></TIMEX3>).

4.3 Results

For the <EVENT></EVENT> tag, we only focus on the "class" attribute. In contrast, the <TIMEX3></TIMEX3> tag includes multiple attributes: TYPE, Value, mod, temporalFunction, anchorTimeID, valueFromFunction, functionInDocument, beginPoint, endPoint, quant, and freq, as specified by the ISO-TimeML annotation guidelines.

For the <EVENT> tag, we assign values to the "class" attribute, which includes the following event classes: REPORTING, PERCEPTION, ASPECTUAL, I_ACTION, I_STATE, STATE, and OCCURRENCE. To identify events, we focus on main events and use dependency parsing to extract the primary verbs and adjectives from the sentence. The similarity of Vietnamese verbs to each class is then assessed based on the definitions provided for each class in English.

For the <TIMEX3> tag, we have developed additional rules for identifying time expressions in Vietnamese, modified HeidelTime's rules to

[2]https://github.com/HeidelTime/heideltime
[3]https://openai.com/index/gpt-4/
[4]https://gemini.google.com/app

better suit Vietnamese, and integrated these with dependency parsing. Some of the time rule changes are listed in Table 2.

Table 2: Statistics on rule changes for identifying time expressions.

Model		DATE	TIME	DURATION	SET
HeidelTime		127	34	8	4
Our model	New rule	20	2	6	1
	Delete rule	2	0	0	0
	Modify rule	2	2	0	0
	New norm	2	0	8	1
	New pattern	15	5	0	1

The models experimented with include: Gemini, GPT-4 (using few-shot prompting for both), HeidelTime, and our improved model.

The results of the models for the <EVENT> tag are detailed in Table 3. Only three models are included here because HeidelTime does not handle event tags for Vietnamese. It can be seen that for event detection, Gemini is currently the most stable model with the best performance. Our model is still relatively modest, achieving 40.87%. GPT-4 has the lowest performance with 37.43%. These results could be due to various reasons, such as: the presence of multiple events in a sentence while the model identifies fewer (since we focus on main events), the difficulty of classifying event types for Vietnamese, etc.

Table 3: Results of all models for <EVENT> tag.

Model	P_{att}	R_{att}	F_{1att}
Gemini	54.22%	40.54%	46.39%
GPT_4o	41.30%	34.23%	37.43%
Our model	**39.50%**	**42.34%**	**40.87%**

Table 4 presents the results of our experiments with the four models for time tag. It shows that large language models (LLMs) underperformed, achieving only around 34.15% and 43.33%. HeidelTime came in third with 74.61%, a respectable score for a model that has been effective for Vietnamese over time. Our model, ranking first with 85.52%, demonstrates that the additional rules, enhancements, and integration with dependency parsing are well-suited and beneficial for Vietnamese.

We presents an example of the differences between the models with the sentence: "Sau khi chuẩn bị cẩn thận, chúng tôi đã báo cáo hơn 1 tiếng." (*After careful preparation, we reported for over an hour."*)

Table 4: Results of all models for <TIMEX3> tag.

Model	P_{att}	R_{att}	F_{1att}
Gemini	48.24%	39.32%	43.33%
GPT_4o	38.02%	30.99%	34.15%
HeidelTime	83.07%	67.71%	74.61%
Our model	**89.01%**	**82.29%**	**85.52%**

For event annotation, all the models are tested with this sentence identified the two main events: "*prepare*" and "*report*":

<EVENT eid="e1" class="I_STATE"> chuẩn bị </EVENT>

<EVENT eid="e2" class="REPORTING"> báo cáo </EVENT>

For time annotation, most models can identify basic time expressions. However, our model provides additional annotations for time-specific phrases unique to Vietnamese:

- Gemini:

  <TIMEX3 tid="t1" type="DURATION" value="P1H">hơn 1 tiếng</TIMEX3>

- GPT-4:

  <TIMEX3 tid="t1" type="DURATION" value="P1H">hơn 1 tiếng</TIMEX3>

- HeidelTime:

  <TIMEX3 tid="t1" type="DURATION" value="P1H" mod="MORE_THAN"> hơn 1 tiếng </TIMEX3>

- Our model:

  <TIMEX3 tid="t3" type="DURATION" mod="AFTER"> Sau khi chuẩn bị cẩn thận </TIMEX3>

  <TIMEX3 tid="t1" type="DURATION" value="P1H" mod="MORE_THAN"> hơn 1 tiếng </TIMEX3>

It can be seen that our model, which integrates dependency parsing, successfully annotated the time span "Sau khi chuẩn bị cẩn thận (*After careful preparation*)". This is one of our improvements, as in Vietnamese, not only specific times but also phrases following words like "khi (*when*)", "sau (*after*)", "trong (*during*)", etc., are considered time expressions that need to be captured and annotated.

5 Conclusions

In this paper, we have presented a case study on the application of the ISO-TimeML annotation scheme to the semantic annotation of Vietnamese documents. We have introduced different examples of temporal and event expressions in Vietnamese and their annotation using ISO-TimeML entities and attributes. With the experiments conducted on large language models and our developed models, the results achieved are quite promising for both event and time annotation.

In the future, we will continue to refine the ISO-TimeML semantic labels for Vietnamese, specifically focusing on entity link tags. Additionally, we are still working on the semantic annotation of the Vietnamese translation of the book "The Little Prince" (Saint-Exupery). This annotation project allows us to explore various aspects of the semantic annotation framework ISO-SemAF in a comparative approach.

Appendix

Table 5: Attribute "class" in Event.

English	Definition	Example
state	Circumstances in which something obtains or holds true.	He mediated the ***crisis***.
reporting	Action of a person or an organization declaring something, narrating an event, informing about an event, etc.	No injuries were ***reported*** over the weekend.
perception	Physical perception of another event	Everyone could ***hear*** the man shouting loudly.
aspectual	Grammatical device of aspectual predication, which focuses on different facets of event history	All non-essential personnel should ***begin*** evacuating the sprawling base
I-action (Intensional Action)	Introducing an event argument describing an action or situation from which we can infer something given its relation with the I-action	They were ***asked*** to take along important papers.
I-state	States referring to alternative or possible worlds	"They don't ***want*** [to play with us]," one U.S. crew chief said.
occurrence	All of the many other kinds of events that describe something that happens or occurs in the world.	Mia ***visited*** Seoul to look me up yesterday.

Developing an Up-to-date Academic Word List for Public Health Emergencies of International Concern: The Case of Mpox

Longxing Li
Faculty of Languages and Translation
Macao Polytechnic University
Rua de Luís Gonzaga Gomes, Macao, China
lxli@mpu.edu.mo

Abstract

The mpox epidemic in many countries has made it a Public Health Emergency of International Concern for two times so far. Learning lessons from the COVID-19 pandemic, the international community has made response plans and proposed measures to contain the epidemic. From the perspective of emergency language service, this paper aims to develop an academic word list on mpox to assist prevention and facilitate communication. The powerful corpus tool Sketch Engine and its rich corpus resources are exploited to make the Mpox Word List, which includes about 300 words. The four-step purpose-oriented procedure for academic word list development is synthesized based on previous literature and the practice of developing this mpox word list. Further research directions in extracting multi-word terms or n-grams and developing supplementary acronym list can be included to facilitate academic exchange and mass communication. This paper is believed to be of significant reference value for further term extraction practice and word list development in public emergencies, crises, and other scenarios.

1 Introduction

In 1970, the first human cases of mpox were diagnosed in the Democratic Republic of the Congo. Decades after, a global outbreak of clade II mpox in 2022–2023 marked the first incidence of widespread community transmission outside of Africa. In July 2022, the World Health Organization (WHO) declared the outbreak a Public Health Emergency of International Concern (PHEIC) which means a public health risk requiring immediate international action. The declarations of PHEIC can rapidly mobilize international coordination, streamline funding, and accelerate the advancement of the development of vaccines, therapeutics and diagnostics. The ultimate purpose of such declaration is to catalyze timely worldwide and evidence-based action to limit the societal impacts of emerging and re-emerging disease risks (Wilder-Smith & Osman, 2020). In May 2023, as the outbreak of mpox came under control, the PHEIC status was reverted. However, a later outbreak of clade I mpox detected in the Democratic Republic of the Congo during 2023 has spread to several African countries. On 14 August 2024, the WHO declared this outbreak a PHEIC again. As of 16 August 2024, fifteen countries were reported to have identified cases of mpox, with 16,839 reported cases and 501 reported deaths (a fatality rate of about 3-4%).

To respond to this PHEIC, the WHO issued Global Strategic Preparedness and Response Plan and proposed mpox control and elimination plans in the Strategic Framework for Enhancing Prevention and Control of mpox 2024–2027. This framework emphasizes integrating efforts of all health programs and coordination among all partners and stakeholders to ensure a continued and robust response for mpox. International risk communication, community engagement, and patient services are essential components to control mpox outbreaks in every context. The clear and consistent terminology is a requisite for quick and smooth communication. Terminology support provided in the forms of academic word lists and terminology management play an important role in public risk communication and emergency language service.

The COVID-19 pandemic in the past few years made us acutely aware of the importance of language services in international public health emergencies. To facilitate communication during the prevention and control of the pandemic, many researchers have developed various word lists with specific purposes and functions. Li and Wang (2021) extracted 364 single-word and 176 multi-word COVID-19 terms using the COVID-19 thematic academic corpus and the corpus tool Sketch Engine. Saed et al. (2022) established a COVID-19 lemmatized word list classified into six categories using Factiva news data and the corpus tool Wordsmith.

At present, there are few attempts at producing a mpox word list. Although COVID-19 and mpox are not spreading on the same scale, there is still a need to prepare for a mpox epidemic on a larger scale. Therefore, learning from previous researchers' experience in producing academic word lists, especially COVID-19 word lists, this paper attempts to develop a specific mpox word list to help its prevention and control.

The attempts of making word list for specific purposes can be traced back to the 1950s. To meet the needs in teaching and learning English vocabulary, West (1953) developed one of the earliest word lists, the General Service List (GSL), in which 2,000 common word families were listed. In recent decades, researchers have expanded the field of word list development by making lists for more specific purposes. The difficulty and importance of medical vocabulary make the word list of English for medical purposes (EMP) an important branch, e.g., the Medical Academic Word List (MAWL) by Wang et al. (2008) and the Medical Academic Vocabulary List (MAVL) by Lei and Liu (2016). Different from MAWL, MAVL only includes words with the minimum frequency higher than 28.57 times per million words (PMWs) to ensure that the included words are frequently used. In developing the COVID-19 word list, Li and Wang (2021) addressed existing problems in previous studies and proposed a purpose-oriented five-step procedure for word list development. The standardized procedure and the way Saed et al. (2022) categorize the words in the list will be referenced to guide the development of the Mpox Word List in the current study.

2 Methods

2.1 The corpus tool Sketch Engine

Sketch Engine (Kilgarriff et al. 2004, Kilgarriff et al. 2014) is the representative of the fourth-generation corpus retrieval tools, which realizes the online retrieval of corpus and offers the core functions: word sketch, word sketch difference, thesaurus, concordance, wordlist, keywords, and n-grams. It has been widely used in lexicology, language teaching, discourse analysis, translation studies, contrastive linguistics, keyword studies, and so on as in Li et al. (2018), Li et al. (2020), Li et al. (2021), and Li (2023). The keywords function is the most important in the production of word lists.

The keywords function of Sketch Engine is designed to compare two corpora to find out the unique or typical words in one corpus relative to the other corpus; these words can help understand the contents or topics of the corpus, so this function is especially suitable for retrieving keywords or extracting terms. The selection of the reference corpus determines the relevance of the extracted candidate items to the topic. Taking the production of the COVID-19 Word List as an example, the word list with EGP corpus as a reference corpus may contain a large number of general medical expressions and has a weaker correlation with the topic than that with EMP corpus as a reference. However, if another medical corpus in Sketch Engine is adopted as a reference corpus, the pertinence and emergency of the COVID-19 Word List can be improved and a large number of general medical words possibly known to the word list users can be reduced. The size of the focus corpus used for terminology extraction does not need to be very big, but a larger corpus covers more terms. The larger the reference corpus is, the better. The size of the COVID-19 corpus and other medical corpora in Sketch Engine is large enough to meet the requirements for the production of the word list.

Keywords are single-word items that appear more frequently in focus corpus than in reference corpus, which can be displayed in lemma, word, or other forms according to the needs and are case sensitive. In other words, the keywords function can select the displayed form of words according to the needs of researchers and extract the single-word terms and multi-word terms simultaneously, thus it significantly enhances the efficiency of word list development. From the introduction above, it can be seen that Sketch Engine is a corpus tool

suitable for providing emergency terminology services.

2.2 Corpus data

The available academic and language data for mpox is not so rich as those for COVID-19 which has a 1.4-billion-word specialized medical corpus CORD-19 in Sketch Engine. So, it would be more challenging to select proper data resources for developing the Mpox Word List. To collect a dataset large enough for keywords extraction, the rich corpora resources in Sketch Engine are explored and the corpus English Trends (2014–today) is considered as a possible source of data. The English Trends Corpus (ETC hereafter) is a monitor corpus consisting of news, research articles, Wikipedia, and texts from other sources. The corpus has been regularly updated with new texts since 2014 and grows by about 70 million words every week. As of August 2024, the corpus has reached a size larger than 82 billion words. The considerable size and its timely update make it a valuable resource to generate sufficient data for emerging or less-frequently discussed topics. A good amount of concordances of monkeypox and mpox are expected to be produced from the ETC, thus a concordance corpus of a reasonable size with mpox as its theme can be built to extract terms.

The next step is to decide which word to be retrieved as the keyword (KWIC) to create the concordance corpus. It should be pointed out that the name of the disease has been changed from monkeypox to mpox now. On November 28, 2022, WHO announced that Mpox should be used to refer to the disease and monkeypox would phase out in one year to reduce stigma, discrimination, and racism against certain animals and groups of people (Damaso, 2022). Therefore, to elicit a wider coverage of data on the epidemic, both words should be retrieved to generate more relevant terms. On 25th August 2024, the author retrieved *monkeypox* and *mpox* in the ETC by confining the data within the academic, encyclopedia, and news genres. The retrieval produced 93,890 and 4,444 occurrences of *monkeypox* and *mpox* respectively, which is large enough for building a concordance corpus on mpox. Due to the limit set by Sketch Engine, the maximum number of lines downloadable for a retrieved concordance is 10,000 with each line having a context of 100 characters left and right of the KWIC. So, 10,000 randomized concordance lines of *monkeypox* and all the 4,444 concordance lines of *mpox* are downloaded to create the Mpox Corpus. The corpus has a total of 671,856 tokens or 553,419 words. Considering that the concordances retrieved from the news genre are included in the Mpox Corpus, another concordance corpus named Mpox Academic Corpus with texts from only the academic and encyclopedia genres is created. The Mpox Academic Corpus, made of 1,244 concordances of monkeypox and 433 concordances of mpox, has a much smaller size of 75,931 tokens or 59,442 words. Later both corpora will be compared as focus corpora in terms of the effectiveness in extracting terms and the relevance of terms extracted.

To extract terms, a reference corpus should be selected to compare with the focus corpus. In Sketch Engine, by default, the largest corpus in the language is selected as the reference corpus to represent general language. This setting tends to generate a longer list of basic terms for academic or medical purposes. To make the list more relevant to mpox, an academic subcorpus of general medical and biological sciences is created from the Directory of Open Access Journals (DOAJ) corpus in Sketch Engine. DOAJ is composed of papers published in open-access journals in all areas of science, technology, medicine, social sciences, and humanities. The corpus is large with 2.6 billion English words and up-to-date with about 90% of the texts published between 2000 and 2017. The rich metadata such as the journal title, country, year of publication, publisher, subject, and article title are retained to facilitate the creation of subcorpora according to different needs. A subcorpus is created using the data from 2014 to 2017 under the subjects related to biological, medical, and health sciences. The subcorpus reaches a size of 8,220,236 words and is named DOAJ-BioMed.

The two mpox corpora and the DOAJ-BioMed corpus are thus diachronically and thematically comparable on the same platform and will be used in producing the word lists. Part 3 will introduce in greater detail the application of Sketch Engine in the production of mpox single-word list.

3 Producing the Mpox Word List

Inspired by the five-step purpose-oriented procedure in word list production by Li and Wang (2021), the author synthesized the procedure into four:

(1) analyze the purpose and users' needs of the word list and formulate principles of the word list development accordingly;
(2) set quantitative and qualitative criteria for item screening based on the principles;
(3) improve the word list by consulting users and medical professionals before publishing the list; and
(4) publish and update the word list.

3.1 Needs analysis and principles for Mpox Word List production

As previously mentioned, the word list serves medical workers, researchers, teachers and students, journalists, and common people, to meet their needs of academic activities, teaching and learning, publicizing, reporting and any other forms of communication. Most users of the word list are expected to be professionals with certain medical knowledge or with a higher education background. Therefore, two basic principles are formulated for producing the word list: first, only terms frequently appearing in the mpox research are included; second, the included terms should also be highly relevant to mpox research. The two principles ensure the high frequency and relevance of the terms listed, thus easing the burden on users and students.

3.2 Terms retrieval and the quantitative selection criteria

Guided by the two principles, the author decided on a specific term retrieval plan and the automatic selection criteria. The Mpox Academic Corpus and the Mpox Corpus are the two potential focus corpora to extract terms. There will be a comparison between the rate of terms accepted from the automatically generated keywords list. The DOAJ-BioMed subcorpus will be the reference corpus.

When retrieving the candidate terms using Sketch Engine's keywords function, most default settings are kept unchanged. For example, the "focus on" value is kept at "1" to elicit words rarely or seldomly used in general language or the reference corpus, which is more suitable for terminology extraction. The option "at least one alphanumeric" is ticked to include the retrieved lexical phrases containing at least one letter or number, such as *10-year-old* and *5G*. The maximum number of candidate terms is set to 1,000, and the single-word items are displayed in lemma (See Figure 1).

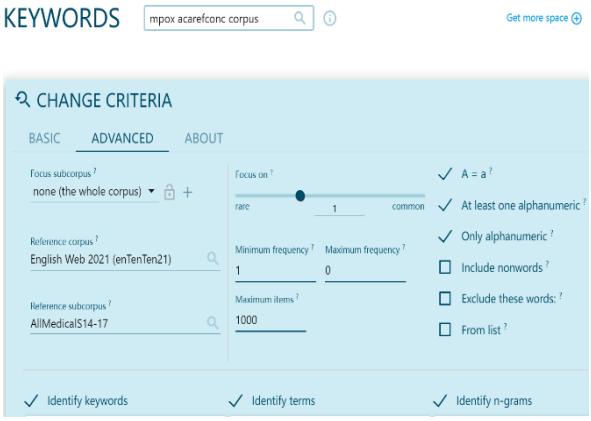

Figure 1: Keywords retrieval interface and settings.

The lists were produced and the retrieval results were saved as Excel files. Figure 2 shows the top 10 candidate single-word terms ranked by the keyness score extracted from the Mpox Academic Corpus. Two rounds of selection are conducted after the automatic generation of candidate terms. The first round of selection of terms is based on the relative frequency and keyness score of the retrieved items. Single-word terms and MWEs may follow different criteria in relative frequency and keyness score. Based on the review of the criteria (Li and Wang, 2021) in previous word list development practice, the minimum relative frequency for the included single-word terms is set at 30 PMWs.

	Lemma	Frequency per million Focus	Reference	Score
1	monkeypox	22,362.41	0.00	22,363.4
2	mpox	7,928.25	0.00	7,929.3
3	mpxv	1,962.31	0.00	1,963.3
4	smallpox	2,449.59	0.29	1,899.6
5	covid-19	1,185.29	0.00	1,186.3
6	tecovirimat	553.13	0.00	554.1
7	orthopoxvirus	487.28	0.00	488.3
8	gbmsm	474.11	0.00	475.1
9	pages	737.51	0.58	467.4
10	drc	737.51	0.68	440.4

Figure 2: Top ten single-word terms ranked by keyness score.

The keyness score is a value used by Sketch Engine to determine the particularity of a certain item in the focus corpus relative to the reference corpus. The higher the keyness score is, the more

prominent the word will be in the focus corpus. Therefore, it reflects the characteristics of the focus corpus and the possibility of a word to be selected as a term. However, there are few studies on the selection criteria based on keyness scores. The score should be varied in different cases. We can determine the score by considering the purpose and appropriate size of the word list. In this paper, the threshold for including single-word terms is set as: keyness score > 25. There are 327 candidate single-word items that meet the two criteria.

3.3 Manual selection of terms

The second round is manual selection based on the author's experience and expertise and consultation with the original context of the terms. Errors, general words, and those less relevant to mpox or the public emergency such as *say*, *pages*, *nation*, and *hong*, are excluded from the candidate list. The shortened list enables the users of the word list to focus on the terms highly related to the topic and improves communication efficiency during the public health emergency.

The manual selection excluded about 10% of the candidate terms extracted from the more specialized Mpox Academic Corpus, which is lower than that from the Mpox Corpus which includes news texts. Therefore, the list produced from the Mpox Academic Corpus, which includes 277 terms, is adopted as the Mpox Word List. This further illustrate that the size of the corpus may not be a barrier for term extraction as long as the focus corpus is properly constructed with a prominent theme.

3.4 The Mpox Word List

Due to the limited space, part of the selected terms ordered by their relative frequency in the focus corpus Mpox Academic Corpus are listed in Table1. The list is presented simply in two grades with the 100-PMWs frequency as the divide. The categorization is flexible subject to users' needs and specific contexts.

Grade I (frequency≥100 PMWs) monkeypox, virus, mpox, vaccine, outbreak, africa, spread, smallpox, mpxv, vaccination, united, acceptance, covid-19, scientist, intention, vaccinate, drc, kingdom, nigeria, zoonotic, tecovirimat, public-health, pandemic, congo, orthopoxvirus, gbmsm, variola, vaccinia, credit, endemic, democratic, sars-cov-2, cdc, warn, worry, non-endemic, plhiv, fluid-filled, mva-bn, lgbtqi, cowpox, a29, gay, vacv, poxviruse, epidemiologist, sub-saharan, orthopoxviruse, announce, med, rimoin, semen, briefing, multi-country, guangdong, portugal, ebola, pheic, mccollum, bodily, lewis, yinka-ogunleye, stockpile, virologist, msm, campus, a27, getty, mpx, bisexual, curb, wealthy, alarm, eradicate, zaire, varv, afp, coronavirus, ogoina, poxviridae, camelpox, seifert, pso, egger, lancet, virological, fatality, infectious-disease, orthopox, non-gbmsm, squirrel, begg, importation, reversion, cholera, archived, unrecognized, prep, surge, post-exposure, ukhsa, grapple, poxvirus, neglected, cynomolgus, containment, deadly
Grade II (frequency＜100 PMWs) lefkowitz, a29-specific, rosamund, rabbitpox, sars-cov-1, medrxiv, hesitancy, amr, ankara, human-to-human, mystery, flu-like, prairie, coloured, pod, transmitted, zika, tame, mers-cov, jynneos, monkeypox-related, director-general, wpr, imvanex, cpxv, non-binary, icalmed, non-african, chunk, hooper, macintyre, angeles, confirmed, transgender, wane, acing, announcement, atlanta, nordic, nat, universities, dnas, authorize, self-sampling, acam2000, cceptance-uptake, transm, mousepox, dimie, cmlv, mbala, lethally, spill, plasmablast, scab, traveler, adept, medium-term, high-income, zoonosis, vigilance, chickenpox, prophylactically, emerging, quarantine, measles, assault, georgia, zoo, rename, pury, neuropsychiatrist, anti-vacv, sometimes-painful, population-wide, heavy-tailed, abuja, orthopoxviruses, virol, yola, hatcher, seminary, mpxvs, conspiracy, hics, covid, sigh, heed, eess, heterotypic, unheeded, trialling, twitter, microevolution, siga, Liberia, skin-to-skin, sars, soar, laboratory-confirmed, wake-up, pledge, reg, scourge, bioterrorism, re-evaluate, asymptomatically, unnoticed, spark, generalist, genre, Utrecht, rope, pep, weakened, towel, peruvian, unvaccinated, stark, re-evaluated, msld, adesola, mpvx, nonendemic, basankusu, tpoxx, eurosurveillance, malembaka, ferré, happi, smallpox-like, pepv, worried, cnns, anti-mpxv, accuse, mass-vaccination, cd3-cd19, anteater, optimization-based, phylogenomic, inbox, uptake, vaccination, linelist, mpox-related, cuimc, convolutional, ntc, ectromelia, pre-outbreak, two-dose, swed, ncdc, mononucleosis-like, glimmer, reemergence, jab, computer-aided, Haiti, s2b, explode, dean, sentiment, treaty, leave-one-out, gambian, attendee, coronavirus, polio,…

Table 1: The selected terms in the Mpox Word List

4 Conclusion

The development of word lists is a fundamental task and a prerequisite for many other emergency services, such as standardization of terminology, emergency medical interpreting and translation,

construction of terminology translation database, machine translation, academic vocabulary teaching and learning, and mass communication. Aiming at providing terminology support as part of the emergency language service for mpox prevention and control, the author clarified the needs for and the purpose of producing the Mpox Word List. Following the principles and criteria in extracting and including terms, the Mpox Word List has been efficiently produced using the corpus tool Sketch Engine and its rich medical corpus resources. The synthesized purpose-oriented procedure for word list development can be used to guide subsequent development of word lists for other specific purposes.

In the future, the multi-word terms or n-grams can be included in the list to cover more essential terms for academic exchange and mass communication. A supplementary acronym list with the full spelling and definitions or explanations of these acronyms can also be made when there are a big number of them to meet the needs of the public, especially the non-professional users. The easy access to the original context of the KWIC and the retrieved items and the embedded Wikipedia links for them can be of tremendous help in developing such lists. In addition, cooperation with users and professionals from various disciplines in the development and application of the word lists should be strengthened, and feedback from medical experts and users should be collected to improve and update the word list on a regular basis. The word list produced in this study will help providers and consumers of emergency language services during international public health emergencies and the method and practice introduced in this paper is also believed to benefit future academic language researchers and academic word list developers.

Acknowledgments

The author would like to acknowledge the three anonymous reviewers of the paper and the conference participants for their valuable comments and feedback.

Disambiguating Low-registered Tones in Taiwan Southern Min

Jarry Chia-Wei Chuang
Department of Linguistics
University of Connecticut, USA
jarry.chuang@uconn.edu
ORCID: 0000-0002-3029-4463

Abstract

The study explores the inherent and prosodic challenges within the low-register tonal domain of Taiwan Southern Min (TSM) through both fieldwork and acoustic analysis, focusing on the tones ST7, CT3, and Q-ST5. By comparing the fundamental frequency (F0) variations across these three surface low tones, the study concludes that ST7 and CT3 should be classified as ML (Mid-Low), whereas Q-ST5—previously underexplored—warrants categorization as LL (Low-Low). Furthermore, the paper highlights the non-cyclic nature of tone sandhi in TSM, a critical feature of the language's tonal behavior. The research also addresses the influence of dialectal variation on the directionality of tonal marks that undergoes tone sandhi, which serves as evidence for tonal reconstruction. Ultimately, the study aims to enrich our understanding of the tonal systems in TSM and, by extension, the tonal dynamics within the broader family of Chinese languages.

1 Introduction

Taiwan Southern Min (TSM) is the variant of Min dialects in Taiwan. In the past, Taiwanese was the lingua franca of Taiwan; currently, it is still one of the primary languages in Taiwan, second to Taiwan Mandarin (TM) in terms of the number of speakers. TSM has many unique characteristics and phonological features valuable for linguistic research, one of which is the phonological operations and variations of tones.

The issue of the tones of TSM has become one of the centerpieces of discussion among phoneticians and phonologists. Observing the discussion of TSM tones and tone sandhi issues, it is not difficult to find that the phonological operation in the low register is particularly intricate. The effect of dialectal variations on TSM also makes the patterns more complicated. Therefore, results from perceptual judgments by researchers cannot be taken for the preliminary reconstructions of TSM low registered tones all the time.

	Contour	Value	Mark	
T1	High-level	55/44	hr, HH	HH
T2	High-falling	53/42	hr, HL	HM

***hr**=high register; **lr** = low register

Table 1: TSM Tonal System (To be revised).

Previous researchers have divergent arguments about the phonological marks of low-registered tones in TSM, in which T3 is the most problematic one. Some consider it a low-level tone (LL), while some argue that the F0-falling beginning of T3 makes itself more like a falling tone. Essentially, the tonal ambivalence and opacity is not the patent of TSM, but are also considered to be an issue in several Chinese dialects (Chuang 2023, 2024; Chuang and Liao 2024). On account of the complexity and the counter opinion, the paper investigates low-registered tones in TSM.

2 TSM Tones

As a tone language, TSM has a rich tonal and prosodic system compared to other Chinese dialects. There are seven lexical tones in TSM, five of which are non-checked tones (including T1, T2,

T3, T5, T7) and two of which are checked tones (T4, T8). See more detailed descriptions and discussions in Fon and Khoo (2025).

In terms of tone-bearing unit (TBU) (Goldsmith 1976) and moraic theory for the phonological weight (Hyman 1985), non-checked tones can be linked to two TBUs. In contrast, it is difficult for a stop consonant to carry a tone, so a checked syllable is connected to only one TBU. When a TSM tone is followed by an XP (i.e., non-sentence-final positions), namely when two lexical tones (T_a, T_b) are adjacent to each other, T_a will be pronounced as a sandhi tone (ST), instead of its citation tone (CT), which can be summarized as the rule of $CT_a \rightarrow ST_a$ / ___ T_b.

3 Tone Sandhi & Variations

TSM has two dialects, Chiang dialect and Quan dialect. Low-registered tone sandhi and the variations are as follows: T7 is a mid-level tone, of which ST is perceptually like CT3. As for T5, its tone sandhi is relatively complicated with two dialectal variants. For Chiang TSM speakers, T5 undergoes tons sandhi, thus with the contour of T7, namely mid-level; for Quan TSM speakers, T5 is perceptually like T3 and in the low tonal domain. With the flow, the (apparently) surface representations of T3 can be three: (1) Sandhi tone of T7, (2) Sandhi tone of T5 in Quan dialect (Q-ST5), and (3) Citation tones of T3 (CT3). Considering the difference in their underlying origins, we are heading to discrimination and examination of the surface and the apparent T3.

4 Literature Review

After reviewing the previous accounts, I found two major tracks for the low-register tones in TSM. Some consider LL is the only way to go for CT3 and ST7, while some assume ML is the key to them. By considering two major opinions, a new possibility of the coexistence of LL and ML in TSM is presented.

4.1 LL

From the perspective of generative phonology, Ang (1997), Tsay and Myers (1996), and Hsiao (1991) assume CT3 and C-ST7 are low-registered low-level tones (l, LL), namely low-level tones (LL). Such phonological analysis is mainly based on perceptual judgment rather than acoustic measurement or analysis, so the results of the proposed tonal reconstructions may not be proper. Besides, F0 in the low-registered domain is already in a low-frequency band, which is difficult to perceive, so the auditory judgment may be interfered with by other phonetic factors. Lack of convincing for the low-level tone may thus be caused. At the same time, it is also difficult to explain CT3 as LL. ST3 is a high-falling tone (HM). Once we consider CT3 to be LL, it is hard to say why the tone sandhi of T3 contributes to a register sandhi from low register to high register as well as a tone sandhi from a level tone to a falling tone. The proposal is not economical and requires a complex tonal transfer with tone sandhi and register sandhi. Therefore, the LL analysis may be open to question.

4.2 ML

Chen (2018) conducted acoustic experiments on TSM tones, measuring the tone contour and pitch of five non-checked tones and their variant tones as tone sandhi. Results of F0 contour showed the changes in its pitch with raising/falling contours. To minimize the individual difference, the study used the normalized F0 as a reference for the analysis. In both young and old TSM speakers' pronunciations, CT3 and ST7 move from the mid-point to the low-pitch band. They are falling, heading to a low pitch. Despite the final low pitch position of the ST7 is slightly higher than that of the former, it was hypothesized by Chen (2018) to be the priming effect of citation tones in tone sandhi. Since CT7 is higher than ST7, it is possible that ST7 being slightly higher is a residual influence. No matter how CT3 and ST7

end differently in a slight manner, the general inclination of pitch-falling is doubtless.

In fact, M. Y. Chen (1987) has already proposed a similar idea. Peng (1997) also used similar acoustic experimental results to illustrate that CT3 and ST7 are in a descending pitch, only that the result of Fig. 3 was analyzed to be 21 at that time. Kuo (2013) corrected the experimental analysis of Peng (1997) and pointed out that the result should have been analyzed to be 31, which suggests they be ML.

4.3 Summary & New Possibility

Summarizing the above results, it is obvious that empirical studies have mostly compared CT3 and ST7 to the low-registered falling tone (ML). Acoustic measurements often do not support the analyses of LL. This further suggests that the phonological representation of TSM low-registered tones needs revising to match the actual situation. According to the acoustic data, CT3 and ST7 basically share the same tuning mode and tuning value. In terms of analysis, it is reasonable to include them in the same type of phonological structure. In other words, either LL or ML is appropriate for the analysis.

In addition, previous literature on TSM low-registered tones has been inclined to Chiang dialect, as it is the advantageous dialect in Taiwan compared to the Quan dialect. So far, nearly no acoustic measurements have been made on Q-ST5. Studies in the past usually do not show Q-ST5 for it is often considered to be the same with ST7 and CT3.

At the end of this paper, a possibility will be raised, where the bias of past analyses is actually an insight into the LL-ML dispute for TSM. With reference to the formal analyses and acoustic surveys presented in the previous section, we suggest that a potential analysis would be that CT3 and ST7 are ML, whereas ST5 in Quan is LL. This is, ML and LL co-exist, yet distributed in different tonal contexts. Difficulties in perceptual interpretation between them may be a source of analytic disagreement in the past.

5 Fieldwork

5.1 Speakers

Seven speakers were initially invited to the reading task in fieldwork, including four male Chiang-TSM (C-TSM) speakers and three male Quan-TSM (Q-TSM) speakers. Their ages ranged from 43 to 71 (Mean = 57.7; SD = 10.54). In this survey, C-TSM speakers were defined as those with ST5 as MM, while Q-TSM speakers were defined as those with ST5 as ML/LL, either falling or level. C-TSM speakers mainly come from C-accented areas along the north coast of New Taipei City (e.g., Wanli, Jinshan, etc.), while Q-TSM speakers come from two Q-accented areas, including Dacun, Changhua City and Muzha, Taipei City.

5.2 Reading List

Before this fieldwork, the researcher designed a corresponding word list for the speakers to read out when recording. The word list mainly consists of 30 disyllabic words A+B. Under normal circumstances, A will be pronounced in the sandhi tone and B in the citation tone. Among the words, A may be ST7 and ST5, and B can be CT3. Each target tonal representation was repeated 10 times in the word list and will not be used in the same word. The word list was provided to the speakers in a randomized manner, with the researcher assisting with word guidance if necessary.

5.3 Acoustic Measurement

In order to obtain the acoustic data of the tones, the measurement mainly focuses on the F0 of the target syllable. Twelve sampling points were extracted to investigate the F0 contour in a row, in which the first sampling point was discarded. The total number of valid sampling points was 11 (t_1...t_{11}). After setting the start and end points, any insufficient sampling points will be compensated by interpolation to construct reasonable data for the gap.

In order to further investigate the acoustic differences, a two-tailed t-test was performed to analyze the different tones at the start (t_1), middle (t_6), and end (t_{11}) points. For statistical analysis, the data will be normalized, and the normalized data includes the F0 height and duration. The main purpose of this operation is to eliminate the effect of individual differences on F0.

6 Results

First of all, this study will report the preliminary F0 data that have not yet been formalized. After that, the researcher will analyze the data of the target tones, by comparing the similarities and

differences among the three target tones. Finally, based on the data, we will propose the possibility of phonological analysis.

6.1 ST7

From the mode of F0, it is clear that ST7 has a falling contour. The maximum average F0 of ST7 is 109.6 Hz, the average midpoint value is 86.4 Hz, and the minimum value is 78.9 Hz. The average span of pitch-dropping is 30.7 Hz, with the average drop of the front section being 23.2 Hz, and that of the back section being 7.5 Hz. The settling of the F0 in the front section is more pronounced, while that in the back section is more moderate.

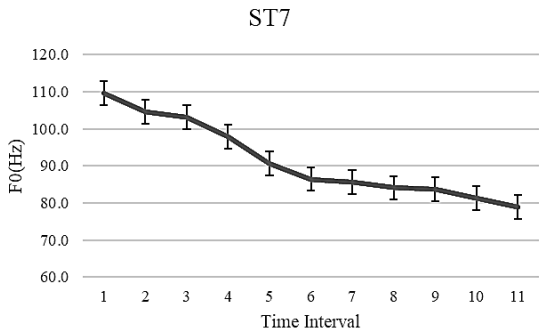

Fig. 2: F0 result of ST7

6.2 CT3

A preliminary analysis of the data reveals that CT3 is a falling key. The maximum average F0 of this key is 99.2 Hz, the average midpoint value is 83.9 Hz, and the minimum value is 77.0 Hz. The average pitch decreases by 22.2 Hz, with an average drop of 15.3 Hz in the front section and 6.9 Hz in the back section. The sinking of the F0 in the front section is pronounced like ST7, and that in the back section is relatively flat.

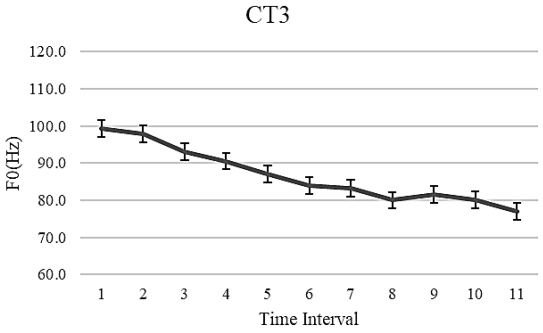

Fig. 3: F0 result of CT3

6.3 Q-ST5

From the F0 contour, Q-ST5 should be a level tone. The maximum average F0 of this key is 87.1 Hz, and the minimum is 81.1 Hz. The average drop of this key is 6.0 Hz, with an average drop of 4.8 Hz in the front section and -2.9 Hz in the back section. Overall, the tone has gentle ups and downs, with only a slight drop in the middle, which is similar to the flat tonal patterns observed in Chen (2018) for high-level and mid-level tones.

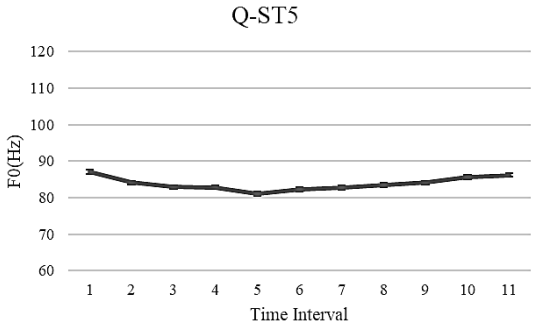

Fig. 4: F0 result of Q-ST5

6.4 Normalized F0

The normalized analysis can facilitate the comparison and difference analysis between the three low-register tones (ST7, CT3, Q-ST5). In the starting point, ST7 has the highest pitch, followed by CT3 and Q-ST5. The difference between the lowest one and the highest one is more than 0.5 units. The mid-point values for all converge and fall between 0.25 and 0.35. The end-point values are inverted and staggered somehow, but not significant with Q-ST5 being the highest value at the end, followed by ST7 and CT3.

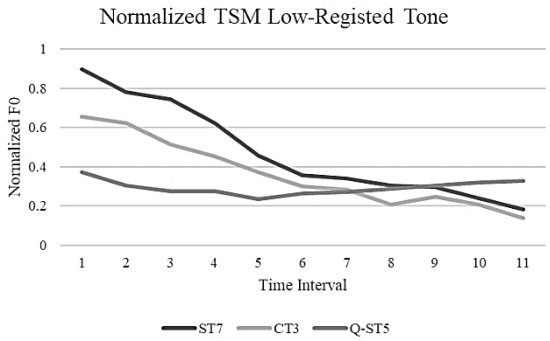

Fig. 5: Normalized F0 results in comparison

A statistical analysis of variance (One-Way ANOVA) was performed on the values of the start points, mid-points, and end points of three tones,

in order to see if there were any significant differences. First, the three sets of start point data were significantly different ($p<.01$) in between, including ST7 and CT3 ($p<.01$), CT3 and Q-ST5 ($p<.01$), and ST7 and Q-ST5 ($p<0.01$). Then, the three sets of midpoint data were not significantly different ($p>0.1$). For the endpoints, Q-ST5 was significantly different from ST7 and CT3 respectively ($p<0.1$), and there was no significant difference between ST7 and CT3 ($p>0.1$).

In general, the results show the representations of TSM tones in the low register are actually not the same. Assumed 0 and 1 to be the high and low boundaries of the low-registered domain, namely M and L, 0-0.5 can be regarded as the low-pitched domain of the low-pitched domain for L, while 0.5-1.0 is the high-pitched domain of the low-pitched domain for M. Summarizing the statistical analyses above, we consider that Q-ST5 is a low-level tone, with little difference in its overall changes, gentle ups and downs, and continuous operation in low-tone domain (L); while ST7 and CT3 should be a mid-falling tone, with both of them moving from the high-tone domain of the low-tone domain (M) to the low-tone one (M), as well as with a clear convergence of both, which suggests that the two of them should have the same tonal end-point target.

	Citation Tone	Sandhi Tone	
		Chiang	Quan
T1	HH	MM	
T2	HM	HH	LM
T3	ML	HM	
T5	LM	MM	LL
T7	MM	ML	

Table 2: TSM Tonal System (Revised).

7 General Discussions

7.1 Revision of TSM tonal system

Based on the above results, the proposal of TSM tonal marks should be revised. This paper proposes to revise the original assumption that ST7 and CT3 are LL (Ang 1997; Tsay and Myers 1996; Hsiao 1991, 2000) to ML, which is low-registered HL. The revised system matches the empirical results of Chen (2018). In addition, based on the F0 pattern and acoustic characteristics of Q-ST5, this paper analyzes Q-ST5, which has rarely been studied in the past, as LL in the low tonal domain. In summary, the modifications of Taiwanese non-checked tones are listed as follows:

7.2 Non-cyclicity of TSM tone sandhi

By the tonal correspondences between citation tones and sandhi tones, we can see that TSM is not a cyclic tone-sandhi language. C-TSM seems to conform to the rules of cyclic modulation, while the tonal system of Q-TSM does not conform to cyclic tone sandhi and cannot be fully cyclic. With comparisons between C-TSM and Q-TSM, I argue that there is no such cyclic tone sandhi in TSM regardless of dialects, since it is impossible for the tonal system of a language to have cyclic and non-cyclic dialects at the same time, simply due to dialectal variations.

In addition, if a language is a cyclic tone-sandhi language, native speakers should have the ability to trace the citation tones from the sandhi tones. However, previous empirical studies on TSM speakers' linguistic knowledge do not support such a claim (Zhang, Lai, and Sailor 2011). This is indirect evidence for the non-cyclicity of tone sandhi in TSM.

7.3 Dialectal Variations

The dialectal difference between Chiang dialect and Quan dialect can be seen from the tone sandhi of T5, which is LM→MM for C-TSM and LM→LL for Q-TSM. The dialectal difference actually reflects the proposed tonal marks to be possible: In the low register, Q-TSM prefers the tone sandhi of the left-side tone, and thus L, which is on the left-side TBU, will be converted to M, resulting in MM. By contrast, C-TSM prefers the tone sandhi of the right-side tone within a syllable, and thus M, which is on the right-side mora, is converted to L, resulting in LL.

8 Conclusion

The study investigated the tonal problems in the low-registered domain in TSM through fieldwork and acoustic analyses. The major focus includes ST7, CT3, and Q-ST5. Based on the comparison of F0 contours among three surface low tones, it is concluded that ST7 and CT3 should be analyzed as ML, while Q-ST5, which has seldom been

investigated before, should be analyzed as LL. This paper further points out the property of non-cyclic tone sandhi in TSM. In addition, the paper discusses the fact that the C-Q dialectal differences are reflected in the directionality of tone marks that undergoes tone sandhi, which can be evidence for tonal reconstruction. It is hoped that the study contributes to a better understanding of the tonal systems of TSM, even of Chinese languages, since many Chinese dialects also have similar problems with low-registered tones.

In fact, tonal identification in the low-registered domain is an issue for many Chinese dialects, especially for the distinction between mid-falling and low-falling/level tones. This is, ML and LL cause problems in tonal identification. The present study suggests that ML and LL are hard to distinguish in perception for misleading assumptions in intuitive judgements by previous formal analyses, while they remain discernible in production as the acoustic analysis has shown in the present study. Such a mismatch in tonal identification predicts the potential tonal merger of TSM low-registered tones in the coming future, where ML and LL may be fused together.

Lastly, the study has some pedagogical implications. For heritage language learners of TSM, understanding the complexities of tone sandhi and the tonal distinctions between ML and LL tones could be especially challenging, as these learners may not have received formal instruction in TSM and may have limited exposure to tonal distinctions. It would be significant to create pedagogical materials that emphasize the restoration and correct usage of these low-register tones, providing exercises and practice specifically targeting L (ML vs. LL).

Acknowledgments

I would like to thank Prof. Hui-lu Khoo and the classmates of the seminar “Phonetic Description and Field Work” at NTNU in Spring 2023, for helpful discussions. I also thank three anonymous PACLIC-38 reviewers for their constructive suggestions.

Coreference Resolution for Vietnamese Narrative Texts

Hieu-Dai Tran[1, 2], Duc-Vu Nguyen[1, 2], Ngan Luu-Thuy Nguyen[1, 2]
[1]University of Information Technology, Ho Chi Minh City, Vietnam
[2]Vietnam National University, Ho Chi Minh City, Vietnam

Abstract

Coreference resolution is a vital task in natural language processing (NLP) that involves identifying and linking different expressions in a text that refer to the same entity. This task is particularly challenging for Vietnamese, a low-resource language with limited annotated datasets. To address these challenges, we developed a comprehensive annotated dataset using narrative texts from VnExpress, a widely-read Vietnamese online news platform. We established detailed guidelines for annotating entities, focusing on ensuring consistency and accuracy. Additionally, we evaluated the performance of large language models (LLMs), specifically GPT-3.5-Turbo and GPT-4, on this dataset. Our results demonstrate that GPT-4 significantly outperforms GPT-3.5-Turbo in terms of both accuracy and response consistency, making it a more reliable tool for coreference resolution in Vietnamese.

1 Introduction

Entity coreference resolution is a critical task in NLP that involves identifying and linking various expressions in a text that refer to the same entity (Jurafsky and Martin, 2014; Ng, 2010; Pradhan et al., 2011). This task is essential for improving the coherence and understanding of texts in applications such as machine translation (Mitkov, 1998), information extraction (Grishman, 1997), and text summarization (Steinberger and Jezek, 2007). Significant achievements have been made in coreference resolution, particularly for the English language, where numerous models and annotated datasets such as OntoNotes and CoNLL-2012 have been developed (Pradhan et al., 2012; Hovy et al., 2006). Techniques range from early machine learning approaches to more recent neural network models (Lee et al., 2017; Clark and Manning, 2016). However, coreference resolution for Vietnamese is still in its developmental stages, primarily due to the lack of comprehensive annotated datasets. As highlighted in Hoang et al. (2023), the development of high-quality annotated datasets for Vietnamese NLP tasks is still an ongoing challenge. The ViHOS dataset, for instance, was created to address this gap in hate and offensive speech detection, indicating the broader need for such resources across various NLP tasks.

LLMs such as GPT-3.5-Turbo and GPT-4 have shown great promise across various domains in NLP, particularly in tasks involving zero-shot and few-shot learning (Brown et al., 2020; Radford et al., 2019). These models can leverage large amounts of data and transfer learning capabilities to perform well even with limited task-specific data. This makes LLMs excellent candidates for exploring tasks like coreference resolution in low-resource languages such as Vietnamese.

Evaluating the performance of LLMs in resolving coreference is an intriguing area of research. With the proliferation of various LLMs, there is substantial potential to explore and benchmark their capabilities in different contexts. Our study aims to address the gap in Vietnamese coreference resolution by leveraging the power of LLMs.

In this research, we collected a dataset from VnExpress, a popular Vietnamese online news platform, encompassing a wide range of narrative texts covering topics such as relationships, daily life, work, and social connections. We established detailed guidelines for annotating entities within these texts and carried out the annotation process manually. Furthermore, we used prompts to extract annotated entities from LLMs and evaluated their performance against our manually annotated dataset.

Our contributions are as follows: (1) we provide a comprehensive annotated dataset of Vietnamese narrative texts, (2) we develop detailed guidelines for entity annotation, (3) we use prompts to obtain annotated entities from LLMs, and (4) we evaluate the performance of LLMs against our annotated

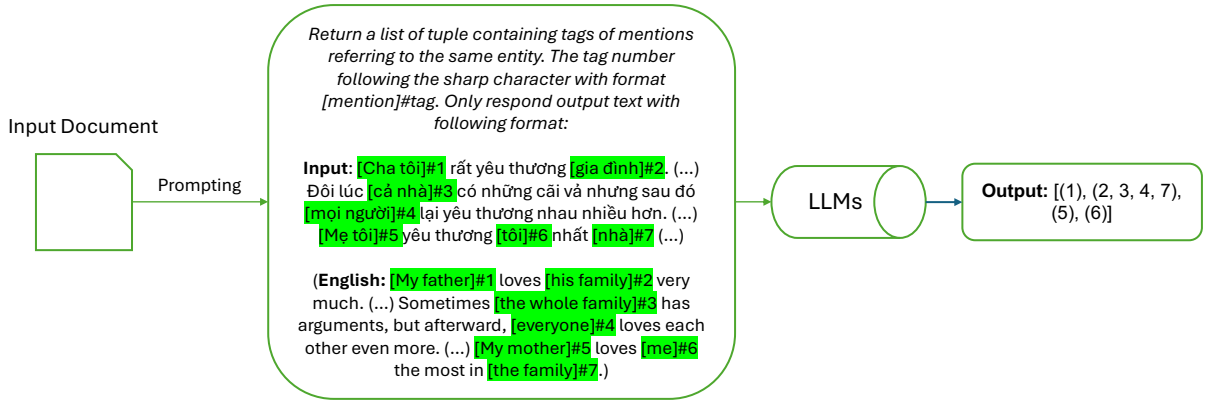

Figure 1: The process of generating mention clusters from raw text using LLMs. The input document is processed to return a list of tuples containing tags of mentions referring to the same entity. For example, in the input text, tags identify various entities and group them into clusters, as shown in the output.

dataset to identify the most effective model for Vietnamese coreference resolution.

The rest of the paper is organized as follows: Section 2 reviews related work, Section 3 describes the dataset and annotation guidelines, Section 4 presents the evaluation of LLMs on the dataset, and Section 5 concludes the paper with future directions.

2 Dataset Construction

2.1 Collecting Narrative Texts

The data for our research was collected from VnExpress, a prominent Vietnamese online news platform, which has been a valuable source for various NLP tasks due to its rich narrative content (Nguyen et al., 2018). Similar efforts to use narrative texts for coreference tasks have been seen in other low-resource languages such as Hindi (Rahman and Ng, 2012).

Originally, the dataset consisted of 1,041 narrative texts, as described in the paper by Nguyen et al. (2023) (Nguyen et al., 2023). The texts are categorized into abusive and non-abusive to identify whether a text contains abusive content. For the purposes of our research, we randomly chose 266 texts from this original dataset. Table 1 shows the breakdown of the total dataset into evaluation and few-shot sets.

All selected texts were in their raw form, devoid of any prior annotations. In the following section, we outline the guidelines used to systematically annotate these texts.

2.2 Annotation Guidelines

In this section, we outline the guidelines and tools used for annotating entities within the selected narrative texts. The annotation process is crucial for ensuring consistency and accuracy in the data, which will be used for coreference resolution tasks. Annotation consistency is critical for the quality of coreference resolution datasets, as highlighted in previous studies (Poesio and Artstein, 2008). The annotation step was handled manually with the assistance of volunteers. Each volunteer was provided with the guidelines to ensure consistent annotation across the dataset.

2.2.1 Tool for Annotation

We utilized the open-source tool, Coreference Annotation Tool with SACR (Oberle, 2018). This tool facilitates faster and more intuitive annotation of entities. It features an intuitive user interface by coloring mentions referring to the same entity with a distinct color, making it easier to identify and annotate entities consistently. Each entity is assigned a unique color. Additionally, the tool supports annotating nested mentions, which is particularly helpful in cases of possessive mentions. After annotation, the tool exports the original text with entities wrapped in the format {M{tag_number} entity_name}. Entities referring to the same entity will share the same tag_number.

2.2.2 Definition of Entities

In our research, we focused on annotating entities that refer to people, excluding non-human entities. This includes individuals, groups of people, organizations, or any reference to humans. We adhered to a set of simple rules for annotating these entities

	Total	Average length	Average mention	Average entity
Few-shot	3	248.6	31	8.6
Evaluation	263	449.5	55.1	9.4

Table 1: The total dataset is divided into two subsets: an evaluation dataset consisting of 263 text files, and a few-shot dataset containing 3 text files.

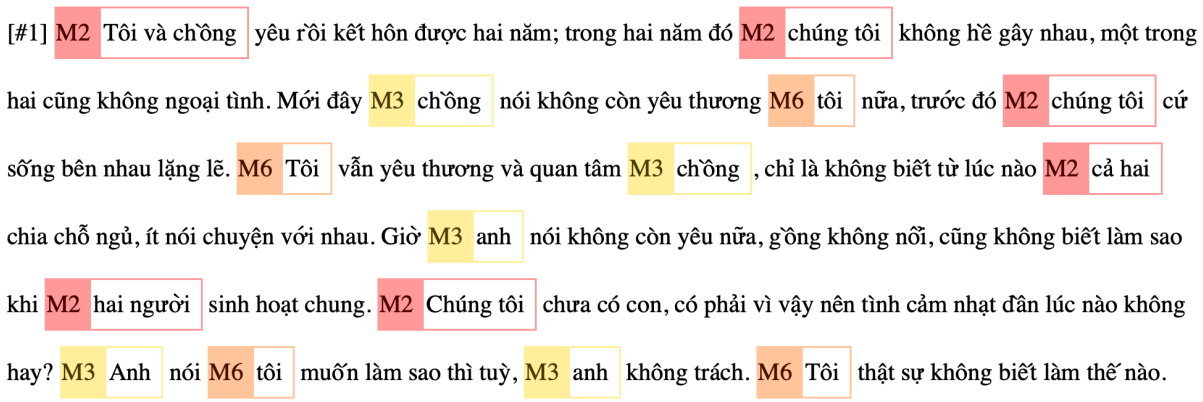

Figure 2: User interface of the Coreference Annotation Tool with SACR

to maintain clarity and consistency:

1. **People Mentions Only**: We annotate only those mentions that refer to entities which are human. We do not consider mentions that are nouns or names but are not human, such as geopolitical entities, objects, or places. For example:

   Original: "Anh ta chăn nuôi vịt ở Thái Lan."
   (English: "He raises ducks in Thailand")
   Annotated: "**{M1 Anh ta}** chăn nuôi vịt ở Thái Lan."
   (English: "**{M1 He}** raises ducks in Thailand")

2. **Groups of People**: Mentions that refer to organizations like WHO, or the Vietnam government, can also be considered groups of people, so we annotate those mentions as well. For example:

   Original: WHO đang làm việc trên một sáng kiến y tế mới.
   (English: "WHO is working on a new health initiative.")
   Annotated: "**{M1 WHO}** đang làm việc trên một sáng kiến y tế mới."
   (English: "**{M1 WHO}** is working on a new health initiative.")

3. **Excluding Adjectives**: When an entity includes adjectives, we annotate only the root noun without the adjective. For example:

   Original: "Chàng trai cao ráo khiến mọi người phải ngước nhìn."
   (English: "The tall guy makes everyone turn their heads.")
   Annotated: "**{M1 Chàng trai}** cao ráo luôn khiến **{M2 mọi người}** phải ngước nhìn."
   (English: "The tall **{M1 guy}** makes **{M2 everyone}** turn their heads.")

4. **Nested Mentions**: Nested mentions are those that exist within another mention. We only annotate nested mentions when they are in an explicit possessive form, which includes the word "của" (meaning "of" in English) in the mention. For example:

   Original: "Mẹ của tôi thường thức dậy vào lúc 5 giờ sáng."
   (English: "My mother usually wakes up at 5 a.m.")
   Annotated: "**{M1 Mẹ của {M2 tôi}}** thường thức dậy vào lúc 5 giờ sáng." (English: "**{M1 My mother**} usually wakes up at 5 a.m.")

In this case, **{M2 tôi}** is the nested mention within **{M1 Mẹ}**, and they are separated by the word "của."

Note: The nested mention **{M2 tôi}** represents "I" in the English translation and is explicitly shown as a nested entity in Vietnamese. However, this nested structure cannot be represented as explicitly in English, which leads to discrepancies in how nested entities are handled between the two languages. This difference poses challenges for cross-linguistic coreference resolution tasks.

These guidelines help ensure that our annotations are focused on the relevant entities for coreference resolution, making the data more useful for subsequent analysis and model training.

3 Prompting

Prompting is a process where we design a prompt to request a response from the LLMs and receive the response back. This technique, especially in the context of few-shot learning, has been shown to significantly improve performance in various NLP tasks (Brown et al., 2020; Gao et al., 2020). The effectiveness of prompts in coreference resolution tasks has been discussed in (Liu et al., 2021), demonstrating their utility in scenarios with limited training data. This step is time-consuming as it often requires trying many different prompts to achieve the desired response. The role of prompting, especially in the context of few-shot learning, has been extensively discussed in recent research (Wei et al., 2021).

In this research, we employed few-shot learning by providing the LLMs with some examples of input and output, then asking them to respond to new inputs. This method helps the LLMs understand not only the context of the query but also the format in which the response should be provided. Few-shot learning has shown significant promise in enhancing the performance of language models across various tasks (Brown et al., 2020; Lin et al., 2021).

Specifically, we took 3 texts annotated from the raw dataset and used them to build the prompt as examples for the LLMs. These 3 texts covered the rules discussed in the "Definition of Entities" section as much as possible with a reasonable amount. This left us with 263 texts to verify, comparing the output we annotated manually against the output generated by the LLMs. The reason why we only took 3 texts is that some LLMs, like GPT-4, accept a limited number of tokens per request. This limitation is a constraint when using the API, and we must ensure that the prompt and expected output stay within this limit.

Before building the prompt, we also had to take a few steps to refine the annotated dataset to build the *gold_clusters*, which is the expected result that we want the LLMs to return. First, we'll format the text annotated with the format **{M{#tag_number} mention}** to **[mention]{#tag_index}**. Here is an example:

> Annotated: **{M1 Em}** trân trọng **{M2 hai người bạn}** rất thân; **{M2 các bạn}** bị **{M3 một nhóm bạn khác}** nói xấu rất nhiều, từ tính cách, lời nói, dáng đi. **{M1 Em}** chắc chắn trước đó **{M2 hai bạn}** không đả động gì tới **{M3 nhóm bạn đó}**...
>
> (English: **{M1 I}** deeply value **{M2 my two close friends}**; **{M2 they}** are being talked about negatively by **{M3 another group of friends}**, criticizing everything from their personality, speech, to their posture. **{M1 I}**'m certain that before this, **{M2 my two friends}** hadn't done or said anything to **{M3 that group}**.)
>
> Indexed: **[Em]#1** trân trọng **[hai người bạn]#2** rất thân; **[các bạn]#3** bị **[một nhóm bạn khác]#4** nói xấu rất nhiều, từ tính cách, lời nói, dáng đi. **[Em]#5** chắc chắn trước đó **[hai bạn]#6** không đả động gì tới **[nhóm bạn đó]#7**...
>
> (English: **[I]#1** deeply value **[my two close friends]#2**; **[they]#3** are being talked about negatively by **[another group of friends]#4**, criticizing everything from their personality, speech, to their posture. **[I]#5**'m certain that before this, **[my two friends]#6** hadn't done or said anything to **[that group]#7**.)
>
> Then the *gold_clusters* should be: [(1, 5), (2, 3, 6), (4, 7)]

The *gold_clusters* is formatted as an array of tuples, such as [(1, 5), (2, 3, 6), (4, 7)], where 1 and 5 are *tag_indices* of mentions that refer to a single entity as illustrated in the *indexed* and *annotated* above. The indices 2, 3, and 6 refer to another distinct entity, while 4 and 7 correspond to yet another entity.

There are two key reasons for using this specific format for *gold_clusters*:

- **Efficiency in LLM Processing**: By formatting the output as tuples representing *tag_indices*, we minimize the number of tokens the LLM needs to generate. This results in a faster response time, which is crucial when processing large datasets or when multiple iterations of prompting are necessary.

- **Seamless Integration into Evaluation**: The tuple-based format is directly aligned with the requirements of our evaluation step. By receiving the output in this format, we can bypass additional processing steps that would otherwise be needed if the full text were returned. This streamlined approach allows us to directly compute the differences between the LLMs' output and the *gold_clusters*, enhancing the efficiency and accuracy of our evaluation process.

These considerations make the tuple-based format an optimal choice for both the performance of the LLMs and the subsequent evaluation of their outputs, ultimately contributing to a more efficient and effective coreference resolution process.

After building the *gold_clusters* for the 3 documents we selected in the previous step, we were ready to construct the full prompt. To do this, we combined the *indexed text* with the corresponding *gold_clusters*. The *indexed text* served as the input, and the *gold_clusters* served as the output, formatted as follows: **Input: {indexed text} Output: {gold_clusters}**. This constituted the few-shot learning part, which we presented to the LLMs for each document we wanted them to process. We refer to this part as the "few-shot prompt."

The next step involved processing each remaining document in the dataset (excluding the 3 documents used to build the few-shot prompt). We followed these steps:

1. **Format the Document to Indexed Text**: Convert the document into the *indexed text* format, as described previously.

2. **Build the Final Prompt**: The final prompt began with the few-shot prompt, followed by a request for the LLMs to return the full output, with the input being the *indexed text* created in step 1.

3. **Send the Final Prompt to LLMs**: Submit the final prompt to the LLMs and save the resulting output for later evaluation against the corresponding *gold_clusters*.

By following this systematic approach, we ensured that the LLMs were provided with consistent and well-structured prompts, which should enhance the accuracy and efficiency of the coreference resolution process. The outputs generated by the LLMs were stored and later compared with the manually annotated *gold_clusters* to evaluate their performance.

4 Evaluation

To evaluate the performance of the LLMs in coreference resolution for Vietnamese narrative texts, we conducted an experiment using two versions of OpenAI's GPT models. Similar evaluation methods using large-scale models for coreference have been employed in other studies, which leverage the CoNLL F1 score and its associated metrics like MUC, B-Cubed, and CEAF$_\phi$ (Pradhan et al., 2011; Luo, 2005). The evaluation was carried out by comparing the outputs generated by these models against the manually annotated *gold_clusters*. The primary metrics used for this evaluation include the CoNLL F1 score, which is an aggregate of three metrics: MUC, B-Cubed, and CEAF$_\phi$.

4.1 Evaluation Metrics

The evaluation metrics used in this study are as follows:

- **MUC (Mention-Pair)**: The MUC metric, introduced by Vilain et al. (1995), evaluates the overlap between predicted and actual coreference clusters by considering links between mentions. The precision and recall for MUC are calculated as follows:

$$\text{Precision} = \frac{L_{\text{correct}}}{L_{\text{predicted}}}$$

$$\text{Recall} = \frac{L_{\text{correct}}}{L_{\text{gold}}}$$

where L_{correct} is the number of correctly predicted links, $L_{\text{predicted}}$ is the total number of predicted links, and L_{gold} is the total number of links in the gold standard. The MUC F1 score is the harmonic mean of precision and recall.

- **B-Cubed**: The B-Cubed metric, proposed by Bagga and Baldwin (1998), evaluates coreference resolution at the mention level. For each mention, precision and recall are calculated as:

$$\text{Precision} = \frac{|C_i \cap G_i|}{|C_i|}$$

$$\text{Recall} = \frac{|C_i \cap G_i|}{|G_i|}$$

where C_i is the set of mentions in the predicted cluster for mention i, and G_i is the set of mentions in the gold cluster for mention i. The overall B-Cubed precision and recall are averaged over all mentions, and the B-Cubed F1 score is the harmonic mean of these averaged values.

- **CEAF$_\phi$ (Constrained Entity Alignment F-Score)**: The CEAF$_\phi$ metric, discussed by Luo (2005), measures the similarity between predicted and actual entity clusters by finding an optimal one-to-one alignment between them. Precision and recall for CEAF$_\phi$ are calculated as:

$$\text{Precision} = \frac{\sum_{i=1}^{n} \phi(C_i, G_i)}{\sum_{i=1}^{n} \phi(C_i, C_i)}$$

$$\text{Recall} = \frac{\sum_{i=1}^{n} \phi(G_i, G_i)}{\sum_{i=1}^{n} \phi(G_i, G_i)}$$

where ϕ is a similarity function, typically the size of the intersection between clusters, and the sums are over the aligned cluster pairs. The CEAF$_\phi$ F1 score is computed as the harmonic mean of precision and recall.

- **CoNLL F1**: The CoNLL F1 score is the average of the F1 scores from the MUC, B-Cubed, and CEAF$_\phi$ metrics, providing an overall evaluation of the coreference resolution performance (Pradhan et al., 2011).

- **Response Consistency**: During the response collection by calling OpenAI's API, we observed that the responses from GPT-4 were more consistent than those from GPT-3.5-Turbo. Specifically, the responses from GPT-3.5-Turbo often included unrelated parts along with the response, requiring additional refinement to extract the final result. Additionally, GPT-3.5-Turbo sometimes returned an unnecessarily annotated full text. In contrast, this problem occurred much less frequently with GPT-4, making it more reliable and reducing the need for post-processing.

4.2 Results

Metric	GPT-3.5-Turbo	GPT-4
CoNLL F1	0.478	0.735
MUC F1	0.640	0.858
B-Cubed F1	0.474	0.723
CEAF$_\phi$ F1	0.321	0.625

Table 2: Comparison of GPT-3.5-Turbo and GPT-4 performance on coreference resolution.

The evaluation results demonstrate the effectiveness of GPT-4 over GPT-3.5-Turbo in Vietnamese coreference resolution across all metrics. The models were assessed using the CoNLL F1 score, which aggregates MUC, B-Cubed, and CEAF$_\phi$ metrics. Table 2 summarizes the performance differences between the two models.

GPT-4 achieved a CoNLL F1 score of 0.735, showing a significant improvement over GPT-3.5-Turbo, which scored 0.478. This indicates that GPT-4 is considerably more effective in accurately linking mentions to the correct entities throughout the dataset. The MUC metric, which evaluates the overlap of predicted and actual coreference clusters, showed that GPT-4 performed exceptionally well with an F1 score of 0.858, compared to 0.640 for GPT-3.5-Turbo. These results suggest that GPT-4 is better at identifying and linking mentions that refer to the same entity, resulting in fewer errors related to missed or incorrect links.

For the B-Cubed metric, which is sensitive to mention-level errors, GPT-4 achieved a score of 0.723, significantly outperforming GPT-3.5-Turbo's score of 0.474. This indicates that GPT-4 assigns individual mentions to the correct entity clusters more accurately. The CEAF$_\phi$ metric, which measures the alignment between predicted and actual entity clusters, further validated GPT-4's capabilities with a score of 0.625, while GPT-3.5-Turbo scored much lower at 0.321. This result highlights GPT-4's consistency and accuracy in entity clustering, aligning more closely with human-annotated gold standards.

Additionally, response consistency during the evaluation process favored GPT-4. GPT-3.5-Turbo

responses often included irrelevant content or returned annotated full texts, requiring additional refinement. In contrast, GPT-4 demonstrated greater consistency, with fewer errors, making it a more reliable tool for coreference resolution tasks with minimal post-processing needed.

4.3 Case Study

In this case study, we identify specific instances where GPT-4 demonstrated superior coreference resolution capabilities compared to GPT-3.5-Turbo, based on the provided narrative text. These instances highlight the differences in handling entity references, contributing to GPT-4's better performance across evaluation metrics.

Case 1: Accurate Clustering of References to the Speaker

- **Example Text:** Mentions of the speaker [Tôi] (I) throughout the text, such as "Tôi 32 tuổi, lấy chồng được chín năm, có hai con gái, đang suy nghĩ việc bỏ chồng" (I am 32 years old, have been married for nine years, have two daughters, and am considering leaving my husband).
- **GPT-4:** Correctly grouped all references to the speaker into a single cluster, maintaining consistency. For example, it included mentions like [Tôi], [tôi], and other references to the speaker across the text into one coherent cluster.
- **GPT-3.5-Turbo:** Merged references to the speaker with unrelated entities such as the husband, resulting in a single, overly broad cluster. This mistake blurred the distinction between different characters, leading to lower precision and recall scores in MUC and B-Cubed metrics.

Case 2: Differentiation Between the Speaker and the Husband

- **Example:** Mentions of the husband [chồng] (husband) and [anh] (he) as distinct from the speaker [Tôi] (I). In the sentence "Tôi cũng vay riêng 290 triệu đồng để trả nợ cho anh" (I also borrowed 290 million VND to pay off his debt), the speaker and her husband are clearly distinct entities.
- **GPT-4:** Successfully differentiated between the speaker and the husband, creating separate clusters for each. This accuracy ensured that references to [chồng] and [anh] were not confused with those referring to [Tôi].
- **GPT-3.5-Turbo:** Often failed to differentiate between these entities, merging them into a single cluster. This error indicates a lack of precision in entity resolution, which can affect the overall understanding of the text.

Case 3: Handling of Family References and Relationships

- **Example:** Mentions involving family relationships, such as "[bố tôi] thấy hai vợ chồng không ổn định công việc" (my father saw that the couple was not stable in their work), where [bố tôi] (my father) and [vợ chồng] (the couple) refer to different entities.
- **GPT-4:** Accurately handled these family-related references, correctly clustering mentions of [bố tôi] separately from [vợ chồng], which denotes both the speaker and her husband.
- **GPT-3.5-Turbo:** Struggled to keep these distinctions clear, sometimes merging family-related terms incorrectly into broader clusters, reducing the specificity needed for accurate coreference resolution.

Case 4: Treatment of Noun Phrases and Generic References

- **Example:** Generic references and noun phrases like [hai con gái] (two daughters) and [con cái] (children), which need to be associated accurately. In the sentence "bỏ chồng lại nghĩ đến con cái" (leaving my husband, I think of the children), references to the children need to be linked correctly.
- **GPT-4:** Effectively grouped these mentions, maintaining a clear cluster that includes all references to the speaker's children, such as [hai con gái] and [con cái].
- **GPT-3.5-Turbo:** Failed to consistently group these mentions, sometimes treating them as unrelated or merging them with other unrelated clusters. This led to inaccuracies in capturing the relationship dynamics within the narrative.

4.4 Discussion

The results clearly demonstrate that GPT-4 is superior to GPT-3.5-Turbo in performing coreference resolution on Vietnamese narrative texts, a finding that aligns with similar studies where advanced transformer-based models outperform earlier architectures (Devlin et al., 2018; Lewis et al., 2020). These findings reinforce the trend that larger, more sophisticated models offer improved capabilities in capturing the nuances of low-resource languages (Conneau et al., 2020). The improvement across all metrics can be attributed to the more advanced architecture and training data of GPT-4, which aligns with findings from earlier work on few-shot learning with large language models (Brown et al., 2020). This allows GPT-4 to better understand the complexities of coreference in a low-resource language like Vietnamese.

While both models showed some level of proficiency, the substantial gap in performance underscores the importance of using more advanced LLMs like GPT-4 for tasks that require a nuanced understanding of language. The evaluation also highlights the areas where further improvements are needed, such as better handling of difficult cases like extracting the exact noun from a complicated noun phrase or understanding the semantics to link the correct entity.

Overall, the use of LLMs in Vietnamese coreference resolution appears promising, with GPT-4 paving the way for more accurate and reliable models that can handle the intricacies of the Vietnamese language.

5 Conclusion

In this study, we explored the application of LLMs, specifically GPT-3.5-Turbo and GPT-4, for the task of coreference resolution in Vietnamese narrative texts. Coreference resolution, a critical component of NLP, involves identifying and linking various expressions in a text that refer to the same entity. This task is particularly challenging for low-resource languages like Vietnamese, where annotated datasets are scarce.

We utilized a dataset originally created by Nguyen et al. (2023) (Nguyen et al., 2023), which was collected from VnExpress and covers a diverse range of narrative topics. We developed detailed guidelines for annotating entities within this dataset and leveraged the few-shot learning capabilities of LLMs to design prompts that allowed these models to perform coreference resolution on the dataset. The evaluation of the models' outputs against the manually annotated *gold_clusters* provided insights into their effectiveness.

The results of our evaluation clearly demonstrate the superiority of GPT-4 over GPT-3.5-Turbo in resolving coreferences in Vietnamese texts. GPT-4 achieved a CoNLL F1 score of 0.735, significantly outperforming GPT-3.5-Turbo, which scored 0.478. This improvement was consistent across all metrics, including MUC, B-Cubed, and CEAF_{ϕ}, indicating that GPT-4 is more adept at accurately identifying and linking mentions to the correct entities.

5.1 Future Work

While this research has made significant strides in improving coreference resolution for Vietnamese, several areas remain open for further exploration. One promising direction is the expansion of the annotated dataset. Increasing its size and diversity by incorporating more narrative genres, regional dialects, and contemporary language use could significantly enhance the robustness and generalizability of the models. Another important avenue is the fine-tuning of models on domain-specific texts, such as legal documents, medical records, or historical texts. This would require the development of specialized annotated datasets and evaluation metrics tailored to specific domains.

Future work could also focus on integrating coreference resolution with other NLP tasks, such as sentiment analysis, machine translation, and information extraction. This integration has the potential to create more holistic language understanding systems capable of handling complex, multi-faceted text analysis tasks. At the same time, the development of more efficient models is critical, particularly for reducing the significant computational costs associated with large-scale models like GPT-4. Techniques such as model distillation or pruning could be explored to achieve a balance between high accuracy and resource efficiency.

Additionally, exploring multilingual and cross-lingual models could leverage the linguistic similarities between Vietnamese and other Southeast Asian languages, potentially enhancing coreference resolution across multiple languages. Cross-lingual transfer learning techniques may prove especially valuable for improving performance in languages with even fewer resources than Vietnamese. The incorporation of external knowledge sources, such

as structured databases or knowledge graphs, could also bolster model performance, particularly in handling entities underrepresented in training data.

Efforts to improve how models handle ambiguities in coreference resolution are equally critical. Challenges such as pronoun resolution or implied entity references require more sophisticated context-awareness mechanisms within the models. Lastly, developing user-interactive coreference resolution tools could add significant value in applications such as content creation, editing, and data analysis. These tools could allow users to guide or correct the resolution process in real-time while leveraging user feedback to continually refine model performance.

The success of LLMs like GPT-4 represents a significant step forward in coreference resolution for Vietnamese. This aligns with findings from other studies that demonstrate the versatility of LLMs across languages and tasks, even those with limited training data (Radford et al., 2019; Raffel et al., 2020). However, there remains substantial potential for further innovation, particularly in areas such as dataset expansion, domain adaptation, model efficiency, and cross-lingual applications. These future directions hold great promise for developing more accurate and reliable NLP systems that can better address the linguistic diversity and complexity of Vietnamese and other low-resource languages.

Linguistic Variations in Korean-to-English and Korean-to-Filipino Translations of Selected K-Dramas

Abstract

This paper investigates the underlying linguistic variations that have prompted different representations or deviations in the translated dialogues of three selected K-dramas with Netflix English subtitles and Viu Filipino dubs: *Reply 1988*, *Weightlifting Fairy Kim Bok Joo*, and *Hotel del Luna*. Delving into K-drama translations in English and Filipino target languages, the study determined linguistic variations in drama transcriptions using Yau's (2018) Linguistic Variations in AVT. Linguistic variations were analyzed in the form of register, dialect, sociolect, diglossia, and humor. The paper found translated dialogues that may present different interpretations of the source language, which may then result in the deviated meanings as the target viewers consume drama content through the subtitles and dubbings. Despite the findings not being limited to this consequence, the Korean-to-English translation tends to be simplified, standardized, and monotonous at times while the Korean-to-Filipino translation has applied some adjustments by using appropriate local nuances. The findings of the study uphold the significance of considering the sociolinguistic factors in translation to foster cultural understanding.

1 Introduction

Translation plays a crucial role in the increasingly diverse international media landscape by enabling cross-cultural representation and communication. As foreign media productions gain recognition in what was once an English-dominated industry, translation has facilitated global exposure to different cultural realities. Methods of audiovisual translation (AVT), such as subtitling and dubbing, help overcome linguistic barriers, making foreign productions accessible worldwide (O'Sullivan & Cornu, 2019).

Effective translation in media involves capturing not only linguistic features but also cultural nuances to maintain authenticity. As Pavesi (2014) notes, audience satisfaction depends on the accurate portrayal of characters, settings, and their dialogues. Through selective mimesis, filmmakers can replicate linguistic conventions that mirror the source language (SL) and the target language (TL), considering elements like intonation, dialect, and idioms (Nedergaard-Larsen, 1993). Since language reflects societal values and structures, incorporating these cultural aspects in translation ensures a more authentic representation (Trudgill, 1983). Moreover, linguistic variations like dialect, register, sociolect, diglossia, and humor present additional challenges in AVT due to differences between the SL and the TL (Yau, 2018). Therefore, a focus on sociolinguistic aspects in AVT can foster cultural sensitivity and build stronger intercultural connections.

Among the media productions that have transcended cultural boundaries through AVT is K-drama, one of the most accessible forms of entertainment with a wide range of storytelling approaches (Han, 2020). It has grown in popularity for highlighting and allowing viewers across the globe to experience Korean culture through their food, fashion, sports, and tourism. To stay abreast with the international audience and meet commercial objectives, K-drama streaming platforms typically include English subtitles, as it is considered the universal *lingua franca*. While most media are translated into English for broader global consumption, AVT can also target specific audiences, such as translating Korean content into Filipino.

As the Philippines is one of the highest consumers of (South) Korean culture, Filipinos have become an integral part of the growing Korean cultural invasion (Blas & Erestain, 2020). Therefore, with the increasing number of Filipino viewers, Viu, one of the main legal distributors of K-

drama series, produced Filipino-dubbed versions to cater to the Filipino local audience.

With the rising demand for global media products, along with the necessity for AVT, it has become a "burgeoning body of research" (Wang, et al., 2020, p. 475). For instance, a study among Asian-Canadian K-pop fans by Yoon (2017) revealed that due to cultural differences between Canada and South Korea, there were numerous instances where translations are often recontextualized and reappropriated to fit into the context of popular Western pop. Similarly, Van Rossum's (2015) study of honorifics in K-drama and translation procedures, focused on the difference between the amateur and professional subtitlers' foreignizing and domesticizing strategies, respectively. Both studies highlight the importance of cultural considerations in Korean translation. On the contrary, Ramière's (2006) study demonstrated that subtitlers claimed to "systematically select strategies on a case-by-case basis, and not to have any form of ideological, aesthetic or didactic agenda" (p. 161). Moreover, they did not follow any guidelines when translating cultural references.

In the Philippines, Montalvo (2015) conducted a comparative analysis of Korean to English subtitles and Korean to Filipino dubs in an episode of the *Empress Ki* drama, focusing on the grammatical and syntactic aspects of the three languages (specifically case markers) in informal and polite discourse. While it explored the pedagogical and linguistic benefits of translating Korean dramas, it did not delve further into the cultural aspects of the three languages.

Parallel to Yoon's (2017) study, Cruz and Joseph (2019), in their comparative critique of *Endless Love,* the Filipino adaptation of the Korean series *Autumn in My Heart,* found that Korean culture was recontextualized to fit the Philippine context through characters' dispositions.

Despite the abundance of research on AVT, there are not many that explore Korean-to-Filipino translations, especially Korean-English-Filipino translations. Although researchers have attempted to scrutinize Korean-to-Filipino translation, these focused on the genre, pedagogy, and politics of language for migration purposes.

Therefore, this study aims to examine English subtitle translations and their Filipino-dubbed versions of K-dramas with focus on the linguistic variations. The results of the study may contribute to research on Korean to Filipino AVT. Furthermore, the results may provide insights on how sociolinguistic factors influence translation.

2 Theoretical Framework

Yau (2018) introduced a sociolinguistic perspective focusing on linguistic variation, the way language is utilized significantly in various contexts by different individuals. The five categories of linguistic variation are *register, dialect, sociolect, diglossia*, and *humor*.

The concept of register refers to "specific styles of speech connected with certain professions or groups within society" (Wardhaugh & Fuller, 2015, p. 52). It is a term that applies to the distinctive styles of speech. The formal and informal language contexts, for instance, influence the translation process substantially, whereas TL translations do not generally have a similar register as the SL.

As adopted by Yau (2018), a dialect is a "variant of language that is recognizably spoken in a particular area" (Spolsky, 1998, p. 122). Speakers may use a variety of styles, registers, and genres to communicate in a range of social contexts. As a result, translating dialectal dialogue could make it challenging to understand the subtitles.

Yau (2018) defined sociolect as *social dialect,* which is a variation of the language spoken by individuals of a specific social group. It could refer to a social class, occupation, cultural background, or age range. The application of sociolect in translation may provide insights on variations in sociolinguistic factors that affect contextual meaning in the TL.

Diglossia refers to a situation in which more than one language variation is spoken in a particular society, as explained by Yau (2018). It occurs when a community uses the same language in two discrete forms. In a diglossic society, formal speeches and significant written interactions are conducted in a high variety (H), whereas regular discussion and informal or casual writing communication are conducted in a low variety (L). Thus, difficulties arise due to the functional separation of linguistic types during translation.

The last concept in Yau's model is humor**.** It is an intriguing context for studying how translated languages are determined from a sociolinguistic viewpoint. To be able to discern and develop humor, it is necessary to understand context and

schemata. Because humor is reliant on sociocultural contexts, its ability to transcend reflects social uses of language in both the source and target cultures.

Yau's (2018) sociolinguistic viewpoint places value on linguistic diversity and how language is used differently by several persons in various situations. This paradigm aided the analysis of linguistic variations in translations that affect the contextual meaning and cultural aspects transferred from the SL to the TL.

3 Methodology

3.1 Research Design

This study used a qualitative-descriptive design. Paltridge (2012) defines it as an approach that examines linguistic patterns of texts with the consideration of their social and cultural contexts. Specific utterances from the three K-dramas were selected for analysis using Yau's (2018) Linguistic Variations in AVT.

3.2 Data Source

The data source for this study are three selected K-dramas with English subtitles available on Netflix and Filipino-dubbed episodes available on Viu, namely: *Reply 1988, Weightlifting Fairy Kim Bok Joo, and Hotel del Luna*. They were selected based on the "Filipino Dubbed: Popular Filipino Dubbed" category of K-dramas on Viu Philippines' (2022). The criteria for selection include the K-drama's availability in both Netflix and Viu Philippines streaming sites, its popularity, and its inclusion of cultural elements (Van Rossum, 2015).

A minimum of three and a maximum of five lines from each K-drama episode were selected depending on the occurrences of linguistic variations in the translations. A total of 27 selected utterances were analyzed: four for register, six for dialect, five for sociolect, seven for humor, and five for diglossia.

3. 3 Data Gathering Procedure

After reviewing episodes from the selected K-dramas on Netflix and Viu, two episodes from each title were analyzed for questionable translations and cultural elements. These episodes, including the original Korean dialogues, English subtitles, and Filipino-dubbed versions were transcribed verbatim into a tabulated corpus. Timestamps and speaker names were included for better organization. Utterances were divided by speaker, and lengthy ones were split based on conceptual meaning.

3.4 Data Analysis

Selected utterances were categorized based on Yau's (2018) categories of linguistic variations in AVT: register, dialect, sociolect, humor and diglossia. These categories were employed to explore how the forms of linguistic variation influenced the translations per se. The findings were used to account for the influence of sociocultural factors on both SL and TLs, thus producing varied representations of the original intended meaning. The study then explains the influence of linguistic variations on the intended contextual meanings of the source text reflected in both translations.

4 Results and Discussion

Using the specified range of three to five selected utterances per episode for its analysis, this section presents the examined 27 units of linguistic variations from the selected K-dramas.

4.1 Register

Register, a crucial aspect of sociolinguistic context, guides the use of linguistic elements such as honorifics, formality, and tone based on the situation, social groups of participants, and the function of language. Dropping of honorifics is a prominently observed variation in K-drama translations. Korean registers are notable in the use of titles like "~님" *(nim)* or "씨" *(ssi)* (Mr., Ma'am, and Sir) and polite markers like "~요" (*yo*) or "입니다" (*ibnida*). In Korean culture, honorifics do not always signify "respect"—they are used for anyone older, in professional settings, for less intimate relationships, and even for humorous effect, so what matters is the nuance. As a complex language, Korean exhibits many variations and choices of register.

The example in Table 1 (See Appendix) demonstrates how Sun Woo, upon starting to date Bora, immediately informs her that he will stop using honorifics, typically ending in the "~요" (*yo*) form, and will no longer address her as "누나" (*nuna*; older sister). In translation, "누나" was rendered as "ma'am" in English and "matanda" (elder) in Tagalog. This change highlights how honorifics in Korean reflect the speaker's level of formality depending on the relationship. Thus, the shift from formal to informal is evident when honorifics are dropped.

Another observable variation in the translations is switching speech style. Lewandowski (2010) explains that a register is a situationally conditioned variety of language, where speakers adjust their speech according to the context.

In Table 4 (See Appendix), Joon Hyung practices how to apologize to Bok Joo, focusing more on varying tones. He practiced in two ways: First, "내가 미안해, 내가 진짜 잘못했어 내가 진짜 죽을 죄를 지었어. 내가 진짜 네가 좋아하는 고기 사줄께 내가." (I'm sorry. I really did something wrong. I committed a sin that deserves death. I will buy you a meat that you really like.), translated to "Bok-Joo, I'm sorry. I'm really sorry. I'm terribly sorry. I'll buy you your favorite meat." in English and to "Alam kong kasalanan ko ang lahat, Bok Joo. Sorry, hindi ko sinasadya. Sorry na talaga, ililibre kita ng favorite mo." (I know it's all my fault, Bok Joo. Sorry, I didn't mean it. I'm really sorry. I'll treat you to your favorite.) in Filipino, which implies sincerity with a low tone. Secondly, "야, 내가 잘못 했어. 내가 고기 살게!" (Hey, I did something wrong. I'll buy you some meat!), translated to "Hey, I'm sorry. I'll buy you some meat." in English and to "Teka, hoy ikaw, Bok Joo, sorry talaga ah, lilibre na lang kita." (Hey, you, Bok Joo, I'm really sorry, I'll just treat you.) in Filipino, which denotes a pretended lack of guilt. As a result, there are discernible register shifts that are primarily concerned with circumstances.

A third variation under register is seen in requesting a favor from someone older. As shown in Table 3 (See Appendix), Yoo Na's formal speaking manner reflects the workplace setting and the seniority of the person she is interacting with. Various speaking situations influence vocabulary choices, and Yoo Na's use of terms like "사장님" (CEO), "드시고" (formal for "eat"), and the polite marker "요"(*yo*) shows her consideration of both the person and the setting. The register of the dialogue was not effectively translated into either target language due to the lack of relevant concepts, even though Filipino also has a polite marker, "po."

Using language appropriately in a particular situation helps establish the level of formality. Similarly, Seo Hee's use of "마십시오" (*masibsi-o*; please don't) further illustrates formality. This dialogue underscores the importance of understanding and applying the appropriate register to suit the context.

4.2 Dialect

Korean dialects, known as 사투리 (*saturi*), refer to regional dialects unique to certain areas. Despite the significant role that the dialectal speech takes part in drama, the subtlety and tone of the speakers' original dialects are unlikely to be transmitted in a "one-to-one correspondence" to the target languages (Yau, 2018, p. 288).

Il Hwa speaks in the Gyeongsang-do 사투리 (*saturi*; dialect), known for its rough, fluctuating tone, which can also sound affectionate depending on the context. This combination gives Il Hwa's speech a bold yet tender quality, reflecting her caring nature. Her accent, lexical choices, and candid tone are cultural and audiovisual elements that are difficult to fully translate (See Table 5, Appendix).

Her use of non-standard dialectal terms like "맞나" (*mat-na*; Is it true?; an agreeing or responsive expression) is common among Gyeongsang-do speakers to show attentiveness. It is equivalent to "진짜" (*jinjja*; really) or "정말" (*jeong-mal*; really) in standard Korean. This dialectal nuance was standardized in the translations, likely due to the difficulty of finding an equivalent dialect. "반피" (*ban-pi*; halfwit) is used by Il Hwa to question her son, No Eul, about why Jeong Hwan is not dating anyone. Her phrase "그러믄 저, 저 뭐 저 정환이 저기가 반피가?" (Then, is Jeong Hwan the '반피'?) is translated as "Is Jung-hwan the only one?" in English and "Si Jung Hwan na lang pala ang wala." (It's only Jeong Hwan who doesn't have [one]) in Filipino. The translations modulate the terms and change the sentence types, losing dialectal nuances.

Throughout the drama, while Il Hwa's speech is rich with Gyeongsang-do dialectal features, these nuances are largely lost in translation due to limitations that smooth over the linguistic variations that give the original dialogue its distinct regional flavor.

The dialects in *Weightlifting Fairy Kim Bok Joo* are not as full-blown as in *Reply 1988*, but the nuances were occasionally woven to add charm into the character's speech and to achieve specific

purposes. In Table 6 (See Appendix) Joon Hyung's default tone is the casual standard Seoul accent, as he playfully rejects his cousin's offer to share an umbrella with "에이, 남자 둘이 미쳤냐?" (Ay, two men together, are you crazy?). This reflects Joon Hyung's mischievous character.

On the other hand, he also produces a dialectal nuance in the delivery of "또 봅세," translated as "see you"" in English and "kitakits" in colloquial Filipino style of farewell. "봅세" conveys a relaxed vibe, often linked to regional dialects of older generations. Hence, this instance demonstrates that Joon Hyung uses it for humorous effect, adding depth to his character.

There were no notable dialectal nuances in *Hotel del Luna*. The drama's plot involves fantasy and spans past, present, and future, incorporating a historical theme, so the dialogue features archaic terms and expressions from the Joseon Dynasty era. The translation distinctions are presented in Table 7 (See Appendix).

The speaker in the dialogue, Kim Sun Bi (or scholar Kim), maintains a traditional way of speaking typical of a Joseon-era elite, holding grudges over being falsely accused of writing vulgar and lascivious stories. His speech shifted from modern formality to an obsolete style, using the archaic verb suffix "-올시다" (*-olsida*). Initially, Kim Sun Bi spoke formally with a neutral tone in the line, "두 분 다 글을 쓰는 작가시지요?" which literally translates to "You two are writers, right?" In the following utterance, his speech style transitioned to an archaic expression when he said "백주올시다" (*baek-ju olsida*), which literally means "This is *baek-ju* (traditional white liquor)." Therefore, the dialogues in Hotel del Luna do not employ regional dialects but instead present different speech styles to reflect distinctive character traits.

Languages convey meanings tied to their speakers' social and cultural contexts, and dialects are no exception. However, adapting an SL dialect into a TL local dialect is often incompatible, resorting to standardization of non-standard forms into standard TL expressions. While this approach conveys the general meaning but often fails to capture the nuanced subtleties of characters' speech. The argument over standardizing dialects remains unresolved, as it can diminish the characters' backgrounds and speech styles (Dyck et al., 2014).

4.3 Sociolect

A sociolect is anchored on social interactions and identifiable social factors such as education, age, residence, and cultural background, among others. With those considerations, the analysis is pinned on three distinct characters from the selected K-dramas, each representing specific social groups.

Sung Deok Sun of Reply 1988: adolescent lower-class

Deok Sun, an 18-year-old high school student who lives in a semi-basement home, a common solution to Korea's 1980s housing crisis (Anantharamakrishnan, 2021; BBC News, 2020). Her family struggles financially due to unpaid debts. These details suggest Deok Sun's language reflects the sociolect of a lower-class female high school student in late 1980s Seoul.

As shown in Table 8 (See Appendix), Deok Sun uses the Korean slang "웬열" (*wen-yeol*; what the heck) to express surprise and frustration when teased by her friends about being 'dumped' by the guys she dated. Her childhood friends make fun of her, prompting her to try harder to save face and prove her popularity. The English translation "Seriously?" conveys denial, while the Filipino "Asa ka pa!" (You wish!) expresses a more escalated tone, even humorously. These expressions are common among people close in age to Deok Sun, though they are not limited to any specific social group.

Jung Jun Hyoong of WFKBJ: Middle-class Sophomore College Athlete in Seoul

Jung Joon Hyung, a character from the coming-of-age sports drama, is a 21-year-old sophomore athlete on Haneol Sport University's swimming team in 2016. After his widowed mother left for Canada to remarry, he was raised by his aunt and uncle, who run a local pharmacy, while his cousin became an obesity doctor. Though he grew up without financial difficulties, he primarily lives in the school dorms with fellow college athletes.

In Table 9 (See Appendix), Joon Hyung references "태릉" (*Taereung*) in a conversation with his gymnast ex-girlfriend, Si Ho. *Taereung*, the Korea National Training Center for elite athletes and Olympians, is well-known to local Korean

viewers. However, in both translations, the term was kept as “Taereung,” which can be unclear to speakers unfamiliar with its cultural significance.

Table 10 (See Appendix) shows the difference in the representation of the borrowed English term “풀” (*pul)* in Korean which literally translates to ‘full. In this context, "풀" refers to the concept of a full course meal, from the main dish to desserts. Joon Hyung uses "풀" to suggest treating Bok Joo to popcorn and drinks at the cinema, which is appropriate in Korean. However, the literal English translation, “I’ll treat you in full,” can be ambiguous. Similarly, the Filipino translation “lahat [pati]” (everything) could exaggerate the meaning to include all expenses, like movie tickets. This example highlights the importance of understanding context and carefully selecting words to effectively convey the intended meaning and overcome linguistic barriers.

Gu Chan Sung (구찬성) of Hotel del Luna: Working Upper Class in Seoul

Gu Chan Sung is the 30-year-old general manager of Hotel del Luna who had humble upbringing. His Harvard MBA was made possible with the help of the hotel owner. The story is set in 2019 Seoul, with Chan Sung living in a remodeled *hanok* courtesy of his wealthy friend Sanchez. He was as an assistant manager at an international hotel chain before working at Hotel del Luna. With these considerations, it can be said that Chan Seong’s speech represents the sociolect of Seoul's upper-middle-class working adults.

The term “회식” (*hwesik*) combines “회” (company/meeting) and “식” (eating/food) to describe a company-sponsored meal for employees (See Table 11, Appendix). Since company dinners are not common in English or Filipino cultures, the term requires additional contextual explanation in translation. Both target languages attempt to convey the concept more clearly: “meal with colleagues” in English and “dinner kasama ang mga workmate” (dinner with workmates) in Filipino, using modulated translations to express the idea more literally. This example demonstrates that despite cultural differences, descriptive translation efforts can effectively convey foreign concepts for better understanding.

The analysis of the three characters illustrates how social factors shape language use, creating unique varieties distinct from standard language. Language acts as a bridge between cultural codes, requiring careful interpretation. While equivalent terms help comprehension, excessive reliance on them may ignore the original context. This aligns with Bassnett's (2007) view that translators should understand both linguistic and cultural complexities to ensure accurate representation and nuanced translation.

4.4 Humor

This section examines how translations considered linguistic differences and various characteristics for the viewers to understand humor.

As shown in Table 12 (See Appendix), Deok-Sun humorously defends herself, claiming she dumped the guys she dated after her friends tease her about always being dumped. In Korean, she uses “찬밥” (*chan-bab*; cold rice) to imply she is overlooked by her friends but popular elsewhere. In Filipino, “cold rice” translates to “bahaw,” meaning someone unattractive or undesirable, changing the humor. Though the context is preserved, the "cold rice" humor is less effective in the English and Filipino translations.

In Table 13 (See Appendix), during their conversation, Bok-Joo, feeling cold, says she is only "wearing" a muffler. Joon-Hyung teases her by correcting her use of the word "wear," as Korean uses different verbs: “입다” (*ib-da*) for clothing and “매다” (*mae-da*) for accessories like mufflers and bags. Bok-Joo mistakenly uses “입다” (*ib-da*) instead of “매다” (*mae-da*). The humor comes from Joon-Hyung's playful attempt to keep her from leaving, as he enjoys their time together. While the translation has been adjusted, non-Korean speakers may miss the original humor due to the cultural and linguistic nuances that are lost in translation.

In a scene where Jang Man-Weol and Chan-Sung eat *naengmyeon* (cold noodles) together, humor arises when Man-Weol jokes, “Let's eat. *Naengmyeon* is getting cold,” playing the irony of “cold noodles” getting cold (See Table 14, Appendix). This joke relies on a cultural understanding of *naengmyeon*, which may be lost to non-Korean audiences unfamiliar with the dish. This analysis highlights the importance of accurately

conveying cultural references in TLs to avoid loss of context and cultural misrepresentation.

4.5 Diglossia

Yau (2018) introduces the concept of diglossia as a "clear functional separation" (Wardhaugh and Fuller, 2015) within the same language that creates "two distinct codes." This section's analysis of diglossia contrasts the high variety with a low variety, attributed to the three key aspects: linguistic situation, cultural function, and lexicon.

To explain the context of this translation (See Table 15, Appendix), Deok Sun picks up the phone and hears a recorded message from her date canceling their plans for Lee Sung Hwan's live concert at the last minute. The message contains a formal apology in high-register Korean, using politeness markers like "-합니다" (*hamnida*) and "-입니다" (*ibnida*) to sound formal and respectful. The speaker also addresses Deok Sun as "덕선씨" (Deok Sun *ssi*) where "씨" (*ssi*) is a respectful suffix similar to "Miss" or "Mister" in English.

In the Filipino translation, a mix of high and low varieties appears. English phrases like "press one, to page" represent a high-variety formality, while Taglish expressions like "nag cancel" and "importante" (more commonly used than "mahalaga") indicate a low variety. The English translation maintains a formal tone but adapts it, translating "실례를 하게 되어" (for I committed a discourtesy) to the more natural "for being disrespectful." The Filipino translation simplifies this to "Nakakahiya" (it's embarrassing), conveying the meaning in a culturally appropriate way.

Al Afnan (2021) suggests that a low variety of language is what individuals acquire at home and use in everyday, casual interactions, such as informal conversations with friends. For example, Tae Kwon speaks to the juniors with the phrase "수고가 많네, 따까리 하느라" (You are working hard, playing the lackey). The slang term "따까리," which corresponds to the English word "lackey," was translated into the informal term "minions" (low variety) in Filipino (See Table 16, Appendix). In other Filipino contexts outside of this drama, the term "sunod-sunuran" (someone who blindly follows) may be used to convey a similar idea. Meanwhile, the English translation lost the sarcastic and humorous nuance, rendering it in a monotonous tone without a counterpart. This shows how high and low language varieties serve different social functions based on context.

Lesada (2017) notes that both diglossia and bilingualism are prominent in the Philippines, particularly in Metro Manila, where English and Tagalog are commonly spoken. This blend has led to the emergence of "Taglish," contributing to widespread bilingualism and social diglossia.

In Table 17 (See Appendix), the Korean text "네 동생 간병인 아줌마다" (It is the caregiver ajumma [a middle-aged woman] of your younger sibling) is translated into Taglish in the Filipino version, where the speaker mixes Tagalog and English, as seen in the term "nag-text." This casual conversation style, using phrases like "응, hey, and hmmm," shows that the speaker is addressing a love interest.

While linguistic variations shape meaning in translation, each can provide appropriate contexts in the target language or pose challenges in conveying the full depth of the original dialogues. These challenges often stem from the lack of equivalent concepts, cultural differences, and linguistic limitations.

4.6 Representation of the Source Language

Yau (2018) claims that translation does not merely serve as a tool in securing intelligibility between languages in AVT but also in bridging linguistic variations — tackling attributed sociocultural contexts in both the SL and the TL. In the case of drama translation, the translated text in subtitles and dubs accounts for the delivery of the dialogues, context, and plot comprehension of the target viewers.

The Korean-to-English translation is generally standardized in that it transmits the essential context but is lacking in terms of sophistication of meaning. With this translation technique constantly applied, the English expressions tend to sound more monotonous and simplified than what is actually said by the drama characters. For example, the translation of addressing or "호칭" (*hoching*; name title) deviated with similar frequency in both TLs. The English and Filipino translations share almost the identical terms to transmit job titles (e.g., head manager [부장님] to sir or Mr. Lee, room service manager [객실장님] to Ms. Choi, Teacher [선생님] to Dr. Jay). Aside

from this, the standardization of the Korean-to-English translation is depicted in the consequences that are associated with the generation-related catchphrase, the verb suffixes that created either formal or archaic terminologies, dialect, interjections, and slang.

Further, various speech styles are present in Hotel del Luna, but they were indistinguishable in the translated versions. Lost in the English and Filipino translations were tone and archaic expressions that were distinctive in the Korean dialogues. Speech tone is also seen on the lexical level in the SL, when characters use specific terms that reflect authoritative speech.

In the transmission of dialect in the TLs, the data shows how dialects were transferred into standard English where no dialectal nuances were noticeable. Moreover, some omissions of expression in particular dialects were observed. For instance, the term, "판박이" (duplicated thing), was passed over in Sun Yeong's utterances. Most pervasively, the interjections like "아이고" (*aigo*) were frequently omitted in the English translation while the Filipino translation conveyed it as "Hay nako." Additionally, slang such as "따까리," the similar context of which is "lackey," was underrepresented. The word is classified as low variety, but it was insufficiently translated in English as "it must be a lot of work for you," while in the Filipino translation, "minions" was used making it closer to the original context in the SL.

Meanwhile, in terms of changing registers to communicate emotions of attachment and formal interaction with older people, the Filipino TL employs the terms "po" and "opo" to denote formality and respect in the Philippine setting. This is different from Korean culture because there is sentence formality in Korean. The particle 요 (*yo*) and the verb suffix 습니다 = (*subnida*) make sentences sound more polite and add formality to a phrase.

Another instance is seen in the fight between Bok Joo and Si Ho. In literal translation, Bok Joo's sentence "열라 이중인격" means "freaking two personalities" which was translated as "sobrang plastik mo!" in Filipino. The word "plastic" in the Philippines refers to the elastic material intended to hold and carry items, but in this context, it refers to a hypocritical person or a backstabber. Thus, even though there is no similar phrase in the source language, the context in Korean has been captured in the Filipino translation.

Additionally, there are instances when humor is translated literally in the Filipino dubs, making it incomprehensible to a broader audience. Selected utterances also demonstrate that the humor is altered when translated into Filipino since some phrases have connotations that Filipino speakers are not necessarily aware of. Therefore, although the Korean-to-Filipino translation appears to be a closer portrayal of the original text, there are instances when certain elements such as formality, honorifics, and humor cannot be translated and understood by a wider audience without prior understanding of both cultures.

5 Conclusion

The analysis of K-drama translations using Yau's categories of linguistic variations shows how sociolinguistic factors significantly impact translations of K-dramas into English and Filipino. Through the close examination of the individual translation methods applied in the translation products, the study discovered how the subjectivity of the translator in their strategic approaches and attempts to communicate what is expressed in the SL may render how a group of people (specifically the speakers of a specific language) may be perceived as the representation of an entire culture by an audience. In addition, the comparative analysis of linguistic variations between the SL and two TLs showed the contrast of how certain sociolinguistic factors play a key role in distinguishing the specific barriers between cultures, beliefs, and social ideologies attached to specific languages.

The English subtitles' translation maintains a surface-level interpretation of conceptual meanings and contextual undertones of the SL. However, the study does not go as far as assuming that this is due to the negligence of the translator; rather, it considers that Netflix subscribers may not all be native English speakers; thus, understandability, clarity, and direct-to-the-point translations prove to be a realistic and practical approach. Unfortunately, it becomes a barrier for the appreciation of the SL's complex nature, defeating the potential of the platform for worldwide representation.

Contrastingly, the study asserts that the Filipino translations of the SL utilized by the Viu dubbed

episodes provided closer representations. Translators have the freedom to use their preferred translation strategies since Filipino dubs are made to cater to the Filipino audience. Nevertheless, intelligibility and commercial considerations are also important possible reasons for this.

Conclusively, this study affirms Yau's (2018) perspective on the importance of considering the categories of linguistic variations for a deeper and a more cohesive understanding of the role of society, culture, identities, and language in translation as well as the correlation of all the identified factors. However, a more exhaustive analysis of an entire series or complete films instead of just selected drama episodes can be conducted to further validate the findings.

Abstract

We introduce a novel method for extracting Filipino spelling variants from a corpus. As an Austronesian language, Filipino exhibits a high degree of inflectional variability. By leveraging linguistic features, crafting rules, and utilizing a representative dataset, we categorize word pairs into three key groups: those adhering to standard guidelines, deviating forms, and competing norms. Our approach highlights significant overlaps with existing documented spelling variants and underscores the potential for enhanced performance in natural language processing (NLP) tasks. Future research should focus on collaborating with language planning bodies to formulate policy recommendations to streamline standardization efforts.

1 Introduction

The proliferation of spelling variants and errors can hinder the performance of various Natural Language Processing (NLP) tasks, including part-of-speech tagging in German (Scheible et al., 2011), intent classification, slot-filling, and response generation in code-mixed data (Yadav et al., 2022), as well as machine translation and sentiment analysis in Nigerian Pidgin (Lin et al., 2024). Addressing these spelling variants during both in the training and decoding phases can enhance performance across NLP tasks.

In the field of education, analyzing spelling variants is equally important. In the Philippines, a Southeast Asian country with 186 languages according to Ethnologue (Eberhard et al., 2024), several educational tools, such as LanguageTool (Oco and Borra, 2011), Gramatika (Go and Borra, 2016), and Balarila (Ponce et al., 2023), have been developed to correct spelling errors, targeting one of the official Philippine languages—Filipino.

Numerous Filipino spelling variants have been documented in the literature, notably by Zuraw (2006), Ilao et al. (2011), and Gallego (2016).

cdiff	Word1	Word2
d vs. r	madumi	marumi
e vs. i	galeng	galing
o vs. u	kompanya	kumpanya
uw vs. w	kuwento	kwento
iy vs. y	piyano	pyano

Table 1: Spelling variants and examples

Some examples of these variants are presented in Table 1, where cdiff is the character difference, and Word1 and Word2 have the same meaning.

One challenge in extracting spelling variants is the occurrence of non-variants or false positives—word pairs that are, in fact, distinct words. Examples are shown in Table 2, with glosses in parentheses. This paper aims to address this issue by proposing a methodology for extracting spelling variants from a corpus, utilizing linguistic features and carefully crafted rules. Our contributions can be summarized as follows:

- We identified various linguistic features and created rules to extract word pairs that are spelling variants;
- We conducted experiments on a monolingual corpus of Filipino texts; and
- We categorized word pairs into three distinct types based on their alignment with existing guidelines.

Our approach has implications for both educational tools and larger NLP applications that rely on accurate word forms for efficient processing.

Filipino language

The focus of this study is the Filipino language, which is characterized by free word order and a high degree of inflection. Beyond education, the extraction of spelling variants plays a critical role

cdiff	Word1	Word2
d vs. r	madikit (sticky)	marikit (pretty)
e vs. i	pare (buddy)	pari (priest)
o vs. u	opo (yes)	upo (eggplant)
uw vs. w	pauwi (go home)	pawi (erase)
iy vs. y	paiyak (to cry)	payak (simple)

Table 2: Example of non-variants

in language standardization. According to a report by National Geographic (Rymer, 2012), one language dies every 14 days, and nearly half of the approximately 7,000 spoken languages worldwide are expected to disappear within the next century (Anderson, 2010). Documenting and compiling dictionaries is an essential step in preserving endangered languages, while standardization ensures consistency and usability in lexicographic work.

In the Philippines, data from Ethnologue (Eberhard et al., 2024) reveals 186 documented languages, making the country a linguistic treasure trove. Of these, nine are non-indigenous, 175 are indigenous, and two have already become extinct. These statistics underscore the urgent need for a comprehensive databank of Philippine languages and highlight the crucial importance of standardization in preserving this rich linguistic heritage.

The Komisyon sa Wikang Filipino (KWF), also known as the Commission on the Filipino Language (CFL), was established under the 1987 Constitution of the Philippines [1]. It serves as the official regulatory body responsible for the development, preservation, and promotion of Filipino and other local Philippine languages [2]. The Philippine orthography has evolved from 20 letters in 1940 to 28 letters in 1987:

- 1940: a, b, k, d, e, g, h, i, l, m, n, ng, o, p, r, s, t, u, w, y
- 1987: addition of eight letters {c, f, j, ñ, q, v, x, z}

Ten years ago, the KWF released the 2014 edition of the National Orthography (sa Wikang Filipino, 2014), which provides guidelines for writing the Filipino language and was used to match the results of our experiments.

Extracting spelling variants

Linguistic features

To extract linguistic features, word unigram models and character n-gram profiles of a given corpus need to be generated. Preprocessing involves tokenization and true-casing. The features we considered are:

- edit distance, a measure of how different two strings (or sequences of characters) are from one another, which is defined as the minimum number of operations (character insertion, deletion, or replacement) needed to transform one string into another (Levenshtein, 1966);
- string length;
- cdiff or character difference to show additions and deletions of characters;
- cdiff index, the index where the cdiff occurred;
- cdiff position (beginning, middle, ending of a word);
- character n-grams, with a minimum value of 3 (trigram) and a maximum value of 4 (4-gram); and
- generalized character n-grams, where consonants and vowels are generalized.

Edit distance has been widely used in cognate and spelling variants detection (Babych, 2016; Messner and Lippincott, 2024; Barteld, 2017; Laarmann-Quante et al., 2022) but there is limited attempt in the past to utilize character n-grams in detecting Filipino spelling variants.

Rule creation

Machine learning is used to identify significant features by constructing a feature set and labeling word pairs as either spelling variants or non-variants. Attribute evaluators (Hall and Smith, 1999), particularly rankers, guide the rule creation process. The results highlight the features that effectively identify spelling variants. Previous studies (Ilao et al., 2011; Gallego, 2016) relied on manual selection. To the best of our knowledge, this is the first attempt to apply a machine learning approach to determine Filipino spelling variants. Once the rules are created, they can be transformed

into regular expressions to efficiently match patterns.

Experimental setup

Data and tools

The corpus used in this study is the August 20 snapshot[3] of the Tagalog Wikipedia (Contributors, 2024). Wikipedia is available in different languages and the Tagalog Wikipedia serves as a representation of the Filipino language [4]. The raw corpus contains 11 million words and 68 million characters. We employed SRILM (Stolcke, 2002) and Apache Tika (Mattmann and Zitting, 2011) to generate word unigram models and character n-gram profiles of the corpus, respectively. Wdiff (Pinard, 1992) was used to identify character differences, while the Waikato Environment for Knowledge Analysis (Weka) (Witten et al., 2011) was used for attribute evaluation. We also utilized Notepad++[5] to convert the rules to regular expressions, enabling the efficient extraction of word pairs.

Additionally, a spreadsheet application and several custom-developed programs were used to automate the population of the feature set, a sample of which is shown in Table 3. The complete feature set includes 4-grams, though these are omitted from the table for clarity. Various n-gram configurations were explored, including cases where the cdiff index is the first letter (n-gram1), second letter (n-gram2), and so on (n-gram3 and n-gram4). For example, if the cdiff corresponding to [-a-]+i+, and with 't' and 'n' as the characters to the left and right, respectively, the 3-grams2 are "tan" and "tin." The notation "gen" (e.g., 3-gram1gen) stands for "generalized," where consonants are replaced with 'C' and vowels with 'V'. The "Class" refers to the label, indicating whether a pair is a variant or non-variant.

Limitations

Due to the multilingual nature of the Philippines, code-switching is inevitable. English words were excluded. Additionally, due to the number of variables involved, the method is limited to an edit distance of 1. Proper nouns and variations at the morphological level, including reduplication, were also excluded.

Feature	Example
word1	aabutan
word2	aabutin
edit Distance	1
string length1	7
string length2	7
cdiff	[-a-]+i+
cdiff index	6
cdiff position	middle
3-gram1 word1	an_
3-gram1 word2	in_
3-gram1gen word1	aC_
3-gram1gen word2	iC_
3-gram2 word1	tan
3-gram2 word2	tin
3-gram2gen word1	CaC
3-gram2gen word2	CiC
3-gram3 word1	an_
3-gram3 word2	in_
3-gram3gen word1	aC_
3-gram3gen word2	iC_
Class	non-variant

Table 3: Sample feature set

cdiff	Word1	Word2
d vs. r	madami	marami
e vs. i	aatakehin	aatakihin
o vs. u	abogado	abugado
uw vs. w	kuwintas	kwintas
iy vs. y	piyansa	pyansa

Table 4: Spelling variants reported in other works

Results and discussion

Spelling variants identified

We were also able to extract spelling variants detected in earlier studies. These spelling variants are shown in Table 4. We noted that only using cdiff would also result to false positives if English words are also extracted (e.g., robber vs. rubber and polling vs. pulling for o vs. u). The list of rules that yielded 100% precision rate for Filipino word pairs, totaling four, are in Table 5, where 'C' is for consonant and 'V' is for vowel. These four rules cover 807 word pairs and the manually-validated data is publicly available online[6]. Exploring various n-gram configurations as part of the feature set proved advantageous.

[6] Public data: https://forms.gle/9gvvu2KYfvAF2wR86

cdiff	Example
ehVC vs. ihVC	doblehin vs. doblihin
omC vs. umC	kompanya vs. kumpanya
CuwV vs. CwV	lenggwahe vs. lengguwahe
CiyV vs CyV	ahensiya vs. ahensya

Table 5: Rules with 100% precision

cdiff	Abecedario	Modern orthography
c vs. k	acalain	akalain
o vs. w	dinadalao	dinadalaw
i vs. y	baitang	baytang
v vs. b	automovil	automobil

Table 6: Abecedario and the modern orthography

Abecedario

Our approach was also able to detect word pairs that reflect both the Abecedario and the modern orthography. The Abecedario is the alphabet used in the early Spanish-influenced orthography of Filipino during the Spanish colonial period. It is derived from the Spanish alphabet and was widely used before the introduction of modernized and standardized forms of orthography. Some examples are provided in Table 6, highlighting the potential for conducting culturomics studies.

Alignment with existing guidelines

For each word pair, we counted the number of occurrences in the corpus and converted these counts into percentages, with the total for both words always adding up to 100%. We observed that certain word pairs, where one form appears 40% of the time or less, do not align with the 2014 edition of the National Orthography. An example under omC vs. umC is "kumpleto" ("complete" in English) with 86% compared to "kompleto" (14%), which is the word listed in the KWF dictionary. Additionally, we identified competing word forms, which we defined as having frequencies between 41% and 60%. Examples of competing forms are shown in Table 7. The percentages are enclosed in parenthesis.

We categorize word pairs into three:

1. those adhering to existing guidelines (61 to 100%);

2. competing norms (41 to 60%) and

3. deviating forms (up to 40%).

Word1 (%)	Word2 (%)
komplikado (42%)	kumplikado (58%)
kompanya (51%)	kumpanya (49%)
kompirmasyon (53%)	kumpirmasyon (47%)
pinupuwersa (50%)	pinupwersa (47%)
lisensiya (48%)	lisensya (52%)

Table 7: Examples of competing norms

In 2018, several years after the release of the 2014 edition, a contest hosted by the Komisyon sa Wikang Filipino (KWF) revealed students' deficiencies in Filipino orthography (De Guzman, CG, 2018). Out of a perfect score of 100, the first place only got a score of 65. These findings underscore the need for technological tools that comply with KWF guidelines such as spell checkers that are freely available and convenient to use.

Cosine similarity

We conducted additional experiments to determine whether the word pairs share semantic meaning. Using Word2Vec (Mikolov et al., 2013), we applied a continuous bag-of-words model (Rong, 2014) with a word window of 5 to compute cosine similarity values. This is inspired by an earlier work which looked at English words (Jatnika et al., 2019). Our results show high similarity values among competing norms with high frequency counts. Low similarity values were noted in Wikipedia articles that appear to be machine translated.

Conclusion

We developed an effective method for extracting spelling variants from a corpus. Through experiments with the Tagalog Wikipedia, we successfully extracted features and created rules using machine learning. As a next step, our findings can be integrated into widely-used Filipino spelling, style, and grammar checking tools to enhance their accuracy and functionality. Furthermore, collaboration with institutions such as the Komisyon sa Wikang Filipino (KWF) could facilitate the consistent application of standardized Filipino spelling across various platforms, promoting linguistic uniformity while supporting language education and preservation. Legitimate variants, including those classified as competing norms and deviating forms, should receive special attention in Filipino language education.

Revisiting Leti metathesis: a use case for boolean monadic recursive schemes

Gérard Avelino
Rutgers University
gerard.avelino@rutgers.edu

Abstract

This paper demonstrates how Boolean monadic recursive schemes (BMRS), a computational method of modeling phonological processes (as proposed in Chandlee & Jardine 2021, characterized in Bhaskar et al. 2020), can model metathesis in Leti, a Timoric language spoken primarily on the island of Leti in the Maluku archipelago. In this language, metathesis—when two segments switch linear position—is morphologically productive and phonologically conditioned. Using data and analyses by Hume (1998) as a starting point, I build on the idea that metathesis is a process that simultaneously deletes a segment and inserts it in a new place, modeling this process using BMRS. In the case of Leti, in certain environments, a word-edge consonant deletes and inserts itself right before its preceding vowel. In contrast with Hume's optimality and correspondence theory-based analysis, however, BMRS can intuitively account for the environments and opaque phonological interactions driving Leti metathesis without having to appeal to linearity constraints and syllable-level representations, showing that Leti metathesis is a local process that applies to segments.

1 Introduction

In addressing the need for reconciling computational models of language with longstanding conventions and assumptions in phonology, Chandlee & Jardine (2021) proposed the use of Boolean Monadic Recursive Schemes (BMRS) for phonological analysis. The BMRS formalism makes use of simple `IF...THEN...ELSE` structures which define the output value of an element according to other input and output structures local to that element. BMRS are described in Bhaskar et al. 2020 as being a logical characterization of the subsequential functions as applied on strings. That is, they can represent processes that have a fixed memory and can be computed deterministically. This is hypothesized by Heinz & Lai (2023) to be the computational class that contains phonological processes. Chandlee & Jardine (2021) argue that BMRS addresses issues found with rule-based frameworks, which undergenerate, and constrained-based grammars like Optimality Theory, which overgenerate. Essentially, BMRS can capture multiple phonological generalizations in a purposefully computationally restrictive way while using representations familiar to phonologists.

In this paper, I will demonstrate how BMRS can model the process of metathesis in Leti, an Austronesian language spoken on the island of Leti in the Maluku archipelago of Indonesia. Metathesis, a process by which two segments apparently switch linear positions, is not only morphologically productive in this language but occurs systematically in a manner that can be explained within the realm of phonology. My analysis will build on the idea that metathesis is a process that simultaneously deletes a segment and inserts it in a new place; in the case of Leti, a consonant deletes and inserts itself right before the vowel that preceded it. I will show how BMRS blocking and licensing structures in two output copies can intuitively capture the phonology behind Leti metathesis. This contrasts with Hume's optimality theory-based analysis (1998) in that a BMRS account does not need to consider linearity and syllable-level constraints to predict the attested outputs.

This analysis is intended to serve as a demonstration for BMRS with a use case in an understudied endangered language with unique features. Not only does this paper present the fact that BMRS can capture phonological generalizations and opaque interactions through an intuitive yet computationally formal manner, but it also shows how computational methods in phonology can provide new insights for the study of typologically unusual languages.

2 Leti

Leti is an Austronesian language in the Timoric group of the Central-Eastern Malayo-Polynesian subfamily. It is spoken by around 7,700 people, primarily on the island of Leti in the Maluku archipelago (Eberhard et al. 2021). Most of the phonological work on Leti was made possible from

data gathered by Aone van Engelenhoven, a linguist and native speaker of Leti. As such, data is primarily taken from the variety of Leti he speaks, Tutukeian.

Hume (1997, 1998) gives the segment inventory for Leti in Tables 1 and 2 for consonants and vowels, respectively.

	labial	dental	alveolar	velar
stop	p, pp	t, tt	d, dd	k, kk
continuant	β/v	s, ss	r, rr	
sonorant	m, mm	n, nn	l, ll	

Table 1: Leti consonant inventory (Hume 1998)

i	u
e	o
ɛ	ɔ
a	

Table 2: Leti vowel inventory (Hume 1998)

There are no diphthongs in Leti. Two consecutive vowels in a string are part of their own respective syllables. Consonant clusters, including geminates, are not underlying; they are products of other morphophonological procesess (Hume et al. 1997, van der Hulst 1995).

Hume (1997, 1998, and in Hume et al. 1997) assumes that underlying forms in Leti can be either consonant- or vowel-final. This contrasts with van der Hulst and van Engelenhoven (1995) who assume only vowel-final forms. The analysis of metathesis in this paper will follow from Hume's work and assumes underlying forms that can be either consonant- or vowel-final. (It should be noted that a similar BMRS analysis should be workable with the interpretation in which there are only underlyingly vowel-final forms.) For consistency, all data within this paper is adapted from Hume 1997, Hume 1998, and Hume et al. 1997.

2.1 Conditions for metathesis

Hume (1997, 1998) notes that metathesis happens in two environments. It can occur phrase-final or phrase-medially. Other phonological processes can happen simultaneously with metathesis.

Hume's (1998) analysis hinges metathesis on Leti constraints on syllable well-formedness. My analysis is agnostic to syllable well-formedness. Instead, I summarize four ways phrase-medial metathesis can occur between two morphemes:

First, when the first morpheme ends in a consonant and the second morpheme begins with a consonant cluster, as in (1):

(1) a. /ukar + ppalu/ → ukrappalu
finger + bachelor = 'index finger'

b. /maun + ppuna/ → maːnuppuna
bird + nest

cf:

c. /ukar + lavna/ → ukarlavna
finger + big = thumb

d. /urun + moa/ → urunmoa
breadfruit + Moa island

Second, when the first morpheme ends in a consonant preceded by a high vowel and the second morpheme begins with a vowel as in (2):

(2) a. /maun + ori-ori/ → maːnʷorʲori
bird + buffalo

b. /rain + iskɔla/ → raːniskɔla
blouse + school

c. /urun + ipar/ → urnipra
breadfruit + slice

Third, when the first morpheme ends in a consonant and the second morpheme begins with a consonant followed by a high vowel as in (3):

(3) a. /ukar + muani/ → ukramwani
finger + man = 'middle finger'

b. /puɔras + liɔra/ → pʷɔrsaljɔra
door + seaside

Fourth, when the first morpheme ends in a high vowel and the second morpheme begins with a single consonant as in (4):

(4) a. /rai + lavan/ → ralʲavna
land + to be big

b. /kkani + tani/ → kkantʲani
plate + soil = 'earthenware plate'

cf:

c. /rai + aan/ → rajaːna
finger + big = thumb

d. /mutu + vnua/ → mutuvnua
people + country

Elsewhere, phrase-medial metathesis does not occur.

Phrase-final metathesis occurs when an underlyingly consonant-final form occurs phrase-finally. In this case, the final consonant always switches places with the vowel preceding it, as in (5).

(5) a. urnu ‘breadfruit’
cf. urun moa ‘breadfruot + Moa Island’

b. bubru ‘porridge’
cf. bubur vetra ‘porridge + maize’

c. βuːra ‘mountain’
cf. βuar lavna ‘mountain + big’

Metathesis marks phrase boundedness in Leti, with metathesized and non-metathesized words receiving different interpretations. For instance, in (6a), with each word in its own phrase, one has a simple declarative sentence. Its counterpart in (6b) with more metathesized components, a new sense appears.

(6) /na vali vatu la eni/
‘3s + turn + stone + go + sand’

a. {nvali} {vatu} {la} {eni}
‘He turns the stone to the beach.’

b. {nvalv^{y}atl^{w}a} {eni}
‘He somehow turns a stone to the beach.’

2.2 Processes on vowels

Because Leti has phonological processes that occur when two vowels appear side by side, when metathesis affects or creates an environment where there are two consecutive vowels, these other rules may also apply. In particular, metathesis interacts with compensatory vowel lengthening and the various ways that high vowels reduce: deletion, secondary articulation, and glide formation (Hume 1997).

Compensatory vowel lengthening occurs when a morpheme with two consecutive vowels undergoes metathesis, and the second of those two vowels switches positions with the otherwise final consonant. The first of the two vowels is then lengthened in its original position. This can be seen in (1b), (2a), (2b), and (4c).

Whenever a high vowel is adjacent to another vowel, the following happens to the high vowel:

(i) it deletes if the second vowel is also high, as in (2b) after metathesis.

(ii) it surfaces as a secondary articulation on the previous consonant if it ends up on the right edge of a morpheme, as in (2a) and (4a); or after a phrase-initial consonant such as in (3b) and (4b).

(iii) it surfaces as a glide word-internally otherwise, as in the second morphemes in (3a) and (3b).

Given the previous data, we can now begin generating a model of the metathesis in Leti using BMRS.

3 BMRS

BMRS, Boolean Monadic Recursive Schemes, as adapted from computational theories of mathematics, logic, and automata, have been proposed as a method of modeling phonological processes (Chandlee & Jardine 2021, Bhaskar et al. 2020). BMRS are structures defined by logical predicates in an `IF...THEN...ELSE` syntax. Each predicate is monadic because they each take a single argument from the input; Boolean, because each returns a value of either true ($\top$) or false ($\bot$); and can be recursive in that they can refer to output predicates in their evaluation. The result of any group of phonological processes is thus described by a set of BMRS functions: the input is the string from underlying forms, and the output is the solution of equations for each index in the input string.

For a further discussion on the computational formalism of BMRS, see Bhaskar et al. 2020; for a fuller picture of adapting BMRS for phonological modeling, including more examples of BMRS in action, see Chandlee & Jardine 2021. Here I will simply present an overview of the BMRS tools needed for the task at hand.

BMRS, particularly as used for phonological modeling, are built off the following ingredients:

(i) Monadic predicates $P(t)$, each taking a single term t and returning $\top$ or $\bot$. BMRS represents both input feature predicates and output feature predicates.

(ii) Terms t, which represent segments and boundaries at a given index point.

(iii) Indices x, a number that represents the position of an element on a string.

(iv) Predecessor function: If t is a term, $p(t)$ is the segment in the preceding index point; $p(t)$ is itself a term.

(v) Successor function: If t is a term, $s(t)$ is the segment in the succeeding index point; $s(t)$ is itself a term.

(vi) Expressions:
  (a) $\top$ and $\bot$ are expressions.
  (b) Any predicate $P(t)$ is an expressions.
  (c) If X, Y, and Z are expressions, then `IF` X `THEN` Y `ELSE` Z is an expression.
  (d) Nothing else.

(vii) An expression of the form `IF` X `THEN` Y `ELSE` Z is evaluated as such:
  (a) If X is true, the value of Y is returned.
  (b) If X is false, the value of Z is returned.

(viii) In an expression of the form `IF` X `THEN` $\top$ `ELSE` Z, X is called a *licensing structure.*

(ix) In an expression of the form IF X THEN $\perp$ ELSE Z, X is called a *blocking structure.*

The output string can be longer than the input string when the predicates are relativized over a copy set. That is, while there is only one output per index, each index has an output for each element in the copy set $\mathcal{C} = \{1, ...m\}$. For a copy set $\mathcal{C} = \{1, 2\}$, for example, there will be two output functions per index. The output string is then composed at each index point by taking the output of the first copy, then the output of the second copy, before moving onto the next index point.

To model Leti metathesis, I propose two copies of each segment in the output to account for the insertion aspect of metathesis. I will also use the following symbols: # will mark morpheme boundaries, while $\rtimes$ and $\ltimes$ will mark the beginning and the end of a phrase, respectively. Output functions will be marked with apostrophes, such as C'_1 and V'_2.

To simplify the BMRS expressions, I will also define the conjunction and disjunction operators as such:

- $F(x)$ AND $G(x) =$ IF $F(x)$ THEN $G(x)$ ELSE $\perp$
- $F(x)$ OR $G(x) =$ IF $F(x)$ THEN $\top$ G(x) $\perp$

The following input and output feature functions will be relevant to the following analysis:

- [±syllabic] - to distinguish between vowels and consonants.
- [±consonantal] - to distinguish between glides and other consonants.
- Place features, specified for vowels: [±round], [±high], [±low].

Consonant features do not affect metathesis, so each consonant will be expressed as a function $C(x)$. In the output, this will be taken to mean all the consonant features at index x. Likewise, as a shorthand, $V(x)$ in the output represents all the vowel features at index x. I use these abstract functions in the interest of space; a full implementation of BMRS would expand these to represent individual features.

Finally, comments for the BMRS code will be provided in the footnotes throughout to facilitate explanation.

4 BMRS for Leti metathesis

Modeling BMRS in metathesis hinges on the nesting of licensing and blocking structures. Licensing structures will reflect conditions in which a phonological process applies, while block structures reflect conditions in which they cannot apply. The final ELSE in each function reflects an elsewhere condition. The interaction between these expressions between the first and second output copies intuitively expresses the different conflicting pressures of Leti phonology.

4.1 Phrase-final metathesis

I will begin with phrase-final metathesis as this has the simplest condition for triggering: if the final segment of a phrase is a consonant, it switches positions with the vowel it follows.

First, I define the function $pf(x) = \ltimes(s(x))$ to show explicitly that the target of metathesis is the phrase final consonant. A monadic predicate like $\ltimes(x)$ simply returns $\top$ if the element at index x is the boundary symbol $\ltimes$. So, $pf(x)$ returns $\top$ if the element in $s(x)$, the index that follows x, is the phrase edge $\ltimes$.

Then, I define the output functions such that when the $phrasefinal(x)$ condition is met, the consonant is instead output in the previous index. Then, the preceding vowel is output to the second copy of its original index to ensure that it appears right after the inserted consonant. This is achieved by adding blocking structures to each of the output functions:

$$
\begin{aligned}
C'_1(x) &= \text{IF } pf(x) \text{ THEN } \perp^{1} \text{ ELSE} \\
&\quad \text{IF } pf(s(x)) \text{ THEN } C(s(x))^{2} \text{ ELSE } C(x)^{3} \\
V'_1(x) &= \text{IF } pf(x) \text{ AND } C(s(x)) \text{ THEN } \perp^{4} \\
&\quad \text{ELSE } V(x)^{5} \\
C'_2(x) &= \perp^{6} \\
V'_2(x) &= \text{IF } V'_1(x) \text{ THEN } \perp^{7} \text{ ELSE } V(x)^{8}
\end{aligned}
$$

Table 3 gives the outcome of using the above BMRS to model phrase-final metathesis on the underlying form /urun/. This graphically illustrates how each of the boolean monadic functions works. For instance $C(x)$ returns $\top$ for index 2, because r is a consonant; $\rtimes(x)$ returns $\top$ for index 5 because this marks the phrase boundary; $pf(x)$ returns $\top$ for index 4 because it is the index at the end of the phrase before the phrase boundary.

Also, highlighted on that table are the cells for the output functions to illustrate which segments

[1] The blocking structure here prevents any phrase-final consonants from surfacing phrase-finally.

[2] This outputs the consonant features from the input phrase-final consonant into the output pentultimate index instead.

[3] Elsewhere, this just outputs the consonant at its input position.

[4] This blocks the vowel before phrase-final consonants from surfacing before that consonant.

[5] This outputs the vowel features from x elsewhere.

[6] The second consonant copy is not needed yet.

[7] If a vowel is in the first copy output, this means it is not involved in metathesis. We won't need this second vowel copy.

[8] If a vowel *is* involved in metathesis, it gets output here.

surface in the output. Note that in index 3, both of the segments end up being output in the same index, but the metathesized consonant is output in the first copy C'_1, while the metathesized vowel is output in the second copy V'_2. As mentioned, first copies get linearized before second copies, which ensures the correct surface form.

Input:	u	r	u	n	⋊
x	1	2	3	4	5
$C(x)$	⊥	⊤	⊥	⊤	⊥
$V(x)$	⊤	⊥	⊤	⊥	⊥
⋊(x)	⊥	⊥	⊥	⊥	⊤
$pf(x)$	⊥	⊥	⊥	⊤	⊥
$C'_1(x)$	⊥	⊤	⊤	⊥	⊥
$V'_1(x)$	⊤	⊥	⊥	⊥	⊥
$C'_2(x)$	⊥	⊥	⊥	⊥	⊥
$V'_2(x)$	⊥	⊥	⊤	⊥	⊥
Output:	u	r	n u		

Table 3: /urun/ → urnu 'breadfruit'

4.2 Phrase-medial metathesis

We can extend the phrase-final BMRS to also account for phrase-medial metathesis. In the previous BMRS functions, $pf(x)$ was the only condition blocking the metathesized consonant from surfacing in its original index location. The next step would then be to add the conditions for phrase-medial metathesis. In cases (1) through (4) in Section 2.1, just like in the case for phrase-final metathesis, the metathesized consonant does not surface at its input index, but instead at the previous input index. Instead of $pf(x)$, we can thus define a function that takes all of the environments where metathesis occurs into consideration. To recap, phrase-medial metathesis occurs:

(7) a. when the first morpheme ends in a consonant and the second morpheme begins with a consonant cluster, as in (1): C#CC;

b. when the first morpheme ends in a consonant preceded by a high vowel and the second morpheme begins with a vowel as in (2): [+high]C#V;

c. when the first morpheme ends in a consonant and the second morpheme begins with a consonant followed by a high vowel as in (3): C#C[+high];

d. when the first morpheme ends in a high vowel and the second morpheme begins with a single consonant as in (4): [+high]#CV.

For the first three of these, the consonant involved in metathesis is the last consonant of the first morpheme in the pair. These first three conditions can be reflected in the following function:

$$\begin{aligned} metC(x) \;=\; & \texttt{IF } C(x)^{9} \texttt{ THEN } pf(x)^{10} \\ & \texttt{OR } (\#(s(x)) \texttt{ AND}^{11} \\ & (C(s(s(x))) \texttt{ AND } C(s(s(s(x)))) \texttt{ OR}^{12} \\ & [\text{+high}](p(x)) \texttt{ AND } V(s(s(x))) \texttt{ OR}^{13} \\ & C(s(s(x))) \texttt{ AND } [\text{+high}](s(s(s(x))))^{14})) \\ & \texttt{ELSE } \bot \end{aligned}$$

The case in (7d), however, involves metathesis across word boundaries. It will get its own shorthand function because there is a different environment for insertion, as this case will have to be called separately at that index:

$$\begin{aligned} mwbC(x)^{15} \;=\; & ((V(s(x)) \texttt{ AND } \#(p(x))) \\ & \texttt{AND } [+high](p(p(x)))) \end{aligned}$$

Now that these two functions are defined, we can add them to the blocking structures in the output function $C'_1(x)$:

$$\begin{aligned} C'_1(x) = & \texttt{IF } metC(x) \texttt{ OR } mwbC(x) \texttt{ THEN } \bot^{16} \\ & \texttt{ELSE IF } metC(s(x)) \texttt{ THEN } C(s(x))^{17} \\ & \texttt{ELSE IF } mwbC(s(s(x))) \texttt{ THEN } C(s(s(x)))^{18} \\ & \texttt{ELSE } C(x)^{19} \end{aligned}$$

The vowel output functions will also have to take these cases into consideration; the vowels involved in metathesis must emerge in the second copy V_2 and not the first copy V_1 in order to take a linear position after the metathesized consonant.

$$\begin{aligned} V'_1(x) \;=\; & \texttt{IF } metC(s(x)) \texttt{ OR } mwbC(s(s(x))) \\ & \texttt{THEN } \bot \texttt{ ELSE } V(x) \\ V'_2(x) \;=\; & \texttt{IF } V'_1(x) \texttt{ THEN } \bot \texttt{ ELSE } V(x) \end{aligned}$$

[9] Metathesize the consonant at x if...

[10] it is phrase final, OR...

[11] if it is word final AND...

[12] the second morpheme begins with a consonant cluster as in (7a) OR...

[13] it is preceded by a high vowel and the second morpheme begins with a vowel as in (7b) OR...

[14] the second morpheme begins with a consonant followed by a high vowel as in (7c).

[15] This stands for '**m**etathesize across **w**ord **b**oundaries'.

[16] If the consonant is involved in metathesis, block the consonant from surfacing at its original index. Otherwise...

[17] ...if we're in cases (6a), (6b), or (6c), that consonant surfaces in the preceding index.

[18] Or if we're in case (6d), that consonant surfaces in the index that precedes the preceding index.

[19] Elsewhere, just output the consonant.

So far, the functions we have defined are sufficient to describe the cases where all the vowels are unchanged except for the fact that they are output after the metathesized consonant. This reflects case (1a), illustrated in Table 4.

Input:	u	k	a	r	#	p	p	a	l	u
x	1	2	3	4	5	6	7	8	9	10
$C(x)$	⊥	⊤	⊥	⊤	⊥	⊤	⊤	⊥	⊤	⊥
$V(x)$	⊤	⊥	⊤	⊥	⊥	⊥	⊥	⊤	⊥	⊤
$\#(x)$	⊥	⊥	⊥	⊥	⊤	⊥	⊥	⊥	⊥	⊥
$metC(x)$	⊥	⊥	⊥	⊤	⊥	⊥	⊥	⊥	⊥	⊥
$C'_1(x)$	⊥	⊤	⊤	⊥	⊥	⊤	⊤	⊥	⊤	⊥
$V'_1(x)$	⊤	⊥	⊥	⊥	⊥	⊥	⊥	⊤	⊥	⊤
$C'_2(x)$	⊥	⊥	⊥	⊥	⊥	⊥	⊥	⊥	⊥	⊥
$V'_2(x)$	⊥	⊥	⊤	⊥	⊥	⊥	⊥	⊥	⊥	⊥
Output:	u	k	r a			p	p	a	l	u

Table 4: /ukar + ppalu/ → ukrappalu 'breadfruit'

The rest of the cases, however, involve various vowel processes that need to be accounted for in the BMRS.

4.3 Accounting for vowel processes

In Section 2.2, I outlined a number of various vowel processes that interact with metathesis. We can account for these in the BMRS with a few modifications.

First, to account for compensatory vowel lengthening, I observe that this only occurs phrase-medially after metathesis within a VVC#CC pattern and phrase-finally after metathesis within a VVC⋊ pattern. I propose that the first vowel in the pair gets output to both copies at its index; being output twice reflects lengthening. This environment can be translated into BMRS as follows:

$$lv(x) \;=\; metC(s(s(x)))\ \texttt{AND}\ V(s(x))$$

And we can insert this into the vowel output function as follows:

$$\begin{aligned} V'_2(x) \;=\; & \texttt{IF}\ lv(x)\ \texttt{THEN}\ V(x)^{20} \\ & \texttt{ELSE IF}\ V'_1(x)\ \texttt{THEN}\ \bot^{21} \\ & \texttt{ELSE}\ V(x)^{22} \end{aligned}$$

Table 5 shows how this applies to the case of (1b).

Next, we must account for environments like (2b) and (2c), where two high vowels would end up adjacent after metathesis. This environment can be generalized as one where metathesis has occurred within a [+high]C#[+high] sequence. To make sure that the [+high] vowel before the metathesized consonant does not surface in either copy at that index, we will need to add a a blocking structure to V'_2.

Input:	m	a	u	n	#	p	p	u	n	a
x	1	2	3	4	5	6	7	8	9	10
$C(x)$	⊥	⊥	⊥	⊤	⊥	⊤	⊤	⊥	⊤	⊥
$V(x)$	⊤	⊤	⊤	⊥	⊥	⊥	⊥	⊤	⊥	⊤
$\#(x)$	⊥	⊥	⊥	⊥	⊤	⊥	⊥	⊥	⊥	⊥
$metC(x)$	⊥	⊥	⊥	⊤	⊥	⊥	⊥	⊥	⊥	⊥
$lv(x)$	⊥	⊤	⊥	⊥	⊥	⊥	⊥	⊥	⊥	⊥
$C'_1(x)$	⊤	⊥	⊤	⊥	⊥	⊤	⊤	⊥	⊤	⊥
$V'_1(x)$	⊥	⊤	⊥	⊥	⊥	⊥	⊥	⊤	⊥	⊤
$C'_2(x)$	⊥	⊥	⊥	⊥	⊥	⊥	⊥	⊥	⊥	⊥
$V'_2(x)$	⊥	⊤	⊤	⊥	⊥	⊥	⊥	⊥	⊥	⊥
Output:	m	a a	n u			p	p	u	n	a

Table 5: /maun + ppuna/ → ma:nuppuna 'bird's nest'

$$\begin{aligned} V'_2(x) \;=\; & \texttt{IF}\ lv(x)\ \texttt{THEN}\ V(x) \\ & \texttt{ELSE IF}\ V'_1(x)\ \texttt{THEN}\ \bot \\ & \texttt{ELSE IF}\ metC(s(x)) \\ & \texttt{AND}\ [+high](x)\ \texttt{AND}\ [+high](s(s(s(x)))) \\ & \texttt{THEN}\ \bot^{23} \\ & \texttt{ELSE}\ V(x) \end{aligned}$$

Table 6 shows how this applies to (2c).

Output:	u	r	n			i	p	r a		

Table 6: /urun + ipar/ → urnipra 'breadfruit slice'

In the interest of space, I will summarize what must be done to account for the last two vowel processes in the BMRS aside from the appropriate licensing and blocking structures for the environments in which they occur:

In the case of high vowels that surface as a secondary articulation on the previous consonant, such as in (2a) and (3b), I suggest that these vowels are output at the same index and the same copy as that previous consonant. So, both C'_1 and V'_1

[20] This licenses a second copy of the vowel and outputs those vowel features.

[21] Nothing is output in V_2 when there is no long vowel environment and the vowel is not involved in metathesis.

[22] The V_2 copy will only surface if it is involved in metathesis.

[23] This blocks V'_2 from surfacing when it is the first [+high] vowel in a [+high]C#[+high] sequence.

will be true in the same index for these instances. This dual input at the same index in the same copy intuitively captures the idea of a secondary articulation.

As for underlying high vowels that surface as a glide, as in (3a) and (3c), I propose that these vowels are output as consonants. The appropriate blocking structures would appear in both V_1' and V_2', and C_1' would include a condition that allows for the output of the vowel features as a consonant.

To sum up this section, BMRS can describe metathesis and vowel processes in Leti using two output copies. The only time a consonant does not output in its original index position is if this consonant is involved in metathesis, instead surfacing in the previous index. As for vowels, the combination of blocking and licensing structures in the two vowel copies reflects when vowels are moved because of metathesis, surface as a glide or secondary articulation, or deleted entirely. The conditions for all of these processes are systematic and regular, and only involve analyses on the individual segments in each form in question. While seemingly complex in form because of the numerous phonological processes involved, the attested outputs are reached through a application of simple Boolean logic.

5 Advantages of BMRS

BMRS, through various applications of blocking and licensing structures, elegantly captures metathesis and the other phonological processes on vowels in Leti as simultaneous applications of processes of deletion and insertion on segments. This is more intuitive and less complex than Optimality Theory or Derivational/Rule-based accounts. BMRS also makes explicit that metathesis is a strictly local process (Chandlee 2014).

One advantage of this BMRS analysis is that it can easily account for other processes in terms of metathesis. For instance, Hume (1998) does not consider situations such as (2c) as involving metathesis, instead analyzing this as a consequence of two unrelated syllable-level processes: the avoidance of onsetless syllables, and a ban on phrase-medial open syllables containing the last vowel of a morpheme.

(2c) /urun + ipar/ → *ur.nip.ra*
breadfruit + slice

Simply concatenating both morphemes together would produce the unattested form **u.ru.nip.ra* that does not have any onsetless syllables. However, syllabification would leave the second /u/ in *urun*, the final vowel in that morpheme, in a now phrase medial open syllable. Thus, according to the analysis in Hume (1998), that /u/ deletes. By analyzing this as metathesis, however, these stipulations on syllable structure are unnecessary. Instead, it is readily apparent that what is happening in (2c) is a case of output-adjacent high vowels deleting.

Hume's (1998) analysis also hinges on other syllable-level processes. For example, in her account, compensatory vowel lengthening is explained as the insertion of a mora to accommodate the metathesized vowel's new position, but this metathesized vowel leaves a mora behind in its original place. This adds another layer of complexity that BMRS does away with. Because the segmental environments for metathesis and compensatory vowel lengthening are both completely regular and predictable with respect to the other processes in the language, BMRS only need to consider the properties of each segment to give the attested outputs. This does not discount, of course, the fact that phonological processes can apply on syllables; BMRS is also able to handle these where it is needed, but I leave a specific implementation to future work.

Additionally, the Hume (1997, 1998) analysis of metathesis and vowel reduction/preservation with Optimality Theory relies on the constraint LINEARITY, defined below in (8).

(8) LINEARITY: "No Metathesis" S_1 is consistent with the precedence structure of S_2 and vice versa. (McCarthy and Prince 1995)

However, LINEARITY adds complexity and the potential for an analysis that overgenerates (see Heinz 2005, Carpenter 2002). An OT account would have to considering gradience (e.g. Hume 1998, 2001) or resort to adaptations of OT like Harmonic Serialism (Takahashi 2018).

Solutions for this, as well as opaque interactions of processes, are known problems of classic OT, but they are all built into the inherently recursive system of BMRS: output functions can look at other output functions.

As an example of how LINEARITY overgenerates in the case of Leti, I present the tableau in Table 7, adapted from Hume 1998.

Each constraint proposed in this tableau in Hume (1998) rules out candidates (a) through (d): ONSET rules out the candidate provided for by simple concatenation; *COMPLEX eliminates candidates with syllables with consonant clusters such as in (b); MAX-V rules out deletion of the vowel in (c); *COMPSEG rules out the situation where the vowel becomes a secondary articulation on the consonant as in (d).

The CRISPEDGE constraint is motivated by cases where there is no metathesis, such as (9). As a consequence of syllabification, candidates with metathesis like (9b) will always violate

ukar + muani	*Complex[24]	Max-V[25]	Onset[26]	*CompSeg[27]	CrispEdge[28]	Linearity
a. u.kar.mu.a.ni			*!			
b. u.kar.mwa.ni	*!					
c. u.kar.ma.ni		*!				
d. u.kar.m^{w}a.ni				*!		
☹ e. uk.ram.wa.ni					*	*
💣 f. u.kar.maw.ni						*
g. uk.ra.maw.ni						**
h. uk.ra.man.wi						***

Table 7: OT tableau for /ukar + muani/ → uk.ram.wa.ni 'index finger', adapted from Hume 1998. Candidates (a) through (e) are from Hume 1998. Candidate (e) is attested, but I present candidates (f), (g), and (h), which do not violate CrispEdge and are thus more optimal.

CrispEdge. The attested form in (9a), however, while it also violates CrispEdge, will not violate Linearity.

(9) a. /lopu + mderi/ → *lo.pum.de.ri*
dolphin + Mderi 'Mderian dolphin'

b. */lopu + mderi/ → *lop.mu.de.ri*

The problem in Table 7 is thus apparent: Candidate (f), in which metathesis occurs entirely within the second morpheme, does not violate CrispEdge at all, and should thus surface as optimal. I also present Candidates (g) and (h), which include even more instances of linear reorganization of segments fully contained within each morpheme: these are still more optimal than the attested candidate (e).

Hume's (1998) solution to this involves another constraint that is proposed as ranking higher than CrispEdge, O-Contiguity-V:

(10) O-Contiguity-V: A contiguous string in the input may not be separated by a vowel in the output. (Hume 1998, adapted from McCarthy and Prince 1995)

This is intended to rule out Candidate (f) in Table 7 as the /a/ in the second morpheme comes in between the /m/ and /w/. The claim is that the /a/ in Candidate (e) does not disrupt output-contiguity by being in between the morphemes. How contiguity applies in the space between two input morphemes is not specified in McCarthy and Prince (1995), and would thus have to be worked out before being implemented. BMRS, on the other hand, already takes word boundaries into account in the underlying representation and thus the conditions for metathesis.

To sum up, this section showed that other accounts of Leti metathesis may introduce more complexity than is necessary to explain the phenomenon, either through the introduction of stipulative syllable-level processes or overly-powerful constraints on linear order.

6 Conclusion

A carefully constructed set of BMRS, with the appropriate blocking and licensing structures, as well as two output copies, can intuitively account for the environments and processes that are involved in Leti metathesis. BMRS also captures the interaction of metathesis with other phonological processes, even ones that are opaque, because BMRS is inherently recursive. Essentially, all the processes involved can simply be reduced to something akin to deletion and insertion, all applied simultaneously. The analysis also shows how metathesis is regular, pervasive, and productive in Leti, which shows that it is a process that should be and can be captured solely within the confines of phonology. BMRS can elegantly resolve the problems and unnecessary complexities from OT and its implementations.

This analysis, however, hinges on those previously done for Leti in Hume 1997, Hume 1998, and Hume et al. 1998, where numerous assumptions are made in order for the data to specifically be workable within an OT framework. Most significant, perhaps, is the assumption that metathesis only occurs with words that are underlyingly consonant final. However, other analyses of Leti, such as van der Hulst and van Engelenhoven 1995, make a different assumption, instead positing that all Leti morphemes are underlyingly vowel final. Or, perhaps, there could be no restriction after all on which type of segments these underlying forms must end with. Testing these with BMRS could be enlightening; these assumptions may not be neces-

[24] *Complex: tautosyllabic consonant clusters are prohibited (Prince & Smolensky 1993 in Hume 1998).

[25] *Max-V: a vowel in the input has a correspondent in the output.

[26] Onset: a syllable has an onset.

[27] CompSeg: a segment may not have more than one place specification (Padgett 1995 in Hume 1998)

[28] CrispEdge: Morpheme and syllable boundaries are aligned (Itô & Mester 1994 in Hume 1998)

sary after all if BMRS can fully account for the environments and processes involved with metathesis in Leti without them.

Along the lines of Chandlee & Jardine (2021) showing BMRS case studies with length and stress interactions in Hixkaryana, Elsewhere Condition effects, and the typology of *NC̥ effects, one hope this author has with this paper is that it builds more interest in the application of BMRS to phonological analyses, particularly in languages with typologically rare features and opaque phonological interactions.

Acknowledgments

I would like to thank the Rutgers Linguistics community for giving this theoretical syntactician/semanticist the opportunity to go beyond his usual work to explore computational phonology. Big thanks particularly go to Prof. Adam Jardine for introducing me to the BMRS framework in his Phonology seminar; his patience and kind guidance are a treasure. Thank you also to my grad student friends in the Rutgers PhonX and MathLing reading groups (Hyunjung Joo, Merlin Udinov, Vincent Czarnecki, Jiayuan Chen, and Quartz Colvin), as well as Prof. Bruce Tesar for allowing me the space to practice this talk and for the helpful feedback. Any errors and misrepresentations in this paper are mine alone.

Kinaray-a Discourse Particles

Marie Claire Duque Cruz
Polytechnic University of the Philippines
mctduque@pup.edu.ph

Marvin C. Casalan
University of Antique
marvin.casalan@antiquespride.edu.ph

Abstract

Discourse particles are syntactically dispensable but are widely present in daily conversation as well as in written discourses. Their meanings are frequently ambiguous and reliant on syntactic structures and pragmatic roles. Particles can have a variety of purposes within the text; they can establish and negotiate authority in talks, convey varying degrees of conviction, and appreciation, stress important ideas, strengthen tone, draw attention among others. This study attempts to explicate the common discourse particles of Kinaray-a, a widely spoken language in Antique Province, Philippines. The analysis is based on spoken and written corpora, which include utterances in naturally occurring conversations, spoken-like narratives, Kinaray online news reports, and literary texts. A summary of identified particles is presented with examples of how these lexicons are used in context. Based on the data, the discourse particles of Kinaray-a are classified into four: emphatic, temporal, confirmation markers, and modal articles. The authors conclude that one can only rely on their linguistic intuitions to dissect the purposes of these particles in different sentences and context.

1 Introduction

Discourse particles are a subject of significant linguistic interest, largely due to their distinctive and often unpredictable behavior in everyday communication. These particles are characterized by their fluid and context-dependent meanings, which vary according to their pragmatic functions and syntactic roles within speech. Unlike more stable linguistic units, discourse particles can fulfill a wide range of functions within a text, such as expressing varying degrees of certainty, surprise, and appreciation; establishing or negotiating conversational dominance; emphasizing key ideas; modulating tone; and drawing attention to specific elements. Due to their inherent variability and context-specific meanings, these particles often resist straightforward translation or morphological analysis, as noted by Nolasco (2005).

Given the unique properties of discourse particles and their pervasive presence in spoken and written texts, exploring their meanings in various contexts offers valuable insights into the sociolinguistic dynamics that shape their use. This paper seeks to identify the most commonly used discourse particles in Kinaray-a, based on a carefully curated corpus, and to analyze their functions within the specific contexts in which they occur. The analysis will focus on how these particles operate within daily speech and their positioning within phrases.

The study distinguishes between two types of particles: lexical and grammatical (Spitz, 2001). Lexical particles are those that enhance meanings of phrases and clauses depending on the context, while grammatical particles signal syntactic constructions. This paper is limited to the discussion of lexical particles.

The paper is anchored on Tanangkingsing's (2009, p.2) Discourse-functional Linguistics framework, which follows Huang's argument stating that "transitivity cannot be prespecified in the lexicon,

but emergences from discourse". This perspective suggests that language is not governed by a fixed set of grammatical rules but is shaped by discourse dynamics and speaker's lived experience with the language. To accurately descrive the real-world usage of Kinaray-a, this study prioritizes spoken data gathered from interviews and narratives, supplemented by written texts. Through this approach, the research aims to provide a more authentic representation of how discourse particles function in everyday Kinaray-a communication. MS Word formatting instructions

2. Methodology

2.1. Corpus

The corpus of this study is categorized into two distinct types: spoken and written. The spoken data comprise natural conversations, spoken-like narratives in contexts such as treating illness and cooking dishes, and pear stories. Natural conversations provide a rich source of spontaneous language use and interaction patterns, essential for linguistic analysis (Labov, 1972). Narratives about treating illness and cooking dishes offer valuable insights into cultural practices and terminologies specific to these everyday activities (Heath, 1983). Additionally, pear stories, which are structured narrative tasks where participants describe a series of events depicted in a video, allow for examining narrative structures and linguistic features across different speakers (Chafe, 1980).

The written corpus, on the other hand, includes select literary pieces authored by renowned Antiqueño literary writers. These literary texts are significant as they reflect the artistic and creative use of the Kinaray-a language, preserving cultural heritage and showcasing stylistic variations (Newell, 1980). Furthermore, the corpus comprises Kinaray-a news reports published online. These news reports are crucial for understanding contemporary language use, journalistic styles, and the dissemination of information within the Kinaray-a-speaking community (Bell, 1991).

By analyzing both spoken and written corpora, this study aims to provide a comprehensive overview of the Kinaray-a language, capturing its use in everyday communication as well as in literary and journalistic contexts.

2.2. Scope

The Kinaray-a variety under examination in this study is prominently utilized in the southern region of Antique Province, Philippines. Specifically, it is widely spoken in the municipalities of Anini-y, Tobias Fornier, San Jose de Buenavista, Sibalom, and Bugasong. Evidently, the province of Antique, located in Panay Island within the Western Visayas region, consists of 18 municipalities, each potentially harboring various dialects of Kinaray-a (Casalan & Dita, 2022).

The linguistic diversity within Kinaray-a can be attributed to the geographical and sociocultural landscape of the province. According to recent research by Casalan and Dita (2022), the different dialects of Kinaray-a represent the rich tapestry of linguistic varieties that coexist within Antique. The language is not only a means of communication but also a carrier of cultural heritage and identity for the local inhabitants.

Linguistic studies, such as those by McFarland (1996) and Lobel (2013), emphasize the importance of understanding regional language variations to appreciate the full linguistic and cultural complexity of an area. For Kinaray-a, the dialectical differences may affect phonology, vocabulary, and even certain syntactic structures, reflecting how language evolves in response to both historical influences and contemporary socio-economic interactions.

Furthermore, language preservation and promotion efforts, as highlighted in the work of Zorc (2020), point to the critical need for documentation and support for regional dialects. The recognition and study of these dialects contribute to a broader understanding of the linguistic heritage and encourage the younger generations to value and maintain their linguistic identity.**Error! Reference source not found.** s pecifies what font sizes and styles must be used for each type of text in the manuscript.

2.3. Participants

To maintain the quality and integrity of the data in the study, the researchers rigorously defined inclusion criteria for the informants. In addition to being literate in Kinaray-a, the informants were required to possess a deep understanding of

Antique culture and traditions. Specifically, the following criteria were set to identify informed and suitable participants:
a) Age. In terms of age, the informants must be at least 18 years old.
b) Language spoken. Kinaray-a should be the first and dominant
language of the speakers.
c) The Kinaray-a variety spoken is observed in the southern part of Antique Province
d) Ethnicity. The informants should be pure Antiqueño, which means
that both parents are Antiqueño and/or the participants' birth place should be in the identified municipalities (i.e., in the southern part of Antique), and they must have lived in the place for at least 10 years.

2.2. Data Gathering and Analysis
To fulfill the study's objectives, the recorded conversations and narrations were meticulously transcribed, classified, and segmented into clauses. The spoken, written, and narrative data underwent verification by Kinaray-a native speakers. Coding was employed to ensure precise identification of the Kinaray-a discourse particles within the data.

During the data gathering process, the research ethical principles were observed. The researchers secured informed consent forms from the informants containing details about the purpose of the study, description, benefits they get as participants, confidentiality, right to refuse or withdraw, and right to ask questions and report concerns.

3. Results and Discussion

3.1. Emphatic particles

Emphatic particles are prevalent in Kinaray-a daily discourse. They usually express added certainty and conviction to an utterance. The most common emphatic particles in Kinaray-a are gid. run, gali, and bay which may carry various meanings or enhance the meanings of neighbor words depending on the context.

3.1.1. gid

Emphatic particles are prevalent in Kinaray-a daily discourse. They usually express added certainty and conviction to an utterance. The most common emphatic particles in Kinaray-a are *gid, run, gali,* and *bay,* which may carry various meanings or enhance the meanings of neighbor words depending on the context.

3.1.1 *gid*

This particle is common among Visayan languages like Cebuano (Tanangkingsing, 2009), Hiligaynon (Santos, 2012), and Aklanon (dela Cruz & Zorc, 1968). Like in these Visayan languages, gid emphasizes a concept in an utterance and may function as an adverbial meaning 'certainly', 'very', or 'really' in different contexts. They are pre-nominal and usually occur with adverbs or adjectives as shown in the following sample utterances:

1. *Pirme gid may espeho ang dresser.*
   Always PAR POS. EXI mirror ABS dresser
   'Dressers certainly always have mirrors.'

2. *Duro gid nga salamat.*
   Much PAR LIG thank
   'Thank you very much.'

3. *Nasadyahan gid ako sa ginhimo mo.*
   Grateful PAR ABS.1s OBL PERF-do GEN.1s
   'I am really grateful for what you did.'

In these sentences, gid functions as an intensifier in most cases. However, this particle behaves differently in the following sample sentences:

4. *Syempre gid lang.*
   Of course PAR PAR
   'Of course.'

5. A: *Sin-o to?*
   Who MED
   Who (is) that?

   B. *Si Albert gid man.*
   ABS Albert PAR PAR
   'I told you (that is) Albert.'

6. *Amo gid man ra tana?*
   MED PAR PAR MED ABS.3s
   'Is he really like that?'

7. *Si nanay gid man to?*
   ABS mother PAR PAR MED
   'Is that really mother?'

8. *Bukot pa gid man kita?*

Not PAR PAR PAR ABS.1p.incl
'Are we not together (in a relationship) yet?'

It is noticeable that in these sentences, *gid* occurs with other particles such as *lang* and *man*. In sentence (5), *gid lang* adds conviction to the expression 'of course', which may be equivalent to 'no doubt' or 'without a doubt' in English. Whereas, in sentence (6), *gid man* denotes affirmation of a previous utterance, and may also be an expression of subtle irritation. It functions like the discourse particle *nga* in Tagalog. In sentences (7), (8), and (9), *gid man* signifies a clarification of previous perceptions or observations. Thus, when it is used for this purpose, the utterances become interrogatives. In this case, it functions like the particle *ba* in Tagalog. In addition, gid man usually occurs postnominal but precedes demonstratives. When two-word demonstratives are used like *amo ra* meaning 'that', *gid man* splits the demonstrative as seen in sample sentence (7).

3.1.2. *run*

This particle may be used to declare something with some degree of emphasis or to point out an observation as shown in the following examples:

9. *Raha run!*
Cooked PAR
'It's already cooked!'

10. *Sunog run ang tinig-ang.*
Burnt PAR ABS rice
'The rice is already burnt.'

11. *Sobra run ri-a.*
too much PAR MED
'That's too much already.

12. *Husto run, salamat.*
Enough PAR thanks
'(That's) enough already. Thanks.'

In these sentences, *run* may be roughly translated to 'already'. In sentence (10), *run* indicates the completion of an action, while in (11), run adds a sense of urgency to the declarative. In sentences (12) and (13), *run* carries an illocutionary act of halting or stopping something.

Another use of *run* is to function as an intensive to express impatience as evident in sentence (14).

13. *Barato run dya!*
Cheap PAR PROX
'This is already cheap!'

The same particle may also be used when calling someone's attention, as seen in (15). Removing the particle *run* will make the sentence incomplete and unnatural.

14. *Ikaw run sunod.*
ABS.2s PAR next
'You're next.'

An unusual *run* behavior may be observed when attached to the lexical item *sige*, which means 'okay' in English, as illustrated in sentence (16).

15. *Sige run.*
okay PAR
'Go ahead' or 'Pretty please.'

The addition of run completely changes the semantics of *sige.* It may be used to mean two different pragmatic functions. First, it may imply permitting someone to do something. It is equivalent to 'go ahead' in English. Second, it may signify a request or convince someone to do something (e.g. a favor). This is similar to 'pretty please' in English. Both sentences are far from the meaning of *sige* when used in isolation.

3.1.3 *gali*

Adding *gali* in sentences may denote different emphatic expressions. For instance, in sentence (17), *gali* is used to express surprise, disbelief, and exclamation.

16. *Ikaw gali ra!*
ABS.2s PAR MED/OBL
'Oh! It's you!

This exclamation is usually used when meeting a friend or an acquaintance after not seeing them for a long time, unexpectedly meeting someone or recognizing an acquaintance in a public place. This particle may function like the interjection 'oh!' in English.

Another use of gali is to signpost an idea or a thought one has remembered. For example:

17. *Ay huod gali! May utang ako kana!*
INTJ yes PAR POS.EXIST owe ABS.1s OBL.3s

'Ah! I remember! I owe you (money)!'

In (18), *gali* is used not only to signpost an idea, but may also indicate a topic shift. For example, when two people are talking about something, and one suddenly remembers an idea, the following utterance would most likely use this discourse particle. This particle may also be used in acknowledging a fact as shown in the following sentence:

18. *Bukot gali kita.*
Not PAR ABS.1p.incl
'Oh right, we're not in a relationship.'

The declarative *bukot kita*, denotatively translated as 'not us' carries an embedded meaning of 'we're not in a (romantic) relationship' or 'there is no us' in English. Adding the particle *gali* indicates acceptance and recognition of this fact.

3.1.4 *man*

Translated in English, the Kinaray-a man may mean 'also' or 'too', as shown in sentences (20) and (21).

19.*Ginabitay man sa dingding ang mga diploma kag sertipiko.*
IMP-hang PAR OBL wall ABS PLU diploma and certificate
'Diplomas and certificates are also hung on the wall.'

20. *Ginagamit man ang mga ulonan, mga kapay kag mga moskitero.*
IMP-use too ABS PLU pillow PLU blanket and PLU mosquito net
'Pillow, blankets, and mosquito nets are used too.'

Apparently, *man* may also be used to indicate irritation:

21. *Ano man?!*
What PAR
'What?'

The addition of *man* in sentence (22) signifies an added interjection of annoyance or frustration, which may be encoded by a simple rise in intonation in English.

The sample dialog below shows another function of man:

22. A: *Nagdaug tana?*
PERF-win ABS.3s
'Did she win?'
B: *Huod man.*
Yes PAR
'Maybe.'

Sentence B in (23) is an example of a response to a yes/no question. The particle *man* introduced a feeling of uncertainty to the initial response *huod* 'yes'. This is equivalent to 'maybe' or 'probably' in English but is more likely to assert the affirmative.

3.1.5 *bay*

The *bay* may also be used as an emphatic particle. In the sample dialog presented below, bay implies a certain degree of forcefulness or insistence to the negation.

23. A: *Andut indi timo magsunod?*
Why not ABS.2s IMP-come
Why don't you (want) to come?

B: *Indi takun bay.*
not ABS.1s PAR
'I just don't!'

The use of *bay* in sentence B in (24) also indicates the speaker's refusal to explain a negative response, which may be equivalent to using 'just' in English. Furthermore, unlike the other emphatic particles, this particle commonly occurs after nominals, pronominals, and demonstratives.

Another example of the emphatic use of *bay* is found in an interrogative:

24. *Bukot tana ma-aram. Ikaw bay?*
not ABS.3s smart ABS.2s PAR
'She may not be smart, but are you?

In this example, *bay* is a suggestive particle that underscores the message recipient's similar quality, 'not smart'.

3.2 Temporal particles

These particles are used in telling the exact time or adding temporal information to the event structure of the clause. Examples of temporal particles in Kinaray-a are *run, pa,* and *lang*.

3.2.1 *run*

As discussed previously in this article, run may be used as an emphatic particle. However, this may also be used in telling time or schedule as indicated in sentence (26) and (27), respectively.

25. *9:30 run.*
    9:30 PAR
‘ It’s 9:30.’

26. *Oras run para magturog.*
    time PAR for sleep
    ‘Time to sleep.’

Both sentences may be phrased without *run*. The function of run in these kinds of sentences is to describe the situation that exists in the present and may foreground an immediate action. Consequently, in sentences (27) and (28), *run* serves a crucial function in the syntactic construction of the clause in relation to its temporal connotation.

27. *Sanda run?*
    ABS.3p PAR
    ‘Are they finally in a relationship?’

28. *Ano run?*
    What PAR
    ‘What now?’

In (27), the addition of run to the pronominal, sanda ‘they’ forms a complete thought which is translated as ‘*they (are) finally?’ in English. The particle in this example essentially indicates a result or outcome of a course of action (in this case, courtship) and signifies an impermanent state (being in a romantic relationship).

The same particle introduces a different temporal connotation. This is evident in sentence (29). Here, *run* highlights the urgency of the question *ano* ‘what’.

3.2.2 *pa*

When *pa* is used with a negative existential, *wara*, it denotes an anticipation of something to happen:

29. A. Wara pa tana didya.
    NEG.EXIST PAR ABS.3s here
    ‘He’s not here yet.’

    B. Wara tana didya.
    NEG. EXIST ABS.3s here
    ‘He’s not here.’

The particle *pa* in sentence 29(a) signals the possibility of someone’s arrival. Whereas, as exhibited in 29(b), the statement is more definite. The same can be said in a similar construction as shown in 30. This particle may be similar to the English ‘yet’.

30. *Wara pa ako nakasakay.*
    Not PAR ABS.1s ride
    ‘I have not (found a) ride yet.’

Subsequently, when the particle is used with a positive existential, it may be interpreted as ‘more’ in English.

31. *May pagkaun pa bilin gamay.*
    POS.EXIST food PAR left some
    ‘There’s some more food left.’

The pa may also mean ‘still’, as shown in 32.

32. *Aga pa.*
    Early PAR
    ‘(It’s) still early.’

33. *Duro pa dya.*
    a lot PAR PROX
    ‘This is still a lot.’

When it is used with an interrogative marker, *ano* ‘what,’ it translates to ‘else’.

34. Ano pa?
    What PAR
    What else?

3.2.3 *lang*

This particle indicates the completion of an action done first, an action to be done for a while, or an action possibly done next time, depending on the context of a sentence. The particle *lang* may be used as a temporal connective indicating a polite expression of asking permission to do something (e.g. going, resting, checking) first (35), for a while (36), and next time (37).

35. *Mauna lang ako.*
    IMP-Go first PAR ABS.1s

'I'll go first.'

36. *Pahuway ta anay dali lang.*
IMP-rest ABS.1p.incl PAR while PAR
'Let us rest for a (little) while.'

37. *Turukun ko lang sa sunod.*
IMP-check ABS.1s PAR OBL next time
'I'll check it next time.'

3.3 Confirmation markers

Confirmation markers usually occur in the clause-final position. They are primarily used to obtain agreement or confirmation from the hearer. These markers are also consequently used when stressing an important matter or commenting on something. Examples of these markers are ha, no, and ay.

3.3.1 *no*

The function of the term no in the following sentences is equivalent to tag questions in English.

38. *Kasweldo kaw run no?*
IMP-receive (salary) ABS.2s PAR PAR
'You already received your salary, didn't you?'

39. *May crush kaw kana no?*
POS.EXIST crush ERG.1s ABS.1s PAR
'You have a crush on him/her, don't you?'

40. *Ikaw nag-utot no?!*
ABS.2s PERF-fart PAR
'You farted, didn't you?'

In sample sentences (38), (39), and (40) above, *no* insinuates a subtle accusation based on the preceding context in each sentence. It is usually followed by an agreement or a denial from the hearer.

3.3.2 *ay*

This particle may be used to attract someone's attention, sometimes in an impolite manner as shown in sample sentences (41) and (42).

41. *Akun lamang ra ay!*
GEN.1s only MED/ABS PAR
'This is mine!'

42. *Tawag ay!*
IMP-call PAR
'(Someone) is calling you.'

The *ay* in (41) and (42) is usually said in rising intonation and may sometimes convey irritation. Another function of ay would be to mark an imperative like in sample sentences (43) and (44).

43. *Ibhiman ako ay!*
IMP-take ABS.1s PAR
'Take me with you.'

44. *Tawas ay!*
Come PAR
'Come with me!'

Using *ay* in imperative sentences like (43) and (44), conveys the speaker's intention to convince the hearer. It adds force and influence to the request, thus compelling the hearer to adhere to the statement. This particle may also be used as an exclamation, like giving a remark or commenting on something. It may also be interpreted as an expression of disbelief.

This is also commonly said in rising intonation and may sometimes be accompanied by a sneer or a knowing grin.

3.3.3 *ha*

This confirmation marker is the opposite of ay especially when it occurs in imperatives.

45. *Dali lang ha.*
moment PAR PAR
'Just a moment, ok?'

46. *Indi kaw maugut sa ihambal ko ha?*
Don't ABS.2s get angry OBL IMP-say GEN.1s PAR
'Don't get mad for what I'm about to say, alright?'

The use of *ha* in both sentences (45) and (46) softens the imperatives. This may be considered a politeness marker, but it is not the same as 'please' in English. What it does to the sentence is it elicits an affirmative response from the hearer. It shows that the speaker is mindful of the hearer's views and sensitivities. Moreover, *ha* may also be used to check the hearer's understanding or assert a request as reflected in a sample sentence (47).

47. *Andaman mo ha?*
IMP-take care ABS.2s PAR
'Take care of it, ok?'

3.4 Modal Particles

Modal particles show the subjunctive or optative mood (Spitz, 2001). This consists of terms that express a doubtful condition or wishful thinking. The terms included in this list are *ayhan, kuno, daw,* and *sana*.

3.4.1. *ayhan*

The closest literal translation of *ayhan* in English is 'maybe'. However, the meaning may vary depending on how it is used in different sentences. For instance, *ayhan* may be an expression of pondering the possibility of rain in sentence (48).

48. *Mauran ayhan?*
    Rain PAR
    'I wonder if it will rain.'

Another use of *ayhan* would be to confirm a belief or express an interest or annoyance, as in (49).

49. *Ayhan nag-adto tana didya? Para mang-away?*
    PAR come ABS.3s here? to mock
    'Is this the reason why he/she came here? to mock (me)?'

In this sample utterance, *ayhan* is used to convey annoyance but, at the same time, functions as an interrogative marker in the causative form. Sentences conveying annoyance using *ayhan* may also result in a different pragmatic function:

50. *Ayhan kung ikaw dya masarangan mo?*
    PAR if ABS.2s PROX CONT-handle OBL.2s
    'How about you do this?'

Sentence (51) is a statement of challenge or daring someone to do something. This statement is commonly said when the speaker is exasperated by the hearer's banters (friendly or not). This may also be used in denoting curiosity or interest in an impression, as shown in sentences (51) and (52).

51. *Ambung ayhan tana?*
    Beautiful PAR ABS.3s
    'Is she really beautiful?'

52. *Bahol run ayhan tana?*
    Grown up already PAR ABS.3s
    'Do you think he's already a grown up?'

In (51) and (52), *ayhan* indicates the speaker's uncertainty on something that interests him or her.

3.4.2. *kuno*

This particle is a quotative marker. It implies that a statement is truthful based on a rumor or a second-hand information.

53. A: Nagdaug tana?
    PERF- win ABS.3s
    'Did he/she win?'

    B: Kuno!
    PAR
    'So, they say.'

54. *Nagdaug kuno tana sa Miss Universe.*
    PERF – win PAR ABS.3s OBL Miss Universe
    'They said she won in Miss Universe.'

The use of *kuno* in these statements indicates that the news or details here may be unverified or that it has been communicated from person to person.

3.4.3 *daw*

The particle *daw* is a variation of *ayhan.* This may also be translated as 'seems'.

55. *Daw mauran.*
    PAR IMP-rain
    'It seems like it will rain.'

56. *Daw masuka ako.*
    PAR vomit ABS.1s
    'I feel like vomiting.'

Using *daw* in these declarative sentences indicates the speaker's expectations of something likely to happen.

3.5 Limiting Particles

The particles under this category express limitation in both quality and quantity. The particles *lang, harus, medyo*, and *mga* restrict an inanimate thing, an action, or a concept in various occurrences.

3.5.1 *lang*

This particle may not only function as a temporal particle but also as a limiting particle. It is

prenominal, and its English counterparts are 'only' and 'just'.

57. May isara lang o darwa ka kwarto ang mga bahay.
POS.EXIS one PAR or two ABS room ERG PLU house
' Houses only have one or two rooms.'

58. *Talagsa lang ang mga kutson o matres sa barrio.*
Few PAR ABS PLU bed or mattress OBL downtown
'There are only few beds and mattresses downtown.'

59. *Simple lang ang party.*
Simple PAR ABS party
'The party is just simple.'

In (57) and (58), the use of *lang* limits the quantity of inanimate things like *kwarto* 'room', *kutson* 'bed', and *matres* 'mattress'. In contrast, in (59), the particle *lang* further moderates the modifier in the utterance.

3.5.2 *harus*

This particle usually precedes the nominals it modifies. It is equivalent to 'almost' or 'barely' in English and halos in Tagalog.

60. *Harus sangka kilo ang bugas.*
PAR one kilo ABS rice
'The rice is almost one kilo.'

61. *Harus malipong ako sa sakit.*
PAR IMP-faint ABS.1s OBL pain.
'I almost fainted from the pain.'

3.5.3 medyo

This limiting particle means 'a little', 'rather', or 'slightly' to modify the degree of the adjectives in the sentence. Sentences (62) and (63) illustrate its use.

62. *Medyo init kung gab-i.*
PAR hot at night
'It's a little hot at night.'

63. Medyo gamay ang sweldo kang bulig didya.
PAR low ABS salary OBL maid here
'A maid's salary here is rather low.'

3.5.4 *mga*

This term is more commonly used as nominal marker that indicates plurality. As a limiting particle, it indicates an approximation of a certain quantity. This particle translates to 'around' or 'about' in English.

64. Mga darwa kami ka simana nagbakasyon.
PAR two ABS.1p.incl ABS week ERF-go on vacation
'We went on a vacation for around two weeks.'

Like *harus* and *medyo, mga* usually precedes the adjectives and nominals it modifies. It is usually followed by a numerical expression of time, quantity, or ordinals.

4. Conclusion

In this paper, Kinaray-a discourse particles are discussed based on their linguistic functions in different uses, considering the pervasiveness of discourse particles in naturally occurring daily conversations. Described here are the five classifications of Kinaray-a discourse particles. These are emphatic, temporal, confirmation markers, and modal articles. One can only rely on their linguistic intuitions to dissect the purposes of these particles in different sentences and context.

It is worth noting that most of the Kinaray-a terms described and analyzed in this paper are also found in its sister languages, Cebuano, Hiligaynon, Aklanon, and Tagalog. These discourse particles may be prepositive, prenominal, or postnominal, and some come at the very end of the clause. Their meanings are quite varied, and many of the literal translations in English cannot fully grasp the meanings of each term.

One limitation of this paper is the limited corpus-based data. It is therefore recommended to consider a larger corpus to study for a more comprehensive results and to understand the functions of discourse particles in appropriate contexts fully. The descriptions in this paper are primarily dependent on the linguistic experiences of the informants. Thus, other discourse particles may have been excluded in this paper. There may also be other uses of the mentioned discourse particles not illustrated in this paper. Further research and fieldwork on this matter are necessary to give a more detailed account of this grammatical unit of Kinaray-a language.

Abstract

Motivated by the paucity of published corpus-based investigations on adjectives in contemporary Philippine English (PhE) and the possibilities offered by a new corpus, the Corpus of Philippine English (COPE), this study is an attempt to describe PhE adjectives in terms of their morphological and syntactic characteristics. Results reveal that characteristics of PhE adjectives generally align with the descriptions of Quirk et al. (1985), Biber et al. (1999), and Huddleston and Pullum (2002). However, some syntactic functions are not evident in the adjectives in the corpus. Moreover, despite the occurrence of compounding, the corpus's lack of newly derived adjectives indicates a certain linguistic conservatism that has been identified in earlier research. Further synchronic and diachronic studies employing more extensive and varied corpora are recommended to validate the findings of this study. In addition, form-and-meaning-based instruction on adjectives can provide learners with adequate knowledge to utilize the wide range of adjective types in English.

1 Introduction

English adjectives play a crucial role in enhancing communication by conveying nuances of meaning, providing additional information, and contributing to the overall expressiveness of communication. Adjectives can "alter, clarify, or adjust the meanings of nouns" (Huddleston & Pullum, 2002, p. 526). Thus, understanding the characteristics of adjectives in different varieties of English is essential for linguists and language enthusiasts alike. In this regard, corpus-based investigations are valuable tools in unraveling the intricate properties of adjectives, deriving insights into their use across communities and their pedagogical implications.

English adjectives demonstrate several defining morphological and syntactic properties (Quirk et al., 1985). Morphologically, adjectives in English can be formed through various derivational processes. They can be marked for comparison to convey varying magnitudes of quality, enabling nuanced expression. Syntactically, the ability of adjectives to function both attributively and predicatively allows for flexibility in expression (Quirk et al., 1985; Huddleston & Pullum, 2002).

The global spread of English has resulted in diverse regional varieties, each legitimate in its own right and each contributing its unique flavor to the language and, ultimately, to its dynamic development. Consequently, variations in adjective use can be linked to historical developments in the evolution of language (Suarez-Gomez & Tomas-Vidal, 2024). Differences in adjectival choice or the formation of adjectives can be influenced by or reflect the local context.

Adjectives offer a rich area of exploration for Philippine English; a corpus-based investigation is valuable to shed light on the characteristics of adjectives in Philippine English. As a data-driven and systematic approach to studying language usage, corpus linguistics offers a quantitative lens through which researchers can identify usage patterns that can aid in examining how adjectives function morphologically and syntactically, specifically as Filipino speakers use them. This can inform English teaching practices and curriculum development and contribute to the broader corpus linguistics and World Englishes fields.

1.1 Morphological characteristics of English adjectives

Gradable adjectives can be marked morphologically to express comparative and superlative degrees, inflectionally with the affixes *-er* and *-est,* or phrasally with the form "more/ most" + adjective (Biber et al., 1999). On the other hand, non-gradable adjectives cannot be marked for degrees of comparison and are modified with emphatic or intensifying adverbs.

Generally, monosyllabic adjectives and adjectives ending in *-y*/*-ly* take inflectional suffixes, while phrasal comparison is typically applied to longer adjectives. Some monosyllabic adjectives can take either form, with emphasis as one possible reason for choosing an alternative over the other. Moreover, disyllable gradable adjectives with no internal morphology, those longer than two syllables, adjectives ending in *-ful, less, -al, -ive,* and *-ous,* and participial adjectives take phrasal comparison. Corpus findings indicate a greater frequency of inflected comparative degree adjectives than superlative degree adjectives and a relatively rare frequency of superlatives in academic writing. Also, there are cases when adjectives are doubly marked for comparison through the combined use of inflectional and phrasal markers (Biber et al., 1999; Huddleston & Pullum, 2002; Quirk et al., 1985).

1.2 Formation of adjectives

Most adjectives are derived from either nouns or verbs – a process called adjectivalization (Sleeman, 2019), which can be realized through derivational affixation and compounding. However, within the realm of derivational morphology, adjectivalization has received significantly less attention than nominalization and verbalization (Lieber, 2016; Trips, 2003).

In addition to derived forms, participial forms (V-ing, V-ed) can function as adjectives. Modification with *very* indicates that a participial form is already lexicalized as an adjective (Quirk et al., 1985).

1.3 Syntactic characteristics of English adjectives

Adjectives are classified into two types based on their syntactic functions. Attributive adjectives premodify the head of a noun phrase, while predicative adjectives function as a subject complement or object complement. Adjectives can also be postpositive or placed immediately after the noun or pronoun that they modify. Additionally, they can function as heads of noun phrases (Biber et al., 1999; Quirk et al., 1985).

Corpus analyses of English adjectives point to differences in the frequency of attributive and predicative adjectives across registers. Both attributive and predicative adjectives occur relatively rarely in conversations. A difference can be seen in written genres: attributive adjectives are more frequent in expository writing, while predicative adjectives are more frequent in fiction compared to other registers (Biber et al., 1999).

1.4 Studies on adjectives in Philippine English and World Englishes (WE)

According to Cao and Fang (2009), adjectives are "an informative but understudied linguistic entity" (p. 207). Studies on adjectives in Philippine English are scarce. In fact, Borlongan and Lim's (2012) meta-synthesis of studies in Philippine English grammar included only one (Borlongan, 2011), which studied adjectives, specifically comparison. Comparing adjectives in the Philippine component of the International Corpus of English (ICE-PHI) with those of the other components, Borlongan (2011) found that ICE-PHI has the most number of occurrences of monosyllabic adjectives in comparison, a trend which he attributed to the wide range of text categories in the ICE-PHI compared to other Englishes in the corpus. Borlongan concluded that PhE follows the general trend toward inflectional over periphrastic comparison across Englishes, a finding echoed in Hagman's (2020) investigation of eight inner and outer circle varieties using the Global Web-Based English (GloWbE Corpus). Likewise, Borlongan found six occurrences of double comparatives in ICE-PHI, reflecting patterns also found in New Zealand English by Hundt et al. (2004). More recently, Bernardo (2017) found two distinctive features of adjectives used in classroom discussions by students of different majors and teachers of varying ranks and educational classification. These features are double comparatives and the use of comparative forms with non-gradable adjectives (e.g., 'perfect').

Meanwhile, corpus-based analyses of Bangladeshi English (Suárez-Gómez & Seoane, 2023) and South African, Nigerian, Ghanaian, Kenyan, and Tanzanian English (Suárez-Gómez &

Tomas-Vidal, 2024) show a preference for analytic constructions. This preference was attributed to their transparency, which makes them easier to learn and use than inflectional comparisons.

1.5 Research Objectives

This research aims to describe the characteristics of adjectives in Philippine English. In particular, it aims to describe adjectives' morphological and syntactic characteristics as represented in a contemporary corpus of spoken and written PhE texts.

2 Methodology

2.1 The Data

The data used in the study is from the Corpus of Philippine English (COPE). COPE was collected and transcribed in 2023 by Doctor of Philosophy in Applied Linguistics students enrolled in Corpus Linguistics and World Englishes classes in a private university in the Philippines. Given time constraints, only two categories from COPE, conversations representing the spoken category and press news reports representing the written category, are included in the study for a more focused analysis. The in-person conversations are 30 files of transcripts with more or less 450 minutes of conversations. Each file usually has about 15 minutes of conversation between two or more Filipino mesolectal speakers conversing in PhE. The researchers provided informed consent forms to participants who conversed for the said category, highlighting that the conversations would be recorded, transcribed, and included in COPE for research purposes, with the assurance that the data would be anonymized. This in-person category was utilized because it is the most informal or casual. In casual conversations, the speakers may not be conscious of their grammar; hence, they may show more PhE features than in formal spoken categories. On the other hand, the press news reports are 50 files of transcripts with a total of more or less 25,000 words, each containing approximately 500 words. The transcripts were taken from publicly available press news reports. The study chose this category because it is written and formal, which are the opposite characteristics of the in-person category. Contrasting features of the categories chosen may help ascertain the possible variations between their features and highlight Philippine English's own identity.

2.2 Data Processing and Analysis

Transcripts were Parts of Speech (POS)-tagged using the Stanford POS Tagger, a software that analyzes texts and identifies the part of speech of each word in the transcripts and the other tokens. It has three proficient tagger models for English, although it can be retrained in any language with a few tweaks in its settings. The English taggers utilize the Penn Treebank tag set (The Stanford Natural Language Processing Group, 2023; Toutanova et al., 2003). The POS-tagged transcripts from the software were downloaded and run in AntConc software. The researchers typed in JJ, the abbreviation for the tagged adjectives in the corpus, and clicked start. All hits of JJ in words search query, with ten tokens as context sized, were saved in Excel. The researchers highlighted the adjectives tagged as JJ in the Excel file and rechecked each to see if they were correctly tagged as adjectives. After that, the researchers analyzed each hit to answer the research questions, with the guidance of Quirk et al. (1985), Biber et al. (1999), and Huddleston and Pullum's (2002) discussion of adjectives' morphological and syntactic features.

Antconc software found 4,178 adjectives in the in-person conversations and press news reports transcripts. Of 2,621 words tagged as adjectives by the POS tagger in the in-person conversation transcripts, 141 were incorrectly tagged. They should have been identified as adverbs, adverbial phrases, coordinating conjunctions, determiners, exclamations, fillers, interjections, names, nouns, prepositions, pronouns, and verbs. In addition, 1,557 words were tagged as adjectives by the POS tagger in the press news report transcripts. Sixteen should have been tagged as adverbial phrases, nouns, prepositions, and verbs. With this, only 2,480 adjectives were identified in the in-person conversations, and 1,541 press news reports were transcripts.

3 Results and Discussion

3.1 Morphological Features of Comparative/Superlative, Participial, Derived, and Compound Adjectives in Philippine English

The formation of comparative and superlative degrees of adjectives in the corpus aligns with the

pattern described by Biber et al. (1999). Monosyllabic adjectives and adjectives ending in *-y* and *-ly* generally take the inflectional comparison, as seen in the cases of *happy, simple, and early*, forming comparatives with *-er* and *angry* and *deadly* forming superlatives with *-est*. Meanehile, among the adjectives given phrasal comparison are gradable adjectives with no internal morphology (e.g., *common, recent, candid, stupid*); adjectives longer than two syllables (*exotic*); adjectives ending in *-ful, -less, -al/-ar, -able, -ive, -ous, -ant,* and compound adjectives or hyphenated words.

Biber et al. (1999, p. 521) provide a phonological explanation for the choice between inflectional and periphrastic comparison: disyllabic adjectives ending in the unstressed vowel *-y* usually take the inflected comparative form, but adjectives ending in *-ly* have a more variable behavior. Similar to Biber et al.'s (1999) corpus findings, the word *likely* was compared using periphrastic forms: one instance for *more likely* and one for *most likely*.

Comparative Forms	No. of words	No. of occurrences	No. of words	No. of occurrences
	-er		more / less + adj.	
Monosyllabic base	33	194	3* *fond, keen, safe (in series)*	3
Polysyllabic base	3 *happy; simple; early*	3	36	35
	-est		most / least + adj.	
Monosyllabic base	23	129	0	0
Polysyllabic base	2 *angry, deadly*	2	23	23

Table 1: Morphological characteristics of comparative and superlative adjectives

Meanwhile, among polysyllabic adjectives in the PhE corpus, there is a greater preference for periphrastic comparison. Among the monosyllabic adjectives, only three were compared periphrastically: *fond, keen,* and *safe. Safe,* in this case, was used as the first in a series with polysyllabic adjectives: *more safe, convenient,* and *exciting* (COPE W1B-013); which may explain why it was given periphrastic comparison.

Generally, findings regarding comparison corroborate Borlongan's (2011) observation that PhE aligns with the broader global pattern of preference for inflectional comparison over periphrastic forms. In contrast, a preference for phrasal forms has been observed in Bangladeshi English (Seoane and Suárez-Gómez. 2023) and African varieties (Suarez-Gomez & Tomas-Vidal, 2024), which is attributed to the transparency of the phrasal form, making it easier to learn and use among non-native speakers. As the current corpus contains only a few adjectives showing comparative alternation, a more extensive corpus or a longitudinal study can further shed light on whether PhE does, or continues to, favor inflectional comparison. Further investigations can also consider the possible influence of local languages, which exhibit both inflectional and phrasal comparisons, on PhE adjectives.

Notably, there is only one instance of comparative forms for non-gradable adjectives in the data (most favorite), reflecting a feature found by Bernardo (2017). According to Biber et al. (1999), degree marking of inherently superlative adjectives is not unusual, particularly in conversations (Biber et al., 1999), suggesting a flexible approach to language use.

Double comparison is attested only once in the data, in the conversation subset: *I think you're much more smarter than me*(COPE S1A-017), combining inflectional and periphrastic comparison and intensification with much. Despite their occurrence in WE varieties, English speakers and grammars generally deem doubly marked comparatives and superlatives unacceptable (Biber et al., 1999; Hagman, 2020). Similarly, earlier PhE studies (Bernardo, 2017; Borlongan, 2011); found rare instances of double comparatives, suggesting that this has not become a prevalent feature of the variety.

Comparative and superlative forms are more common in the conversation transcripts than in the news articles, as journalism tends to emphasize objectivity and factual reporting. Similar to frequencies observed by Biber et al. (1999), the words *better*, *best,* and *bigger* occurred most frequently in the conversation transcripts, while *better, bigger, lower, more, stronger,* and *higher* occurred most frequently in the news articles. These words generally have evaluative meanings. However, contrary to Biber et al.'s findings, there are fewer superlative adjectives in the news articles (46) compared to conversations (85) in this corpus. Most of the phrasal comparisons occur in the news articles, reflecting the need for more specific vocabulary in news ítems (Biber, 1999)

3.1.1 Formation of Adjectives

3.1.1.1 Participial Forms

The corpus contains a plethora of participial adjectives formed from the-*ing* and *-ed* forms of verbs. Some of these adjectives can serve both

attributive and predicative functions. There are more *-ed* (58%) than *-ing* forms (42%) in the corpus. Most of the participial adjectives are used predicatively.

The most frequent *-ed* forms are *stressed, excited, interested,* and *surprised.* Notably, *(fully) vaccinated is* also frequent, considering that the time frame of the corpus coincided with the COVID-19 pandemic period. This suggests that adjectives in PhE are used based on immediate contexts, indicating English's responsiveness to sociopolitical events and reflecting the influence of global events on language use and development (Crystal, 2003, 2012; Gustilo et al., 2021).

3.1.1.2 Derived Adjectives

Many of the adjectives in the corpus are derived from other lexical classes. There are more derived adjectives in the news (266) than in the conversation (248) component, with 460 unique derived adjectives identified from the two components combined. Most of these adjectives are attributive.

Similar to the findings of Biber et al. (1999), most of the derived adjectives are derived from *-al (e.g., natural, agricultural),* followed *by -ic (e.g., academic, symptomatic,); -ive (administrative, executive),* and *-ble* (*affordable, predictable*).

So far, analysis of the derived forms does not reveal emerging or new lexical items. There is, however, a novel expression in the conversation data, which involves the use of the suffix *-ish*, in *due in the first weekish of classes* (S1A-020). Here, the suffix may mean in the general vicinity of the first week of classes, with no particular date, which corresponds to the manner of or similar to the meaning of the suffix.

3.1.1.3 Adjectival Compounds

The corpus contains examples of adjectival compounds, some already part of the standard lexicon, such as *lighthearted*, *well-rounded,* and *short-term*. Other forms appear to be emergent. Most of these forms are in the news articles.

These compounds reveal insights into how new words may be formed in (Philippine) English, confirming the productivity of compounding as a word-formation process (Dimaculangan & Gustilo, 2018; Hadziahmtovic Jurida & Pavlovic, 2023). For adjectives, compounding may be more productive than derivation. For instance, Gustilo et al. (2021) found a significant number of new compound adjectives in their investigation of the emerging lexicon from the COVID-19 pandemic.

Notably, the word type was used in forming expressions such as Japanese lantern-type kind of thing, Skinny-girl type, and Just a regular cigarette, not the marijuana type. Biber et al. (1999) explain that in such cases, the suffix -type (or like) retains its meaning as a separate word, placing the resulting words in between affixation and compounding; these words are only ad hoc descriptions and not lexicalized (Biber, 1999). This demonstrates how compounding is utilized as a flexible strategy in PhE to fuse existing lexical elements to create nuanced meanings without requiring new derivations, with expressions created concerning unique communicative needs and contexts.

Expectations of the news genre, which favors vocabulary that is clear and understandable to readers, may explain the scarcity of derivations in the corpus. Biber et al. (1999) noted fewer derived adjectives in the news than in academic writing, while adjectival compounds are more frequent in the news than in conversation due to the need to express information more succinctly than through relative clauses. Moreover, while the conversational context may offer wider latitude for the creative use of adjectives, the data suggest that PhE speakers use existing lexical ítems for ease and clarity of communication.

Furthermore, the relatively rare occurrence of innovations and novel derivations resulting in neologisms may suggest that PhE is negotiating its position between stability and innovation regarding adjective use. As Borlongan (2011) pointed out concerning Schneider's (2003, 2007) model of the evolution of postcolonial Englishes, while PhE is increasingly diverging from exonormative standards and innovating independently, it still shows signs of linguistic conservatism.

This finding, however, can be due to the limited scope of the dataset analyzed. Further analysis of the COPE or additional subcomponents may reveal more insightful patterns of innovation across various contexts.

3.2 Syntactic Features of attributive, predicative, postpositive, exclamatory, and noun phrase head adjectives in Philippine English

Table 2 reveals that adjectives are more frequent in in-person conversations than in press

news reports. This may be because of the speech style used in the different categories. One employs a formal style, while the other employs a casual style of speech. In casual settings, people tend to utilize more attributive adjectives to express their thoughts, feelings, and emotions. They provide vivid mental representations to their interlocutors so that they can understand what they convey quickly (Yaguchi et al., 2010). On the other hand, news reports usually follow a formal, neutral, objective style and tone, so the lines are more straightforward than the in-person conversations (Schröder, 2010). They focus on facts rather than embellishing their reports with extensive adjectives that may be subjective and indicate biases. Audience is also a factor for the said results. Casual conversations often involve only a few participants or a smaller and more personal audience where people may freely express their opinions, feelings, and personal experiences, which may add emotional depth to the conversations (Blankenship & Craig, 2012; Schröder, 2010). However, in news reports, writers aim to reach a broader audience. Their use of adjectives may be more restrained as they must carefully choose them to maintain an unbiased tone. Time constraints may also be a factor. Casual conversations have no limit on their time. They take as much time as possible to understand each other's ideas. In helping the other person understand the idea, the speaker employs several adjectives that can aid the receiver in understanding the message. Conversely, news reports have time or space constraints. They have to provide complete information with such a limitation, which calls for a need to be direct-to-the-point and disregard the use of extensive adjectives.

Syntactic Roles/Functions of Adjectives	Frequency by Category		Total
	In-Person Conversations	Press News Reports	
Attributive	1,184	1,256	2,449
Predicative	1,287	274	1,555
• Subject Predicative	1,277	263	1,534
• Object Predicative	10	11	21
Post-Positive	9	0	9
	2,480	1,541	4,021

Table 2: Frequency of syntactic roles/ functions of adjectives

In in-person conversations, attributive is the second highest function of adjectives identified with 1,184 counts. On the other hand, it is the highest in the press news reports category, with 1,256 counts. This is unusual since in-person conversations should have more attributive adjectives (Schröder, 2010). This result can be attributed to the fact that the press news reports have 50 transcripts while the in-person conversations only have 30. Although each in-person conversation transcript is 15 minutes' worth of conversation, the interlocutors' relationship may also be a factor that resulted in such a strange result. Interlocutors close to each other may tend to provide extensive attributive adjectives in the conversation to express themselves more and convey their message. However, those whose relationships are just acquaintances may be reluctant to use more of it as there is not much emotional bond between them. Aside from this, since they knew that the conversations were being recorded, they might have limited their conversation with each other, not freely and comfortably expressing their thoughts and emotions. Concerning the attributive adjectives' syntactic features, the corpus revealed that the adjectives are positioned before the noun they modify, which conforms to the prescribed word order of "standard" English (Quirk et al., 1985; Biber et al., 1999; Huddleston & Pullum, 2002). It was also noted that there are several phrases in which a couple of adjectives are seen before the noun they modify, as in:

(1) a *strong friendly* performance
(2) the *physical spiritual emotional* abuse — in-person conversations
(3) a *big big big* lawn

(4) a *political economic social* and *cultural* development
(5) *additional* and *steady* supply — news press reports
(6) a *rational* and *historical* appreciation

This may signify that Filipinos provide a couple of attributive adjectives for a noun that they want to modify, which helps the recipient to have a clearer understanding of the message. Although the frequent use of attributive adjectives to modify a noun in a sentence may not be determined by nationality, this may still be influenced by linguistic and cultural norms, which can be checked and explored with a larger Philippine English corpus. Another peculiarity noticed is that a few sentences that employ attributive adjectives

did not follow the ruling on the order of adjectives. The typical order starts with quantity, followed by quality, size, age, shape, and color (Celce-Murcia et al., 1983; Quirk et al., 1985). These sentences usually repeat the attributive adjective they employ to modify the noun. One example is the sentence three in the previous paragraph.

(3) a *big big big* lawn

The word big was also used as an intensifier in the noun phrase. This may be a manifestation of the first language (L1) transfer. Filipinos typically repeat adjectives to intensify their modification of a noun, as in *"malaking malaking malaking…"* instead of using another adjective or adverb, "extremely big…" The English language tends to avoid repeating words as this is considered redundant. Such occurrences show that although Filipinos mostly conform to the rules of "standard" English, there are still instances that show the transfer of L1 to the second language (L2).

As for the predicative adjectives, 1,287 hits were found in the in-person conversation transcripts – the highest syntactic function of adjectives in the said category. Having this as the highest function identified is not odd. Speakers can use attributive or predicative adjectives in casual conversations, depending on their intention and context. Speakers may use a mix of both functions as there are no strict rules. Meanwhile, there were only 274 hits of the same function in the press news reports category, which is the second highest. It can be seen that the frequency of attributive adjectives in the said category is far higher than that of predicative adjectives. This conforms to the findings of Biber et al. (1999), which reveal that predicative adjectives are less frequent than attributive adjectives in such expository papers. Unlike attributive adjectives that directly modify the noun clearly and concisely and provide specific details without the tendency to introduce subjective evaluations, predicative adjectives are susceptible to it. Predicative adjectives, as seen in the corpus, are often placed after linking verbs to describe the subject. Such a function may only introduce subjectivity or opinion. As mentioned earlier, news reports prioritize clarity, brevity, and objectivity, so having predicative adjectives might negatively affect the report's objectivity. In both categories, it is noticeable that a few object predicative adjectives were found, 10 in the in-person conversations and 11 in the press news reports category. This shows that speakers and writers of the corpus transcripts value brevity and straightforwardness. Object predicative adjectives may lead to longer and more complex sentence structures, increasing ambiguity and confusion. This may be why the predicative adjectives in both categories are rare compared to attributive adjectives.

Generally, the predicative adjectives found in both categories often conform to the standard word order of subject + linking verb + predicative adjective (Biber et al., 1999; Huddleston & Pullum, 2002; Quirk et al., 1985). However, some sentences from in-person conversations that employ predicative adjectives end with an invariant question tag, as in:

(7) You're *hard-headed*, right?
(8) You're *fully vaccinated*, right?
(9) It's not a *harsh* punishment, right?

} in-person conversations

It can be surmised that the question tag "right?" may also be a manifestation of the L1 transfer. Filipinos use this as a translation of the Tagalog term "*di ba*?" often employed when speakers seek agreement on their statement from the message recipients. This supports the findings of Westphal (2020), which reveal that Filipinos often use question tags when conversing in English and that they utilize invariant question tags, including "right?" more than the variant ones (e.g., "isn't it?"). It is worth noting that they were only identified in the said category as they may not be appropriate for news reports.

Finally, post-positive adjectives were also found in the corpus. All nine are from in-person conversations. The sentences that employ post-positive adjectives often start with a subject, followed by a post-positive adjective, and then with or without additional information, as in:

(10) I want to relax with *someone close* to me.
(11) I always crave for *something sweet.*
(12) Hopefully, *God-willing.*

} in-person conversations

However, one may notice the deviation of the ninth phrase, which started with an adverb, expressing a sense of hope or expectation regarding the action or event that follows. This may also be an effect of the L1 transfer to the speaker. This may be translated as *"Sana, awa ng Diyos"* in Tagalog or simply an attempt to translate the popular Visayan word, *"Puhon."* This is a response to a statement one agrees to be hopeful about, recognizing the external factor of divine will.

While many attributive and predicative adjectives and a few post-positive adjectives are

found in the corpus, it is worth noting that no exclamatory and noun phrase head functions of adjectives were found in the results.

In summary, all the syntactic functions of adjectives that transpired in the corpus conform to the "standard" English's syntactical features based on Quirk et al. (1985), Biber et al. (1999), and Huddleston and Pullum's (2002) discussion of adjectives' syntactic features. This may show how adept Filipino speakers are in English grammar and that they conform to these rules in sentences despite the difference in sentence patterns, with English exhibiting a subject-verb sentence pattern in contrast to the subject-last pattern of Filipino. Although Filipinos generally show good command of the English language, the transfer of L1 to L2 still manifests. Some of these manifestations of L1 transfer seen in the corpus include using repetition of adjectives as intensifiers instead of employing another adjective or adverb to intensify the word it modifies. Another is using question tags, predominantly the invariant question tag "right?" as the translated version of the invariant question tag in Tagalog, which is *"di ba?"* Lastly, there is an incongruence of the post-positive adjective in sentence 12 to the word order pattern subject + post-positive adjective + with or without additional information for sentences employing a post-positive adjective. This peculiarity may be seen as an attempt to translate the Tagalog phrase following the same word order, *"Sana, awa ng Diyos,"* or the widely used Visayan word, *"Puhon."* Such findings may be investigated in a more diverse and extensive corpus to establish whether these truly manifest the L1 transfer and, hence, may be considered as the unique features of Philippine English and if some more features and patterns can be identified as features of it.

4 Conclusion

This study aimed to contribute to the discourses on the identity of Philippine English that underexplored and underrepresented the grammatical class of adjectives of Philippine English by attempting to provide a corpus-based description of adjectives in Philippine English using the Corpus of Philippine English (COPE). Specifically, this analyzed the morphological and syntactical features of the different types of adjectives observed in COPE. After the rigorous building and POS-tagging of the corpus, the transcripts were processed using Antconc software. Results were carefully rechecked and analyzed based on the frameworks of Quirk et al. (1985), Biber et al. (1999), and Huddleston and Pullum (2002).

In terms of morphology, results reveal that PhE adjectives conform to the descriptions of Quirk et al. (1985), Biber et al. (1999), and Huddleston and Pullum (2002). There is a preference for inflectional comparisons for monosyllabic adjectives and phrasal comparisons for longer and derived adjectives. Only one instance of double comparison was found in the corpus. Moreover, there is no evidence of productive adjective formation through derivation that results in new lexical items, but there is considerable evidence of compounding to form new words.

As for the syntactical features, the results indicate that only the attributive, predicative, and post-positive adjectives transpired in the corpus. They generally conform to Quirk et al. (1985), Biber et al. (1999), and Huddleston and Pullum's (2002) discussion of adjectives' syntactic features, reflecting the Filipino speakers' adeptness in English grammar despite the difference in the sentence patterns (i.e., English - subject first; Filipino - subject last). However, some peculiar incongruence to the prescribed syntactic features was found in the corpus that may be attributed to the L1 transfer, including repetition of adjectives for intensification, affixing an invariant question tag, di ba, in sentences with predicative adjectives, and a non-conformance to the word order pattern for a phrase that employs post-positive adjectives, as in the case of the post-positive adjective, "God-willing," which can be a word-per-word translation of the Filipino commonly used phrase response *"Sana, awa ng Diyos"* or an attempt to translate the Visayan word *"puhon."* These results imply that the morphological and syntactical features of adjectives seen in COPE generally conform to Quirk et al. (1985), Biber et al. (1999), and Huddleston and Pullum's (2002) description of adjectives. The relative lack of emerging features and new lexical formations support earlier findings that observed a certain degree of stability in the lexicón and gramar of PhE when compared to other Asian varieties (Borlongan, 2016; Borlongan & Lim, 2012).

However, some syntactic functions were not evident in the corpus. This may indicate that Filipinos are not used to employing them in written

and spoken discourses, which may be due to differences between English and their native language or to culture or genre-specific linguistic conventions.

The findings of this study have important implications for language teaching and research. First, exposing learners to varied adjectives and their features in meaningful contexts and experiences may help them use adjectives more confidently and help enrich the characteristics of adjectives in PhE. Extensive discussion of these adjective features, focusing on meaning and form and using corpora to show authentic examples of adjective use, can help achieve this goal. For instance, teachers can develop activities such as role-play exercises, debates, and journalistic writing, which can encourage students to use adjectival forms appropriately. Integrating meaningful adjective use in the English language curriculum may help further build Philippine English's inimitable identity in the context of World English.

Researchers interested in conducting a similar study may utilize more extensive and varied data to determine consistency with the present data and provide better insight into the current and emerging morphological and syntactical patterns distinct in Philippine English.

Acknowledgments

We would like to express our gratitude to Dr. Shirley N. Dita for motivating us to conduct this study.

THE LEXICAL CATEGORIES OF THE TINONANON-MONO*β*U

Jerson S. Catoto **Joveth Jay Montaña**

jcatoto13@gmail.com, montanajovethjay@gmail.com

Abstract

Language is an intrinsic facet of the human race, and fostering investigations that equate sophisticated methodologies is of utmost significance. This function as an extensive foundation for the *Tinonanon MonuƄu* community that will eventually be passed down to future generations.The *Tinonanon-MonoƄu* is a unique sub-group of the Manobo found in Arakan Valley Complex. It is derived from the Tinanan River that flows from Mt Sinaka and joined with the Kulaman River. An in-depth interview among ten (10) bearers of the language from the Barangays of Greenfield, Kinawayan, and Sto. Niño was done. This paper infers that the *Tinonanon MonuƄu* language has corresponding expressions for lexical varieties such as noun *(ngaran),* verb *(kudwaw'ng),* adjective *(kudbuyo – Ƅuyo),* preposition *(notowwan),* and conjunction *(ponsuppay).* This study offers an enlightenment on the idiosyncrasies, peculiarities, and functions of the *Tinonanon MonuƄu* language. Indeed, apart from culture, language is also an imperative approach to further promote the diversified cultural legacy.

1 Introduction

The Arakan Valley Complex is the home to the Tinonanon-Monoβu, an ethnolinguistic group distinct from the Obo Manobo and the Matigsalug. However, speakers of the language are intelligible with the Obo Manobo. The Tinonanon-Monoβu language is not yet catalogued by the Ethnologue, which calls for its documentation. Various linguists believe that many of the world's languages may disappear by the end of the 21st century, particularly those spoken by minority groups.

2 Research Question

What are the lexical categories of the Tinonanon-Monoβu?

3 Methodology

3.1 Data Description

The primary data collected consisted of recorded interviews with 10 native speakers of the Tinonanon-Monoβu language. These recordings were transcribed and analyzed to identify lexical categories.

3.2 Geographical Scope

The research was conducted in the Municipality of Arakan, where the Tinonanon-Monoβu language is primarily spoken.

3.3 Participant Profile

The study's participants included 10 native speakers of Tinonanon-Monoβu, aged 25–75, all familiar with the linguistic structures of their language.

3.4 Limitations

This research was limited by the small sample size, the time constraints of fieldwork, and the lack of prior documentation of the Tinonanon-Monoβu language.

3.5 Method of Data Collection

Data collection involved in-depth interviews and recording natural language usage among participants, with a focus on eliciting examples of nouns, verbs, and adjectives.

4 Result and Discussions

In this section, I discussed some features of the lexical categories of the *Tinonanon MonuƄu* language. This will help gain new insights into the

richness of this language in the Municipality of Arakan and the nearby towns. Below are the corresponding translations of lexical categories of the aforenamed language accounted with its lexical examples that are taken from the participants' statements during the in-depth interview.

Ngaran (Noun)

Stemming from the data collection and conforming to the informants' authentic remarks, the substitution of nouns in their language, *Tinonanon MonuƄu* is *ngaran*. The term *ngaran* is analogous to naming, an act of giving or assigning a name to something. This finding is supported by the statements of the informants.

> *"Nobbuttan kod otten od towwan ko tu bullas no ngaran ini so noun gamit ini so linahan doy no kuwa meen ikas ngaran ko so id ko bullas ko."* (I understand it, if I would give a replacement term of noun using our language it would be *ngaran*). **Informant 1**

In the same vein, this claim is also supported by the informants 2,3 and 7.

> "Unggad kaay to Tinonanon no linahan ini so noun no *id lag. Ini en kos ud osengon no ngaran. Ngaran kos translation."* (In *Tinonanon* language, noun is what we call *ngaran*. *Ngaran* is the translation of a noun). **Informant 2**

> *"Bilang sukkad no Tinonanon MonuƄu kos noun to kuddi no pud labbot so ngaran en sikkanden."* (As a *Tinonanon Monubu*, I comprehend noun as *ngaran*). (**Informant 3**)

> *"Iling to mongo tad do gina od ko lag ta no ngaran en sikkanden".* (The same with your examples earlier I could say that noun is *ngaran*) **Informant 7**

This asserts that noun is *ngaran* in *Tinonanon MonuƄu* since the majority of their responses are all the same. *Ngaran* could also be specified as *lallow* or *sangod* comparable to the nickname. Native speakers of the mentioned language tend to use *lallow* or *sangod*, particularly the elders since they believe naming a person is inappropriate and could divulge *mwokan* or disrespect or bad luck.

Therefore, as a sign of appreciating the value of their peers, they tend to employ *lallow* or *sangod* like brother-in-law *(ayaw)*, sister-in-law *(ipag)*, father, grandfather *(ama)*, mother, grandmother *(ina)*, male, female elders *(apo)*, friends *(suwod)*, sibling, friends *(tobboy)*, *etcetera*.

Tinonanon MonuƄu makes use *ngaran* or naming based on its classification, the name of a person, place, animal, etc. Naming is the first human action found in the Old Testament. This is through providing, giving, or assigning names. The giving of names may have to appear ordinary but the most eccentric action (Van Mannen et al., 2007). Below are several examples of *ngaran*.

1.

I want to buy a dress.

"Kotosan a od bulli to ugget."

[want I ***(present)***buy of dress.]

2.

The old lady used a winnowing basket to separate the rice from the rice chaff.

"Id uttapan to boyag no molitan kos buggas gamit dos nihû amoy od kowora dos uttap. "

[***(past)*** separate of **old lady** the **rice *(past)*** use the **winnowing basket *(present)*** remove the rice chaff].

3.

The chair is small.

"Disok dos unsaran."

[small the chair.]

Above are the following instances of *ngaran* in *Tinonanon MonuƄu*. The mentioned language embraces its abundance particularly in the feature of lexical categories. *Tinonanon MonuƄu* language does not follow the standard structure of English grammar on the contrary, they harness V-S-O word constituent order, particularly in speaking. However, the S-V-O can be applied, but the bearer of the language made sure they utilized the V-S-O since this crafted the

peculiarity of their language. *Tinonanon MonuƄu* language's unique features have a salient function in harnessing words through English sentences.

In addition, *Tinonanon MonuƄu* has two types of nouns: singular noun *(sukkad no ngaran)* and plural noun *(moura no ngaran)*. In due course, *Tinonanon MonuƄu* used *mongo* instead of adding *-s, -ies,* etcetera in signifying the pluralization. The employment of *mongo* in the word or sentence/s suggests that a specific noun is in plural form.

1.

Sukkad no Ngaran

I saw a cat in the cabinet.

"Nokita ko dos mingko diyon to kaƄan."

[***(past)***see I the cat in cabinet.]

2.

Moura no Ngaran

I saw cats in the cabinet.

"Nokita ko dos mongo mingko diyon to kaƄan."

[***(past)***see I the are cat in cabinet.]

If we look thoroughly at the given examples, no variations occur within the noun, *mingko* or cat. Adding *mongo* is imperative, making it evident that the specified word is plural.

Kudwaw'ng (Verb)

Adding to the lexical categories of *Tinonanon MonuƄu* is *kudwaw'ng*. *Tinonanon MonuƄu* informants inferred the verb as *kudwaw'ng*. *Kudwaw'ng* is the accurate indication of verbs in their native tongue since verbs appertain to movement or concepts. Below are the participants' justifying assertion of *kudwaw'ng* relative to the verb.

> *"Action word ma unno? Kuwa ini sikkanden to linahan doy ikas kudwaw'ng."* (It is an action word, right? So, in our language this is *kudwaw'ng*). **Informant 1**
>
> *"Unggad inis verb kaay to Tinonanon MonuƄu ini sikkanden kos kudwaw'ng, mongo lag nu duwon kudwaw'ng."* (When we talk about verb, in our language this is *kudwaw'ng*. These are words that shows action). **Informant 2**
>
> *"Kuwa ini sikkanden ikas od waw'ng o ko kudwaw'ng bos to konami no inosengan."* (This is *waw'ng* I mean *kudwaw'ng* in our language). **Informant 3**

The verbalization of *kudwaw'ng* is supported by most of the informants. Their statements provide the justifications:

> *"Kon od lubbasan ko ini so verb to konami no linahan yon ko Ƅo ud ko buggoy so kudwaw'ng."* (*Kudwaw'ng* is another term that I could replace). **Informant 8**
>
> *"Od ko lag ko no kudwaw'ng ini sikkanden pomon to mongo tad woy depinisyon no id lag do."* (Based on the definition and examples that you had given I could say that it is *kudwaw'ng*). **Informant 10**

The term *kudwaw'ng* in *Tinonanon MonuƄu* denotes action or concept. It transpires from the root word *waw'ng*, to act or to move. Many participants acknowledged *kudwaw'ng* as the precise terminology of the verb rather than *waw 'ng*. Both are similar which alludes to action, but they possess distinct differences. *Kudwaw'ng* is an expression referring to action words or concepts; stand *(lohinat)*, eat *(kaan)*, cook *(iluto)*, love *(ginawa)*, dream *(tohinoppon)*, think *(pundom)*. Otherwise, *waw'ng* means to move, for instance, *waw'ng ka* or make a move. Hence, the researcher deduced *kudwaw'ng* as the most veracious term of the verb.

1.

"Id kaan dos minuƄu to kannon."

The man ate food.

[***(past)***eat the man of rice.]

2.

I will dance.

"Od sogengke a simag."

[***(future tense)***dance I tomorrow.)

3.

The horse runs fast.

"Mosiyapat od lungkusso dos kuda ko."

[fast ***(present)***run the horse I.]

The tenses of verbs also exist in the *Tinonanon MonuƄu* language like *od*, which signifies either present or future depending on its usage in the sentence. Subsequently, *od* is applicable in future tense through additional markers of adverbs of time such as *later, tomorrow, etcetera*. On the other hand, *id* represents that the action has already been completed. The utilization of tenses of verbs serves as an identifier of whether the action occurs in the present, past, or future.

1.

I wash the dishes.

"Od unaƄan ko dos mongo unaƄon."

[***(present)***wash I the are dish.]

2.

I washed the dishes.

"Id unaƄan ko dos mongo unaƄon."

[***(past)***wash I the are dish.]

I will wash the dishes.

"Od unaƄan ko dos mongo pinggan kangkan."

[***(future tense)***wash I the are dish <u>later</u>.]

The underlined word serves as a time marker that indicates the employment of *od* in the verb signifies future tense.

Kudbuyo– Ƅuyo (Adjective)

The bearer of the language veraciously linked the adjective to *kudbuyo-Ƅuyo*. *Kudbuyo-Ƅuyo* is an earmark in modifying and giving attributes or characteristics using the expression of an adjective. Exhibited below are the participants' authentic statements affirming the claim of *kudbuyo-Ƅuyo*.

> *"Kon od lag ki no adjective no to langun-langun peen ini sikkanden kos kudbuyo-Ƅuyo."*
> (When we say adjective, it is *kudbuyo-Ƅuyo*).
> **Informant 1**

The claim of Informant 1 has been supported by Informants 2 and 4

> *"Unggad ikas adjective, kaay to Tinonanon MonuƄu. Id ngaranan ikas sikkanden no kudbuyo-Ƅuyo."*
> (Speaking of

adjectives in *Tinonanon MonuЂu*, we refer to it as *kudbuyo-Ђuyo* in our language). **Informant 2**

"Kudbuyo-Ђuyo to sukkad no mgo linahan iling to mgo lag do gina no ngaran owoy to sukkad po nu ngaran." (*Kudbuyo-Ђuyo* is the same as an adjective which gives characteristics or attributes to a noun or pronoun). **Informant 4**

The *Tinonanon MonuЂu* speakers possess their expressions in conveying description that connotes adjectives such as *loddoy, uwa-uwa,* and *kudbuyo-Ђuyo*. They obtain a distinct lexicon in furnishing general and specific wording of giving descriptions. The terms *loddoy* and *uwa-uwa* are utilized for particular details when relating to the features of the face. On the contrary, equating to overall characteristics is designated as *kudbuyo-Ђuyo* relative to the adjective. We employ *kudbuyo-Ђuyo* in describing nouns and pronouns.

Tinonanon MonuЂu possessed their expressions in conveying descriptions of adjectives the same as *loddoy, uwa-uwa,* and *kudbuyo-Ђuyo*. They obtain a distinct lexicon in furnishing general and specific wording of giving descriptions. The terms *loddoy* and *uwa-uwa* are utilized for particular details when relating to the features of the face. On the contrary, equating to overall characteristics is designated as *kudbuyo-Ђuyo* relative to adjectives. *Kudbuyo-Ђuyo* used in describing nouns and pronouns.

Tinonanon MonuЂu consists of classifications of adjectives, the before the noun *(kounnan no ngaran)* and after the certain verb *(potinundog tud waw'ng)*. The *kounnan no ngaran* indicates when the adjective in the given sentence is placed before the noun. For instance, *"Kotoosan ko dos mokawag no ugget."* [want I of the yellow of dress.] The term *mokawag* or yellow is regarded as an adjective and placed before the noun *ugget* or dress.

On the other hand, *potinundog tud waw'ng* can be identified when the adjective is next to the verb. Example, *"Id lungkusso no mosiyapat dos kuda."* [***(past)***run of fast is/the horse.]. Noticeably, our adjective *mosiyapat* or fast appears after the verb, *lungkusso* or run. The researcher enlisted several examples of *kudbuyo-Ђuyo*.

1.

The girl is beautiful.

"Molihonnoy dos molitan."

[beautiful the girl.]

2.

Our house is small.

"Disok dos konami no ubpan."

[small the our of house.]

3.

The man walks fast.

"Mosimbukot od ipanow dos minuЂu."

[fast ***(present)***walk the man.]

Based on the given example, most of the descriptive words appear at the beginning of the sentence.

Notowwan **(Preposition)**

Tinonanon MonuЂu participants remark *notowwan* as comparative to preposition. *Notowwan* introduces or gives information to which something can be found or situated. It consists of word marking to determine the placement of certain things.

"Ini so preposition to Tinonanon MonuЂu ini

sikkanden kos notowwan." (This preposition in *Tinonanon MonuƄu,* it called *notowwan*).

Informant 2

"Ini sikkanden dos ud omawon no notowwan so ud tuddowon den kon ingkon notaow dos sukkad no linahan." (This is called *notowwan* because it tells where the location of a certain statement is).

Informant 6

In rendering with the above notions, the researcher stipulated several instances below. It intends to offer a steer-clear example of *notowwan*.

1.

The cat is in the cabinet.

"diyon to kaƄan dos mingko."

[in cabinet the cat.]

2.

The glass is on the table.

"duton to untoran dos pokawan."

[on table the glass.]

3.

I stand at the door.

"Id lohinat a diyon to subbangan."

[***(past)***stand I at door.]

It is perceived that, *in* and *at* have similar expressions in *Tinonanon MonuƄu*, their variation occurs depending on their function in the sentence. The utilization of -*in* alludes to giving out insights near to the subject. On the contrary, -*at* is employed when providing details situated far from the sight of the subject.

***Ponsuppay* (Conjunction)**

Ponsuppay is an abbreviation in *Tinonanon MonuƄu,* known as a conjunction in English. It is labeled as adding new words or another word to make the thought complete and essentially not gauche. There are various terms analogous to *ponsuppay* such as *pud suppayon, pud ubpowon, pud duromannon,* and *pud suppaton*. Based on the information gathered, most of those who took in the study asserted *ponsuppay* relative to conjunction. Hence, to make it understandable the researcher exhibited the participants' comments to help strengthen the claim of conjunction as *ponsuppay*.

"Ini bos conjunction kuwa inis sikkanden ikas ponsuppay to linahan woy sukkad po no linahan." (This is called *ponsuppay* in our language. It helps connect one word and another word).

Informant 1

"Ini bos conjunction ini bo kos ponsuppay." (This conjunction is called *ponsuppay*).

Informant 5

"Kaay ki to conjunction to konami ud ko omow roy ini sikkanden to ponsuppay. Toman to lag do gina iddos, "and" *no "owoy" mo ika to konami."* (In conjunction, we call this *ponsuppay*, just like what you have

said, the term *and* which we call, *owoy)*.(**Informant 7**

Presenting below are some examples of conjunction as *ponsuppay*:

1.

I want to take a bath, but I'm tired.

"Kotosan a od pomolihos peru naƄulloy a."

[want I ***(present)***take a bath, but tired I.]

2.

I know how to write because the teacher taught me.

"Notoweg ad od batok oyya so id nonowwan a to mo-istra."

[know I ***(present)***write because ***(past)***teach I of teacher.]

When discussing conjunction, the mentioned tribe has also its corresponding key term. This just proves that the language aside from other languages encompasses greatness in terms of language. *Tinonanon MonuƄu* has a corresponding substitution of conjunction as *ponsuppay* to their language; but *(peru),* because *(oyya so),* so that *(pomon so),* between *(noko ollot, nokotungnga,* above *(daƄow),* under, below *(dawom),* beside *(tokeleran),* behind *(noko oyyog)* and many more.

This truly authenticates that the *Tinonanon MonuƄu* language is not just rich in culture but also in language. Although its language has not been studied thus, it is a remarkable experience to be the first to investigate and unveil its lexical categories.

Implications to the *Tinonanon MonuƄu* Community

The lexical varieties presented in this study served as a guideline to the bearer of the language especially, young learners. Through this research, native speakers are much more aware that they also encompass the idiosyncrasy of language. This function as a guide to the indigenous community to truly appreciate and enrich their language hence, preservation of the language is essential.

A significant concern for investigating the mentioned language is to ensure that the *Tinonanon MonuƄu* language is discovered and to help the preservation, cultural heritage, and its distinctive identity. In the course of this research, I discovered that the *Tinonanon MonuƄu* language encapsulates uniqueness not just in culture but also in language. These peculiarities of language can be passed down to younger generations. This study can contribute to the body of knowledge, particularly to the *Tinonanon MonuƄu* community. Above all, this research calls for language experts to work for the documentation of this language unique among the Manobos of Arakan, Cotabato, Philippines.

Acknowledgment

I would like to express my deepest gratitude to the College of Education of Cotabato Foundation College of Science and Technology (CFCST) for their unwavering support and resources, which were instrumental in the completion of this research.

Special thanks to the tribal leaders of the Tinonanon-Monoβu community, whose guidance and cooperation were crucial in facilitating the data collection process. Your assistance in connecting with the community and providing insights into the cultural context of the language has been invaluable.

I am immensely grateful to the informants who participated in this study. Your willingness to share your knowledge and experiences has significantly contributed to the understanding and documentation of the Tinonanon-Monoβu language.

A Multidimensional Analysis of U.S. Diplomatic Discourse on the Israel-Palestine Conflict: Textual and Emotional Dimensions Using Plutchik's Wheel

Xiao Shanshan,

Shanghai International Studies University, China

Abstract
This paper aims to explore the dimensions of textual and sentiment variations in U.S. diplomatic discourse within the context of the Israel-Palestine conflict. Following Biber's (1988) research framework, our Principal Factor Analysis (PFA) uncovered five textual dimensions across the 11 sub-registers of U.S. diplomatic texts. Emotion analysis based on Plutchik's wheel shows that the positive emotion 'trust' predominates across all subgenres, followed by the negative emotions 'fear' and 'anger.' The correlation matrix of emotions and dimensions reveals that 'trust' is positively associated with Dimension 4, while both 'fear' and 'anger' correlate with Dimension 3.

Keywords: Multidimensional Analysis; Plutchik wheel; US diplomatic discourse; Israel-Palestine conflict

1. Introduction

As globalization accelerates, soft power has become a crucial element in shaping a nation's influence on the world stage. Soft power, complementing economic and military strength, forms the foundation of a nation's diplomatic effectiveness, primarily constructed through diplomatic discourse. Diplomatic discourse is often regarded as the 'communication of communication,' transcending cultural boundaries by conveying globally acceptable ideas, regardless of language barriers. The strategic use of diplomatic discourse has, in turn, become pivotal in strengthening a nation's soft power. However, the language of diplomacy has increasingly shifted toward promoting conflict and confrontation rather than civility and shared ideals in the context of global conflicts (Jaber, 1997; Afzaal et al., 2022).

Over the past century, regional security issues, such as the expansion of Israeli settlements in Palestine, have escalated into global crises, threatening the peace process worldwide. Throughout the history of the Israel-Palestinian conflict, the diplomatic decisions of U.S. political leaders have always been directly correlated with the progress of peace-making efforts between the two states. Therefore, the U.S. stance on this issue remains at the forefront of discussion. Although U.S. support for Israel, largely

influenced by domestic evangelical Christians, has rarely been challenged by political analysts or experts, the stance taken by each U.S. president and the approaches employed in mediating the conflict have fluctuated.

According to Mohamad (2019), the U.S. approach to Israel and Palestine is marked by the well-worn double-standard policy that contradicts international law. He examined presidential involvement in Israeli-Palestinian relations, with particular attention to Presidents George W. Bush, Barack Obama, and Donald Trump. During the Bush and Obama administrations, the endorsement of a two-state solution in response to Israeli settlement expansion reflected U.S. efforts to gain support from Arab states while maintaining the 'strategic alliance' with Israel. However, such mediation efforts under the two-state solution were undermined during Trump's presidency. By recognizing Jerusalem as the capital of Israel and relocating the U.S. embassy from Tel Aviv to Jerusalem, Trump further hindered the peace process and effectively ended prospects for a two-state solution.

Among all U.S. presidents, Trump's alignment with Israel exhibited the clearest bias, where Palestinians' opportunities to seek peace and receive humanitarian aid were almost entirely disregarded. Furthermore, Trump's nationalist doctrine permeated global discourse, catalyzing radical nationalist movements among Jewish Zionists. The political annexation with Arab states and the proposal to construct an 'Arab NATO' also underscore the U.S.'s decisive role in Middle Eastern political affairs. As President Sadat of Egypt famously stated, the U.S. holds '99% of the cards' in the Middle East (Siniver, 2022; Afzaal et al., 2022; Zhang et al., 2023). Therefore, it is essential to critically examine U.S. diplomacy in the Israel-Palestine conflict.

Against this background, this study provides a comprehensive analysis of U.S. diplomatic discourse on the Israel-Palestine conflict through an integrated framework of multidimensional analysis and emotional analysis, aiming to unravel the nuanced U.S. stance toward the intractable conflict. This stance is reflected in various types of diplomatic texts and the emotions associated with different diplomatic subgenres.

1.1 Literature Review

Starting from 1990s, diplomatic discourse has been extensively studied under the scope of linguistics particularly focusing on the explicit or implicit linguistic features and metaphors. (Hu and Li, 2018; Chilton & Lakoff, 2005). For instance, the stylistic feature manifest in diplomatic discourse is invariably a research oci that has been examined under a wide range of theoretical frameworks. For instance, Donahue & Prosser (1997) applied rhetorical analysis, contrastive discourse analysis and functional analysis to various global and regional political issues such as north and south Korean conflict and Israeli-Palestine issue and pointed out that linguistic polysemy is one of the major contributors to the diplomatic misinterpretation. Under Biber's Multidimensional (MD) model, Li (2014)

delves into more complex sentence structures, attributive adjectives and prepositional phrase, etc. Taking materials from Chinese and American government websites, Zhang et al. (2023) investigated into the dimensional differences between two countries under Biber's Multidimensional model. The result of this study indicates that national position and national interest have a significant impact on the linguistic features of diplomatic discourse as China's diplomatic discourse is of "learned exposition" while American diplomatic discourse is of "involved persuasion".

Sentiments, emotions, appraisals and the key terms alike forms a key part of in the field affective computing (Hakak et al., 2017). It utilizes various natural language processing techniques to extract the underlying emotions from the level of document, sentence, word and aspect. The concrete statistical methods used for emotion analysis are similar to that for sentiment analysis. Hakak et al. (2017) summarized these methods as follows in Figure 2. Emotion is distinct from sentiment as it has a theoretical origin in psychology (Dixon, 2012). It is defined as a complicated state of feeling that contributes to switches in thoughts, actions, behavior and personality. Therefore, emotion analysis is not restricted to the identification of the basic psychological condition but to formulate a 6-scale or 8-scale emotion model (Nandwani & Verma, 2021). There are various frameworks in demarcating the basic categories of emotions, including SemEval, Standford Sentiment Treebank, international survey of emotional antecedents and reactions (ISEAR). Nandwani & Verma (2021) summarized the emotion model into categorical and dimensional category through which the emotions are represented by distinct parameters. In the dimensional emotion model, the emotions are measured along three axis (valence, arousal and power). The valence indicates the polarity of emotion while arousal measures the extent of excitement of certain feeling. "Power" in dimensional model positions the psychological states in 2D space and restricts the emotions in a continual scale. In the categorical emotion model, emotions are categorized into discrete such as happiness, anger, sadness and fear. Researchers often uses 6-8 emotional categories in their model. Seminal researches concerning the emotion models is seen in literature review in Nandwani & Verma (2021). They provided a brief summary on the mainstream emotion model of these two categories as well as the dataset used for emotion analysis (see in Table 3 and Table 4). The present dissertation utilizes the dimensional Plutchik model for emotional analysis along with the Stanford Sentiment Treebank in the measurement of sentiments.

Table 1 Review of the mainstream emotion model (Nandwani & Verma,2021)

Emotion model	Type of model	No. of states	Psychological states	Representations	Discussion
Ekman model (Ekman 1992)	Categorical	6	Anger, disgust, fear, joy, sadness, surprise	–	Ekman's model consisted of six emotions, which act as a base for other emotion models like Plutchik model
Plutchik Wheel of Emotions (Plutchik 1982)	Dimensional	–	Joy, pensiveness, ecstasy, acceptance, sadness, fear, interest, rage, admiration, amazement, anger, vigilance boredom, annoyance, submission, serenity, apprehension, contempt, surprise, disapproval, distraction, grief, loathing, love, optimism, aggressiveness, remorse, anticipation, awe, terror, trust, disgust	Wheel	Plutchik considered two types of emotions: basic (Ekman model + Trust +Anticipation) and mixed emotions (made from the combination of basic emotions). Plutchik represented emotions on a colored wheel
Izard model (Izard 1992)	–	10	Anger, contempt, disgust, anxiety, fear, guilt, interest, joy, shame, surprise	–	–
Shaver model (Shaver et al. 1987)	Categorical	6	Sadness, joy, anger, fear, love, surprise	Tree	Shaver represented the primary, secondary and tertiary emotions in a hierarchal manner. The top-level of the tree presents these six emotions
Russell's circumplex model (Russell 1980)	Dimensional	–	Sad, satisfied, Afraid, alarmed, frustrated, angry, happy, gloomy, annoyed, tired, relaxed, glad, aroused, astonished, at ease, tense, miserable, content, bored, calm, delighted, excited, depressed, distressed, serene, droopy, pleased, sleepy	–	Emotions are presented over the circumplex model
Tomkins model (Tomkins and McCarter 1964)	Categorical	9	Disgust, surprise-Startle, anger-rage, anxiety, fear-terror, contempt, joy, shame, interest-Excitement	–	Tomkins identified nine different emotions out of which six emotions are negative. Most of the emotions are defined as a pair
Lövheim Model (Lövheim 2012)	Dimensional	–	Anger, contempt, distress, enjoyment, terror, excitement, humiliation, startle	Cube	Lövheim arranged the emotions according to the amount of three substances (Noradrenaline, dopamine and Serotonin) on a 3-D cube

Table 2 Review of the mainstream dataset used for emotion/ sentiment analysis

Dataset	Data size	Sentiment/emotion analysis	Sentiments/emotions	Range	Domain
Stanford Sentiment Treebank (Chen et al. 2017)	118,55 reviews in SST-1	Sentiment analysis	Very positive, positive, negative, very negative and neutral.	5	Movie reviews
	9613 reviews in SST-2	Sentiment analysis	Positive and negative	2	Movie reviews
SemEval Tasks (Ma et al. 2019; Ahmad et al. 2020)	SemEval- 2014 (Task 4): 5936 reviews for training and 1758 reviews for testing	Sentiment analysis	Positive, negative and neutral	3	Laptop and Restaurant reviews
	SemEval-2018 (Affects in dataset Task): 7102 tweets in Emotion and Intensity for ordinal classification (EI-oc)	Emotion analysis	Anger, Joy, sad and fear	4	Tweets
Thai fairy tales (Pasupa and Ayutthaya 2019)	1964 sentences	Sentiment analysis	Positive, negative and neutral	3	Children tales
SS-Tweet (Symeonidis et al. 2018)	4242	Sentiment Analysis	Positive strength and Negative strength	1 to 5 for positive and −1 to −5 for negative	Tweets
EmoBank (Buechel and Hahn 2017)	10,548	Emotion analysis	Valence, Arousal Dominance model (VAD)	–	News, blogs, fictions, letters etc.
International Survey of Emotional Antecedents and Reactions (ISEAR) (Seal et al. 2020)	Around 7500 sentences	Emotion analysis	Guilt, Joy, Shame, Fear, sadness, disgust	7	Incident reports.
Alm gold standard data set (Agrawal and An 2012)	1207 sentences	Emotion analysis	happy, fearful, sad, surprised and angry-disgust(combined)	5	Fairy tales
EmoTex (Hasan et al. 2014)	134,100 sentences	Emotion analysis	Circumplex model	–	Twitter
Text Affect (Chaffar and Inkpen 2011)	1250 sentences	Emotion analysis	Ekman	6	Google news
Neviarouskaya Dataset (Alswaidan and Menai 2020)	Dataset 1: 1000 sentences and Dataset 2: 700 sentences	Emotion analysis	Izard	10	Stories and blogs
Aman's dataset (Hosseini 2017)	1890 sentences	Emotion analysis	Ekman with neutral class	7	Blogs

1.2 Data and Methodology

1.2.1 Data

The corpus of this study (Corpus of US Diplomatic Discourse concerning Israel-Palestine Conflict, CUSDD-IPC) comprises diplomatic discourses of US both at UN and at diplomacy from the period of Oct 1st, 2023- June 1st, 2024. The data of the corpus is extracted from the official website of US Department of State "Israel-Hamas conflict" column (https://www.state.gov/israel-hamas-conflict-latest-updates), employing python web-scraping. In the first step, the program browses across pages in the website to scrape the meta-data, including title, categorization (sub-genre), url address linked to the content. Subsequently, the program iterates all the urls from the meta-data and extract the expected postings in texual forms. Then the data was manually checked for missing columns and formatting issues. The ultimate form of data is presented in Table 1.

In the final step, all the texts are read from the excel repository into load folders and coded according to publication date and sub-genre (i.e.

1_2024_5_15_Readout.txt, 3_2024_5_13_Readout.txt). As summarize in Table 1, the final corpus contained 11 sub-genres, with a total of 227 texts and 185,866 tokens. The 11-subgenres are of different textual forms and average text length, serving various diplomatic purposes.

Specifically, FPC briefing is a special column in the U.S. Department of State website issued by the Foreign Press Center on Israel-Hamas conflict. The interviews are mostly realtime recording and transcription of the conversations between Secretary Blinken and the interviewer. Joint statements, also form of official document, are used by the foreign governments to publicly announce shared positions, agreements, commitments and cooperate efforts on Israel-Hamas conflict. The releases are taken from other section such as U.S Department of Defense and White House that representing the stance of key decision-makers. Readout, in this corpus, is the governmental summary and a report on the key spokesmen (Anthony. J. Blinken, Mathew Miller)'s speeches, events, meeting, etc., to inform the public about major decision and agreements. On average, the text length of FPC briefing and U.S Department Releases are substantially shorter than other sub-genres. A closer look at the interview reveals that Interview, Remarks and Remark to the Press share similar styles as most of them take the form of conversation. The homogeneity of linguistic forms across the three sub-genres is due to the fact that they are realtime-generated texts with loose structures compared with briefings.

Table 3 Corpus Description

Sub-genres	**Number of texts**	**Number of tokens**	**Average Text Length**
FPC briefing	3	186	62
Interview	20	32626	1631.30
Joint Statement	3	985	328.33
Media Note	8	4388	548.50
Press Statement	23	5586	242.87
Readout	94	29727	316.24
Remarks	52	81988	1576.60
Remarks to the Press	8	9701	1212.63
Special Briefing	4	15429	3857.25
U.S Department to Defense Release	1	61	61
White House Release	11	5189	471.72
Total	227	185866	818.79

1.2.2 Methodology

This study adopts a two-ponged approach which connects Biber's Multidimensional analysis with the emotion analysis, to explore the uniqueness of register-internal variation of US diplomatic discourse as well as the stance and emotions represented in US

diplomacy towards Israel-Palestine conflict. Principal factor analysis (PFA) is used to extract the optimal number of textual dimensions from the CUSDD-IPC corpus. These factors are then interpreted according to the communicative purposes/ pragmatic functions that are associated with the included linguistic features.

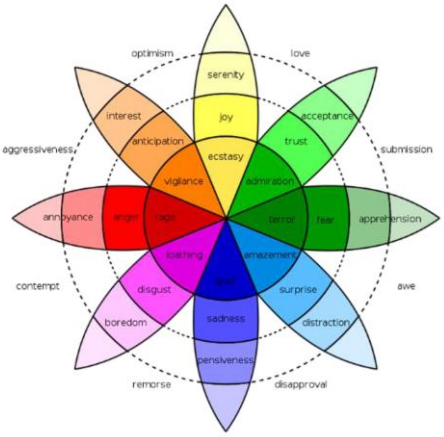

Figure 1 Plutchik' s wheel of emotions

Subsequently, we use Plutchik's wheel of emotions for identification and analysis of emotions from texts. NRCLex is employed for the annotation of 8 basic emotions. Pyplutchik, a python library that integrates Plutchik wheel into the data visualization library matplotlib, is used to plot out these emotions. Ultimately, the emotion terms are correlated with the identified dimensions in order to check their interrelationship.

1.3 Research Questions

(1) Does U.S. diplomatic discourse show register-internal multidimensionality? If yes, what is the distribution of sub-registers along these dimensions?
(2) How is the U.S. stance toward the Israel-Palestine conflict represented in the emotions in each subgenre?
(3) How are emotions correlated with the identified textual dimensions in U.S. diplomatic discourse?

2. Results

2.1 Dimensions of diplomatic sub-registers

Dimension 1 comprises of 33 features, only 2 of which are with negative loadings. Total other nouns (NN) and phrasal coordination (PHC) both indicate high information density. But the negative loading on PHC is smaller than all the other loadings in terms of its absolute value. The occurrence of PHC with nouns usually occur in structures like Secretary Blinken and President Elsisi discussed… to coordinate the Arabian partners, …has an obligation to distinguish between terrorists and civilians to indicate "us vs them" or political counterparts. For instance, text 1 demonstrates a consecutive use of phrasal coordination in the Remark article to pack highly homogeneous information in one sentential unit. The co-occurrence of nouns and phrasal coordination on the negative axis shows that texts are neatly packed with information. On the positive side, all 31 features have significant loadings larger than 0.5. In particular, contractions, present tense, demonstrative pronouns and first person pronouns have the positive loadings greater than 0.8. Instances like what's, there're are common cases of form reduction

(contraction). The use of contraction reduces the extent of information certainty and results in "homogenous, generalized, uncertain" content (Biber,1988). Another feature that is associated reduction of form on the positive side is pro-verb do. It substitutes the verb phrases in a contextually recognizable position with a simplified form "do" and is usually used in colloquial/ casual discourses. Demonstrative pronouns such as "this" "that" are usually detached from its original referent thus carrying more uncertainty and less information focus. Analytic negation (XX0) and be as main verb (BEMA) also have heavy loadings on Dimension 1. Analytic negation "not" and be as main verb indicates high fragmentation, thus contributing to less information density. They often co-occur with discourse particles such as anyway, well that serve as loosen structure of coherence.

Text 1 Remark (101_2023_11_4_Remarks)
Palestinians and Israelis deserve to live in peace with dignity, with security and freedom from occupation and freedom from fear.
Text 2 Readout (128_2022_10_20_Readout)
What's happening in Israel and Gaza is what we're handling around-the-clock.

The subordination features that are considered to be characteristic of spoken discourses also cluster with high loadings in this dimension (Biber, 1988; Poole & Field, 1976). Causative subordinator, conditional subordinator, wh-clauses form a typically involved and context-restricted group. These subordinators often come along with authors' stance-taking as well as elaboration under different constraints. The elaboration under the restriction of context serves functional and affective functions instead of informational. The complementary distribution of these involved/ affectional features with informational features evinces the fundamental and ubiquitous oral/literature contrast (Connor-Linton & Amoroso, 2014). Other features like amplifiers, private verbs, emphatics, present tense also occur in Biber (1988)'s framework, demonstrating "heightened feeling" and heavy interpersonal touch. However, the exception on our dimension 1 that is distinct from Biber's dimension 1 lies in the occurrence of downtoners, possibility modal, that adjective/verb complements and that relative clauses on objective positions. The overall distribution of linguistic features in Dimension 1 highly overlaps with exploratory investigation of Biber (1988). It suggests that the contrast of "informational vs involved" still applies to the sub-genres of US diplomatic texts even though they are considered institutional.

Table 4 Features with loadings on Dimension 1

Dimension1	**Feature**	**Loadings**
AMP	Amplifier	0.588
ANDC	Independent Clause Coordination	0.572

CAUS	Causative Subordinator	0.716
COND	Conditional Subordinator	0.649
DEMO	Demonstratives	0.557
DEMP	Demonstrative Pronouns	**0.841**
DPAR	Discourse Particles	0.700
DWNT	Downtoner	0.595
EMPH	Emphatics	0.596
EX	Existential There	0.817
FPP1	First Person Pronouns	**0.812**
POMD	Possibility Modals	0.603
SPP2	Second Person Pronouns	0.746
THAC	That adjective complements	0.505
THVC	That Verb Complement	0.682
TOBJ	That relative clauses on Object Positions	0.567
VPRT	Present tense	**0.847**
XX0	Analytic Negation	0.750
[BEMA]	BE as a main verb	0.741
[CONT]	Contraction	**0.929**
[PRIV]	Private Verbs	0.667
[PROD]	Pro-verb do	0.723
[STPR]	Stranded Preposition	0.650
[THATD]	Subordinator that deletion	0.614
[WHCL]	WH Clause	0.689
[WHQU]	WH Questions	0.583
NN	**Total other nouns**	**-0.515**
PHC	**Phrasal Coordination**	**-0.357**

Dimension 2 shows the cluster of 3 linguistics features, all with significant positive factor loadings that are larger than 0.8. The largest loading is on agentless passives. Unlike by passives that reveals the agent at non-subject position, agentless passives are used on the occasion where less focus is given to the agent while more given to the patient or entity that is been acted upon (Biber 1988). It is usually used in the procedural discourse when the texts are with repetitive but non-significant or publicly-acknowledged agents. The use of passives along with adverbs indicates higher extent of abstractness as well as focus on complicated logical representations. Infinitives [TO] is a necessary part of verb completement, which is used to formulate the basic stance of the speaker and highlight the opinion of the speak. The heavy bearings on both markers of abstractness and persuasion is surprising if individualized from the context of diplomatic conflicts. This could be summarized as a style diplomatic persuasion when the actions of agents (usually diplomats) are implicit and attitude interwoven with intense logical reasoning. Most intended actions on the conflict, in this case, are abstracted away from the listeners or recipient as diplomat's acts of persuasion does not rely on concrete and practical methods.

Table 5 Features with loadings on Dimension 2

Dimension2	Features	Loadings
TO	Infinitives	0.906
[PASS]	Agentless Passives	1.004
RB	Adverbs	0.830

The 3 features on Dimension 3 have moderate factor loadings ranging from 0.5 to 0.76. Average word length, with the positive loading of 0.754, falls into the category of lexical specificity. Unlike the common pattern of co-occurrence, it is not grouped with other features under this category such as type-token ratio. But its high loading indicates this dimension is featured with high information exactness. Such feature occurs in well-curated texts such as statements and official releases in the case of diplomatic discourse. Prepositional phrase and attributive adjective are the markers of high integration, that is, the way profuse information is wrapped into few words. Texts with frequent occurrence of prepositional phrases as well as high word length have compact information structure.

Table 6 Features on Dimension 3 with loadings

Dimension3	Features	Loadings
AWL	Word Length	0.754
JJ	Attributive Adjective	0.597
PIN	Total Prepositional Phrases	0.522

Dimension 4 and Dimension is characterized by 8 lexico-grammatical features with positive loadings around 0.5. Present participial WHIZ deletions and Wh relative clauses on subject position are often used with nouns and nominalization for information elaboration. While present participial WHIZ deletions extends the previous information in adding new descriptive information, Wh relative clauses on subject positive adds further specification on the referent. The perfect aspect occurs more in the description of past events. The features that cluster in Dimension 4 demonstrate high specificity and concreteness. Dimension 5 has four loadings from opposite sides of the axis. Split auxiliaries and Predicative modals co-occur on the positive side while past tense time adverbials group on the negative side. The feature co-occurrence on the positive side is reminiscent of the Biber's general MD analysis on speech and writing as well. On the negative pole, past tense and time adverbial cluster with less significant loadings. The complementary distribution of predictive modal with past tense indicates the strategic maneuvering of events in the

diplomat's discourse.

Table 7 Features on Dimension 4 with loadings

Dimension4	**Features**	**Loadings**
[WZPRES]	Present participial WHIZ deletion relatives	0.594
[WHSUB]	WH relative clauses on subject position	0.508
[PEAS]	Perfect Aspect	0.486
[NOMZ]	Nominalization	0.410

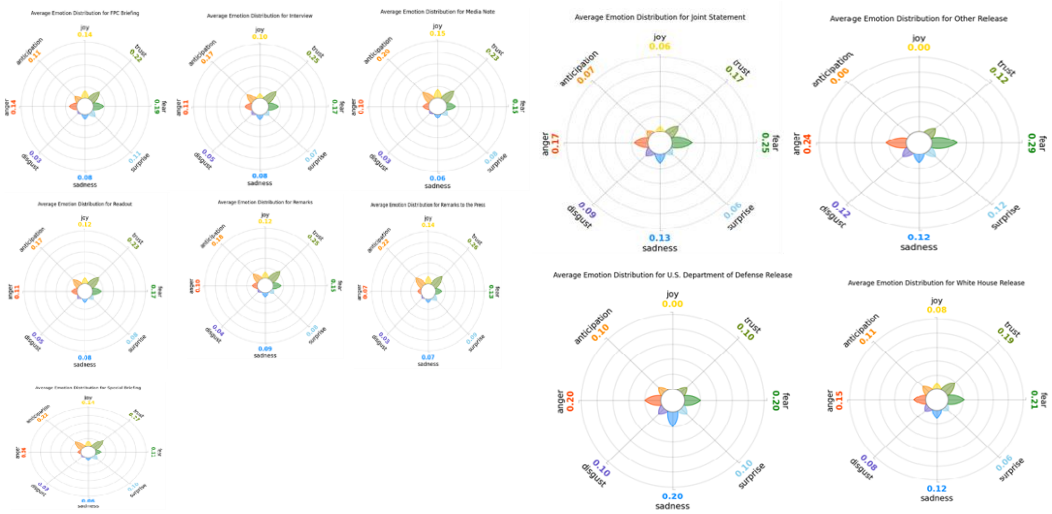
2.2 Emotion analysis based on Plutchik wheel

Figure 3 demonstrates the distribution of 8 basic emotions in the diplomatic sub-genres.



(a) Emotions wheel dominated by “trust” (b) Emotion wheel dominated by “fear/anger”

Figure 3 8 basic emotion components

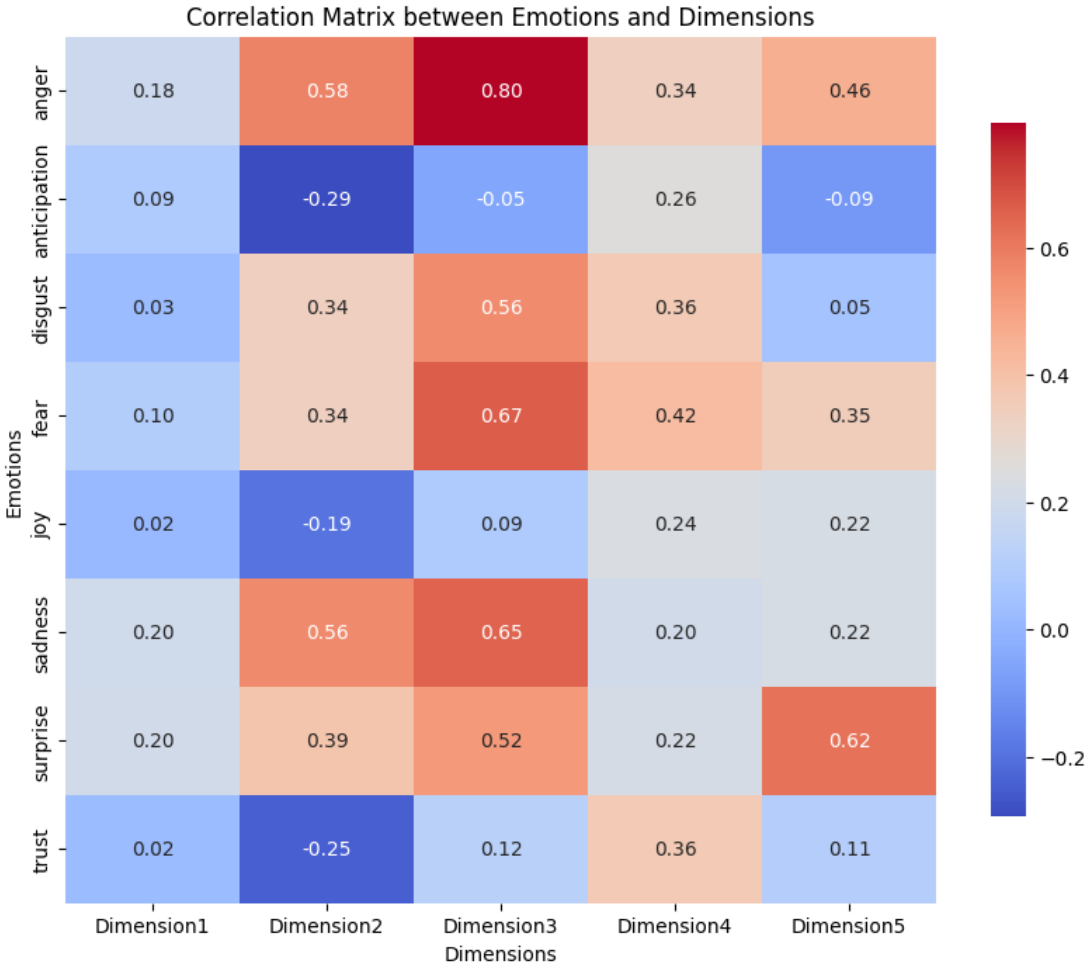


Figure 4 Correlation matrix between Dimensions and Emotions

Conclusion

This study offers multidimensional insights on the discourses of U.S. diplomatic discourse regarding the Israel-Palestine issue, emphasizing the importance of textual and emotional elements. Utilizing Biber's (1988) paradigm and Principal Factor Analysis, the study highlights five textual dimensions inside several sub-registers of U.S. diplomatic writings. The results of the study indicate that Dimension 1 significantly groups subordination characteristics linked to spoken discourse, including causal and conditional subordinators, wh-clauses, and additional traits that signify engagement and contextual limitation. Furthermore, our emotional study utilizing Plutchik's wheel reveals a predominance of 'trust,' accompanied by notable instances of 'fear' and 'anger,' corresponding to Dimension 4 and Dimension 3, respectively. This suggests that 'trust' promotes a favorable diplomatic position, whereas 'fear' and 'anger' expose points of tension and conflict within the dialogue.

Syntactic cues may not aid human parsers efficiently in predicting Japanese passives

Masataka Ogawa
The University of Tokyo / 3-8-1, Komaba, Meguro-ku, Tokyo, 153-8902, Japan
ogawa.phiz@gmail.com

Abstract

Our study demonstrates that the human parser may not predict passive constructions from syntactic elements preceding the sentence-final verb in Japanese by comparing the reading time and comprehension accuracy of V-(*r*)*are* passive and V-∅ active sentences. In SVO languages like English, where the syntactic structures of actives and passives differ, reading times for passives are often shorter, and comprehension accuracy is comparable for both constructions. However, in Japanese, an SOV language, where the syntactic structures of actives and passives are similar, prior studies found numerically longer reading times and lower comprehension accuracy for passives. We hypothesized that if reading times for passives were shorter as in SVO languages, a case marker in passives might signal the passive construction and reduce reading times for passives. Controlling verb classes that assign different case markers to non-subject NPs, we carried out a self-paced reading (SPR) task where participants read sentences at their own pace, to determine if syntactic cues facilitate the prediction of V-(*r*)*are* before the sentence-final verb. A comprehension question to assess comprehension accuracy followed each trial of the SPR task. The results did not reveal that differences in case markers led to faster reading times or higher accuracy for passives. Rather, we corroborated the previous findings: increased reading times and lower accuracy for Japanese passives.

There are contradicting views on how reading times and comprehension accuracy are different between passives and actives in SVO and SOV languages. Studies on SVO languages suggest that the processing load for passives is the same or less than for actives, with parsers predicting passives as they read (e.g. Paolazzi et al., 2016, 2017, 2019). Conversely, research on Japanese, an SOV language, have indicated that passives lead to processing difficulties (Tamaoka et al., 2005; Kinno et al., 2008; Tanaka et al., 2017). Even in experiments with equivalent morphological complexity of both active and passive verbs, reading times for passives were longer, and comprehension was less accurate (Ogawa, 2023). However, these previous research did not clarify if a passives can be predicted from syntactic cues before the sentence-final verb.

We performed a self-paced reading (SPR) task, where participants read sentences at their own pace, to determine if syntactic cues facilitate the prediction of Japanese passives V-(*r*)*are* before the sentence-final verb. While comparing reading times between the passive and its active counterpart V-∅, we controlled verb classes assigning different case markers to non-subject NPs, hypothesizing that certain markers predict passives. However, we found no evidence that the human parser predicts passive construction from the case marker in Japanese. Instead, we replicated robust findings of longer reading times and lower accuracy for passives using V-(*r*)*are* and V-∅, which were not employed in a previous SPR experiment (Ogawa, 2023).

Section 1 reviews contradicting results in various languages on reading time of passives, and explain why Japanese case marker can contribute to the prediction of voice/diathesis. Section 2, their comprehension accuracy. Section 3 outlines the methodology and Section Section 4 reviews results of the experiment.

1 Can passives be read faster?

Paolazzi et al. (2016; 2017; 2019) performed SPR experiments in English and discovered shorter or equivalent reading times for verbs and post-verbs

The glossing abbreviations in this article follow Leipzig Glossing Rules (Department of Linguistics of Max Planck Institute for Evolutionary Anthropology, 2008, last accessed on July 15, 2022), Brown and Anderson (2006), , except INFR. -: affix boundary / =: clitic boundary / ACC: accusative / ADV: adverb / DAT: dative / INFR: inferential mood / NOM: nominative / PASS: passive / POL: polite register / PST: past / Q: question particle

in passive sentences, compared to those in active sentences. They suggested that the auxiliary verb *be* and the preposition *by* in passive constructions aid in predicting the (post-)verb region, as the auxiliary verb *be* signals the upcoming presence of a verbal past participle. Paolazzi et al. (2019; 2021b) argue that in passives, elements before the verb increase predictability for verbs, leading to reduced reading times. They noted that, as the verb and preposition *by* signal a subsequent non-subject NP in passive, such a NP is more predictable in passives. This increased predictability reduces reading times for the post-verbal region in passives, in contrast to actives where only the verb serves as a cue for the region.

However, in Japanese, reading times were numerically longer for passive verbs, although there was unclear statistical support (Ogawa, 2023). They compared reading times using benefactive V-*te morau* passives and V-*te ageru* actives, where the morphological complexity of the verbs in both constructions was equalised. This suggests that the delay in reading times is likely due to the process of associating thematic roles with grammatical relations in passive sentences rather than differences in morphological structure between active and passive verbs. Furthermore, Ogawa (2023) argued that the difference in reading times between active and passive sentences in previous studies on English is due to the fact that only passives have morphosyntactic cues in English.

Indeed, it is challenging to control for morphosyntactic complexity when comparing reading times between actives and passives in English. Paolazzi et al.'s (2019) SPR experiment compared reading times for the past-tensed main verb in active sentences and the past participle in passive sentences as the same region. Both constructions contained a subject NP preceding the verb, but only passives include the copula *be* in an additional region. This created an imbalanced design where only the passives had a predictor (*be*) for the passive voice, whereas actives lacked any corresponding predictor. However, this issue can be avoided by using SOV languages like Japanese.

As the verb appears at the end of the sentence in Japanese, markers that signal the sentential diathesis would necessarily precede the verb, if such exist. Moreover, the structure of the subject and the object/oblique NP can be very similar in Japanese, with the only difference being the case marker (adposition) attached to the object/oblique NP, as shown in (1).

(1) a. V-(*r*)*are* passive; $=o_{\text{ACC}}$-verb
Takahashi=ga *Ōtsuka=ni*
T.=NOM Ō.=DAT
*naguritobas-***are***-ta.*
hit-PASS-PST
'Takahashi was punched by Ōtsuka.'

b. V-∅ active; $=o_{\text{ACC}}$-verb
Ōtsuka=ga *Takahashi=***o**
Ō.=NOM T.=ACC
naguritobashi-ta.
hit-PST
'Ōtsuka punched Takahashi.'

Since Japanese adpositions are consistently present in both active and passive sentences, this avoids the imbalance of having adpositions in one construction but not the other, and allows for a clearer comparison to examine whether the human parser predicts a passive sentence when reading the adposition attached to the oblique NP, if the predictors of the sentence diathesis are adpositions. In fact, it is plausible that the ease of predicting actives versus passives in Japanese varies depending on the adposition used.

Muraoka (2006) had participants complete sentences by filling in a sentence-final VP after being presented with subject and non-subject NPs. Results indicated that predictions for what follows the non-subject NP depend on its case marking (see also Figure 3 in Appendix A.). Muraoka (2006) suggested that a $=ni_{\text{DAT}}$-marked NP predicts either an $=o_{\text{ACC}}$-marked NP (forming a ditransitive construction) or a verb, while an $=o_{\text{ACC}}$-marked NP predicts a verb will directly follow.

Muraoka (2006) did not specify which voice is predicted when encountering a $=ni_{\text{DAT}}$-marked NP or $=o_{\text{ACC}}$-marked NP. However, their data indicate that passive verbs were predicted with a $=ni_{\text{DAT}}$-marked NP, but not with an $=o_{\text{ACC}}$-marked NP. Hence, only a $=ni_{\text{DAT}}$-marked NP, not an $=o_{\text{ACC}}$-marked NP, could signal that the parser is reading a passive sentence. If so, the reading time difference introduced by such a voice/diathesis prediction can be found between the $=ni_{\text{DAT}}$-marked and $=o_{\text{ACC}}$-marked NP.

Moreover, in Japanese active, the accusative $=o$ marks the object for some verbs ($=o_{\text{ACC}}$ verbs, (1)),

whereas the dative =*ni* marks the object for others (=ni_{DAT} verbs, (2)). We can utilise this asymmetrical case pattern to test whether Japanese case marker can signal the voice of subsequent VP or the diathesis of entire sentence.

(2) a. V-(*r*)*are* passive; =ni_{DAT}-verb
Takahashi=ga *Ōtsuka=ni*
T.=NOM Ō.=DAT
*nagurikakar-***are***-ta.*
hit-PASS-PST
'Takahashi was lunged at by Ōtsuka.'

b. V-∅ active; =ni_{DAT}-verb
Ōtsuka=ga *Takahashi=***ni**
Ō.=NOM T.=DAT
nagurikakat-ta.
hit-PST
'Ōtsuka lunged at Takahashi.'

2 Are passives comprehensible?

Paolazzi et al. (2021b) noted that processing difficulties for passives in English arise during comprehension questions written in active voice inquiring thematic roles, such as questions asking *who* performed an action on *whom*. They showed that participants responded less accurately to active voice comprehension questions about thematic relations of passive target sentences. Similar findings were also reported in German (Grillo et al., 2019; Meng and Bader, 2020).

In contrast to the findings in SVO languages, several studies in Japanese have indicated that the passive constructions using V-(*r*)*are* impose greater processing difficulties compared to their active counterparts (Tamaoka et al., 2005; Yokoyama et al., 2006; Kinno et al., 2008; Tanaka et al., 2017). Tamaoka et al. (2005), for instance, carried out experiments in which participants judged the sensibility of various sentence structures, including active and passive constructions presented in the canonical SO order and non-canonical OS order of NPs. Longer reaction times were found for passives than for actives in both word order conditions, despite nearly equivalent error rates. These results suggested that human parsers encounter a larger processing cost when comprehending passives.

Several fMRI studies found that when participants judged whether a written V-(*r*)*are* passive correctly described a picture of one stick figure acting on another, more activation was triggered in the left inferior frontal gyrus compared to the corresponding active sentences (Kinno et al., 2008; Tanaka et al., 2017). Kinno et al. (2008) concluded that the syntactic reanalysis occurred to comprehend the patient denoted by a =*ga*-marked nominative NP in passives. However, Yokoyama et al. (2006) observed a similar activation in that cerebral region, when they compared the cognitive demands of uninflected V-∅ active verbs and inflected V-(*r*)*are* passive verbs in a lexical decision task. They concluded that unmarked active verbs are treated as unitary words, while marked passive verbs involve morphological decomposition. Thus, a brain activity specific to passives is expected, although it is arguable whether this is caused by processing diathesis (entire sentence level) or voice (verbal morphological level).

Further evidence for lower comprehension accuracy of Japanese passives comes from Ogawa (2023), which employed a similar comprehension question paradigm as Paolazzi et al. (2021b). They minimized the morphological difference between active and passive sentences, which was a limitation of previous studies, by using benefactive active/passive pairs (V-*te ageru* and V-*te morau*). Therefore, they concluded that the observed decrease in accuracy for passive comprehension was caused by the cognitive process that links the patient to the grammatical subject in passives, rather than morphological factors.

3 Self-paced reading experiment with comprehension question

Existing literature has provided evidence that passive sentences in Japanese demand more time to read and present greater difficulties for precise understanding. Nevertheless, the potential role of the dative case marker =ni_{DAT} in passives as a signal for the passive construction, which could consequently decrease reading times, has not been extensively explored. Thus we explored two key issues: first, we investigated whether the parser predicts a passive voice for the subsequent VP upon reading a =ni_{DAT}-marked NP in the oblique region, thereby initiating constructing a passive structure at this or the post-oblique region. If so, the processing load for constructing the passive structure would increase reading times in the pre-verbal region (i.e. a =ni_{DAT}-marked NP) under the passive condition compared to the active condition. Second, we examined whether passives incur a greater parsing cost compared to actives at the verb and later regions.

To achieve these objectives, we employed an SPR experiment using a moving window paradigm (Just et al., 1982). We also appended a comprehension question task after each trial of the SPR experiment. This was to assess if Japanese V-(*r*)*are* passives, relative to V-∅ actives, impose a higher processing load to comprehend.

3.1 Participants

The same participants who were recruited for a previous study (Ogawa, 2023) also participated in the current experiment. Full details can be found in that paper. Note, however, that a total of 262 native Japanese speakers were recruited online, and we excluded eight participants from our analyses who did not meet the native speaker criteria.

3.2 Stimuli

3.2.1 Target sentences

As outlined in Table 1, we controlled the voice by employing V-∅ active or V-(*r*)*are* passive as the main verb chunk (R5). We also manipulated the oblique marker in R3 by using $=o_{\text{ACC}}$ and $=ni_{\text{DAT}}$. If $=ni_{\text{DAT}}$ in Japanese functions similarly to the passive predictors *be* and *by* in English (Paolazzi et al., 2019, 2021b), it would signal the human parser that the entire sentence is passive. Consequently, reading time would increase only for active sentences with $=ni_{\text{DAT}}$-verbs. This increase occurs because the parser, predicting a passive sentence after encountering $=ni_{\text{DAT}}$ in R3, experiences a surprisal effect when discovering that the sentence is actually active in R5.

This required the verb class in R5 to be a verb that take a $=ni_{\text{DAT}}$-marked object ($=ni_{\text{DAT}}$-verb) or those that take a $=o_{\text{ACC}}$-marked object ($=o_{\text{ACC}}$-verb). $=ni_{\text{DAT}}$-verbs are much rarer than $=o_{\text{ACC}}$-verbs. However, a number of verbal compounds consisting of two verbs (V-V compounds) take a $=ni_{\text{DAT}}$-marked object, while others take a $=o_{\text{ACC}}$-marked object. These $=ni_{\text{DAT}}$- and $=o_{\text{ACC}}$-V-V compounds were selected from the lexical compound verbs listed in the Compound Verb Lexicon (Kageyama, 2013). These lexical compounds are assumed to be registered in the lexicon due to their strong unity as words, preventing other grammatical elements from being inserted between the two verbs. It is unlikely that such V-V compounds are derived by syntactic operations (Kageyama, 1993). We also confirmed that both lexical $=ni_{\text{DAT}}$- and $=o_{\text{ACC}}$-V-V compounds chosen for target sentences can be used as passive verbs to a similar extent, based on the high MI and LogDice scores reported in NINJAL-LWP for BCCWJ (National Institute for Japanese Language and Linguistics and Lago Institute of Language, 2012).

We employed verbs corresponding to Type 1 'Direct effect on patient' in the hierarchy of two-place predicates proposed by Tsunoda (1985; 2009), to use eventive passive sentences for the passive condition as in previous studies of English and German (Paolazzi et al., 2016, 2017, 2019, 2021a,b; Grillo et al., 2019; Meng and Bader, 2020).

In line with earlier research (Witzel and Witzel, 2011; Koizumi and Imamura, 2017; Ogawa, 2023), we measured reading times in the verb region (R5) and the following modal particle region (R6) as indicators of cognitive load during the processing of verbal voice and sentential diathesis. The load elicited in R5 may spill over to R6 (Just et al., 1982, 232–233) or manifest later, prolonging reading times in R6 (delay, Just et al., 1982, 236). Thus, increased reading time could potentially occur in R5, R6, or both. Analogous to the inclusion of R6, we placed an action-denoting adverb (R4) after the oblique NP (R3). This design allowed us to detect any cognitive load related to the prediction of a passive structure triggered by the oblique NP before reading the verb.

3.2.2 Questions to measure comprehension accuracy

Each V-(*r*)*are* passive and V-∅ active target sentence in the SPR tasks was paired with a variant of the questions exemplified in Appendix B. These questions aimed to test whether participants correctly interpreted the thematic relation of each target. These questions were derived from the first NP (NP1; R2), second NP (NP2; R3), verb (R5), and modal (R6) of the target sentences. We counterbalanced the correct responses ("yes" or "no") by presenting NP1 and NP2 in the questions in either the same sequence as in the trials of SPR task or in the inverse order.

To investigate the potential facilitatory effect of voice priming between a question and its target, as observed by Ogawa (2023) for Japanese benefactive active and passive sentences, we also counterbalanced the voice of the target sentences and comprehension questions. This resulted in two conditions: (1) a matched condition, in which an active question was paired with an active target, and a passive question with a passive target; and (2) a mismatched condition, in which an active question was paired with a passive target or vice versa.

Voice	Verb class	R1: Locative ADVP	R2: First NP [NP1]	R3: Second NP [NP2]	R4: ADV on action	R5: Verb	R6: Modal particle
active	$=o_{ACC}$-verb	*Kyōshitsu=de*	*Takahashi=ga*	***Ōtsuka=o***	*chikarazuyoku*	***naguritobashi-ta***	*rashī*
		classroom=LOC	T.=NOM	Ō.=ACC	forcefully	hit-PST	INFR
		'In the classroom, Takahashi seems to have forcefully punched Ōtsuka.'					
	$=ni_{DAT}$-verb	*Kyōshitsu=de*	*Takahashi=ga*	***Ōtsuka=ni***	*chikarazuyoku*	***nagurikakat-ta***	*rashī*
		classroom=LOC	T.=NOM	Ō.=DAT	forcefully	hit-PST	INFR
		'In the classroom, Takahashi seems to have lunged at Ōtsuka with a powerful punch.'					
passive	$=o_{ACC}$-verb	*Kyōshitsu=de*	*Takahashi=ga*	***Ōtsuka=ni***	*chikarazuyoku*	***naguritobas-are-ta***	*rashī*
		classroom=LOC	T.=NOM	Ō.=DAT	forcefully	hit-PASS-PST	INFR
		'In the classroom, Takahashi seems to have forcefully been punched by Ōtsuka.'					
	$=ni_{DAT}$-verb	*Kyōshitsu=de*	*Takahashi=ga*	***Ōtsuka=ni***	*chikarazuyoku*	***nagurikakar-are-ta***	*rashī*
		classroom=LOC	T.=NOM	Ō.=DAT	forcefully	hit-PASS-PST	INFR
		'In the classroom, Takahashi seems to have been lunged at Ōtsuka with a powerful punch.'					

Table 1: Experimental conditions with a sample item for the SPR task

We confirmed the grammaticality of all stimuli, including 16 target and 48 distractor sentences in the main trials and six practice items.

3.3 Procedure

We employed PennController for Internet Based Experiments (PCIbex; https://farm.pcibex.net/), a web application for psycholinguistic research. Participants accessed the site solely from their personal computers, and access from any mobile device was restricted.

A video introduction outlining the experimental design was automatically shown to participants. The video clarified that each of the 64 trials would involve an SPR task followed by a comprehension question. Participants completed six practice trials preceding the main experiment to familiarise themselves with the protocol.

In the SPR task, stimuli were initially masked by underscores, with each region unveiled sequentially upon pressing the space bar. Sentences were presented without inter-word or inter-region spaces, adhering to the standard Japanese typesetting. The stimuli were displayed using the Noto Sans Japanese font in black on a white background.

Upon completing the last region of a sentence, participants pressed the space bar to trigger a comprehension question, which was fully displayed immediately. Participants answered by selecting either the F key to indicate 'yes' or the J key for 'no'. The experiment withheld feedback on the accuracy of the answers. The correct answers ('yes' or 'no') were counterbalanced across targets and distractors during the experiment.

Following each question, a prompt instructed participants to press the space bar when ready to start the next trial. This message remained on the screen until the participant chose to proceed, allowing them to control the pace of the experiment.

The aforementioned procedure follows the method outlined in Ogawa (2023). However, this experiment uniquely counterbalanced several factors unlike previous studies: the voice of the target sentence (i.e., V-∅ active versus V-(*r*)*are* passive), the verb class (i.e., $=ni_{DAT}$-verbs versus $=o_{ACC}$-verbs), the voice of the comprehension question (i.e., V-∅ active versus V-(*r*)*are* passive), and the correct responses (i.e., whether 'yes' or 'no' was correct). Thus, one of 16 stimulus lists was presented following a Latin-square design.

3.4 Data exclusion criteria

We excluded data from 55 participants who either participated multiple times or were suspected of doing so. Data from 50 participants were also discarded due to improper presentation of stimuli or suspicion thereof. Moreover, data from two participants were removed because of recording errors on the server. Adopting Paolazzi et al's (2019) criterion, we excluded data from four participants whose overall accuracy for distractors was below 75%. Consequently, the final analysis included data from 143 participants.

For the analysis of reading time data, we excluded trials where participants incorrectly answered the corresponding comprehension question. We further filtered out reading times less than 80 ms from the data, following Paape et al. (2021), as this duration is considered the minimum time required for linguistic information to affect oculomotor control (Altmann, 2011).

3.5 Statistical analyses

We fit Bayesian generalised linear mixed models using the `brms` package (Burkner, 2021) in `R` (R Core Team, 2021). The models included correlated varying intercepts and slopes for participants

and items. In `brms`, `cmdstanr` (Gabry and Češnovar, 2021) estimated coefficients and `bridgesampling` (Gronau and Singmann, 2021) computed Bayes factors based on `stanfit` objects transferred `rstan` (Guo et al., 2021). Models were run with four chains and 2,000 warm-up and 50,000 post-warm-up iterations in each chain. The NUTS sampler was configured to target a mean acceptance probability $\delta = 0.9$.

We evaluated the impact of each explanatory variable on the response variables (reading time and accuracy) by calculating Bayes factors BF_{10}. They provide the quantitative support for the alternative model, which incorporates the explanatory variable of interest, in comparison to the null model lacking that variable. A $BF_{10} > 1$ indicates that the explanatory variable has an effect on the response variable, whereas a $BF_{10} < 1$ indicates the absence of an effect. We adopted Lee and Wagenmakers's criteria (2013, derived from Jeffreys, 1939/1998) to interpret the strength of evidence for the presence or absence of an effect, as shown in Table 2.

BF_{10}	Strength of evidence
For the alternative model	
$100 < BF_{10}$	Extreme
$30 < BF_{10} \leq 100$	Very strong
$10 < BF_{10} \leq 30$	Strong
$3 < BF_{10} \leq 10$	Moderate
$1 < BF_{10} \leq 3$	Anecdotal
For the null model	
$\frac{1}{3} < BF_{10} \leq 1$	Anecdotal
$\frac{1}{10} < BF_{10} \leq \frac{1}{3}$	Moderate

Table 2: Criteria for interpreting Bayes factors (Lee and Wagenmakers, 2013, derived from Jeffreys, 1939/1998, excerpt relevant to the current study)

Given the substantial susceptibility of Bayes factors to prior settings for the explanatory variables and intercept (Nicenboim et al., to appear), we conducted prior predictive checks to calibrate the priors for intercepts, explanatory variables, and covariates, following Schad et al's (2020a; 2022) methodologies. Moreover, we calculated BF_{10} iteratively for each explanatory variable using normally-distributed priors with a mean of zero and a range of standard deviations (Nicenboim et al., 2020; Ogawa, 2023). This approach allowed us to observe the trends in BF_{10} and coefficients across different prior specifications. See Appendix C. for further details.

3.5.1 Reading time

We modelled the reading times using a log-normal distribution. The key explanatory variables were:

- the target voice (V-∅ active or V-(*r*)*are* passive)
- the verb class difference for each target voice
  - $=ni_{DAT}$-verbs or $=o_{ACC}$-verbs in active voice
  - $=ni_{DAT}$-verbs or $=o_{ACC}$-verbs in passive voice.

Sum-coding was applied to the target voice variable, and nested sum-coding to the verb class differences (Schad et al., 2020b). The covariates in the model included the number of characters in the region and the absolute trial order, both of which were standardised (Nicenboim et al., to appear). Details are provided in Appendix C.

3.5.2 Comprehension accuracy

Accuracy of the comprehension questions was analysed with mixed effects logistic regressions. We focused on seven key explanatory variables:

- the target voice
- priming (match versus mismatch in voice between target and comprehension question)
- the interaction of the two factors above
- the verb class difference for each target voice and priming
  - active $=ni_{DAT}$-verbs versus $=o_{ACC}$-verbs in both target and question
  - passive $=ni_{DAT}$-verbs versus $=o_{ACC}$-verbs in both target and question
  - $=ni_{DAT}$-verbs versus $=o_{ACC}$-verbs in active target and passive question
  - $=ni_{DAT}$-verbs versus $=o_{ACC}$-verbs in passive target and active question

The first three variables were sum-coded and the rest were nested sum-coded. The *z*-transformed absolute trial order was also included as a covariate. Further details can be found in in Table 5 in Appendix C.

3.6 Predictions

3.6.1 Reading time

If a $=ni_{DAT}$-marked NP strongly predicts passives in Japanese and such predictions facilitate the reading of passives, shorter reading times for passives could be observed in the verb region (R5). Furthermore, if the parser begins constructing the passive

structure in R3 or immediately after in R4 due to the presence of a =*ni*$_{\text{DAT}}$-marked NP, longer reading times may also occur in these regions.

However, only in the active =*ni*$_{\text{DAT}}$-verb condition, the presence of a =*ni*$_{\text{DAT}}$-marked NP would mislead the parser into anticipating a passive sentence. This would cause surprisal and longer reading times in R5 of =*ni*$_{\text{DAT}}$-verbs, as the actual sentence turns out to be active in that region.

It is, nonetheless, also unsurprising to find longer reading times in passives in both =*ni*$_{\text{DAT}}$- and =*o*$_{\text{ACC}}$-verbs, as even when the morphological structure of verbs is matched as closely as possible, passive verbs in Japanese may still result in longer reading times (Ogawa, 2023).

We may also observe the same reading time pattern at R6, due to a spill-over and/or delay of the processing cost from the verb region (R5).

3.6.2 Comprehension accuracy

As priming effects were found both between active targets and questions, and between passive targets and questions (Ogawa, 2023), higher accuracy is expected when target and the question share the same voice, and lower accuracy when they not.

If, in addition, a =*ni*$_{\text{DAT}}$-marked NP serves as a predictor for passive sentences, the prediction of a passive structure could facilitate more accurate comprehension of passive targets. Thus, even in the passive condition, accuracy is expected to be as high as in the active condition. However, in the active =*ni*$_{\text{DAT}}$-verb condition, the parser may initially predict a passive structure at R3 but then realize at R5 that the sentence is actually active. This could lead to surprisal, resulting in a significant drop in accuracy specifically in this condition.

4 Results

4.1 Longer reading times for passives

V-(*r*)*are* passives elicited longer median and mean reading times than V-∅ actives, especially in the verb region (R5), as shown in Table 3. As highlighted in Figure 5 in Appendix D., Bayes factor analyses indicate moderate to very strong evidence in support of the effect of voice. These results align with the previous finding of increased reading times for Japanese passives (Ogawa, 2023).

However, no significant differences in reading times were found between actives and passives in R3 and R4. Bayes factors for these regions were below 1, signifying an absence of the voice effect. Therefore, it remains inconclusive whether the parser actively predicts passive constructions upon reading the case marker =*ni*$_{\text{DAT}}$.

Interestingly, when comparing reading times of R6 between active =*ni*$_{\text{DAT}}$-verb condition and active =*o*$_{\text{ACC}}$-verb condition, the reading times were longer after active =*ni*$_{\text{DAT}}$-verbs, and Bayes factors indicate moderate evidence supporting a difference. This suggests that in the active =*ni*$_{\text{DAT}}$-verb condition, the parser may initially predict a passive structure at R3 by =*ni*$_{\text{DAT}}$ but recognise at R5 that the sentence is indeed active, leading to a delayed reanalysis at R6.

Voice	Verb class	R3: NP2 Median (Mean)	R4: ADV Median (Mean)	R5: Verb Median (Mean)	R6: Modal Median (Mean)
V-∅ active	=*ni*-verb	800 (1143.9)	664 (940.4)	823 (1088.5)	526 (696.4)
	=*o*-verb	754.5 (1069.9)	647.5 (858)	916 (1141.8)	508.5 (619.7)
V-(*r*)*are* passive	=*ni*-verb	816 (1142)	648.5 (877.1)	1120.5 (1528.7)	543 (753.8)
	=*o*-verb	752 (1101.5)	679 (977.5)	1093 (1544.4)	538 (716.3)

Table 3: Median and mean reading time (ms) by condition

4.2 Lower comprehension accuracy for passives

Figure 1 illustrates that, overall, accuracy is lower for passives compared to actives. It also shows that accuracy is higher when the voice of the target sentence matches that of the corresponding question, regardless of whether the target is active or passive. This result is strongly supported by Bayes factors, which provide moderate to extreme evidence, as shown in Figure 2.

Paolazzi et al. (2021b) discussed the increased accuracy in passive sentence comprehension when both the target sentence and the question are passive. Our results support this finding and also demonstrate that comprehension accuracy is higher when both the target and the question are active. This phenomenon, where accuracy is higher when the voice of the target sentence matches that of the question, is independent of the voice, corroborating earlier findings (Ogawa, 2023).

However, the differences between =*o*$_{\text{ACC}}$-verbs and =*ni*$_{\text{DAT}}$-verbs, regardless of voice or priming conditions, were not supported by Bayes factor analysis. In fact, the Bayes factors consistently fell below 1. Therefore, there is no significant benefit to passive sentence comprehension from the case marker itself.

5 General discussion and conclusion

5.1 Predicting a passive construction from a case marker may be difficult

Our main purpose in this study was to determine whether the human parser can predict passive constructions from linguistic elements preceding the sentence-final verb in Japanese, before confirming this by reading the verb. We hypothesized that case markers such as $=o_{\text{ACC}}$ and $=ni_{\text{DAT}}$ function as passive predictors. To test this, we conducted an SPR experiment tracking reading times and examined accuracy through comprehension questions.

The results did not provide evidence that differences in case markers lead to faster reading times or higher accuracy for passive sentences. However, similar to previous research on Japanese passives (Ogawa, 2023), we demonstrated increased reading times and lower accuracy for verbs in passives. Unlike Ogawa (2023), we found strong evidence through Bayes factor analysis for this increase in reading time. It is important to note that while Ogawa (2023) controlled for morphological complexity by using V-*te morau* benefactive passive and V-*te ageru* benefactive active, our study used pairs of V-(*r*)*are* passive and V-∅ active, which differ in morphological structure and character count. This discrepancy may have contributed to the statistically significant results. Yet, given that character count was a covariate in our statistical models, the increased reading times for passive sentences cannot be solely explained by morphological complexity or word length.

Based on previous research, which suggests that case markers preceding verbs can help the human parser predict sentence structures (Muraoka, 2006), the current reading time results could be interpreted as indicating that the case marker $=ni_{\text{DAT}}$ contributes to predicting ditransitive constructions rather than passives. This is because $=ni_{\text{DAT}}$ is used in ditransitive constructions (e.g., NP=ga_{NOM} NP=ni_{DAT} NP=o_{ACC} V), as well as passives. Therefore, the parser might find it difficult to predict passive sentences solely from the presence of $=ni_{\text{DAT}}$.

In fact, Muraoka (2006)'s results (see Figure 3 in Appendix A.) show that an accusative NP forming ditransitive sentences (211 occurrences) is predicted more frequently than a passive verb (45 occurrences) immediately following $=ni_{\text{DAT}}$. Consequently, if the human parser predicts that the sentence is a ditransitive construction upon encountering $=ni_{\text{DAT}}$ and expects an $=o_{\text{ACC}}$-NP to follow,

the presence of a passive verb (R5) would cause surprisal, as it indicates that the expected ditransitive construction is impossible. However, in the active $=ni_{\text{DAT}}$-verb condition, the reading times in R5 were as short as those in the active $=o_{\text{ACC}}$-verb condition, even that condition was also against the prediction of ditransitives. Therefore, it cannot be conclusively stated that $=ni_{\text{DAT}}$ primarily predicts ditransitive constructions. Rather, it is also possible that the case marker $=ni_{\text{DAT}}$ does not efficiently contribute to predicting either passive or ditransitives.

It is worth considering that the sentence completion task in Muraoka (2006) (which involves both comprehension and production) and the current SPR experiment (which is comprehension-oriented) might differ in their sensitivity to detecting the prediction of elements that follow $=ni_{\text{DAT}}$. Future SPR experiments comparing reading times of the regions following $=ni_{\text{DAT}}$ in ditransitive and passive sentences could provide a more precise understanding of the case marker's role in the prediction during sentence comprehension.

5.2 Priming influences comprehension accuracy for both passives and actives

Regarding accuracy for passive sentences, we observed a robust priming effect: accuracy was higher when the voice of the target sentence matched that of the corresponding question, regardless of whether the target was active or passive. Despite this priming effect, overall comprehension of passive sentences remained lower compared to active sentences.

As shown in Figure 2, Bayes factor analyses indicated that there was no difference between the effect of voice match versus voice mismatch within actives and the effect of voice match versus voice mismatch within passive sentences (i.e., no significant interaction between target voice and priming). This suggests that both actives and passives are equally error-prone when the voice of the target sentence and the comprehension question differ.

Previous structural priming research using SPR experiments has shown that a less frequent construction is more primable (Wei et al., 2016). Given that passives are less frequent than actives in Japanese (Aoyama, 2023), passives would be more primable, leading to a larger difference in accuracy between voice-matched and voice-mismatched conditions for passives compared to actives. However, Ogawa (2023)'s experiment comparing benefactive passives and benefactive actives found that both constructions were error-prone when there was a voice mismatch, and our experiment replicated this finding. Therefore, these studies suggest that, contrary to previous research, the priming effect may be more robust than construction frequency.

Acknowledgements

I extend my sincere gratitude to Kei Furukawa, Chuyu Huang, Takeshi Kishiyama, and Itsuki Minemi for their insightful discussion. Their feedback significantly enhanced the clarity of the current paper. I am also heavily indebted to Yue Teng for improving the usability of my PCIbex application. The author affirms that this acknowledgment is expressed with the prior consent of all the aforementioned colleagues.

Research funding for this study was provided by Grant-in-Aid for JSPS Fellows Grant Numbers JP19J21705.

Lastly, I wish to express my appreciation to all participants who engaged in the experiment.

Appendix C. Contrasts to code explanatory variables and priors used in the current study

Reading time

Our key explanatory variables for reading time data are the following three factors: the target voice (V-

$\emptyset$ active versus V-(*r*)*are* passive) and the verb class difference for each target voice (=ni_{DAT}-verbs versus =o_{ACC}-verbs in active voice [active.o.vs.ni], and =ni_{DAT}-verbs versus =o_{ACC}-verbs in passive voice [passive.o.vs.ni]). We sum-coded the target voice, and for each target voice, we coded the verb class difference using nested sum contrast: =ni_{DAT}-verbs versus =o_{ACC}-verbs in active voice (active.o.vs.ni), and =ni_{DAT}-verbs versus =o_{ACC}-verbs in passive voice (passive.o.vs.ni), as shown below.

$$\text{voice} = \begin{cases} 1 & \text{(passive)} \\ -1 & \text{(active)} \end{cases}$$

$$\text{active.o.vs.ni} = \begin{cases} 1 & \text{(active =}ni_{\text{DAT}}\text{-verb)} \\ 0 & \text{(passive verbs)} \\ -1 & \text{(active =}o_{\text{ACC}}\text{-verb)} \end{cases}$$

$$\text{passive.o.vs.ni} = \begin{cases} 1 & \text{(passive =}ni_{\text{DAT}}\text{-verb)} \\ 0 & \text{(active verbs)} \\ -1 & \text{(passive =}o_{\text{ACC}}\text{-verb)} \end{cases}$$

According to prior predictive checks, we used the following priors for target voice and the verb class difference for each target voice: $\text{N}(0, 0.5)$, $\text{N}(0, 0.25)$, $\text{N}(0, 0.1)$, $\text{N}(0, 0.075)$, $\text{N}(0, 0.05)$, $\text{N}(0, 0.025)$, $\text{N}(0, 0.01)$, $\text{N}(0, 0.0075)$, $\text{N}(0, 0.005)$, $\text{N}(0, 0.0025)$, $\text{N}(0, 0.001)$. Table 4 shows priors for other parameters.

Coefficient	R3: Second NP	R4: ADV on action	R5: Verb	R6: Modal particle
Intercept	$\text{N}(6.7, 0.1)$	$\text{N}(6.5, 0.2)$	$\text{N}(6.9, 0.2)$	$\text{N}(6.3, 0.1)$

Abstract

A Sign Language Translation (SLT) model is one example of a large-scale model, resulting from the use of video dataset and deep learning models. For practical use of the Deaf community, SLT models are meant to be eventually deployed on mobile devices, for instance. However, large-scale models entail high resource requirements from mobile devices with limited capacity. Tiny Machine Learning (TinyML) is a rapidly emerging field that can condense large-scale models for deployment on low-resource devices. By leveraging TinyML techniques, this research refines an adapted 2D Convolutional Neural Networks (CNN) and Transformer Neural Networks (TNN) model by Camgoz et al. (2020). The teacher model is trained on the 2D CNN and TNN model using the Filipino Sign Language - Non-manual Signals (FSL-NMS) dataset by Rivera and Ong (2018b). Through knowledge distillation, the student model achieved 45% higher BLEU-4 score compared to the teacher model, and a 5.4 compression ratio. These results highlight the potential of knowledge distillation techniques on compressing and improving SLT models. This work paves the way for the development of more accessible communication tools for the Filipino Deaf community and non-signers.

1 Introduction

Sign Language Recognition (SLR) often requires multi-modal large-scale models that converts videos into words, phrases, or sentences. Continuous SLR (CSLR) is a further improvement of SLR which interprets multiple sign language gestures without delineation between gestures. These CSLR models, however, typically require a vast amount of data to train to achieve high accuracy. This makes most CSLR models more complex and larger compared to isolated SLR models (Zhou et al., 2022). Another model that aims to develop a more robust approach for translating sign language videos to text that learns the grammar and morphology of the sign language is a Sign Language Translation (SLT) model. However, state-of-the-art SLT models are trained on large datasets using deep learning techniques, also often resulting to larger models.

The main goal of SLT models is to help the Deaf community, thus it should be deployed eventually to be used. A few FSL-related applications are interpreters that are mostly used for learning FSL (e.g. Senyas by (Alberto et al., 2022), and 3D animation of Aesop's Fable by (Cueto et al., 2020)). These are manually translated FSL signs to text, and vice versa, that may benefit from automatic translation systems.

As several studies have shown isolated Filipino CSLR models performing with over 90% accuracy (shown in Section 2.1), and SLT studies reaching a BLEU-4 of over 20 as demonstrated by Camgoz et al. (2020), it is about time to also consider the possibilities of deployment to reach the intended users. However, all of these studies produced large models which entail high resource requirements on mobile devices with limited capacity. This makes deep learning applications difficult to deploy on mobile devices (Wang et al., 2018).

TinyML is a growing sub-field of machine learning that is dedicated to run Artificial Intelligence (AI) algorithms on devices with limited resources, without needing heavy computation or internet connectivity. It minimizes dependability and latency issues. Additionally, it provides enhanced privacy by reducing the need to send personal data to the cloud (Kallimani et al., 2023).

Several TinyML applications include detection of eating habits (Nyamukuru and Odame, 2020), and detection of medical face mask (Mohan et al., 2021). In addition, TinyML has already been explored in various fields such as audio analysis (e.g. audio wake words (Zhang et al., 2017)), image recognition (e.g. visual wake words (Chowdhery et al., 2019), gesture recognition (Amir et al.,

2017)), psychological/behavioral metrics (e.g. activity detection (Hassan et al., 2018)), and industry telemetry (e.g. anomaly detection (Koizumi et al., 2019)) (Dutta and Bharali, 2021).

This work utilizes TinyML techniques to condense a large-scale model for Filipino Sign Language (FSL) to a lightweight and efficient model that can potentially be deployed on a variety of devices, including smartphones, wearable devices, and even embedded systems.

FSL is a mode of communication by the Deaf community in the Philippines. According to Newall et al. (2020), approximately 15% of Filipinos suffer from moderate to severe hearing impairment. By developing innovative TinyML-powered FSL tools, there is an opportunity to enhance communication avenues for the Filipino Deaf community. This is important for promoting inclusivity, as well as enabling their fuller engagement in a variety of social activities.

The rest of this paper is organized as follows. Section 2 enumerates works related to TinyML and FSL. Section 3 describes the characteristics and preparation of the Filipino Sign Language - Non-manual Signals (FSL-NMS) dataset (Rivera and Ong, 2018b). Section 4 discusses the methodology used in applying TinyML in Filipino SLT, wherein a 2D Convolutional Neural Networks (CNN) and Transformer Neural Networks (TNN) model by Camgoz et al. (2020) is adapted and trained on the FSL-NMS dataset for the teacher model. Section 5 reports the results and analysis of the teacher model and the student model using the BLEU scores and ROUGE metric. Lastly, the conclusions and recommendations are presented in Section 6.

2 Related Work

2.1 Filipino Sign Language Recognition

In recent years, there has been growing interest in developing deep learning-based approaches for FSL recognition. Deep learning models have the potential to learn the complex patterns in FSL signs and phrases, and to achieve high accuracy on image-based recognition tasks.

In the study of Cabalfin et al. (2012), they used Manifold Projection Learning model where signs are predicted based on the computation and comparison of Dynamic Time Warping (DTW), and Longest Common Sub-sequence Similarity Matching (LCSSM). Their dataset consists of 72 isolated Filipino signs. Their highest recognition rates using DTW are 89% on 10 signs and 40% on all 72 signs. Using LCSSM, their highest recognition rates are 93% on 10 signs 31% on 72 signs.

As machine learning techniques become more prominent, the study by Ramos et al. (2019) focused on using Support Vector Machine (SVM) and K-Nearest Neighbor (KNN) which are both classification techniques. They used Histogram of Oriented Gradients (HOG) for feature extraction on 26 isolated gestures of FSL alphabets, achieving 94.49% accuracy.

A paper by Montefalcon et al. (2021) takes this further by applying a deep learning-based approach for Filipino Sign Language (FSL) recognition using CNN architecture, specifically ResNet-50, which extracts features from static images of FSL number signs ranging from (0-9). The model achieves a validation accuracy of 86.7% when the epoch value equals 15. Similarly, their subsequent study (Montefalcon et al., 2023) proposes a continuous SLR model for FSL recognition using Long Short Term Memory (LSTM) model. MediaPipe Holistic is used to extract features from video files of 15 Filipino phrases performed by three FSL signers. The LSTM model achieves an accuracy of 94% on the test set, outperforming their previous ResNet model with an accuracy of 87%. They have indicated on their analysis that facial components affect the performances, marking it an important set of features for recognition.

A similar study by Tupal et al. (2022) utilizes MediaPipe Holistic and LSTM. Their FSL recognition models applied InceptionV3, LSTM, and Gated Recurrent Units (GRU). When trained on a dataset comprising 20 foundational FSL words with at least 20 samples each, the model, leveraging the GRU achieved the highest accuracy of 86.74%.

A different study that focuses on facial expressions in FSL is conducted by (Rivera and Ong, 2018a), wherein 3D Animation Units (AU) extracted using Microsft Kinect are used as features. SVM is also used, achieving 87.14% as the highest accuracy. However, it was emphasized that hand signs must be recognized together with the facial expressions for the model to understand the context.

Overall, all the mentioned studies make significant contributions to the field of FSL recognition. As can be seen, different approaches yield different performances. However, despite using the same approach, performances can still differ as the amount, structure, and quality of the dataset differs.

Nonetheless, although it is still hampered by the challenge of limited available datasets, the burgeoning field of FSL recognition has made remarkable progress with the aid of deep learning approaches.

2.2 TinyML

Despite the increasing studies on SLR for FSL, there is still minimal studies focusing on the possibility of deployment on, for instance, mobile devices for practical use. Deep learning approaches in FSL may have promising results, but, despite using small datasets, it results to large models that are difficult to port to mobile or wearable devices.

Recent advancements in TinyML have focused on the development and optimization of machine learning models for deployment on resource-constrained devices. These techniques aim to reduce model size, power consumption, and computational requirements while maintaining acceptable levels of accuracy.

Model pruning has emerged as a pivotal technique in TinyML, addressing the challenge of deploying neural networks on devices with stringent memory constraints.

Han et al. (2015) demonstrated that by systematically removing weights with minimal impact on the output, the size of neural networks could be significantly reduced without a substantial loss in accuracy. Complementing this, quantization has been recognized for shrinking the model's memory footprint further.

Gupta et al. (2015) showcased that converting weights and activations from floating-point to lower-precision formats not only reduces the size but also accelerates inference, making it a vital technique for TinyML applications.

Knowledge distillation is another technique that has gained traction in TinyML. Hinton et al. (2015) introduced the concept of training a smaller "student" model to emulate the behavior of a larger "teacher" model. This process effectively compresses the knowledge of a complex network into a more compact and efficient form, making it suitable for deployment on low-power devices.

The automatic discovery of efficient architectures through Network Architecture Search (NAS) has also been a recent research focus. Zoph et al. (2018) explored the use of NAS to find models that are not only accurate but also computationally efficient for TinyML. This approach leverages the power of machine learning itself to design architectures that are tailored for performance on resource-constrained devices.

The convergence of machine learning and embedded systems is at the heart of TinyML. Warden and Situnayake (2019) emphasized that the goal of TinyML is to enable the deployment of AI in environments where traditional models would be impractical. By leveraging techniques like model pruning, quantization, knowledge distillation, and NAS, TinyML seeks to make AI ubiquitous, extending its reach to the most resource-constrained environments.

3 FSL-NMS Dataset Preparation

The dataset used in this study is the Filipino Sign Language - Non-manual Signals (FSL-NMS) dataset by Rivera and Ong (2018b). It is originally used for studying the different types of facial expressions in FSL.

The dataset contains a total of 50 sentences, featuring a broader array of signs and more specific emotions, including common phrases such as 'thank you' and 'good morning'. Among these are expressions like 'I am proud of you!' and 'Our team won!', as well as more complex sentiments like 'I am heartbroken' and situation-specific statements such as 'I saw a ghost.' Additionally, the dataset included various questions and time-specific greetings, enhancing its diversity and applicability in different contexts.

The dataset incorporated five videos, each featuring a different signer who sequentially signed the 50 sentences. The group of signers included three females and two males, providing a variety of signing styles and body languages. This diversity is crucial in enriching the dataset's value. These videos are then carefully edited and trimmed to ensure each sign is clearly presented, with each sign tailored to showcase a specific sign for about five seconds, totaling to 250 videos.

3.1 Data Annotation

The model used in this study (to be discussed further in Section 4.1) requires gloss translations (e.g. you how), in addition to the sentence translations (e.g. How are you?). Gloss translations are literal translations of each sign as it appears to its equivalent word or phrase, while sentence translations follow the English grammar. Since the dataset is created for the study of facial expressions, it initially did not include glosses, necessitating the annotation of glosses for the 50 sentences. Some

Words/Sentence	# of Sentences	
	Original	Augmented
1	0	0
2	15	111
3	115	777
4	85	518
5	30	222

Table 1: Distribution of Sentence Lengths in the FSL-NMS Dataset before and after Augmentation

entries were unintentionally skipped, while some have similar glosses that are only differentiated by facial expressions. This reduced the dataset to a total 44 sentences with unique gloss annotations. Refer to Appendix A for the complete list of gloss annotations.

The FSL-NMS dataset consists of a total of 245 samples, with the distribution of sentence lengths (n-grams) shown in Table 1.

3.2 Dataset Augmentation

As the dataset is particularly small for training a CNN-based SLT model, data augmentation is used to increase the diversity and volume of training data. This is crucial in enhancing the robustness of the model against various visual and environmental conditions. The FSL-NMS dataset, originally consisting of 245 samples, is expanded through mirroring, shifting and padding, adding noise, adding minimal motion to mimic jitters, and color adjustment, such as converting the videos to greyscale. The augmentation helped simulate a wider range of signing scenarios, thereby preparing the model to perform reliably in diverse settings.

After augmentation, the FSL-NMS dataset consists of a total of 1628 samples, distributed as shown in Table 1.

3.3 Sentence Distribution

The distribution of the sentences across the train, development, and test sets follows the 70-15-15 ratio, respectively. This structured allocation extends to each individual sign translation, ensuring that the counts of each sign are proportionately split according to these percentages across the different sets. This approach ensures a balanced representation of each sign in every subset, which is crucial for preventing model bias towards over-represented signs in any particular set.

4 TinyFSL Model

This study adapted a transformer-based architecture for an end-to-end training of a combination of CSLR and SLT model using the FSL-NMS dataset (Rivera and Ong, 2018b). Due to the complexity of the adapted model, knowledge distillation is applied to compress it to a lightweight and efficient model. Knowledge distillation is a technique where a smaller and more computationally efficient model (the 'student') is trained to approximate the performance of a larger, more complex model (the 'teacher') by learning from the teacher's outputs (Hinton et al., 2015). The basic architecture of knowledge distillation is illustrated in Figure 1.

4.1 Teacher Model Training

A 2D Convolutional Neural Networks (CNN) and Transformer Neural Networks (TNN) model by Camgoz et al. (2020) is adapted in this study. It is a transformer-based architecture that combines CSLR and SLT, and allows training in an end-to-end manner. To produce the teacher model, it is trained using the augmented FSL-NMS dataset. It has two parts: sign to gloss recognition, and gloss to text translation.

In the sign to gloss recognition, Squeezenet (Iandola et al., 2016) is first used to embed video frames. Second, these spatial embeddings are positionally encoded and then fed to the self-attention layer of the sign to gloss recognition part to learn the contextual relationship between frames. Lastly, the output of the self-attention layer is passed through a feed forward layer that produces the spatio-temporal representations.

In the gloss to text translation, a linear layer is first used embed the words of the target sentence. Second, these word embeddings are positionally encoded, and then fed to a masked self-attention layer of the gloss to text translation part to extract contextual information. The self-attention layer is similar to the one utilized in the sign to gloss recognition part, but it is masked to ensure that context was only modeled between previous words. Third, the extracted representations are combined with the spatio-temporal representations previously learned from the sign to gloss recognition. It is then given to the encoder and decoder module that learns the mapping between the video frames and the output text. Lastly, the output of the encoder and decoder module is passed through a feed forward layer that learns to generate one word at a time

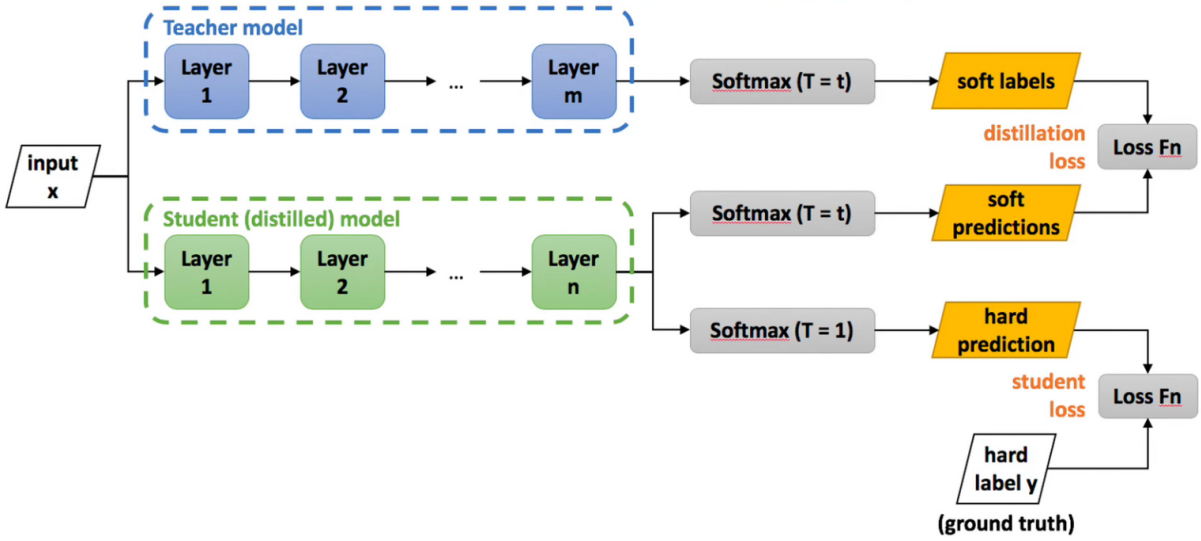

Figure 1: Knowledge Distillation Architecture (Sachdeva, 2023)

until it produces an <EOS> token which signifies the end of a sentence.

For this study, a dimension size of 512 and Xavier initialization (Glorot and Bengio, 2010) is used for both the spatial and the word embeddings. Three transformer layers with 8 heads each are used for the encoder and decoder, while the feed forward layer has a size of 2048. This teacher model is trained using the augmented FSL-NMS dataset (Rivera and Ong, 2018b) and has served as the foundation for distilling knowledge to the student model.

The teacher model, with its greater capacity, is initially trained on a given task, producing "soft targets", which are the output probabilities that contained nuanced information about the inter-class relationships learned by the model. A key aspect of the soft targets generation process is temperature scaling, which is introduced via a temperature parameter T in the softmax function. This parameter controls the "softness" of the probability distribution over classes. A higher temperature can lead to a softer distribution, which is crucial for aiding the student model's learning from the teacher's outputs (Hinton et al., 2015).

Utilizing the trained teacher model, soft targets are generated by processing the dataset through the teacher model and applying temperature scaling to the softmax function as shown in Equation 1, where q_i is the softened probability for class i, z_i is the logit for class i, and T is the temperature parameter.

$$q_i = \frac{\exp(z_i/T)}{\sum_j \exp(z_j/T)} \quad (1)$$

These softened probabilities provided a richer signal than hard labels alone, allowing the student model to learn more effectively.

4.2 Student Model Design and Training

Designing the student model involved determining the appropriate architecture that balanced performance with computational efficiency. Inspired by the success of TinyBERT (Jiao et al., 2020), where the student model contained 4 and 6 layers compared to the teacher model's 12 layers, the study proposed starting with a student model with approximately 30% of the teacher model's layers. This served as a starting point, and the architecture could be adjusted iteratively based on empirical performance.

With that, the student model's architecture is adjusted from the teacher model's 3 layers to the student model's 2 layers. Additionally, the student model's embeddings and hidden sizes are reduced from 512 to 256, and the feed-forward size is reduced from 2048 to 1024, all aimed at simplifying the student model while maintaining performance. The difference between the student and teacher model is summarized in Table. 2.

The student model is trained on the same dataset. It is trained not only on the hard targets (the actual labels) but also to mimic the soft targets produced by the teacher model. This is achieved through a

	Teacher	Student
Layers	3	2
Embedding Size	512	256
Feedforward Size	2048	1024

Table 2: Number of Parameters for the student and teacher model

loss function that combined the traditional loss (i.e. cross-entropy with the hard targets) with a distillation loss that measured the discrepancy between the soft targets of the teacher and student models (Hinton et al., 2015). The traditional cross-entropy loss is shown in Equation 2, where y_i is the true label and p_i is the predicted probability for class i.

$$L_{CE} = -\sum_i y_i \log(p_i) \tag{2}$$

The distillation loss is often computed using the Kullback-Leibler divergence between the softened outputs of the teacher and student models, which is defined as shown in Equation 3, where q_i^T and q_i^S are the softened probabilities for class i from the teacher and student models, respectively.

$$L_{KD} = \sum_i q_i^T \log\left(\frac{q_i^T}{q_i^S}\right) \tag{3}$$

The overall loss function is a weighted sum of the traditional loss and the distillation loss, shown in Equation 4, where α is a hyperparameter that balanced the two loss components, and T^2 is a scaling factor for the distillation loss.

$$L = \alpha L_{CE} + (1-\alpha)T^2 L_{KD} \tag{4}$$

4.3 Hyperparameter Tuning

Optimizing the student model's performance hinged on the careful tuning of hyperparameters. Key parameters such as temperature, hard label weight, and the loss weight for different types of knowledge are crucial in refining the distillation process (Lu et al., 2022).

Grid search is initially applied with the original dataset (i.e. no data augmentation performed yet) to find the optimal combination of temperature (T) until the highest performance is achieved on the validation set. The initial values of the temperature range from 1.5 to 3.0 with an interval of 0.5, while the alpha is set to 0.5. The search was not started from $T = 1$ anymore as it indicates no temperature scaling at all. The initial results indicated the top three T for further analysis are 1.5, 2.5, and 3. These values are then used for training on the augmented dataset.

After the temperature yielding the highest performance is determined, grid search is applied with the augmented dataset to find the optimal alpha (α). The values of α range from 0.3 to 0.7 with an interval of 0.2. This method provided a practical yet effective means of hyperparameter tuning.

The student model is iteratively trained with different values of T and α, then its performance is evaluated on the validation set. The combination of T and α that yielded the highest performance is then selected for the final student model.

4.4 Evaluation and Iteration

The teacher and student model's performances are evaluated using separate test sets. The Bilingual Evaluation Understudy (BLEU) metric is used for evaluation to measure the quality of machine-translated output. The ROUGE metric is also employed to measure the recall of the student model.

The results of the teacher and student model are then compared to analyze the impact of the proposed knowledge distillation methods. If the performance, measured by both BLEU and ROUGE, did not meet the desired criteria, iteration on the previous steps and refinement of the student model's architecture and hyperparameters are re-conducted.

5 Results and Discussion

Significant adjustments are made to adapt the student model for efficiency. This included reducing the number of layers, embedding size and hidden layer sizes of the student model compared to the teacher model. These modifications aim to create a model with reduced capacity, optimizing it for efficiency while striving to maintain performance levels of the translation. The performance of the translation model is measured by using BLEU and ROUGE, while model compression is measured by using compression ratio.

5.1 BLEU and ROUGE Performances

As shown in Table 3, the combination of the hyperparameters $T = 3, \alpha = 0.5$ yielded the highest BLEU and ROUGE scores among the top three combinations from the hyperparameter tuning that is initially performed on the original dataset. In line with this, further experiments are conducted with the nearby hyperparameters, $T = 3, \alpha = 0.3$

Model	T	α	Set	BLEU-1	BLEU-2	BLEU-3	BLEU-4	ROUGE

Table 3: BLEU and ROUGE Scores of the Student and Teach Models on the developement set (DEV) and test set (TEST) using different T and α. BLEU-n scores reflect the model's precision in matching n-grams to reference translations from single words (BLEU-1) to four-word phrases (BLEU-4). ROUGE assesses recall, showing how well the model captures the reference's n-grams.

and $T = 3, \alpha = 0.7$ focusing on α, as well as increasing the temperature to $T = 3.5$ with $\alpha = 0.5$ to explore potential improvements. These explorations aimed to determine if a slight adjustment in α or an increase in T would enhance model performance even further.

The combination of $T = 3, \alpha = 0.5$ performed better in terms of BLEU scores across the different combinations tested and compared to their respective teacher models' results. The utilization of temperature T in the softmax function for knowledge distillation is pivotal in the experiments. A higher T led to a softer probability distribution, crucial for effective knowledge transfer from the teacher model to the student model. This is particularly evident in the improvements in BLEU scores with $T = 3$, demonstrating that a softer distribution can enhance learning in more complex configurations.

The cumulative BLEU score provides a single, comprehensive measure of translation quality. As shown in Table 3, the student model exhibits higher cumulative BLEU scores across all n-gram levels compared to the teacher model, indicating a more robust performance. Its BLEU-1 (BLEU for 1-gram) score of **25.61** in the TEST set suggests a more effective word matching, while its BLEU-4 (BLEU for 4-gram) score of **14.84** shows stronger performance in generating accurate four-word sequences compared to the teacher model.

Both the teacher model and the student model demonstrate strong performance with more frequent and shorter n-grams, particularly 1-grams and 2-grams. The teacher model is able to correctly predict the following words across different sentences: 'i', 'am', 'you', 'are', 'so', 'slow', 'not', 'fine', 'shocked', 'my', 'worried', 'nervous', and 'tired'. The student model is able to correctly predict the same set of words except 'my', but with the addition of the following words: 'old', 'proud', 'of', '12', 'years'. Majority of these words have higher frequency across different sentences. Sentences with a combination of these words also has higher accuracy than sentences that are composed of words that do not frequently appear in the dataset. This explains why its accuracy diminishes as the n-gram length increases, indicating a need for further training and exposure to a broader variety of sequences. Incorporating more diverse and complex n-grams into the training dataset could improve the model's robustness and accuracy across different n-gram lengths.

The better performance of the student models compared to the teacher model, as observed in the experiments, can be traced back to several factors integral to the distillation process itself. First, knowledge distillation efficiently transfers "soft target" from the teacher to the student model, not only reducing over-fitting, but also acts as a form of regularization, optimizing error learning from the teacher model and preventing the student from becoming too confident prematurely. Second, the student model inherits robust features from the teacher,

facilitating a more streamlined learning process. Third, the student models often show enhanced adaptability to specific tasks or datasets, thanks to tailored adjustments like the softmax temperature, focusing learning on task-relevant aspects of the data. These collective advantages contribute to the distilled models' improved performance in terms of accuracy, robustness, and efficiency, underlining the value of knowledge distillation in resource-constrained environments.

5.2 Compression Ratio

While the translation performance of the student model showed favorable results compared to the teacher model, it is also important to measure the compression ratio. This can show if the model size is reduced, while maintaining performance.

Results revealed a significant reduction in the model size from the original teacher model to the compressed version, the student model. The file size of the teacher model is 320.98 MB, It represents a baseline for performance but is impractical for deployment in memory-limited environments. In contrast, the student model is compressed to 59.33 MB. This indicates a **5.4** compression ratio, indicating effective compression without compromising the model's utility.

This drastic reduction showcases the potential of advanced model compression techniques, such as quantization and pruning, which are essential for deploying deep learning models on mobile and embedded devices.

6 Conclusions and Recommendations

This research marks a significant breakthrough in Filipino Sign Language (FSL) recognition and translation, employing Tiny Machine Learning (TinyML) to refine and enhance a sophisticated model that integrates 2D Convolutional Neural Networks (CNN) and Transformer Neural Networks (TNN) trained on an FSL dataset of sentences. The potential of TinyML techniques, specifically knowledge distillation, in compressing and improving a large-scale model is shown in the comparison of the teacher and student model performances in terms of BLUE and ROUGE scores, and compression ratio.

The student model achieved a BLEU-4 score of 14.84 and a ROUGE score of 24.46, which is 45% and 5% higher than the teacher model respectively. Although the highest BLEU-4 score of the original 2D CNN and TNN model by Camgoz et al. (2020) adapted in this study is 21.59, the performance of our model is still promising given the use of a relatively small dataset. The augmented FSL-NMS dataset (Rivera and Ong, 2018b) used by our model comprises of 1628 samples which are composed of 2 to 5 words each, while the Phoenix14-T dataset used by Camgoz et al. (2020) comprises of 8257 samples which are composed of 1 to 52 words each. As mentioned in Section 2.1, use of larger datasets can possibly lead to better performances in translation. For an SLT task, the model would benefit more from longer and continuous sentences, as it can learn the context and morphology of the language.

Aside from improved performances in translation, its capability in condensing a large-scale model is evident as the student model has reached a 5.4 compression ratio, with respect to the teacher model. As there are other TinyML techniques as enumerated in Section 2.2, there are still a lot of room for improvements. This study opens the opportunities for future enhancements and deployments of SLT models on mobile, and wearable devices. Looking ahead, this lays a solid foundation for future technological enhancements and deeper integration of the Deaf community into the societal fabric, underscoring the profound societal benefits of inclusive technology.

Acknowledgments

This research is funded by DOST-PCIEERD Project No. 1211355 in cooperation with DLSU-RGMO (Project No. 24N 2TAY22-3TAY23.) and DLSU-Science Foundation, Philippines.

The authors would like to extend their appreciation to Juls Andrada and Joi Villareal for the dataset annotation, and the De La Salle University-College of Computer Studies for providing the tools and facilities.

A Gloss Translations of the Sentences from FSL-NMS

The complete list of sentences and its corresponding gloss translations from the FSL-NMS dataset is shown in Table 4. Gloss translations are literal translations of the word or phrase as they appear when signed, separated by a space. This do not follow the English grammar yet.

Sentences	Glosses
John likes Mary.	john likes mary
You are sick.	you sick
Is it new year?	new fireworks
How are you?	you how
How old are you?	age you how much
You are sick!	you sick
I am fine.	fine
I am 12 years old.	old 12 year
Does john like Mary?	john like mary
Happy new year!	happy new fireworks
Good morning!	good morning
Good noon!	good noon
My head is not painful.	headache not
I do not like you.	not like you
I am not tired.	not tired
You are not slow.	you not slow
This is not hard.	not hard
My head is painful.	headache
I like you.	like you
I am tired.	tired
You are slow.	slow
This is hard.	hard
My head is very painful.	headache very
I like you very much.	like you very much
I am so tired.	much tired
You are so slow!	you much slow / much slow
This is very hard.	much hard
I hate you!	hate
You are disgusting!	disgusting
I am scared.	scared
I am nervous.	nervous
I am worried.	worry
I am shocked!	shocked
I saw a ghost.	ghost
Thank you.	thank you
The trip is exciting.	trip exciting/joyful
The show is amazing.	show amazing
I am proud of you!	proud you
Our team won!	class/group win
I am sorry.	sorry
My dog died.	dog die
I am alone.	alone
I am heartbroken.	heartache
I failed the exam.	fail exam

The language of police reports: A forensic linguistic analysis

Marvin C. Casalan
University of Antique

Abstract

Police reports are crucial supplemental papers that are part of the criminal justice system in the Philippines. When used as evidence and a source of information in prosecution, these narratives should be written clearly, accurately, and y, and factually. Therefore, the process of how police reports should be written is deemed beneficial to some professionals. This paper analyzes, understands, and describes the linguistic features and organizational structure of police reports, specifically the blotter, incident, after-operation, and investigation reports, taken from the pre-selected police stations in the Philippines. In order to attain its objectives, a qualitative content analysis approach is utilized. The general structure of the police reports is analyzed in this research utilizing Swales, J. (2004) framework on moves and Coulthard and Johnson's (2007) idea on forensic linguistics. The results show that legal text has its own convention. This kind of narrative also contains unique linguistic features, and these lexical features have uncommon meanings. In the end, pedagogical implications in the teaching and learning process are presented, and further studies using legal texts are recommended.

1 Introduction

1.1 Background of the Study

The application of language within legal frameworks has a historical presence, yet the systematic examination of forensic linguistics started to take shape during the 1960s and 1970s (Olsson, 2004). Shuy (1998) notes that a significant early advancement in forensic linguistics was the focus on authorship attribution, which began to receive increased attention with the introduction of innovative methods for analyzing linguistic characteristics.

Forensic linguistic casework and research have seen significant expansion, reflected in the growth of language and law studies an increase in published books and articles, and a rise in the number of linguists acting as expert witnesses globally. The studies illustrate the progression of methodologies and the varied applications of forensic linguistics within the legal field, underscoring its importance in improving the precision and dependability of legal proceedings.

Numerous academics have viewed linguistics' contributions to three domains such as spoken legal practices, written legal texts. For instance, Danielewicz-Betz (2012) analyzed the role of forensic linguistics in criminal investigations, judicial processes, and legal conflicts. The study highlights the efficacy of linguistic analysis in the interpretation of legal texts and courtroom dialogue. Meanwhile, Levi and Walker (1990) examine the reflection of power through language in legal contexts, specifically regarding the linguistic practices of legal professionals and defendants.

Another notable discussion regarding forensic linguistics was presented by Leonard, Ford, and Christensen (2017). The study examined the application of linguistic science within legal contexts, focusing on authorship analysis and trademark infringement cases. Their research demonstrates the practical application of linguistic expertise in diverse legal contexts. The studies mentioned illustrate the developing methodologies and varied applications of forensic linguistics within the legal field, emphasizing its importance in improving the exactitude and reliability of legal processes.

Forensic linguistics is a branch of applied linguistics, which involves with language as evidence and use the application of linguistic knowledge, methods, and insights to areas like criminal investigations, court cases, and trials.

One notable work on forensic linguistics was done by Vijayan (2015). His paper highlighted the significance of forensic linguistics in evaluating statements and confessions, particularly for law enforcement and criminal investigation agencies in India. He emphasized that the role of language in efficiently resolving cases should be prioritized.

Forensic linguistics has proven to be valuable in many court cases globally. For example, Shuy's (2014) book The Language of Murder Cases: Intentionality, Predisposition, and Voluntariness explores how analyzing the language used by suspects, defendants, law enforcement, and lawyers can help clarify unclear legal terminology. He looks into smaller language components including syntax, lexicon, and phonology as well as speech events, schemas, agendas, speech actions, and conversational strategies. He emphasizes how these variables can have a big impact on how murder cases turn out. Shuy explores how language functions in each case, drawing on his own testimony in fifteen high-profile murder trials. Ultimately, he concludes by discussing how his analyses were interpreted by juries grappling with the often unclear concept of reasonable doubt.

Considering the above premise, one interesting legal data point worth studying using a forensic linguistics framework is police reports.

A police report is a written account of a crime, incident, or series of events (Harris, 2013). Although a witness may occasionally give an account of the incident, the victim or complainant usually visits the police station to report and explain what happened. After that, police draft a report to start an inquiry. When the lawyer files charges against a suspect, the prosecutor's office may utilize this report as the basis for additional investigation.

Like all other government workers, police officers must fill out a variety of forms and documentation. One example of such a document is the police report, which serves several functions and needs to contain accurate, thorough, and instructive information on a crime or incident.

It is a considerable claim that at the moment, there is a dearth of research and literature on the linguistic features and overall structure of police reports. Conducting research through the lens of forensic linguistics can therefore provide new insights and expand existing knowledge about the structure of police reports. It is from this crucial perspective that the researcher chose to undertake the present study, hoping to contribute to the understanding of how the language of police reports is formulated based on its features, rhetorical moves, and its implications for teaching and learning process.

1.2 Significance of the Study

Police reports are essential and crucial supplementary documents required by those involved in the criminal justice system especially in the Philippines. An accurate and clear police report is important evidence and a source of information in prosecution, if any. Therefore, being aware of the convention of how police reports should be written is essential to those who are concerned for writing them as well as to the pre-service police officers.

The academic community can benefit from this study, particularly the professor covering grammar and technical writing for criminology students. The students will be aware for the students of what suitable language should be used in making police reports. They will also be coached on the organization of the police reports. Furthermore, helping to clarify the nature of police reports and their variations from other forms of technical reports will be this study. Moreover, this work will add to the body of knowledge since, in the field of forensic linguistics, there are a few studies applying law enforcement data as issues.

1.2 Research Questions

The goal of this research paper is to analyze and describe the overall structure of police reports as well as the language features of the written reports from the two police stations in the Province of Antique, Philippines. The following questions are the focus of the paper:

1. How is a police report structured?
2. What linguistic details do police officers typically observe when writing reports?
3. What pedagogical implications can be drawn from the analyzed police reports?

1.3 Theoretical Framework

The move structure concept of Swales (2004) is followed in this work. According to Swales, a genre move is a discursive or rhetorical unit that serves a unified communicative purpose in spoken or written communication. The move framework served as foundation of this paper, which is defined by Richard and Schmidt (2002) as a discourse unit that can be smaller than an utterance. The paper is based on the definition of forensic linguistics provided by Coulthard and Johnson (2007), which is the application of linguistic knowledge, techniques, and analysis to legal concerns.

2 Methodology

2.1 Research Design

In this study, a qualitative content design was used. According to Creswell (2014), a qualitative approach involves doing research such case studies, focus groups, and interviews. Schreier (2012), on the other hand, explains content analysis as a qualitative technique for interpreting and analyzing text and its meanings (Braun & Clarke, 2006). Content analysis will help the reader comprehend the linguistic aspects of police reports by coding and classifying information found in the data. It is appropriate to apply the method while examining police report structure because qualitative analysis entails finding themes, patterns, or categories in the material that has been gathered.

2.2 Research Materials

This study used 10 police reports as the corpus of the paper for analysis. These legal texts were obtained from two police stations in the province of Antique, Philippines. The said police offices are located in the central part of the province. One is considered the smallest town having 11 barangays in terms of population and land area. The other one is known for its wider police jurisdiction, having 36 barangays.

The types of reports utilized in this study include blotter, incident, after-operation, and investigation reports. The researcher selected these specific reports based on the documents provided by police officers, considering that some reports contain sensitive information that may be used in legal proceedings. It should be noted that the research was dependent only to the data provided by the police office. To obtain the necessary copies for the study, the researcher engaged with three different police officers over several days. This inclusion criterion was chosen because these police reports are relatively recent, reducing the likelihood of structural discrepancies, particularly since the study does not involve a diachronic analysis. The ten police report adequately offer a thorough understanding of the research topic, provided that the data allows for meaningful analysis of patterns, themes, and relationships (Guest, Bunce, & Johnson, 2006).

2.3 Sample Selection

Before conducting the analysis, the researcher followed a systematic procedure for data collection. First, he secured a permission letter to the Chiefs of Police at the target police stations within the province requesting access to police reports. He also explained what are the police reports for and the purpose of the study. Second, upon securing the permission, he requested copies of police reports from the investigators of the stations that could be used as part of the research corpus. He then selected the cases that met the inclusion criteria for analysis. Finally, he assured the investigators and Chiefs of Police that all files would remain confidential and that any identifying information, such as names and locations, would be anonymized.

2.4 Ethical Consideration

To observe the ethical protocols required to conduct research, the researcher secured approved permission letters from the heads of police stations before obtaining 10 police reports. The study analyzed police reports, particularly their linguistic features and structures, for academic purposes. In analyzing the data, names, organizations, and institutions involved in the incidents were sanitized. Meaning to say, they removed and replaced by codes instead. The original reference numbers of 10 police reports were changed, and the researcher chronologically assigned numbers to each report as a code of reference. Through these procedures, ethical consideration is observed.

2.5 Data Analysis Procedure

The researcher used the following steps to achieve the study's objectives: First, the researcher formulated research questions. Second, a sample for content analysis was chosen from the collected police reports. Third, the data set was used to create content categories. Fourth, the analytical units were decided upon. For this paper, a sentence is considered as one unit. Fifth, to confirm the accuracy of the findings, the researcher employed an intercoder to carry out the coding procedures and results. The researcher's colleague, serving as an intercoder, holds a master's degree in English Language and teaches a technical writing course to Criminology students. The final step in the analysis process involved completing the content analysis procedures. These procedures included: (a) identifying the relevant data from the police reports in alignment with the research questions; (b) analyzing the linguistic elements, rhetorical devices, and structural steps within the reports; (c) summarizing and interpreting the findings; and (d) drawing conclusions based on the findings.

3. Results and Discussion

3.1 The Structure

Writing police reports has the moves and steps which make up their overall structure. Their rhetorical moves are examined in this study. This section of the paper provides a thorough analysis of the structure of the police reports considered in the study based on the collected data. It should be noted that the "investigation reports," which are utilized in the prosecution process, are the subjects in this part of the analysis of the paper. It is for the reason that this type of police report provides more thorough information than other report types.

Move 1 - *Identifying and establishing the jurisdiction of the Police Report*

This move seeks to identify the police office where the report and related circumstances are archived. This action includes information on the police report's date, subject, source, and recipient. The primary objective of this move is to offer insight into the location of the production of the police report as a genre. The following procedures can be used to identify this move:

Step 1: Determining the location of the institution

Republic of the Philippines
NATIONAL POLICE COMMISSION
PHILIPPINE NATIONAL POLICE
ANTIQUE PROVINCIAL POLICE OFFICE
******** MUNICIPAL POLICE STATION***
******, Antique*

The example provided above is consistent across all the data used in the study, with the only variation being the police station from which the report originates. The institution, municipality, and province name appear at the top of the police report, as the sample illustrates. The same results can be found in the work of Sumaljag, 2018.

Step 2: Indicating the recipient, source, subject, and date of the written report

MEMORANDUM
FOR : The Provincial Director
Antique Police Provincial Office
******, Antique*
FROM : Officer-in-Charge
SUBJECT : Investigation Report on Direct Assault upon an Agent of Person in Authority and Slight Physical Injuries
*DATE : *****, 2018*

(PR8)

In the above example, the recipient, sender, subject, and the date of the report are stated. This step of Move 1 indicates who is concerned involved in the process. Specifically, it identifies who sends and who receives the document. This step is present in all of the investigation reports.

Move 2 - *Categorizing the facts and their circumstances*

The police officer who is responsible for doing the reports has to gather the facts and their circumstances from the complainant, victim, or witness. After hearing the details from the complainant/victim/witness, the police officer has to analyze the details of the circumstances and compare them based on the described human behavior found in the criminal code. The said process aims to check if the human behavior performed by the victim matches any one of the behaviors stipulated in the said code. There are two steps in order to achieve this move.

Step 1: Establishing the legal or technical classification

AUTHORITY
OIC's Verbal Instruction
Standard Operation Procedure (SOP)

(PR7)

The aforementioned statement demonstrates how the reported incident was classified legally according to the station commander's intentions. As previously stated, upon receiving a report, a police officer is required to get from the complainant any pertinent information on the incident. After considering these data, the officer determines whether the act was criminal or not. It is presumed that the facts in the aforementioned case have already been confirmed and identified.

Step 2: Providing circumstances of the reported fact

MATTERS TO BE INVESTIGATED
*To determine the facts and circumstances surrounding the case of Direct Assault upon an Agent of Person in Authority and Slight Physical Injuries committed by *****.*

*To determine the criminal liabilities of the abovementioned person and the liabilities of SPO2 *****. (PR8)*

The steps in Move 2 entail describing the incident's spatiotemporal circumstances, which calls for a precise determination of the event's location and time. Examples of data from the steps in Move 2 of the police reports are shown in the aforementioned extracts. The content of these

structures is generally consistent, albeit they may change based on the type of the investigation.

Move 3 - *Narrating the facts*
This section of police report is considered the primary move of the report as it presents the verified facts. The police officer utilizes the information provided by the complainant, witness, or victim to construct a detailed account of the incident, which is then incorporated into this part of the report. Usually, this move provides a story about the crime or incident, including its causes and effects. The person giving the information could be a witness, victim, or even a suspect in the crime. Both viewpoints must be included in the process because the police report typically includes the victim's and, occasionally, the offender's versions of the facts.

Step 1: Highlighting the presence of the victim or complainant

> *FACTS OF THE CASE*
> *At around 9:30 in the evening of *****, 2017, a trouble transpired at ***** Store situated at *****, Antique when Alias ***** asked the hand of ***** for a blessing as a sign of respect, however ***** who happened to be at the said store and believed to be drunk suddenly punched Alias ***** several times for unknown reason. (PR8)*

> *At about 8:15 in the evening of *****, 2017, Punong Barangay ***** of Bggy. ***** of this municipality informed this station through cell phone call that there was a hacking incident transpired therein. (PR3)*

The above examples clearly demonstrate that the inclusion of the victim or complainant's name is essential in this move. This pattern represents the initial step in narrating the facts of the incident.

Step 2: Substantiating the circumstances

> *Upon seeing the situation, ***** intervened and pacified ***** who in turn vented his ire to ***** and intentionally punched him several times which landed [sic] on his mouth and to other [sic] parts of his body. On that instance, SPO2 *****, PNP member of ***** MPS who co-incidentally [sic] present in the area rendering his duty, instinctively pacified ***** and ordered him to stop punching ***** but instead of heeding, ***** picked up two (2) pieces of stones and supposed to [sic] struck the said Police Officer. Before he release[d] the stone, the said Police Officer prompted to draw his issued service 9mm Berreta pistol and shot ***** on the left forearm purposely to neutralize/maim him. Spot report was immediately sent to POPB and PIDMB for their information. (PR8)*

> *Investigation conducted disclosed that on said DTPI, the victim was hacked several times by the suspect hitting the victim's head and other parts of the body by a bolo. The suspect was believed to be drunk when the incident happened. He just appeared in front of the victim, who was doing some construction works outside his house, and hacked him with unknown reason and escaped. (PR3)*

The police officer or investigator, in this step, recounts the details of the incident. A detailed description is provided to enable the reader to visualize the sequence of events.

Step 3: Depicting the perpetrator's actions

> *The sworn judicial affidavit of SPO2 ***** revealed how he first ordered ***** to cease from assaulting ***** followed by the introduction of his authority as a POLICE OFFICER**. *Despite the warning given, the respondent armed with stones, more or less 1.6 and 1.84 kgs each still struck the said Police Officer, which prompted him to draw his issued Pistol and shot the respondent on the arm to repel the attack. (PR8)*

> *The said driver while driving his vehicle towards south direction of this municipality boarded/hauled with five (5) sacks of charcoal without pertinent documents. The subject suspect together with his vehicle hauled with charcoal was brought to ***** Municipal Police Station for further investigation and documentation and will be turned over to CENRO *****. (PR10)*

Police reports' narratives give an overview of previous occurrences and classify them as either criminal or non-criminal incidents. Following that, the police officer records these incidents in

the sequence that the witness or victim/complainant stated them.

Orientation, complication, evaluation, resolution, and conclusion are the five sections that comprise the Move 3 narrative. Details on the people engaged in the occurrence, the time and place, and the situational background are given in the orientation section. It's necessary to remember, however, that not all four components are present in the orientation part of each type of police report.

The narrative section of the police report is the most crucial part, as it contains the complicating action of the incident. This section focuses on the main issue of the event. Following the complications, the evaluation section signals that the complicating action is nearing its end. It becomes clear that the complications are coming to a close when the narrative begins to offer a resolution, which is the next part of the five components. After the resolution comes the evaluation, where the narrator's attitude towards the issue is revealed, and the final sequence of events in the complicating action is presented. The last part of the narrative section is conclusion, which, as the term implies, marks the end of the narrative.

It is important to understand that police reports vary from one another in terms of the quantity and complexity of structural components, as was mentioned in the descriptions of police reports above. This observation is based on the data used in this study.

Move 4 - *Identifying the participants in the incidents*

The purpose of Move 4 is to identify the roles of individuals involved in the incident, particularly in the narrative of Move 3. These individuals may be categorized as the complainant, victim, suspect, or witness. This move can be broken down into three steps:

Step 1: Identifying the victim and/or complainant

> *The sworn statements of ***** and SPO2 ***** as well as the pieces of evidence showed that there was indeed an assault on ***** committed by ***** wherein the former suffered a slight physical injury as stated in his Medico Legal Report. (PR8)*

Step 2: Identifying the perpetrator

> *The said warrant of arrest was returned to the court of origin along with the living body of the accused ***** who posted his cash bond thru his bondswoman ***** in the amount of Ten Thousand Pesos (Php10,000.00). (PR7)*

Step 3: Identifying the action done to the incident/circumstance

> *Furthermore, the victim was immediately brought to ***** for immediate medical treatment on board of PNP Patrol but later transferred at *****, Antique on board of Municipal Ambulance for further treatment. However, continues hot and pursuit operation is being conducted by this office for possible arrest of the suspect. (PR3)*

> *At around 8 o'clock in the morning of *****, 2017 accused ***** Alias ***** was arrested at *****, Antique. He was then apprised of his constitutional rights in a local dialect and brought to the Police Station for documentation. A Spot Report was sent to PIDMB & POPB for their information. (PR7)*

Move 5 - *Identifying the personnel responsible for the report*

Step 1: Specifying the police officer who authored the report

> *Prepared:*
> *****
> *Investigator*
> *Police Officer 3*

Step 2: Identifying the police station head.

> *Noted:*
>
> *****
> *Police Senior Inspector*
> *Chief of Police*

The framework developed by Swales (2004) has been utilized as the main theoretical basis for analyzing the moves in the police reports studied in this paper. The findings show variations in the frequency of moves and steps across the corpus. The police reports vary from one another, with certain moves and steps present in some reports but absent in others.

Moves and steps also exhibit overlap, meaning that steps one and two of a particular move are combined into a single paragraph. Based on the findings of this study, it can be inferred that the move does not universally apply across genres. Duenas (2007) supports this, noting that certain moves and steps can vary depending on the specific case or incident.

Additionally, the results suggest that, to some degree, the rhetorical structure of police reports is influenced by the type of case or incident.

In police reports, Move 1 includes two steps: specifying the recipient, source, subject, and date of the report, as well as the address of the police station.

In the report, this information is crucial. The purpose of this maneuver is to tell readers about the incident's time and location.

Move 2, which consists of two steps, deals with the fact and its conditions.

Move 3, in contrast, focuses on narrating the facts or circumstances of the report. This section offers the investigator's interpretation of the facts by outlining the complainant's account, the current situation, and describing the perpetrator's behavior. Narrating the facts involves providing a detailed account of the actions of those involved in the incident.

Move 4 identifies the intended recipient of the police report highlighting that the report is generated according to the nature and location of the reported incident. For instance, a police report related to a murder would be directed to a specialized unit responsible for handling homicide cases.

Finally, Move 5 identifies the personnel responsible for preparing the report highlighting the importance of acknowledging the author of the report for purposes of reference and accountability.

3.2 Linguistic Features

There are two linguistic levels identified in the data. These are lexical and syntactical.

3.2.1 Lexical Features

The usage of jargon is one characteristic found in the corpus at the lexical level. Jargon is technical or specialized jargon that only people in a certain group or who work in a certain trade or profession can understand. For example, there are several terminologies used in the legal profession that are referred to as jargon—words that are frequently used by judges and attorneys but are unknown to others outside the industry.

The following are the jargon found in the police reports used in this paper: *warrant of arrest, medico legal, inquest proceedings, sworn judicial affidavit,* and *probable cause*.

It should be noted, by the way, that the "PR" symbol after each extract means "Police Report," and the number thereafter stands for the reference code of the report assigned by the author.

> *Upon receipt of the Warrant of Arrest, the undersigned directed the Warrant PNCO PO1 ***** and the station's tracker team composed of ***** to check the whereabouts of *****. (PR7)*

> *The Medico Legal Report states to wit; hematoma and swelling lateral aspect lower lip, left and swelling mandibular area, left. (PR8)*

> *The sworn judicial affidavit of SPO2 ***** revealed how he first ordered ***** to cease from assaulting ***** followed by the introduction of his authority as a POLICE OFFICER. (PR8)*

> *A case of Direct Assault Upon Agent of Person in Authority and Slight Physical Injury was referred to the Prosecutor for Inquest Proceedings on *****… (PR8)*

> *…this Office finds probable cause in charging ***** of Direct Assault Against an Agent of Person in Authority… (PR8)*

Archaism, which is the term for an old word or expression that is no longer used in its original sense or that is exclusively used in particular fields or studies, is another lexical feature that has been found. The style of official papers, including business letters, legal terms, and diplomatic communications, frequently contains archaisms. The following archaic terms are found in the corpus: thereafter, herein, wherefore; hereunder, and whereabouts.

> *…and the station's tracker team composed of ***** to check the whereabouts of ***** (PR7)*

> *Immediately thereafter, PNP personnel of this office led by PInsp. ***** together with six 6 PNCO proceeded to the area to verify… (PR3)*

> *… and tried to strike it to the victim prompting the herein reportee to pacify [sic] the suspect who [sic] later escaped and ran towards… (PR1)*

> *Wherefore premises considered, this Office finds probable cause in charging ***** of Direct Assault … before the Provincial Prosecutor's Office. (PR8)*

> *This is to certify that quoted hereunder is true extract copy from WCPD Blotter Book of ***** Municipal Police Station … (PR6)*

The next lexical feature is the legal doublet. A legal doublet is a standardized expression composed of two or more words commonly used

in legal English. These phrases typically consist of paired terms that share similar meanings (synonyms). The origin of such doubling is often linked to the historical shift of legal language from Latin to French and then to English.

Doublets as expressions are also considered synonyms. Their groups are composed of words or concepts with related meanings. Their existence could be traced through the evolution of legal language from Latin to French to English. Since these doublets are frequently superfluous and redundant, many modern legal scholars and authors advocate doing away with them. For the purpose of interpretation, it is still important to identify these doublets.

> *Reporting person personally appeared in this station and reported that on the said DPTI, his mother… (RP1)*
>
> *… with six (6) PNCO's proceeded to the area to verify the veracity of said report and to conduct investigation (PR3)*
>
> *…cable wires were [sic] damaged and cut apart which led to… (PR9)*
>
> *…apprehend and arrested a tricycle for hire bearing a Plate Number *****, owned and driven by ***** (PR10)*
>
> *…was brought to ***** Municipal Police Station for further investigation and documentation and will be turned-over to… (PR10)*

Another feature is proformation. In a sentence, a pro-form is a word that can take the place of another word, phrase, or combination of words. Proformation is the process of replacing other words with pro-forms (Quirk et al., 1985). The word "said," which occurs 18 times, is the most common pro-form in the corpus. Here are a few examples:

> *Further stated that he exerted effort to locate the same but found futile. (PR2)*
>
> *…he collected said electronic tools and put them [sic] in the unfinished cabinet before he went [sic] to sleep (PR4)*
>
> *As a result, said cable wires were [sic] damaged and cut apart which led to [sic] a total internet signal interruption in the whole ***** area… and later identified that said cable wires were [sic] owned by ***** (PR9)*

The last one is the frequency of the word "alleged". Among the 10 Police Reports, the word alleged/alleging have six occurrences. Below are the extracts, which show how those words are used:

> *Further alleged that prior to the incident, reportee saw his mother having a conversation to his cousin/suspect in the street but later he noticed that they were shouting… (PR1)*
>
> *Reporting person personally appeared at this station and reported alleging that on said DTPI, while driving his tricycle from ***** Municipal Hall going to ***** of this municipality, he noyiced that his wallet… (PR2)*
>
> ***** (carpenter) further alleged that on said DTPI, he collected said electronic tools and put… (PR4)*

The habitual use of the term "allege" can be attributed to the idea that the contents of police reports are mainly based on the narration of the ones who report the incidents. It is therefore expected that circumstances reported are still allegations unless the perpetrator is proven guilty.

3.2.2 Syntactical Feature

Syntactical feature is another component of police reports. Three key characteristics are evident at the syntactical level: the use of passives, prepositions, and complex sentences.

It is evident that police reports employ the passive voice. This construction is used to emphasize the person or entity undergoing an action, rather than the one performing it. The most important person or object in the incident is highlighted in police reports by using passives, which make them the sentence's subject. The usage of passives throughout the corpus is seen by the following excerpts:

> *…victim was hacked several times by the suspect hitting the victims head and other parts of his body with the used of bolo (PR3)*
>
> *…it was taken by a culprit while he was in deep sleep (PR4)*
>
> *…and another two (2) succeeding cell phone calls were [sic] received by the victim (PR5)*
>
> *…said warrant of arrest was returned to the court of origin along with the living body of the accused ***** who posted his cash bond… (PR7)*

Police reports also make considerable use of prepositions. In these reports, prepositional phrases, consisting of a preposition followed by a noun phrase, are utilized for various purposes.

Examples are presented below:

> *… in the evening of January 18, 2017…*
>
> *...upon receipt of the Warrant of Arrest… (PR7)*
>
> *…around 9:30 in the evening… (PR 8)*
>
> *…and tried to strike it to the victim (PR1)*
>
> *…about 7:00 AM of the same date (PR4)*

The corpus of this study contains numerous complex sentences, which consist of one independent clause and at least one dependent clause. Complex sentences are employed in police reports to convey comprehensive details about a situation within a single statement. Examples of this usage are provided in the following excerpts from the police reports:

> ****** (carpenter) further alleged that on said DTPI, he collected said electronic tools and put them [sic] on the unfinished cabinet before he went [sic] to sleep, when he woke up in the morning he discovered that the said electric tools were [sic] already missing, and he (*****) strongly believed that they [sic] were taken by the culprit while he was deeply [sic] sleeping. (PR4)*
>
> *About 4:35 PM—At this time and date, one ***** alias *****, male, married, 41-year-old (BOD *****), company driver and a resident of ***** personally appeared in [sic] this station and caused into record alleging that on or about 4:15 o'clock in the afternoon of May ***** while traversing ***** Direction of this province driving *****, he accidentally hit the main cable wire (fiber optic cable) across the national highway and attached to the electric post located at *****.*
>
> *At around 4:30 AM of this date, elements of this Municipal Police Station led by SPO4 *****, deputy COP, together with other PNP Personnel under direct supervision of PSI *****, acting COP, apprehend and arrested a tricycle for hire bearing a Plate Number *****, make/brand *****, Engine *****, Chassis *****owned and driven by ******, 41 yo (DOB *****), married and a resident of Brgy *****.*

Police reports are vital in resolving cases, as they use language to accurately convey the facts of the incidents. Legal language, particularly in prosecution, possesses unique characteristics and serves various functions in court. Analyzing the language in the police reports examined in this study revealed two key linguistic features: lexical and syntactic. At the lexical level, five features were identified in the corpus: the use of jargon, archaisms, doublets, pro-forms, and the frequent use of the word "allege."

The findings of this paper align with Danet's (1985) assertion that the distinct characteristics of legal texts and documents are defined by their lexical aspects. He also emphasized that the lexical features of legal texts often carry specialized meanings. In the corpus, common jargon or technical terms include warrant of arrest, medico-legal, sworn judicial affidavit, inquest proceedings, and probable cause. These technical terms are inherently legal and often contain Latin and French words. Additionally, Tiersma (1999) noted that Latin remains in use as a legal language, with legal maxims often presented in Latin to convey a sense of dignity and authority.

An additional lexical characteristic of the corpus is the usage of archaic phrases like "thereafter," "herein," "wherefore," "hereunder," and "whereabouts." These terms are used to refer to specific sections of a document or specific people. Despite efforts to make legal language in contracts clear and complete, there are situations when the usage of outdated terminology and other components can make it inflexible and challenging to understand (Madrunio, 2022). The conservative mindset of lawyers who follow traditional legal writing standards could be a basis for the use of archaism in numerous legal publications. It should be noted, however, that the primary reason these keywords are used in legal English is to prevent the use of the same words repeatedly in the text.

The use of doublets in the corpus is another interesting lexical feature. The doublets found in the corpus are: appeared in this station and reported; verified the veracity; damaged and cut apart; apprehended and arrested; and investigation and documentation. Haigh (2015) defined doublets as standard phrases consisting of two or more words that are similar in meaning. Doublets are word pairs, which are frozen expressions that are irreversible. The reason for using a doublet in

the sentence is when you want to emphasize something and when you want the text to be more comprehensible.

Additionally, the corpus includes pro-form formulations like "same" and "said." According to Quirk et al. (1985), a pro-form is a type of function word or expression that substitutes another word, phrase, clause, or sentence while retaining its meaning from the context. These formats are employed for quantification, like when restricting a proposition's variables, or to prevent recurrence. In the police reports, for instance, the word "said" serves as a sentence or context rather than a verb as it does not function as a verb but instead represents a phrase or context.

The word "alleged" appears frequently in the corpus. As previously mentioned, the repeated use of "allege" can be attributed to the fact that police reports are primarily based on the accounts of those reporting the incidents. Consequently, the police officer responsible for writing the report opts to use "alleged" instead of directly accusing the suspect of committing the crime, in order to uphold the principle of due process of law.

Syntactical features are more prominent than lexical ones. The corpus includes complicated sentences, prepositional phrases, and the use of passive constructions as syntactical features.

The use of passive voice serves to depersonalize the information, lending a more professional and objective tone to the statement. The main purpose of the passive voice is to depersonalize the data included in the phrase. As a result, legal documents like police reports often feature passive verb constructions. While active sentence structures are sometimes possible, there are instances where the specific agent is omitted from the sentence. In this case, the use of active voice is not feasible. Passive constructions highlight the action rather than the actor. There are several reasons for using passive voice in police reports. One is to exclude the agent when it is already obvious. You could also use the passive voice to highlight the action rather than the person who carried it out. This technique demonstrates objectivity and authority.

Another notable feature in the corpus of this paper is the use of prepositions in the sentences. Prepositional phrases are often strung together, and frequently, they are misplaced. Prepositions typically precede a noun or pronoun and provide information about how, when, or where an event occurred. He also pointed out that since there are no strict rules for using prepositions, non-native English speakers often encounter difficulties with their proper usage.

Sentence structure takes into account a number of factors, including length and complexity. Coordinate and subordinate clauses are both present in a full sentence in legal English. It is typical to find all kinds of subordinates included in a single statement. Due to this custom, legal papers become extremely formal and sophisticated, with lengthy sentences as a result of these patterns. The paper reveals that short sentences are uncommon in legal English and that this will lead to frequent clausal coordination. Tiersma (1999) noted in his paper that legal language sentences are lengthier than those in other styles. Because of that reason, these sentences are more complicated since they contain numerous clauses.

3.3 Pedagogical Implications

The Technical Writing course is part of the Bachelor of Science in Criminology degree. The objective is to improve students' writing skills, particularly in the application of appropriate vocabulary and the analysis of police report structures. This study acknowledges its importance and practical ramifications for academic institutions providing Bachelor of Science in Criminology degrees. College educators may reference the findings of this study and deduce potential pedagogical applications in the teaching and learning process. Instructing criminology students on the construction of police reports will prepare them for their forthcoming responsibilities.

The linguistic characteristics revealed in this study assist non-experts in comprehending the intended message. Moreover, well produced police reports might function as essential investigation instruments in resolving situations during prosecutions.

The framework established by Swales & Feak, (2004) is essential for the formulation of police reports, since it emphasizes the critical components that must be incorporated. By following this format, the report writer may guarantee that the story remains precise, coherent, and factual. Furthermore, comprehending the rhetorical framework of police reports assists prospective writers in producing thorough and accurate information. This general template functions as a beneficial resource for inexperienced police officers, assisting them in adhering to set norms and aligning their writing with community expectations.

Studying forensic linguistics provides students with specialized abilities that connect language and law, presenting excellent professional prospects while enhancing critical thinking, social awareness, and a profound comprehension of the role of language in the judicial system. Moreover, the examination of language in forensic circumstances necessitates accuracy. Students acquire the ability to identify patterns, discern discrepancies, and draw inferences from linguistic data, hence enhancing their attention to detail.

Teachers of criminal justice courses for students in related programs may necessitate that their students compose police reports critically, effectively, and simply. Consequently, students analyzing these reports acquire the ability to articulate intricate scenarios in a systematic and cohesive manner, which is advantageous in professional environments where accurate communication is essential.

4. Conclusion and Recommendations

This study utilizes content analysis with police reports as the corpus, examining the rhetorical moves based on Swales (2004) paradigm. Report contains five rhetorical moves, although the steps within each move differ, and new steps were identified. Some steps were absent in the corpus, others overlapped between models, and some were embedded within other steps. These variations are anticipated when compared to other genres described by Swales and Feak (2004). The results also revealed two linguistic features in the corpus: lexical and syntactical levels.

The researcher recommends that future studies explore other types of police reports as the corpus for analysis. This approach would allow for the potential identification of additional linguistic features that may emerge in the findings. The results from examining different police reports could be used to further support or highlight the similarities and/or differences in the rhetorical devices and linguistic elements addressed in this study.

Belief revision and formation in grammar: The Japanese inferential evidential *no*

Lukas Rieser
Tokyo University of Agriculture and Technology
Fuchu, Japan
rieserl@go.tuat.ac.jp

Abstract

Japanese *no* is a pragmatic particle encoding **evidential meaning**. However, analyses of *no* as a general evidence marker are challenged by puzzling restrictions it imposes on mirative utterances. To account for these, we analyze *no* as a marker of **inferential evidence**, predicting how its meaning interacts with declaratives and interrogatives, and linking it to related uses of the complementizer. This is implemented as an establishedness restriction on the proffered content within a framework differentiating **premises and expectations** in addition to evidence and belief, thereby modeling the status of a proposition within processes of evidence-based belief revision and formation.

1 Overview

In section 2, we use mirative utterances with *no* as the core data point to generalize over extant evidence restrictions, propose a new, unified restriction to inferential evidence, and discuss connections between the particle and the complementizer *no*. In section 3, we sketch the premise-and-expectation framework used to analyze *no* in section 4, where we implement the inferential evidence requirement as a ban on content accepted as a premise before the utterance. Using this analysis, we account for various uses of the particle *no* in section 5, touching on soliloquous *vs.* discourse-oriented uses, interaction with the fellow pragmatic particles *yo* and *ne*, pragmatic reasoning and its use in the narration of belief revision, and how *no* is used in non-canonical assertions. Section 6 briefly discusses broader implications for linguistic theory.

2 What *no* does

While there is an emerging consensus in the formal literature a that *no* carries evidential meaning, it is not clear what kind of evidence it marks. To address these questions, we examine the mirative use of "*noda*-constructions". These are assertions where *no* occurs with the copula *da*, which have been the main focal point of the extensive descriptive literature on Japanese *no* as both a complementizer (COMP) and a pragmatic particle (PRT). On their mirative use, they come with puzzling restrictions on evidence that cannot be explained by simply assuming, with a number of previous analyses, that *no* marks any kind of contextual evidence.

We propose that these restrictions can be accounted for by analyzing *no*(PRT) as a marker of inferential evidence for the utterance content, providing grounds for it within a process of belief revision and/or formation. This overlaps with, but is distinct from, *no*(COMP) as an elaboration marker.

2.1 Mirative utterances and *no*

In order to formulate our generalization on what type of evidence is marked by *no*(PRT), we build on observations by Oshima (2024) on *no* in mirative utterances. Oshima gives the following example for *no* as an obligatory mirative marker (we take it to be a more general evidence marker) expressing speaker surprise over an observed state of affairs (*i.e.* over contextual evidence):

Scenario Expecting A be away for fieldwork for another week, S sees A at the office and utters:

(1) A, modot-teta ??(n da).
INTJ return-RES.PST *no* COP
"Oh, you're back."

In (1), evidence has just become available in the utterance situation that causes the speaker to revise a previous assumption and assert the prejacent[1] based on this evidence, which licenses *no*, rather than on a previously held conviction.

2.2 Generalizations on evidence restrictions

While the presence of evidence can thus license *no*, this is not the case for all types of evidence.

[1] The propositional content of an utterance.

Oshima formulates two restrictions on evidence marked by *no* in mirative utterances building on Noda (1997)'s comprehensive observations on uses of *noda*-constructions. Below, we discuss these two restrictions and their limitations in turn, and suggest an alternative, unified generalization.

2.2.1 All-focus ban / QUD requirement

First, Oshima proposes that *no* as a mirative marker requires that there must be a "non-trivial" QUD[2] (more specific than "What's up?") regarding the prejacent. The following examples shows a cases where this is violated, the speaker is unlikely to have specific expectations about the prejacent:

Scenario Entering a hotel room right after checking in, S finds a dead cockroach on the bathroom floor.

(2) A, gokiburi-ga shin-deru (?? n da).
INTJ cockroach-NOM die-RES.NPST *no* COP
"Oh, there's a dead cockroach."

The claim is that *no* is not licit in (2) because the discovery is too out-of-the-blue, as it is implausible that the speaker has wondered whether or not the prejacent holds before utterance time. This QUD requirement can be circumvented by having the scenario include a QUD answered by the prejacent:

Scenario S hears A scream, then fall silent. Rushing to the rescue, S finds A staring at a cockroach.

(3) A, gokiburi-ga shin-deru ??(n da).
INTJ cockroach-NOM die-RES.NPST *no* COP
"Oh, there's a dead cockroach."

When a *why*-question to which the prejacent is the answer is made contextually salient, *no* is admissible in (3), parallel to the standard case of the mirative use of *no* in (1). However, as we argue in section 2.4.2, this can also be explained by an overlap with the explanation use of *no*(COMP).

2.2.2 Establishedness requirement

For the establishedness requirement, Oshima gives the following example, where the speaker likely has an expectation that they would make the train (otherwise the running would've been futile), so that the all-focus ban or QUD requirement is insufficient to explain the badness of *no*:

Scenario Running for a train, speaker and addressee miss it in the nick of time:

(4) A, maniawa-na-katta (??n da).
INTJ make.it-NEG-PST *no* COP
"Ah, we didn't make it."

[2]Question under discussion, *cf.* Roberts (2012).

The claim of the establishment requirement is that the fact that the speaker has missed the train is too recently established, based on examples like the following variation with a modified context, where *no* is not only required, but preferred:

Scenario A leaves running for a train, comes back with a disappointed expression shortly thereafter:

(5) A, yappari maniawa-na-katta ??(n da).
INTJ after.all make.it-NEG-PST *no* COP
"Ah, you didn't make it after all."

The claim is that in (5), the truth of the prejacent (A being late) has been established for a certain amount of time rather that immediately before the utterance as in (4). There is, however, another key difference: the speaker is inferring the truth of the prejacent from contextual evidence in (5), rather than direct experience as in (4). The following example controls for evidence type:

Scenario The speaker is on a team surveilling the addressee via CCTV. The addressee is running for a train and misses it in the nick of time:

(6) A, maniawa-na-katta ??(n da).
INTJ make.it-NEG-PST *no* COP
"Ah, [they] didn't make it."

On this scenario, the truth of φ has become established just as it is being observed by the speaker, however this is not the speakers own experience, but an observation via visual evidence. As this licenses the use of *no*, it is likely that information source or processing type is the actual requirement, rather than establishedness. We propose that the reason *no* is bad in (4) as well as in (2) is that the evidence is too direct, without need for reasoning.

2.3 The inferential evidence requirement

We propose that the licensing requirements for mirative *no*(PRT) can be reduced to a requirement for a process evidence-based inference, and that this can be implemented as to a ban of direct acceptance of the prejacent. This covers both the QUD-requirement on (2) and the establishedness-requirement on (4): in either case, the directly observed state of affairs is identical to the prejacent, and therefore immediately accepted as a premise, rather than serving as grounds for belief revision and/or formation — there are no intermediate stages of reasoning required to license *no*(PRT). We label the type of evidence satisfying this **inferential evidence**, and briefly discuss our claim in the context of the literature on evidentiality.

In languages where the marking of information source is obligatory, "inference" (based on tangible evidence) and "assumption" (based on logical reasoning general knowledge) can be distinguished, *cf* Aikhenvald et al. (2007). While *no*(PRT) is closer to the former in marking marking the presence of tangible evidence, it can also involve logical reasoning. However, these categories are not necessarily applicable to Japanese, evidential *no* is not part of a grammatical system of obligatory information source marking, making it an "evidential strategy" rather than a grammatical evidential. Aikhenvald (2004) proposes that *no* refers to "validation of information rather than the way it was obtained"[3], which can be understood as encoding the status of information within a reasoning process. We take this to support our implementation of *no*(PRT)'s contribution in terms of non-establishedness of the prejacent rather than in terms of explicit limitations on information source.

Our inferential evidence is close in spirit to Lau and Rooryck (2017)'s definition of *indirect* evidentiality as arriving at a state of knowing through intermediate stages, where in *inferential* evidentiality these are stages of reasoning. We use the label inferential to highlight the necessity of a reasoning process and to indicate that there is no restriction on the source of evidence as such, but on its status within a belief revision and formation process.

2.4 Distinguishing *no*(PRT) from *no*(COMP)

The specific evidential restrictions on *no*(PRT) are likely to have developed in a process of pragmaticalization from discourse-connective uses of *no*(COMP), *cf.* Rieser (2017), and their functions can in some cases overlap, in particular where there is a linguistic antecedent whose prejacent refers to inferential evidence. In order to analyze *no*(PRT) as an independent lexical item, it is therefore crucial to distinguish it from *no*(COMP). Comparing falling interrogatives to assertions in mirative contexts provides some insights on this distinction.

2.4.1 Restrictions on *no*(PRT) in interrogatives

(7) through (9) show final falling (*i.e.* soliloquous) interrogatives in the mirative scenarios for from section 2.1. Whereas *no* was preferred in assertions in all three cases, it is actually **dis**preferred in (7), the core mirative example narrating evidence-based belief revision, but optional in (8) and (9).

[3]Albeit based on observations by Aoki (1986) which do not make reference to the specific restrictions discussed here.

Scenario Expecting A be away for fieldwork for another week, S sees A at the office and utters:

(7) A, modot-teta (?no) ka.
INTJ return-RES.PST *no* INT
"Oh, are you back."

Scenario S hears A scream, then fall silent. Rushing to the rescue, S finds A staring at a cockroach:

(8) A, gokiburi-ga shin-deru (no) (ka).
INTJ cockroach-NOM die-RES.NPST *no* INT
"Oh, is there a dead cockroach."

Scenario A leaves running for a train, comes back with a disappointed expression shortly thereafter:

(9) A, yappari maniawa-na-katta (no) ka.
INTJ after.all make.it-NEG-PST *no* INT
"Ah, did you not make it after all."

We take this to show that *no*(PRT) is dispreferred in mirative falling interrogatives (we return to reasons for this in section 5), in contrast to mirative assertions. This raises the question of why *no* is optional in (8) and (9), examples where the alleged QUD- and establishment requirements are contextually satisfied. On our view, this is because the functions of *no*(COMP) and *no*(PRT) overlap, and the explanation / elaboration functions of the former are licensed in (8) and (9), but not in (7).

2.4.2 Explanation, elaboration, evidentiality

Table 1 relates functions of *no*(COMP) to evidence-marking by *no*(PRT): φ is the *no*-utterance's prejacent, ψ a contextually salient proposition, and ε (inferential) evidence. These are related by defeasible entailment $\rightsquigarrow$, to be specified in the analysis.

no(COMP)	explanation	$\exists\psi : \varphi \rightsquigarrow \psi$
	elaboration	$\exists\psi : \psi \rightsquigarrow \varphi$
no(PRT)	evidential	$\exists\varepsilon : \varepsilon \rightsquigarrow \varphi$

Table 1 Functions of *no*(COMP) and *no*(PRT)

Note that *no*(COMP) functions as both an explanation and elaboration marker, whereas evidence-marking with *no*(PRT) is related to elaboration[4] with the added restriction to inferential evidence. In (8), the scream (ψ) is explained by the cockroach in (φ) , and in (9), the long face (ψ) is explained by the failure to make it (φ), *i.e.* these are cases of explanation by *no*(COMP) rather than evidence-marking by *no*(PRT), which is not licensed.

[4]While explanation is a cross-linguistically common function of complementizer constructions, including English "It's that. . . /Is it that. . . ?", elaboration is more rare but fully productive for *no*(COMP), which is likely what made bridging contexts for development of its evidential function available. For more detailed discussion, *cf.* Rieser (2024).

3 The expectative framework

We model the evidential restrictions from *no* in a framework that differentiates differentiates between **premises** (what an agent takes as a basis for inferential reasoning) and **expectations** (what an agent assumes to hold by default based on premises, but is not a premise in itself). Within this framework, evidence is a subset of premises, which also include established speaker beliefs, so that expectations arise from both evidence and extant beliefs, reflecting the role of evidence in belief formation and revision. This allows modeling inferential evidence marking as *no*(PRT) requiring grounds (evidence) to expect the prejacent, along with a ban on prejacents that are speaker premises (beliefs) before utterance, requiring an inferential process to be in progress at utterance time.

3.1 Premises and expectations

(10) defines the set of x's premises Π^x as all propositions π that x believes to be true, written as $B_x\pi$. (11) defines the set of x's expectations Ξ^x as all propositions ξ that x believes to normally hold, written with the normality modal OUGHT[5]. The overall context C^x is defined as their union in (12).

(10) $\quad \Pi^x = \{\pi \mid B_x(\pi)\}$

(11) $\quad \Xi^x = \{\xi \mid B_x\textsc{ought}(\xi)\}$

(12) $\quad \mathrm{C}^x = \Pi^x \cup \Xi^x$

3.2 Evidence

(13) defines E^x, the set of evidence available to x, as subset of Π^x containing all evidence (represented as propositions) ε[6] that are premises of x and support (an) expectation(s) of x.

(13) $\mathrm{E}^x \subset \Pi^x = \{\varepsilon \mid \varepsilon \in \Pi^x \wedge \exists \xi \in \Xi^x : \varepsilon \rightsquigarrow \xi\}$

Evidence giving rise to an expectation is written as $\rightsquigarrow$, introduced above to describe the explanation, elaboration, and evidentiality uses of *no*. As a conditional relation, this is equivalent to restriction of OUGHT's modal base with φ[7], written as Ξ_φ in (14). Note that, when restriction of the modal base with φ gives rise to any expectations, this makes φ evidence per the definition in (13).

(14) $\quad \Xi^x_\varphi = \Xi^x \cup \{\xi \mid \varphi \rightsquigarrow \xi\}$

[5] *Cf.* Yalcin (2016), Rieser (2020a) for analyses of OUGHT as a normality modal rather than "weak epistemic modality".

[6] E^x should also include source and reliability information to account for core grammatical evidentials and cases of conflicting evidence. As this is not relevant for evidence restrictions from *no*(PRT), they are not formally implemented.

[7] This treats conditionals as modals, *cf.* Kratzer (2012).

3.3 Context update

In order to reflect narration of belief revision and formation by *no*, we model utterances as context change potentials (CCPs)[8], where conditions on an input context set C^x are paired with an update output context set C'^x. This is implemented as in (15), where an utterance U with a prejacent p is defined as a set of pairs of input and output contexts which are admissible as they comply with the felicity conditions in F^U characteristic to U (for our purposes, DEC or INT). Pragmatic particles are defined as utterance modifiers that add felicity conditions $\mathrm{F}^{\mathrm{PRT}}$, which have to be compatible with the original felicity conditions of the utterance.

(15) $[\![U(p)]\!] = \{\langle \mathrm{C}^x, \mathrm{C}'^x\rangle \mid \mathrm{F}^U\}$

(16) $[\![\textsc{prt}[U(p)]]\!] = \{\langle \mathrm{C}^x, \mathrm{C}'^x\rangle \mid \mathrm{F}^U \cup \mathrm{F}^{\mathrm{PRT}}\}$

The CCPs of *no* in a falling interrogative and in an assertion (falling declarative) are given in (17) and (18), where x is resolved to the speaker S. Conditions on subsets of the input and output contexts are written as Π^{C^x} and $\Pi^{C'^x}$, respectively.

(17) $[\![no(\textsc{int}(p))]\!] = \{\langle \mathrm{C}^x, \mathrm{C}'^x\rangle \mid \mid \exists \varepsilon \in \mathrm{E}^{C^x} : p \in \Xi^x_\varepsilon \wedge p \notin \Pi^{C^x}\}$

(18) $[\![no(\textsc{dec}(p))]\!] = \{\langle \mathrm{C}^x, \mathrm{C}'^x\rangle \mid \mid \exists \varepsilon \in \mathrm{E}^{C^x}\colon p \in \Xi^x_\varepsilon \wedge \neg p \notin \Pi^{C^x} \wedge p \notin \Pi^{C^x} \wedge p \in \Pi^{C'^x}\}$

For the following discussion of interactions with other pragmatic particles and discourse-oriented uses of *no*(PRT), we only give the felicity conditions F for each example without the full CCP notation for ease of exposition.

4 Expectative analysis of *no*

These definitions in places, we model the restrictions that *no*(PRT) imposes on the utterance context as the two pragmatic presuppositions in Table 2.

	pres 1	pres 2
no(p)	$p \in \Xi^x_{\mathrm{E}}$	$p \notin \Pi^x$

Table 2 Restrictions from *no*(PRT)

Presupposition 1 requires evidence in the utterance context that supports an expectation that the prejacent holds. This is written as p being a member of x's evidence-based expectation set Ξ^x_{E}. Presupposition 2 is a requirement that at first seems unrelated to the type of evidence, stating that the prejacent cannot be a premise in the input context.

[8] See Heim (1983) for the basic concept, Davis (2011) for an application to pragmatic particles in Japanese.

4.1 Relating the prejacent

Presupposition 1 links the prejacent of *no*(PRT) to elaboration by *no*(COMP): the latter relates the prejacent to a contextually salient utterance, the former to evidence. Table 3 translates the definition from Table 1 into our framework, yielding presupposition 1 as a context restriction on *no*(PRT).

	general	context restriction
elaboration	$\exists\psi : \psi \rightsquigarrow \varphi$	$\exists q \in \Pi^x : p \in \Xi^x_q$
evidential	$\exists\varepsilon : \varepsilon \rightsquigarrow \varphi$	$\exists\varepsilon \in \Pi^x : p \in \Xi^x_\varepsilon$

Table 3 Restrictions from *no*(COMP) and *no*(PRT).

4.2 Restricting *no*(PRT) to inferential evidence

Presupposition 2 restricts evidence that can license *no*(PRT) to **inferential evidence** by banning prejacents already accepted at utterance time ($p \notin \Pi^x$) — in an inference process, evidence is not directly accepted as a belief, but used as grounds for deciding whether to accept an expectation arising from it. In the mirative case, the observed evidence is the basis of a process by which an expectation to the contrary is discarded and replaced by a new premise, *i.e.* a belief revision process is narrated by the *no*(PRT) utterance.

The indirect implementation of inferential evidence, rather than direct restriction of admissible types of ε, is not only welcome from the perspective of formal parsimony (the machinery is needed for capturing functions of speech acts and other particles), but also as Japanese does not mandatorily and unambiguously restrict evidence by modality[9].

4.3 Declaratives, interrogatives, and *no*(PRT)

The analysis of *no*(PRT) proposed above readily captures its interaction with declarative (*da*) and interrogative (*ka*) morphology, as summarized in Table 4. Note that the presupposition of *no* overlaps with DEC in requiring evidence (grounds) supporting the prejacent, and with INT in requiring the prejacent *not* to be a premise before utterance.

	presupposition	update
no(p)	$p \in \Xi^x_{\mathrm{E}} \wedge \quad p \notin \Pi^x$	–
ka(p)	$p \notin \Pi^x$	–
da(p)	$p \in \Xi^x_{\mathrm{E}} \wedge \neg p \notin \Pi^x$	$p \in \Pi^x$

Table 4 Restrictions from *no*(PRT), INT, and DEC.

[9] Apparent markers of visual evidence (*mitai*, *yooda*) or hearsay evidence (*rashii*, *sooda*) are ambiguous with inference or quotation marking, suggesting there is no direct grammatical restriction of evidence source in Japanese.

5 Accounting for uses of *no*(PRT)

Interaction with *da*(DEC) and *ka*(INT) sheds light on how *no*(PRT) is licensed in mirative scenarios — to illustrate, (19) is repeated from (1) and (7).

Scenario Expecting A be away for fieldwork for another week, S sees A at the office and utters:

(19) A, modot-teta {??(n da)/(?no) ka?}.
INTJ return-RES.PST *no* COP *no* INT

The scenario for (19) is one of belief revision: speaker S revises an expectation $\neg p$ to a belief p. Under this scenario, *no* is preferred in the declarative, but dispreferred in the interrogative. We propose that the contrast in acceptability of *no* can be accounted for by considering how its meaning overlaps with that of its host utterances.

In the declarative utterance, the presence of evidence is already marked by *da*(DEC), so that *no*(PRT) contributes the condition that p not be a premise before utterance ($p \notin \Pi^S$), *i.e.* the restriction to inferential evidence that we have argued above explains its badness where p is directly accepted as a premise. That marking evidence as inferential with *no*(PRT) is strongly preferred here rather than just optional is due to pragmatic reasoning, in particular the principle of MAXIMIZE PRESUPPOSITION, as discussed in section 5.2.

In the interrogative utterance, the non-premise status of p is already marked by *ka*(INT), so that *no*(PRT) would contribute the condition that there be evidence making p expected in the utterance situation ($p \in \Xi^S_{\mathrm{E}}$). Marking inferential evidence with *no* is dispreferred in absence of an indication of revision to p, as this would imply sustained speaker doubt, incompatible with the scenario.

Our claim that the licensing of *no* in mirative scenarios depends on an indication of belief revision is supported by the observation that *no* is optional in falling interrogatives when the particle *yo* is added to mark imminent belief revision (see section 5.1.1). This, in turn, supports our claim that, in mirative declaratives, *no* is strongly preferred as it marks evidence as inferential — the non-premise condition is also marked by *ka*(INT), so that *no* is optional rather than preferred in *yo*-interrogatives.

In the remainder of this section, we apply our analysis to more uses of *no*(PRT), discussing discourse-oriented *vs.* soliloquous uses and interaction of *no* with the particles *yo* and *no* (5.1), the role of pragmatic reasoning in narrating belief revision and conveying bias (5.2), and *no* in non-canonical (directive and commissive) assertions (5.3).

5.1 Discourse, soliloquy, and evidence

Oshima (2024) gives two discourse-oriented versions of the original mirative assertion, illustrating how *no* interacts with the particles *ne* and *yo*:

Scenario Expecting A be away for fieldwork for another week, S sees A at the office and utters:

(20) A, modot-teta ??(n da) ne.↑
INTJ return-RES.PST *no* COP *ne*
"Oh, you're back."

Scenario S has learned that Mari is back in the office an hour ago. A says "I wonder when Mari will come back."

(21) Moo modotteki-teiru (??n da) yo.
already return-RES.NPST *no* COP *yo*
"She is back already."

In (20), directed at the returnee, *ne* indicates that addressee A is already aware of prejacent p, and *no* is preferred, as in the original mirative assertion. In (21), directed at a third party, *yo* indicates that A is not yet aware of p, and *no* is dispreferred. Below, we show how to account for this contrast in our framework, and how *no* can be licensed with *yo*.

5.1.1 Interaction with *yo* and *ne*

The expectative framework models how *no*(PRT) interacts with the particles *yo* and *ne*, in addition to *ka*(INT) and *da*(DEC). Table 5 shows context restrictions for *yo* and *ne* based on Rieser (2020b), along with definitions repeated from Table 4.

	presupposition	update
$no(p)$	$p \in \Xi^x_{\mathrm{E}} \wedge \; p \notin \Pi^x$	–
$ka(p)$	$p \notin \Pi^x$	–
$da(p)$	$p \in \Xi^x_{\mathrm{E}} \wedge \neg p \notin \Pi^x$	$p \in \Pi^x$
$yo(p)$	$p \notin \Xi^x_{\Pi}$	$p \in \Xi^x_{\Pi}$
$ne(p)$	$p \in \Xi^x$	–

Table 5 Restrictions from *no*, *ka*, *da*, *yo* and *ne*.

In (20), *ne*↑ forces discourse-orientation as rising intonation (↑) resolves x in the presupposition to A, resulting in the CCP restrictions in (22).

(22) $p{\in}\Xi^{C^S}_{\mathrm{E}} \wedge \neg p{\notin}\Pi^{C^S} \wedge p \notin \Pi^{C^S} \wedge p{\in}\Xi^{C^A} \wedge p{\in}\Pi^{C'^S}$

In (20), the evidence requirements from DEC and *no*(PRT) overlap: $p{\in}\Xi^{C^S}_{\mathrm{E}}$ is part of utterance meaning without *no*, which only contributes $p \notin \Pi^S$, *i.e.* restriction to inferential evidence. Marking inferential evidence is preferred, in parallel to the soliloquous version of (20) without *ne*.

In (21), *yo* indicates the addressee is not expecting the prejacent, and updates the addressee's premises with the speaker's assertion, presented as grounds for expecting p[10], resulting in the CCP restrictions in (23).

(23) $p{\in}\Xi^{C^S}_{\mathrm{E}} \wedge \neg p{\notin}\Pi^{C^S} \wedge p{\notin}\Xi^{C^A} \wedge p{\in}\Pi^{C'^S} \wedge p{\in}\Xi^{C'^A}_{\Pi}$

Here, *no*(PRT) is strongly dispreferred due to the inferential evidence being incompatible with p being a premise, as required by the scenario.

5.1.2 Shifting the locus of evidence

The following scenario for (21) makes *no*(PRT) acceptable with *yo* by shifting the locus of evidence:

Scenario S has learned that Mari is back in the office an hour ago, as both S and A have seen her. A says "I wonder when Mari will come back."

(24) Moo modotteki-teiru ??(n da) yo.
already return-RES.NPST *no* COP *yo*
"She is back already."

The underlined part of the scenario states that evidence for the truth of the prejacent is also available to the addressee in addition to the speaker, making *no*(PRT) is preferred in (24), in contrast to (21). On our analysis, this *no*(PRT)'s participant variable being resolved to the addressee, resulting in the additional restrictions from *no*(PRT) in (25).

(25) $p{\in}\Xi^{C^A}_{\mathrm{E}} \wedge p{\notin}\Pi^{C^A}$

Together with the conditions from *yo*-assertion in (23), (25) indicates that *both participants* have evidence for the prejacent ($p{\in}\Xi^{C^{S,A}}_{\mathrm{E}}$, as x is resolved to S in DEC, to A in *no*(PRT). This contrasts with A neither having accepted p as a premise ($p{\notin}\Pi^{C^A}$) nor expecting it ($p{\notin}\Xi^{C^A}$). The speaker uses this to prompt the addressee to initiate a process of belief revision by retrieving the evidence available to them, making p expected ($p{\in}\Xi^{C'^A}_{\Pi}$), and setting it up for acceptance ($p{\in}\Pi^{C^{S,A}}$).

5.1.3 Interaction with *yo* in interrogatives

Recall that *no* was dispreferred in falling interrogatives in mirative scenarios, *cf.* (19). However, when *yo* is added, *no* becomes optional, as in this soliloquous example from Taniguchi (2016), where the speaker does not yet accept the prejacent as a premise, but is considering to do so:

Scenario S observes someone about to eat something S had thought unfit for human consumption:

(26) Sonna mono taberu (no) ka yo.
such.a thing eat.NPST *no* INT *yo*
"[They're] (not) going to eat that!?"

[10] *Cf.* Unger (2019)'s parallel account of how exclamative and mirative utterances can serve as evidence sources.

Recall that we have argued the badness of *no* in falling interrogatives is due to *ka*(INT) not marking the establishment of the prejacent p as a premise in contrast to the update $p{\in}\Pi^x$ from *da*(DEC). In (26), *yo* indicates establishment of p as an *expectation* ($p \in \Xi^x_\Pi$), making an (imminent) belief-revision reading available and licensing inferential evidence marking with *no*. The CCP restrictions from (26) on our analyses are shown as in (27). Note that the evidence requirement from *no*(PRT) is its only contribution, as $p{\notin}\Pi^{C^S}$ is also encoded by INT.

(27) $p{\notin}\Pi^{C^S} \wedge p{\notin}\Xi^{C^S} \wedge p{\in}\Xi^{C^S}_{\mathrm{E}} \wedge p{\in}\Xi^{C'^S}$

The input conditions contain an apparent contradiction between $p \notin \Xi^{C^S}$ and $p \in \Xi^{C^S}_{\mathrm{E}}$, which reflects how (26) narrates the belief revision context: S not expect p based on previously entertained premises, but only on the basis of evidence that has become available in the utterance situation. The addition of *yo* licenses this interpretation, as it narrates evidence-based expectation formation.

Full formal reflection of this account of the interaction of *no*(PRT) and *yo* in falling interrogatives would require a full split of the expectative context into general and evidence-based expectation sets and/or a more detailed implementation of their interaction. However, as falling interrogatives with *yo*, are licensed in mirative contexts where the speaker does not believe or expect p (conditions from INT and *yo*), and contextual evidence supporting p comes up, there is pragmatic motivation to interpret *no*(PRT) as an indicator of relative evidence strength. Some support for this comes from the interaction of *no* with bias patterns of polar interrogatives discussed in 5.2.2.

5.2 Narrating belief revision and formation

Our analysis directly accounts for *no*(PRT) not being licensed when the prejacent is directly accepted via the evidence requirement formulated in section 2.3, implemented as in 4.2. In our account of the felicity of *no* in its different uses, we have made reference to pragmatic reasoning to explain, among other contrasts, why *no* is preferred in mirative declaratives, but dispreferred in interrogatives in section 5. Below, we propose MAXIMIZE PRESUPPOSITION as the pragmatic principle behind these contrasts within the narration of belief revision, and discuss the related issue of evidential and epistemic bias marking in polar questions, which, as a corollary, related evidence-marking with *no*(PRT) to the elaboration function of *no*(COMP).

5.2.1 MAXIMIZE PRESUPPOSITION and *no*

The core example for narration of belief revision with *no*(PRT) and its licensing in declaratives *vs.* interrogatives is repeated in (28) from (19).

Scenario Expecting A be away for fieldwork for another week, S sees A at the office and utters:

(28) A, modot-teta {??(n da)/(?no) ka?}.
INTJ return-RES.PST *no* COP *no* INT

Starting from the preference for making the inferential evidence restriction explicit by adding *no*(PRT) to the declarative in (28) can be accounted for by in the spirit of the maxim MAXIMIZE PRESUPPOSITION[11] — the presupposition to be maximized in this case being the restrictions on the input context: while the bare utterance is principle compatible with a context in which the prejacent is not a speaker premise, the availability of *no*(PRT) to overtly mark this restriction makes it preferred.

As for the interrogative version of (28), we have argued that adding *no*(PRT) would mark the presence of evidence while no belief revision is made explicit, in conflict with a scenario where belief revision is taking place. From the perspective of maximizing context restrictions, an interrogative version of (28) is dispreferred when there is a declarative version available that makes revision explicit, although strictly speaking maximizing the update, rather than the presupposition, side of the CCP.

A possible counterexample to the maximization of explicit input restrictions is the case of falling interrogatives with *yo* discussed in section 5.1.3, where evidence-marking with *no* is optional, rather than preferred. We propose that this is due to it marking evidence in principle strong enough to make the prejacent a premise, the imminent revision scenario being on the borderline in terms of evidence strength.

5.2.2 Marking bias in polar questions

Another example for the role of pragmatic reasoning are negative polar questions, where *no* adds epistemic bias rather than the expected evidential bias, as in this example from Sudo (2013):

Scenario A, who heads a student meeting and knows who will be present, says: "We are all here now. Shall we start the meeting?"

(29) Daremo hokani ko-nai (no)?
nobody else come-NEG.NPST *no*
"{Is nobody else/Isn't anyone else} coming?"

[11] *cf.* Schlenker (2012) for a discussion in the context of pragmatic reasoning.

(29) without *no* indicates contextual evidence (in form of A's utterance) for the (negated) prejacent, giving rise to **evidential bias**, parallel to English "Is nobody else coming?". Marking of this evidence with *no* is optional and, when added, gives rise to **epistemic bias**, indicating there is a contrary speaker expectation, *i.e.* narrating revision of epistemic bias based on contextual evidence, parallel to English "Isn't anyone else coming?".

A similar effect occurs when *no* is added to falling interrogatives: *ka*(INT) encodes epistemic bias, *i.e.* that the speaker is reluctant to accept the prejacent, even in the face of evidence, making them incompatible with a belief-revision scenario. When *yo* is added to the interrogative to indicate expectation revision which includes epistemic bias, the addition of *no* adds evidential bias, indicating that belief revision is likely in light of the evidence.

Finally, note that *no* in (29) is actually ambiguous between COMP and PRT as there is a linguistic antecedent that the content of the question elaborates on. This is a likely bridging context for the development of *no*(PRT) as an evidential marker, underlining the importance of narration of (potential) belief revision for understanding its meaning.

5.3 Non-canonical assertions with *no*

The analysis of *no*(PRT) we propose is also able to account for two of its rather marked uses in assertions: the "order" (30) and "resolution" (31) uses, here in examples adapted from Oshima (2024):

Scenario S is a police officer arresting a suspect:

(30) Te-o agete, kocchi-o muku ??(n da).
hand-ACC lift here-ACC turn.NPST *no* COP
"Lift your hands and turn over here."

Scenario S is psyching themselves up for a fight:

(31) Ore-wa nantoshitemo, aitsu-ni katsu ??(n da).
I-TOP do.whatever he-DAT win.NPST *no* COP
"I'll beat him, no matter what it takes."

In both cases, the prejacent is not an accepted premise before the utterance, and assertion is used non-conventionally in directive and commissive illocutionary acts. Marking with *no*(PRT) makes the prejacents' status as non-premises explicit. Here, the goal of assertion is not to accept the prejacents based on evidence for their truth, but on grounds for directives and commissives, *i.e.* the speaker's volition. Thus, the utterances making their prejacents premises convey that addressee (30) or speaker (31) must adjust their course of action. As in mirative assertions, marking this update is preferred by MAXIMIZE PRESUPPOSITION.

6 Summary and outlook

We have analyzed *no*(PRT) by capturing the restrictions it imposes on admissible contexts within a framework differentiating between premises and the expectations based on them. On our analysis, *no*(PRT) is licensed by inferential evidence, modeled as a condition for the prejacent being an evidence-based expectation and a ban on the prejacent being accepted as a premise before utterance. As these conditions overlap with the declarative marker *da* and the interrogative marker *ka*, the analysis directly reflects their interactions with *no*, as well as connections to *no*(COMP) and the particles *yo* and *ne*, which we captured in the same framework. Our account of various uses of *no*(PRT) as narrations of evidence-based belief revision lays the groundwork for expansion of the analysis to other pragmatic particles, sentence-final expressions and evidential expressions, and development of the framework by formally reflecting evidence source, a finer-grained distinction of evidential and epistemic grounds, and pragmatic reasoning.

The premise- and expectation framework we propose formally captures evidentiality without hard-coding a reference to evidence source into the analysis. This is particularly relevant for analyzing grammatical evidence-marking that, like the inferential evidence requirement of *no*(PRT), encodes evidence for the prejacent within a process of belief formation rather than systematic and/or obligatory evidence source marking. This also connects to phenomena like the aforementioned negation in polar questions, including non-propositional negation, giving rise to evidential and epistemic bias patterns which are notoriously elusive but readily accountable as conditions on the prejacent as a (non-)premise or (non-)expectation in our framework. Finally, rethinking the traditional Gricean distinction between evidence and belief within a context split into premises (including evidence) and expectations, provides a novel way of formally capturing grounds for commitment to linguistic content, for instance what admissible evidence sufficient for asserting a prejacent is, and how linguistic antecedents can serve as, or be presented as, evidence within the discourse. This covers uses of pragmatic markers seeking to convince the addressee to accept the utterance context based on the speaker's assertion. Such uses are frequent, but often explained as "pragmatically marked" as they elude formal analysis.

Attitudinal evaluation of university students' online comments on their teachers: Insights from Appraisal Theory

Kristine D. de Leon
Sohar University, Sultanate of Oman
kdacia@su.edu.om

Abstract

Following Martin and White's (2005) Appraisal Theory on attitude: affect, judgment, and appreciation, this study investigates the evaluative language of students' online comments towards their teachers. The findings indicate that judgment is the most frequently expressed attitude, as students use online comments to inform and guide peers, especially during enrollment. The findings suggest that judgment is the most frequently expressed attitude, as students use online comments to inform and guide peers, especially during enrollment. Additionally, these comments centered on evaluating teacher performance, focusing on their capabilities and the complexities of their teaching. In the affect system, students often express happiness, using words like "love" and "like" to describe their teachers, and in the appreciation system, students often refer to the impact related to class evaluations and assessment complexity. The results, therefore, highlight the significant influence of students' perceptions on their ratings of teachers and classes, aligning with Tanabe and Mori's (2013) assertion that these perceptions shape overall evaluations. From a pedagogical perspective, the study suggests that teachers should prioritize improving their teaching effectiveness and nurturing strong interpersonal relationships with students. Additionally, teachers need to be aware of the lasting impact of classroom experiences, as negative interactions can affect students' attitudes and performance long after the events.

Keywords: Appraisal theory, evaluative language, evaluation, online coments

1 Introduction

The study of the way writers or speakers convey their attitudes, emotions, or assessments through linguistic choices has garnered increasing attention to many researchers. Consequently, the language of evaluation emerged. Some researchers termed it stance (Biber, 2006; Prencht, 2003), while others preferred to call it evaluation (Bednarek, 2006; Martin & White, 2005; Thompson & Hunston, 2000). Evaluation, according to Hunston and Thompson (2000), is "the broad cover term for the expression of the speaker or writer's attitude or stance towards, viewpoint on, or feelings about the entities or propositions that he or she is talking about." In order to investigate the writer or speaker's attitude towards a particular correspondence or communication, different elements of a particular language have to be considered in order to capture the evaluation or stance of the writer or speaker. These elements that encompass the language of evaluation could be lexical items such as adjectives (e.g., terrible and exciting), adverbs (e.g., unfortunately and interestingly), nouns (e.g., success and failure), and verbs (e.g., fail and doubt), or they could be part of grammar (e.g., past tense and tag questions), or a text per se (Hunston & Thompson, 2000). This was further supported by Conrad and Biber (2000) when they emphasized that the analysis of evaluation has to include grammatical aspects, specifically focusing on adverbial markers of stance in both spoken and written language. Their research suggests that the interplay between lexis and grammar is critical for comprehensively understanding evaluative language. A further emphasis was also made by Channell (2000), when she claimed that the meanings of words can vary significantly among speakers. This then highlights the complexity of the human mental lexicon.

However, evaluative language goes beyond grammar and lexicon as the expression of stance varies considerably depending on the context (Biber, 2006).

Studies on evaluative language cover various genres and context. For example, Marin-Aresse and Nunez-Perucha (2006) provided insights into using evaluative language in journalistic contexts, highlighting how evaluative language varies across different genres and cultures. In line with this, Caldwell (2009) utilized interviewees' evaluative language in constructing their identities and managing their public personas in the media, and Bednarek (2014), who analyzed the evaluative strategies employed in promotional blurbs for television series revealed how positive evaluations are crafted to enhance appeal and influence audience perceptions. In a classroom discourse, teachers who skillfully employ positive evaluative language can significantly motivate students and create a more engaging classroom atmosphere (Rahayu et. al, 2020; Zhu, 2023).

The influence of evaluative language extends beyond academic and journalistic contexts. With the rise of digital media, computer-mediated communication emerged, and one area that has piqued the interest of numerous researchers is the comments section across various online platforms. The comments in this section, referred to as Online comments, represent a significant form of digital communication, which allows Internet users to express their thoughts and reactions, therefore serving as a medium of engagement. These comments specifically provide users with a way to engage with the content and each other, offering opinions, feedback, questions, or discussion points. The public nature of online comments invites an array of opinions, which can be found in many forms, from short replies to lengthy discussions and from positive affirmations to critical feedback. These, therefore, are key features of interactive online spaces.

Given that online comments are publicly accessible, they exhibit unique characteristics that differentiate them from other registers, such as traditional writing and speaking, primarily due to their informal nature and the immediacy of the interaction (Ehret & Taboada, 2020). Thus, commenters, as pointed out by Myers (2010), are often concerned with how they position and present themselves in a space shared with other participants. Moreover, commenters provide a significant prevalence of both positive and negative evaluations, highlighting the argumentative nature of online comments, therefore, emphasizing the importance of recognizing the complexity of online interactions (Cavasso & Taboada, 2021), making the study of communication strategies and the specific language used in online comments a compelling area of investigation.

Thus, “different meanings for different speakers” (Channell, 2020) indicates that interpretation is essential for understanding how evaluative language, where the same term may evoke different responses depending on the speaker's background and context, and that context shapes language use, particularly in online comments where the audience and purpose can significantly influence the evaluative language employed. Several studies on online comments focused on online news comments (e.g. Cavasso & Taboada, 2021) and product reviews (e.g. Kheovichai, 2014). This paper, therefore, aims to focus on students' online comments directed towards their teachers through the lens of evaluative language, an area that has been underexplored in existing literature since most papers on evaluative language related to academic context focused on teachers’ talk or comments or certain pedagogy or teaching strategies (e.g. Shrestha, 2022). Given the increasing prevalence of computer-mediated communication in educational contexts, understanding how students articulate their thoughts and feelings about their teachers in online forums, which are informal platforms, can be beneficial as students are not hindered by certain evaluation structures.

Most studies on student evaluations of teaching (SET) focus on formal evaluations used by various educational institutions for different purposes, such as assessing teacher effectiveness. The evaluation of teachers by students is critical, as it can influence teaching practices and institutional policies. Delaney et al. (2010) highlight that various factors, including engagement and interpersonal relationships, are perceived by students as indicators of effective teaching. This finding is also supported by Fan (2012), who found that positive teacher-student relationships significantly correlate with improved student performance. This suggests that interpersonal interactions between students and teachers enhance students' evaluations of their instructors, which in turn impacts the overall educational experience. Additionally, this notion is

reinforced by Hu (2023), who notes that students value teachers who can adapt their teaching methods to address diverse learning needs, as well as those who actively involve them in the learning process (Munna & Kalam, 2021).

However, the integrity of student evaluations can be called into question due to several factors, such as grading leniency (Greenwald & Gilmore, 1997), which can significantly influence students' perceptions of teaching effectiveness, thereby leading to inflated teaching evaluations. Furthermore, perceived teacher personality traits (Tanabe & Mori, 2013) can also affect student evaluations of teaching (SET). In contrast, Palali et al. (2023) argue that there is no relationship between student grades and SET, nor between the number of a teacher's publications and SET. They suggest that SET scores may reflect the teacher's personality and students' personal classroom experiences.

As previously mentioned, most studies have concentrated on formal student evaluations. In contrast, this study focuses on informal evaluations through online comments made by students on a dedicated website, using the Appraisal approach, which is highly likely not adopted in the STE. This, therefore, can contribute to the broader understanding of teacher-student dynamics especially in digital environments. Specifically, the study seeks to answer the following questions:

1. What is the attitudinal evaluation of the students toward their teachers?
2. How are the three systems of attitude—namely affect, judgment, and appreciation—employed in the online comments of the students?

2 Framework

Evaluation is a broad concept; therefore, some researchers have developed different frameworks to address this complexity. Bednarek (2006) is one such researcher. She investigated evaluation in media discourse and, to support her analysis, proposed a new theory on evaluation consisting of nine parameters. These parameters are divided into two systems. The first system includes the core evaluative parameters: comprehensibility, emotivity, expectedness, importance, possibility/necessity, and reliability. The second system encompasses the peripheral evaluative parameters: evidentiality, mental state, and style. According to Bednarek (2006), this new evaluation framework, which includes more than twice the parameters of Thompson and Hunston's (2000) framework—comprising good–bad/positive–negative, certainty, expectedness/obviousness, and relevance/importance—offers a more nuanced approach to capturing the complexity of evaluation. Bednarek's framework proved effective in distinguishing between the evaluative styles of newspapers and tabloids and demonstrated its flexibility in solving issues related to evaluation, outperforming earlier approaches.

While Bednarek's nine-parameter framework may be one of the most comprehensive in evaluation research, this study adopts Martin and White's (2005) framework on mapping feelings and emotions, as it better suits the analysis of students' comments on their professors posted in online comment sections. Martin (2000) defines Appraisal as a system used "to negotiate emotions, judgments, and valuations, alongside resources for amplifying and engaging with these evaluations" (p. 145). The Appraisal framework is classified into three elements: engagement, attitude, and graduation. This study focuses solely on attitude, as the researchers seek to analyze the evaluation of attitudes expressed in students' comments toward their teachers.

Attitude, additionally, has three systems—affect, judgment and appreciation, and the definition of Martin and White (2005) of these three systems are as follows:

"Affect is concerned with registering positive and negative feelings: do we feel happy or sad, confident or anxious, interested or bored" (p.42) ?

"Judgement deals with attitudes towards behaviour, which we admire or criticise, praise or condemn" (p.42).

"Appreciation involves evaluations of semiotic and natural phenomena, according to the ways in which they are valued or not in a given field" (p.43).

Each of these three systems of Attitude was further classified by Martin and White (2005). See Appendix for the different frameworks of the three systems of Attitude with their classifications.

In addition, to further grasp the concept of the appraisal framework of Martin and White (2005), an overview is provided below.

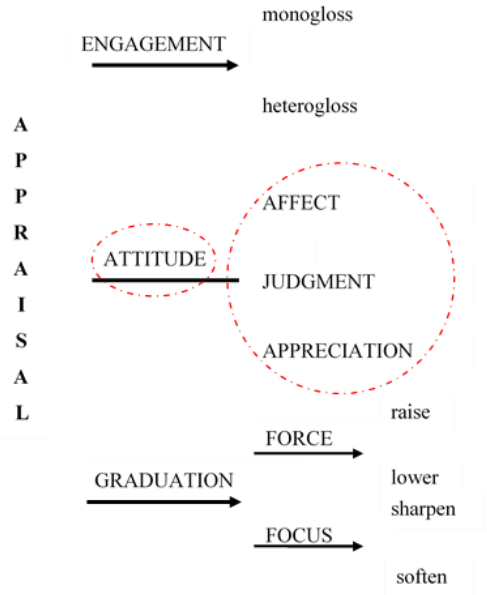

Figure 1: Martin and White's (2005) appraisal framework

3 Methodology

3.1 Research Design

This study is descriptive and examines the three systems of attitude—affect, judgment, and appreciation—to determine the students' attitudinal evaluation of their professors, based on Martin and White's (2005) Attitude framework.

3.2 Material

The material for this study was taken from an online comment section on a website built by a group of students. The purpose of this website is to provide information to their fellow classmates and schoolmates about professors at their university. Students posted comments regarding which professors their peers should choose or avoid. This online comment platform proves particularly useful during enrollment periods as it offers insights into professors' personalities and teaching styles.

3.3 Data Collection

Cluster sampling was used in this study. Since faculty names are categorized based on the colleges to which they belong, the researchers decided to use 10% of the faculty members population, including both part-time and full-time faculty with various ranks, from each college.

To gather the comments about these faculty members, the researchers accessed the web page of each randomly selected professor. Two comments were chosen for each faculty member, yielding a total of 164 comments. The comments were not randomly selected due to the bilingual nature of many responses. Some comments were in English, some in Filipino, and some in a mixture of both.

For ease of coding and analysis, the researchers opted to select comments written in English or containing only one or two Filipino words, which were typically enclitics or function words.

3.4 Data

The online comments were analyzed using Martin and White's (2005) framework, and each analysis was coded with abbreviations representing the classifications of the different systems of Attitude, following the coding system used by Martin and White. The abbreviations are as follows:

+	'positive attitude'
_	'negative attitude'
Des	'affect: desire'
Hap	'affect: happiness'
Sec	'affect: in/security'
Sat	'affect: dis/satisfaction'
Norm	'judgment: normality'
cap	'judgment: capacity'
Ten	'judgment: tenacity'
Ver	'judgment: veracity'
Prop	'judgment: propriety'
Imp	'appreciation: reaction: impact'
Qual	'appreciation: reaction: quality'
Bal	'appreciation: composition: balance'
Comp	'appreciation: composition: complexity'
Val	'appreciation: valuation'

Table 1: Coding Guide

The codes imp, qual, bal and comp are initially not in the list of codes of Martin and White (2005). These (4) codes replaced the two (2) original codes namely reac for appreciation: reaction and comp for appreciation: composition, so that it would be easier for the researchers to identify the type of reaction or composition found in the data. Aside from the codes above, Martin and White (2005) suggested differentiating negative attitude and grammatically negated attitude. Thus, neg as negative was also used in the coding which had a different function with (-) which represents negativity as well. The (-) was used for negative attitude, while neg was used for grammatically negated attitude. An example for this was not like which had to be coded as neg +hap and not –hap

unless if the word was unlike. Another code that was used is "t" which pertains to "ideational tokens/invocations" (Martin &White, 2005, p. 75). For example, the sentence "a comment from the student would blow her up" which was addressed to the teacher was coded as t, +prop because blow her up has a connotation which means that the teacher [her] would get very angry if someone would comment on her.

To ensure clarity in the data analysis, not only were codes used, but a table was also created following the suggestions of Martin and White (2005). This table included columns to distinguish between different systems of attitude: affect, judgment, appreciation, appraiser, appraised, and appraising items. Each column serves a specific function: the appraiser represents the source of the attitude, while the appraised can be a person being judged (judgment) or an object being appreciated (appreciation). In the case of affect, the appraiser is the one experiencing the emotion (emoter), and the appraised can be a thing, person, or activity receiving the emotion. Appraising items, on the other hand, refer to lexicogrammatical elements that convey evaluations.

In analyzing the data, three inter-coders were employed to ensure consistency and accuracy of the findings. In instances where discrepancies arose, a systematic discussion was initiated to address these differences and reach a consensus.

4 Results and Discussions

4.1 Attitudinal evaluation of students' comments to their professors

Table 1 shows the frequency of the different types of evaluation identified by the researchers, which were categorized as either positive or negative.

ATTITUDE	Positive (%)	Negative (%)
Affect	6.62	7.93
Judgment	83.79	73.17
Appreciation	9.59	18.90
Total	100	100

Table 2: Attitudinal evaluation of students' comments

As can be seen in table 2, there is a wide gap between affect and judgment and between appreciation and judgment. It is quite clear in the table that the foregrounded system is judgment with around 80% of the overall appraised items. With this, it could then be deemed that most of the comments given by the students are about the character or personality of the teacher. This is not really unexpected given that the data is about students' comments to their teacher. Comment as defined in Merriam-Webster is an "an observation or remark expressing an opinion or attitude". Thus, the comments that the students gave are based on their interactions with their teacher in their everyday classes in the university. Examples of the comments that the students gave to their professor are shown below.

Example 1

She is approachable and motherly but she is
+prop +prop
inconsiderate…
-prop

Example 2

Humiliating students in front of the class
-prop

In example 1, the teacher's personality inside the classroom is being positively and negatively judged by the student. It shows that the student who commented this in a way like the teacher since he/she could easily discuss his/her concerns with their studies and with the use of the word motherly which pertains to mother, the student could have perceived the teacher as kind and caring, which are some of the characteristics of a typical mother. However, there is an attitude of a teacher that the student does not like, and this is the teacher's inconsideration probably to the student or to the class where the student belongs. In the next example, the student evaluated the teacher as someone who humiliates students in the class, which could be traumatizing to the students since it could affect their self-esteem. Students' hurtful experiences inside the classroom could form lasting memories (Uitto, 2011), and could lead to disengagement and anxiety (Zhu, 2023). Thus, this student who was probably one of the students who were humiliated had expressed his/her experience with this teacher to warn other students.

The least type of attitude used in the comments of the students is appreciation. As stated by Martin and White (2005), appreciation is drawn on things, performances, or occurrences, and since the thrust of the website is to inform their fellow students the teachers to pick or choose when they enroll in a particular subject; hence, most likely the comments should have adequately covered the class itself or the activities or tasks employed in the classroom.

The very low percentage of the usage of this type of attitude in the comments of the students is quite surprising. A reason for this could be that the students are more concerned about the personality of the teacher than the classroom activities or tasks that the teachers employ in his/her classes because students could have viewed a teacher with a pleasing personality as someone who could help and guide them in their studies. As Fan (2012) claimed, a healthy teacher-student relationship could lead to high academic performance. Hence, knowing a teacher's personality can be a good plan before enrolling a particular class because it could have made the students more prepared in terms of how they would interact with their chosen or assigned teacher. Examples on the comments that have appreciation are as follows:

Example 3
her quizzes are hard and LONG
-comp -comp

Example 4
her class is too boring
-imp

The examples above illustrate that most of the time appreciation is used when the students comment on their class or on the type of quizzes that the teacher usually gives. Example 3 implicates that students do not want to have a difficult evaluation or assessment. Students even prefer to have multiple choice type of evaluation than an essay type (Struyven et al., 2005). Example 4, however, implies that students want to have fun while learning. Thus, it would then be a challenge for a teacher on how to meet these demands of the students considering that there are pedagogical aspects that have to be addressed as well.

4.2 Affect, Judgment, and Appreciation in students' online comments

To answer the second question of this paper on how the three elements of attitude—affect, judgments and appreciation—are employed in the comments of the students, the following tables below would be discussed.

Table 3: Affect evaluation on the students' comments: Student as the emoter

Affect	Desire		Un/happiness		In/security		Dis/satisfaction		Total
	+	-	+	-	+	-	+	-	
	2	0	10	0	1	0	1	0	14
Invoked			4	2				0	6
TOTAL	2	0	14	2	1	0	1	0	**20**

Table 3 presents the evaluation of the students to their teachers, which represents that the emoters or the appraisers are the students; thus, the focus here is the students' feelings or emotions towards their teachers. As can be seen, happiness has the highest number of occurrences with more than half of the total number of occurrences in which affect evaluation was used by the students in evaluating their teacher. This reveals that students are happy with their teacher and only a few of them are not happy, and students who expressed happiness use words such as like and love referring to their affection for their teacher. Some of the comments of the students are as follows:

Example 5 *I love her so much* [+hap]
Example 6 *Some of my friends really liked him* [+hap]

Another observation is that students express happiness with their teachers if he or she has a pleasing personality. Some of the comments mentioned about the teacher being cheerful and happy. However, some comments expressed the likeness of the student to their teacher due to the grade that the teacher gave. If the students have gotten high grade or if they have passed the subject, then they are happy with their teachers. This phenomenon is similarly found in Greenwald and Gillmore (1997) study in which they claimed that expected course grades are correlated with the evaluation the students give to their teachers; therefore, higher evaluations are expected if the grades are leniently given. An example of a student's comment is presented below.

Example 7 *She passed me so I like her* [+hap]

Teachers are not sole appraisers or the receiver of the emotions of the students. Some of these could be the quizzes, subjects, class, or grades. Examples are:

Example 8 *Problem would be his quizzes* [t,-hap; quizzes]

Example 9 *...like the (subject) because of her* [+hap; subject]

Example 10 *could barely keep themselves awake* [t,-sat; class]

Example 11 *Quite disappointed* [–dis; grade]

Example 8 on the one hand illustrates the dislike of the student towards the quizzes of the teacher. This does not entail that the student does not like the teacher. The student may probably like the teacher but not the quizzes that he/she gives due to their level of difficulty. Example 9, on the other hand, the teacher is the reason for making the student like the subject, but it does not mean that the teacher is the recipient of the emotion which is love. The next example relates to the classroom experience, illustrating that students may appear bored, and this does not necessarily mean the teacher is responsible for creating a dull atmosphere. The subject itself could be inherently less engaging. Nonetheless, teachers can improve the classroom environment by incorporating various active learning strategies, which have been shown to increase student engagement and satisfaction. (Munna & Kalam, 2021). The last example is about the grade of the students. When students feel disappointed with their grades, it may reflect their self-regulation abilities and the overall learning environment. This, comment, therefore, does not equate as a direct critique of their teacher, but a teacher plays a crucial role in processing their emotions through a positive and constructive student-teacher conversation (Sanders & Anderson, 2010). These examples above represent an overview of how students evaluate, and these show that students know that in choosing a teacher, other factors have to be considered, not just the teacher's personality.

The students are not the sole emoters or appraisers in the comments. The teachers are emoters or appraisers as well and these are based on the students' observation and perception on their teachers' feelings or mood in the class. Table 3 presents the summary of the affect of the teachers.

Affect	Desire		Un/happiness		In/security		Dis/satisfaction		Total
	+	-	+	-	+	-	+	-	
	3	1	8	2			2		16
t (Invoked)								1	1
TOTAL	3	1	8	2	0	0	2	1	**17**

Table 4: Affect evaluation on the students' comments: Teacher as the emoter

As presented in Table 4, happiness comprised almost half of the total occurrences in which the teachers are the emoter which is also the prevalent affect category when the students are the emoters. This shows that students are very observant of their teacher's emotions towards them or towards the class itself. Some of the examples are given below.

Example 12 *likes to give a lot of incentives* [+hap]
Example 13 *loves telling stories* [+hap]

These examples show the teacher's engagement inside the classroom. As seen in example 13, using stories could be one strategy the teacher employs to have a more inclusive and relatable classroom environment. According to Doqaruni (2023), "narrative approaches to teaching are pretty effective in achieving moral, pedagogical, and intercultural functions" (p.157).

The next is judgment. Table 5 below provides the use of judgment in the students' online comments and the judgment here construe the attitude of the students to their teacher and their teacher's behavior.

Judgment	Normal		Capability		Tenacity		Veracity		Propriety		Total
	+	-	+	-	+	-	+	-	+	-	
	22	9	101	27	6	6	1	1	95	22	290
T (invoked)	1	2	81	23	6	8			52	23	196
	23	11	182	50	12	14	1	1	148	44

Table 5: Judgment evaluation on the students' comments

As can be seen in the table above, it is apparent that the capability has the highest number of occurrences in the online comments of the students, and between the positive and negative capability, the positive capability is prevalent. In the positive capability, the students' comments showed that students give more importance to the teachers' teaching performance or mastery of the subject rather than to his/her academic rank or educational attainment, and if they are not satisfied with the teachers' performances then they would evaluate the teacher negatively. One of the students commented that some teachers have the highest degree that could attain in the academe, but they do not know how to teach. Another student additionally commented that the teacher is a good researcher but not a good teacher. As what Palali et al. (2018) argued, research can enhance teaching through the integration of current knowledge, but it

does not equate to effective teaching pedagogy. This view of students can be a challenge for teachers to hone their skills not just in researching and mastering the subject matter itself but also in mastering the art of teaching. Examples are shown below that demonstrates the evaluation of the students on their teachers, both positively and negatively.

Example 14 *She knows what she's teaching*. [+cap]
Example 15 *Really vague in teaching* [-cap]
Example 16 *She teaches very well.* [+cap]
Example 17 *Gives unclear instructions* [-cap]
Example18 *...simplifies complicated terms* [t,+cap]

Additionally, it has to be noted that almost half of the positive capability occurrences are invoked (t) attitude, which implies that the students did not explicitly wrote their comments on how capable their teachers are. Example 18 above exhibits a comment that can be considered as invoked. Instead of stating that the teacher is good in teaching, the student described the goodness of the teacher in teaching by stating how the teacher can make the terms in their subject easy to understand for the students.

Another noticeable element that is commonly used in the online comments is propriety, especially the positive propriety. The students appreciate teachers with good character and it is one of their bases in choosing or recommending a teacher to another students.

The common characters that pleased the students are generosity, consideration, approachability of the teacher. The students commend teachers who are generous in giving grades. As mentioned earlier, the higher or the better grades they get from a particular teacher, the more likely they are to evaluate the teacher positively, and in the online comments, this type of teacher is highly recommended to their classmates or schoolmates. Another one is a consideration. This could be directly or indirectly related to their grades. In their comments, consideration can be directly related to grades when a teacher gives a passing grade to a student who has a failing grade but only needs few points to pass the subject. It could also indirectly if the teacher accepts late papers or requirements of the student. Approachability is another character that students like about a teacher, and several studies have claimed that it is indeed a prominent characteristic of an effective teacher (e.g. Delaney et. al, 2010; Hu, 2020). The students prefer a teacher whom they can talk easily because they feel that they could raise any concerns they have about their subject, requirement or grades without being anxious on the reaction of the teacher. A This, therefore, emphasizes the significance of positive teacher interpersonal behavior, which can create a supportive classroom environment, meeting students' emotional and interpersonal needs (Zheng, 2022). Some lines from the comments that demonstrate the above characters mentioned are as follows:

Example 19 *One of the kindest* [+prop]
Example 20 *Most considerate* [+prop]
Example 21 *won't give you a nervous vibe* [t, neg –prop]

In the propriety, negative evaluations were also given to the teachers. However, the ratio is almost 1:4. Thus, for every negative comment that was written in the online, four positive comments were written too. The comments with negative propriety are usually the exact opposite of the comments of positive propriety which denotes that if the teacher, for example, is not generous, considerate, and approachable, there is a huge probability that the student would comment negatively about this teacher. Examples taken from the comments are the following:

Example 22 *She gives low grades* [t,-prop]
Example 23 *Don't forget to greet him good morning or else....* [t,-prop]

The above table shows that more than half of the students' comments are positive. This reveals that even if the students have negative comments, but overall they have positive views towards their teacher. Another element of attitude that will be discussed is the appreciation. The table below presents the appreciation evaluation of the students' comments.

Appreciation	Reaction				Composition				Valuation		Total
	Impact		Quality		Balance		Complexity				
	+	-	+	-	+	-	+	-	+	-	
	18	9	5	2		2	9	10	3	2	60
t (invoked)	1	2	1	2			3	2	2		13
TOTAL	19	11	6	4	0	2	12	12	5	2	73
	30		10		2		24		7		

Table 6: Appreciation evaluation on the students' comments

As can be seen in the table above, impact as part of reaction has the highest number of occurrences in the online comments. Most of the time, the appraised items under impact is the class or discussions. The students usually express their opinion on whether the class or discussions are boring, chill, fun or interesting. Thus, these words are also commonly seen in their comments when they refer to their class, discussions, lessons and other learning activities.

Example 24 *It gets fun* [+imp]
Example 25 *Class is never boring* [+imp]

Another attitude that is commonly present in their comments under appreciation is complexity. This time, most of the items the students appraised are the tests. For them, the more complex the test is, the less they appreciate it. However, it is important to note that these individuals are college students, and it is expected that their assessments will be challenging, particularly in their core subjects. Therefore, evaluating a test positively or negatively based solely on its level of difficulty seems questionable. Some examples are shown below:

Example 26 *Easy pass* [t, +comp]
Example 27 *Quizzes are fine* [+comp]

In the appreciation element of attitude, the comments revealed that students appreciate their class, test or quiz, subject and lesson if they are less complicated. Thus, the more lenient the professor in doing and giving these different school activities, the more the students appreciate them. This therefore further supports Greenwald and Gillmore (1997) claim that students who find the course manageable tend to rate their teachers more favorably. This presents a potential conflict of interest, as teachers have obligations and responsibilities that they must fulfill to provide quality education to their students.

5 Conclusion

The study on evaluation based on the attitude system of the Appraisal Theory of Martin and White (2005) gives enlightenment on the attitude used by students in their online comments and how do the three systems of attitude used in the students' online comments. It was revealed in the study that the type of attitude that was foregrounded in the online comments is judgment, and this is due to the nature of the online which is to give information and to help their fellow students about the teachers they have to choose especially during enrollment time. Additionally, the three systems of attitude presented the different functions of the different systems of attitude in the online comments. First, the most prevailing category in the affect is the use of happiness in which the students express their happiness through the use of love and like and these words are usually addressed to their teacher. Second, in the judgment, capabilities followed by complexities are the commonly employed types of judgment in approving or disapproving their teacher's performance and attitude. Third, in the appreciation, the two frequently used categories are impact and complexity. Impact is often used when the students evaluate classes, while complexity are often used when they evaluate tests or quizzes. These three elements facilitated in revealing the perception of the online commenters or in this case the students toward their teachers. Thus, teachers must be more aware of how students perceive them and their classes. According to Tanabe and Mori (2013), the rating of a class such as interesting is positively influenced by students' perception and students' perception of their teachers affects the overall rating. Therefore, students' perception of the class as a whole and the teacher could influence each other

The study yields several important pedagogical implications. First, teachers need to refine their teaching skills, as students tend to favor educators who demonstrate effective teaching abilities over those who possess high educational qualifications but lack pedagogical competence. Second, the interpersonal relationships between teachers and students appear to significantly influence students' academic achievement. Consequently, it is crucial for teachers to cultivate and strengthen their relationships with their students. Lastly, the experiences that students encounter within the classroom, particularly negative ones, can leave lasting impressions and may even be traumatic. Therefore, teachers must be more mindful and deliberate in their actions and interactions within the classroom environment.

Appendix A

Different frameworks of the three systems of Attitude with their classifications.

AFFECT (Emotions; reacting to behavior)

	Positive	Negative
Dis/inclination	miss, long for, yearn for…	wary, tearful, terrorized…
Un/happiness	cheerful, like, love…	sad, broken hearted, dreary..
In/security	confident, assured, comfortable…	uneasy, surprised…
Dissatisfaction	satisfied, impress, charmed…	furious, jaded, bored with…

JUDGMENT (Ethics; evaluation behavior)

Social Esteem (Venial)	**Positive (admire)**	**Negative (criticize)**
Normality 'Is he or she special?'	lucky, charmed, normal…	unfortunate, pitiful, tragic…
Capacity 'Is he or she capable?'	powerful, vigorous, robust…	mild, weak, slow, stupid…
Tenacity 'Is he or she reliable, dependable'	brave, dependable, tireless...	rash, cowardly, unreliable…
Social Sanction (Moral)	**Positive (praise)**	**Negative (condemn)**
Veracity ' Is he or she honest?'	honest, credible, frank…	deceitful, fake, deceptive…
Propriety ' Is he or she beyond reproach?'	Just, sensitive, caring…	Bad, immoral, unfair…

APPRECIATION (Norms about how products, performances, and naturally occurring phenomena are valued)

	Positive	Negative
Reaction: impact 'Did it grab me?'	arresting, captivating, engaging…	dull, boring, tedious…
Reaction: quality 'Did I like it?'	lovely, splendid, appealing…	plain, ugly, revolting…
Composition: balance 'Did it hang together'	harmonious, unified, proportional…	unbalanced, discordant
Compositoin: complexity 'Was it hard to follow?'	simple, elegant, intricate…	ornamental, extravagant…
Valuation 'Was it worthwhile'	challenging, profound, deep…	shallow, insignificant…
