Introduction

The Eighth Conference on Machine Translation (WMT 2023) took place on Wednesday, December 6 and Thursday, December 7, 2023, immediately preceding the 2023 Conference on Empirical Methods in Natural Language Processing (EMNLP 2023).

This is the eighth time WMT has been held as a conference. The first time WMT was held as a conference was at ACL 2016 in Berlin, Germany, the second time at EMNLP 2017 in Copenhagen, Denmark, the third time at EMNLP 2028 in Brussels, Belgium, the fourth time at ACL 2019 in Florence, Italy, the fifth time at EMNLP-2020, which was held as an online event due to the COVID-19 pandemic, the sixth time at EMNLP 2021 at Punta Cana, Dominican Republic, and the seventh time at EMNLP 2022 in Abu Dhabi, United Arab Emirates. Prior to being a conference, WMT was held 10 times as a workshop. WMT was held for the first time at HLT-NAACL 2006 in New York City, USA. In the following years the Workshop on Statistical Machine Translation was held at ACL 2007 in Prague, Czech Republic, ACL 2008, Columbus, Ohio, USA, EACL 2009 in Athens, Greece, ACL 2010 in Uppsala, Sweden, EMNLP 2011 in Edinburgh, Scotland, NAACL 2012 in Montreal, Canada, ACL 2013 in Sofia, Bulgaria, ACL 2014 in Baltimore, USA, EMNLP 2015 in Lisbon, Portugal.

The focus of our conference is to bring together researchers from the area of machine translation and invite selected research papers to be presented at the conference.

Prior to the conference, in addition to soliciting relevant papers for review and possible presentation, we conducted 13 shared tasks. These consisted of 13 translation tasks: General translation, Terminology, Literary translation, Word-level autocompletion, Sign language, Biomedical, Low-resource Indic language translation, Large-scale machine translation evaluation for African languages, Metrics, Quality estimation, MT test suites, Automatic post-editing, and Parallel data curation.

The results of all shared tasks were announced at the conference, and these proceedings also include overview papers for the shared tasks, summarizing the results, as well as providing information about the data used and any procedures that were followed in conducting or scoring the tasks. In addition, there are short papers from each participating team that describe their underlying system in greater detail.

Like in previous years, we have received a far larger number of submissions than we could accept for presentation. WMT 2023 has received 50 full research paper submissions (not counting withdrawn submissions). In total, WMT 2023 featured 18 full research paper presentations and 71 shared task presentations.

WMT 2023 featured a panel on the role of large language models for machine translation. The invited panelists were: Eleftheria Briakou (University of Maryland), Arul Menezes (Microsoft), and José de Souza (Unbabel).

We would like to thank the members of the Program Committee for their timely reviews. We also would like to thank the participants of the shared task and all the other volunteers who helped with the evaluations.

Barry Haddow, Tom Kocmi, Philipp Koehn, and Christof Monz

Co-Organizers

Organizers:

Barry Haddow (University of Edinburgh)
Tom Kocmi (Microsoft)
Philipp Koehn (Johns Hopkins University)
Christof Monz (University of Amsterdam)

Program Committee:

Sadaf Abdul Rauf (Fatima Jinnah Women Unversity)
David Ifeoluwa Adelani (University College London)
Jesujoba Alabi (Saarland University)
Antonios Anastasopoulos (George Mason University)
Mihael Arcan (University of Galway)
Duygu Ataman (New York University)
Eleftherios Avramidis (German Research Center for Artificial Intelligence (DFKI))
Parnia Bahar (AppTek)
Petra Barancikova (Charles University in Prague)
Jasmijn Bastings (Google)
Rachel Bawden (Inria)
Meriem Beloucif (Uppsala University)
Toms Bergmanis (Tilde)
Alexandra Birch (University of Edinburgh)
Frederic Blain (Tilburg University)
Nikolay Bogoychev (University of Edinburgh)
Marine Carpuat (University of Maryland)
Francisco Casacuberta (Universitat Politècnica de València)
Sheila Castilho (Dublin City University)
Boxing Chen (Huawei)
Colin Cherry (Google)
Vishal Chowdhary (MSR)
Chenhui Chu (Kyoto University)
Raj Dabre (NICT)
Steve DeNeefe (RWS Language Weaver)
Michael Denkowski (Amazon)
Shuoyang Ding (Amazon)
Miguel Domingo (Universitat Politècnica de València)
Kevin Duh (Johns Hopkins University)
Koel Dutta Chowdhury (Saarland Informatics Campus, Saarland University)
Hiroshi Echizen'ya (Hokkai-Gakuen University)
Cristina España-Bonet (DFKI GmbH)
Miquel Esplà-Gomis (Universitat d'Alacant)
Mikel L. Forcada (Universitat d'Alacant)
George Foster (Google)
Atsushi Fujita (National Institute of Information and Communications Technology)
Mercedes García-Martínez (Pangeanic)
Jesús González-Rubio (WebInterpret)

Isao Goto (NHK)
Thamme Gowda (Microsoft)
Jeremy Gwinnup (Air Force Research Laboratory)
Thanh-Le Ha (Zoom Video Communications)
Nizar Habash (New York University Abu Dhabi)
Greg Hanneman (Amazon)
Yifan He (Google)
Jindřich Helcl (Charles University in Prague)
John Henderson (Mechanical Learning)
Amr Hendy (Microsoft)
Nico Herbig (German Research Center for Artificial Intelligence (DFKI), Saarland Informatics Campus)
Christian Herold (RWTH Aachen University)
Mika Hämäläinen (Metropolia University of Applied Sciences)
Kenji Imamura (National Institute of Information and Communications Technology)
Yuchen Eleanor Jiang (ETH Zurich)
Josef Jon (Charles University)
Baikjin Jung (POSTECH)
Diptesh Kanojia (University of Surrey)
Huda Khayrallah (Microsoft)
Julia Kreutzer (Google)
Mateusz Krubiński (Charles University)
Roland Kuhn (National Research Council of Canada)
Gaurav Kumar (Bloomberg LP)
Anoop Kunchukuttan (Microsoft AI and Research)
Wen Lai (LMU Munich)
Surafel M. Lakew (Amazon.com, Inc)
Ekaterina Lapshinova-Koltunski (University of Hildesheim)
Samuel Larkin (National Research Council Canada)
Giang Le (University of Illinois Urbana-Champaign)
Gregor Leusch (eBay)
William Lewis (University of Washington)
Samuel Läubli (University of Zurich)
Jean Maillard (Meta AI)
Andreas Maletti (Universität Leipzig)
Arne Mauser (Snowflake)
Antonio Valerio Miceli Barone (The University of Edinburgh)
Amit Moryossef (Bar-Ilan university, University of Zurich)
Kenton Murray (Johns Hopkins University)
Mathias Müller (University of Zurich)
Graeme Nail (University of Edinburgh)
Graham Neubig (Carnegie Mellon University)
Jan Niehues (Karlsruhe Institut of Technology)
Xing Niu (Amazon AI)
Tsuyoshi Okita (Kyushu institute of technology)
Arturo Oncevay (The University of Edinburgh)
Daniel Ortiz-Martínez (University of Barcelona)

Santanu Pal (Wipro)
Jianhui Pang (University of Macau)
Stephan Peitz (Apple)
Sergio Penkale (Lingo24)
Mārcis Pinnis (Tilde)
Maja Popović (ADAPT, Dublin City University)
Reinhard Rapp (University of Mainz)
Vikas Raunak (Microsoft)
Ricardo Rei (Unbabel/INESC-ID)
Matiss Rikters (AIST)
Annette Rios (University of Zurich)
Elizabeth Salesky (Johns Hopkins University)
Rico Sennrich (University of Zurich)
Patrick Simianer (Lilt)
Felix Stahlberg (Google Research)
David Stap (University of Amsterdam)
Katsuhito Sudoh (Nara Institute of Science and Technology (NAIST))
Víctor M. Sánchez-Cartagena (Universitat d'Alacant)
Felipe Sánchez-Martínez (Universitat d'Alacant)
Aleš Tamchyna (Memsource)
Gongbo Tang (Beijing Language and Culture University)
Brian Thompson (Amazon)
Jörg Tiedemann (University of Helsinki)
Antonio Toral (University of Groningen)
Ke Tran (Amazon)
Jonas-Dario Troles (University of Bamberg)
Masao Utiyama (NICT)
David Vilar (Google)
Martin Volk (University of Zurich)

Wei Wang (Apple AI/ML)
Taro Watanabe (Nara Institute of Science and Technology)
Marion Weller-Di Marco (Ludwig-Maximilians-Universität München)
Tong Xiao (Northeastern University)
François Yvon (ISIR CNRS & Sorbonne Université)
Xianfeng Zeng (Pattern Recognition Center, WeChat AI, Tencent)
Chrysoula Zerva (Instituto de Instituto de Telecomunicações, Instituto Superior Técnico, University of Lisbon)
Dakun Zhang (SYSTRAN)
Zhong Zhou (Carnegie Mellon University)
Vilém Zouhar (ETH Zurich, Charles University)

Table of Contents

Conference Program

Wednesday, December 6, 2023

8:45–9:00 ***Opening Remarks***

9:00–10:30 **Session 1: Shared Task Overview Papers I**

9:00–9:30 *Findings of the 2023 Conference on Machine Translation (WMT23): LLMs Are Here but Not Quite There Yet*
Tom Kocmi, Eleftherios Avramidis, Rachel Bawden, Ondřej Bojar, Anton Dvorkovich, Christian Federmann, Mark Fishel, Markus Freitag, Thamme Gowda, Roman Grundkiewicz, Barry Haddow, Philipp Koehn, Benjamin Marie, Christof Monz, Makoto Morishita, Kenton Murray, Makoto Nagata, Toshiaki Nakazawa, Martin Popel, Maja Popović and Mariya Shmatova

9:30–9:45 *Findings of the WMT 2023 Biomedical Translation Shared Task: Evaluation of ChatGPT 3.5 as a Comparison System*
Mariana Neves, Antonio Jimeno Yepes, Aurélie Névéol, Rachel Bawden, Giorgio Maria Di Nunzio, Roland Roller, Philippe Thomas, Federica Vezzani, Maika Vicente Navarro, Lana Yeganova, Dina Wiemann and Cristian Grozea

9:45–10:00 *Findings of the WMT 2023 Shared Task on Discourse-Level Literary Translation: A Fresh Orb in the Cosmos of LLMs*
Longyue Wang, Zhaopeng Tu, Yan Gu, Siyou Liu, Dian Yu, Qingsong Ma, Chenyang Lyu, Liting Zhou, Chao-Hong Liu, Yufeng Ma, Weiyu Chen, Yvette Graham, Bonnie Webber, Philipp Koehn, Andy Way, Yulin Yuan and Shuming Shi

10:00–10:15 *Findings of the Second WMT Shared Task on Sign Language Translation (WMT-SLT23)*
Mathias Müller, Malihe Alikhani, Eleftherios Avramidis, Richard Bowden, Annelies Braffort, Necati Cihan Camgöz, Sarah Ebling, Cristina España-Bonet, Anne Göhring, Roman Grundkiewicz, Mert Inan, Zifan Jiang, Oscar Koller, Amit Moryossef, Annette Rios, Dimitar Shterionov, Sandra Sidler-Miserez, Katja Tissi and Davy Van Landuyt

10:15–10:30 *Findings of the WMT 2023 Shared Task on Parallel Data Curation*
Steve Sloto, Brian Thompson, Huda Khayrallah, Tobias Domhan, Thamme Gowda and Philipp Koehn

10:30–11:00 ***Coffee Break***

Wednesday, December 6, 2023 (continued)

11:00–12:30 Session 2: Shared Task System Description Posters I

11:00–12:30 General Translation Task

11:00–12:30 *Samsung R&D Institute Philippines at WMT 2023*
Jan Christian Blaise Cruz

11:00–12:30 *NAIST-NICT WMT'23 General MT Task Submission*
Hiroyuki Deguchi, Kenji Imamura, Yuto Nishida, Yusuke Sakai, Justin Vasselli and Taro Watanabe

11:00–12:30 *CUNI at WMT23 General Translation Task: MT and a Genetic Algorithm*
Josef Jon, Martin Popel and Ondřej Bojar

11:00–12:30 *SKIM at WMT 2023 General Translation Task*
Keito Kudo, Takumi Ito, Makoto Morishita and Jun Suzuki

11:00–12:30 *KYB General Machine Translation Systems for WMT23*
Ben LI, Yoko Matsuzaki and Shivam Kalkar

11:00–12:30 *Yishu: Yishu at WMT2023 Translation Task*
Luo Min, yixin tan and Qiulin Chen

11:00–12:30 *PROMT Systems for WMT23 Shared General Translation Task*
Alexander Molchanov and Vladislav Kovalenko

11:00–12:30 *AIST AIRC Submissions to the WMT23 Shared Task*
Matiss Rikters and Makoto Miwa

11:00–12:30 *MUNI-NLP Submission for Czech-Ukrainian Translation Task at WMT23*
Pavel Rychly and Yuliia Teslia

11:00–12:30 *Exploring Prompt Engineering with GPT Language Models for Document-Level Machine Translation: Insights and Findings*
Yangjian Wu and Gang Hu

Wednesday, December 6, 2023 (continued)

11:00–12:30 *Treating General MT Shared Task as a Multi-Domain Adaptation Problem: HW-TSC's Submission to the WMT23 General MT Shared Task*
Zhanglin Wu, Daimeng Wei, Zongyao Li, Zhengzhe YU, Shaojun Li, Xiaoyu Chen, Hengchao Shang, Jiaxin GUO, Yuhao Xie, Lizhi Lei, Hao Yang and Yanfei Jiang

11:00–12:30 *UvA-MT's Participation in the WMT 2023 General Translation Shared Task*
Di Wu, Shaomu Tan, David Stap, Ali Araabi and Christof Monz

11:00–12:30 *Achieving State-of-the-Art Multilingual Translation Model with Minimal Data and Parameters*
Hui Zeng

11:00–12:30 *IOL Research Machine Translation Systems for WMT23 General Machine Translation Shared Task*
Wenbo Zhang

11:00–12:30 *GTCOM and DLUT's Neural Machine Translation Systems for WMT23*
Hao Zong

11:00–12:30 Test Suites

11:00–12:30 *RoCS-MT: Robustness Challenge Set for Machine Translation*
Rachel Bawden and Benoît Sagot

11:00–12:30 *Multifaceted Challenge Set for Evaluating Machine Translation Performance*
Xiaoyu Chen, Daimeng Wei, Zhanglin Wu, Ting Zhu, Hengchao Shang, Zongyao Li, Jiaxin GUO, Ning Xie, Lizhi Lei, Hao Yang and Yanfei Jiang

11:00–12:30 *Linguistically Motivated Evaluation of the 2023 State-of-the-art Machine Translation: Can ChatGPT Outperform NMT?*
Shushen Manakhimova, Eleftherios Avramidis, Vivien Macketanz, Ekaterina Lapshinova-Koltunski, Sergei Bagdasarov and Sebastian Möller

11:00–12:30 *IIIT HYD's Submission for WMT23 Test-suite Task*
Ananya Mukherjee and Manish Shrivastava

11:00–12:30 *Test Suites Task: Evaluation of Gender Fairness in MT with MuST-SHE and INES*
Beatrice Savoldi, Marco Gaido, Matteo Negri and Luisa Bentivogli

11:00–12:30 Biomedical Translation Task

11:00–12:30 *Biomedical Parallel Sentence Retrieval Using Large Language Models*
Sheema Firdous and Sadaf Abdul Rauf

11:00–12:30 *The Path to Continuous Domain Adaptation Improvements by HW-TSC for the WMT23 Biomedical Translation Shared Task*
Zhanglin Wu, Daimeng Wei, Zongyao Li, Zhengzhe YU, Shaojun Li, Xiaoyu Chen, Hengchao Shang, Jiaxin GUO, Yuhao Xie, Lizhi Lei, Hao Yang and Yanfei Jiang

11:00–12:30 *Investigating Techniques for a Deeper Understanding of Neural Machine Translation (NMT) Systems through Data Filtering and Fine-tuning Strategies*
Lichao Zhu, Maria Zimina, Maud Bénard, Behnoosh Namdar, Nicolas Ballier, Guillaume Wisniewski and Jean-Baptiste Yunès

11:00–12:30 Literary Translation Task

11:00–12:30 *MAX-ISI System at WMT23 Discourse-Level Literary Translation Task*
Li An, Linghao Jin and Xuezhe Ma

11:00–12:30 *The MAKE-NMTVIZ System Description for the WMT23 Literary Task*
Fabien Lopez, Gabriela González, Damien Hansen, Mariam Nakhle, Behnoosh Namdarzadeh, Nicolas Ballier, Marco Dinarelli, Emmanuelle Esperança-Rodier, Sui He, Sadaf Mohseni, Caroline Rossi, Didier Schwab, Jun Yang, Jean-Baptiste Yunès and Lichao Zhu

11:00–12:30 *DUTNLP System for the WMT2023 Discourse-Level Literary Translation*
Anqi Zhao, Kaiyu Huang, Hao Yu and Degen Huang

11:00–12:30 *HW-TSC's Submissions to the WMT23 Discourse-Level Literary Translation Shared Task*
Yuhao Xie, Zongyao Li, Zhanglin Wu, Daimeng Wei, Xiaoyu Chen, Zhiqiang Rao, Shaojun Li, Hengchao Shang, Jiaxin GUO, Lizhi Lei, Hao Yang and Yanfei Jiang

11:00–12:30 *TJUNLP:System Description for the WMT23 Literary Task in Chinese to English Translation Direction*
Shaolin Zhu and Deyi Xiong

11:00–12:30 African Languages Translation Task

11:00–12:30 *Machine Translation for Nko: Tools, Corpora, and Baseline Results*
Moussa Doumbouya, Baba Mamadi Diané, Solo Farabado Cissé, Djibrila Diané, Abdoulaye Sow, Séré Moussa Doumbouya, Daouda Bangoura, Fodé Moriba Bayo, Ibrahima Sory 2. Conde, Kalo Mory Diané, Chris Piech and Christopher Manning

11:00–12:30 Sign Language Translation Task

11:00–12:30 *TTIC's Submission to WMT-SLT 23*
Marcelo Sandoval-Castaneda, Yanhong Li, Bowen Shi, Diane Brentari, Karen Livescu and Gregory Shakhnarovich

11:00–12:30 *KnowComp Submission for WMT23 Sign Language Translation Task*
Baixuan Xu, Haochen Shi, Tianshi Zheng, Qing Zong, Weiqi Wang, Zhaowei Wang and Yangqiu Song

11:00–12:30 Parallel Data Curation Task

11:00–12:30 *A Fast Method to Filter Noisy Parallel Data WMT2023 Shared Task on Parallel Data Curation*
Nguyen-Hoang Minh-Cong, Nguyen Van Vinh and Nguyen Le-Minh

11:00–12:30 *A Sentence Alignment Approach to Document Alignment and Multi-faceted Filtering for Curating Parallel Sentence Pairs from Web-crawled Data*
Steinthor Steingrimsson

12:30–14:00 ***Lunch Break***

14:00–15:30 Session 3: Research Papers on Document-Level Translation and Use of Large Language Models

14:00–14:15 *Document-Level Language Models for Machine Translation*
Frithjof Petrick, Christian Herold, Pavel Petrushkov, Shahram Khadivi and Hermann Ney

14:15–14:30 *ChatGPT MT: Competitive for High- (but Not Low-) Resource Languages*
Nathaniel Robinson, Perez Ogayo, David R. Mortensen and Graham Neubig

14:30–14:45 *Large Language Models Effectively Leverage Document-level Context for Literary Translation, but Critical Errors Persist*
Marzena Karpinska and Mohit Iyyer

14:45–15:00 *Identifying Context-Dependent Translations for Evaluation Set Production*
Rachel Wicks and Matt Post

15:00–15:15 *Machine Translation with Large Language Models: Prompting, Few-shot Learning, and Fine-tuning with QLoRA*
Xuan Zhang, Navid Rajabi, Kevin Duh and Philipp Koehn

15:15–15:30 *Towards Effective Disambiguation for Machine Translation with Large Language Models*
Vivek Iyer, Pinzhen Chen and Alexandra Birch

15:30–16:00 ***Coffee Break***

Wednesday, December 6, 2023 (continued)

16:00–17:30 Session 4: Research Papers on Translation Modelling

16:00–16:15 *A Closer Look at Transformer Attention for Multilingual Translation*
Jingyi Zhang, Gerard de Melo, Hongfei Xu and Kehai Chen

16:15–16:30 *Bridging the Gap between Position-Based and Content-Based Self-Attention for Neural Machine Translation*
Felix Schmidt and Mattia Di Gangi

16:30–16:45 *Visual Prediction Improves Zero-Shot Cross-Modal Machine Translation*
Tosho Hirasawa, Emanuele Bugliarello, Desmond Elliott and Mamoru Komachi

16:45–17:00 *The Gender-GAP Pipeline: A Gender-Aware Polyglot Pipeline for Gender Characterisation in 55 Languages*
Benjamin Muller, Belen Alastruey, Prangthip Hansanti, Elahe Kalbassi, Christophe Ropers, Eric Smith, Adina Williams, Luke Zettlemoyer, Pierre Andrews and Marta R. Costa-jussà

17:00–17:15 *Towards Better Evaluation for Formality-Controlled English-Japanese Machine Translation*
Edison Marrese-Taylor, Pin Chen Wang and Yutaka Matsuo

17:15–17:30 *There's No Data like Better Data: Using QE Metrics for MT Data Filtering*
Jan-Thorsten Peter, David Vilar, Daniel Deutsch, Mara Finkelstein, Juraj Juraska and Markus Freitag

Thursday, December 7, 2023

9:00–10:30 Session 5: Shared Task Overview Papers II

9:00–9:15 *Results of WMT23 Metrics Shared Task: Metrics Might Be Guilty but References Are Not Innocent*
Markus Freitag, Nitika Mathur, Chi-kiu Lo, Eleftherios Avramidis, Ricardo Rei, Brian Thompson, Tom Kocmi, Frederic Blain, Daniel Deutsch, Craig Stewart, Chrysoula Zerva, Sheila Castilho, Alon Lavie and George Foster

9:15–9:30 *Findings of the WMT 2023 Shared Task on Quality Estimation*
Frederic Blain, Chrysoula Zerva, Ricardo Ribeiro, Nuno M. Guerreiro, Diptesh Kanojia, José G. C. de Souza, Beatriz Silva, Tânia Vaz, Yan Jingxuan, Fatemeh Azadi, Constantin Orasan and André Martins

9:30–9:45 *Findings of the Word-Level AutoCompletion Shared Task in WMT 2023*
Lemao Liu, Francisco Casacuberta, George Foster, Guoping Huang, Philipp Koehn, Geza Kovacs, Shuming Shi, Taro Watanabe and Chengqing Zong

9:45–10:00 *Findings of the WMT 2023 Shared Task on Machine Translation with Terminologies*
Kirill Semenov, Vilém Zouhar, Tom Kocmi, Dongdong Zhang, Wangchunshu Zhou and Yuchen Eleanor Jiang

Thursday, December 7, 2023 (continued)

10:00–10:15 *Findings of the WMT 2023 Shared Task on Automatic Post-Editing*
Pushpak Bhattacharyya, Rajen Chatterjee, Markus Freitag, Diptesh Kanojia, Matteo Negri and Marco Turchi

10:15–10:30 *Findings of the WMT 2023 Shared Task on Low-Resource Indic Language Translation*
Santanu Pal, Partha Pakray, Sahinur Rahman Laskar, Lenin Laitonjam, Vanlalmuansangi Khenglawt, Sunita Warjri, Pankaj Kundan Dadure and Sandeep Kumar Dash

10:30–11:00 ***Coffee Break***

11:00–12:30 **Session 6: Shared Task System Description Posters II**

11:00–12:30 **Metrics Task**

11:00–12:30 *ACES: Translation Accuracy Challenge Sets at WMT 2023*
Chantal Amrhein, Nikita Moghe and Liane Guillou

11:00–12:30 *Challenging the State-of-the-art Machine Translation Metrics from a Linguistic Perspective*
Eleftherios Avramidis, Shushen Manakhimova, Vivien Macketanz and Sebastian Möller

11:00–12:30 *Tokengram_F, a Fast and Accurate Token-based chrF++ Derivative*
Sören DREANO, Derek Molloy and Noel Murphy

11:00–12:30 *Embed_Llama: Using LLM Embeddings for the Metrics Shared Task*
Sören DREANO, Derek Molloy and Noel Murphy

11:00–12:30 *eBLEU: Unexpectedly Good Machine Translation Evaluation Using Simple Word Embeddings*
Muhammad ElNokrashy and Tom Kocmi

11:00–12:30 *Cometoid: Distilling Strong Reference-based Machine Translation Metrics into Even Stronger Quality Estimation Metrics*
Thamme Gowda, Tom Kocmi and Marcin Junczys-Dowmunt

11:00–12:30 *MetricX-23: The Google Submission to the WMT 2023 Metrics Shared Task*
Juraj Juraska, Mara Finkelstein, Daniel Deutsch, Aditya Siddhant, Mehdi Mirzazadeh and Markus Freitag

Thursday, December 7, 2023 (continued)

11:00–12:30 *GEMBA-MQM: Detecting Translation Quality Error Spans with GPT-4*
Tom Kocmi and Christian Federmann

11:00–12:30 *Metric Score Landscape Challenge (MSLC23): Understanding Metrics' Performance on a Wider Landscape of Translation Quality*
Chi-kiu Lo, Samuel Larkin and Rebecca Knowles

11:00–12:30 *MEE4 and XLsim : IIIT HYD's Submissions' for WMT23 Metrics Shared Task*
Ananya Mukherjee and Manish Shrivastava

11:00–12:30 *Quality Estimation Using Minimum Bayes Risk*
Subhajit Naskar, Daniel Deutsch and Markus Freitag

11:00–12:30 *Evaluating Metrics for Document-context Evaluation in Machine Translation*
Vikas Raunak, Tom Kocmi and Matt Post

11:00–12:30 *Semantically-Informed Regressive Encoder Score*
Vasiliy Viskov, George Kokush, Daniil Larionov, Steffen Eger and Alexander Panchenko

11:00–12:30 *Empowering a Metric with LLM-assisted Named Entity Annotation: HW-TSC's Submission to the WMT23 Metrics Shared Task*
Zhanglin Wu, Yilun Liu, Min Zhang, Xiaofeng Zhao, Junhao Zhu, Ming Zhu, Xiaosong Qiao, Jingfei Zhang, Ma Miaomiao, Zhao Yanqing, Song Peng, shimin tao, Hao Yang and Yanfei Jiang

11:00–12:30 Quality Estimation Task

11:00–12:30 *Unify Word-level and Span-level Tasks: NJUNLP's Participation for the WMT2023 Quality Estimation Shared Task*
Xiang Geng, Zhejian Lai, Yu Zhang, shimin tao, Hao Yang, Jiajun CHEN and Shujian Huang

11:00–12:30 *HW-TSC 2023 Submission for the Quality Estimation Shared Task*
Yuang Li, Chang Su, Ming Zhu, Mengyao Piao, Xinglin Lyu, Min Zhang and Hao Yang

11:00–12:30 *Scaling up CometKiwi: Unbabel-IST 2023 Submission for the Quality Estimation Shared Task*
Ricardo Rei, Nuno M. Guerreiro, JosÃ© Pombal, Daan van Stigt, Marcos Treviso, Luisa Coheur, José G. C. de Souza and André Martins

11:00–12:30 *SurreyAI 2023 Submission for the Quality Estimation Shared Task*
Archchana Sindhujan, Diptesh Kanojia, Constantin Orasan and Tharindu Ranasinghe

Thursday, December 7, 2023 (continued)

11:00–12:30 *MMT's Submission for the WMT 2023 Quality Estimation Shared Task*
Yulong Wu, Viktor Schlegel, Daniel Beck and Riza Batista-Navarro

11:00–12:30 *IOL Research's Submission for WMT 2023 Quality Estimation Shared Task*
ZEYU YAN

11:00–12:30 Word-Level Autocompletion Task

11:00–12:30 *SJTU-MTLAB's Submission to the WMT23 Word-Level Auto Completion Task*
Xingyu Chen and Rui Wang

11:00–12:30 *PRHLT's Submission to WLAC 2023*
Angel Navarro, Miguel Domingo and Francisco Casacuberta

11:00–12:30 *KnowComp Submission for WMT23 Word-Level AutoCompletion Task*
Yi Wu, Haochen Shi, Weiqi Wang and Yangqiu Song

11:00–12:30 Termninology Translation Task

11:00–12:30 *Terminology-Aware Translation with Constrained Decoding and Large Language Model Prompting*
Nikolay Bogoychev and Pinzhen Chen

11:00–12:30 *Lingua Custodia's Participation at the WMT 2023 Terminology Shared Task*
Jingshu Liu, Mariam Nakhlé, Gaëtan Caillout and Raheel Qadar

11:00–12:30 *Domain Terminology Integration into Machine Translation: Leveraging Large Language Models*
Yasmin Moslem, Gianfranco Romani, Mahdi Molaei, John D. Kelleher, Rejwanul Haque and Andy Way

11:00–12:30 *OPUS-CAT Terminology Systems for the WMT23 Terminology Shared Task*
Tommi Nieminen

11:00–12:30 *VARCO-MT: NCSOFT's WMT'23 Terminology Shared Task Submission*
Geon Woo Park, Junghwa Lee, Meiying Ren, Allison Shindell and Yeonsoo Lee

Thursday, December 7, 2023 (continued)

11:00–12:30 Automatic Postediting Task

11:00–12:30 *HW-TSC's Participation in the WMT 2023 Automatic Post Editing Shared Task*
Jiawei Yu, Min Zhang, Zhao Yanqing, Xiaofeng Zhao, Yuang Li, Su Chang, Yinglu Li, Ma Miaomiao, shimin tao and Hao Yang

11:00–12:30 Indic Languages Translation Task

11:00–12:30 *Neural Machine Translation for English - Manipuri and English - Assamese*
Goutam Agrawal, Rituraj Das, Anupam Biswas and Dalton Meitei Thounaojam

11:00–12:30 *GUIT-NLP's Submission to Shared Task: Low Resource Indic Language Translation*
Mazida Ahmed, Kuwali Talukdar, Parvez Boruah, Prof. Shikhar Kumar Sarma and Kishore Kashyap

11:00–12:30 *NICT-AI4B's Submission to the Indic MT Shared Task in WMT 2023*
Raj Dabre, Jay Gala and Pranjal Chitale

11:00–12:30 *Machine Translation Advancements for Low-Resource Indian Languages in WMT23: CFILT-IITB's Effort for Bridging the Gap*

Abstract

This paper presents the results of the General Machine Translation Task organised as part of the 2023 Conference on Machine Translation (WMT). In the general MT task, participants were asked to build machine translation systems for any of 8 language pairs (corresponding to 14 translation directions), to be evaluated on test sets consisting of up to four different domains. We evaluate system outputs with professional human annotators using a combination of source-based Direct Assessment and scalar quality metric (DA+SQM).

1 Introduction

The Eighth Conference on Machine Translation (WMT23)[1] was held at EMNLP 2023 and hosted a number of shared tasks on various aspects of machine translation (MT). This conference built on 17 previous editions of WMT as a workshop or a conference (Koehn and Monz, 2006; Callison-Burch et al., 2007, 2008, 2009, 2010, 2011, 2012; Bojar et al., 2013, 2014, 2015, 2016, 2017, 2018; Barrault et al., 2019, 2020; Akhbardeh et al., 2021; Kocmi et al., 2022).

Following last year's shift from focusing mainly on the news domain, we have continued to explore the capabilities of "General Machine Translation". While the news domain provided a clear and familiar benchmark, we realized the need to test MT in more diverse settings. Our goal is to assess MT systems' ability to handle a broader range of language use. How to test general MT performance is a research question in itself. Countless phenomena could be evaluated, the most important being:

- various domains (news, medicine, IT, patents, legal, social, gaming, etc.)
- style of text (formal or spoken language, fiction, technical reports, etc.)
- robustness to non-standard (or noisy) user-generated content (grammatical errors, code-switching, abbreviations, etc.)

Evaluating all phenomena is nearly impossible and creates numerous unforeseen problems. Therefore, we decided to simplify the problem and start with an evaluation of different domains. We selected the following domains: news, e-commerce, social/user-generated content (UGC), speech, and manuals. They were chosen to represent topics with different content styles and to be understandable for humans without special in-domain knowledge, thus not requiring specialized translators or human raters for evaluation. Due to limited access

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 1–42
December 6–7, 2023.

to monolingual data across all languages, each language direction contains only a subset of up to four domains.

In addition to language pairs evaluated last year:

Czech→Ukrainian,
English↔Chinese,
English→Czech,
English↔German,
English↔Japanese,
English↔Russian,
Ukrainian→English,

we introduce a new language pair to WMT, namely:

English↔Hebrew.

Other than language pairs, there are several differences with respect to last year's task. All language pairs are provided with the sentence boundaries marked except for English↔German, where we decided to experiment with paragraph-level translation. Another significant change for this year is the unification of our human evaluation protocol. We no longer rely on reference-based MTurk evaluation and move the evaluation towards source-based DA+SQM evaluation (introduced last year) with professional annotators. Finally, this year's shared task included an increased number of test suites (Section 6), allowing the evaluation of MT outputs from different perspectives, including a range of linguistic phenomena, purposely difficult sentences, specialist domains, gendered translations and non-standard UGC translation.

All General MT task submissions, sources, references and human judgements are available at Github [2]. The interactive visualization and comparison of differences between systems can be browsed online on an interactive leaderboard[3] using MT-ComparEval (Klejch et al., 2015; Sudarikov et al., 2016).

The structure of the paper is as follows. We describe the process of collecting, cleaning and translating the test sets in Section 2 followed by a summary of the permitted training data for the constrained track Section 3. We list all submitted systems in Section 4. The human evaluation approach of DA+SQM is described in Section 5. Finally, Section 6 describes the test suites and summarises their conclusions.

[3] http://wmt.ufal.cz

Summary of the WMT2023 General MT task
The main findings are as follows:

- Large Language Models (LLMs) exhibit strong performance across the majority of language pairs, although this is based only on two LLM-based system submissions. Test suite analysis revealed that although GPT4 excelled in some areas (e.g. UGC translation) struggled with other aspects such as speaker gender translation and specific domains (e.g. legal), whereas it ranked lower than encoder-decoder systems when translating from English into less-represented languages (e.g. Czech and Russian)

- We have observed a decline in the number of submissions into the constrained track. Consequently, we plan to re-evaluate the definition and the incentives of the constrained track and consider incorporating open-source LLMs in future evaluations.

- We demonstrate the feasibility of paragraph-level German↔English tasks, although more investigation would be required before generalising to all language pairs.

- Professional human translations do not always guarantee high quality. For Hebrew↔English, our references are likely to be post-edited MT, while for Chinese→English, the reference translation is worse than the majority of automatic translations.

- The manual evaluation results obtained from DA+SQM and MQM methods yield comparable cluster rankings.

2 Test Data

In this section, we describe the process of collecting data in Section 2.1, followed by the explanation of preprocessing steps in Section 2.2. Producing human references is summarized in Section 2.3 and lastly test set analysis is conducted in Section 2.4.

2.1 Collecting test data

As in the previous years, the test sets consist of unseen translations collected especially for the task. This has become even more important with the rise of LLMs trained on unspecified training data. To prevent possible contamination, we focused on collecting as recent data as possible across various

Table 1: Test set statistics per direction and domain (rows marked * are over all domains). Note that en→de shares source test data with the other from-English directions, but as translation and evaluation for both en→de and de→en were carried out on the paragraph level (a segment therefore being a paragraph rather than a sentence), this results in a lower number of segments per document. The domain name is as indicated in the released test sets and domain type indicates the broader domain category.

domains. This task is incredibly difficult and needs further investigation in future years. There are three main limitations:

- Finding sources with different domains.
- Finding data that are in the public domain or under open licenses.
- Finding recently created data to minimize the risk of them being part of the training pipelines.

The test sets are publicly released to be used as translation benchmarks. Here we describe the test sets' production and composition.

We decided to collect data from 5 domains (news, social/user-generated, e-commerce, manuals, and speech). For all language pairs, we aimed for a test set size of 2,000 sentences and to ensure that the test sets were "source-original", namely that the source text was first written in the source language, and then the target text is the human

translation. This is to avoid "translationese" effects on the source language, which can have a detrimental impact on the accuracy of evaluation (Toral et al., 2018; Freitag et al., 2019; Läubli et al., 2020; Graham et al., 2020). We collected roughly the same number of sentences for each domain. For some languages, we could not locate high quality data and therefore we selected more sentences from other domains. Note that descriptions in this section refer to source monolingual data when mentioning a language.

News domain For most languages this domain contains data prepared in the same way as in previous years (Akhbardeh et al., 2021). We collected news articles from February 2023 extracted from online news sites, preserving document boundaries. We expect that news domain text will generally be of high quality. The news in Hebrew was kindly provided by the Israeli Association of Human Language Technologies (IAHLT).[4] These are samples of originally Hebrew texts from news published in Israel Hayom[5] in 2022.

E-commerce domain (product reviews) This domain consists of user reviews of different Amazon products selected from the publicly available multilingual corpus (Keung et al., 2020). This corpus was designed for multilingual text classification and consists of reviews written in English, Japanese, German, French, Spanish, and Chinese, between 2015 and 2019. We used the test parts of the English, German, Japanese and Chinese corpora for extracting the source part of the WMT test set. The reviews were selected so that the resulting corpus covers each product, all rating scores for the product, and the lexical diversity is maximized. The lexical diversity was estimated as a simple ratio between the number of distinct words/characters (vocabulary) divided by the total number of words/characters.

Social/user-generated domain For English and German, we relied on the Mastodon Social API.[6] Mastodon is a federated social network that is compatible with the W3C standard ActivityPub (Webber et al., 2018). Users publish short-form content similar to tweets that are referred to as "toots" for historical reasons. As this is a decentralized social media network, different servers have very different data, policies, communities, and uses. We decided to use `mastodon.social`, the original server, as it has a large community as well as publicly available toots. We collected data in early May of 2023. We used the reported language ID label, but were only able to collect enough data in German and English. We only collected toots with more than 150 characters in length in order to allow for data that was more likely to be semantically interesting for evaluating translation systems.

For Hebrew, we used comments on news articles from the Israel Hayom site mentioned above. This data was also provided by IAHLT.

For Russian, we used data from the Geo Reviews Dataset containing reviews about organizations published on Yandex Maps and open for academic and research purposes.[7]

For Japanese, we used product descriptions of a b2b e-commerce site and search advertising text ads for the social and user-generated domain, because we could not obtain high-quality data for this domain type. MonotaRo Co., Ltd. provided product descriptions of their private label brands listed on their b2b e-commerce site.[8] We defined a document for a product description as a combination of a title, product description, and cautionary note. CyberAgent, Inc.[9] provided search advertising text ads with their client's consent. We defined a document for an ad as the longest possible combination of multiple titles and descriptions.

Manuals For this domain, we primarily sourced scanned versions of different mostly gaming manuals provided by Centific[10]. These were then converted to digital text format using Optical Character Recognition (OCR) technology. Given the inaccuracies of OCR, the digitized content underwent a subsequent post-editing phase, where humans reviewed and corrected any errors. The selection of manuals ranged across various sources, and none of them were older than five years.

Speech The exact data types used in the "conversational" or "speech" domain vary across language pairs.

For English→Czech, the data comes from the test set which was created for the 2023 instance of

AutoMin 2023 (Ghosal et al., 2022).[11] The texts are manually curated transcripts of project meetings, same in style as released in ELITR Minuting Corpus (Nedoluzhko et al., 2022). The meetings were held mostly remotely or in a hybrid form, all meeting participants were non-native speakers of English and the meetings were always on rather technical and in-depth topics. Our manual curation corrected ASR errors (but not errors in English grammar or vocabulary) and de-identified the transcripts, replacing names with placeholders ("PERSONxy", "PROJECTxy" and similar). For person names, round brackets are used at the beginnings of lines to indicate the speaker and square brackets are used in the text when the person was mentioned. The data contain also some markup, e.g. "<unintelligible/>". These conventions are likely to be distorted by translation systems and we also noticed that they were distorted in the reference translation (the style of the brackets was ignored). This tiny detail can influence both manual and automatic scoring on this domain.

For Japanese, we used question-answer pairs from a community question-answering service. NTT Resonant Inc., which recently merged with NTT DOCOMO, INC., provided question-answer pairs from their website, *Oshiete! goo*.[12] For every question-answer pair, we defined a document as a combination of a question and its best answer marked by the user.

Czech and Ukrainian source texts Source texts for Czech→Ukrainian and Ukrainian→English translation included the News domain as described above and texts collected through the Charles Translator for Ukraine.[13] With users' consent, the service can log their inputs for the purpose of creating a dataset of real use cases. The datasets are extracted from the inputs collected from May 2022 to April 2023.

The Charles Translator mobile app supports voice input, which is converted to text using Google ASR (automatic speech recognition). The texts collected this way were marked as the `voice` domain. For Ukrainian→English, the remaining Ukrainian inputs were classified either as `clipboard` (texts inserted to the Charles Translator using the *Paste from clipboard* button) and `other`. The `clipboard` texts are more likely to include formal communication copied from web sites, but we noticed it includes personal communication (copied from chat applications) as well. Thus for Czech→Ukrainian, we decided to classify the remaining Czech inputs either as `official` (formal communication) or `personal` (personal communication), ignoring whether they were inserted from a clipboard or written using a keyboard.

The texts were filtered and pseudonymized in the same way as last year (Kocmi et al., 2022), so for example we asked the annotators not to delete or fix noisy inputs as long as they are comprehensible. There was one exception from this rule this year: the Czech `voice` domain data was post-edited to fix ASR errors, including missing punctuation and casing.

The source texts were translated by professional translators principally following the brief in Appendix C. Last year, parts of the Ukrainian→Czech test set was detected to be post-edited MT. Therefore this year, we decided to hire two professional translators directly without the mediation of a translation agency, we emphasised the rule that the translations must be done from scratch (without MT postediting and without translation memories). We could not detect any MT postediting in the resulting translations.

2.2 Human preprocessing of test data

Although testing of robustness of MT is an important task, the noisy data introduces problems for human translators and annotators. Therefore, we decided to discard data considered too noisy. Furthermore, publicly available data often contains inappropriate content, which can stress either human translators or human annotators, leading to a decrease in the quality (for example, translators refuse to translate political content considered censored in their countries).

Therefore, we asked humans to check collected data and carry out minor corrections (mainly checking sentence splits and discarding similar or repeated content). This was sufficient for the news domain because it was often clean and without serious problems. However, with the expansion towards general MT, we find ourselves running into an issue of source data being noisier and less well formatted and that therefore needs to be handled before translation. Furthermore, we asked them to remove shortest documents to keep longer context. The source data for test sets therefore goes through

[11] https://ufal.github.io/automin-2023/
[12] https://oshiete.goo.ne.jp/
[13] http://translator.cuni.cz

human validation checks involving linguists discarding inappropriate content altogether and carrying out minor textual corrections to the data. You can find the linguistic brief for prepossessing in Appendix B.

2.3 Test set translation

The translation of the test sets was performed by professional translation agencies, according to the brief in Appendix C. Different partners sponsored each language pair and various translation agencies were therefore used, which may affect the quality of the translation.

Regrettably, upon reviewing translations procured from one of the agencies (the one responsible for English to Hebrew and Hebrew to English translations), it appeared that the translations might have been post-edited from publicly available online translation systems. This observation contradicts the initial instruction provided for agency that precluded the use of any automated translation platforms. While the agency has asserted that their professional translations conducted translations from scratch, our evaluation suggested otherwise. Moving forward, we propose to build a step-by-step verification system to avoid such discrepancies.

Human translations would not be possible without the sponsorship of our partners: Microsoft, Toloka AI, Google, Charles University, NTT, and Dubformer.

2.4 Test set analysis

As described previously, the chosen domains, sources for the data and the number of sentences per domain was subject to the availability of high quality data in each language direction. For example, while the news domain was available for all language directions, social media data was only available for English, German (both from Mastodon) and Hebrew (from comments on news articles). The number of documents, segments, average document length and type-token ratio (of the source side of the test sets) are given in Table 1.

Document context Document context is available for all language directions, although the average document length varies both by domain and language direction. Manuals tend to represent the longest domains, followed by the news domain. The social media domain tends to represent the shortest documents. along with reviews. Note that this year, we piloted translation and evaluation of en→de and de→en at the paragraph level (with each segment therefore containing several sentences), with the aim of avoiding the constraint of having a one-to-one mapping at the level of the sentence between source texts and their translations. This is visible in the statistics in Table 1 as the number of segments is lower for these two directions, as is the average document length.

Lexical diversity We can compare the type-token ratio (TTR) to get an idea of the relative lexical diversity of (i) domains and (ii) original vs. translated sentences.[14,15] Raw TTRs for each language pair and domain are shown in Table 11 in Appendix D. Regarding domains, the TTR appears highest for texts mastodon, perhaps illustrating the diversity of conversational topics and also of the potentially non-standard nature of the texts. User reviews appear to have the lowest TTR, most likely due to the fact that similar vocabulary is used across reviews. The TTR of course differs according to the language in question, according to the differing morphological properties.

Anonymisation and markup A particularity of the 'speech' domain is the presence of placeholders for anonymised elements and markup (in the form of tags). For example, there are 35 placeholders surrounded either by square or rounded brackets to indicate different people, organisations and projects (e.g. (PERSON1), [PERSON9], [ORGANIZATION4], [PROJECT8], etc.). The 'person' tags are used both in-text to replace the names of people and at the beginning of lines to indicate who is talking. Markup is added to indicate speakers talking at the same time (<parallel_talk>), unintelligible passages (<unintelligible/>), laughter (<laugh/>) and other noise (<other_noise/>).

2.5 Test suites

In addition to the test sets of the regular domains, the test sets given to the system participants were augmented with several *test suites*, i.e. custom-made test sets focusing on particular aspects of MT translation. The test suites were contributed and evaluated by test suite providers as part of a

[14]The TTR is the ratio of unique tokens to total tokens, and it is higher the diverse the vocabulary of a text is. It is dependent on the morphological complexity of a language, but can also vary due to other factors.

[15]Texts are tokenised using the language-specific Spacy models (Honnibal and Montani, 2017) where available. For Hebrew, we took the multilingual Spacy model, since a language-specific one was not available.

decentralized sub-task, which will be detailed in Section 6.

3 Training Data

Similar to the previous years, we provide a selection of parallel and monolingual corpora for model training. The provenance and statistics of the selected parallel datasets are provided in Appendix in Table 9 and Table 10. Specifically, our parallel data selection include large multilingual corpora such as Europarl-v10 (Koehn, 2005), Paracrawl-v9 (Bañón et al., 2020), CommonCrawl, NewsCommentary-v18, WikiTitles-v3, WikiMatrix (Schwenk et al., 2021), TildeCorpus (Rozis and Skadiņš, 2017), OPUS (Tiedemann, 2012), UN Parallel Corpus (Ziemski et al., 2016), and language-specific corpora such as CzEng-v2.0 (Kocmi et al., 2020), YandexCorpus,[16] ELRC EU Acts, JParaCrawl (Morishita et al., 2020), Japanese-English Subtitle Corpus (Pryzant et al., 2018), KFTT(Neubig, 2011), TED (Cettolo et al., 2012), CCMT, and back-translated news. Links for downloading these datasets were provided on the task web page;[17] in addition, we automated the data preparation pipeline using MTDATA (Gowda et al., 2021).[18] MTDATA downloads all the mentioned datasets, except CCMT and CzEng-v2.0, which required user authentication. This year's monolingual data include the following: News Crawl, News Discussions, News Commentary, CommonCrawl, Europarl-v10 (Koehn, 2005), Extended CommonCrawl (Conneau et al., 2020), Leipzig Corpora (Goldhahn et al., 2012), UberText and Legal Ukrainian.

4 System submissions

This year, we received a total of 72 primary submissions from 17 participants. In addition, we collected translations from online MT systems across all language pairs. Online system outputs come from 6 public MT services and were anonymized as ONLINE-{A,B,G,M,W,Y}, which added additional 77 system outputs. The participating systems are listed in Table 2 and detailed in the rest of this section.

Finally, we added translations by three contrastive systems. Two of them are based on the NLLB translation model (NLLB Team et al., 2022) modified by (Freitag et al., 2023) to have a suboptimal performance, using (i) greedy search (NLLB_Greedy) and (ii) following minimum Bayes risk decoding (MBR) optimizing the BLEU metric (NLLB_MBR_BLEU). Neither of them is the official (and better performing) NLLB model. The third contrastive translation is produced by the large language model GPT4 using 5-shot prompting with fixed random translation examples, using the exact prompt by Hendy et al. (2023) together with their predefined few-shot examples. For languages not evaluated in their study, we took examples from the last WMT test sets.

Appendix E provides details of the submitted systems if the authors provided such details.

4.1 Constrained and unconstrained tracks

For presentation of the results, systems are treated as either constrained or unconstrained. A system is classified as constrained if the authors reported training only on the provided data and adhering to the rules describing the use of publicly available pre-trained models. The constrained track imposes restrictions on training data, metrics, and pretrained models, while the unconstrained track provides unrestrained flexibility.

The constrained track limitations are mainly around the training and testing data, together with the limitation on pretrained models:

- **Training data:** Only data specified for the current year are permissible, see Section 3. Multilingual systems can be used as long as they only use WMT23 data.
- **Metrics:** The training pipeline can use pretrained metrics evaluated in previous WMT Metrics shared tasks, e.g., COMET (Rei et al., 2022), Bleurt (Yan et al., 2023).
- **Pretrained models:** only the following list of models is allowed together with all their public sizes: mBART (Liu et al., 2020), BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019), XLM-RoBERTa (Conneau et al., 2020), sBERT (Reimers and Gurevych, 2019), and LaBSE (Feng et al., 2022).
- **Linguistic tools:** Basic tools like taggers, parsers, and morphology analyzers are allowed.

Table 2: Participants in the General MT shared task. Online system translations were not submitted by their respective companies but were obtained by us, and are therefore anonymized in a fashion consistent with previous editions of the task.

The online systems and contrastive systems are treated as unconstrained during the automatic and human evaluation.

4.2 OCELoT

We used the open-source OCELoT platform[19] to collect system submissions again this year. The platform provides anonymized public leaderboards[20] and was also used for two other WMT23 shared tasks: Biomedical (Neves et al., 2023) and Sign Language Translation (Müller et al., 2023). As in previous years, only registered and verified teams with correct contact information were allowed to submit their system outputs and each verified team was limited to 7 submissions per test set. Submissions on leaderboards with BLEU (Papineni et al., 2002) and CHRF (Popović, 2015) scores from SacreBLEU (Post, 2018) were displayed anonymously to avoid publishing rankings based on automatic scores during the submission period. Until one week after the submission period, teams could select a single primary submission per test set, specify if the primary submission followed a constrained or unconstrained setting, and submit a system description paper abstract. These were mandatory for a system submission to be included in the human evaluation campaign.

5 Human Evaluation

Human evaluation for all language translation directions is performed with source-based ("bilingual") Direct Assessment (DA, Graham et al., 2013) of individual segments in document context with Scalar Quality Metrics (SQM) guidelines, mostly following the setup established at WMT22 (DA+SQM, Kocmi et al., 2022). DA+SQM asks the annotators to provide a score between 0 and 100 on a sliding scale, but the slider is presented with seven labelled tick marks, as demonstrated in Figure 1.

Two different annotation platforms and four distinct pools of annotators (Table 3) are used for annotation of different language pairs. We use the open-source framework Appraise (Federmann, 2018) for the evaluation of English→Czech, English↔{Chinese, German, Japanese}, and Czech→Ukrainian. Toloka AI[21] hosts the evaluation of English↔{Hebrew, Russian, Ukrainian} using their own implementation of the source-based document-level DA+SQM task, which is as close as possible to the Appraise user interface.

We keep the selection process of documents for annotation mostly the same as in the previous year. The only change made in order to align closer with the MQM-based evaluation run at the Metrics shared task (Freitag et al., 2023) is to present the first 10 segments from a document instead of random 10 consecutive segments.

We again collect both segment-level scores and document-level scores, but compute rankings based on segment scores only.

5.1 Human annotators

Annotations for different language pairs are provided by four different parties with their pool of annotators of distinct profiles as presented in Table 3. We shift towards more professional or semi-professional annotators' pools and decide not to use MTurk annotations as in past years for reference-based DA evaluation for into-English language directions.

Assessments for English↔{Chinese, German, Japanese} are provided by Microsoft and their pool of bilingual target-language native speakers, professional translators or linguists, highly experienced in MT evaluation. Microsoft monitors the annotators' performance over time and permanently removes from the pool those who fail quality control, which increases the overall quality of the human assessment.

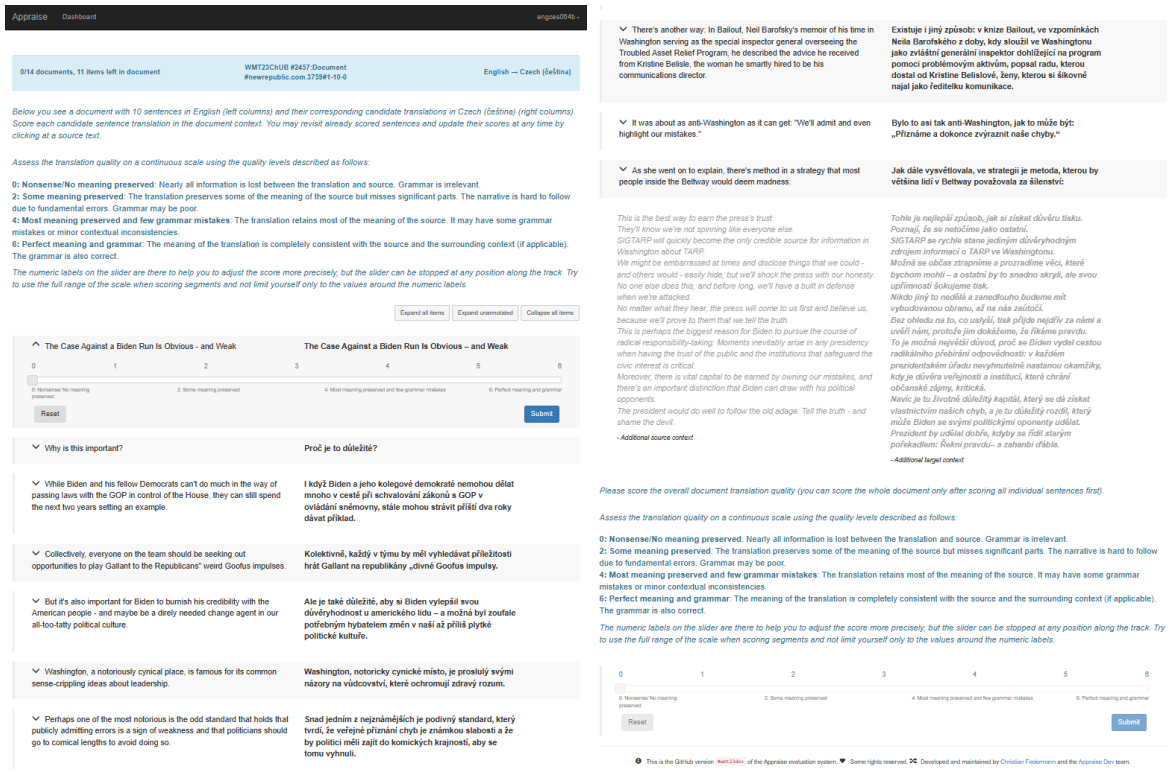
Charles University provides annotators for language pairs involving the Czech language, i.e., English→Czech and Czech→Ukrainian. Their annotators are linguists, translators, researchers and students who are native speakers of the target language with high proficiency in the source language.

DA scores for English↔{Hebrew, Russian, Ukrainian} are collected by Toloka AI using their paid crowd of bilingual target-language native speakers. Toloka AI tests proficiency of their annotator crowd across different NLP annotation tasks and allowed only annotators who deemed reliable according to their quality control measures.

5.2 Document selection and quality control

The document selection process remains the same as in the previous year with minor changes. We first randomly sample a subset of document snippets from each of the domains for annotations, sampling the domains with approximately the same number of segments per domain. This ensures that

[19] https://github.com/AppraiseDev/OCELoT
[20] https://ocelot-wmt23.mteval.org
[21] https://toloka.ai



(a) Top part of the screen with segment-level scoring.

(b) Bottom part of the screen with document-level scoring.

Figure 1: Screenshot of the document-level DA+SQM configuration in the Appraise interface for an example assessment from the human evaluation campaign for out of English language pairs. The annotator is presented with the entire translated document snippet randomly selected from competing systems (anonymized) with additional static contexts, and is asked to rate the translation of individual segments and then the entire document on sliding scales between 0 and 100.

all systems in the given language pairs are evaluated on the same subset of the test set, allowing fair comparison between them. As in previous years, we aim to collect approximately 1,500 assessments per system per language pair. Due to concerns about having sufficient annotations, we create two batches of HITs, each providing half of the required assessments, such that at least all segments in the first batch could be covered for all systems, with the second campaign completed if possible.

For HIT generation for English↔German, which feature paragraph-level test sets (documents consist of paragraphs instead of sentences), we simply consider a whole paragraph as a "segment", collecting paragraph-level assessments. In that regard, we collect fewer DA scores per system comparing to other language pairs, but the human evaluation covers a larger subset of the testsets.

Last year, we used snippets of at most 10 randomly selected consecutive segments from a document as "documents" for document-level annotation. This year, we use 10 first segments from a document instead, in order to align with the MQM-based evaluation used at the Metrics shared task (Freitag et al., 2023).

All HITs consist of exactly 100 segments and are generated as in the past:

1. Snippet-system pairs are randomly sampled (from the restricted set of pre-sampled snippets) to create up to 80 segments;
2. Random snippets for the remaining 20 (or more) segments are duplicated from the first 80 to serve as quality control items;
3. BAD references are introduced to the random segments in the duplicated snippets to have about 12-14% of quality control segments per HIT.

BAD translations are created by replacing an embedded sequences of tokens in the segment with a random phrase of the same length from a different reference segment.[22]

We perform quality control by measuring an annotator's ability to reliably score BAD translations

[22]For full details, see the HIT and batch generation code: https://github.com/wmt-conference/wmt23-news-systems

Language pairs	Annotators' profile	Tool
English↔Chinese/German/Japanese	Microsoft annotators: bilingual target-language native speakers, professional translators or linguists, experienced in MT evaluation	Appraise
Czech→Ukrainian	Paid translators and target-language native speakers	Appraise
English→Czech	Czech paid linguists, annotators, researchers, students with high proficiency in English	Appraise
English↔Hebrew/Russian/Ukrainian	Toloka AI paid crowd: bilingual target-language native speakers high-performing in other task types	Toloka.ai

Table 3: Annotators' profiles and annotation tools for each language pair in human evaluation.

Language Pair	Sys.	Assess.	Assess/Sys
Chinese→English	16	20,535	1283.4
Czech→Ukrainian	14	23,191	1656.5
German→English	14	13,573	969.5
English→Chinese	16	24,551	1534.4
English→Czech	16	25,527	1595.4
English→German	13	14,267	1097.5
English→Japanese	17	26,115	1536.2
Japanese→English	18	27,858	1547.7

Table 4: Amount of segments evaluated in the WMT23 manual evaluation campaign; including human references as systems; after excluding quality control items and document-level scores.

Language Pair	Ann.	HITs	HITs/Ann.
Chinese→English	13	128	9.8
Czech→Ukrainian	9	146	16.2
German→English	21	82	3.9
English→Czech	36	162	4.5
English→German	22	87	4.0
English→Japanese	21	164	7.8
English→Chinese	13	154	11.8
Japanese→English	20	174	8.7

Table 5: Numbers of individual annotators taking part in the WMT23 human evaluation campaign and the average number of HITs collected per annotator.

significantly lower than corresponding original system outputs using a paired significance test with $p < 0.05$. We pair two HITs into a single annotation task with about 24-28 quality control segments to ensure a sufficient sample size for the statistical test. In campaigns hosted on Appraise, if an annotator is not able to demonstrate reliability on BAD references, they are excluded from further annotations, the HITs are reset and annotated from scratch by another annotator if possible.

The total number of assessments collected for each language pair and the average number of assessments per system in WMT23 manual evaluation are presented in Table 4.

5.3 Calibration HITs

Last year we introduced calibration HITs, which this year we collect for all language pairs. A calibration HIT is a HIT with 100 randomly selected segments, which is identical for and completed by all annotators, in addition to their regular annotation HITs. We release these alongside the other annotations and the anonymized mapping between annotators and HITs in order to enable additional analysis. With a small set of sentences annotated by all annotators, we are better able to examine questions about inter-annotator consistency and provide data for future research in this area.

Table 5 shows the number of unique annotators per language pair along with the total number of HITs and average number of HITs per annotator. We leave more detailed analysis of collected calibration data to future work.

5.4 Human ranking computation

The official rankings shown in Table 6 are generated on the basis of the segment-level raw DA+SQM scores that are collected within document context for all language pairs.[23] Whole documents with at least one quality control segment (i.e., BAD references) and HITs that failed to pass quality control are removed prior to computing the rankings.[24]

In this year's evaluation, we have chosen not to normalize scores by discontinuing the use of z-scores, given their potential to exacerbate system comparisons (Knowles, 2021). While utilizing raw scores is not flawless—considering each annotator employs distinct annotation strategies — we have sought to counteract this by distributing

[23]The code used to generate the rankings in Table 6 can be found here: https://github.com/AppraiseDev/Appraise/blob/main/Campaign/management/commands/ComputeWMT23Results.py

Table 6: Official results of WMT23 General Translation Task. Systems ordered by DA score; systems within a cluster are considered tied; lines indicate clusters according to Wilcoxon rank-sum test $p < 0.05$; rank ranges indicate the number of systems a system significantly underperforms or outperforms; grayed entry indicates resources that fall outside the constraints provided. All language pairs used document-level evaluation.

systems evenly across annotators. This approach aims to minimize the potential bias of a particularly stringent annotator disproportionately penalizing a single system. Ideally, every annotator would assess documents translated by all systems; however, this could introduce task repetitiveness concerns. For future considerations, employing calibration HITs (see Section 5.3) to normalize each annotator's behaviour could offer a promising solution.

All segment-level scores are averaged per system to compute the system-level scores. The clusters are computed using the Wilcoxon rank-sum test with $p < 0.05$. Rank ranges indicate the number of systems a particular system underperforms or outperforms: the top end of the rank range is $l + 1$ where l is the number of losses, while the bottom is $n - w$ where n is the total number of systems and w is the number of systems that the system in questions significantly wins against.

Tables with head-to-head comparisons between all systems are included in Appendix G.

At the time of preparation of the camera-ready version of the paper, we have not been able to collect the required number of high-quality assessments for language pairs run through Toloka AI that would meet WMT standards for human evaluation. In that regard, we decided not to publish official rankings based on manual evaluation for English↔{Hebrew, Russian, Ukrainian} until the conference, we are planning to address it later.

5.5 Comparison of human evaluation methods

In collaboration with the metrics shared task (Freitag et al., 2023), human annotation data for the Chinese→English and English→German direction was collected using two different approaches: the source-based DA+SQM approach, and the Multi-dimensional Quality Metrics (MQM) framework (Freitag et al., 2021). We present the rankings produced by the two approaches in Table 7.

Upon examining the system rankings and individual clusters produced by both techniques, it is evident that DA+SQM produces fewer clusters. This suggests that it might not be sufficiently robust to differentiate smaller system differences, whereas MQM creates more detailed clusters. One potential explanation is that DA+SQM, constrained by budgetary restrictions, might be under-powered. As highlighted by Wei et al. (2022), the 1500 segments we gather per system might not suffice to segregate systems in a more detailed manner.

Conversely, the largest difference in the evaluation techniques is the cost. While MQM manages to establish more refined clusters, its deployment is significantly more costly and complex, especially when training professionals. An interesting question would be determining the number of MQM labels that could be procured within the budget allocated for DA+SQM.

It is also important to note that the set of data over which each of these rankings was produced may have differed slightly due to the sampling (e.g., the distribution over topic domains or the amount of coverage of the full test set), making it difficult to determine whether these differences in rankings represent differences due to data or due to different annotation methods.

6 Test Suites

As can be seen in the general MT task, the improvement of translation quality has made it difficult to discriminate MT output from human translation with the current evaluation methods. Nevertheless, there are still cases where MT has difficulties, delivering outputs which despite seeming fluent and being surrounded by other seemingly perfect translations, entail serious flaws. In general evaluation methods, such flaws can get "hidden in the average" or simply get missed altogether. In an effort to shed light to these cases, evaluation via test suites is embedded in the shared task.

6.1 Setup of the sub-task

Test suites are custom extensions to standard test sets, constructed so that they can focus on particular aspects of the MT output. Here, the evaluation of the MT outputs takes place in a decentralized manner as a part of a sub-task, where test suite providers were invited to submit their customized test sets, following the setting introduced at the Third Conference on Machine Translation (Bojar et al., 2018).

Every test suite provider submitted a source-side test set, which the shared task organizers appended to the standard test sets of the shared task. The corresponding outputs from the MT systems of the shared task were returned to the test suite providers, who were responsible for running the evaluation, based on their own custom evaluation methods. The results of each test suite evaluation, together with the relevant analysis, appear in separate description papers.

6.2 Submissions

The test suite sub-task received 5 submissions with 6 test suites, whose overview can be seen in Table 8. The descriptions of each submission and their main findings are given below.

DFKI (Manakhimova et al., 2023) test suite offers a fine-grained linguistically motivated analysis of the shared task MT outputs, based on more than 11,500 manually devised test items, which cover up to 110 phenomena in 14 categories per language direction. Extending their previous test suite efforts (e.g. Avramidis et al., 2018; Macketanz et al., 2022), the submission of this year includes an updated test set featuring new linguistic phenomena and focuses additionally on the participating LLMs. The evaluation spans German→English, English→German, and English→Russian language directions.

Some of the phenomena with the lowest accuracies for German→English are *idioms* and *resultative predicates*. For English→German, these include *mediopassive voice*, and *noun formation(er)*. As for English→Russian, these include *idioms* and *semantic roles*. GPT4 performs equally or comparably to the best systems in German→English and English→German but falls in the second significance cluster for English→Russian.

HW-TSC (Chen et al., 2023) propose a systematic approach to select test sentences with high-level of difficulty from the Wiki Corpus. The strategy considers the difficulty level of a sentence from four dimensions: *word difficulty, length difficulty, grammar difficulty* and *model learning difficulty*. They open-source two Multifaceted Challenge Sets for Chinese→English and English→Chinese, each of them containing 2,000 sentences. Then, they use these challenge sets to test the shared task systems, presenting results by three automatic metrics.

The resulting system ranks are quite different from the official results. The authors point out that systems that perform well on average test sets may not perform as well on sets with high difficulty. If the ranking difference is caused by domain issues, the top-ranked systems on the official test sets may not be so general. GPT4 is ranked in the first two positions in Chinese→English but its rank in

Table 8: Overview of the participating test suites.

English→Chinese is much lower (ranks 4-9).

IIIT HYD (Mukherjee and Shrivastava, 2023) This test suite covers five specific domains (entertainment, environment, health, science, legal) and spans five distinct writing styles (descriptive, judgments, narrative, reporting, technical-writing) for English–German. The authors conduct their analysis through a combination of au- tomated assessments and manual evaluations.

Based on their evaluation, it is evident that both ONLINE-B and ONLINE-Y consistently surpassed other MT systems in performance across a diverse array of writing styles and domains. When focusing on GPT4, whereas it performs comparably to the best systems for most domains and writing styles, it gives considerably worse results when applied to the legal domain, and the writing style of judgments.

MuST-SHE^{WMT23} and INES (Savoldi et al., 2023) By focusing on the en-de and de-en language pairs, the authors rely on these newly created test suites to investigate systems' ability to translate feminine and masculine gender and produce gender-inclusive translations. Furthermore, they discuss metrics associated with the test suites and validate them by means of human evaluations.

The results indicate that systems achieve reasonable and comparable performance in correctly translating both feminine and masculine gender forms for naturalistic gender phenomena. Instead, the generation of inclusive language forms in translation emerges as a challenging task for all the evaluated MT models, indicating room for future improvements and research on the topic.

Concerning GPT 4, it is noticeable that its overall accuracy is 2% worse than the best MT system, whereas it achieves a relatively low accuracy with regard to the feminine gender, when evaluating whether the first-person singular references to the speaker are translated according to the speaker's linguistic expression of gender.

RoCS-MT (Bawden and Sagot, 2023) The RoCS-MT Challenge Set is designed to test MT systems' robustness to user-generated content (UGC) displaying non-standard characteristics, such as spelling errors, devowelling, acronymisation, etc. It is composed of non-standard English comments from Reddit, manually normalised and professionally translated into four of the WMT 2023 target languages, German, Czech, Ukrainian and Russian, and also French.

Through automatic and manual analysis of system outputs, we find that many of the phenomena remain challenging for most systems, but to varying degrees depending on the phenomenon, the particular instance (notably how frequent the non-standard word is) and the system, especially with respect to the quantity of training data. For example, non-standard instances of words (e.g. through devowelling or through phonetically inspired spelling) are often either omitted in the translation or copied unchanged. When non-standard words are translated, it is often in their standard form, but with some exceptions, for example capitalisation is sometimes preserved. However, there is often inconsistency within a same system's outputs.

GPT4-5shot has a clear lead over all other systems, correctly translating even some of the most challenging examples. It sometimes (although inconsistently) reproduces non-standardness in its outputs, but also does not always remain entirely faithful to the source sentence. However, aside the huge disparity in the amount of training data compared to other systems, notably the constrained ones, the lack of access to its training data is a serious obstacle to any meaningful scientific comparison; we cannot know which phenomena were seen during training and how frequently, and more

crucially, we cannot verify whether RoCS-MT sentences were seen during training.

7 Conclusions

The General Machine Translation Task at WMT 2023 covered 14 translation pairs, where the only non-English language pair was Czech→Ukrainian. Source based DA+SQM was the main human golden truth. The evaluation included 72 primary submissions from 17 participants, 6 online systems and 3 additional contrastive systems including GPT4. It was performed by 155 human (semi-)professional annotators, who contributed more than 175,000 judgments altogether. For most language pairs (apart from English→Czech), MT systems produce outputs that cannot be identified as being worse than the manually produced references translations in a statistically significant way, using our current evaluation methods.

It is apparent that this year, the amount of unconstrained submissions are lower thank in past years (27 submissions by 11 participants). Additionally, for some language pairs there are only few submissions by participants, and therefore they are dominated by many online systems, of whom we have no technical descriptions. We are therefore considering ways to encourage participation in the future, whereas redefining the constrained setting may be needed.

It is the first time that Large Language Models (LLMs) are included in the Shared Task as translation systems. Although the technology is very apparent in NLP research, we received only one submission using LLM methods (Lan-BridgeMT), whereas one dominant commercial LLM (GPT4) was included via our own efforts. GPT4 was in the first significance cluster for all systems translating towards English, but fell in the second significance cluster (rank 3-5) for English→Czech, whereas a similar sign was given by one of the test suites for English→Russian (rank 3; Manakhimova et al., 2023). Additionally, test suites providers noted that GPT4 outputs are not always faithful to the source sentence (Bawden and Sagot, 2023) and that they have some issues with speaker gender translation (Savoldi et al., 2023) and specific domains (Mukherjee and Shrivastava, 2023, e.g. legal;). Due to the closed-source nature of commercial tools, it is hard to know the exact reasons for these findings, although they confirm previous observations that GPT models have difficulties with under-represented languages (Hendy et al., 2023). We believe that a more transparent comparison including open source LLMs should be sought for the future.

8 Limitations

We investigated a research question of testing general capabilities of MT systems. However, we have simplified this approach. Firstly, we only used four domains that are not specialized. Secondly, we used only cleaner sentences, avoiding noisy in the source sentences.

Although we accept human judgement as a gold standard, giving us more reliable signal than automatic metrics, we should mention that human annotations are noisy (Wei and Jia, 2021) and their performance is affected by quality of other evaluated systems (Mathur et al., 2020).

Different annotators are using different ranking strategy which may have an effect on the system ranking as we are using raw scores.

9 Ethical Consideration

Several of the domains contained texts that included personal data, for example the speech data (See Section 2.4 for more details). Entities were replaced by anonymisation tags (e.g. #NAME#, #EMAIL#) to preserve the anonymity of the users behind the content.

The sentences in Ukrainian datasets were collected with users' opt-in consent, and any personal data related to people other than well-known people was pseudonymized (using random first names and surnames). Sentences where such pseudonymization would not be enough to preserve reasonable anonymity of the users (e.g. describing events uniquely identifying the persons involved) were not included in the test set.

As described in Section 2.2 and in the linguistic brief (Appendix Section B), inappropriate, controversial and/or explicit content was filtered out prior to translation, particularly keeping in mind the translators and not exposing them to such content or obliging them to translate it. A few sentences containing explicit content managed to escape the filter, and we removed these sentences from the test sets without translation.

Human evaluation using Appraise for collecting human judgements was fully anonymous. Automatically generated accounts associated with annotation tasks with single-sign-on URLs were dis-

tributed randomly among pools of annotators and did not allow for storing personal information. For language pairs for which we used calibration HITs, we received lists of tasks completed by an individual anonymous annotator. Annotators have been well paid in respect to their countries.

Acknowledgments

This task would not have been possible without the sponsorship of monolingual data, test sets translation and evaluation from our partners. Namely Microsoft, Charles University, Toloka AI, Google, NTT Resonant, Dubformer, and Centific.

Additionally, we would like to thank Rebecca Knowles, Sergio Bruccoleri, Mariia Anisimova and many others who provided help and recommendations.

Barry Haddow's participation was funded by UK Research and Innovation (UKRI) under the UK government's Horizon Europe funding guarantee [grant number 10039436 – UTTER].

Rachel Bawden's participation was funded by her chair position in the PRAIRIE institute funded by the French national agency ANR as part of the "Investissements d'avenir" programme under the reference ANR-19-P3IA-0001 and by her Emergence project, DadaNMT, funded by Sorbonne Université.

Maja Popović's participation was funded by the ADAPT SFI Centre for Digital Media Technology, funded by Science Foundation Ireland through the SFI Research Centres Programme and co-funded under the European Regional Development Fund (ERDF) through Grant 13/RC/2106.

Martin Popel's participation was funded by GAČR EXPRO grant LUSyD (GX20-16819X).

Eleftherios Avramidis's participation was funded by the German Research Foundation (DFG) through the project TextQ (grant num. MO 1038/31-1, 436813723), and by the German Federal Ministry of Education and Research (BMBF) through the project SocialWear (grant num. 01IW2000).

This work has been using data and tools provided by the LINDAT/CLARIAH-CZ Research Infrastructure (https://lindat.cz), supported by the Ministry of Education, Youth and Sports of the Czech Republic (Project No. LM2023062).

B Preprocessing cleanup brief for linguists

Human check briefing

In this task, we wish to check the data to remove all inappropriate content, remove repetitive content, or correct minor problems with the text.

The data is automatically broken down into individual sentences, which may contain wrong sentence splitting that needs to be fixed. Each paragraph is separated by empty lines. Keep the document-separators intact.

We ask you to read each document and either:

- Delete document completely if it contains any of following issues. Be on the save side, rather remove documents where you are uncertain
    - Remove documents written in different language (natural code-switching is fine)
    - Remove inappropriate content (such as sexually explicit, vulgar, or otherwise inappropriate)
    - Remove controversial content (propagandist, controversial political topics, etc.)
    - Remove content that is too noisy or doesn't resemble natural text (such as documents badly formatted, hard to understand, containing unusual language, lists of numbers/data, or other structured data generated automatically)
- Keep document while checking
    - Fix sentence-breaking, each line must be one sentence (do not reformulate, simply remove or add end of lines on a proper place).
    - Remove or move fragments of sentences to previous or following sentence (for example emoticons, one or few words sentences)
    - Fix minor issues and keep it (do not spent too much time on fixing it).
        - It is fine to keep some errors or problems
        - Remove boilerplates (segments that break the document, for example ads, page numbers, signatures, artefacts, …)
    - If a given document has more than around 30 sentences, consider splitting it by adding an empty line on a meaningful place splitting it into paragraphs

This task shouldn’t take much longer than reading through documents.

C Translator Brief for General MT

Translator Brief

In this project we wish to translate online news articles for use in evaluation of Machine Translation (MT). The translations produced by you will be compared against the translations produced by a variety of different MT systems. They will be released to the research community to provide a benchmark, or "gold-standard" measure for translation quality. The translation therefore needs to be a high-quality rendering of the source text into the target language, as if it was news written directly in the target language. However, there are some constraints imposed by the intended usage:

- All translations should be "from scratch", without post-editing from MT. Using post-editing would bias the evaluation, so we need to avoid it. We can detect post-editing so will reject translations that are post-edited.
- Translation should preserve the sentence boundaries. The source texts are provided with exactly one sentence per line, and the translations should be the same, one sentence per line. Blank lines should be preserved in the translation.
- Translators should avoid inserting parenthetical explanations into the translated text and obviously avoid losing any pieces of information from the source text. We will check a sample of the translations for quality, and we will check the entire set for evidence of post-editing.
- Please do not translate the anonymization tags (e.g. #NAME#), but use the same form as in the source text. These tags are used to de-identify names and various other sensitive data. In other words, translation must contain given tag #NAME# on a position where it would naturally be placed before anonymization.
- If the original data contain errors, typos, or other problems, do not try to fix them (or introduce them in the translation), instead try to prepare correct translation as if the error wouldn't be in the source.

The source files will be delivered as text files (sometimes known as "notepad" files), with one sentence per line. We need the translations to be returned in the same format. If you prefer to receive the text in a different format, then please let us know as we may be able to accommodate it.

D Additional statistics of the test sets

Table 11 shows the type-token ratios for the source and target side of each of the test sets, shown for the four main domains. As mentioned previously, texts are tokenised using the language-specific Spacy models (Honnibal and Montani, 2017) where available. For Hebrew, we use the multilingual Spacy model as no language-specific model is available. The type-token ratio is calculated as the number of unique tokens divided by the total number of tokens. The absolute value depends not only on the lexical diversity of the text but also on the morphological complexity of the language in question.

E News Task System Submission Summaries

This section lists all the submissions to the translation task and provides the authors' descriptions of their submission.

E.1 AIRC (Rikters and Miwa, 2023)

AIRC trained constrained track models for translation between English, German, and Japanese. Before training the final models we first filtered the parallel and monolingual data (Rikters, 2018), then performed iterative back-translation as well as parallel data distillation to be used for non-autoregressive model training. We experimented with training Transformer models, Mega (Ma et al., 2022) models, and custom non-autoregressive sequence-to-sequence models with encoder and decoder weights initialised by multilingual BERT base. Our primary submissions contain translations from ensembles of two Mega model checkpoints and our contrastive submissions are generated by our non-autoregressive models.

E.2 ANVITA (no associated paper)

ANVITA-ZhJa Machine Translation system for WMT2023 Shared Task:General MT(News). This paper describes ANVITA-ZhJa MT system, architected for submission to WMT 2023 General Machine Translation(News) shared task by the ANVITA team, where the team participated in 4 translation directions: Chinese, Japanese→English and English→Chinese, Japanese. ANVITA-ZhJa MT system comprised of four NMT models.Chinese, Japanese→English and English→Chinese, Japanese multilingual models for primary and Chinese→English and English→Chinese bilingual models for contrastive submissions. Base MT models are built using transformer(base) architecture, trained over the organizer provided parallel corpus and subsequently used deep transformer with added layers and other parameters. We also distilled corpus using heuristics based filtering and used model ensemble for enhanced performance.

E.3 CUNI-DocTransformer (Popel, 2020)

Exactly the same system as submitted in WMT20, document-level Transformer trained with Block Backtranslation.

E.4 CUNI-GA (Jon et al., 2023)

Our submission is a result of applying a novel n-best list reranking and modification method on translation candidates produced by two other competing systems, CUNI-Transformer and CUNI-DocTransformer. Our method uses a genetic algorithm and MBR decoding to search for optimal translation under a given metric (in our case, a weighted combination of ChrF, BLEU, COMET22-DA, and COMET22-QE-DA).

E.5 CUNI-Transformer (Popel, 2020)

The English↔Czech sentence-level models are exactly the same as submitted in WMT20 (Popel, 2020). The Ukrainian↔Czech models are very similar, also trained with Block Backtranslation.

E.6 GTCOM (Zong, 2023)

GTCOM uses transformer as the basic architecture and leverages multilingual models to improve translation quality. Besides, GTCOM does a lot of data cleaning and data augmentation work.

E.7 HW-TSC (Wu et al., 2023b)

HW-TSC's submission is a standard Transformer model equipped with our recent technique.

E.8 IOL-Research (Zhang, 2023)

This paper describes the IOL Research team's submission system for the WMT23 General Machine Translation shared task. We participate in two language translation directions, including English-to-Chinese and Chinese-to-English. Our final primary submissions belong to constrained systems, which means for both translation directions we only use officially provided monolingual and bilingual data to train the translation systems. Our systems are based on Transformer architecture with pre-norm or deep-norm, which has been proven to be helpful for training deeper models. We employ methods such as back-translation, data diversification, domain fine-tuning and model ensemble to build our translation systems. Another important aspect is that we carefully conduct data cleaning and use as much monolingual data as possible for data augmentation.

E.9 TeamKYB (LI et al., 2023)

We here describe our neural machine translation system for the general machine translation shared task in WMT 2023. Our systems are based on the Transformer with base settings. We trained our model with preprocessed train data. We collect multiple checkpoint from our model and performed inference with several hyperparameter settings. Collected translations were processed via some rule-based corrections. We chose best translation from the results by using N-best ranking method.

E.10 Lan-BridgeMT (Wu and Hu, 2023)

With the emergence of large-scale models, various industries have undergone significant transformations, particularly in the realm of document-level machine translation. This has introduced a novel research paradigm that we have embraced in our participation in the WMT23 competition. Focusing on advancements in models such as chatGPT and GPT4, we have undertaken numerous prompt-based experiments. Our objective is to achieve optimal human evaluation results for document-level machine translation, resulting in our submission of the final outcomes in the general track.

E.11 MUNI-NLP (Rychlý and Teslia, 2023)

MUNI-NLP system is a standard transformer.

E.12 NAIST-NICT (Deguchi et al., 2023)

In this paper, we describe our NAIST-NICT submission to the WMT'23 English-Japanese general machine translation task. Our system generates diverse translation candidates and reranks them with a two-stage reranking system to find the best translation. We first generate 50 candidates each from 18 different translation methods using a variety of techniques to increase the diversity of the translation candidates. We trained 7 different models per language direction using different combinations of hyperparameters. From these models we used various decoding algorithms, ensembling the models, and using kNN-MT. The 900 translation candidates go through a two-stage reranking system in order to find the most promising candidate.The first step compares the 50 candidates from each translation method using DrNMT and returns the one with the highest score. The final 18 candidates are ranked using COMET-MBR, and the highest scoring is returned as the system output. We found that generating diverse translation candidates improves the translation quality by using the well-designed relanker model.

E.13 PROMT (Molchanov and Kovalenko, 2023)

This paper describes the PROMT submissions for the WMT23 Shared General Translation Task. This year we participated in two directions of the Shared Translation Task: English to Russian and Russian to English. Our models are trained with the MarianNMT toolkit using the transformer-big configuration. We use BPE for text encoding, both models are unconstrained. We achieve competitive results according to automatic metrics in both directions.

E.14 SRPH (Cruz, 2023)

We submit single-model encode-decoder Transformer systems for the constrained English to Hebrew and Hebrew to English translation directions. Our dataset is cleaned and filtered via a combination of heuristic-based, ratio-based, and embedding-based (LaBSE) methods, resulting in a dataset with high alignment. We train models with heavy use of back-translation and decode using Noisy Channel Reranking using a reverse model and a language model trained with contest data.

E.15 SKIM (Kudo et al., 2023)

The SKIM team submission took a standard procedure of building ensemble Transformer models, including base-model training, data augmentation using back-translation of base models, and retraining several final models using back-translated training data. Each final model has its own architecture and configuration, including a 10.5B parameter at most, substituting self and cross sublayers in decoder with cross+self-attention sub-layer (Peitz et al., 2019). We select the best candidate from large candidate pools, namely 70 translations generated from 16 distinct models for each sentence, with an MBR reranking method using COMET and COMET-QE (Fernandes et al., 2022). We also applied data augmentation and selection techniques to training data of the Transformer models.

E.16 UPCite-CLILLF (no associated paper)

In this biomedical shared task, we have created data filters to better "choose" relevant training data for fine-tuning, among provided training data sources. In particular, we have used the textometric analysis tool ITRAMEUR to filter the segments and terms that characterize the test set and then extracted them from training data to fine-tune MBart-50 baseline (`decoder_attention_heads: 16`, `decoder_ffn_dim: 4096`, `decoder_layers: 12`, `encoder_attention_heads: 16`, `encoder_ffn_dim: 4096`, `encoder_layers: 12`, `num_hidden_layers: 12`, `max_length: 200`, `epoch: 3`). In doing so, we hope to meet several objectives : to build feasible fine-tuning strategy to train biomedical in-domain fr<->en models ; to specify filtering criteria of in-domain training data and to compare models' predictions, fine-tuning data and test set in order to better understand how neural machine translation systems work. We will also compare the pipeline of the shared task of this year to those of the past 2 years to evaluate the benefits of our training strategies of in-domain machine translation models.

E.17 UvA-LTL (Wu et al., 2023a)

We present our WMT system, UvA-MT, in the WMT 2023 shared general translation task. This year, we developed a single Multilingual Machine Translation (MMT) system to participate in the two-directional translation track between English and Hebrew. The main architecture is based on the prior work of Beyond Shared Vocabulary (Wu and Monz, 2023). We scaled it up to a transformer-large level (422M parameters). Additionally, we employed back translation to generate synthetic data and labeled them with a new language tag. After convergence, we further fine-tuned the system without using synthetic data. Several domain shift techniques were also introduced, such as the domain-aware language model, to filter monolingual data.

E.18 YiShu (Min et al., 2023)

Yishu's team participated in WMT23 Machine Translation Competition and adopted the most advanced neural machine translation method. They use Transformer model structure and use large-scale parallel corpus for training. In order to improve the translation quality, the team adopted cutting-edge data preprocessing technology, various attention mechanisms and improved decoding strategies. In addition, they also carried out in-depth parameter adjustment and model optimization. Yishu team incorporated evaluation indicators such as BLEU and TER into the training constraints of the model to achieve better translation performance. They strive for high accuracy and fluency in the competition, and strive to achieve excellent results in the field of translation.

E.19 LanguageX (Zeng, 2023)

LanguageX's submission is a many-to-many encoder decoder transformer model.

F Automatic scores

This section contains automatic metric scores. While human judgement is the official ranking of systems and their performance, we share automatic scores to show expected system performance for various testsets.

We use COMET (Rei et al., 2020) as the primary metric and chrF (Popović, 2015) as the secondary metric, following recommendation by (Kocmi et al., 2021). We also present BLEU (Papineni et al., 2002) scores as it is still a widely used metric. The COMET scores are calculated with the default model `Unbabel/wmt22-comet-da`. The chrF and BLEU scores are calculated using SacreBLEU (Post, 2018). Scores are multiplied by 100. We ranked the systems according to their scores. Unconstrained systems are indicated with a grey background in the tables.

G Head to head comparisons

Following tables show differences in average human scores for each language pair. The numbers in each of the tables' cells indicate the difference in average human scores for the system in that column and the system in that row.

Because there were so many systems and data conditions the significance of each pairwise comparison needs to be quantified. We applied Wilcoxon rank-sum test to measure the likelihood that such differences could occur simply by chance. In the following tables $\star$ indicates statistical significance at $p < 0.05$, † indicates statistical significance at $p < 0.01$, and ‡ indicates statistical significance at $p < 0.001$, according to Wilcoxon rank-sum test.

Each table contains final rows showing the average score achieved by that system and the rank range according to Wilcoxon rank-sum test ($p < 0.05$). Gray lines separate clusters based on non-overlapping rank ranges.

Abstract

We present an overview of the Biomedical Translation Task that was part of the Eighth Conference on Machine Translation (WMT23). The aim of the task was the automatic translation of biomedical abstracts from the PubMed database. It included twelve language directions, namely, French, Spanish, Portuguese, Italian, German, and Russian, from and into English. We received submissions from 18 systems and for all the test sets that we released. Our comparison system was based on ChatGPT 3.5 and performed very well in comparison to many of the submissions.

1 Introduction

We describe the eighth edition of the Biomedical Translation Task[1] that was part of the Eighth Conference on Machine Translation (WMT23). Similar to previous years, we released multiple test sets based on biomedical abstracts that we retrieved from the PubMed database.[2]

We addressed six languages pairs, namely German (de), Spanish (es), French (fr), Italian (it), Russian (ru), and Portuguese (pt), from and into English, as following:

- German into English (de2en) and English into German (en2de);
- Spanish into English (es2en) and English into Spanish (en2es);
- French into English (fr2en) and English into French (en2fr);
- Italian into English (it2en) and English into Italian (en2it);
- Russian into English (ru2en) and English into Russian (en2ru);
- Portuguese into English (pt2en) and English into Portuguese (en2pt).

Different from the previous editions of the shared task, we did not release test sets for Chinese–English or English–Chinese. Novel this year is that we relied on ChatGPT 3.5 to create a performance point of comparison (cf. Section 3), instead of our baseline systems from the previous years.

2 Test sets

We created the test sets following a similar procedure to previous years. We downloaded the set composed of daily update files from Pubmed[3] on

[*]The contribution of the authors are the following: MN prepared the MEDLINE test sets, performed test set validation, manual validation, and organized the shared task; AJY performed test set validation, manual validation, the automatic evaluation and co-organized the shared task; AN compiled information on participants' methods, performed test sets validation, manual validation and annotations of chatGPT outputs on the en2fr test set; RB, GMDN, RR, PT, FV, MVN, LY, DW performed test set validation and/or manual validation; and CG used OpenAI API to create the ChatGPT 3.5 point of comparison; All authors approved the final version of the manuscript. Proceedings of the Eighth Conference on Machine Translation (WMT), pages 43–54
December 6–7, 2023.

April 26, 2023 and searched for articles that contained abstracts in both English and one of the six languages that we consider. We then randomly selected 100 bilingual abstracts for each of the language pairs.

For all language pairs, we split the sentences of the abstracts using SciSpacy (Neumann et al., 2019) and aligned them with the Geometric Mapping and Alignment (GMA) tool.[4] Native speakers of the languages manually checked the alignment quality in the Appraise tool (Federmann, 2018). In this evaluation, we classified the automatically aligned sentences into five categories:

1. "OK": both sentences contain the same information;
2. "Source>Target": the source sentence contains more information than the target one;
3. "Target>Source". the target sentence contains more information than the source one;
4. "Overlap": both source and target sentences have information not contained in the other one;
5. "No Alignment": the sentences refer to completely different contents, or one of hem is missing.

We present the results in Table 1. The highest alignment rates, i.e. the "OK" ones, were for Portuguese (at least 90%, both en2pt and pt2en), and the lowest ones for Russian (only 52% for en2ru). For the latter, we notice that the biggest difference with respect to the other language pairs is that many sentence pairs are not aligned, i.e. the "No Alignment" ones. The percentages for "Source>Target", "Target>Source", and "Overlap" are similar to the other language pairs. An analysis of these errors shows that they are due both to the sentence splitting and the alignment tool.

We released our test sets in two submission systems: (i) our Google form as announced on our shared task's web site; (ii) in OCELoT,[5] both in the General and in the Biomedical test sets.

3 Comparison system - ChatGPT 3.5

Instead of providing a baseline this year, we choose to provide translations from the ChatGPT 3.5 model through the OpenAI API. We refer to ChatGPT as a comparison system rather than a baseline, as it does not satisfy the usual criterion for a baseline as being a transparent, well-understood and reproducible model that provides a good (generally) lower bound against which to compare systems. Notably, the model is closed-sourced and trained on huge amounts of data, of which the details are not openly known.

ChatGPT 4 excels at many tasks (Chen et al., 2023; Jahan et al., 2023), including translation. Researchers from Tencent identified in a limited early evaluation done before the API was available ChatGPT 4 as a good translator (Jiao et al., 2023). Please note that we abstained from using the stronger ChatGPT 4 and used instead the faster but expectedly weaker ChatGPT 3.5. More precisely we used the model snapshot "gpt-3.5-turbo-0613", computed on June 13th 2023 but with the training data "up to Sept 2021"[6]. This reduces the risk of data contamination with respect to the abstracts used in our test sets, which were published in 2023.

The ChatGPT variants are large and trained on large quantities of data, but are generalist systems. Ideally, systems dedicated to translation or specialized in biomedical translation would be able to outperform them, or at least outperform the faster lower-quality version that we proposed here as a point of comparison. Otherwise, there are fewer reasons remaining for developing and using an alternative machine translation (MT) system: data privacy, self-hosting, usage in low-resources, non-connected systems.

We used the following prompt to perform the translations and to keep ChatGPT from producing any comments beyond the translation text itself: **"You are a helpful assistant specialised in biomedical translation. You will be provided with a sentence in {src}, and your task is to translate it into {trg}."** where {src} was the source language and {trg} was the target language (e.g. src = Italian and trg = English).

Using ChatGPT through the API proved to be more challenging than expected and seemed to act as a stress test for the API servers or for the cloudfare content distribution network proxy they use. For example we hit various intentional limitations, such as a rate limit of 90,000 tokens per minute. We then faced multiple other errors: read time out

Table 1: Statistics (number of sentences and percentages) of the automatic alignment quality of the MEDLINE test sets.

in the object "HTTPSConnectionPool" with host api.openai.com, HTTP 502 (bad gateway), and "internal error". After writing our API calling code in an idempotent way, we were able to interrupt it whenever it was stuck and restart it whenever we stopped it or it stopped with an error. To this end, the script would skip over the existing translations and proceed with sending for translation, one by one, the rest of the entries not yet translated.

The overall experience remained positive, as building the ChatGPT 3.5 translations involved 674,470 tokens, resulting in a total API cost of only 1.15 USD. However, we have no information on the CO_2 impact of the computation, which should include the impact of inference for translations as well as a fraction of the impact of training the ChatGPT 3.5 model. Writing the scripts and executing them took less than three days. The execution itself was fast; as we reported here, at times we exceeded the API limit of 90,000 tokens per minute.

4 Teams and systems

After the release of the test sets, the teams had around two weeks to process the data and submit their translations. We collected submissions from the two systems (our Google form and OCELoT) belonging to 18 teams (or systems), as listed in Table 2. We allowed up to three runs for each team and language pair. From all submissions, we skipped only one translation from one team, namely the one for fr2en from UPCite-CLILLF, since it was in French (instead of English).

This year, the Google submission form also included questions on material and methods used by participants. The questions were identical to those used in 2022. The response rate was lower than in previous years (2020-2022) when the questionnaire was operated separately from the submission system and teams were asked to complete the survey after submission. In Ocelot submissions, participants were asked to submit a narrative description of their method. None of the teams reported the CO_2 impact of their participation in the task.

Many teams approached the task with transformer-based neural MT (NMT), relying on existing implementations. The use of prompting autoregressive models was also introduced this year. Table 3 presents details of the teams' methods.

5 Automatic evaluation

We present BLEU scores (Papineni et al., 2002) for the automatic evaluation in Tables 4 and 5. This includes translations received from both submission systems (Google Form and OCELoT).

For both en2de and de2en test sets, the submissions from HuaweiTSC, ZengHuiMT, GPT4-5shot, and PROMT teams obtained higher scores than our comparison system (ChatGPT) according to BLEU. The BLEU scores of the Lan-BridgeMT submissions (which use GPT3 and GPT4) came very close to those of ChatGPT for most language pairs, e.g., en2es, en2it, and were sometimes higher, e.g., fr2en, it2en, and ru2en. Most of the ONLINE system submissions also got higher BLEU scores than ChatGPT. However, it is worth bearing in mind the possibility that the ONLINE systems had previously seen our test sets in the large data on

which they were trained, or were used by the authors to assist the production of the abstracts used in the test sets. Although we use the ChatGPT model based on data prior to 2022, meaning that it could not be trained on the parallel abstracts used in the test sets, it is also possible that ChatGPT was used by authors to produce the abstracts that form part of the test set.

6 Manual evaluation

We carried out a manual validation of the quality of the translations for some language pairs using the "3-way ranking" task in the Appraise tool. It consists of a pairwise comparison with three text spans, for example for en2pt: (i) the source text in English, (ii) translation A in Portuguese, and (iii) translation B also in Portuguese. The text is either a sentence or the whole abstract, i.e., we carried out the validation for each sentence and then for the complete abstract.

The evaluator should choose one of the following four options: (i) A=B, i.e., both translations have similar quality; (ii) A>B, i.e., translation A is better than translation B; (iii) A<B, i.e., translation A is worse than translation B; and (iv) error flag in case one or both of the translations do not refer to the same source text.

For the language pairs that we considered, we randomly selected the abstracts until we had at least 100 sentences. We restricted the abstracts

to those in which the rate of well aligned (OK) sentences was at least 80%. We considered all pairwise combinations from the following translations: (i) the reference translation, as originally available in PubMed, (ii) translations from ChatGPT 3.5, and (iii) translations from systems that directly took part on the Biomedical Translation Task, and not only on the General Task (see Table 2).

We present the results in Tables 6 and 7. We compute a significance test (Wilcoxon test) when

comparing the systems (or reference translation) and we show in bold and with a star (⊛) those cases in which one system (or the reference translation) was better than the other one.

None of the teams could outperform the reference translation for all of the language pairs. Further, for all language pairs that we checked, the quality of the translations from ChatGPT was similar to the reference translation at the sentence level, i.e., there was no significant difference in the results. However, on the abstract level, the ChatGPT translations were found to be better than the reference translations for some language pairs, namely, en2ru and fr2en.

For some of the languages (e.g. en2de), the rankings from the automatic and manual translations appear consistent. The BLEU score from the HuaweiTSC team was much higher than the one from Lan-BrigdeMT (0.43 versus 0.35), and indeed, the quality of the translations from HuaweiTSC was better than the ones from Lan-BrigdeMT. There are however some differences in rankings. For example the manual rankings do not correspond exactly to the automatic rankings for ru2en, fr2en and en2it. Notably, ChatGPT appears to be penalised by BLEU and does better in the manual rankings.

6.1 Quality of the translations

We discuss below, for some language pairs, some of the mistakes that we observed during the manual validation of the submissions.

en2de Similarly to the last few years, the quality of the translations into German was very high. Overall, the individual translations were often similar and differed only in nuances, such as the order of the syntactic constituents. Some models seemed to favour compound nouns more often than others (e.g., Lammellentrennung vs Trennung der Lamellen). However, this usually had no impact on the translation quality. Some systems translated idioms, such as "window of opportunity", literally into German. Especially specialist terms were translated differently by the individual models and it was rather challenging to judge which of the translated terms has better quality (see Example 1).

(1) **en:** The most common surgical fixation options are cerclages and screws, ...
de$_1$: Die häufigsten chirurgischen Fixierungsoptionen sind Zerkel und Schrauben, ...
de$_2$: Die häufigsten chirurgischen Fixierungsmöglichkeiten sind Zuggurte und Schrauben, ...
de$_3$: Die häufigsten operativen Fixationsmöglichkeiten sind Cerclagen und Schrauben, ...

en2es As observed in the last few years, the overall quality of the translations into Spanish was very high. MT systems output was indistinguishable from human translations in many occasions for both systems evaluated: ChatGPT and Lan-Bridge.

The reference translation outperformed Lan-Bridge when evaluating sentences and abstracts. The reference translation was more consistent in the abstracts, had a higher fluency in the translation and a better choice of terminology than Lan-BridgeMT.

For example, "illness recurrence" was translated as "recurrencia' by Lan-Bridge, whereas the reference translation used a more appropriate term "recidiva". Another example in the translation of the term "coronary heart disease", that Lan-Bridge translates literaly as "enfermedad coronaria", while the reference translation uses the medical term "cardiopatía coronaria".

As mentioned, the reference translation was more fluent when compared to Lan-Bridge, oftetimes having a slightly better word order, better concordance subject/verb and using punctuation (commas and full stops) more fluently. Similarly, the reference translation slightly outperformed ChatGPT when comparing abstracts.

However the baseline translation was better than the reference translation at sentence level, this was due to a more overall fluent and consistent translation of abstracts observed in the reference translation when compared to ChatGPT. It must be noted that ChatGPT performed very well compared to the reference translation in most abstracts evaluated manually.

In the following example ChatGPT used the correct punctuation for numbers above 1,000 in Spanish and the reference translation used the incorrect punctuation and was penalized for this fact.

(2) **ChatGPT:** Se incluyeron un total de 22,148 pacientes de 40 estudios.
Reference: Se incluyó un total de 22.148 pacientes de 40 estudios.

When compared against each other, ChatGPT outperformed Lan-Bridge both at the abstract level

and at the sentence level. As with the reference translation, ChatGPT was more fluent, had a better choice of terminology (domain specific terms) and was more consistent overall at abstract level.

The ChatGPT translation was more fluent in the following example with a better usage of wording. Lan-bridge followed the English source text more closely which made the output less idiomatic.

(3) **ChatGPT:** IO redujo los niveles de glucosa en sangre, restableció el peso corporal y mejoró

la sensibilidad a la insulina, así como la tolerancia a la insulina y a la glucosa en ratones diabéticos.
Lan-bridge: IO redujo los niveles de glucosa en sangre, restableció el peso corporal y mejoró la sensibilidad a la insulina junto con la tolerancia a la insulina y la tolerancia a la glucosa en ratones diabéticos.

While issues are still being observed by the MT systems evaluated manually this year, these are no longer major translation issues as in past years. The issues observed this year for the translations from English to Spanish were minor issues that affect the overall final quality, but can be remediated by editing the MT output to provide better terminology, specially domain specific, more fluent sentences and a better overall consistency in the translation (specially for abstracts).

en2fr Translation quality was somewhat uneven this year. While some translations were very high quality and often similar or identical to reference translations, others exhibited serious issues including inserting erroneous information (see Example 4) or conveying meaning drastically different (see Example 5) or opposite to the original sentence (see Example 6). This type of error can have a severe impact when it results in incorrect medical information (Example 6) or incorrect description of a social group (see Example 5).

(4) **en:** Analysis (. . .) showed that. . .
fr$_1$: L'analyse (. . .) a montré que. . .
fr$_2$: * L'analyse (. . .) a montré que. . . (Traduit par Docteur Serge Messier)

(5) **en:** The criminalization of Black people
fr$_1$: La criminalisation des Noirs
fr$_2$: * La criminalisation des personnes blanches

(6) **en:** blood potassium level ≥ 6.5 mmol/L
fr$_1$: taux de potassium sanguin supérieur à 6,5 mmol/L
fr$_2$: * taux sanguin de potassium inférieur à 6,5 mmol/L

The translation of numerical values was also unreliable: example 5 illustrates the adequate translation of *6.5 mmol/L* into *6,5 mmol/L*, however in another abstract the study population of *52 dogs* was erroneously translated by *54 chiens*.

Issues remain with acronym translation where acronyms are often kept verbatim upon definition (e.g., *developmental disabilities (DD)* translated as *troubles du développement (DD)* instead of the reference translation *troubles du développement (TD)* although consistency seems improved: acronyms, albeit erroneous, are often used throughout a text.

The comparison of translations exhibiting different types of issues also remains difficult. In example 7, although *enquête* is a better translation for *survey* in the context, translation **fr$_1$** was preferred to **fr$_2$** because of the correct translation for *asking about*, which was central to the sentence.

(7) **en:** A survey asking about training
fr$_1$: Un sondage demandant des informations sur la formation
fr$_2$: * Une enquête demandant une formation

Overall, the one-to-one comparisons seemed quite consistent in ranking the systems and reference, and suggest that perhaps the most serious issues identified were concentrated in a few systems.

In addition to the manual evaluation through appraise, a complementary assessment of ChatGPT outputs was conducted, with a focus on *Acronyms* and *Lab Values*, which had been studied in our clinical case descriptions last year. We found that overall, 39 out of 50 test documents contained acronyms and only 3 contained lab values. The low frequency of lab values in the test set suggests that this particular source of translation difficulty for automatic system is not present in random scientifc abstracts. Furthermore, we cannot draw conclusions on the performance of ChatGPT on lab value translations. *Acronym* translations were considered correct when the ChatGPT translation was identical to the reference translation or consisted of an attested acronym use in similar context. Correct acronym translations (74%) included frequent acronyms such as CI (confidence interval), OR (odds ratio) or MRI (magnetic resonance imaging). In other cases, acronyms were either untranslated (16%) or erroneous (10%). These cases included acronyms for terms that were unfrequent or ad-hoc to the documents - albeit often a major topic. It should be noted that they were a source of inconsistent acronym translations in 14 documents - 36% of test documents with acronyms.

fr2en Translation quality was good overall and sometimes indistinguishable from reference translations. Aside from a problem with certain words being dropped at the beginning of translations, sometimes mid-word (quite possibly due to a bug by one or several of the systems), the errors made were similar to previous years.

Term and acronym translation (see Example 8) remained a serious problem and one that was highly influential in reranking decisions, i.e. more so than other errors such as those involving grammar, style or naturalness. In addition to acronym translation errors, we also observed that acronym placement was not always coherent (e.g. an acronym not being defined at the first instance and used consistently afterwards), but in practice this did not influence reranking decisions because of the presence of more serious errors.[7]

(8) **fr:** La migraine est la maladie neurologique la plus fréquemment rencontrée...
en$_1$: Migraine is the most common neurological disorder...
en$_2$: *Mimine is the most frequently encountered neurological disease...

The translation of non-domain-specific terms also posed problem, either those that were ambiguous in context (Example 9), including pronoun translation (for example *sa/son* 'his/her/its/their' being translated as *its* rather than 'his/their' or involving some degree of polarity (Example 10). On a similar note, the omission of words, mainly adjectives and adverbs (e.g. *relativement* 'relatively' and *souvent* 'often') sometimes made the difference between two translations, as did missing final punctuation (when no other errors were present).

(9) **fr:** ...les traitements oraux anciens...
en$_1$: ...older oral treatments...
en$_2$: *...ancient oral treatments...

(10) **fr:** ...un profil d'effets indésirables peu favorable
en$_1$: ...an unfavorable adverse effect profile
en$_2$: *...a slightly favorable side effect profile.

Finally, as in previous years, not all reference translations of were entirely faithful to the French source abstract (paraphrasing, missing or added information). This resulted in some cases in the reference translation being ranked below a system output, including imperfect outputs. Caution should therefore be taken when drawing conclusions about translation quality concerning humans, since intentional paraphrasing by the authors resulted in good abstracts but inferior in terms of our manual evaluation criteria. This partly explains why ChatGPT is "better" than the reference translations for this language pair.

en2it The quality of the translation was on average higher than the previous years. Most of the sentences compared was almost identical and fluent in terms of the quality of language. From a terminological viewpoint, it is possible to identify some inaccuracies in the choice of translating terms in the target language. For example, in *tumour recurrence*, the correct translation of *recurrence* is *recidiva* instead of *ricorrenza*.

Another frequent mistake, which is also a frequent mistake for language learners, is the translation of *hair* in sentences like "hair cortisol concentration (HCC) in healthy and ill cows". In these cases, *hair* must be considered as the hair of animals of body parts, therefore *peli*, and not scalp hair, in Italian *capelli*.

In some cases, there were better choices made by the reference system. For example, in the case of the phrase "[the author] is an initiate into the topic", ChatGPT used *iniziato* to translate *initiate* while a better equivalent would be in this case *novizio* as proposed by the reference system.

Finally, from a syntactic point of view, the results were very similar and only in a few cases we could find a construction that sounded odd or not easy to read. For example, the sentence "Flowmetry data always showed a more or less sudden disappearance of vasomotion." was translated by the reference system with *I dati della flussometria hanno sempre mostrato una più o meno improvvisa scomparsa della vasomotricità* while it would be more appropriate the translation of provided by the baselinte *I dati di flussometria mostravano sempre una scomparsa più o meno improvvisa della vasomozione.*

en2pt The results show that many translations, either from the referenc, ChatGPT, or from the Lan-BridgeMT team, were as good as the reference translation for many sentences (cf. Table 6,

[7] This could be something to look out for in future years when evaluating whole abstracts, when the translation quality allows such fine-grained observations.

"Sentences"). However, there were many cases on which we decide that one passage was better than the other, we discuss some of these differences here.

The most serious mistake that we found was the translation of "back pain" into "pressão arterial" (blood pressure), probably because both of them have the same acronym in English, i.e., "BP".

(11) **en:** The high incidence and worsening of BP ...
pt$_1$: A alta incidência e agravamento do PC ...
pt$_2$: A alta incidência e o agravamento da pressão arterial ...

Similar to previous years, we still found cases in which the English (or simply a wrong) acronym was used (cf. exmple below). Some similar errors might only be noticed when checking the complete text (abstract), and not only single sentences, such as when the translation includes an acronym that was not defined previously.

(12) **en:** ... Creutzfeldt-Jakob disease (CJD) ...
pt$_1$: ... doença de Creutzfeldt-Jakob (DCJ) ...
pt$_2$: ... doença de Creutzfeldt-Jakob (CJD) ...

In some cases, even though both passages were correct, we found that the translation was better due to the use or more medical concepts.

(13) **en:** ... headache attributed to ischemic stroke ...
pt$_1$: A cefaleia atribuída ao acidente vascular cerebral isquêmico ...
pt$_2$: ... a dor de cabeça atribuída ao derrame isquêmico ...

Sometimes the translation included terms that were not suitable, even thought the meaning was close to the source, and it the might have been understood by many readers.

(14) **en:** ... which were analyzed fully and individually.
pt$_1$: ... que foram analisados na íntegra individualmente.
pt$_2$: ... que foram analisados de forma completa e individual.

We chose translation which better describe the facts, depending of the use active or passive voice. Further, in case of passive voice, we preferred caes in which the subjective is closer to the verb, or even before it. We find that it improves the readability.

(15) **en:** The patients underwent magnetic resonance imaging.
pt$_1$: Os pacientes realizaram ressonância magnética. (active voice)
pt$_2$: Os pacientes foram submetidos a ressonância magnética. (passive voice)

(16) **en:** Twelve articles were included in the analysis.
pt$_1$: Foram incluídos na análise 12 artigos.
pt$_2$: Doze artigos foram incluídos na análise.

ru2en While the quality of ru2en translations continues to impress, one recurrent issue centers around the proper handling of abbreviations and acronyms. Often, an acronym is introduced early in the abstract, and holds a clear, defined meaning. Yet, as the text progresses, these acronyms are frequently mishandled by translation systems, failing to link them to their previously established acronym, and frequently transliterating an acronym created in Russian text. This issue manifests itself nearly every time an acronym appears, which makes translations of abstracts that include acronyms not consistently reliable.

For example, the term Ischemic Stroke is introduced in the abstract and abbreviated to "ИИ" which corresponds to the Russian term "ишемического инсульта". One of the reference translations correctly uses the acronym IS to refer to Ischemic Stroke, while the other comes up with an unrelated abbreviation AI.

(17) **ru:** В исследование включили 120 пациентов (57 женщин и 63 мужчины, средний возраст 58,4±6,4 года) в позднем восстановительном периоде ИИ.
en$_1$: The study included 120 patients in the late recovery period of IS, 57 women and 63 men, average age 58.4±6.4 years.
en$_2$: The study included 120 patients (57 women and 63 men, median age 58.4±6.4 years) in the late recovery period of AI.

7 Conclusions

We presented the finding of the edition of the WMT Biomedical Translation Task. We received submission from 18 systems and compared them to translations from ChatGPT 3.5.

In the automatic evaluation, some systems were scored higher than BLEU according to the comparison system (ChatGPT 3.5). In the manual evaluation, none of the systems were systematically better

than the reference translation for all of the language pairs that we evaluated. However, in a couple of cases, namely, for fr2en and en2ru, the translations from ChatGPT were preferred over the reference translations. We presented a details discussion of the errors that we found during the manual evaluation.

Limitations

Our test sets comprise 50 abstracts per language pair/directions. Further, due to the time consuming, difficulty of the task, and number of submissions, the manual evaluation was only carried out for a small sample. However, since our task has been running for eight years, the cumulative number of test sets is satisfactory for testing purposes, and maybe even for few-shot training approaches.

We did not carry out manual evaluation for some of the language pairs (directions), e.g., it2en, for which we do not have experts who are native speakers in the target language and have a very good knowledge in the source language. However, we always release the test sets and the submission files from the participants, with which anyone can carry out further experiments or manual evaluations.

Ethics Statement

Our test sets were derived from PubMed, a database of biomedical citations. These publications are often used in many areas of the medicine, including decision about diagnostic and treatment of patients. Automatic translation in this domain should be used as part of a larger framework that should include human experts for the interpretation of the translations and, if necessary, correct and adapt the text accordingly.

Abstract

Translating literary works has perennially stood as an elusive dream in machine translation (MT), a journey steeped in intricate challenges. To foster progress in this domain, we hold a new shared task at WMT 2023, the first edition of the *Discourse-Level Literary Translation*. First, we (Tencent AI Lab and China Literature Ltd.) release a copyrighted and document-level Chinese-English web novel corpus. Furthermore, we put forth an industry-endorsed criteria to guide human evaluation process. This year, we totally received 14 submissions from 7 academia and industry teams. We employ both automatic and human evaluations to measure the performance of the submitted systems. The official ranking of the systems is based on the overall human judgments. In addition, our extensive analysis reveals a series of interesting findings on literary and discourse-aware MT. We release data, system outputs, and leaderboard at `http://www2.statmt.org/wmt23/literary-translation-task.html`.

1 Introduction

In past decades, the evolution of machine translation (MT) has undergone significant improvements in accuracy and efficiency, leading to many practical applications in various fields (Bojar et al., 2014; Barrault et al., 2019; Farhad et al., 2021; Kocmi et al., 2022). Despite its success, MT still struggles in certain intricate scenarios to deliver translations that meet high standards (Läubli et al., 2018; Koehn and Knowles, 2017). Translating literary texts is considered to be the greatest challenge for MT due to its complex nature (Toral and Way, 2018; Toral et al., 2018; Ghazvininejad et al., 2018):

- *Rich Linguistic and Cultural Phenomena*: literary texts contain more complex linguistic and cultural knowledge than non-literary ones (Voigt and Jurafsky, 2012; Ghazvininejad et al., 2018). To generate a cohesive and coherent output, MT models require an understanding of the intended meaning and structure of the text at discourse level (Wang et al., 2016, 2018a,b, 2019, 2023b). Furthermore, it demands skillful adaptation of cultural references, idioms, and subtle expressions to capture the essence of the original work in target languages.
- *Limited Data*: existing document-level datasets are news articles and technical documents (Liu and Zhang, 2020; Thai et al., 2022); there is limited availability of copyrighted, discourse-level, parallel data in the literature domain. This makes it difficult to develop models that are able to handle the complexities of literary translation.
- *Long-Range Context*: literature such as novels have much longer contexts than texts in other domains (e.g. news articles). Translation models need to acquire the capacity of modeling long-range context for learning translation consistency and lexical choice (Wang et al., 2017; Wang, 2019; Matusov, 2019; Du et al., 2023).
- *Unreliable Evaluation Methods*: literary evaluation needs to measure the meaning and structure of the text, and the nuances and complexities of the source language. A single automatic evaluation using a single reference is unreliable. Thus, professional translators with well-defined error typologies and targeted automatic evaluation are considered a complement (Matusov, 2019).

With the swift progression of MT and the notable advancements in Large Language Models (LLM) (Ouyang et al., 2022b; OpenAI, 2023), our curiosity is piqued regarding the efficacy of MT and LLM in the realm of literary translation. We aim to explore the extent to which these technologies can aid in addressing the intricate challenges of translating literary works. Therefore, we hold the first edition of the *Discourse-Level Literary Translation* in WMT 2023. Literary texts encompass a wide range of forms, including novels, short stories, poetry, plays, essays, and more. Among

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 55–67
December 6–7, 2023.

Figure 1: The word cloud represents institute and companies from different regions that downloaded the GuoFeng Webnovel Corpus.

these, *web novels*, also known as online or internet novels, represent a unique and rapidly growing subset of literature. Their popularity, accessibility, and diverse genres set them apart. As they provide not only an extensive volume of text but also exhibit distinctive linguistic features, cultural phenomena, and simulations of societies, web novels can serve as valuable resources and challenging for MT research. This year, the shared task mainly focuses on *document-level web novels*, and we introduce a document-level benchmark dataset and establish human evaluation criteria specifically tailored to address the challenges of literary translation:

- **Benchmark Dataset**: We build and release a copyrighted and high-quality Chinese-English training corpus, comprising 2 million sentences sourced from 179 web fictions. This dataset preserves both book-level and chapter-level contexts, and features manually-aligned sentence pairs. We also provide three types of testsets, varying in distribution and document length (in Section 2).
- **Evaluation Methods**: In order to evaluate the translation quality of the participating systems we used both automatic and human evaluation methods. About automatic evaluation, we employ document-level sacreBLEU (d-BLEU) as our metric, which is computed by matching n-grams in the whole document (Liu et al., 2020; Post, 2018). In terms of human evaluation, we propose a well-defined criteria by adapting multidimensional quality metrics (MQM) (Lommel et al., 2014) to fit the context of literary translation. Note that all evaluations are case-sensitive (in Section 3).

Figure 2: Illustration of discourse-level literary translation, which is sampled from our Web Fiction Corpus. Colored words demonstrate rich linguistic phenomena.

We introduce the task overview and submission form in Section 4. This year, 14 submissions were received from 7 different teams, which are detailed in Section 5. We report the evaluation results in Section 6 followed by the conclusion in Section 7.

2 The GuoFeng Webnovel Corpus

We release a copyrighted and high-quality Chinese-English corpus on web novels. Additionally, we provide in-domain pretrained models as supplementary resources. As shown in Figure 1, a total of 45 institutes and companies from various regions have downloaded our dataset, showing that the prposed tasks and data have garnered widespread interest.

2.1 Datasets

Copyright Copyright is a crucial consideration when it comes to releasing literary texts, and it is also one of the primary reasons for limiting the scale of data in this domain. We, Tencent AI Lab and China Literature Ltd., are the copyright owners of the web fictions included in this dataset. In order to promote the advancement of research in this field, we make this data available to the research community, subject to certain terms and conditions.

- After registration, WMT participants can use the corpus for non-commercial research purposes and follow the principle of fair use (CC-BY).

- Modifying or redistributing the dataset is strictly prohibited.
- You should cite the this paper and claim the original download link.

Data Processing The web novels are originally written in Chinese by web novel writers and then translated into English by professional translators. Our data processing involves a combination of automated and manual techniques: 1) we match Chinese books with its English counterparts based on bilingual titles; 2) within each book, Chinese-English chapters are aligned using Chapter ID numbers; 3) within each chapter, we build a MT-based sentence aligner to align sentences in parallel, preserving the sentence order in the chapter; 4) human annotators are engaged to review and correct any discrepancies in sentence-level alignment. To ensure the retention of discourse information, we permit null alignments. We totally spent 6 months addressing copyright issues and around 40,000 euros for human annotation. Figure 2 shows the final format of our corpus.

Training/Validation/Testing Data Table 3 lists data statistics of our dataset. As seen, the *training set* contains 23K continuous chapters from 179 web novels, covering 14 genres such as fantasy science and romance. To enable participants to evaluate model performance by themselves, we provide two *unofficial validation/testing sets* with one reference. For dataset_1, books overlap with the training data, whereas dataset_2 contains unseen books. The participants can regard each chapter as a document to train and test their discourse-aware models. Apart from this, parallel training data in the General MT Task can also be used for data augmentation. In the final testing stage, participants use their systems to translate the *official testing set* (Test_{final}). We select around 20 consecutive chapters from each book. Thus, we participants could treat all chapters within a book as a long document[1]. As seen, the document length of Test_{final} is quite longer than other sets. The final testset contains two references: Reference 1 is translated by human translators and Reference 2 is bult by manually aligning bilingual text in web page. The genres in the valid and test sets are sampled evenly.

[1]The participants can still regard one chapter as a document, which depends on the models' length capability.

2.2 Pretrained Models

Apart from training dataset from web novels, we also provide in-domain pretrained models as supplementary resources. These models can be used to finetune or initialize MT models.

- **RoBERTa (base)**: The original model features a 12-layer encoder and is trained on the Chinese Wikipedia (Liu et al., 2019). It has a hidden size of 768 and a vocabulary size of 21,128 using whole word masking. We continuously train it with Chinese literary texts (84B tokens) (Wang et al., 2023a).
- **mBART (CC25)**: This original model is equipped with a 12-layer encoder and a 12-layer decoder, having been trained on a web corpus spanning 25 languages (Liu et al., 2020). It boasts a hidden size of 1024 and a vocabulary size of 250,000. We continuously train it with English and Chinese literary texts (114B tokens) (Wang et al., 2023a).

Besides, general-domain pretrained models listed in General MT Track are also allowed in this task: mBART, BERT, RoBERTa, sBERT, LaBSE.

3 Evaluation Methods

It is still an open question whether human and automatic evaluation metrics are complementary or mutually exclusive in measuring the document-level and literary translation quality. Thus, we report both automatic and human evaluation methods, and officially rank the systems based on the overall human judgments.

3.1 Automatic Evaluation

We use widely-used sentence- and document-level evaluation metrics: 1) *sentence-level*: we employ sacreBLEU (Post, 2018), chrF (Popović, 2015), TER (Snover et al., 2006) and pretraining-based COMET (Rei et al., 2020); 2) *document-level*: we mainly use document-level sacreBLEU (d-BLEU) (Liu et al., 2020), which is computed by matching n-grams in the whole document. For d-BLEU, We combine all sentences in each document as one line and then conduct sacreBLEU metric. Note that all evaluations are case-sensitive. We employ *sacrebleu*[2] to calculate sacreBLEU, chrF, TER and d-BLEU with *sacrebleu* using two references. The command is: `cat output | python -m`

[2]https://github.com/mjpost/sacrebleu with signature: `nrefs:2|case:mixed|eff:no|tok:13a|smooth:exp|version:2.3.1`.

Dataset	#Book	#Chap.	#Sent.	#Word	|D|
Train	179	22.6K	1.9M	32.0M	1.4K
Valid_1	22	22	755	18.3K	832
Test_1	26	22	697	19.5K	884
Valid_2	10	10	853	16.0K	1.6K
Test_2	12	12	917	16.7K	1.4K
Test_{final}	12	239	16.7K	337.0K	*28.1K

Figure 3: Data statistics of the GuoFeng Webnovel Corpus on number of book, chapter (#Chap.), sentence (#Sent.), word, and genre distribution in training set. The #Word is based on English texts. For dataset_1, books overlap with the training data, whereas dataset_2 contains unseen books. Thus, each chapter is treated as a separate document. For Test_{final}, around 20 consecutive chapters from each book are selected, treating all chapters within a book as a long document. The document length (|D|) is calculated by dividing #Word divided by the number of documents.

`sacrebleu reference*`. We employ *unbabel-comet*[3] to calculate COMET score using *Reference 1*. The command is: `comet-score -s input -t output -r reference1` (default model).

3.2 Human Evaluation

The human evaluation was performed by professional translators using an adaptation of the multidimensional quality metrics (MQM) framework (Lommel et al., 2014). For example, we consider the preservation of literary style and the overall coherence and cohesiveness of the translated texts. As shown in Table 6, we put forth an industry-endorsed criteria to guide human evaluation process. The main error types are:

- **Accuracy (Acc.)**: The target text does not accurately reflect the source text, allowing for any differences authorized by specifications.
- **Fluency (Flu.)**: Issues related to the form or content of a text, irrespective as to whether it is a translation or not.
- **Style (Sty.)**: The text has stylistic problems.
- **Terminology (Ter.)**: A term (domain-specific word) is translated with a term other than the one expected for the domain or otherwise specified.
- **Locale Convention (Loc.)**: The text does not adhere to locale-specific mechanical conventions and violates requirements for the presentation of content in the target locale.
- **Others (Oth.)**: Other issues such as the signs of MT, gender bias and source errors.

MQM utilizes a scorecard format to quantify the quality assessment results. Evaluators assign numerical values to identified translation errors based on error types, severity, etc., making the assessment results more intuitive. The overall quality score is calculated based on per-word translation accuracy:

$$\text{S} = 1 - \frac{5 \times C_{\text{Min.}} + 10 \times C_{\text{Maj.}} + 25 \times C_{\text{Cri.}}}{\text{Total Word Count}}$$

where where we set four error severity levels: Neutral (Neu.), Minor (Min.), Major (Maj.), Critical (Cri.) with 0/5/10/25 severity penalty. $C_\star$ denotes the number of errors. The "Total Word Count" is calculated based on source input (Chinese word). Considering our task is centered on Zh-to-En translation, we engaged four evaluators who are native English speakers and also fluent in Chinese.

4 Task Description

Overview The shared task will be the translation of literary texts between Chinese→English. Participants will be provided with two types of training datasets: (1) discourse-level GuoFeng Webnovel Corpus; (2) General MT Track Parallel Training Data. Additionally, they are provided two types pretrained models: (1) in-domain pretrained models, including In-domain RoBERTa (base) and In-domain mBART (CC25). (2) other general-domain pretrained models listed in General MT Track. Note that basic linguistic tools are allowed

[3] https://github.com/mjpost/sacrebleu.

in the constrained condition as well as pretrained language models released before February 2023.

In the final testing stage, participants use their systems to translate an official testing set. The translation quality is measured by a manual evaluation and automatic evaluation metrics. All systems will be ranked by human judgement according to our professional guidelines and translators. Participants can submit either constrained (i.e. only use the training data specified above) or unconstrained (i.e. it allows the participation with a system trained without any limitations) systems with flags, and we will distinguish their submissions.

Goals The main goals of the task are to:

- Encourage research in machine translation for literary texts.
- Provide a platform for researchers to evaluate and compare the performance of different machine translation systems on a common dataset.
- Advance the state of the art in machine translation for literary texts.

Submission and Format Submissions will be done by sending us an email to our official email. Each team can submit at most 3 MT outputs per language pair direction, one primary and up to two contrastive. The requirements of submission format are (1) Keep 12 output files that are identical to the testing input files. (2) In the output files, ensure that each line is aligned with the corresponding input line.

5 Participants' and Baseline Systems

Here we briefly introduce each participant's systems and refer the reader to the participant's reports for further details. Table 1 shows the summary of systems and participant teams.

5.1 MaxLab (constrained)

The team from University of Southern California, Information Sciences Institute introduce three translation systems. The *Primary System* is built on a paragraph-level transformer, trained on a paragraph-aligned corpus (with a source side cap of 256 characters), executing translations at the paragraph level. The *Contrastive System 1* deploys a sentence-level transformer, capitalizing on the sentence alignment data available in the datasets. The *Contrastive System 2* adopts a paragraph-level Mega model (Ma et al., 2022). The Mega model proposed a single-head gated attention mechanism equipped with an exponential moving average, which achieves comparable performance compared to Transformers having with fewer parameters. In pre-processing, the team opted for Byte-Pair Encoding (BPE) for tokenization. And they employed Jaccard similarity for sentence alignment during the post-processing phase.

5.2 MAKE-NMT-VIZ (constrained)

The team from Université Grenoble Alpes introduced three translation systems. The *Primary System* finetune the mBART (CC50) model using Train, Valid_1, Test_1 of the GuoFeng Corpus, adopting settings similar to those described by Lee et al. (2022). Specifically, they finetune models for 3 epochs, utilizing the GELU activation function, a learning rate of 0.05, a dropout rate of 0.1, and a batch size of 16. For decoding, a beam search of size 5 was employed. The *Contrastive System 1* is implemented upon a finetuned concatenation transformer (Lupo et al., 2023) with two training steps: (1) a sentence-level transformer is trained for 10 epochs using General, Valid_1, Test_1 datasets; (2) a document-level transformer is finetuned using pseudo-document data (3-sentence concatenation) from Train, Valid_2, Test_2 data for 4 epochs. They use ReLU as an activation function, along with an inverse square root learning rate, a dropout rate of 0.1, and a batch size of 64. For decoding, a beam search of size 4 was employed. The *Contrastive System 2* is a sentence-level transformer model trained for 10 epochs using General, Valid_1, Test_1 datasets. The training adopted an inverse square root scheduled learning rate, a dropout rate of 0.1, and a batch size of 64. Decoding was done using a beam search of size 4.

5.3 TJUNLP (constrained)

The team from Tianjin University introduced a *Primary System* based on a sentence-level Transformer model. The training consists of two phases: initially, it undergoes 100k steps on a dense model, followed by a 50k step fine-tuning on mixture of experts (MOE). They adopt the Polynomial Decay as their learning rate scheduling strategy, with a learning rate set at 2e-4, a dropout rate of 0.1, and a batch size encompassing 4096 tokens. For decoding, a beam search of size 5 was employed. For pre-processing, the team opted for SentencePiece Model (SPM) for tokenization.

ID	Team	Institution	Flag	#System	Main Methods
1	MaxLab	University of Southern California	⊙	3	para-level Transformer
2	MAKE-NMT-VIZ	Université Grenoble Alpes	⊙	3	mBART
3	TJUNLP	Tianjin University	⊙	1	sent-level Transformer
4	DLUT	Dalian University of Technology	⊗	1	GPT-3.5-turbo
5	NTU	Nantong University	⊗	1	Opus-MT
6	HITer-WMT	Harbin Institute of Technology	⊗	2	Llama-7b
7	HW-TSC	Huawei Translation Services Center	⊗	3	doc2doc Transformer

Table 1: The summary of system submission and their participant teams. We also report the number of systems (#System) and the constrained (⊙) and unconstrained (⊗) flags.

5.4 NTU (unconstrained)

The Nantong University team introduce a *Primary System*. It is based on a pretrained MT model, Opus-MT,[4], which is trained on OPUS dataset (Tiedemann and Thottingal, 2020). The model is finetuned on one NVIDIA Tesla A100 80 GB where the learning rate is 5e-5, batch size is 64, max length is 512 and the epoch number is 10.

5.5 DLUT (unconstrained)

The team form Dalian University of Technology introduce a *Primary System* based on GPT-3.5-turbo (Brown et al., 2020). They mainly propose prompt engineering, data filtering, and document segmentation to activate the capabilities of LLMs for discourse-level translation (Zhao et al., 2023).

5.6 HITer-WMT (unconstrained)

The team form Harbin Institute of Technology (Harbin) introduce two translation systems. The *Primary System* centers on instruction fine-tuning, executed through the Llama-7b model within the Parrot framework (Jiao et al., 2023).[5] Specifically, they build an instruction dataset from two comprehensive chapters of our existing training corpus according to methodologies in Peng et al. (2023). This dataset was fine-tuned using Llama-7b over 3 epochs with a learning rate of 2e-5. The *Contrastive System* utilizes the GuoFeng mBART Model provided by the shared task. This model was trained over 10 epochs at a learning rate of 1e-4, with gradient clipping applied to stabilize training.

5.7 HW-TSC (unconstrained)

The team form Huawei Translation Services Center exploit a variety of techniques. They introduce an unconstrained Document-to-Document Translation system. They first train a sentence-level Transformer-big model with a 25-layer encoder and a 6-layer decoder, and perform domain adaptation with novel data on this model. They obtain a strong baseline using data augmentation methods including Back Translation, Forward Translation, and Data Diversification. They then perform incremental training using the Doc2Doc technique to turn the model into a document-level translation model. They also conduct document-level data augmentation using the Multi-resolutional Document-to-Document approach (Sun et al., 2022), and ensue the consistency of NE translations in a document with TrAining Data Augmentation (TADA). They submit three systems: the *Primary System* uses all strategies. In contrast to the primary system, the *Contrastive System 1* system does not use TADA, and the *Contrastive System 2* sets the beam size to 6 during inference, while 10 for other tasks.

5.8 Baseline Systems (unconstrained)

We select three representative systems as baselines. *Commercial Translation System*: we use Google Translate,[6], which usually performs state-of-the-art in translation performance. *Commercial LLM Systems*: we employ GPT-4 (8K) API[7] to translate documents, which is known for its extensive context modeling capabilities (Ouyang et al., 2022a; Wang et al., 2023c). *Open-sourced LLM Models*: we enhance Llama (2K) (Touvron et al., 2023) on document-level translation by using the 200K general-domain document-level training set (Du et al., 2023). All testing were conducted between August 1st and 30th, 2023. In the future, we will use more diverse model architectures such as non-autoregressive translation model (Gu et al., 2017;

Table 3: Evaluation results of baseline and primary systems in terms of **human evaluation**. We report MQM score and System Rank.

Ding et al., 2020, 2021; Wang et al., 2023d).

6 Evaluation Results

6.1 Automatic Evaluation

We report the automatic evaluation scores of all submissions in Table 2. The evaluation metrics includes 1) sentence-level BLEU, chrF, COMET, TER; and 2) document-level d-BLEU. To calculate d-BLEU, we first concatenate all continuous sentences in one book as on line, and then employ sacreBLEU to obtain scorers. To compute d-BLEU, we merge all the consecutive sentences from a single book into one continuous line, and then utilize the sacreBLEU to generate the scores.

Among constrained Primary systems, the MAKE-NMT-VIZ system shows impressive performance and achieves the best in terms of all metrics. Similarly, the HW-TSC⋆ Primary system achieves the best in constrained settings. As introduced in Section 5, MAKE-NMT-VIZ mainly finetune the mBART pretrained model while HW-TSC⋆ train a doc2doc Transformer model using a number of data augmentation methods.

In the majority of teams, the primary system exhibits superior performance compared to the corresponding contrastive system. The exceptions to this trend are noted in the cases of HITer-WMT⋆ and HW-TSC⋆, where this pattern does not hold. Among the baseline systems, Google Translate, a commercial translation service, outperforms both

Type	Systems	Annotator				Average
		1	2	3	4	
Baselines	GPT-4⋆	95.84	73.38	76.71	87.52	83.36
	Llama-MT⋆	94.18	65.06	78.37	83.36	80.24
	Google⋆	85.02	42.60	59.23	21.13	52.00
Primary (con)	MAKE-NMT-VIZ	97.50	83.36	92.51	91.68	**91.26**
	MaxLab	86.69	61.73	71.71	74.21	73.59
	TJUNLP	88.02	55.07	20.97	69.22	58.32
Primary (uncon)	HW-TSC⋆	91.68	83.36	83.36	91.68	**87.52**
	DLUT⋆	95.01	69.22	84.19	90.02	84.61
	NTU⋆	85.02	39.27	28.45	62.56	53.83
	HITer-WMT⋆	57.57	21.80	0.00	31.78	27.79

Table 4: Analysis of human scores by different annotators on **one sampled document**. We report four annotators' scores and average score of Baselines, primary constrained and unconstrained (⋆) systems.

Annotator	1	2	3	4
1	-	-	-	-
2	0.858	-	-	-
3	0.824	0.878	-	-
4	0.752	0.875	0.676	-
Average	0.902	0.976	0.927	0.891

Table 5: Pearson correlation coefficient between scores by different annotators in Table 4.

commercial and open-source LLMs (GPT-4 API and Llama-MT) in terms of d-BLEU scores. Interestingly, both the top-1 ranked Primary constrained and the top-2 ranked unconstrained systems surpass the performance of the commercial MT system.

6.2 Human Evaluation

Table 3 presents the results of the human evaluation and system rank for the Primary submissions. We enlisted four human annotators to evaluate 5 documents, comprising a total of 2,194 words sourced from distinct books within the final testset for each translation system.

As seen, the MAKE-NMT-VIZ system outperforms the other three constrained systems, while DLUT⋆ ranks first among the four unconstrained systems. This is not fully consistent with the automatic evaluation results in Table 2. Moreover, the top-2 unconstrained systems outperform the best constrained system, highlighting the benefits of external knowledge. This observation is consistent with that of automatic evaluation.

Among the baseline systems, the LLM system performs the best, whereas the MT system shows the poorest performance, diverging from the observations of automatic evaluation. Interestingly, the literary MT-enhanced models perform comparable with some systems such as MaxLab and Google Translate.

6.3 Analysis

Inter-Annotator Agreement We engaged four annotators to independently review an identical document (i.e. 601 words) selected from the testset. Table 4 outlines the individual scores given by each annotator and the corresponding average scores. The findings illustrate that (1) while there is variance in the exact scores assigned by different annotators, their scoring trends align; (2) the results on this sample may diverge from those obtained from a larger dataset, highlighting the necessity of human evaluation on a larger scale.

In our effort to understand the consistency among the human evaluators, we conducted a Pearson correlation analysis on their scoring patterns. Table 5 illustrates the pairwise Pearson correlation coefficients for the scores given by each annotator. The results indicate a high degree of agreement among the annotators. For example, Annotator 2 demonstrated a very high correlation with Annotator 3 ($r = 0.878$) and Annotator 4 ($r = 0.875$). Besides, the Average Scores also reveal strong evaluator consensus on translation quality. This consistency underscores the reliability of the evaluators' judgments across the assessed translations.

Error Type We further analyze the error distribution in human-annotated results. Figure 4 classifies and counts the errors identified in the evaluated

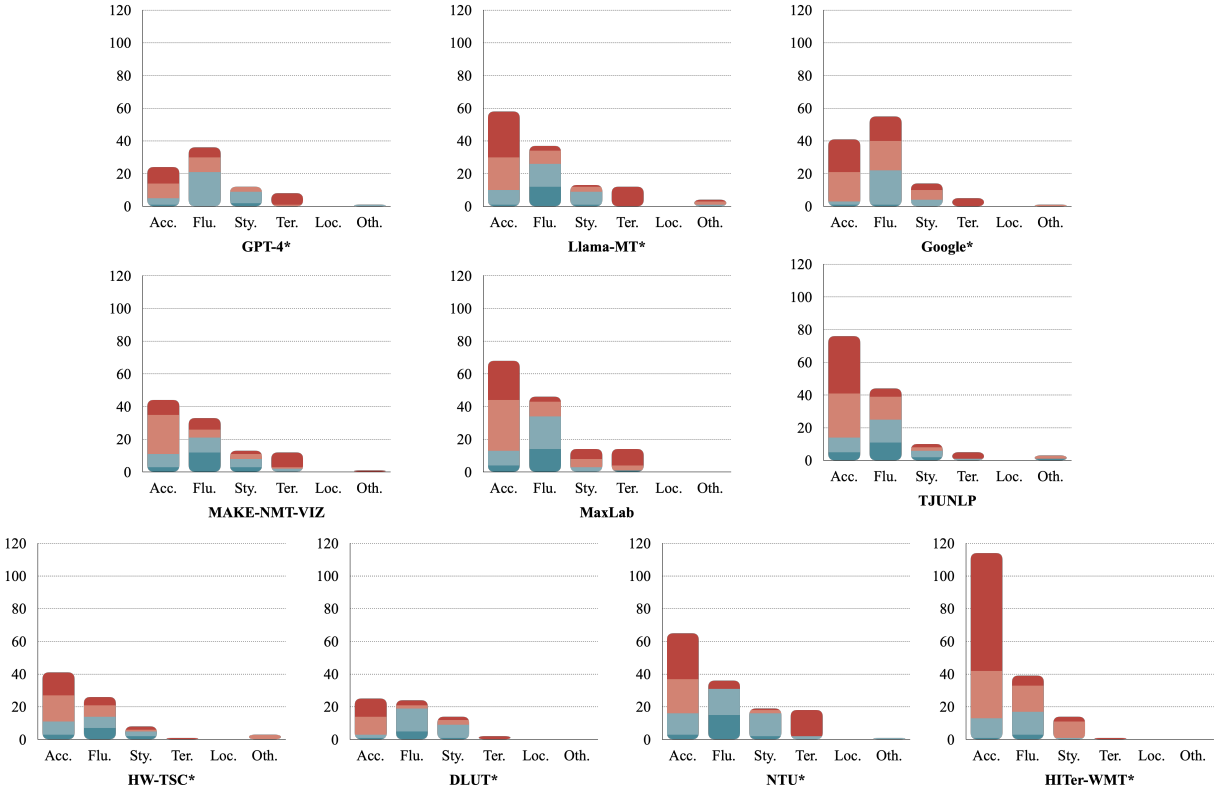

Figure 4: Analysis of error types in human annotations: Accuracy (Acc.), Fluency (Flu.), Style (Sty.), Terminology (Ter.), Localization (Loc.), and Other (Oth.). We report the count of error checkpoints in four evaluated documents. The four error severity levels are presented in different colors: Neutral (blue), Minor (light blue) , Major (light red), Critical (red). Systems marked with ⋆ are unconstrained, while others are constrained.

documents by their severity. This visualization allows for a direct comparison of the error profiles of each system, highlighting their strengths and weaknesses in different aspects of translation quality.

In the baseline systems analysis, GPT-4⋆ registers a higher frequency of Minor errors, particularly in Fluency and Style, indicating areas where refinement could enhance the translation's naturalness and adherence to stylistic norms. Llama-MT⋆, by contrast, has a pronounced incidence of Major and Critical errors in Accuracy and Terminology, raising concerns about the fidelity and technical precision of its translations. Google⋆ stands out with its Fluency errors, suggesting potential issues in maintaining a coherent and natural flow compared to the language models.

Regarding the constrained systems, MAKE-NMT-VIZ displays an even spread of errors, with relatively fewer instances in each category, which points to a well-rounded performance in capturing nuances across various aspects of translation. Both MaxLab and TJUNLP exhibit an increased number of Accuracy and Fluency errors, suggesting challenges in delivering translations that are not only faithful to the source material but also exhibit a seamless and natural flow in the target language.

The unconstrained systems, particularly HW-TSC⋆ and DLUT⋆, show a notable reduction in errors related to Accuracy and Fluency when compared to their constrained counterparts. This trend suggests that the lack of constraints may afford these systems more flexibility, resulting in translations that are more accurate and fluid. However, the overall error distribution across different systems highlights the complex trade-offs and challenges inherent in machine translation, underscoring the need for continued innovation and optimization in the field. In the future, we will also consider hallucination errors (Zhang et al., 2023).

7 Conclusion and Future Work

We believe that the WMT2023 Shared Task on discourse-level literary translation will be a valuable contribution to the field of machine translation and will encourage further research in this area. We discuss the potential limitations of this edition of the shared task as follows:

- *Language Pair*. This year, we only focus on Chinese→English direction. However, we have a long-term plan to continuously organize this task, and will extend the copyrighted dataset into Chinese-Russian and Chinese-German language pairs next year.
- *Literary Genre*. This year, we mainly used the Web Fiction Corpus which is only one type of literary text. We use Web Fiction for two reasons: (1) its literariness is less complicated than others (e.g. poetry, masterpiece); (2) such bilingual data are numerous and continuously increased. We will consider to extend more literary genres such as poetric translation in the next year.
- *Discourse Benchmark*. We have accumulated some discourse- and context-aware benchmarks (Xu et al., 2022, 2023; Wang et al., 2023a). These benchmarks are pivotal for assessing the proficiency of LLMs in handling complex language structures and contextual nuances. As participation of LLM-based systems in our shared tasks increases, we anticipate integrating these benchmarks more comprehensively into our future evaluations to better measure and understand the evolution of LLM capabilities in linguistic context and discourse comprehension.

Machine translation of web novels not only holds research value but also offers practical application prospects (Huang et al., 2021; Lyu et al., 2023). This shared task serves to spur competitive innovation and fosters the advancement of sophisticated machine translation systems capable of navigating the intricate nuances of literary works. Anticipating the future, our objective is to broaden the engagement in the forthcoming shared task, inviting an extensive range of collaborators from industry and academia alike to contribute their unique insights and expertise.

Acknowledgements

We would like to thank the WMT2023 organizers for providing us the opportunity to explore this new task. We also express our gratitude to the experts on the Shared Task Committee for their efforts in organization, evaluation, and advisory roles:

Type	Granular	Definition	Examples
Accuracy	Addition	The target text includes text not present in the raw.	A translation includes portions of another translation that were inadvertently pasted into the document or the translator has added too many details of his own.
	Omission	Content is missing from the translation that is present in the source.	A paragraph present in the source is missing in the translation.
	Mistranslation	The target content does not accurately match the raw.	A source text states that a medicine *should not be* administered in doses greater than 200 mg, but the translation states that it should be administered in doses greater than 200 mg (i.e., negation has been omitted).
	Misnomer	The target text is more/less specific than the raw.	1. The source text refers to a boy but is translated with a word that applies only to young boys rather than the more general term. 2. The source text uses words that refer to a specific type of military officer but the target text refers to military officers in general.
	Untranslated	Content that should have been translated has been left untranslated.	A sentence to be translated into English was left in Chinese.
Fluency	Punctuation	Punctuation marks missing or used in a wrong way.	An English text uses a semicolon where a comma should be used.
	Spelling	Issues related to spelling of words. (Including those of capitalization, hyphenated words, and use of asterisk for censored swear words.)	The English word "Translation" is spelled "Transaltion".
	Grammar	Issues related to the grammar or syntax of the text, other than spelling and orthography. (especially inconsistency of the tenses and conditionals)	An English text reads "The man was seeing the his wife."
	Inconsistency	The text shows internal inconsistency.	A text uses both "app." and "approx." for "approximately".
Style	Awkwardness	A text is written with an awkward style.	A text is written with many embedded clauses and an excessively wordy style. While the meaning can be understood, the text is very awkward and difficult to follow.
	Inconsistent	Style is inconsistent within a text.	One part of a text is written in a light and terse style while other sections are written in a more wordy style.
	Unidiomatic	The content is grammatical, but not idiomatic.	The following text appears in an English translation of "我们衷心感谢他": "We thanked him with heart" where "with heart" is an understandable, but non-idiomatic rendering, better stated as "heartily".
Terminology	Mistranslation	A genre-specific or cultural-specific terminology is wrongly translated.	A Chinese word "修士" is translated into "practitioner" rather than the expected "cultivator".
	Inconsistent	Terminology is used in an inconsistent manner within the text.	"斗罗大陆" is translated into "Douluo Land" in the first few chapters and then into "Soul Land".
Locale Convention	Location Format	Using the wrong format for address, name etc.	A Chinese address "北京市朝阳区花园路22号" is translated into "Beijing, Chaoyang district, Huayuan Road N.22" instead of the expected "N.22, Huayuan Road, Chaoyang District, Beijing".
	Number Format	The translated date, time, currency, telephone use formats inappropriate for its locale.	An English text has 2012-06-07 instead of the expected 06/07/2012.
Others		Other issues that haven't been included in this list.	E.g. signs of MT, mimetic word, gender bias, source errors etc.

Abstract

This paper presents the results of the Second WMT Shared Task on Sign Language Translation (WMT-SLT23)[1]. This shared task is concerned with automatic translation between signed and spoken[2] languages. The task is unusual in the sense that it requires processing visual information (such as video frames or human pose estimation) beyond the well-known paradigm of text-to-text machine translation (MT). The task offers four tracks involving the following languages: Swiss German Sign Language (DSGS), French Sign Language of Switzerland (LSF-CH), Italian Sign Language of Switzerland (LIS-CH), German, French and Italian. Four teams (including one working on a baseline submission) participated in this second edition of the task, all submitting to the DSGS-to-German track. Besides a system ranking and system papers describing state-of-the-art techniques, this shared task makes the following scientific contributions: novel corpora and reproducible baseline systems. Finally, the task also resulted in publicly available sets of system outputs and more human evaluation scores for sign language translation.

1 Introduction

This paper presents the outcome of the Second WMT Shared Task on Sign Language Translation (WMT-SLT23). This shared task focuses on automatic translation between signed and spoken languages. Our main goal is working towards including signed languages in NLP research (Yin et al., 2021).

Sign language translation requires processing visual information (such as video frames or human pose estimation) beyond the well-known paradigm of text-to-text machine translation (MT). As a consequence, viable solutions need to consider a combination of Natural Language Processing (NLP), computer vision (CV), computer graphics and animation techniques.

We build on and extend the work done for the first shared task on sign language translation (WMT-SLT22; Müller et al., 2022). Compared to the first edition, we

- extended our competition to more languages (three language pairs instead of one),
- provided much more training data for Swiss German Sign language compared to last year (437 hours instead of 16),
- emphasized sign languages as the target language instead of the source, for instance, by offering official baseline systems for spoken-to-signed translation (not offered last year).

In this second edition of the shared task, we considered the following languages: Swiss German Sign Language (DSGS), French Sign Language of Switzerland (LSF-CH), Italian Sign Language

[1] https://www.wmt-slt.com/

[2] In this paper we use the word "spoken" to refer to any language that is not signed, no matter whether it is represented as text or audio, and no matter whether the discourse is formal (e.g. writing) or informal (e.g. dialogue).

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 68–94
December 6–7, 2023.

of Switzerland (LIS-CH), German, French, and Italian. We offered four tracks: DSGS-to-German translation, German-to-DSGS translation, French-to-LSF translation, and Italian-to-LIS translation.

Four teams participated in the task, which we consider a success. All teams submitted to the DSGS-to-German track, while there were no submissions to any of the tracks where a sign language is the target language.

The remainder of this paper is organized as follows:

- We give some background on sign languages and sign language processing in §2.
- We describe the shared task tracks and submission procedure in §3.
- We report on the corpora we built and distributed specifically for this task in §4 and §5.
- We describe all submitted systems, including our baselines in §6.
- We ran both an automatic and a human evaluation. We explain our evaluation in §7.
- We share the main outcomes in §8 and discuss in §9.

2 Background

In recent years, Sign Language Processing (SLP) has emerged as a sub-area of Natural Language Processing (NLP). Within this field, automatic sign language translation (SLT; or sign language machine translation, SLMT) represents a more specialized discipline, aiming to develop technology that facilitates translation between sign languages and spoken or written languages, but also between sign and sign languages. However, the challenges related to SLP and SLT differ from those of NLP and MT for spoken languages in both range and complexity. Due to the different modality, lack of structured, high-quality, high-quantity data, and the lack of NLP tools, joint efforts from the fields of sign linguistics and computational linguistics, computer science, machine learning, computer vision, 3D animation and others are needed in order to advance this field.

In this section we give an introduction to sign languages (§2.1) and describe the societal and academic relevance of SLP (§2.2). Then we give an overview of SLP in general (§2.3) and of SLT in particular (§2.4) For a general motivation for a shared task involving sign languages see Müller et al. (2022).

2.1 Sign languages

Sign languages are natural languages with their own grammatical structures and lexicons, primarily used by the deaf and hard-of-hearing communities. Contrary to the popular belief that sign language is universal, hundreds of different SLs have been documented so far.

Nature of sign languages Sign languages are visuo-gestural languages. A signer conveys an utterance using their body: through the expression of manual features (hand configuration, location, and orientation) and non-manual features (including facial expressions, mouthing and mouth gestures, gaze and torso direction). The linguistic system of SLs makes use of these specific channels. Information is expressed simultaneously (as opposed to the sequential nature of spoken language), organized in three-dimensional space, and iconicity plays a central role (Woll, 2013; Perniss et al., 2015; Slonimska et al., 2021).

Writing systems To date, SLs have no universally accepted written form or graphical system for transcription (Pizzuto and Pietrandrea, 2001; Filhol, 2020). Several notation systems, such as HamNoSys (Hanke, 2004) or SignWriting (Sutton, 1990; Bianchini and Borgia, 2012), are used in research or teaching but are rarely adopted as a writing system in everyday life, limiting the standardisation of data collection and processing. In SL research, a common practice is therefore to use glosses – text-based, semantic labels for signs, typically borrowed from the corresponding regional spoken language.

A common misconception among MT researchers is that transcribed glosses are a full-fledged writing system for sign languages. In reality, glossing can only be seen a linguistic tool, useful for annotating corpora for linguistic studies (Johnston, 2010). Glosses do not adequately represent the meaning of an SL utterance and, more importantly, "deaf people do not read or write glosses" in everyday life (Müller et al., 2023).

2.2 Relevance of sign language processing

SLP is a research area with high potential societal and academic impact.

Societal impact The overall aim of SLP is to provide language technology for sign languages, which currently are somewhat overlooked, since the vast majority of NLP systems are designed only for spoken languages. This means that more research in SLP could result in more equal access to language technology.

The more specific goal of SLT is to facilitate communication between the deaf and hard-of-hearing communities on the one side and the hearing community on the other side. There is a need for this because speakers of spoken languages and signers of sign languages experience communication difficulties (the same kind of difficulties encountered by speakers of different spoken languages). We emphasize that these technologies should be developed in such a way, so that deaf/hard-of-hearing and hearing people can benefit from them in an equal measure.[3]

Besides aiding direct communication, SLT would improve accessibility to spoken language content, given that spoken languages are often a second language for deaf people, where they exhibit varying proficiency. The reverse direction is also crucial, for example to automatically subtitle signed content to make it accessible to people who do not know sign languages (Bragg et al., 2019).

Academic relevance In the field of NLP, working on sign languages is highly innovative and timely. Recently, a call for more inclusion of signed languages in NLP (Yin et al., 2021) was widely publicized, and an ACL initiative for Diversity and Inclusion[4] targets SL processing as well.

And even though sign languages are still a niche topic in the general field of NLP (the vast majority of NLP systems are designed for spoken languages, not for signed languages), the advancement and spread of SLP tools, calls, initiatives and events lead to knowledge transfer not only within the academic spheres, or between researchers, developers and users, but also, more importantly, between deaf, hard-of-hearing and hearing individuals involved in the process.

[3]We distance ourselves from the audistic view that only deaf people are in need (of access to spoken language discourse). Language barriers are inherently two-way, and addressing them involves both parties.

[4]https://www.2022.aclweb.org/dispecialinitiative

2.3 Sign language processing

Sign language processing is an interdisciplinary field, bringing together research on NLP and computer vision, among other disciplines (Bragg et al., 2019). For a general overview in the context of NLP see Yin et al. (2021); Moryossef and Goldberg (2021).

Tasks SLP involves a variety of (sub)tasks with individual challenges. Widely known tasks are sign language recognition, sign language translation, and sign language production (or *synthesis*). Sign language recognition usually refers to identifying individual signs from videos; see Koller (2020) for an overview. Sign language translation refers to the task of transforming sign language data to a second language, no matter whether signed or spoken; see De Coster et al. (2022) for a comprehensive survey. Finally, sign language production refers to rendering sign language as a video, using methods such as avatar animation (Wolfe et al., 2022) or video generation.

SLP research is challenging for a number of different reasons. The ones we chose to highlight here are linguistic properties, availability of data, and availability of basic NLP tools.

Linguistic challenges SLP is challenging because the characteristics of sign languages (§2.1) cannot be fully handled with existing methods, for instance, the multilinearity, the use of the signing space, and the iconicity. As explained earlier, SLP needs to take into account manual and non-manual cues in order to capture a complete linguistic picture of an SL utterance (Crasborn, 2006). Information is spatio-temporal in nature and the data is simultaneously conveyed by a number of articulators. Signing makes frequent use of indexing strategies for example to identify referents introduced earlier in the discourse or timelines (Engberg-Pedersen, 1993). In other words, a sign language utterance is not a simple sequence of lexical units.

Sign languages have an established vocabulary but are also lexically productive to allow for the definition of new signs or constructions to be used to depict entities or situations (Johnston, 2011).

Availability of data Given the current research landscape in NLP, sign languages are under-resourced. An analysis by Joshi et al. (2020) places all sign languages considered in this study in the category "left behind" (together with many spoken

languages). Existing resources are small and heterogeneous. They are created under a variety of circumstances and vary in quality (e.g. video resolution), signer demographics (e.g. deaf vs. hearing signers), richness of annotation (e.g. glosses, sentence segmentation, translation to a spoken language), and linguistic domain (e.g. only weather reports, hence a very limited domain).

Also, not all corpora are easily accessible online and some have restrictive licenses that disallow NLP research. A survey of SL corpora available in Europe can be found in Kopf et al. (2021). For an account of further challenges relating to data see De Sisto et al. (2022).

Lack of basic linguistic tools SLP currently lacks fundamental NLP tools that are readily available for spoken languages. Such tools include automatic language identification (Monteiro et al., 2016), sign segmentation (De Sisto et al., 2021), sentence segmentation (Ormel and Crasborn, 2012; Bull et al., 2020b) and sentence alignment (Varol et al., 2021). Although there are experimental solutions, they are not yet viable in practice.

Tools like these would be crucial to create better corpora by constructing them automatically, as is routinely done for spoken languages (Bañón et al., 2020), and develop better high-level NLP solutions.

2.4 Sign language translation

In recent years, different methods to tackle SLT have been proposed, most of them suggesting a cascaded system where a signed video is first converted to an intermediate representation and then to spoken text (similarly for text-to-video translation). Intermediate representations (with individual strengths and weaknesses) include pose estimation (§5.3), glosses or writing systems such as HamNoSys (§2.1, writing systems).

There is existing work on gloss-to-text translation (e.g. Camgöz et al. 2018; Yin and Read 2020) and vice versa (e.g. Stoll et al., 2020), pose-to-text translation and vice versa (e.g. Ko et al. 2019; Saunders et al. 2020a,b,c; Inan et al. 2022; Viegas et al. 2023) and systems involving HamNoSys (e.g. Morrissey 2011; Walsh et al. 2022), or AZee expressions, designed to be used as input to avatar synthesis systems (Bertin-Lemée et al., 2023). Recently, direct video-to-text translation was also proposed by Camgöz et al. (2020a,b). For rendering sign language output, avatars are commonly used (Wolfe et al., 2022), as well as methods to generate videos of realistic signers (e.g. Saunders et al. 2022).

Parallel datasets In terms of datasets, past work in SLT can be characterized as focusing very much on a narrow linguistic domain, most of the work was done on one single data set called `RWTH-PHOENIX Weather 2014T` (Forster et al., 2014). PHOENIX has a size of 8k sentence pairs and contains only weather reports. The biggest parallel corpus for a European sign language to date, the Public DGS Corpus (Hanke et al., 2020), contains roughly 70k sentence pairs.

Thus, there is a clear shortage of usable parallel corpora, and existing ones are orders of magnitude smaller than what is considered an acceptable size for spoken language MT (as a rule of thumb, at least hundreds of thousands of sentence pairs). Nevertheless, there are plenty of spoken languages that also have little parallel data and MT methods have been developed specifically for low-resource MT (Sennrich and Zhang, 2019).

Evaluation For spoken language MT a variety of automatic metrics exist. These include more conventional, string-based metrics such as BLEU (Papineni et al., 2002) or chrF (Popović, 2015), as well as recent, learned metrics based on embeddings like COMET (Rei et al., 2020). In the context of SLT, no automatic metrics are validated empirically, but if the target language is spoken, many existing metrics are reasonable to use. However, if sign language is the target language, no automatic metric is known at the time of writing, and the only viable evaluation method is human evaluation. Apart from last year's shared task, a human evaluation of SLT systems has never been conducted on a large scale before, and there are open questions regarding the exact evaluation methodology and what the ideal profile (e.g. hearing status, language proficiency) for evaluators should be.

3 Tracks and submission procedure

We offered four translation directions ("tracks"): translation from DSGS to German and vice versa, French to LSF-CH, and Italian to LIS-CH.

For DSGS to German, submitted systems were ranked on a leaderboard. For all other directions, no automatic ranking was shown since automatic metrics of translation quality do not exist for sign languages as the target language.

We provided baseline systems for both translation scenarios (translating from or to a sign language). We were prepared to provide human evaluation for all submitted systems, regardless of the translation direction or language pair.

We deliberately did not limit the shared task to any particular kind of SL representation as input or output of an MT system. For DSGS-to-German translation, participants were free to use video frames, pose estimation, or something else. For German-to-DSGS participants were free to submit a video showing pose estimation output, an avatar, or a photo-realistic signer.

Participants had to submit their translation outputs on the OCELoT platform[5] which displayed an unofficial public leaderboard based on automatic metrics. Participants were allowed to make up to seven submissions and were asked to mark one of them as their primary submission.

Main outcome Four teams (including one from Northeastern University whose submission we consider a baseline) participated in our task. All of them submitted to the DSGS-to-German track, while there were no submissions for other translation directions.

4 Data

For this task we provided separate training, development and test data. While the training data was available from the beginning, the test data has been released in two stages, starting with a release of the test sources only.

Table 1 gives a high-level overview of our training, development and test data.

4.1 Licensing and attribution

Both datasets (SRF23 and Signsuisse) can be used for non-commercial research. Please note that distributing the datasets or making them accessible to third parties is not permitted, either in their original or edited form. In addition, this overview paper should be cited if the corpora are used.

4.2 Training Data

The training data comprises two corpora called Signsuisse (Jiang et al., 2023a) and SRF23 (Jiang et al., 2023b). Signsuisse is a multilingual dictionary containing lexical items in DSGS, LSF-CH and LIS-CH, represented as videos and glosses. Additionally, Signsuisse contains sentence-level parallel data as well, since there is one example sentence to show the use of the sign in context for each lexical item. SRF23 contains parallel data between DSGS and German, and its linguistic domain is general news. Both datasets are distributed through SwissUbase[6], where individual researchers had to agree with the usage terms and apply for access before downloading.

Training corpus 1: Signsuisse Lexicon We collected $18,221$ lexical items from the Signsuisse website, $17,221$ of which are released as training data and $1,000$ are reserved for testing and therefore not included in the training data release. The lexicon contains three languages: (i) DSGS (9044 items, 500 reserved), (ii) LSF-CH (6423 items, 250 reserved), and (iii) LIS-CH (2754 items, 250 reserved).

The lexical items are represented as videos and glosses, which enable sign-by-sign translation from spoken to signed languages. The videos were recorded with different framerates, either 24, 25, or 30 fps, and the video resolution is 640 x 480.

Training corpus 2: SRF23 These are daily national news and weather forecast episodes broadcast by the Swiss National TV (Schweizerisches Radio und Fernsehen, SRF)[7]. The episodes are narrated in Standard German of Switzerland (different from Standard German of Germany, and different from Swiss German dialects) and interpreted into Swiss German Sign Language (DSGS). The interpreters are hearing individuals, some of them children of Deaf adults (CODAs).

The subtitles are partly preproduced, and partly created live via respeaking to automatic speech recognition. While both the subtitles and the signing are based on the original speech (audio), due to the live subtitling and live interpreting scenario, a temporal offset between audio and subtitles as well as audio and signing is inevitable (Müller et al., 2022). It should also be pointed out that there are differences between interpreted and non-interpreted language (Dayter, 2019) due to source language interference and time constraints. SL during real-time interpretation tends to closely follow the grammatical structure of the spoken language (Leeson, 2005).

[7] https://www.srf.ch

		SRF23		Signsuisse		Total	
	direction	**episodes**	**segments**	**segments**	**lexical items**	**segments**	**lexical items**
training	DSGS↔DE	771	231834	9044	9044	240878	9044
	FR→LSF-CH	-	-	6423	6423	6423	6423
	IT→LIS-CH	-	-	2754	2754	2754	2754
development	DSGS↔DE	3	712	-	-	712	-
test	DSGS→DE	1	246	250	250	496	250
	DE→DSGS	1	258	250	250	508	250
	FR→LSF-CH	-	-	250	250	250	250
	IT→LIS-CH	-	-	250	250	250	250

Table 1: Overview of training, development and test data. SRF23 and Signsuisse are two different training corpora (§4.2). Segment count for the training corpora is after automatic sentence segmentation. The training data and development data for DSGS→DE and DE→DSGS are identical, while the test data is different. There was no designated development data for LSF-CH and LIS-CH.

Different from the first edition of the shared task (WMT-SLT22), the offset between the signing and the subtitles was not manually corrected for the training data of the current edition. On the other hand, the size of the training data is much larger than last year, presenting a different trade-off. See Table 2 for a comparison between this year's and last year's SRF resources. While last year our focus was providing training data of the highest quality, this year our focus was offering a large, noisy dataset that lends itself to data cleaning or filtering experiments such as automatic alignment.

Additional resources We encouraged participants to consider the MEDIAPI-SKEL corpus with parallel examples between French Sign Language and French (Bull et al., 2020a) as a further resource. Besides, we suggested that participants re-use the training corpora released for last year's shared task (Müller et al., 2022).

4.3 Development data

We did not provide any dedicated development data for this edition of the shared task. As is customary for WMT shared tasks, we encouraged participants to use last year's development and test data as development data for the current year.

4.4 Test data

We distribute separate test data for our four translation directions. See Table 1 for an overview.

DSGS→DE The test data consists of segments taken from undisclosed SRF23 and Signsuisse material (see §4.2 for a general description). The final test set is balanced, containing roughly 50% Signsuisse and 50% SRF23 examples. For the SRF23 part one episode was manually aligned using the iLex editor (Hanke and Storz, 2008), and the signer is a "known" person that appeared in the training set. We did not intend to test generalization to unknown signers during the shared task evaluation campaign. For the Signsuisse part we do not use the isolated lexical entries themselves for testing, but the example sentences associated with each lexical item.

DE→DSGS Same procedure as DSGS→DE, except that a different SRF23 episode and different sentences from Signsuisse are reserved for this translation direction.

FR→LSF-CH 250 undisclosed sentences from Signsuisse.

IT→LIS-CH 250 undisclosed sentences from Signsuisse.

5 Data preprocessing

For each data set described in §4 we provided videos and corresponding text in a spoken language. In addition, we included pose estimates (location of body keypoints in each frame) as a convenience.

5.1 Video processing (only SRF23)

Videos are re-encoded with lossless H264 and use an mp4 container. The framerate of videos is unchanged, meaning either 25, 30 or 50. We are not distributing the original videos but ones that are preprocessed in a particular way so that they only show the part of each frame where the signer is located (cropping) and the background is replaced with a monochrome color (signer masking), see Figure 1 for examples.

	SRF22	SRF23
Number of episodes	29	771
Time span of episodes	March 2020 to March 2021	July 2014 to May 2021
Total duration videos	16 hours	437 hours
Total number of subtitles (before/after sentence segmentation)	14265 / 7071	354901 / 231834
Number of signers	3	4
Subtitle segmentation	manual	automatic
Subtitle alignment	manual	audio

Table 2: Comparison between SRF training data of the 2022 and 2023 edition of the WMT-SLT shared task. Subtitle segmentation=ensuring that each subtitle unit is one entire sentence. Subtitle alignment=Subtitle times are either manually corrected to match the signing in the video (manual) or are matched with the audio track (audio).

Figure 1: Illustration of video preprocessing steps (cropping, instance segmentation and masking). From left to right: original frame, cropped frame, masked frame. Taken from Müller et al. (2022).

Cropping We manually annotate a rectangle (bounding box) around where the signer is located for each video. We then crop the video to only keep this region using the FFMPEG library.

Signer segmentation and masking To the cropped video we apply an instance segmentation model, Solo V2 (Wang et al., 2020), to separate the background from the signer. This produces a mask that can be superimposed on the cropped video to replace each background pixel in a frame with a grey color (`[127,127,127]` in RGB).

The video processing steps described above are only necessary for the SRF23 data, since Signsuisse footage is recorded against a neutral background and showing only one signer in the center of each frame.

5.2 Subtitle processing (only SRF23)

Since SRF23 subtitles are not manually aligned, automatic sentence segmentation[8] is used to redistribute text across subtitle segments, see Table 3 for examples. This process also adjusts timecodes in a heuristic manner if needed. For instance, if automatic sentence segmentation detects that a well-formed sentence stops in the middle of a subtitle, a new end time will be computed. The end time is proportional to the location of the last character of the sentence, relative to the entire length of the subtitle. See Example 2 in Table 3 for an illustration of this case.

5.3 Pose processing (both corpora)

"Poses" are an estimate of the location of body keypoints in video frames. The exact set of keypoints depends on the pose estimation system, well-known ones are OpenPose (Cao et al., 2019)[9] and MediaPipe Holistic (Lugaresi et al., 2019)[10]. Usually such a system provides 2D or 3D coordinates of keypoints in each frame, plus a confidence value for each keypoint.

The input for pose processing are cropped and masked videos (§5.1). See Figure 2 for examples of pose estimation on our data.

OpenPose We use the Openpose 137 model (which is the default) for the Signsuisse data and the Openpose 135 model for the SRF data. The two models are both widely used and the 137 model has two additional keypoints because it represents

Es geht um die Umsetzung	4 00:00:24,708 -> 00:00:31,720 Die Invalidenversicherung Region Bern startete dieses Pilotprojekt und will herausfinden, ob man es zukünftig umsetzen kann.

Table 3: Examples of automatic sentence segmentation for German subtitles. The subtitles are formatted as SRT, a common subtitle format. Taken from Müller et al. (2022).

Figure 2: Examples of the output of pose estimation systems overlaid over the original video frames. Left: OpenPose, right: MediaPipe Holistic. Taken from Müller et al. (2022).

the wrists twice. OpenPose often detects several people in our videos, even though there is only one single person present. We distribute the original predictions which contain all people that OpenPose detected.

MediaPipe Holistic As an alternative, we also estimate signers' poses with the MediaPipe Holistic system developed by Google. Unlike our OpenPose model, which only provides 2D joint locations, MediaPipe produces both 2D and 3D joint location coordinates. For the SRF data, values from Holistic are normalized between 0 and 1, instead of referring to actual video coordinates.

Unlike the first edition of the task, where the keypoints were stored in a JSON format, to deliver the pose data for more compact storage and faster I/O, in WMT-SLT 23 the binary .pose format of Moryossef and Müller (2021) was used.

6 Baselines and submitted systems

In this section we describe the submissions to our shared task. In case there are substantial differences between the primary and secondary submissions of a team we opted to describe the primary submission here. At the time of writing this overview paper three out of four teams have given us detailed information about their submissions. The submissions are summarized in Table 4.

Overall, the participating teams have diverse academic backgrounds, but their expertise is leaning towards NLP more than computer vision. All submitted systems are sequence-to-sequence models based on Transformers (Vaswani et al., 2017). Participants mostly chose to represent sign language data as video frames (using a visual feature extractor on the encoder side). Only the baseline system opted for Mediapipe pose features instead.

Two systems, by KNOWCOMP and TTIC, are unconstrained because their visual or spoken text components are pretrained on other datasets. Their approaches are best summarized as a combination of visual embeddings and pre-trained language models. TTIC used additional monolingual video data from OpenASL for pretraining, and no submission used monolingual text in a spoken language.

Two teams have published their code, with another team planning to do so in the future.

6.1 Baseline by Northeastern University (DSGS→DE)

Based on the models of the previous challenge, we pre-train the baseline signed-to-spoken system using a Transformer architecture. We use the fairseq seq2seq translation library (Ott et al., 2019), and the open-source implementation of the architecture by Tarrés et al. (2023). We first train a Sentencepiece tokenization model on the German text of the example sentences of the Signsuisse dataset. Then, we train the model on the Mediapipe Holistic poses on the Signsuisse example sentences. We, then, validate and test the model on the extracted Mediapipe Holistic poses of both the Signsuisse and SRF DSGS-to-German datasets. The final output is detokenized to result in spoken German text.

6.2 Baseline by UZH (DE→DSGS, FR→LSF-CH, IT→LIS-CH)

As a naive solution, we choose a sign-by-sign translation baseline (Moryossef et al., 2023). The system gets German text as input, performs text-to-gloss translation, then for each gloss looks up a sign in the Signsuisse lexicon. The estimated poses from each sign are then concatenated and smoothed out, to create a single pose video with the translation into a sign language.

Since there were no submissions by participants to these tracks, this baseline was not used for any subsequent evaluation.

6.3 Submission by KNOWCOMP (Xu et al., 2023)

The team proposed a framework which combines a pre-trained visual model to extract visual embeddings with a GPT2-based language model to translate into text.

The framework first utilises an I3D model (Varol et al., 2022) pre-trained on the BSL-1K corpus (Albanie et al., 2020) to extract 1024-dimensional tensors for a 64-frame video input. The video extractor, i.e. the I3D model, generates a 1024-dimensional tensors as the visual representation of the input video (64 frames). For decoding, a German-GPT2 (Radford et al., 2019) large language model (LLM) is used to generate the final translations. To establish an alignment between the visual and the textual embeddings from the two models, the team trains an embedding alignment block to project the obtained visual embeddings into textual embeddings.

This is implemented by stacking 6 Transformer encoder layers together. Two fully connected neural networks are placed before and after the alignment block to extend the visual embeddings into a sequential format and to densify the aligned embeddings into prefix embeddings for German-GPT2, respectively.

Before training their model KnowComp first employs a data preprocessing step where the raw data is divided into smaller video segments which are then matched with the corresponding ground truth German translations. To ensure that the input observes the visual model requirements, i.e. input of 64 frames, they downsample the video segments taking the first of each three frames. In cases where the video segment is smaller than 64 frames, pure black frames are appended. Next, the video frames are resized to 224 x 224.

At training time, to enhance training efficiency, the parameters of the visual and the translation models are first frozen; later, at a certain iteration, the parameters of GPT2 are unfrozen. This strategy ensures that the randomly initialized Transformer encoder does not compromise the LLM. The hyperparameters they used are: batch size of 4, learning optimizer Adam (Kingma and Ba, 2015) with a learning rate of $5e-6$, and unfreezing the training parameters at iteration 66000. The input and output lengths of GPT2 were set to 20. The number of heads in the multi-head attention was set to 8; the prefix length for GPT2 to 4. Before the visual embeddings were fed to the alignment block, the sequence length was adjusted to 2×4, where 4 is the GPT2's prefix number. They ran their experiments on an NVIDIA GeForce GTX 1080 Ti with 11G VRAM.

6.4 Submission by TTIC (Sandoval-Castaneda et al., 2023)

The system by the TTIC team uses as visual backbone the VideoSwin Transformer (Liu et al., 2022) and the T5 model by Raffel et al. (2020) for translation into text. The VideoSwin model was pretrained on the visual (video) side of OpenASL (Shi et al., 2022, thus excluding the English translations) using the codebook from a discrete variational auto-encoder (dVAE, Ramesh et al., 2021) to produce the labels in the self-supervision objective. Next, the model was fine-tuned for the task of isolated sign language recognition on the gloss-based version (Dafnis et al., 2022) of the WLASL2000 dataset (Li et al., 2020).

The input data was segmented into non-overlapping, padded chunks of 16 frames in order to meet the input requirements of VideoSwin. The outputs were concatenated together.

Following the findings of Uthus et al. (2023) that English pre-trained T5 and fine-tuned for ASL to English translation produces state-of-the-art results, the TTIC team used a T5 model pre-trained on the German Colossal Cleaned Common Crawl (GC4) corpus.[11] They used pre-trained checkpoints from HuggingFace (Wolf et al., 2019). To tokenize the target side, SentencePiece (Kudo and Richardson, 2018) trained on the same data was used to produce a vocabulary of 32,128 tokens.

Their system employs a convolutional layer that is trained to project the sequence of visual features into a single vector per time step. The T5 embeddings layer is replaced by this convolutional layer. The cross-entropy loss was used for the BEVT pre-

[11] https://german-nlp-group.github.io/projects/gc4-corpus.html

training, the ISLR fine-tuning, the text-to-text pre-training as well as for the translation. At inference time, the diverse beam search algorithm (Vijayakumar et al., 2016) with 5 beams, 5 beam groups and a diversity penalty of 1 was used. In contrast to KNOWCOMP, the TTIC team used 8 GPUs to train their system.

6.5 Submission by CASIA

Finally, we received several submissions from the National Laboratory of Pattern Recognition at the Institute of Automation, Chinese Academy of Sciences (submission ID: CASIA). No system paper was submitted and the authors did not provide further information.

7 Evaluation Protocols

We performed both a human (§7.1) and an automatic (§7.2) evaluation of translation quality. Our final system ranking is based on the human evaluation only.

7.1 Human evaluation

Our human evaluation follows the setting we established last year for SLT human evaluation with custom guidelines (Müller et al., 2022), which was originally adapted from the evaluation protocol used at the recent WMT conferences (Kocmi et al., 2022).

Scoring method We employed the source-based direct assessment (DA; Graham et al., 2013; Cettolo et al., 2017) methodology with document context, extended with Scalar Quality Metric (SQM; Freitag et al., 2021). Assessments were performed on a continuous scale between 0 and 100 as in traditional DA but with 0-6 markings on the analogue slider and custom annotator guidelines specifically designed for our task.

As a result of the human evaluation, the systems are ranked from best to worst, after averaging the segment-level DA scores given by the human annotators. In contrast to previous evaluation campaigns (Akhbardeh et al., 2021) which calculate the rankings based on standardized scores (z-scores), we decided to not do so, because the large number of zero-scored items led to a rather skewed standardization scale which affected the calculation of the clusters. We did not make any distinction between segment-level and document-level scores, simply including the latter as additional data for computing the average scores.

After ranking the systems based on their average scores, they are grouped into significance clusters, following the Wilcoxon rank-sum test. Rank ranges give an indication of the translation quality of a system within a cluster and are based on the same head-to-head statistical significance tests.

Inter- and intra-annotator agreement was measured with Fleiss κ (Fleiss, 1971). This should be considered an approximation, noting the concerns of Ma et al. (2017) that kappa coefficients are not suitable for continuous scales. In order to calculate the coefficient, the values have been discretized in seven bins in the scale 0-6, since those were the scores marked on the continuous evaluation bar that was given to the annotators.

Settings of evaluation campaign We used the Appraise evaluation framework[12] (Federmann, 2018) for collecting segment-level judgments. As there were submissions in the DSGS-to-German direction only (§6), we only set up a sign-to-text human evaluation campaign. Annotators were presented with video fragments as source context and translation outputs of a random document fragment from an MT system. The reference translation and the official baseline were included as additional system outputs. Document fragments were created from (up to) twelve consecutive segments. The SRF23 part of the test set was evaluated within the document context. Because the Signsuisse part is a collection of utterances without document boundaries, we presented up to twelve random segments at once but emphasized in the guidelines that those are unrelated and should be assessed independently.

A screenshot of an example annotation in Appraise is presented in Figure 3. The full instructions to evaluators in English and German are listed in Appendix B.

Data and scripts used for generating tasks and computing the final system rankings are publicly available in a Github repository.[13]

We hired three evaluators who are native German speakers and trained DSGS interpreters. All of them had prior experience with evaluation of MT output. Each evaluator was assigned an identical set of annotation tasks comprising the entire test set and all participating systems, including the baseline system and the reference translation. As last year, we did not include any quality control items in the annotation tasks as we had multiple independent

annotations of the entire test set and because of the very low quality of translations, which would make them indistinguishable from segments with randomly replaced words or phrases used as quality control items.

Feedback from evaluators After completing the evaluation all three evaluators filled out the feedback form we used last year regarding the evaluation procedure and the Appraise platform, where they gave us additional informal feedback.

7.2 Automatic evaluation

As in the previous edition, to complement our human evaluation (which provides the main ranking) we also provide an automatic evaluation. We evaluate the submissions from DSGS into German using three automatic metrics: BLEU (Papineni et al., 2002), chrF (Popović, 2015) and BLEURT (Sellam et al., 2020). We note that learned, semantic metrics correlate better with human judgement (Kocmi et al., 2021), but if they consider the source text as an input (e.g. COMET; Rei et al., 2020), they cannot be used in our context because our source is video and not text. There is no known learned metric which supports sign language videos. We use sacreBLEU (Post, 2018) for BLEU[14] and chrF[15] and the Python library for BLEURT.[16] In all cases, we estimate 95% confidence intervals via bootstrap resampling (Koehn, 2004) with 1000 samples.

8 Results

8.1 Human evaluation

Assessment scores All three evaluators completed all tasks, which gave us three independent judgements for each segment from the official test set. In total, for the output of five systems, we collected 7,800 segment-level and 792 document-level assessment scores, which averages to 1,718 scores per system.

System ranking The official system ranking is presented in Table 5. The significance clusters are indicated with horizontal lines. According to our human evaluation (Table 5), the submission by TTIC has achieved an average score of 0.7 on the scale of 0 to 100, compared to a score of 83.8 for human translations. The score of TTIC is significantly better than the other systems in the table. All other systems ended up in the same cluster with overall lower translation quality.

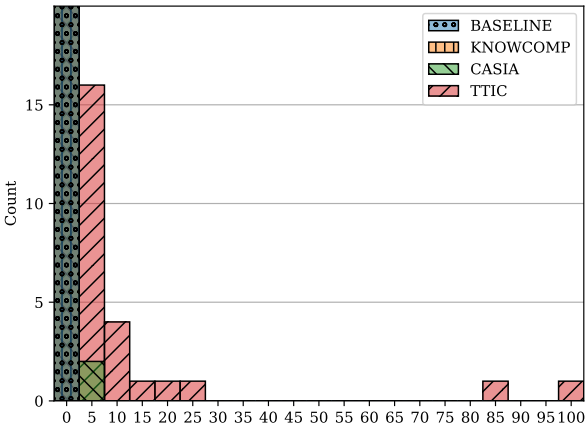

Figure 4: Histogram with the distribution of the system outputs at the DA score scale (x axis) with overlapping semi-transparent bars, discretized into 20 bins. For every segment we include only the average of all ratings. Bin 0, where most ratings belong (up to 496), is cropped to 20 to make the histogram visible.

Distribution of scores In order to make the distribution of DA scores more interpretable, it is visualized in Figure 4. TTIC had one segment with a score of 99 out of 100, one with 83, one for each of the scores 22, 18 and 15, then 4 segments with a score of about 10, and 16 segments with a score of about 5. CASIA had two segments with a score of about 5. The rest of the segments, including all the outputs from the KNOWCOMP and BASELINE systems, have been given a score very close to 0.

Some example outputs of the highest-scoring translations are listed in Table 6. One can see that TTIC came close to correctly translating the general introductory greetings of the news, but for the rest of the MT ouputs, rated less than 20 out of 100, only a few words match the reference.

Annotator agreement In Table 7 we are reporting intra-annotator agreement for every annotator, measured with Fleiss κ (Fleiss, 1971) over 134 segments which were evaluated twice. (Landis and Koch, 1977; Agresti, 1996). The inter-annotator agreement is $\kappa = 0.80 \pm 0.01$. One can observe that the intra-annotator agreement and all 3 intra-annotator agreements are substantial ($0.61 < \kappa \leq 0.80$) based on Landis and Koch, 1977).

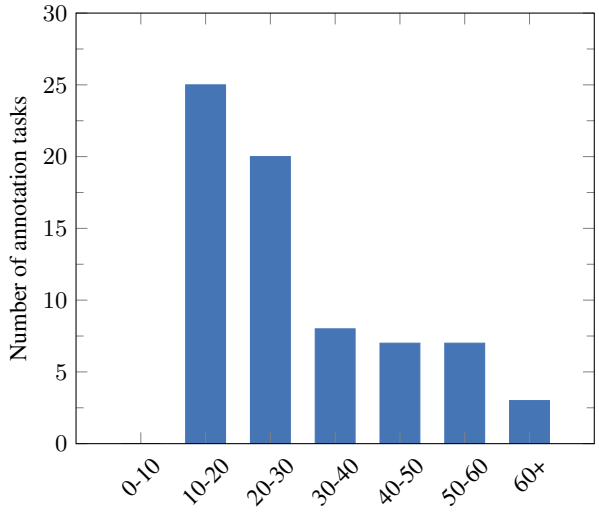

Figure 5: Number of task completion times (a task consists of 100 segments) grouped into 10-minute buckets, after removing top and bottom 5-percentiles.

Evaluation speed A single task requiring providing 100 segment-level and about 12 document-level scores took on average 29 minutes to complete, after excluding 5% of slowest and fastest task annotations. The majority of tasks were finished in between 10 and 30 minutes as shown in Figure 5. This is substantially faster than last year, which averaged around 45 minutes per task.

Feedback from evaluators After completing the evaluation all three evaluators filled in a form meant for feedback regarding the evaluation procedure and the Appraise platform. All evaluators gave us additional informal feedback.

In general, evaluators reported that their experience with Appraise was positive (two of them had used Appraise before), and that our instructions were clear. All of them would be willing to do similar work in the future. They found source videos understandable and the documents or segments given were neither too long nor too short. The general method of assessing translations (DA with SQM) was not found difficult nor stressful, but on the contrary annotators thought it was efficient, simple, fast and practical.

Concerning Appraise development, nobody experienced technical problems, which is an improvement over last year, when two people experienced major technical issues. Evaluators suggested that the user interface could be improved in some places. For instance, automatically playing videos could make evaluations more efficient, the videos should be bigger by default, there should be more keyboard shortcuts and there should be a quick way to give a low score to an entire document.

As explained in more detail below (§9.3), and similar to last year, evaluators told us that some videos do not have ideal cuts, in the sense that the beginning or end are slightly cut off. This is perhaps inevitable in continuous signing, or a problem in our manual alignment process.

Full responses to the feedback form submitted by evaluators are listed in Appendix C.

8.2 Automatic evaluation

Table 8 summarises the results of the automatic evaluation. In general, the translation of the Signsuisse subset (SS) and the SRF23 subset seem to have a similar complexity, especially according to chrF and BLEURT evaluation scores. BLEU, on the other hand, shows higher translation quality for SRF in selected systems by CASIA and TTIC. Both teams are able to significantly outperform the baseline system according to the three evaluation metrics. TTIC achieves the best scores with their primary submission TTIC.423. Although chrF points out another of their submissions as the best system, the difference with respect to the primary submission is not statistically significant.

9 Discussion

9.1 General translation quality

Overall, all systems perform poorly in our shared task, as there is an extreme difference in average score between all systems and the human reference translation. The systems exhibit well-known problems of natural language generation such as overfitting to few high-probability hypotheses and hallucination (Lee et al., 2018; Raunak et al., 2021).

The best submitted system in the best case achieves an average score of about 1 out of 100 (where the human translation achieved 69 out of 100), which indicates that current automatic translations are not usable in practice, unlike spoken language MT where in specific scenarios experiments have shown systems to be on par with human

Table 8: Automatic evaluation of all the submission for the full WMT-SLT test set (all), the Signsuisse subset (SS) and the SRF23 subset. Mean and 95% confidence intervals obtained via bootstrap resampling are shown. Primary submissions manually evaluated are boldfaced.

translation (Hassan et al., 2018; Popel et al., 2020). This assessment of general translation quality is unchanged from last year, see Müller et al. (2022) for potential reasons that still apply to the current shared task.

9.2 No submissions for spoken-to-signed translation directions

No teams participated in a track where a sign language is the target language (§3). We believe this could be due to the fact that generating sign language may appear considerably harder to participants. The problem of signed-to-spoken translation fits well into existing translation paradigms and toolkits, because using arbitrary features on the source side is easier than generating arbitrary numerical data (such as a video). Decoding text on the target side is considerably easier and more well-defined in NLP than decoding a video or similar data structure.

We thought that providing a baseline system for spoken-to-signed translation (§6.2) may help lower the barriers to entry but clearly, more measures are needed. A different hypothesis is that our shared task in its current form does not appeal to scientists working in the field of sign language generation or avatar technology. They may have felt alienated by aspects of the shared task which are familiar to MT researchers, but would need more explanation or introduction for people from neighboring fields.

9.3 Low scores of human translations

When looking at the domain-specific results (Table 5b and c), we observe that the human translation in SRF was ranked considerably lower than Signsuisse (69% against 98%). This difference warrants further investigation, as does the fact that a percentage of 69% is by itself rather low. We explain potential reasons for this below, attributing the difference to the way the corpora were generated.

Interpretation vs. translation SRF is partially generated as live interpretation of the spoken TV shows (spoken-to-sign), where interpreters are under time pressure. Due to specific efficiency strategies they occasionally omit content to keep up with the spoken audio. Therefore, since here we are evaluating the performance of the systems in the opposite direction (sign-to-spoken) it may as well very often be that the content of the interpretation does not match the one of the written or spoken sentence. However, as explained in Section 4, the Signsuisse part of the testset derives from a lexicon, containing sentences recorded as examples of particular lexicon entries. Since these have been generated for the purpose of being included in the lexicon, the accuracy of the translation is expected to be much higher than the one achieved within live interpretation.

Video editing issues The measured bad human performance on SRF may also be explained by the fact that the video cuts are sometimes not ideal,

i.e. the beginning or end of an SL utterance is cut off, as noted by our evaluators. This may have occurred because segmenting continuous signing is difficult and there is no ideal way to separate seamless transitions.

In the future these problems could perhaps be mitigated by including more frames from the left and right border of a video clip, or simply discarding sentences with unclear boundaries.

Role of discourse context A third reason may be that SLs are probably more dependent on context than spoken languages, e.g. because of index signs. This means that evaluating an isolated SL utterance (the equivalent of one sentence in a spoken language) may lead to low scores. This is a phenomenon that would more likely occur in a news report of SRF, as compared to the isolated example sentences of Signsuisse.

Contrary to what was observed for the evaluation of the human translation, the two submitted MT systems TTIC and CASIA perform significantly better on SRF than on Signsuisse. Here we may provide the assumption, that since the amount of training sentences from SRF is bigger than the ones from Signsuisse, the systems are optimized better for that domain. Additionally, it has been noted that in interpretation settings similar to the ones of SRF, the linguistic characteristics of the signing may be more closely related to German than in an offline translation setting, such as the one in Signsuisse.

9.4 Quality of training data and unexplored potential

Compared to last year we offered considerably more training data (hundreds of hours worth of video compared to dozens last year; §4.2). However, while last year all training data was manually corrected, this year we offered the data as-is. The SRF23 training data is best understood as a comparable corpus, or web-crawled parallel corpus including various types of noise (Khayrallah and Koehn, 2018). For instance, the time stamps of the German subtitles are more aligned with the audio signal present in the broadcast and do not account for the delay of live-interpreted signing. Any naive extraction of parallel examples from SRF23 without any alignment tools or shifting subtitle times will result in noisy training data.

As far as we know no participant investigated ways to improve the alignments automatically, which is perhaps because we did not explain this well in our online documentation. One reason for this may be that we did not make it clear enough to participants that one of our training corpora is effectively un-aligned. But essentially, it means there is unexplored potential in improving or filtering the training data instead of training on the raw corpora.

9.5 Limitations of shared task setup

The limitations we identified in last year's findings paper still apply. Briefly, the limitations concern the lack of generalization across signers, the favourable recording conditions of our sign language data and interpretation vs. translation setups. See Müller et al. (2022) for a more comprehensive description.

10 Conclusion and future directions

In this paper we present the second WMT Shared Task on Sign Language Translation (WMT-SLT23). We consider automatic sign language translation, and sign language processing in general, to be of wide public interest and to have a high potential impact in a societal and academic sense (§2).

Compared to last year we ran our shared task for three language pairs instead of one, we distributed considerably more training data (albeit with a higher amount of noise) and we put more emphasis on scenarios where sign languages are the target language.

Four teams participated in the second edition of the shared task. Overall, we observed low system performance with an average human evaluation score of about 1 out of 100 (for the best-performing system), which is not usable in practice. The main reasons for this outcome are a lack of usable training data, a modality gap (considering that most existing work in MT is based on text) and a lack of basic NLP tools specifically for sign languages.

Future of the shared task After two successful iterations the shared task is now well established, in the sense that suitable protocols are in place for human and automatic evaluation, reasonable baseline systems exist, as well as several training corpora and official WMT test sets.

So far our shared tasks have certainly helped to paint a more realistic picture of the translation quality of state-of-the-art systems, but they have not led to any major technical innovation. This may be because technologies more fundamental than machine translation do not exist for sign languages, or are not reliable enough. For this reason we will

consider running shared tasks on more fundamental problems in SLP such as alignment, segmentation, or automatic filtering of parallel corpora.

In the future we could also try to shift the focus away from interpreted news broadcast material as the basis for training and test data. A major challenge to overcome is that interpreted material is available in larger amounts, while signing produced by conventional, off-line translation or produced by native signers is harder to come by. Nevertheless, using non-interpreted material largely avoids alignment shifts in the training data and leads to higher scores for the human translations of the test data, among other advantages.

11 Ethical statement

Within this shared task, two main ethical considerations emerge: the potential impact of SL technology on target users and privacy considerations.

Research in sign language processing, if not executed carefully, may inadvertently cause harm to end users, especially members of deaf communities. Hearing scientists should refrain from prescribing what sort of language technology should be accepted by deaf or hard-of-hearing individuals and should avoid claiming that their approach "solves" any particular problem. Ideally, research of this nature should include deaf and hard-of-hearing people, not only at evaluation time but in the entire development cycle (Fox et al., 2023).

Secondly, there is a concern for the privacy of individuals depicted in SLP datasets. For the specific use case of sign language data, proper anonymisation is impossible, since identifying details such as facial expressions are crucial for sign language communication. We have obtained written permission of all individuals shown in our datasets. Storing and processing pose estimation features instead of raw videos may be an alternative that provides anonymity (and has other generalization effects such as ignoring differences in race, gender, clothing, background, etc.). However, in our shared task and related literature, (Moryossef et al., 2021; Tarrés et al., 2023) video features outperform pose features.

Acknowledgements

The organizing committee acknowledges funding from the following projects: the EU Horizon 2020 projects EASIER (grant agreement number 101016982) and SignON (101017255), the Swiss Innovation Agency (Innosuisse) flagship IICT (PFFS-21-47) and the German Ministry of Education and Research (BMBF) through the project SocialWear (01IW20002).

Finally, we would like to extend heartfelt thanks to the DSGS interpreters who performed our human evaluation: Heidi Stocker, Janine Criblez and Tanja Joseph.

B Appraise instructions to human evaluators

B.1 Sign-to-text direction

B.1.1 English

Below you see a document with 10 sentences in Swiss-German Sign Language (Deutschschweizer Gebärdensprache (DSGS)) (left columns) and their corresponding candidate translations in German (Deutsch) (right columns). Score each candidate sentence translation in the document context. You may revisit already scored sentences and update their scores at any time by clicking on a source video.

Assess the translation quality on a continuous scale using the quality levels described as follows:

- 0: Nonsense/No meaning preserved: Nearly all information is lost between the translation and source. Grammar is irrelevant.
- 2: Some Meaning Preserved: The translation preserves some of the meaning of the source but misses significant parts. The narrative is hard to follow due to fundamental errors. Grammar may be poor.
- 4: Most Meaning Preserved and Few Grammar Mistakes: The translation retains most of the meaning of the source. It may have some grammar mistakes or minor contextual inconsistencies.

- 6: Perfect Meaning and Grammar: The meaning of the translation is completely consistent with the source and the surrounding context. The grammar is also correct.

Please score the overall document translation quality (you can score the whole document only after scoring all individual sentences first). Assess the translation quality on a continuous scale using the quality levels described as follows:

- 0: Nonsense/No meaning preserved: Nearly all information is lost between the translation and source. Grammar is irrelevant.
- 2: Some Meaning Preserved: The translation preserves some of the meaning of the source but misses significant parts. The narrative is hard to follow due to fundamental errors. Grammar may be poor.
- 4: Most Meaning Preserved and Few Grammar Mistakes: The translation retains most of the meaning of the source. It may have some grammar mistakes or minor contextual inconsistencies.
- 6: Perfect Meaning and Grammar: The meaning of the translation is completely consistent with the source and the surrounding context. The grammar is also correct.

B.1.2 German

Unten sehen Sie ein Dokument mit 10 Sätzen in Deutschschweizer Gebärdensprache (DSGS) (linke Spalten) und die entsprechenden möglichen Übersetzungen auf Deutsch (rechte Spalten). Bewerten Sie jede mögliche Übersetzung des Satzes im Kontext des Dokuments. Sie können bereits bewertete Sätze jederzeit durch Anklicken eines Eingabevideos erneut aufrufen und die Bewertung aktualisieren.

Bewerten Sie die Übersetzungsqualität auf einer kontinuierlichen Skala mit Hilfe der nachfolgend beschriebenen Qualitätsstufen:

- 0: Unsinn/Bedeutung nicht erhalten: Fast alle Informationen zwischen Übersetzung und Eingabevideo sind verloren gegangen. Die Grammatik ist irrelevant.
- 2: Ein Teil der Bedeutung ist erhalten: Die Übersetzung behält einen Teil der Bedeutung der Quelle bei, lässt aber wichtige Teile aus. Die Erzählung ist aufgrund von grundlegenden Fehlern schwer zu verstehen. Die Grammatik kann mangelhaft sein.
- 4: Der grösste Teil der Bedeutung ist erhalten und es gibt nur wenige Grammatikfehler: Die Übersetzung behält den grössten Teil der Bedeutung der Quelle bei. Sie kann einige Grammatikfehler oder kleinere kontextuelle Unstimmigkeiten aufweisen.
- 6: Perfekte Bedeutung und Grammatik: Die Bedeutung der Übersetzung stimmt vollständig mit der Quelle und dem umgebenden Kontext (falls zutreffend) überein. Auch die Grammatik ist korrekt.

Bitte bewerten Sie die Übersetzungsqualität des gesamten Dokuments. (Sie können das Dokument erst bewerten, nachdem Sie zuvor alle Sätze einzeln bewertet haben.) Bewerten Sie die Übersetzungsqualität auf einer kontinuierlichen Skala mit Hilfe der nachfolgend beschriebenen Qualitätsstufen:

- 0: Unsinn/Bedeutung nicht erhalten: Fast alle Informationen zwischen Übersetzung und Eingabevideo sind verloren gegangen. Die Grammatik ist irrelevant.
- 2: Ein Teil der Bedeutung ist erhalten: Die Übersetzung behält einen Teil der Bedeutung der Quelle bei, lässt aber wichtige Teile aus. Die Erzählung ist aufgrund von grundlegenden Fehlern schwer zu verstehen. Die Grammatik kann mangelhaft sein.
- 4: Der grösste Teil der Bedeutung ist erhalten und es gibt nur wenige Grammatikfehler: Die Übersetzung behält den grössten Teil der Bedeutung der Quelle bei. Sie kann einige Grammatikfehler oder kleinere kontextuelle Unstimmigkeiten aufweisen.
- 6: Perfekte Bedeutung und Grammatik: Die Bedeutung der Übersetzung stimmt vollständig mit der Quelle und dem umgebenden Kontext (falls zutreffend) überein. Auch die Grammatik ist korrekt.

C Feedback from evaluators

Tables 9 and 10 detail for each evaluator the feedback answers and comments regarding the human evaluation procedure and the Appraise system. All three evaluators submitted a response.

	Answer 1	**Answer 2**	**Answer 3**
What is your experience in assessing machine translation outputs?			
	Low: I have done it once or a long time ago	Moderate: I have done it a few times	Low: I have done it once or twice before, or a long time ago
Please specify how much you agree or disagree with the following statements.			
Generally, my experience with the tool was positive	Agree	Agree	Agree
Instructions were clear	Neutral	Strongly agree	Strongly agree
Quality levels 0-6 were helpful to me	Neutral	Neutral	Agree
Source videos were understandable	Strongly agree	Agree	Strongly Agree
There was too much repetitiveness	Strongly agree	Neutral	Strongly agree
Documents were too long	Disagree	Disagree	Neutral
Segments were too short	Disagree	Disagree	Disagree
In some cases, the context was insufficient	Neutral	Neutral	Disagree
I experienced technical issues	Neutral	Neutral	Disagree
I would be willing to do similar work in the future	Agree	Agree	Agree
This evaluation campaign featured the Direct Assessment with Scalar Quality Metrics method. What do you think about this method? On a scale between -3 (negative) and 3 (positive) it was...			
difficult/easy	+1	+3	+3
stressful/relaxed	0	+3	+2
laborious/effortless	+2	+2	-2
slow/fast	+2	+2	0
inefficient/efficient	+2	+2	+2
boring/exciting	-1	+2	0
complicated/simple	+1	+2	+3
annoying/enjoyable	-1	+2	0
limiting/creative	-1	0	0
impractical/practical	0	+2	+3

Table 9: Feedback from evaluators about the human evaluation setup and the Appraise platform.

Answer 1		Answer 2	Answer 3
Please provide more details related to the statements above that you think can be useful to us. What was most troublesome? What could we improve?			
(original in German) - Ich hätte ein grösseres Video geschätzt (ohne dass ich das jedes Mal aktiv anklicken muss) > Z.B. bei Klicken auf Play, automatische Vergrösserung und bei Ende der Wiedergabe automatisch zurück auf die Skala. - Die Videoschnitte waren - v.a. bei einem Modell (langer Lag!) - sehr schlecht. Video und Text stimmten deshalb oft nicht überein. Schwierig für die Beurteilung! - Es kam oft vor, dass ganze Dokumente schon auf einen Blick als "komplett falsch" ersichtlich waren (Texte komplett unverständlich). Da wäre es hilfreich, wenn man ein gesamtes Dokument als "ROT" beurteilen könnte, ohne jedes einzelne Video zu beurteilen.	(translated into English) - I would have appreciated a larger video (without having to actively click that every time) > E.g. when clicking play, automatic enlargement and at the end of playback automatically back to the scale. - The video cuts were - especially with one model (long lag!) - very bad. Video and text therefore often did not match. Difficult for the evaluation! - It often happened that whole documents appeared at a glance as "completely wrong" (texts completely incomprehensible). There it would be helpful if one could judge a whole document as "RED" without judging every single video.	Some of the film clips were poorly edited and therefore did not match the translated text. Certain written formulations are not common in Switzerland. There are some very German formulations. The German text was taken over, there was no real translation.	The large amount of nonsense translations could lead to the fact that one does not work concentrated any more.
What were the main or most common issues with the automatic translations?			
(original in German) Es gab wenig Probleme technischer Art. Nur 1x kein Zugang zum Dokument. Ab und zu (aber selten!) eine Meldung, dass die "Resultate" nicht angenommen/gespeichert werden konnten.	(translated into English) There were few problems of a technical nature. Only 1x no access to the document. Now and then (but rarely!) a message that the "results" could not be accepted/saved.	Some of the film clips were poorly edited and therefore did not match the translated text.	The large amount of nonsense translations.

Table 10: Feedback comments from evaluators about the human evaluation setup and the Appraise platform.

Findings of the WMT 2023 Shared Task on Parallel Data Curation

Abstract

Building upon prior WMT shared tasks in document alignment and sentence filtering, we posed the open-ended shared task of finding the best subset of possible training data from a collection of Estonian-Lithuanian web data. Participants could focus on any portion of the end-to-end data curation pipeline, including alignment and filtering. We evaluated results based on downstream machine translation quality. We release processed Common Crawl data, along with various intermediate states from a strong baseline system, which we believe will enable future research on this topic.

1 Introduction

A machine translation (MT) system is only as good as the data it is trained on. However, the academic research community often overlooks the details of this task, using pre-curated corpora.

To promote research in this area, this shared task[1] focuses on finding pairs of sentences or documents that are translations of each other based on a collection of web crawled data. MT models are trained by the organizers on the data found by participants, and performance is then judged using automatic metrics. This shared task builds on prior shared tasks on document alignment (Buck and Koehn, 2016a) and sentence filtering (Koehn et al., 2018, 2019, 2020). However, this task is intentionally open-ended, and designed to allow participants to improve on various different parts of the data curation pipeline.

We chose the Estonian-Lithuanian language pair for several reasons. The amount of data we extracted in that language pair was enough to train a reasonable MT model, while being small enough that the task was still accessible to academic participants with limited hardware resources. We avoided English, as many toolkits are developed/optimized on English data, and results on English may not generalize well. And finally, we avoided languages which were closely related, as this could favor methods which do not generalize well.

To lower the barrier to entry and allow participants to focus their research and compute resources, we release intermediate stages of a strong baseline data curation system. We encourage future work to build upon resources provided in this shared task.

This paper gives an overview of the task, presents its results, and provides some analysis.

2 Related work

Parallel data has been required for training machine translation systems ever since the field transitioned to statistical machine translation (Brown et al., 1990). To train that first statistical system, Brown et al. aligned English-French sentences from the proceedings of the Canadian Parliament, often referred to as Hansards, using a very simple system to segment each side into sentences and then align them using only sentence length (Brown et al., 1991). The field of parallel data curation has come a long way since then, with modern methods extracting billions of sentence pairs in hundreds of languages, as opposed to the few million enabled by Hansards.

Currently, there are two main approaches to parallel data curation: (1) document and sentence alignment, and (2) comparable corpora methods.

Document & Sentence alignment The first approach is very similar in spirit to that used on Handards: Parallel documents are identified and then document pairs are aligned at the sentence level to produce sentence-level translation pairs. These steps are referred to as document alignment and sentence alignment, respectively. The web has become the default source of documents (Resnik, 1998), where businesses, governments, and individuals regularly release documents and translations of

[1] http://www2.statmt.org/wmt23/data-task.html

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 95–102

those documents–for example a user manual that is published in several languages. A very simple and computationally inexpensive approach to finding parallel documents is to locate URLs which differ in no more than a language code (Resnik and Smith, 2003). However, more accurate (and computationally expensive) methods have also been developed which look for documents which appear to contain similar information, for example by translating all documents into one language and then finding pairs via TF-IDF similarity (Buck and Koehn, 2016b). More recent approaches to document alignment have relied on finding similar vectors after converting documents into multilingual vectors, created via combining sentence embeddings (Thompson and Koehn, 2020) or by embedding entire documents (Guo et al., 2019). A WMT shared task on document alignment was held in 2016 (Buck and Koehn, 2016a).

Once parallel documents have been located, they are sentence aligned. Sentence alignment consists of finding a bipartite graph which matches minimal groups of sentences that are translations of each other. This is necessary because content may have been inserted or deleted in the translation process, and sentences may have been combined or split in the translation process. Additionally, sentence segmentation errors may cause sentences to be split or combined. An example of an early sentence alignment algorithm is Gale-Church (Gale and Church, 1993), which like the original IBM system uses only the length of each sentence, making it very computationally efficient but not particularly accurate. Bleualign (Sennrich and Volk, 2010, 2011) used an MT system to convert one text into the language of the other and then performed n-gram matching, similar to the BLEU MT metric (Papineni et al., 2002). A more recent sentence aligner is Vecalign (Thompson and Koehn, 2019), which uses multilingual sentence embeddings and a dynamic programming approximation (Salvador and Chan, 2007) which makes the algorithm linear with respect to the number of sentences being aligned. Widely used datasets created via document and sentence alignment include Paracrawl (Bañón et al., 2020) and CCAlign (El-Kishky et al., 2020).

Comparable Corpora A recent alternative to document and sentence alignment is to discard document information and simply create a collection of sentences in each language, and then find translation pairs by looking for sentences which are nearby by in a multilingual embedding space. LASER (Artetxe and Schwenk, 2019) was proposed for this task. The authors additionally proposed a margin-based score which gives preference to sentence pairs which are more similar to one another than other potential matches by at least a minimum margin. Approximate nearest neighbor search (Johnson et al., 2019) is used to make the search for sentence pairs tractable. Examples of widely-used datasets created via the comparable corpora method include Wikimatrix (Schwenk et al., 2021a) and CCMatrix (Schwenk et al., 2021b).

2.1 Parallel Corpora Filtering

Once data has been aligned, it is customary—especially for data coming from the web—to perform data filtering to remove low quality translation pairs before using the data for training, as unfiltered web-crawled data harms translation performance (Khayrallah and Koehn, 2018). There have been three prior shared tasks on bitext filtering at WMT (Koehn et al., 2018, 2019, 2020).

Popular approaches to data filtering include LASER margin filtering (Chaudhary et al., 2019), using an approach similar to the comparable corpora method described above, and dual conditional cross entropy (Junczys-Dowmunt, 2018), which trains NMT models on held-out clean data in both the forward and reverse directions and uses them to compute cross-entropy scores for the data being filtered. Sentence pairs with divergent or poor cross-entropies are down-weighted.

3 Shared Task Definition

This shared task presented the open-ended problem of finding the best possible subset of aligned sentence pairs from unaligned documents sourced from the internet. Participants were evaluated on downstream machine translation system performance.

Parallel data curation from web can be computationally demanding due to the sheer scale of webcrawled data. For this reason, in addition to our documents, we also released pre-computed intermediate steps from a baseline, so participants can choose to focus on one aspect of the task (e.g. sentence filtering.)

For this shared task, the organizers provided:

- Web-crawled data, as unique sentences or unique documents

- LASER2 sentence embeddings
- K-nearest neighbors by cosine similarity from our baseline
- End-to-end scripts for MT training and evaluation

End-to-end scripts enabled participants to supply a set of sentence ids and train and evaluate a Sockeye MT model (Hieber et al., 2022). Alongside the scripts, we provided a simple baseline based on 1-best cosine similarity.

Participants were allowed to use only pre-trained models and datasets publicly released with a research-friendly license on or before May 1, 2023.

3.1 Dataset

All of our inputs were derived from the 2023-06 snapshot of Common Crawl. We extracted the plain text from HTML using the *trafilatura* library (Barbaresi, 2021), and ran the first 2,000 characters through the 176-language fasttext language id model (Joulin et al., 2016a,b).

We kept all documents classified as Estonian or Lithuanian, unless their hostnames were included in the following lists from the blocklist project:[2] abuse, basic, crypto, drugs, fraud, gambling, malware, phishing, piracy, porn, ransomware, redirect, scam, torrent. No further data filtering was performed.

We split documents into paragraphs at line breaks, and segmented resulting paragraphs into sentences using the Media Cloud sentence splitter.[3]

Each unique sentence was given a Globally Unique IDentifier (GUID) and tagged with a language id based on *fastText*.

3.1.1 Dataset Statistics

Our dataset includes documents taken from 402,920 hosts. Only 24,319 of these hosts included documents in both languages. Table 1 includes overall counts on a per language basis.

3.1.2 Intermediate Outputs From Baselines

We provide participants with intermediate outputs from our baseline systems as additional resources, such that prospective participants could be able to access sentence embedding or sentence pair similarity information without needing computational resources to create these themselves.

[2] https://github.com/blocklistproject/Lists

[3] https://github.com/mediacloud/sentence-splitter

	Estonian	Lithuanian
# Hosts	199,813	227,426
# Documents	3,449,211	4,571,947
# Sentences	53,234,425	63,488,253
# Sents w/ LangId	36,870,945	46,969,824

Table 1: Counts of unique hosts, documents, sentences, and sentences identified as the correct language in our dataset

We provide outputs of embedding each sentence with the LASER 2 model (Heffernan et al., 2022). We also release a smaller version of the embeddings, projected down to 128 dimensions via PCA and converted to float16.

To create baseline sentence pair alignments, we removed sentences detected as non-Estonian or non-Lithuanian, and used the FAISS library (Johnson et al., 2019) to index our LASER2 embeddings for fast retrieval. We applied L2 normalization to the embeddings, and added them to a flat inner product index, so that the resulting scores were equivalent to cosine similarity. We queried each index with embeddings in the other language, and returned the top eight results. These raw cosine similarity scores are shared with participants as a potential resource, and serve as the basis for our baseline submissions.

4 Evaluation

We evaluated submissions by using the curated data to train machine translation systems.

For preprocessing, we split sentences into subwords by applying Byte-Pair Encoding (BPE) (Sennrich et al., 2016) using 32,000 merge operations. The BPE vocabulary is learned jointly for the source and target language. We apply a minimum vocabulary frequency of 100 per language.

We use Sockeye (Hieber et al., 2022) to train Transformer (Vaswani et al., 2017) translation models with 512 hidden units, 8 attention heads, 6 layers and feed-forward layers of size 2048. For training we use an effective batch size of 400k target tokens. We use 4096 target tokens per GPU, and gradient accumulation to obtain 400k target tokens regardless of the number of GPUs.

We use the Adam optimizer (Kingma and Ba, 2014) with $\beta_1 = 0.9$ and $\beta_1 = 0.98$, an initial learning rate of 0.06325, a linear warmup for 4000 updates and an inverse square root learning rate

# Sents	Min Margin Score	EMEA	EUbookshop	Europarl	JRC-Acquis	average

Table 2: Comparison of different training data sizes and margin score cutoffs on development set BLEU.

decay. Checkpoints are written every 500 updates and training is stopped once validation perplexity does not improve for 12 checkpoints. The checkpoint with the lowest validation perplexity is used as the final checkpoint.

All systems are trained on nodes with 8 V100 GPUs. We use BLEU (Papineni et al., 2002) and chrF (Popović, 2015) as quality metrics. Evaluation metrics are computed using Sacrebleu (Post, 2018).

We considered data from four domains for evaluation: EMEA,[4] EUbookshop,[5] Europarl,[6] JRC-Acquis,[7] and EUconst.[8] All data is released by OPUS (Tiedemann, 2012). From each domain, we created a dev, test, and held-out-test set. We use up to 10,000 lines for each. If less data is available, it is split between the three sets. We also kept EUconst as a held-out domain.

5 Systems

We report the results of four different systems: the baseline, two participant systems, and a contrastive system.

5.1 Baseline

The naive baseline was designed to give participants a simple end-to-end system, so they could focus on any part of the pipeline to improve upon. While participants were not required to build upon the baseline, doing so lowered the barrier to entry.

As described in Section 3.1.2, we used the LASER 2 model to embed all Estonian and Lithuanian sentences, indexed them with FAISS, and computed the eight nearest neighbors' cosine similarities for each sentence in each language. We provided these cosine similarity scores as an additional resource for participants.

Our naive baseline was created by taking all sentence pairs whose cosine similarities whose 1-best neighbor exceeded or matched the threshold of 0.9 in the Estonian → Lithuanian direction, meaning that multiple target sentences could be aligned to the same source.

This naive baseline was designed to be an end-to-end solution to allow participants to improve on any of the individual parts (filtering, alignment, margin scoring, etc).

5.2 Steingrímsson

Steingrímsson (2023b) first perform document alignment and sentence alignment, and then use matches from the provided top1-cosine data for sentences which were not aligned via document/sentence alignment.

They perform sentence alignment of all document pairs within each web domain and score the alignments to locate document pairs, similar to Thompson and Koehn (2020), to find high-quality document pairs. They use the recently proposed SentAlign[9] (Steingrímsson, 2023a; Steingrímsson et al., 2023b) sentence aligner, which in turn uses LaBSE (Feng et al., 2022) sentence embeddings.

They also perform extensive bitext filtering, using several different language ID tools and the filtering method proposed in Steingrímsson et al. (2023a) which uses perplexities of a GPT-2 model (Radford et al., 2019), LAESR embeddings (Chaudhary et al., 2019), NMTScore (Vamvas and Sennrich, 2022) using Prism (Thompson and Post, 2020a,b), and WAScore (Steingrímsson et al., 2021), as well as Bicleaner AI (Zaragoza-Bernabeu et al., 2022).

5.3 Nguyen-Hoang et al.

Nguyen-Hoang et al. (2023) focus on using the phrase based dictionary to distill the high-quality sentences and making a pipeline to re-ranking the top-K cosine similarity.

They begin with the released data, and an MGiza-based (Gao and Vogel, 2008) dictionary. They then extract sentence pairs using the a top-1 cosine score

Table 4: Held-out test BLEU and ChrF scores. Top1_cosine is the baseline, and Marginscore 3.2M is the contrastive system.

and a threshold. From there, the dictionary is used to translate the source sentences. These dictionary-translated sentences are then compared with the translation from the baseline data. The translation from the baseline data is filtered based on the edit distance. Then a NMT model is trained, and the final threshold is set based on NMT model performance.

Nguyen-Hoang et al. (2023) also perform an analysis on the cosine score threshold, demonstrating how varying this value impacts both corpus size and translation quality.

5.4 Contrastive System

The participants in this task both performed data filtering on top of the the top-1 cosine baseline.

Since no participants experimented with using margin scoring, which Schwenk et al. (2021b) found significant for improving the quality of LASER-based mining, the organizers created a stronger contrastive system that did so.

We calculated margin scores for our four nearest neighbors in both directions. We performed competitive linking,[10] such that each sentence appeared only once in our contrastive submission. Although we computed cosine similarities for the eight nearest neighbors, no appreciable difference was found in MT quality by using k=8 instead of k=4 when computing margin scores.

We sorted our data by margin score and compared different data sizes, as shown in Table 2. We used a minimum margin score of 1.027 and data size of 3.2 million lines since it scored the highest on all development sets and had the highest average score.

6 Results

Table 3 and Table 4 show the BLEU and ChrF results of the naive top-1 cosine baseline, participant submissions, and the contrastive margin score system. Of the baseline and two participant systems, we bold the best and systems within 0.1 of the best. Overall, both participants improved over the naive baseline. On the held-out test sets, Steingrímsson had higher BLEU on EMEA and EUbookshop, while Nguyen-Hoang et al. had higher BLEU on Europarl, JRC-Acquis, and the held-out domain of EUconst.

We see that the contrastive margin score system outperforms the naive top-1 cosine baseline. This confirms the finding of Schwenk et al. (2021b) that margin scoring outperforms raw cosine similarity. The contrastive margin score system also outperforms the participant submissions that directly build and improve upon the naive top-1 cosine baseline.

Data filtering and alignment tend to be complimentary, so the filtering methods proposed by the

[10] Referred to as the "max strategy" by Schwenk et al. (2021b).

participants would likely improve upon the contrastive margin score system if they were applied on top of it.

7 Conclusion

While data curation is the first step in the training of any MT (or machine learning) model, this tends to be a less-published-upon topic in academic research.

In this shared task, we have released the processed webcrawled data, and a baseline system with intermediate outputs. We hope this task lowers the barrier of entry and allow participants to focus on any aspect of the data curation pipeline (document alignment, sentence alignment, filtering, etc.) We have trained and evaluated MT systems on the datasets curated by participating teams. We have presented results for two participant submissions, in addition to two more systems built by the shared task organizers.

We hope this work serves as a building block for future research on this topic.

Abstract

In this paper, we describe the constrained MT systems submitted by Samsung R&D Institute Philippines to the WMT 2023 General Translation Task for two directions: en→he and he→en. Our systems comprise of Transformer-based sequence-to-sequence models that are trained with a mix of best practices: comprehensive data preprocessing pipelines, synthetic backtranslated data, and the use of noisy channel reranking during online decoding. Our models perform comparably to, and sometimes outperform, strong baseline unconstrained systems such as **mBART50 M2M** and **NLLB 200 MoE** despite having significantly fewer parameters on two public benchmarks: FLORES-200 and NTREX-128.

1 Introduction

This paper describes Samsung R&D Institute Philippines's submission to the WMT 2023 General Translation task. We participate in two translation directions: en→he and he→en, submitting two **constrained** single-direction models based on the Transformer (Vaswani et al., 2017) sequence-to-sequence architecture. We employ a number of best practices, using a comprehensive data preprocessing pipeline to ensure parallel data quality, create synthetic data through carefully-curated backtranslation, and use reranking methods to select the best candidate translations.

Our systems achieve strong performance on public benchmarks: 44.24 BLEU and 33.77 BLEU for FLORES-200 and NTREX-128 en→he, respectively, and; 42.42 BLEU and 36.89 BLEU on FLORES-200 and NTREX-128 he→en, respectively. Our systems outperform **mBART50 M2M** and slightly underperform against **NLLB 200 MoE** despite having significantly less parameters compared to these unconstrained baselines.

We detail our data preprocessing, model training, data augmentation, and translation methodology. Additionally, we illustrate hyperparameter sweeping setups and study the effects of hyperparameters during online decoding with reranking.

2 Methodology

2.1 Data Preprocessing

Given that a significant portion of the training dataset is synthetically-aligned, we need to use a comprehensive data preprocessing pipeline to ensure good translation quality. In particular, we use a combination of heuristic-based, ratio-based, and embedding-based methods to filter our data.

Heuristic-based The following heuristic-based filters based on Cruz and Cheng (2021) are used before applying the others:

- **Language Filter** – We use use `pycld3`[1] to filter out sentence pairs where one or both sentences have more than 30% tokens that are neither English nor Hebrew.
- **Named Entity Filter** – We use NER models (Bareket and Tsarfaty, 2021; Yang and Zhang, 2018) to check if both sentences in a pair have matching entities (if any). Pairs that contain entities that do not match are removed.
- **Numerical Filter** – If one sentence in a pair has a number (ordinal, date, etc.), we also check the other sentence if a matching number is present. If a match is not detected, the pair is removed.

Ratio-based We employ ratio-based filters on tokenized sentence pairs following Cruz and Sutawika (2022) and Sutawika and Cruz (2021). We first tokenize using SacreMoses[2] then apply the following ratio-based filters:

[1] https://pypi.org/project/pycld2/
[2] https://github.com/alvations/sacremoses

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 103–109
December 6–7, 2023.

	Pairs	Words (en)	Words (he)
Original	72,459,348	701,991,594	566,555,530
Original Filtered	48,278,395	385,975,984	312,639,617
Synthetic en→he	10,000,000	165,595,289	145,849,940
Synthetic en→he Filtered	7,143,725	115,239,312	95,954,020
Synthetic he→en	73,278,018	1,471,827,973	1,056,677,671
Synthetic he→en Filtered	47,372,416	659,409,236	541,376,459

Table 1: Corpus Statistics. "Filtered" refers to the number of pairs / words that remain after the filtering script is applied to the dataset. Note that "Words" is an approximation gathered by using the `wc -l *` command on the plaintext files.

- **Length Filter** – We remove pairs containing sentences with more than 140 characters.
- **Token Length Filter** – We remove pairs that contain sentences with tokens that are more than 40 characters long.
- **Character to Token Ratio** – We remove pairs where the ratio between character count and token count in at least one sentence is greater than 12.
- **Pair Token Ratio** – We remove pairs where the ratio of tokens between the source and target sentences is greater than 4.
- **Pair Length Ratio** – We remove pairs where the ratio between the string lengths of the source and target sentences is greater than 6.

Embedding-based Finally, we experiment with the use of sentence embedding models to compute embedding-based similarity between a sentence pair. We use LaBSE (Feng et al., 2020) models to embed both the source and target sentences then compute a cosine similarity score between the two. The pair must have a similarity score $0.7 \leq s \leq 0.96$ to be kept.

Statistics on the original and filtered corpus can be found on Table 1.

After preprocessing the parallel data, we learn a shared BPE (Sennrich et al., 2015b) vocabulary using SentencePiece[3] (Kudo and Richardson, 2018) with 32,000 units. All models in this paper use the same shared vocabulary.

2.2 Model Architecture

We experiment with two model sizes for each language pair: a **`Base`** model with 65M parameters and a **`Large`** model with 200M parameters. Both models use the standard Transformer (Vaswani et al., 2017) sequence-to-sequence architecture and are trained using Fairseq (Ott et al., 2019) with the hyperparameters listed in Table 2.

Training Hyperparameters	
Parameters	65M and 200M
Vocab Size	32,000
Tied Weights	Yes
Dropout	0.3
Attention Dropout	0.1
Weight Decay	0.0
Label Smoothing	0.1
Optimizer	Adam
Adam Betas	β_1=0.90, β_2=0.98
Adam ϵ	ϵ=1e-6
Learning Rate	7e-4
Warmup Steps	4,000
Total Steps	1,000,000
Batch size	64,000 tokens

Table 2: Hyperparameters used during training. When reporting model sizes, **`Base`** refers to 65M parameters, while **`Large`** refers to 200M.

We parallelize with 8 NVIDIA Tesla P100 GPUs and initially train for a total of 100K steps for experimentation. For the submitted systems trained with backtranslated data, we train for a total of 1M steps.

2.3 Backtranslation

We use backtranslation (Sennrich et al., 2015a) as a form of data augmentation to improve our initial models. We generate synthetic data via combined top-k and nucleus sampling:

$$\sum_{i=0}^{\delta_k} P(\hat{y}_i^{(T)}|x; \hat{y}^{(T-1)}) * \delta_{temp} \leq \delta_p \quad (1)$$

[3] https://github.com/google/sentencepiece

Backtranslation Hyperparameters	
Top-k (δ_k)	50
Top-p (δ_p)	0.93
Temperature (δ_t)	0.7
Beam	1.0
Length Penalty	1.0

Table 3: Hyperparameters used during backtranslation.

where δ_k is the top values considered for top-k sampling, δ_{temp} is the temperature hyperparameter, and δ_p is the maximum total probability for nucleus sampling.

Backtranslation is only performed once using the provided monolingual data. We produce a total of 10,000,000 synthetic sentences for the en→he direction and 73,278,018 synthetic sentences for the he→en direction. The same data preprocessing used on the original parallel corpus is then applied to the synthetic corpus. We produce backtranslations using **Large** 100K models with the sampling hyperparameters listed in Table 3.

Statistics on generated synthetic data before and after filtering can be found on Table 1.

2.4 Noisy Channel Reranking

We further improve translations by using Noisy Channel Reranking (Yee et al., 2019), which reranks every candidate translation token $\hat{y}_i^{(T)}$ using Bayes' Rule, as follows:

$$P(\hat{y}_i^{(T)}|x;\hat{y}^{(T-1)}) = \frac{P(x|\hat{y}^{(T-1)})P(\hat{y}^{(T-1)})}{P(x)} \quad (2)$$

where $P(\hat{y}_i^{(T)})$ refers to the probability of the ith candidate token at timestep T given source sentence x and current translated tokens $\hat{y}^{(T-1)}$.

All probabilities are parameterized as standard encode-decoder Transformer neural networks: the **Direct Model** $f_{\phi_D}(x,\hat{y}^{(T-1)})$ models $P(\hat{y}_i^{(T)}|x;\hat{y}^{(T-1)})$ or translation between source to target language; the **Channel Model** $f_{\phi_C}(x|\hat{y}^{(T-1)})$ models $P(x|\hat{y}^{(T-1)})$, or the probability of the target translating back into the predicted translation, and; the **Language Model** $f_{\phi_L}(\hat{y}^{(T-1)})$ models $P(\hat{y}^{(T-1)})$ or the probability of the translated sentence to exist. $P(x)$ is generally not modeled since it is constant for all y. This allows us to leverage a strong language model to guide the outputs of the direct model, while using a channel model to constrain the preferred outputs of the language model (which may be unrelated to the source sentence).

Decoding Hyperparameters	
Beam	5
Length Penalty	1.0
k2	5
CM Top-k	500
δ_{ch} en→he	0.2297
δ_{lm} en→he	0.2056
δ_{ch} he→en	0.2998
δ_{lm} he→en	0.2594

Table 4: Hyperparameters used for the final submission models. The values listed for δ_{ch} and δ_{lm} are the ones used for the final submission models. For testing with **Large 100K** models, we set both δ_{ch} and δ_{lm} to 0.3. "k2" refers to the number of candidates sampled per beam while "CM Top-k" refers to the number of most frequent tokens in the channel model's vocabulary that is used as its output vocabulary during decoding to save space.

During beam search decoding, we rescore the top candidates using the following linear combination of all three models:

$$P(\hat{y}_i^{(T)}|x;\hat{y}^{(T-1)})' = \frac{1}{t}log(P(x|\hat{y}^{(T-1)}) + \frac{1}{s}[\delta_{ch}log(P(x|\hat{y}^{(T-1)}) + \delta_{lm}log(P(\hat{y}^{(T-1)}))] \quad (3)$$

where s and t are source / target debiasing terms, δ_{ch} refers to the weight of the channel model, and δ_{lm} refers to the weight of the language model.

For Noisy Channel Reranking, our direct and channel models use the same size and setup at all times (i.e. if the direct model is a **Large** model trained for 100K steps, then the channel model is also a **Large** model trained for 100K steps in the opposite translation direction).

For the language model, we train one **Base**-sized decoder-only Transformer language model for English and one for Hebrew. We concatenate the cleaned data from the parallel corpus with the provided monolingual data for each language to train the LM. We use the same training setup as with translation models, except we use a weight decay of 0.01 and a learning rate of 5e-4.

Hyperparameters used for decoding with Noisy Channel Reranking can be found in Table 4.

2.5 Evaluation

We evaluate our models using two metrics: BLEU (Papineni et al., 2002) and ChrF++ (Popović, 2015), both scored via SacreBLEU[4] (Post, 2018). We develop our models using both the FLORES 200 (Costa-jussà et al., 2022) and NTREX 128 (Federmann et al., 2022) datasets, using the validation sets during training and reporting scores on the test sets.

To benchmark our models' performance, we mainly compare BLEU and ChrF++ against two (unconstrained) models: **`mBART 50 M2M`** (Tang et al., 2020), a 610M-parameter finetuned version of **`mBART`** for many-to-many translation, and **`NLLB 200 MoE`** (Costa-jussà et al., 2022), the full 54.5B-parameter mixture-of-experts version of **`NLLB 200`** for many-to-many translation.

2.6 Hyperparameter Search

To find the best values for δ_{ch} and δ_{lm}, as well as to understand how these parameters affect performance, we use Bayesian Hyperparameter Search. We use the **`Large`** 1M + BT models and run 1000 iterations of search, keeping the length penalty static at 1.0, and sampling both δ_{ch} and δ_{lm} from a gaussian with minimum of 0.01 and maximum of 0.99.

We perform this for both en→he and he→en translation directions and use the results for the final submission model.

3 Results

A summary of our results on benchmarks can be found on Table 5.

3.1 Benchmarking Results

Our submission systems (**`Large` 1M + BT + NC**) exhibit strong performance on both translation directions. On FLORES-200, we achieve 44.24 BLEU for en→he and 42.42 BLEU for he→en. The same systems score 33.77 BLEU for en→he and 36.89 BLEU for he→en on NTREX-128.

We note that these systems perform strongly when compared against much larger, unconstrained baseline models. On FLORES-200, we significantly outperform **`mBART 50 M2M`** on en→he by +24.75 BLEU and on he→en by +11.92 BLEU despite having 67% less parameters (200M vs 610M). Notably, our system performs only slightly worse compared to **`NLLB 200 MoE`** despite having **96% less parameters** compared to the mixture-of-experts model. On FLORES-200, we perform -2.56 BLEU worse on en→he and -6.58 BLEU worse on he→en compared to **`NLLB 200 MoE`**.

3.2 Hyperparameter Search Results

In order to find optimal hyperparameters for both δ_{ch} and δ_{lm}, we ran bayesian hyperparameter search for both at the same time while keeping length penalty static. We plot the results of the hyperparameter search over 1000 iterations in Figure 1.

We observe that performance is optimal when both hyperparameters are set to 0.2∼0.3, making performance increasingly worse as both hyperparameters approach closer to 1. We hypothesize that this signifies the model capturing the original distribution close enough that it does not need much correction or aid from the accompanying language model. Noisy channel reranking, however, is still empirically shown to be useful in this case as guidance from the language model produces better candidates in cases where the direct model may be searching a too-constrained space.

3.3 Ablations

We explored multiple configurations of our submission systems in terms of model size, presence of synthetic data during training, and the use of reranking methods during online decoding. Our results show that each step improves performance directly:

- The initial **`Base` 100K** performs at 39.88 BLEU for en→he on FLORES-200.
- Increasing the size to 200M parameters (**`Large` 100K**) improves performance by +1.38 BLEU.
- Adding backtranslated data (**`Large` 100K + BT**) is by far the most beneficial, improving performance by +2.06 BLEU.
- We then experiment with longer training times (1M iterations for **`Large` 1M + BT**) to adapt to the new dataset size, increasing the score by +0.44 BLEU.
- Finally, using noisy channel reranking (**`Large` 1M + BT + NC**) improves the score by +0.48 BLEU.

NLLB 200 MoE (54.5B)	46.80	59.80	49.00	67.40	-	-	-	-

Table 5: Compiled results for all experiments. "BT" refers to the model being trained with backtranslated data in addition to original filtered data. "NC" refers to the use of Noisy Channel Reranking. Evaluation scores for **NLLB 200 MoE** are taken from its official published scores for FLORES-200. We fail to report independent NTREX-128 scores for **NLLB 200 MoE** due to a lack of computational resources.

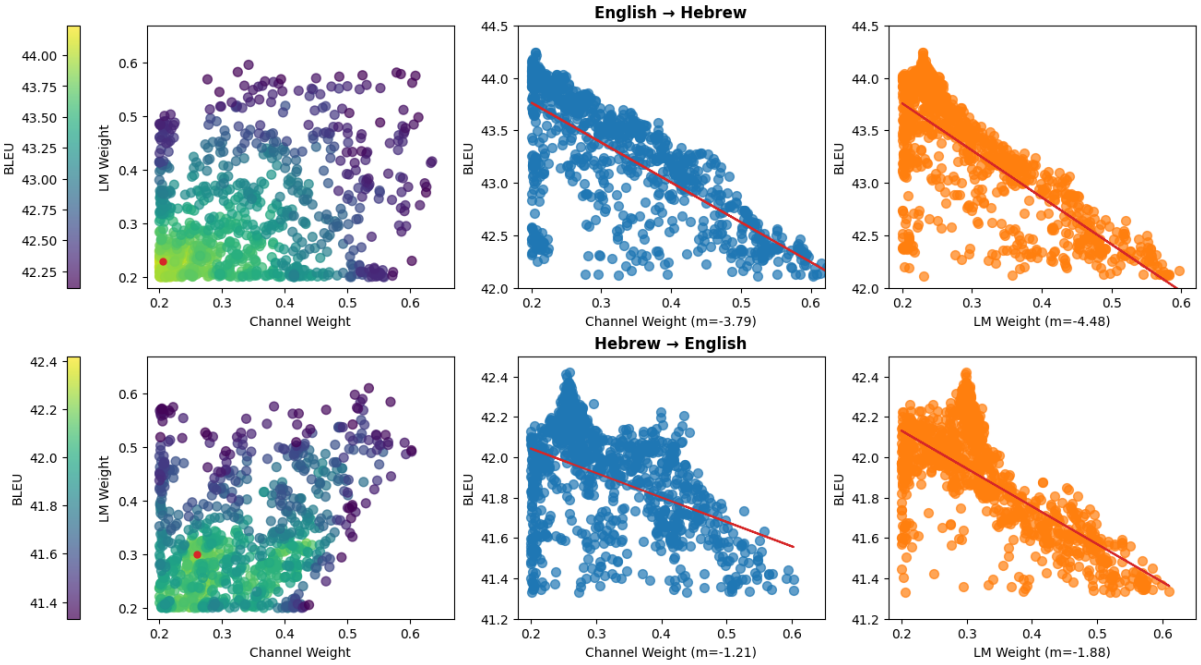

Figure 1: Bayesian hyperparameter search results for δ_{ch} and δ_{lm} while keeping constant length penalty. The leftmost column shows BLEU score against both δ_{ch} and δ_{lm} with the best performing model (**Large** 1M + BT + NC) plotted in red. The middle and rightmost columns show δ_{ch} and δ_{lm} against BLEU, respectively, with their respective regression lines (in red) and regression coefficient (m) in the caption.

Overall, all of our methods improve performance by a total of 4.36 BLEU for the en→he direction on FLORES-200.

We note an interesting jump in performance from **Base 100K** to **Large 1M + BT + NC** on the FLORES-200 he→en direction at +30.36 BLEU. **Base 100K** underperforms at 12.06 BLEU, and we hypothesize that this is due to the model not having enough capacity to embed information from Hebrew, which causes it to greatly benefit from the guidance of a language model during noisy channel reranking.

4 Conclusion

In this paper, we describe our submissions to the WMT 2023 General Translation Task. We participate in two constrained tracks: en→he and he→en.

We submit two monodirectional models based on the Transformer architecture. Both models are trained using a mix of original and synthetic back-translated data, filtered and curated using a comprehensive data processing pipeline that combines embedding-based, heuristic-based, and ratio-based filters. Additionally, we employ noisy channel reranking to improve translation candidates using a language model and a channel model trained in the opposite direction.

On two benchmark datasets, our systems outperform **mBART50 M2M** and perform slightly worse than **NLLB 200 MoE**, both unconstrained systems with significantly more parameters.

Our results show that established best practices still perform strongly on constrained systems without the need for extraneous data sources as is with unconstrained systems for the same translation directions.

Limitations

We benchmark on datasets that are publicly available with permissive licenses for research.

We note that we are unable to study scale properly for translation models due to a lack of stronger compute resources. The same constraint also prevents us from training multiple iterations of the same model with differing random seeds. Our systems' true performance may thus be higher or lower depending on the machine random state at the start of training time.

Lastly, our models are trained on Hebrew, which is a language that we do not speak. We are therefore unable to manually evaluate if the output translations are correct, natural, or semantically sound.

Ethical Considerations

Our paper replicates best practices in data preprocessing, model training, and online decoding for translation models. Within our study, we aim to create experiments that replicate prior work under comparable experimental conditions to ensure fairness in benchmarking.

Given that we do not speak the target language in the paper, we report performance in comparison to other existing models. We do not claim that "strong" performance in a computational setting correlates with good translations from a human perspective.

Lastly, while we do not use human annotators for this paper, the conference (WMT) itself does for human evaluations on the General Translation Task. We disclose this fact and note that annotations (and therefore scores) may be different across many speakers of Hebrew.

Abstract

In this paper, we describe our NAIST-NICT submission to the WMT'23 English ↔ Japanese general machine translation task. Our system generates diverse translation candidates and reranks them using a two-stage reranking system to find the best translation. First, we generated 50 candidates each from 18 translation methods using a variety of techniques to increase the diversity of the translation candidates. We trained seven models per language direction using various combinations of hyperparameters. From these models we used various decoding algorithms, ensembling the models, and using kNN-MT (Khandelwal et al., 2021). We processed the 900 translation candidates through a two-stage reranking system to find the most promising candidate. In the first step, we compared 50 candidates from each translation method using DrNMT (Lee et al., 2021) and returned the candidate with the best score. We ranked the final 18 candidates using COMET-MBR (Fernandes et al., 2022) and returned the best score as the system output. We found that generating diverse translation candidates improved translation quality using the well-designed reranker model.

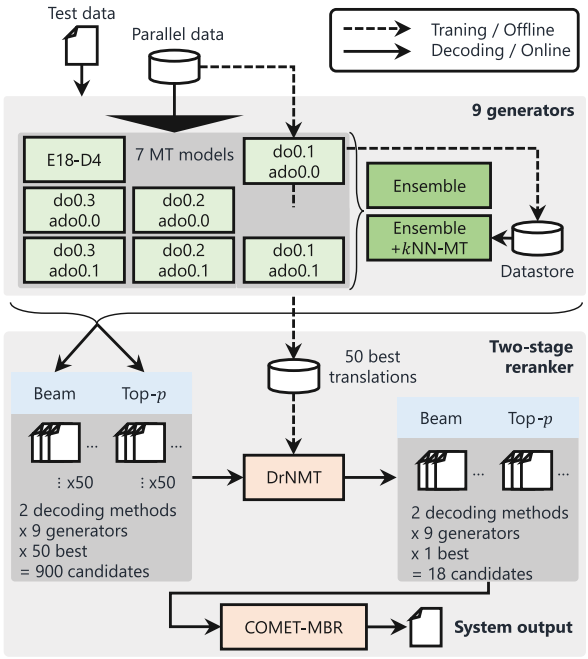

Figure 1: Overview of our system. "E18-D4" denotes "18-layer encoder and 4-layer decoder", and "do" and "ado" denote "dropout" and "dropout after applying attention softmax", respectively.

1 Introduction

We participated in the WMT'23 general machine translation task for English-to-Japanese (En-Ja) and Japanese-to-English (Ja-En) translation. Our team aimed to improve translation performance using only the provided parallel data. Our system generates diverse translation candidates and reranks them using a two-stage reranking system to find the best translation.

Figure 1 shows an overview of our system. We trained 7 Transformer (Vaswani et al., 2017) NMT models per language direction using various combinations of hyperparameters. The translation generator consists of 9 instances: 7 MT models, the ensemble model, and a kNN-MT (Khandelwal et al., 2021) system that interpolates tokens from retrieved examples using the ensemble model. The generator generates the 50-best translations each from two decoding methods: beam search and top-p sampling. This combination allows the generator to find diverse translation candidates. Next, the 900 candidates (9 generators $\times$ 2 decoding methods $\times$ 50 best) are passed to our two-stage reranker to find the best translation. The first step of reranking uses DrNMT (Lee et al., 2021) to rerank the 50-best translation candidates to select the 1-best translation from each of the 18 generator and decoding method combinations. DrNMT is trained to maximize the BLEU (Papineni et al., 2002) score, whereas we use the second step reranking to find the highest COMET (Rei et al., 2020) score expectation from the remaining candidates. The 18

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 110–118
December 6–7, 2023.

candidates from the first step are reranked using COMET-MBR (Fernandes et al., 2022) to select the best translation that is returned by the system.

Our experiments show that our two-stage reranker outperforms the BLEU, chrF, and COMET scores by DrNMT alone, and the BLEU and chrF scores by COMET-MBR alone in both En-Ja and Ja-En translation tasks on wmttest2022 (Kocmi et al., 2022).

2 Preprocessing

For the training data, we used the provided bilingual parallel data, which included JParaCrawl v3 (Morishita et al., 2020), News Commentary v18.1, Wiki Titles v3, WikiMatrix, the Japanese-English Subtitle Corpus (Pryzant et al., 2017), the Kyoto Free Translation Task Corpus (Neubig, 2011), and the Web Inventory of Transcribed and Translated Talks (Cettolo et al., 2012). We did not backtranslate the monolingual data due to resource constraints for training MT models and a reranker model.

As the English translation of the Japanese-English Subtitle Corpus was only available in lowercase, we trained a Moses truecaser (Koehn et al., 2007) using the other corpora to add capitalization to the subtitle corpus. After truecasing, the first letter of each sentence was capitalized using detruecasing to produce sentence-case English text that matched the casing in the other corpora.

We cleaned the data by removing duplicate lines and applying language filtering. Because much of the training data were crawled from the internet, we used fasttext (Joulin et al., 2016a,b) to predict the language of each sentence and removed sentences that were not predicted to be in the correct language. This helped to reduce noise in the dataset by removing sentences with garbage tokens.

We tokenized text into subword units using sentencepiece (Kudo and Richardson, 2018). Since our system generates many candidates using multiple models, we preliminary measured the generation speed and selected the number of vocabulary with the fastest decoding. Our initial experiments demonstrated that when the target language was Japanese, a vocabulary size of 32k resulted in fewer tokens needing to be generated, which increased the translation speed. However, when the target language was English, a vocabulary size of 16k was faster than an English vocabulary of 32k. Therefore, we trained separate dictionaries for English and Japanese, with the English-side dictionary containing nearly 16k tokens and the Japanese-side containing nearly 32k tokens. The character coverage of the tokenizers also varied between languages. We trained the English tokenizer with 100% character coverage, whereas character coverage for Japanese was 99.98%.

After subword segmentation, we removed all sentences shorter than one token or longer than 250 tokens. We also removed all sentences in which the number of tokens in one language was more than double the number of tokens in the translation, i.e., the ratio of tokens between the source and target was >2.0. The number of sentence pairs before/after preprocessing is shown in Table 1.

	#sentence pairs
No filter	33,875,242
+ deduplicate	29,940,444
++ language filter	29,279,161
+++ length filter	27,880,378

Table 1: Number of sentence pairs in the training data after each preprocessing step.

3 Translation System

3.1 Generator

The generator generates diverse translation candidates from multiple models and multiple decod-

ing methods. The generator consists of seven MT models, an ensemble of the seven models, and the ensemble enhanced with kNN-MT (Khandelwal et al., 2021) for a total of 9 instances.

3.1.1 MT models

The 7 MT models are trained from the provided parallel data. Our MT model with the default setting is shown in Table 2. Six of the seven models vary from the default setting only in dropout and attention dropout, while the last varies the number of layers. Our model has two types of dropouts whose values are varied: "dropout (do)" and "attention dropout (ado)". The dropout (do) is applied to the token embedding layer and the outputs of the sub-layers within each layer, i.e., the outputs of the attention layers and feed-forward network. The attention dropout (ado) is applied after softmax to the attention weights, i.e., before multiplying the values. Six models are trained with varying dropouts, one for each combination of $\mathrm{do} = \{0.1, 0.2, 0.3\}$ and $\mathrm{ado} = \{0.0, 0.1\}$. In addition to the models that vary dropout, we trained a deep-shallow model (Kasai et al., 2021), which has 18 encoder layers and 4 decoder layers. For each model, we averaged the parameters of the last 10 checkpoints (10,000 training steps).

3.1.2 kNN-MT

Datastore construction kNN-MT (Khandelwal et al., 2021) requires a datastore to be constructed to store the translation examples to be accessed during decoding. Let $\boldsymbol{x} = (x_1, \ldots, x_{|\boldsymbol{x}|}) \in \mathcal{V}_X^{|\boldsymbol{x}|}$ and $\boldsymbol{y} = (y_1, \ldots, y_{|\boldsymbol{y}|}) \in \mathcal{V}_Y^{|\boldsymbol{y}|}$ denote a source sentence and target sentence, respectively, where $|\cdot|$ is the length of the sequence, and $\mathcal{V}_X$ and $\mathcal{V}_Y$ are the vocabularies of the source language and target language, respectively. The datastore for kNN-MT consists of translation examples in the form of key–value pairs, as shown in Figure 2. Each target token y_t from the translation examples is stored in the datastore with a d-dimensional key ($\in \mathbb{R}^d$), which is the representation of the translation context $(\boldsymbol{x}, \boldsymbol{y_{<t}})$ obtained from the decoder of the pre-trained NMT model. The datastore $\mathcal{M} \subseteq \mathbb{R}^d \times \mathcal{V}_Y$ is formally defined as a set of tuples as follows:

$$\mathcal{M} = \{(f(\boldsymbol{x}, \boldsymbol{y}_{<t}), y_t) \mid (\boldsymbol{x}, \boldsymbol{y}) \in \mathcal{D}, 1 \leq t \leq |\boldsymbol{y}|\}, \quad (1)$$

where $\mathcal{D}$ denotes parallel data and $f : \mathcal{V}_X^{|\boldsymbol{x}|} \times \mathcal{V}_Y^{t-1} \to \mathbb{R}^d$ returns the intermediate representation of the final decoder layer from the source sentence and prefix target tokens. The representation used as the key vector is the vector that is passed into the final feed-forward layer (Khandelwal et al., 2021).

In our system, we used the model trained with the default settings (as seen in Table 2) to obtain the keys for the datastore.

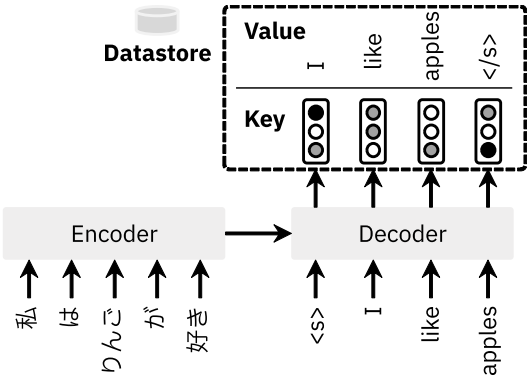

Figure 2: Datastore construction.

# of probed clusters	32

Table 3: Hyperparameters of our kNN indexes and kNN-MT.

kNN index To search the k-nearest-neighbor tokens efficiently, we used FAISS (Johnson et al., 2019). For the kNN indexes, we used `faiss.IndexIVFPQ` which consists of an inverted file index (IVF) that performs k-means clustering and product quantization (PQ) (Jégou et al., 2011) which divides a vector into M sub-vectors and performs vector quantization in each subspace. Note that in IVFPQ, the codewords of PQ are learned from the residual vectors from the centroids of the IVF. Additionaly, we used optimized PQ (OPQ) (Ge et al., 2014) to reduce the quantiza-

tion error of PQ. The hyperparameters of our kNN indexes are summarized in Table 3.

Decoding During decoding, kNN-MT retrieves the k-nearest-neighbor key–value pairs $\{(\boldsymbol{k}_i, v_i)\}_{i=1}^{k} \subseteq \mathbb{R}^d \times \mathcal{V}_Y$ from the datastore $\mathcal{M}$ using the query vector $f(\boldsymbol{x}, \boldsymbol{y}_{<t})$ at timestep t. Next, $p_{k\mathrm{NN}}$ is calculated as follows:

$$p_{k\mathrm{NN}}(y_t|\boldsymbol{x}, \boldsymbol{y}_{<t}) \propto \sum_{i=1}^{k} \mathbb{1}_{y_t=v_i} \exp \frac{-\|\boldsymbol{k}_i - f(\boldsymbol{x}, \boldsymbol{y}_{<t})\|_2^2}{\tau}, \quad (2)$$

where τ is the temperature parameter for $p_{k\mathrm{NN}}$. Then, kNN-MT generates the output probability by computing the linear interpolation between the kNN and MT probabilities, $p_{k\mathrm{NN}}$ and p_{MT}, respectively:

$$P(y_t|\boldsymbol{x}, \boldsymbol{y}_{<t}) = \lambda p_{k\mathrm{NN}}(y_t|\boldsymbol{x}, \boldsymbol{y}_{<t}) + (1-\lambda) p_{\mathrm{MT}}(y_t|\boldsymbol{x}, \boldsymbol{y}_{<t}). \quad (3)$$

kNN-MT with the ensemble model kNN-MT is typically used with a single model, whereas in our system, we obtain the output probability for each token by interpolating between the kNN probability and the probability from the ensemble model. The output probability from the ensemble kNN-MT is formulated by defining p_{MT} in Equation 3 as follows:

$$p_{\mathrm{MT}}(y_t|\boldsymbol{x}, \boldsymbol{y}_{<t}; \boldsymbol{\theta}) = \frac{1}{|\boldsymbol{\theta}|}(p_{\mathrm{MT}}(y_t|\boldsymbol{x}, \boldsymbol{y}_{<t}; \theta_1) + \ldots + p_{\mathrm{MT}}(y_t|\boldsymbol{x}, \boldsymbol{y}_{<t}; \theta_{|\boldsymbol{\theta}|}), \quad (4)$$

where $\boldsymbol{\theta} = \{\theta_1, \ldots, \theta_{|\boldsymbol{\theta}|}\}$ denotes the parameters of the trained MT models; $|\boldsymbol{\theta}| = 7$ in our system. The kNN-MT decoding interpolated between the token distribution of the retrieved translation context tokens and the full ensemble of models. As such, the weight assigned to the kNN token distribution was kept small so as not to overpower the information from the ensemble. We used $\lambda = 0.1$ and $\tau = 100$ in the kNN-MT decoding shown in Table 3.

3.1.3 Decoding algorithms

From each model, we output the 50 best hypotheses generated using beam search with a beam width of 50. For diversity, we generated another 50 hypotheses using top-p sampling with $p = 0.7$ and a beam width of 50. We formed an ensemble of models to produce two more sets of 50 hypothesis sentences from beam search and top-p sampling.

3.2 Reranker

We use a two-stage reranker consisting of an intra-system reranker, which selects the best of the 50 hypotheses from each system, and an inter-system reranker, which selects the best hypothesis from the 18 remaining candidate translations.

3.2.1 DrNMT

Discriminative reranking for NMT (DrNMT) (Lee et al., 2021) is a discriminative model that learns to predict the distributions of the evaluation scores of a set of translation hypotheses given a source sentence. DrNMT is similar to a quality estimation model (Zerva et al., 2022), but it is optimized to distinguish the better translation from hypotheses generated from a single system. In addition, it cannot be used for comparing inter-systems because the weights for features are tuned using the translation hypotheses of the development set. We used BLEU (Papineni et al., 2002) as the evaluation metric for this first-stage reranker.

Model The DrNMT model takes as input a source sentence $\boldsymbol{x} \in \mathcal{V}_X^{|\boldsymbol{x}|}$ concatenated with a hypothesis translation $\boldsymbol{y}^{(j)} \in \mathcal{V}_Y^{|\boldsymbol{y}^{(j)}|}$. The DrNMT model passes this into XLM-R (Conneau et al., 2020), which is a multilingual pre-trained encoder. The hidden state of the `[CLS]` token then represents the combination of the source and hypothesis and is converted into a scalar score by the classification head of RoBERTa (Liu et al., 2019). We used an input dimension of 1,024, a hidden dimension of 768, and output dimension of 1. The activation function for the classification head is tanh.

Objective The objective function minimizes the KL-divergence between the DrNMT model distribution and the distribution of BLEU scores of the n-best hypotheses; that is, the objective function $\mathcal{L}(\theta)$ is as follows:

$$\mathcal{L}(\theta) = \mathrm{KL}[p_T \parallel p_M] = -\sum_{j=1}^{n} p_T\left(\boldsymbol{y}^{(j)}, \boldsymbol{y}^*\right) \log p_M\left(\boldsymbol{y}^{(j)}|\boldsymbol{x}; \theta\right), \quad (5)$$

where n denotes the number of translation hypotheses, and p_M and p_T denote the distributions of the DrNMT model and BLEU scores, respectively. $\boldsymbol{y}^*$ denotes the reference translation of $\boldsymbol{x}$. The BLEU scores are normalized using min-max scaling and the distribution of the BLEU scores is emphasized

using the temperature coefficient T. In this paper, we use $T = 0.5$.

Training We trained the DrNMT model using the 50 best translation hypotheses generated by the model with the default configuration for each source sentence over the entire training set, i.e., 28M source sentences. The model is trained using early stopping, which selects the checkpoint with the maximum BLEU score in the validation set.

Tuning The score of the first-stage reranker is a weighted sum of the DrNMT model score, translation model score, and length penalty. This combination of scores is similar to minimum error rate training (Och, 2003). The weights that maximize the BLEU score of the validation set were learned and used.

Implementation We used the implementation published in FAIRSEQ[1]. Note that this implementation uses SACREBLEU (Post, 2018) to compute the BLEU scores. We modified the published code of DrNMT to change the SACREBLEU tokenizers according to the target language because the published implementation always calls the English tokenizer.

3.2.2 COMET-MBR

COMET-MBR (Fernandes et al., 2022) performs minimum Bayes risk (MBR) decoding (Kumar and Byrne, 2004; Eikema and Aziz, 2020; Müller and Sennrich, 2021; Eikema and Aziz, 2022) using a COMET (Rei et al., 2020, 2022) model trained on direct assessments. A translation $\hat{\boldsymbol{y}}^{\text{MAP}} \in \mathcal{V}_Y^{|\boldsymbol{y}^*|}$ is typically generated using maximum-a-posteriori (MAP) decoding as follows:

$$\hat{\boldsymbol{y}}^{\text{MAP}} = \underset{\boldsymbol{y} \in \mathcal{Y}}{\operatorname{argmax}} \log p(\boldsymbol{y}|\boldsymbol{x}), \tag{6}$$

where $\mathcal{Y} \subseteq \bigcup_{i=1}^{\infty} \mathcal{V}_Y^i$ is the search space of target sentences. In MBR decoding, instead of finding the most probable translation, the goal is to find the translation that minimizes the Bayes risk as follows:

$$\hat{\boldsymbol{y}}^{\text{MBR}} = \underset{\boldsymbol{h} \in \bar{\mathcal{Y}}}{\operatorname{argmax}} \underbrace{\mathbb{E}_{\boldsymbol{y}' \sim p(\boldsymbol{y}|\boldsymbol{x})}[u(\boldsymbol{y}', \boldsymbol{h})]}, \tag{7}$$
$$\approx \frac{1}{m} \sum_{j=1}^{m} u(\boldsymbol{y}^{(j)}, \boldsymbol{h})$$

where $\bar{\mathcal{Y}} \subseteq \mathcal{Y}$ is a set of translation hypotheses and $u : \mathcal{Y} \times \mathcal{Y} \to \mathbb{R}$ is the utility function. In this paper, we used COMET[2] (Rei et al., 2020, 2022) as utility function u. Note that we share the hypotheses $\bar{\mathcal{Y}}$ and the sample set for expectation estimation $\{\boldsymbol{y}^{(1)}, \ldots, \boldsymbol{y}^{(m)}\}$, except for $\boldsymbol{h}$, i.e., $\{\boldsymbol{y}^{(1)}, \ldots, \boldsymbol{y}^{(m)}\} = \bar{\mathcal{Y}} \setminus \{\boldsymbol{h}\}$. Thus, given a candidate set, the computational complexity of MBR decoding is in the order of $\mathcal{O}(m^2)$, which results in a slower inference speed when m is large.

3.2.3 Two-stage reranking

We applied two-stage reranking with DrNMT and COMET-MBR, which allowed us to use each model for the task it was trained to handle best, to optimize for two metrics and to reduce the inference speed of reranking.

In the first stage, DrNMT (Lee et al., 2021) is used to prune the 50 candidates for each candidate set generated from each of the 18 combinations of decoding methods and generators. As DrNMT is trained to rerank the n-best candidates from a single model, it is ideally suited to the task of reranking the candidates generated with the same combination of model and decoding method, i.e., within a system. In the second stage, COMET-MBR (Fernandes et al., 2022) is used to select the system output from the 18 candidate translations selected by DrNMT.

We use COMET-MBR to rerank the best outputs of each system because COMET was trained on translation scores from the output of various models from previous WMT translation tasks, making it well suited to inter-system comparisons. Each of the two stages is trained to optimize a different metric: Stage one uses BLEU, which evaluates surface forms, whereas stage two uses COMET, which evaluates semantics. Additionally, the inference speed of COMET-MBR makes it time-consuming for large candidate sets, but pruning with DrNMT, which performs inference in a single forward computation, reduces the computational cost.

4 Experimental Results

We evaluated the translation performance of our system on wmttest2022 (Kocmi et al., 2022). We measured the BLEU and chrF scores using SACREBLEU, and the COMET score using `Unbabel/wmt22-comet-da`. The models of our

DrNMT+Oracle-COMET-DA	900	30.5	39.1	90.2	29.0	53.7	85.5

Table 4: Experimental results of our system on wmttest2022. "# of cands." denotes the number of candidates generated by the translation generator. The **bold scores** indicate the best scores in each translation direction.

generator were trained using FAIRSEQ (Ott et al., 2019). We used KNN-SEQ[3] (Deguchi et al., 2023) for kNN-MT generation built on top of FAIRSEQ. The first stage of our reranker, DrNMT, was also built using FAIRSEQ, whereas COMET-MBR was built using COMET (Rei et al., 2020).

Table 4 shows the results of our system. In the table, the translation candidates of "1-best of the ensemble" were generated using the ensemble model without kNN-MT using beam search decoding. The candidates of "DrNMT" were generated using the ensemble model and the 50-best translations were obtained using beam search decoding. As DrNMT uses the log probability of an MT model for inference, it cannot compare candidates generated by different MT models or generation methods. The results show that DrNMT not only improved the BLEU scores but also the chrF and COMET scores from the 1-best translation, despite only being trained to maximize the BLEU score. "COMET-MBR" reranks all candidates, i.e., 900 translations (= 9 generators $\times$ 2 decoding methods $\times$ 50 best candidates). COMET-MBR achieved the highest COMET scores for both En-Ja and Ja-En, but the BLEU and chrF scores were not improved for Ja-En, and the inference speed of COMET-MBR with 900 translation candidates was slow. Our primary system used "DrNMT+COMET-MBR" described in Section 3.2.3. This method obtained higher scores for all metrics compared with using DrNMT alone in both translation directions, in addition to the highest BLEU and chrF scores overall. To summarize, our results show that using the rerankers appropriately as intra- and inter-system rerankers is effective for improving translation quality. DrNMT+Oracle-COMET-DA is the oracle performance of the second stage reranker, i.e., the score computed by the largest COMET-DA score for candidates after reranking the 50-best of each system using DrNMT (first stage reranker). Our DrNMT+COMET-MBR scores underperformed the oracle performance, and we leave its improvement for future work.

In addition, we investigated which hypothesis was selected as the system output in DrNMT+COMET-MBR. Figure 3 shows the percentages of counts selected as the system output. In the figure, when the system output comes from multiple hypotheses, i.e., duplicated hypotheses are selected, each hypothesis is counted as selected. The results show that the hypotheses generated by beam search of the ensemble and ensemble+kNN-MT models were selected as the system outputs roughly 40% in En-Ja and 50% in Ja-En. Thus, half of the system outputs were not selected from hypotheses generated from the ensemble model using beam search. Therefore, it can be said that "DrNMT+COMET-MBR" outperformed "DrNMT" by selecting from the hypotheses generated by various generators and various decoding methods.

5 Conclusion

In this paper, we described our submission as a joint team of NAIST and NICT (NAIST-NICT) to the WMT'23 general MT task. We participated in this task in the En-Ja and Ja-En translation directions. We built our system using a diverse translation generator and two-stage reranker. In future work, we will investigate qualitatively how translation diversity contributes to translation quality.

Limitations

A limitation of our system is its reliance on large computation resources. As our system generates 50 candidates using two decoding methods from

[3] https://github.com/naist-nlp/knn-seq

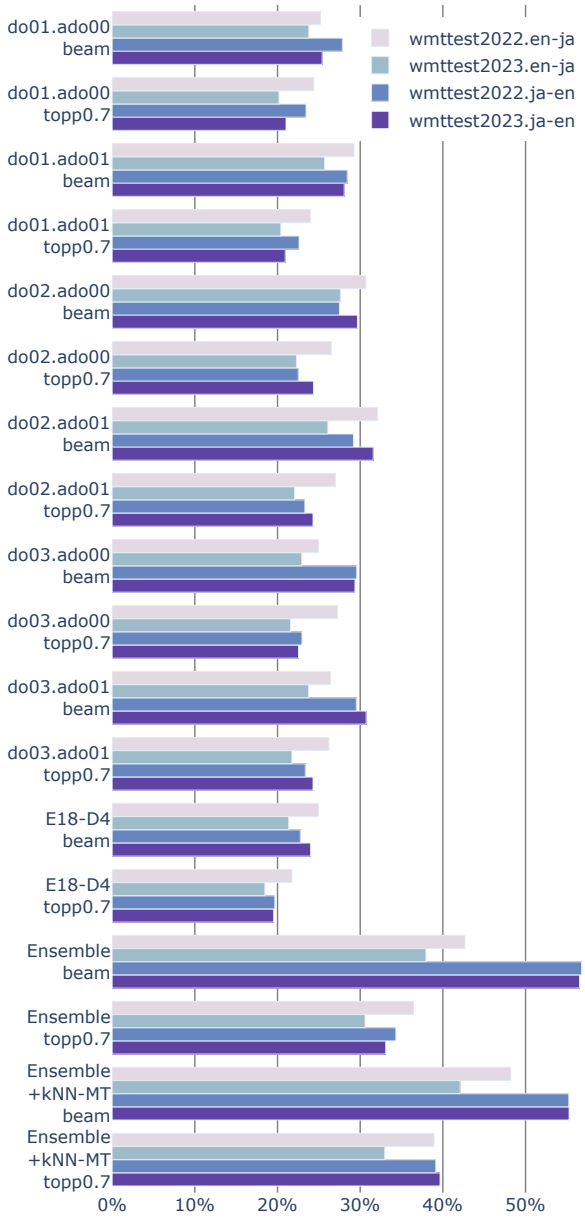

Figure 3: Percentages of counts selected as the system output by COMET-MBR.

each of the nine generators, it requires significant resources. The beam size of 50 is larger than most machine translators and requires more computing power (memory and time).

Note that the reranking approach cannot output translations of higher quality than those translated by the generators.

Ethics Statement

Our system did not restrict the training data and the translator's outputs. Therefore, similar to other translation systems, it may generate factually inaccurate translations.

CUNI at WMT23 General Translation Task: MT and a Genetic Algorithm

Josef Jon and **Martin Popel** and **Ondřej Bojar**
Charles University, Faculty of Mathematics and Physics
Institute of Formal and Applied Linguistics
{jon,popel,bojar}@ufal.mff.cuni.cz

Abstract

This paper presents the contributions of Charles University teams to the WMT23 General translation task (English to Czech and Czech to Ukrainian translation directions). Our main submission, CUNI-GA, is a result of applying a novel n-best list reranking and modification method on translation candidates produced by the two other submitted systems, CUNI-Transformer and CUNI-DocTransformer (document-level translation only used for the $en \rightarrow cs$ direction). Our method uses a genetic algorithm and MBR decoding to search for optimal translation under a given metric (in our case, a weighted combination of ChrF, BLEU, COMET22-DA, and COMET22-QE-DA). Our submissions are first in the constrained track and show competitive performance against top-tier unconstrained systems across various automatic metrics.

1 Introduction

Our submission for this year's WMT General translation task (Kocmi et al., 2023) is based on the previous submissions of our team (Popel et al., 2019, 2022) and MBR decoding in combination with genetic algorithm (GA). We describe the method in separate work (Jon and Bojar, 2023). The main goal of our submission is to find out whether our approach improves the translation quality perceived by humans. For this reason, we submitted both the base system translations and the mutated and reranked (i.e. GA-processed) translations for the human evaluation.

As all the parts of the approach are described in detail in the mentioned papers (as well as all the related work), we will restrict ourselves to providing a short overview of the main points in Section 2. In Section 3, we describe the datasets, tools and parameters used to obtain results presented in Section 4. Finally, we draw conclusions from the results.

2 Methods

Our submissions make use of two features that are not typical for current MT systems: document-level context and translation refinement through a genetic algorithm.

2.1 Document level translation

We use document-level NMT for the $en \rightarrow cs$ direction. The approach is described in Popel et al. (2019). Since all the training data for this direction have document boundaries, a document-level training set is created by extracting all sequences of consecutive sentences with at most 3000 characters. The final training set consists of pairs of such examples, where both sides have the same number of sentences. Sentences are separated by a special token. We also use Block backtranslation (Popel, 2018; Popel et al., 2020; Gebauer et al., 2021; Jon et al., 2022a).

2.2 Genetic algorithm

Our approach (Jon and Bojar, 2023) utilizes MBR decoding (Goel and Byrne, 2000; Kumar and Byrne, 2004; Amrhein and Sennrich, 2022; Freitag et al., 2021; Müller and Sennrich, 2021; Jon et al., 2022b) in conjunction with the genetic algorithm (GA) (Fraser, 1957; Bremermann, 1958; Holland, 1975). By merging and mutating translations generated by an MT system, we aim to find the best translation under a specific metric. This is a new strategy for creating translation candidates in NMT. We illustrate one iteration of the whole process in Figure 1. The top, yellow part shows the steps that are the same as in simple reranking. We have an initial population of candidates, for example, n-best list produced by an MT model, that is scored by *fitness function*, in our case, a sum of MBR decoding scores using an MT evaluation metric and QE scores. At this point, for reranking, the process would stop after selecting the best-scoring translation candidate. In GA, we continue by splitting

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 119–127
December 6–7, 2023.

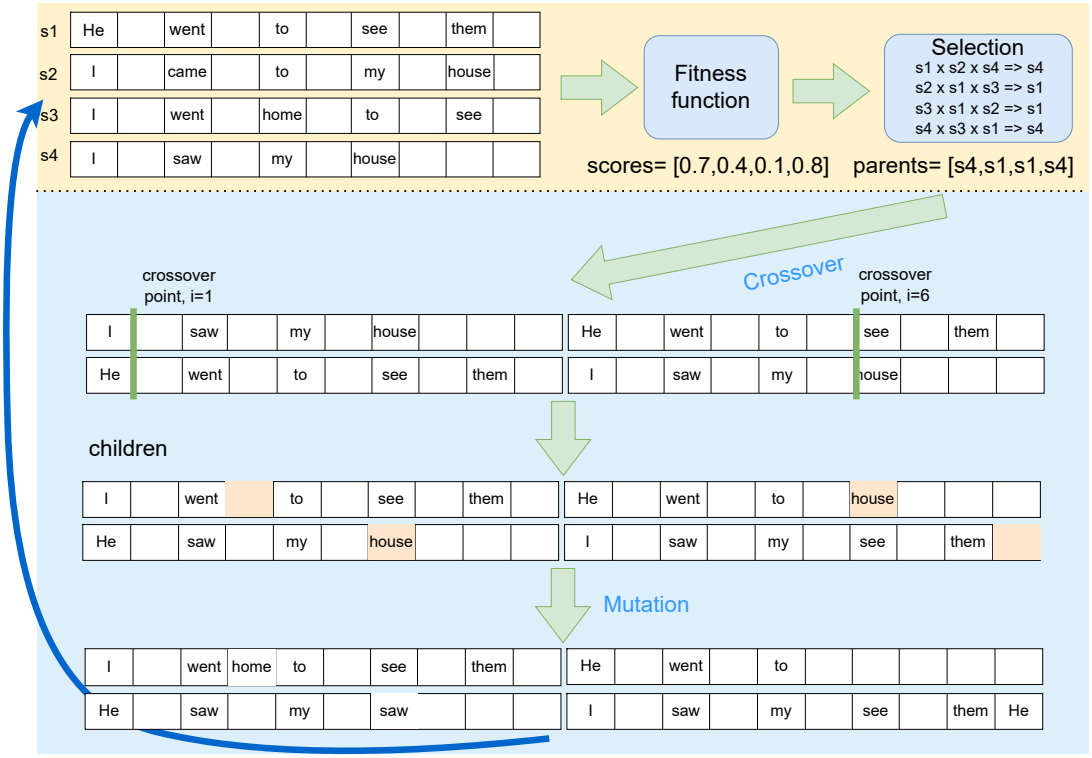

Figure 1: One iteration of the GA algorithm for a population of 4 individuals. The steps with a yellow background are equivalent to simple reranking, the steps with blue background introduce the operations of the genetic algorithm. Figure taken from Jon and Bojar (2023)

a well-scoring subset of the candidate sentences at random points and reattaching them in a different order, by a process called cross-over. These combined candidates are mutated at random places, meaning some of the tokens are either deleted or replaced by different tokens from a set of suitable candidate tokens. Also, new tokens can be added this way. These modifications result in a new population of translation candidates and the whole process is repeated from the start. A more detailed description of our approach is available in Jon and Bojar (2023).

MBR decoding NMT models generate a probability distribution over potential translations for a specified input sentence. The widely used method to derive the ultimate translation from this distribution is "maximum-a-posteriori" (MAP) decoding. However, the computational demands of precise MAP decoding lead to the adoption of approximations like beam search, referenced by Koehn et al. (2003). Recent literature, such as Stahlberg and Byrne (2019) and Meister et al. (2020), has shed light on several constraints of MAP and proposed alternatives.

MBR decoding is one such alternative. It uses a utility function to select the translation, aiming to minimize expected loss or *risk*. Typically, MT metrics are employed as these utility functions. In practice, candidate translations produced by the MT model are used as an approximation of the set of all possible translations. In such case, if we only use purely reference-based metrics (like BLEU), MBR decoding becomes a consensus decoding, where the chosen candidate is the one closest to all the others. However, novel MT metrics also take source sentence into account, so the process is more complex than a simple search for the most average translation. The MBR decoding has seen renewed interest with the introduction of the new generation of metrics (Amrhein and Sennrich, 2022; Freitag et al., 2021; Müller and Sennrich, 2021; Jon et al., 2022b).

3 System description

Our models are based on submissions of our team from previous years (Popel et al., 2022, 2019). We resubmit those (*CUNI-Transformer* and *CUNI-DocTransformer* submissions) and we also submit an additional translation: the outputs of these models combined, mutated and rescored by the GA

described in Section 2.2 (*CUNI-GA* submission).

3.1 Tools and data

All our submissions are constrained, using only the training data provided by the task organizers, specifically the CzEng 2.0 (Kocmi et al., 2020) corpus. We used English to Czech `newstest-18` and `newstest-22` as validation sets for the genetic algorithm approach. Due to the computational requirements of our method, we only evaluate the first 150 sentences of each test set. We didn't run any validation experiments for GA in the $cs \rightarrow uk$ language pair, we used the same parameters as for $en \rightarrow cs$. We have only translated the general translation test set using GA, the test suits translations for *CUNI-GA* are copied from the *CUNI-DocTransformer* submission.

3.2 Models

We use Transformer models. For the dev set experiments, we use same models as Jon and Bojar (2023) (i.e. `transformer-big` using MarianNMT (Junczys-Dowmunt et al., 2018) with default hyperparameters). For the final submissions, the models are the same as in last year's submissions: Popel et al. (2022) for $cs \rightarrow uk$ and Popel et al. (2019) for $en \rightarrow cs$.

3.3 GA parameters

We refrained from searching for the optimal values of GA parameters due to the significant computational demands of our method.

For the results on the validation set, we used exactly the settings described by Jon and Bojar (2023), i.e. Transformer model trained on the CzEng 2.0 (Kocmi et al., 2020) corpus in $cs \rightarrow en$ direction (i.e. the opposite direction to the task). We used beam search with size 20 to produce a 20-best list and sampled an additional 20 translations from the model to create an initial population of 40 candidates, which we copied 50 times to obtain a population size of 2000.

We used different NMT models (see Section 3.2) and a different number of initial sentences for the shared task submissions. For the $cs \rightarrow uk$ direction, the starting population consists of the top 35 hypotheses produced by beam search from the two models described in Popel et al. (2022) (top-10 from the *CUNI-Transformer-inca-roman* and top-25 from the *CUNI-Transformer* model).[1] This set is replicated 50 times, leading to a total population of 1750 candidates. For $en \rightarrow cs$ we use a concatenation of n-best lists with beam sizes 4 and 10 from both *CUNI-DocTransformer* and *CUNI-Transformer* (28 candidates in total), also copied 50 times over, resulting in population size of 1400. To combine document-level and sentence-level translations, we re-split the translated documents back into sentences.

To choose parents for the succeeding generation, we use tournament selection with $n = 3$. These parents are then merged at a crossover rate of $c = 0.1$. The mutation rate, for altering non-empty genes (i.e. tokens) to other non-empty genes m, is $1/l$, where l denotes the chromosome's (chromosome is a sequence of tokens, representation of one translation candidate) length[2] For transitions from an empty to a non-empty gene (i.e. addition of a word) and vice versa (i.e. deletion), the rate is $\frac{m}{10}$. The GA runs for 250 and 130 generations for $cs \rightarrow uk$ and $en \rightarrow cs$, respectively.

3.4 Metrics

The translations are evaluated by the following metrics: ChrF (Popović, 2015), BLEU (Papineni et al., 2002), BLEURT (Sellam et al., 2020), multiple versions of COMET (Rei et al., 2020, 2021, 2022b,a,c) and UniTE (Wan et al., 2022). We abbreviate some of the longer metrics' names further in the text in order to save space.[3]

For both BLEU and ChrF, we utilize SacreBLEU (Post, 2018). In all experiments, ChrF uses a $\beta = 2$ setting (ChrF2). We rely on the original implementations for COMET,[4] BLEURT,[5] and UniTE[6] scores.

4 Results

This section presents automatic metric scores on validation sets and the official test set.

4.1 English to Czech

The first translation direction is English to Czech, where we submitted the outputs of our older sentence-level (*CUNI-Transformer*) and document-level (*CUNI-DocTransformer*) systems, as well as

[1] The *CUNI-Transformer-inca-roman* uses preprocessing using romanization and inline casing (Popel et al., 2022).

[2] See Jon and Bojar (2023) for a more detailed description.

Table 3: Scores of translations on the first 150 sentences of `newstest-22` created by GA. The fitness metric is a weighted sum of COMET, COMET-QE, BLEU and chrF, with weight shown in columns 2 to 5. The first column shows which version of COMET and COMET-QE was used. Higher is better for all the metrics. The best results for each COMET version are bold.

a combination and modification of both using our GA approach.

GA vs. reranking Jon and Bojar (2023) provide a comparison of the genetic algorithm approach to a simple reranking using the same objective metrics. In that work, a sum of CMT20, QE20 and BLEU is used as the fitness metric. The results are copied in Table 1. The baseline translations are obtained via beam search. The same work also shows that for UniTE, CMT22, CMT21-MQM held-out metrics[7], GA significantly outperforms simple reranking with the same objective metric. However, BLEURT, CMTH22 and chrF seem to favor reranking only.

For our current work, we ran additional experiments. We use a weighted sum of COMET, COMET-QE, chrF and BLEU as the objective (fitness) metric. We compare older and newer versions of both COMET and COMET-QE, represented by CMT20/QE20 and CMT22/QE22, respectively. Since the objective metrics lose their relevance for evaluation once we optimize for them, a set of held-out metrics is selected to better estimate the translation quality. The results for the first 150 sentences of `newstest18` are presented in Table 2, and the scores for the first 150 sentences of `newstest22` are presented in Table 3.

We vary the weights of the different fitness metrics to see the effect on the held-out metrics (columns $\mathbf{w_{CMT}}$, $\mathbf{w_{QE}}$, $\mathbf{w_{BLEU}}$ and $\mathbf{w_{chrF}}$). The last column shows a portion of cases where the final selected candidate was not part of the initial population, the other columns show values of the respective scores.

We see an interesting difference between CMT22/QE22 and CMT20/QE20. While optimizing only for CMT20 or CMT20+QE20 hurts other scores greatly (for example UniTe and BLEURT), optimizing solely for CMT22+QE22 does not have such an adverse effect on other metrics. We hypothesize multiple factors play a role in this. One of them might be the better robustness of the newer versions, which are designed to deal better with hallucinations and unexpected target tokens that could be introduced by the GA. CMT20 and especially QE20 were previously shown to be partially insensitive to this kind of errors (Guerreiro et al., 2023), but they could be detected by the other metrics, hence the lower scores.

Final submission Overall, the results suggest the best choice is to simply average CMT22 and QE22 scores ($w_{CMT} = 0.5$, $w_{QE} = 0.5$). We did not have the complete evaluation at hand by the time of the submission, so we used weights $w_{CMT} = 0.4$, $w_{QE} = 0.4$, $w_{BLEU} = 0.1$ and $w_{chrF} = 0.1$ for the submitted test set translation. We use a completely different NMT system than in the dev set experiments to create the initial population for the submission, as described in 3.3.

We show the automatic scores of all the submissions on the test set in Table 4. The *CUNI-GA* submission outperforms both the base submissions *CUNI-Transformer* and *CUNI-DocTransformer* across all metrics. It ranks comparably to the best unconstrained system using COMET, but lags behind in chrF and BLEU.

We analyzed the percentages of the final submitted translated sentences that were present in some of the initial n-best lists and the percentage of novel sentences, created by the GA. We show these results in Table 5. We see that 21.7% of the final submitted sentences are new, not contained in any of the initial n-best lists, but rather created by the GA mutation and crossover operations.

4.2 Czech to Ukrainian

We also ran the GA on a concatenation of n-best lists produced by the two $cs \rightarrow uk$ models, see Popel et al. (2022) for details on these systems. We used beam size 10 for the *CUNI-Transformer-inca-roman* model and beam size 25 for the *CUNI-Transformer* model, resulting in 35 initial candidate sentences. We did not perform any parameter tuning on the validation set, we used the same parameters as for the $en \rightarrow cs$ submission. We present the automatic metrics results on the test set in Table 6. Our submissions outperform the only other constrained system and are competitive with the unconstrained systems, scoring best in COMET and 2nd in chrF and BLEU. For COMET and chrF, GA outperforms the unmodified baseline translation, while in BLEU, the baseline scores slightly better.

Again, we show what is the percentage of final best translations selected for submission contained in either of the initial n-best lists and the percentage of new translations, created by GA operations, in Table 7. 35.1% of the final submitted translations are novel.

[7]Means metrics not used as a part of the fitness function. Note that these metrics are not completely independent, they can be still linked to the fitness metrics by spurious correlations caused by data and model architecture similarity

Table 4: Results of automatic evaluation on $en \rightarrow cs$ testset. Unconstrained systems are indicated with a grey background. Coincidentally, all three $en \rightarrow cs$ unconstrained systems are our submissions described in this paper. CUNI-GA is better than the two baselines according to all three metrics.

	doc-4	doc-10	sent-4	sent-10	new
contains	36.3%	42.1%	31.4%	52.8%	21.7%
unique	2%	6.8%	0.7%	17.5%	
merge	50.0%		53.5%		
u-merge	24.7%		33.3%		

Table 5: Percentages of final best scoring in CUNI-GA English to Czech submission sentences by the initial n-best list they are contained in (doc-4 denotes document-level, beam size 4 and so on). The first row shows how many sentences from the final translation were present in the respective n-best list, while the last column shows the percentage of completely new sentences, that were not present in any of the lists. The second row looks at the percentages of final sentences that are uniquely in exactly one of the lists. The last two rows show the same for merged doc-level and sent-level lists, i.e. we concatenated both beam sizes for each into one list.

5 Future work

Our setting allows many straightforward modifications to potentially improve the results of our method. First of all, MBR decoding works well on a large, diverse set of initial candidates, obtained for example by sampling. In our experiments, we only use short n-best lists produced by beam search. An additional benefit stemming from the diversity of the initial candidates is a more dive diverse set of possible tokens for replacement mutations.

Second, we did not run any search for the parameters of the GA process (crossover and mutation rates, number of generations, population size, selection method), due to the large computational costs of this approach. We believe a set of better parameters could be found easily by, for example, a grid search. Finally, the metrics used for the fitness function are combined by a simple weighted sum. Multi-criterion genetic algorithms can be explored for a better approach to combine multiple evaluation scores for the translations.

Also, reranking and modifying the translations on a sentence level can introduce inconsistencies previously mitigated by using document-level MT, losing the advantages of document-level processing. Deutsch et al. (2023) show that using sentence-level metrics for whole document-level segments might be a viable option for avoiding this issue.

6 Conclusion

We confirm that using MBR decoding in combination with a genetic algorithm can improve scores in selected evaluation metrics, while creating original novel translations. We show that our systems are competitive in both submitted language pairs, winning among constrained systems based on automated evaluation metrics.

♢Tohoku University ♠NTT Communication Science Laboratories

Abstract

The SKIM team's submission used a standard procedure to build ensemble Transformer models, including base-model training, back-translation of base models for data augmentation, and retraining of several final models using back-translated training data. Each final model had its own architecture and configuration, including up to 10.5B parameters, and substituted self- and cross-sublayers in the decoder with a cross+self-attention sublayer (Peitz et al., 2019). We selected the best candidate from a large candidate pool, namely 70 translations generated from 13 distinct models for each sentence, using an MBR reranking method using COMET and COMET-QE (Fernandes et al., 2022). We also applied data augmentation and selection techniques to the training data of the Transformer models.

1 Introduction

This paper provides a system description of submissions by our team, called SKIM[1], at WMT-2023. We took part in English to Japanese (En→Ja) and Japanese to English (Ja→En) General Machine Translation tracks (Kocmi et al., 2023). We specifically participated in the constrained track, which places restrictions on the available data and pre-trained models.

The trial of this year's submissions is a reranking part. Our submission system consists of multiple translation models, followed by a reranking module (Kobayashi, 2018) based on COMET (Rei et al., 2022a) and COMET-QE (Rei et al., 2021). This reranking approach serves to identify and select high-quality translations from the hypothesis candidate set generated by multiple translation models. Among the Transformer-based translation models, we also incorporated a large Transformer model with 10.5B parameters. We also applied data augmentation techniques based on our previous year's system (Morishita et al., 2022b). We briefly describe the system overview, including the experimental results that could not be submitted.

[1]The team name is an anagram of the first letters of the authors' last names.

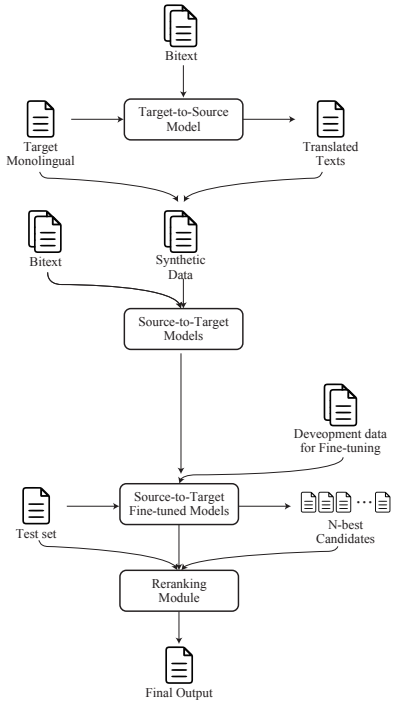

Figure 1: System overview.

2 System Overview

An overview of our submission system is shown in Figure 1. Following the development process used for last year's system (Morishita et al., 2022b), we used Transformer (Vaswani et al., 2017) as the model architecture and conducted pre-training and fine-tuning. In the pre-training phase, we used both a synthetic dataset created by back translation (Sennrich et al., 2016) and the provided bitext dataset. Here, we refer to the target-to-source translation model to generate this synthetic dataset as the initial translation model. Furthermore, we conducted fine-tuning on the translation models derived from pre-training using high-quality bitext

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 128–136
December 6–7, 2023.

Initial Translation Model	
Subword Size	32,000
Architecture	Transformer (big) with FFN size of 4,096
Optimizer	Adam ($\beta_1 = 0.9, \beta_2 = 0.98, \epsilon = 1 \times 10^{-8}$)
Learning Rate Schedule	Inverse square root decay
Warmup Steps	4,000
Max Learning Rate	0.001
Dropout	0.3
Gradient Clip	1.0
Batch Size	1,280,000 tokens
Number of Updates	50,000 steps
Averaging	Save a checkpoint every 200 steps and average the last eight
Implementation	`fairseq` (Ott et al., 2019)
Pre-training Configuration	
Subword Size	64,000
Architecture	(See Table 4)
Optimizer	Adam ($\beta_1 = 0.9, \beta_2 = 0.98, \epsilon = 1 \times 10^{-8}$)
Learning Rate Schedule	Inverse square root decay
Warmup Steps	4,000
Max Learning Rate	0.001
Dropout	0.3 / 0.1
Gradient Clip	0.1 / 1.0
Batch Size	1,024,000 / 64,000 tokens
Max. Num. of Updates	60,000 / 100,000 (stoped at 64,000)
Averaging	Save a checkpoint every 2,000 steps and average the last ten
Implementation	`fairseq` (Ott et al., 2019)
Fine-tuning Configuration	
Subword Size	Identical to Pre-training Configuration
Architecture	(See Table 4)
Optimizer	Adam ($\beta_1 = 0.9, \beta_2 = 0.98, \epsilon = 1 \times 10^{-8}$)
Learning Rate Schedule	Fixed
Warmup Steps	N/A
Max Learning Rate	0.00001
Dropout	0.3 / 0.1
Gradient Clip	1.0
Batch Size	16,000 / 14,400 tokens
Number of Updates	400 / 200
Averaging	Save a checkpoint every ten steps and average the last ten
Implementation	`fairseq` (Ott et al., 2019)

Table 1: List of hyper-parameters. We used the initial translation model for creating synthetic data, pre-training configuration to construct pre-training models described in Section 4.2, and fine-tuning configuration to construct models for submission. Note that we used slightly different settings for 10.5B models in a few parameters. We show their settings at the righthand side of the slash mark (/). We used several different model configurations for ensembling. See Table 4 for more details.

datasets (i.e., development data provided by the organizers). When developing last year's submission system, we found that fine-tuning with clean data enhanced translation quality more effectively than domain adaptation. Therefore, we used a similar fine-tuning approach for this year's submission system. By using these datasets, we trained multiple Transformer-based translation models with heterogeneous configurations. During the inference phase, we translated the source sentences using these translation models individually and selected the final translation results using a subsequent reranking process. As reranking, we tried two methods: one used COMET-QE and the other used COMET-MBR (Fernandes et al., 2022) extended to the outputs of multiple models.

Corpus	w/o Filtering	w/Filtering
JParaCrawl v3.0	25.7 M	25.0 M
WikiMatrix	3.89 M	3.64 M
JESC	2.80 M	2.57 M
Wiki Titles v3	757 K	327 K
KFTT	440 K	371 K
TED Talks	242 K	224 K
NewsCommentary v18	3.8 K	3.7 K

Table 2: Number of sentence pairs in bitext corpus.

3 Dataset Construction

3.1 Provided Data

Bitext Corpus We used all the provided bitext corpora: JParaCrawl v3.0 (Morishita et al., 2022a), News Commentary v18, Wiki Titles v3, WikiMatrix, Japanese-English Subtitle Corpus (JESC) (Pryzant et al., 2018), The Kyoto Free Translation Task (KFTT) Corpus (Neubig, 2011), and TED Talks (Cettolo et al., 2012). We filtered out the potentially noisy pairs using the straightforward parallel corpus filtering methods, just as we did with last year's system (Morishita et al., 2022b). Table 2 shows the size of each dataset with/without filtering. Compared to the previous year, the organizers updated the NewsCommentary, resulting in an increase of 1.8 K sentences.

Monolingual Corpus We also used the following provided monolingual data: News Crawl, News Commentary, and Common Crawl. We back-translated the monolingual sentences using a target-to-source model (i.e., an initial translation model) trained only with the provided bitext dataset, as described in Section 3.2, and used them as synthetic data (Sennrich et al., 2016).

	#sent. pairs	#subwords (JA)	#subwords (EN)
En→Ja	587 M	12.9 B	15.0 B
Ja→En	681 M	17.2 B	16.7 B

Table 3: Statistics of synthetic data used for pre-training.

3.2 Building Pre-Training Data

Synthetic Data Construction To augment the training data, we constructed synthetic data by applying the initial translation model trained with bitext to the monolingual data. As a preprocessing step, we truecased[2] both the bitext and monolingual data. We then tokenized the data into subwords using the `Sentencepiece` tool (Kudo and Richardson, 2018) with the unigram language model option.

We set the vocabulary size to 64,000, the same as the previous year's submission. To integrate insights from the method to create vocabulary for recent large-language models (Touvron et al., 2023), we activated the "byte_fallback" and "split_digits" options. Through preliminary experiments, we confirmed that activating these options leads to enhanced translation performance. As our initial translation model, we used the identical initial translation model we used for last year's submission system (Morishita et al., 2022b). The detailed hyperparameters are described in the initial translation model section of Table 1. Finally, we respectively translated 3.3 B (English) and 1.4B (Japanese) monolingual sentences.

Data Cleaning For both the provided bitext and synthetic data, we carried out cleaning based on a combination of sentence embeddings and handcrafted rules.

For both the bitext and synthetic data, we removed the too-long sentences (>500 characters) and using the `langid`[3] toolkit, removed the sentences that were identified as not being written in English or Japanese.

For the synthetic data, we further applied a sentence embedding-based filtering approach. We took advantage of LaBSE (Feng et al., 2022) to embed the Japanese and English sentences into the same embedding space. We then scored and ranked the parallel sentence pairs based on the cosine similarity of their sentence embeddings. We subsequently filtered out the following items from the synthetic data:

- Duplicated sentence pairs
- Sentences with over 150 words[4] or single words with over 40 characters
- Sentences where the ratio between the word and the character count is > 12
- Sentences that contain invalid Unicode characters
- Sentence pairs where the source/target word ratio exceeds 4
- sentence pairs where the source/target length ratio exceeds 6
- sentence pairs where the source and target sentences are identical
- sentence pairs where the cosine similarity is greater than 0.96[5]

Finally, we respectively selected the top 587M and 681M (approximately) sentences, respectively, from the translated 1.4 B and 3.3 B monolingual sentences as the En→Ja and Ja→En synthetic data for the rank orders. Table 3 shows the statistics of the synthetic data used for our pre-training.

3.3 Fine-Tuning Data

As mentioned in Section 2, during the development of last year's submission system, we found that fine-tuning the model with clean data was more effective for improving translation quality than domain adaptation. Following this finding, we used the WMT'20 test set, WMT'20 development set, WMT'21 test set and WMT'22 test set as clean data for fine-tuning. The WMT'20 test and development sets were all used as clean data. However, for the WMT'21 and WMT'22 test sets, only the opposite language direction data were used (i.e., only Ja→En data were used as clean data for the En→Ja models) because these data were used for development and evaluation. The clean data included 9,002 sentences for En→Ja and 9,026 sentences for Ja→En.

4 Primary Translation Module

We trained several Transformer models for the reranking in the decoding phase. We describe the

[2] https://github.com/moses-smt/mosesdecoder/blob/master/scripts/recaser/truecase.perl

[3] https://github.com/saffsd/langid.py

[4] We tokenized the Japanese sentences using MeCab (Kudo, 2006) with the IPA dictionary. Note that this tokenization is for this cleaning purpose only.

[5] We found that sentence pairs with high cosine similarities can be noisy; for example, the source and target sentences are sometimes identical. Thus, we removed them from the training data.

details of the models in this section. Furthermore, alongside the newly trained models, we reused the primary translation models from the previous year's submission system (Morishita et al., 2022b).

4.1 Model Configuration

We independently trained models with heterogeneous model configurations. Our configuration has several notable characteristics: a cross+self-attention mechanism and a large number of parameters (i.e., 10.5B). In the following sections, we describe the details of the configurations.

Cross+Self-Attention Mechanism We introduced a cross+self-attention mechanism (Peitz et al., 2019) to the Transformer decoder. This mechanism was expected to reduce the model parameters and provide faster training while maintaining the translation performance. In this approach, we eliminated the decoder's cross-attention layer and unified the self-attention and cross-attention into a single attention layer. Specifically, the self-attention layer within the Transformer decoder simultaneously performs the cross-attention calculation by concatenating the output from the encoder's final layer to the query and key matrices.

Suppose Q, K, and V are the query, key, and value matrices, respectively; H_{enc} is the matrix form of concatenating all the output vectors of the encoder's final layer; W_q, W_k, W_v are the weight matrices for the query, key, and value, respectively; and d_k denotes the dimension of the key matrix. It is then formulated as follows:

$$\begin{aligned} &\text{Attention}(Q, K, V, H_{enc}) = \\ &\qquad \text{softmax}\left(\frac{Q_{concat} K_{concat}^T}{\sqrt{d_k}}\right) V' \\ &Q_{concat} = (Q \oplus H_{enc}) W_q \\ &K_{concat} = (K \oplus H_{enc}) W_k \\ &\qquad V' = V W_v \end{aligned} \tag{1}$$

where $\oplus$ means concatenating two matrices in this equation.

Note that cross+self-attention, as well as standard self-attention, assume Q, K, and V to be identical matrices, namely, $Q = K = V = H_{dec}$, where H_{dec} is the matrix form of concatenating input vectors of the corresponding decoder layer.

10.5B Model As demonstrated in Kaplan et al. (2020), the performance of neural models improves as the number of parameters increases. Moreover, previous WMT shared tasks systems, such as Chen et al. (2020), achieved improvements in translation quality using model scaling. Following this insight, we attempted to scale up the translation model. Considering the constraints of GPU memory and training time, we finally configured the model size to be 10.5B parameters.

We also applied the position encoding methods used in last year's submission system (Morishita et al., 2022b). Namely, in the encoder, we employed relative position encoding (Shaw et al., 2018). In the decoder, we used SHAPE (Kiyono et al., 2021). We specified the maximum shift size of SHAPE to be 10.

Previous year's submission models We also incorporated the transformer models developed for the previous year's submission system as the primary translation module. We introduced the bottom-to-top (B2T) connection (Takase et al., 2023) to these models for training stability and relative position encodings (Shaw et al., 2018) to improve their generalization ability to unseen sentence lengths during training. For more details, please refer to (Morishita et al., 2022b).

4.2 Pre-Training

We trained each translation model shown in Table 4 with the filtered bitext and synthetic data described in Section 3.2. In this phase, we used the pre-training configuration shown in Table 1.

Following last year's submission system (Morishita et al., 2022b), the bitext was upsampled until it reached to a ratio of 1:1 with the synthetic data. Moreover, we used the tagged back-translation technique (Caswell et al., 2019) by adding a special token ⟨BT⟩ to the beginning of the source sentences in the synthetic data.

4.3 Fine-Tuning

The fine-tuning data are detailed in Section 3.3, and the hyperparameters utilized during training are as described in Table 1.

4.4 Ensemble

We ensembled the fine-tuned models, except for the 10.5B model, due to the computational resource limitations. We included the ensembled model and individual model outputs as the reranking candidates.

Direction	Configuration	#Params.	Cross+self attention	LN pos.	Encoder				Decoder

Table 4: List of model configurations used by the primary translation module. The upper half of the table shows the models also used in last year's submission system (Morishita et al., 2022b), and the lower half shows the models newly trained this year. d_{model} and d_{ffn} respectively denote sizes of embedding and feedforward layers. LN pos. means the position of layer normalization. Post. denotes that layer normalization is applied after the residual connection. Pre. denotes that layer normalization is performed before the residual connection. ABCI-Base and NTT-Base were each trained with two different seeds.

5 Reranking

To enhance translation quality, we applied a reranking process to the candidate set of hypotheses translated by each model described in Section 4. We conducted a comparative analysis of the various methods, as presented in the following sections.

5.1 Methods

The reranking approach was used to obtain the final output $\hat{y}$ from C, where C represents the candidate set generated by multiple translation models for a given source x.

Quality Estimation (QE) This approach involves scoring the candidates using quality estimation methods (e.g., COMET-QE) and selecting the one with the highest score, as follows:

$$\hat{y} = \underset{c \in \mathcal{C}}{\operatorname{argmax}} \, \text{QE}\,(x, c)\,. \tag{2}$$

where, $\text{QE}(\cdot, \cdot)$ is a quality estimation function.

Minimum Bayes Risk (MBR) This method uses reference-based metrics such as COMET, to yield the best output as follows (Fernandes et al., 2022);

$$\hat{y} = \underset{c_i \in C}{\operatorname{argmax}} \frac{1}{|C|} \sum_{c_j=1}^{|C|} \text{RefMetric}\,(c_i, c_j)\,. \tag{3}$$

where $\text{RefMetric}(\cdot, \cdot)$[6] is a reference-based metric. Note that MBR uses reference-based metrics but not reference texts. MBR is applied to the output of a single model in Fernandes et al. (2022). We extended this method to the outputs from multiple models.

MBR after QE (QE → MBR) This approach is a combination of QE and MBR (Fernandes et al., 2022). We denoted the top-p samples from set C, according to the score calculated by the quality estimation function $\text{QE}(\cdot, \cdot)$, as $C_{\text{top-p}}$. Then, MBR was applied for $C_{\text{top-p}}$.

5.2 Post Evaluation

We experimented with the performance of the translation models and the reranking process. Note that this experiment was conducted after the primary system was submitted.

5.2.1 Experimental Setup

We used WMT21-COMET-QE[7] and WMT22-CometKiwi (Rei et al., 2022b)[8] for the QE, and WMT22-COMET-DA[9] as the refernece-

[6] Some reference-based metrics, such as COMET, also use source x as an input.

[7] https://unbabel-experimental-models.s3.amazonaws.com/comet/wmt21/wmt21-comet-qe-mqm.tar.gz

[8] https://huggingface.co/Unbabel/wmt22-cometkiwi-da

[9] https://huggingface.co/Unbabel/wmt22-comet-da

Models		En→ Ja	Ja → En
NT5	single model	8	8
	4-models ensemble	1	1
	all models ensemble	1	1
NTT	single model	70	40
	all models ensemble	10	10
Failab-LM		10	10
Total		100	70

Table 5: Breakdown of candidates for reranking. The NT5 four-model ensemble consists of ABCI-EncBig, ABCI-EncDeep, Failab-EncBig, and Failab-DecBig. The NT5 all-model ensemble consists of NTT-Base (two different seeds), ABCI-Base (two different seeds), ABCI-EncBig, ABCI-EncDeep, Failab-EncBig, and Failab-DecBig. The NTT all-model ensemble consists of NTT-A to NTT-G.

based metric for MBR. WMT22-COMET-DA was also used as the evaluation metric. The candidate sets contained 100 hypothesis for En→Ja and 70 for Ja→En. The breakdown of each candidate set is shown in Table 5.

5.2.2 Reranking Analysis

Table 6 shows the results of the reranking. Oracle (a) is the upper-bound setting, selecting the final output by using WMT22-COMET-DA with reference text (denoted r):

$$\hat{y} = \underset{c \in \mathcal{C}}{\operatorname{argmax}} \, \texttt{WMT22-COMET-DA}\,(c, r)\,. \quad (4)$$

Comparing the QE and MBR approaches (f and g vs. q) showed that MBR achieved higher performance. As for the QE approach, WMT21-COMET-QE achieved better performance than WMT22-CometKiwi in both translation directions (f vs. g). Therefore, we used WMT21-COMET-QE for the QE → MBR approach. The best performance was achieved by the QE → MBR at smaller p (h, i, j and k) in both translation directions. Moreover, QE → MBR often achieved a higher performance than MBR. These results suggest that the poor quality hypothesis in the candidates has a negative impact on MBR reranking.

5.2.3 10.5B Model Analysis

As described in Section 4.1, we trained a large-scale translation model with 10.5B parameters (failab-LM). The experimental results showed that the 10.5B parameters models were inferior to the best single model. However, when comparing the loss, we found that the 10.5B parameters models achieved a lower loss than the other smaller models. These results might suggest that 10.5B is overparametrized for sentence-level translation. For document-level translation, there may be an opportunity to harness the potential of the large number of parameters. However, the availability of document-level parallel corpora for En↔Ja is limited, highlighting the necessity of expanding the resources for document-level data.

In studies on large language models (LLMs), several papers discuss the scaling laws. For example, Hoffmann et al. (2022) introduces the optimal number of tokens with respect to model size, which is often referred to as the Chinchilla rule in the community. If we straightforwardly apply this rule to MT models, the optimal tokens of the 10B parameters MT model are estimated to be 205.1B tokens. This is much larger than the tokens we used to train for 10.5B parameter models. Therefore, we posit that effectively harnessing the 10.5B model may be possible by increasing both the quantity of training data and the number of training steps. We could not investigate this perspective due to the limited time and computational resources. Thus, we leave to clarify this perspective for future work.

5.2.4 Effectiveness of applying cross+self-attntion

In a preliminary experiment, we confirmed the effectiveness of applying cross+self-attention by comparing performance with the standard setup (cascading computation of self- and cross-attentions) of Transformer encoder-decoder models. Table 7 shows the results of our preliminary experiments. As we see, there were no considerable performance degradations when we compared the performance of cross+self-attention models (NTT-F) with those of standard self-attention and cross-attention cascading models (NTT-B).

In addition, cross+self-attention models reduce the computation of cascading self- and cross-attention into single cross+self-attention. Therefore, the cross+self-attention models are slightly faster and require less memory than standard self-attention and cross-attention cascading models.

6 Submission System

Initially, we planned to submit several versions of the system, with the highest-scoring system selected as the final version. However, the reranking process took longer than expected, and we were

ID	Candidates	Reranker	En→Ja		Ja→En	
			wmt22test	wmt23test	wmt22test	wmt23test
(a)	All	`Oracle`	0.9298	0.9136	0.8804	0.8737

unable to submit multiple submissions within the time limit. Therefore, the system that was actually submitted system was slightly different from the one described in this paper, as follows:

- For the En→Ja system, we submitted the results of the ensembled model of NTT-A to NTT-G.
- For the Ja→En system, we opted for the `QE(Top 80%)` → `MBR` configuration.

Unlike the post evaluation setting (Section 3.3), these models were fine-tuned using all of the WMT'20 test set, the WMT'20 development set, the WMT'21 test set, and the WMT'22 test set.

7 Conclusion

This paper described our submission system for the constrained track of the WMT'23 general translation task. We developed a translation system for En↔Ja. We perform reranking on the candidates generated by multiple translation models, which include a large-scale model with 10.5 billion parameters. Post evaluation (Section 5.2) confirmed the limitations of sentence-level translation quality improvement through model scaling and the effectiveness of our reranking approach.

Acknowledgments

We thank an anonymous reviewer who provided feedback. Also, we would like to also appreciate the member of Tohoku NLP Group for their cooperation in conducting this research. This work was mainly done under the NTT-Tohoku University collaborative research agreement. The work of Jun Suzuki was partly supported by JST Moonshot R&D Grant Number JPMJMS2011 (fundamental research).

KYB General Machine Translation Systems for WMT23

Shivam Kalkar, Ben Li and Yoko Matsuzaki

NRI Digital, Ltd,
{s-kalkar, b4-li, y-matsuzaki}@nri.co.jp

Abstract

This paper describes our approach to constructing a neural machine translation system for the WMT 2023 general machine translation shared task. Our model is based on the Transformer architecture's base settings. We optimize system performance through various strategies. Enhancing our model's capabilities involves fine-tuning the pretrained model with an extended dataset. To further elevate translation quality, specialized pre- and post-processing techniques are deployed. Our central focus is on efficient model training, aiming for exceptional accuracy through the synergy of a compact model and curated data. We also performed ensembling augmented by N-best ranking, for both directions of English to Japanese and Japanese to English translation.

1 Introduction

In the context of the WMT 2023 general machine translation shared task for Japanese to/from English, we tackle the inherent challenges posed by the diverse linguistic structures of these languages. The transformative impact of the Transformer model on neural machine translation is undeniable. While current trends prioritize larger models and extensive datasets, our focus remains on achieving efficient translation with modest resources. This study underscores our use of a compact model and limited computational assets to enhance translation quality.

Built upon the Transformer model's base settings, our approach uses pre-trained models trained on Japanese-English parallel data (Morishita et al., 2019). A previous study involved fine-tuning on various datasets, yielding excellent translation within specific domains (Kalker et al., 2021). In this study, we refined our fine-tuning dataset and systematically tuned hyperparameters to optimize results. Post-fine-tuning, we harnessed model ensembling techniques to amalgamate multiple model outputs, leading to better translation quality. Our study highlights the specifics of our system configurations and methods, offering a concise overview of our strategies.

2 Data selection and Preprocessing

In this section, we elaborate on the process of creating our fine-tuning dataset for the Neural Machine Translation (NMT) system, with a focus on enhancing translation quality for the WMT competition. Our approach involved meticulous data selection and preprocessing to ensure the effectiveness of our system. We describe the details behind selecting the base dataset, incorporating additional parallel corpora, and performing data cleaning to curate a high-quality training dataset.

2.1 Base Dataset Selection

Our foundational dataset for training the initial NMT models is derived from the JParacrawl Version 3 dataset, which offers a diverse array of content spanning various domains. This choice was made due to its comprehensive coverage, which provides a strong starting point for training the base NMT models.

2.2 Augmenting the Dataset

Upon training our base models, we identified an opportunity to further enhance translation quality by incorporating additional datasets. To achieve this, we integrated parallel corpora obtained from sources recommended by the WMT competition organizers. This augmentation was aimed at increasing the diversity of the training data, which often contributes to improved translation accuracy.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 137–142
December 6–7, 2023.

2.3 Data Cleaning

Data cleaning played a pivotal role in refining the quality of our training dataset. During this stage, we implemented several key steps to ensure the integrity of the data:

Language Focus: Given our goal of improving Japanese-to-English translation, we focused on maintaining language homogeneity within the dataset. Therefore, non-Japanese languages, such as Korean and Chinese, as well as their corresponding English translations, were deleted from the dataset.

Sentence Length and Quality: To uphold the overall coherence and effectiveness of the NMT model, we eliminated sentences that were excessively short or of low quality. This step aimed to prevent the model from learning suboptimal translation patterns and to maintain a high standard of translation output. Furthermore, to maintain coherence, we curate our training data by excluding sentences longer than 250 subwords (see 3.1).

Translation Pair Quality: Translation Pair Quality: JParacrawl v3 provides a score for translations labeled as "Accuracy", so we removed sentences with lower scores from the dataset. The threshold for the score was set at 0.5 for training data and 0.75 for the validation dataset. This procedure was not applied to the other parallel corpora.

Normalize symbolic characters: Normalize symbolic characters: Especially for Japanese sentences, since the language has more variations of symbolic characters like 「」, 『』, and "" for quotation marks. We added pre-processing to normalize symbolic characters based on rules. We decided that emojis were not included in this process, as these characters are translated as they are. By adding these rule-based translations, the final BLEU score increased by +0.1.

2.4 Final Dataset Composition

The outcome of our data selection and preprocessing efforts yielded a curated dataset (22.2M). We divided the processed data into a training dataset and a test dataset (2.5M) to evaluate model quality. The training dataset was further divided into a train and a validation to perform fine-tuning on our NMT models.

We also developed a fusion dataset by combining the processed JParacrawl v3 training data with other parallel corpora that were provided by WMT 2023. The dataset finally contains 49.9M sentences (Figure 1, Table 1).

Figure 1 Dataset development

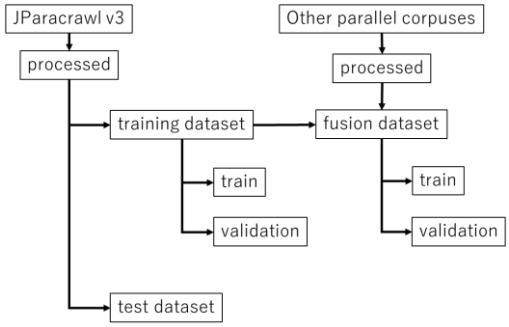

Table 1 Data selection summary

Dataset	Sentences
JParaCrawl Ver.3	25.7M
JParaCrawl Ver.3 (processed)	22.2M
Other Parallel Corpus	33.8M
Other Parallel Corpus (processed)	27.7M
Fusion Corpus (JParacrawlVer3 + Other Parallel)	49.9M

3 Tokenization

3.1 SentencePiece Toolkit for Tokenization and Detokenization

We use the SentencePiece toolkit (Kudo and Richardson, 2018) for tokenization. SentencePiece is suited for languages with complex linguistic structures and compound words. Its efficacy is pronounced in languages with ambiguous word boundaries, agglutinative morphology, and compound word usage. This enables the extraction of subword components from intricate terms, enhancing our tokenization precision. It can remove meta-symbols from translated output, ensuring fluidity and linguistic correctness in the final translations.

3.2 Customized Vocabulary

To bridge vocabulary disparities between our base model (JParacrawl Version 1) and our Fusion Corpus, we train a SentencePiece tokenizer. This

tokenizer aligns with our data's linguistic nuances, enhancing token accuracy. Our SentencePiece model employs a vocabulary size of 32,000 tokens.

4 Model Training

This section details the training process of our translation models using the fairseq toolkit. The selection and configuration of models, as well as the optimization parameters, are presented. Additionally, our model training strategy (Figure 2), including the utilization of advanced techniques such as mixed-precision training and beam search during decoding, is outlined.

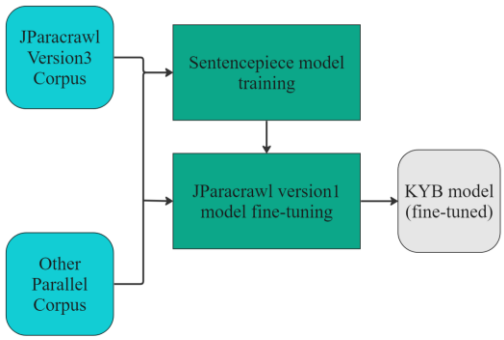
4.1 Model Selection and Configuration

From the array of available models, including MBART and JParacrawl, our evaluation led us to opt for Jparacrawl due to its favorable accuracy-performance trade-off. Jparacrawl models are underpinned by the Transformer architecture (Vaswani et al., 2017) with base settings. The encoder and decoder feature six layers each, embedding sizes of 512, and feed-forward embedding sizes of 2048. Eight attention heads are employed for both the encoder and decoder. Dropout with a probability of 0.3 is applied to enhance generalization. The Adam optimizer with $\alpha = 0.001$, $\beta1 = 0.9$, and $\beta2 = 0.98$ is utilized. A square root decay learning rate schedule with a linear warmup of 4000 steps is implemented. Gradient clipping maintains stability by ensuring gradients do not exceed a norm of 1.0. Mini-batches contain around 5,000 tokens, with gradient accumulation of 64 mini-batches per update. Training spans 24,000 iterations, with model parameter snapshots saved every 200 iterations. The final model is an average of the last eight snapshots. The use of mixed-precision training optimizes performance on modern GPUs.

4.2 Decoding Strategy

During decoding, various beam search sizes (2, 4, 6, 8) were employed to compare translation results. We also compared the best checkpoint and averaged checkpoint to obtain various translation results. In the training of the Ja to En model, we also compared the optimal trade-off between translation quality and computational efficiency by optimizing the training precision.

Figure 2 Model training system



4.3 Training Environment

Our model training is executed on Google Cloud Platform's compute engine equipped with 4-T4 GPUs. Mixed precision (float16) training takes approximately 12 hours and full precision (float32) training takes approximately 30 hours. Although the BLEU score is higher for full precision, the difference is not so large (+0.6, Table 2). So, we decided to use mixed precision for training the Fusion Corpus. We used the train-validation-test split ratio of 90:5:5.

Table 2 En-Ja models summary

Test Dataset	Model	Training Precision	BLEU score	change
JPC V3	JPC V1	-	38.0	0.0
JPC V3	KYB	Mixed (fp16)	45.3	+7.3
JPC V3	KYB	Full (fp32)	45.9	+7.9
Fusion	JPC V1	-	22.3	0.0
Fusion	KYB	Mixed (fp16)	29.8	+7.5

※JPC: Shorthand for JParacrawl
*The results used the best checkpoint with beam size 4. Test set was based on JPC V3 data.

Table 3 Ja-En models summary

Test Dataset	Model	Training Precision	BLEU score	change
JPC V3	JPC V1	-	19.2	
JPC V3	KYB	Full (fp32)	43.8	+24.6

*The results used the best checkpoint with beam size 4. Test set was based on JPC V3 data.

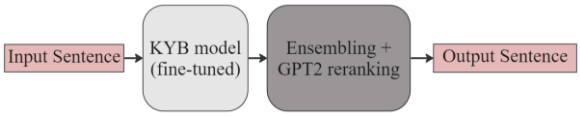
4.4 Performance Evaluation

To assess the efficacy of our trained models, we employ validation data from our dataset. The sacreBLEU metric (Post, 2018) is employed to calculate BLEU scores, offering a quantitative evaluation of translation quality. For testing, we used a set of 2.5M sentences from JParacrawl v3.

5 Model Ensembling with N-Based Reranking

In this section, we delve into the intricacies of our advanced model ensembling approach (Figure 3) coupled with N-Based Reranking, a technical strategy inspired by Le et al. (2021). Our objective is to optimize translation quality through a combination of models and a refined reranking mechanism.

Figure 3 Model inference system



5.1 Model Averaging via Ensembling

Our ensembling technique involves the aggregation of multiple trained model files. Through model averaging, we synthesize the insights and strengths of various models into a unified translation framework. This process not only enhances the stability of our translation outputs but also contributes to an overall improvement in translation quality. Moreover, we implemented checkpoint averaging by considering the last eight checkpoints to create an averaged model and employed in-training evaluation to identify the best checkpoint model.

5.2 N-Based Reranking Strategy

The crux of N-Based Reranking revolves around the calculation of token probabilities and sentence perplexities for translations generated by distinct checkpoint files of our fine-tuned model. We generate 4 alternative translations for each source sentence by using different beam search sizes for one checkpoint file. We compared 6 checkpoint files for the En-Ja side from three different trained models, which yielded 24 different translations for each source sentence. For the Ja-En side, we use two different checkpoints from trained models and use the previous study's model to make 12 alternative translations for each source sentence. This multifold approach introduces diversity into our pool of translation candidates, a crucial aspect of refining translation quality.

To identify the optimal translation candidate among these alternatives, we employ a GPT-2 based ranker (Radford et al., 2019). The ranker computes perplexity for each alternative translation, then chooses the lowest perplexity score as the most proper translation. We submitted the best translation result from all the alternative translations.

6 Post-processing of translation

We found specific tendencies of mistranslation, such as adding double quotation marks, deleting part of the quotation marks, or repeating a specific word endlessly in our translation results. These phenomena are typical problems in machine translation tasks, so we added post-processing to reduce the mistranslations.

After the post-processing, we submitted our results. Our final submission was scored as shown in Table 4 in the automatic evaluation.

Table 4 Submission results

Submission	COMET	BLEU	chrF
Ja-En	76.6	17.6	43.9
En-Ja	80.8	17.8	27.7

7 Discussion and Future Work

7.1 Discussion

In this study, we participated in the general translation task to achieve better translation quality with a relatively compact model and dataset. We made two different datasets: one is based on JparaCrawl version 3 data (JPC V3), and the other included additional parallel corpora provided by WMT23 (Fusion Corpus). The results of our local test suggested that the JPC V3 fine-tuned model shows a better BLEU score than the Fusion Corpus fine-tuned model. However, we exercised caution in interpreting these scores, since the test dataset

contains only sentences from Jparacrawl v3 dataset. The model trained with same origin data might show the result of overfitting to the domain of JPC3 dataset, even the test and train dataset contains different sentences. We then tried to ensemble these different models to achieve more robust translation results. Additionally, we generated alternative translations using different inference parameters for each model and then chose the most proper translation by using PPL.

We use GPT-2 to calculate PPL in this study since the model's knowledge of language is somewhat better than BERT's (see Appendix for a comparison of PPLs). Using a pre-trained large model is obviously effective when computational resources are limited. We use PPL to select a better result from the alternative translations; however, PPL is a relative metric of how fluent the sentence is or how acceptable the sentence order is for the model, so it is not a direct metric of translation quality (Kalkar et al., 2022; Wang et al., 2022). According to that, we recognize that the method that relies on PPL still has some limitations in improving the quality of translations.

Additionally, we added some post-processing to reduce specific mistranslations through the model. Although we carefully cleaned up noisy symbolic characters such as quotation marks from the training dataset, the model's output is still not reliable for translating symbolic characters properly. We performed some rule-based translations to modify symbolic characters.

7.2 Future Work

Back-Translation / Forward-Translation

To improve our translation pipeline, we explored the integration of back-translation as a potential enhancement. Back-translation involves using a trained model to translate from the target language back to the source language (forward-translation is vice versa), effectively creating a synthetic parallel dataset. While we attempt to do the back-translation, we need to consider the quality of the synthetic dataset, especially the variety of translations. When our synthetic dataset does not have enough variation in translation, the model can be easily overfit to the specific translation pattern.

To avoid that, we tried to use a common API for translation, like the Google API; however, this proved to be a very time-consuming task to obtain enough dataset for training (e.g., when one response takes 1 sec, it takes more than 55h to obtain 200,000 sentences). In this study, we attempted to perform back/forward translation, however, we were not able to obtain enough volume of content with reasonable quality. We would like to find a practical method to develop datasets with reasonable quality for back or forward translation in future work.

8 Conclusion

In this study, we embarked on an extensive exploration of high-efficiency model training strategies, leveraging limited computational resources alongside a streamlined model architecture rooted in the Transformer framework's base settings. Our investigation yielded crucial insights and techniques that converge to create a high-quality translation system. Through our experimentation, we identified data cleaning, model averaging, ensembling, beam search, finetuning, parameter-tuning, and post-processing as pivotal techniques, enhancing the quality of our compact model and modest dataset.

Abstract

This paper introduces the Dtranx AI translation system, developed for the WMT 2023 Universal Translation Shared Task. Our team participated in two language directions: English to Chinese and Chinese to English. Our primary focus was on enhancing the effectiveness of the Chinese-to-English model through the implementation of bilingual models. Our approach involved various techniques such as data corpus filtering, model size scaling, sparse expert models (especially the Transformer model with adapters), large-scale back-translation, and language model reordering. According to automatic evaluation, our system secured the first place in the English-to-Chinese category and the second place in the Chinese-to-English category.

1 Introduction

This year, the Dtranx AI team participated in the WMT2023 Universal Translation Sharing Task and focused on enhancing the performance in the zh-en and en-zh language directions. For data preprocessing, we employed various methods, including knowledge-based rules, language detection, and language modeling, to clean parallel, monolingual, and back-translated data. Our data primarily comprised large-scale data mining and back-translation. Additionally, we applied punctuation regularization, byte pair encoding (BPE) Sennrich et al. (2015), and subword regularization methods Provilkov et al. (2019) for processing the data, which yielded excellent results across all languages.

In the modeling section, we have made enhancements to Fairseq Ott et al. (2019) by increasing the model's depth and width. Specifically, we augmented the Transformer model et al.Vaswani et al. (2017) by significantly increasing the number of layers and widening the model architecture.This modification allows the model to capture more complex patterns and dependencies in the data. Additionally, we have embraced the concept introduced by Bapna et al. Bapna et al. (2019) to expand the Transformer model by incorporating language-specific adapters, thus bridging the gap between diverse languages. Lastly, we integrated the dense Transformer model with the sparse Adapter model and leveraged the language model to reranking the final results, leading to further improvements in system performance.

For both English and Chinese translation tasks, we have developed separate systems. We have enhanced the model capacity and applied Adapter fine-tuning techniques, while also incorporating additional proprietary data for system training purposes.During the model inference phase, we have implemented reordering techniques to select more optimal translations. Based on automatic evaluation, our system achieved first place in English to Chinese translation and second place in Chinese to English translation.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 143–149
December 6–7, 2023.

2 Method

2.1 Data

In this section, we will present our primary dataset, which consists of bitext data and monolingual data sources, along with the preprocessing methods employed to prepare this initial data. Additionally, we will provide details about the setup utilized for training our baseline model.

2.1.1 Bitext Data

For the Chinese-English-English-Chinese language pairs, we utilize all bitext data in the shared task and include additional data sources for English-Chinese conversion. During data processing, we implemented the following knowledge-based rules for enhancement:

Remove empty sentences.
Eliminate escaped HTML characters.
Standardize different punctuation variations.
Normalize spacing.
Remove sentences with repetition marks, including single characters repeated more than four times, two characters repeated more than three times, and three characters repeated more than twice.
Delete sentence pairs with inconsistent punctuation at the end of the original and translated texts.
Remove sentence pairs with a source/target token ratio exceeding 1:3 (or 3:1).
Delete segments that exceed 150 tokens in length.
Remove sentence pairs with fewer than 5 tokens in the source text or translation.
Convert traditional Chinese characters to simplified Chinese characters.
Delete corpora with an unaligned number of parentheses.
Delete corpora with an unaligned number of Arabic numerals.
Remove corpora with non-native character ratios greater than 0.4.

We employed Moses Koehn et al. (2007) for normalizing spacing and punctuation. We utilized all accessible data sources to train our model.

Considering the aforementioned concerns regarding corpus quality, we implemented additional filtering steps to ensure data availability. Initially, we attempted to filter out low-quality sentence pairs using the word alignment method of fast-align Dyer et al. (2013). We retained the top 80% of sentence pairs based on the alignment score(a score generated by the word alignment model that measures the quality of word alignment between source and target sentences), encompassing all directions. Subsequently, we trained the Transformer model for all languages using Fairseq, following a similar approach as outlined in the study conducted by Bei et al. Bei et al. (2019). The scores were calculated as follows:

$$Score_{sentence} = PPL \tag{1}$$

$$Score_{combine} = \lambda * Score_{src} + (1 - \lambda) * Score_{tgt} \tag{2}$$

Here, we employ PPL as an abbreviation for perplexity, which represents the perplexity of the sentence language model. The value of λ, on the other hand, is determined empirically

based on language pairs and ranges from 0.2 to 0.8. For instance, if our source language is English and the target language is Chinese, we would set λ to 0.7.

Finally, the training data, as presented in Table 1, was carefully curated to serve as the foundational resource for our model training. This bilingual training dataset consists of 50 million sentence pairs in the Chinese-English (zh-en) language pair,and it can be utilized bidirectionally.

Language Pair	Data
zh-en	50M

Table 1: Ultimate bitext training data

Language Pair	Data
zh	72M
en	10M

Table 2: Ultimate monolingual data

2.1.2 Monolingual Data

To ensure the quality of our data and to create synthetic parallel texts, we harnessed the capabilities of a well-trained bilingual model. We compiled high-quality monolingual corpora in various languages from reputable sources, including news commentaries, europarl, and news crawls. The monolingual data, after undergoing a rigorous filtering process, is presented in Table 2.

2.1.3 Tokenizer

We opted for SentencePiece Kudo and Richardson (2018) as the training tool for our subword tagger. To enhance subwording efficiency, we adopted the approach of Tran et al. Tran et al. (2021) by employing sampled text with a temperature of 5. For the bilingual model, we utilized a vocabulary of 32,000 words.

In addition, we integrated the subword regularization method Provilkov et al. (2019) Raffel et al. (2020) into the tagged text. This technique was exclusively applied to the source side, as it has the potential to enhance the model's robustness by allowing different subword tokenizations.

2.2 Model Architectures

We have developed a dedicated model for bidirectional translation between Chinese and English, capitalizing on our proficiency as native Chinese speakers. To enhance the quality of our training data, we integrated a private corpus comprising approximately 20 million high-quality sentence pairs spanning various domains, including general text, technology, medicine, law, finance, and more.

Regarding "basic fine-tuning," our approach involves parameter adjustments, including fine-tuning the learning rate, the number of training epochs, and batch sizes. These adjustments are made to optimize the model's adaptation to the specific translation task at hand.

In the realm of back-translation, we harness English and Chinese monolingual corpora. This approach leverages monolingual text data in both languages, enriching the model's translations by back-translating them into English. This technique seamlessly augments the diversity of our training dataset.

As for the specifications of our Transformer model, it features 12 encoder layers and 6 decoder layers, each equipped with 8 attention heads. The embedding size is set to 512, and the width of the feed-forward neural network (FFN) is 4096. Additionally, we have incorporated techniques like Layer Normalization and residual connections to stabilize the model training process.

2.2.1 Language Specific Adapter

In essence, a language-specific adapter layer is a dense layer that incorporates residual connections and nonlinear projections. The hyperparameter "b" represents the dimension of the internal dense layer. These adapter layers consist of a multitude of globally shared parameters, along with several task-specific layers. This unique design allows us to train and optimize individual models for multiple languages.

Bapna et al. Bapna et al. (2019) demonstrated the improved translation performance achieved by machine translation models employing adapters. Therefore, following the training of our bilingual models, we integrated adapter layers into them and subsequently conducted additional training and fine-tuning on these adapter layers. To be specific, for the Chinese-English and English-Chinese models, we introduced a language-specific adapter with a dense layer dimension of 4096.

Regarding the incorporation of adapters in the bilingual models, we seamlessly integrate the adapter layers into the existing architecture, where they operate alongside the standard layers. The globally shared parameters refer to the model parameters that are common across various languages and tasks, which are shared among different adapter layers in the model.

For the fine-tuning of the adapters, we utilized additional bilingual data specific to the translation tasks. These adapters were fine-tuned with the same data used for training the main translation model, allowing them to adapt to the particular translation requirements of our task.

2.2.2 Finetune

To enhance the model's performance, we implemented in-domain fine-tuning, a proven effective technique in previous news translation tasks. We generated various types of fine-tuned data using the following approach. According to the studies conducted by Li et al. Li et al. (2020) and Wang et al.Wang et al. (2021), low-frequency and high-frequency words often pertain to domain-specific nouns and other related terms that directly reflect the topic at hand. However, this year's shared task has transitioned from the news domain to a more generalized translation task. Recognizing that previous fine-tuning using news domain data could potentially have a detrimental effect on the model, we adopted the strategy outlined by Li et al. Li et al. (2020) and Wang et al. Wang et al. (2021), which involves selecting topic-related data based on a test set. Subsequently, we identified specific data for further fine-tuning and conducted experiments on the 2022 news development set, subsequently applying the refined model directly to the 2022 test set.We fine-tuned the full model, not just the adapters, to ensure it was well-suited for the task at hand.

2.2.3 Model Ensemble

Model integration has been widely adopted as a technique in previous WMT sharing tasks. To mitigate bias towards more recent training data, it is common practice to average multiple checkpoint parameters of the model. Specifically, during training, we consistently take the average of the last five checkpoints. In the fine-tuning phase, we fine-tune the hyperparameters (e.g., num epoch and num average checkpoints) based on the performance on the development set and directly apply them to the test set of WMT23.

3 Results

3.1 Experimental setup

Each model was trained on eight NVIDIA A100 GPUs, each equipped with 40 GB of memory. Additionally, we employed high-volume processing and higher learning rates, as mentioned in Ott et al. Ott et al. (2018). The maximum learning rate was set to 0.0005, and we used 10,000 warm-up steps. All dropout probabilities were set to 0.1. To expedite training, we utilized half-precision floating-point numbers (FP16). In the context of multilingual training, we incorporated source language labels and target language labels to leverage the distinctions between languages. Following the approach proposed by Tran et al. Tran et al. (2021), we segmented the data into multiple parts and downsized the data in both the high-resource direction and in synthetic backtranslation for each training cycle.

3.2 Results

We trained bilingual models for English to Chinese (en-zh) and Chinese to English (zh-en). In our model, we enhanced the model capacity by introducing specific adapter layers for each translation direction, addressing the unique linguistic challenges of each language pair. These adapter layers do not induce sparsity; instead, they add more trainable parameters to the model. Each model has dedicated adapters for en-zh and zh-en, as they are not shared between the bilingual models. To refine our training set, we extracted additional relevant corpus from the raw text in the test set. This extracted data was structured using the language model and augmented through reverse translation. The results demonstrate the effectiveness of our systematic approach, and we achieved the highest scores on the COMET evaluation metric. These outcomes are detailed in Table 3 and Table 4

4 Conclusion

In this paper, we present Dtranx AI's submission to the WMT2023 Universal Translation Shared Task. For the Chinese-English and English-Chinese language pairs, we adopt a bilingual model as the fundamental structure and enhance it through various strategies. These include increasing the model capacity, fine-tuning with Adapters, incorporating private relevant corpus,

and optimizing the translation output by reordering. Our experimental results demonstrate the effectiveness of these optimization techniques.

Abstract

This paper describes the PROMT submissions for the WMT23 Shared General Translation Task. This year we participated in two directions of the Shared Translation Task: English to Russian and Russian to English. Our models are trained with the MarianNMT toolkit using the transformer-big configuration. We use BPE for text encoding, both models are unconstrained. We achieve competitive results according to automatic metrics in both directions.

1 Introduction

The WMT Shared General Translation Task is an annual event where different companies and researchers build and test their systems on the test sets provided by the organizers. This year we decided to participate in two directions: English to Russian and Russian to English. We use the standard transformer-big configuration for our models. The English-Russian model is basically the same as last year, whereas the Russian-English model is a new one built for WMT23.

The rest of the paper is organized as follows: in Section 2 we describe in detail the systems we submitted to the Shared Task. In Section 3 we present and discuss the results. We conclude the paper in Section 4 with discussion for possible future work.

2 Systems overview

All of our WMT22 submissions are `MarianNMT`-trained (Junczys-Dowmunt et al., 2018) transformer-big (Vaswani et al., 2017) systems. We use the `OpenNMT` toolkit (Klein et al., 2017) version of byte pair encoding (BPE) (Sennrich et al., 2016b) for subword segmentation. Our BPE models are case-insensitive, we use special tokens in the source and target sides to process case (see Molchanov (2019) for details).

All of the systems are unconstrained, i.e. we use all data provided by the WMT organizers, all publicly available data and some private data crawled from different web-sources.

We also augment our training data with two types of synthetic data: 1) back-translations (Sennrich et al., 2016a) and 2) synthetic data with placeholders as described in Pinnis et al. (2017). The back-translations are obtained using the previous versions of our NMT models which are baseline transformers trained with less data (and without some up-to-date data like the news 2021 corpora from statmt.org). We also tag all our synthetic data with special tokens at the beginning of the source sentences as described in Caswell et al. (2019).

All models are trained with guided alignment which is used at translation time to handle named entities and document formatting. We obtain alignments using the `fast-align` (Dyer et al., 2013) tool.

The data statistics for the Russian-English language pair are presented in Table 1.

The details regarding different directions can be found in the next Section.

WMT stands for the data available for the News Task on the statmt.org/wmt22 website; OPUS is the data from the OPUS website apart from the data available for the News Task; Private stands for private company data.

2.1 Data preparation

There are several stages in our data preparation pipeline. These are mostly common filtering techniques. The main stages of the pipeline are:

- Basic filtering
  This includes some simple length-based and source-target length ratio-based heuristics, removing tags, lines with low amount of alphabetic symbols etc. We also remove lines which appear to be emails or web-addresses and duplicates.

- Language identification
  The algorithm is a fairly simple ensemble of three tools: `pycld2`[1], `langid` (Lui and Baldwin, 2012), `langdetect`[2]. We mainly use pycld2 as it is by far the fastest tool of the three. If pycld2's output differs from the hint language, we perform additional checks using the other two libraries, and the final language is determined by majority vote. For large monolingual corpora we use only pycld2.

- Bicleaner filtering
  We use the bicleaner (Ramírez-Sánchez et al., 2020) tool to filter parallel data. We discard all sentence pairs with the score threshold <= 0.3.

- Scoring with NMT models
  We finally score all parallel data and back-translations with our intermediate models. We use a score threshold to discard a portion of the data. The exact threshold is determined by human evaluation. The discarded data includes non-parallel sentences (i.e. pairs of sentences where the source does not correspond to the target in part or fully) and low-quality synthetic translations.

- Dual conditional cross-entropy filtering
  This year we use this algorithm again for both directions as described in Junczys-Dowmunt (2018).

2.2 English-Russian

The English-Russian system is basically the same as last year (Molchanov et al., 2022). It was trained in two steps. First, we build the baseline model on all available data. Second, we fine-tune the model on data of high quality. Specifically, we remove the ParaCrawl, UN and OpenSubtitles corpora. The training corpus then consists of the remains of the human data mixed with the back-translations of the news corpora (2020, 2021) from statmt.org. This approach shows good results according to automatic metrics and general translation quality. The reason for doing this is that we aim for our models to be used mostly for translation of news and formal texts like various types of documents.
The system was trained with separate vocabularies, the sizes of the BPE models are 24k for the source side and 48k for the target side.

Table 2: Examples of degradations for the 2023 Russian-English model.

2.3 Russian-English

The Russian-English model was built basically on the same data and in the same way as the English-Russian model. The only difference is that we use English news and Wikipedia for back-translations. The previous version of the Russian-English model was also built on the same data, but with the transformer-base configuration.

The first version of the model that we trained on this data had shown almost no improvements, both in terms of automatic and human evaluation (on average the model improved by 0.5 BLEU points on our internal test sets compared to Model2022 using the transformer-base configuration). What is more important is that we observed some serious degradations: hallucinations and critical mistakes. The examples are presented in Table 2. We investigated the problem and found out that some of our clients' data was used for training without proper filtering. This was part of our private data. We then applied the full filtering pipeline to the private data and discarded around 20k sentence pairs (roughly 0.03% of all data) with low quality. Then we retrained the model on the filtered data, and this fixed all the critical mistakes we had encountered. Surprisingly, we also gained additional 1 BLEU points on average on our internal test sets compared to the first version. All we did was just remove 0,03% of bad sentence pairs from the training data. The average BLEU score on our test sets improved from 36.66 to 38.05 points.

3 Results and discussion

The results are presented in Table 3.

As we can see, we outperform our baselines (i.e. previous versions of the models). The gains we observe, however, are not that large.

System	BLEU	chrF	COMET
English-Russian			
Model2022	30.5	55.4	82.3
Russian-English			
Model2022	32.4	58.0	-
Model2023	**32.8**	**58.4**	**80,9**

Table 3: Results for different systems in both directions. The submitted systems are marked in bold. Model2022 stands for our previous version of the Russian-English system which we consider the baseline. The English-Russian system remains the same.

However, other test sets, such as the TICO-19 evaluation set [3] (Anastasopoulos et al., 2020), show more substantial improvements. The BLEU score on that test set has grown from 33.8 to 35 points.

Poor performance on the generaltest2023 set can be due to the problems that our submitted models have with translation of colloquial content. This can be explained by our data preparation scheme. As we have already mentioned above, we want our models to translate formal text better and thus 'sacrifice' colloquial data. The examples of such mistranslations are presented in Table 4. Both examples illustrate colloquial slang which our model cannot translate properly. In the first example the word 'please' is substituted by 'pls', and thus the model 'thinks' it is a abbreviation of some kind. In the second example the author substitutes the word 'because' with a slang word 'becuz', and the model transliterates it.

We made a thorough investigation into the generaltest2023 sets. Thus, we found out that there are four major topics for the Russian-English test set: 1) movie reviews; 2) news of any

[3] https://tico-19.github.io/index.html

kind; 3) user reviews; 4) abstracts from research papers in medical domain. The English-Russian test set domains are similar. We estimate that at least half of the English-Russian test set is made up of Reddit posts and online customer reviews which often use internet slang and have spelling anomalies of some kind, e.g. "eye wud liek 2 aply 4 vilage idot", "WhY dO pPl FiNd ThE NeW SeT ExPeNsIvE." All these domains except for news were actually unexpected by our model.

source	Model2022
pls change	Изменение PLS
Becuz i have less than 3000 points.	Бекуз у меня меньше 3000 очков.

Table 4: Examples of incorrect translations for the English-Russian model considering the colloquial content.

4 Conclusions and future work

In this paper we presented our submissions for the WMT23 Shared General Translation Task. We show good results in both directions we participate. We clearly outperform our baselines in both directions. A detailed analysis of the translations shows us that we lose quality in translation of colloquial speech. We have already started to work in this direction. We have synthesized data where, e.g., 'please' is substituted with 'plz' and so on. We plan to train our model on this synthetic data so that it could deal with such colloquial examples.

Abstract

This paper describes the development process of NMT systems that were submitted to the WMT 2023 General Translation task by the team of AIST AIRC. We trained constrained track models for translation between English, German, and Japanese. Before training the final models, we first filtered the parallel and monolingual data, then performed iterative back-translation as well as parallel data distillation to be used for non-autoregressive model training. We experimented with training Transformer models, Mega models, and custom non-autoregressive sequence-to-sequence models with encoder and decoder weights initialised by a multilingual BERT base. Our primary submissions contain translations from ensembles of two Mega model checkpoints and our contrastive submissions are generated by our non-autoregressive models.

1 Introduction

We describe the machine translation (MT) systems submitted to the WMT 2023 General Translation task developed by the team of AIST AIRC. We experimented with data quality control by carefully filtering out noisy examples from parallel and monolingual data sets before training, and corpora selection by holding out specific web-crawled data. We also compared several modelling approaches by contrasting the well-known Transformer architecture (Vaswani et al., 2017) to several more recent ones, such as the Mega model (Ma et al., 2023), as well as our own custom implementation of a non-autoregressive model with the encoder and decoder initialised by BERT checkpoints. During the shared task submission week another new efficient architecture was published – the Retentive Network (RetNet; Sun et al., 2023), which we include in the paper as an ablation study.

Our main findings are: 1) non-autoregressive models can reach comparable output quality to the best autoregressive models while improving inference latency up to 9x; 2) modern efficient autoregressive models like RetNet and Mega not only slightly outperform the Transformer in latency, but also in output quality; and 3) models trained on sentence-level data struggle to translate whole paragraphs – splitting them into sentences helps a lot, especially for the non-autoregressive model.

2 Data

We only participated in the constrained track of the shared task; therefore, we limited our data set use to only the corpora provided by the shared task organisers. In specific experimentation configurations, we chose to leave out web-crawled data such as Paracrawl and WikiMatrix, but eventually kept them in our final submissions.

All parallel training data and monolingual data for back-translation were filtered before starting any training, which has been proven very effective in previous WMT shared tasks (Pinnis et al., 2017, 2018) and detailed by Rikters (2018). Parallel data distillation was performed only for training the non-autoregressive models, while for all autoregressive models, we used only pure clean parallel data.

For the system development process, we selected News Test sets from previous older WMT shared tasks as development data and the most recent ones as evaluation data. Full statistics of the data we used are shown in Table 1.

2.1 Data Selection

We initially experimented with excluding the web-crawled parallel corpora and training models using only data from other sources, since web-crawled data are generally considered to be of a lower-quality tier. The Paracrawl corpora are also several times the size of all other data combined, and took longer to finish the filtering process. In addition, to not overwhelm the full combined training data set with lower-quality data, we 1) limited the English-

German Paracrawl to 50 million parallel sentences; and 2) up-scaled all data from other sources to match the amount of the Paracrawl data after filtering by doubling for English-German and tripling for English-Japanese.

2.2 Filtering

Even though all training data need not always be perfect and methods like back-translation and data distillation intentionally generate somewhat noisy additional training data, some types of noise are more harmful than others. Since most training corpora are produced partially or fully automatically, errors such as misalignments between source and target sentences or direct copies of source to target can occur, as well as some amounts of third language data in seemingly bilingual data sets.

To avoid such problems, we used data cleaning and pre-processing methods described by Rikters (2018). The filtering part includes the following filters: 1) unique parallel sentence filter; 2) equal source-target filter; 3) multiple sources - one target and multiple targets - one source filters; 4) non-alphabetical filters; 5) repeating token filter; and 6) correct language filter. We also perform pre-processing consisting of the standard Moses (Koehn et al., 2007) scripts for punctuation normalisation, cleaning, and Sentencepiece (Kudo and Richardson, 2018) for splitting into subword units. The filters were applied to the given parallel sentences, monolingual news sentences before performing back-translation, and both sets of synthetic parallel sentences resulted from back-translating the monolingual news.

2.3 Distillation

Since previous research has proven that knowledge distillation (Hinton et al., 2014) is highly beneficial for non-autoregressive machine (NAR) translation models (Kim and Rush, 2016), we chose to skip training our NAR models during the baseline training phase. When the baselines were trained, evaluated and compared, we used the highest-scoring baseline models for sentence-level knowledge distillation of the clean parallel training data.

2.4 Back-translation

Increasing the amount of in-domain training data with synthetic back-translated corpora (Sennrich et al., 2016) has become a common practice in cases with considerable amounts of in-domain monolingual data. However, since the shared task recently shifted from 'news' to 'general' text translation, the definition of what would be considered in-domain data became less clear. Furthermore, for the constrained track the selection of provided monolingual data from the organisers was limited to news and web-crawled data while noting that the 'general' test sets may include user generated (social network), conversational, and e-commerce data as well. For our experiments we continued to assume that a significant portion of the test data would still be from the news domain. Therefore, we chose to only use the provided monolingual News crawl, News discussions, and News Commentary corpora for back-translation.

2.5 Post-processing

In post-processing of the model output we aimed to mitigate some of the most commonly noticable mistakes that the models were generating. We mainly noticed two often occurring problems in output from all models: 1) difficulties in translating emoji symbols; and 2) occasional repetitions of words or phrases.

While all English and German alphabet letters and even Japanese characters are covered in the large training data corpora, the unicode emoji were mostly formed and clearly defined only in the past decade, and new emoji are still added every year or two with the next release planned for late

2024[1]. Emoji are also not often present in MT training data, therefore full emoji coverage is absent from model vocabularies, which leads to occasional <*unk*> tokens being generated as output if emoji were present in the input. In order to keep using the models without re-training, we replaced any <*unk*> tokens in the output using a dictionary of any emojis appearing in the input.

Furthermore, the occasional hickuping or hallucinating of models on less common input sequences seems ever present, sometimes generating repetitions of tokens or phrases. We replaced any consecutive repeating n-grams with a single n-gram. The same was applied to repeating n-grams that have a preposition between them, i.e., *the victim of the victim*.

Both post-processing approaches gave BLEU score improvements of around 0.1 - 0.2.

3 Model Configurations

While it is often possible to train ever larger models on more data requiring infinitely growing amounts of compute power which later become costly to deploy, we decided to approach our selection from the perspective of limiting environmental impact. In our pursuit of the final submission, we aimed to explore several modelling approaches with efficient decoding while still striving to maintain or improve output quality. For this we chose the baseline Transformer model as our baseline, the recently introduced Mega model (Ma et al., 2023), a custom implementation of a non-autoregressive model with BERT-initialised encoder and decoder, and as an ablation study trained after the shared task submission deadline – RetNet (Sun et al., 2023). Each model was trained on a single machine with four Nvidia V100 (16GB) GPUs until convergence on development data (no improvement on validation loss for 7 checkpoints).

The total trainable parameter counts for the four models are as follows: Transformer - 73,886,208; RetNet - 77,930,496; Mega - 63,367,854; BnB - 384,214,027.

3.1 Transformer

We used Marian (Junczys-Dowmunt et al., 2018) to train transformer architecture (Vaswani et al., 2017) models with the default transformer-base parameter configuration of 6 layers, 8 attention heads, model dimension of 512, feed-forward dimension of 2048, and dropout of 0.1. We also used an optimiser delay of 8 to simulate larger batches, which is is known to improve final output quality (Bogoychev et al., 2018).

3.2 Mega

Ma et al. (2023) propose a moving average equipped gated attention mechanism (MEGA) - a single-head gated attention mechanism equipped with exponential moving average to incorporate inductive bias of position-aware local dependencies into the position-agnostic attention mechanism. Compared to the Transformer model, MEGA has a single-head gated attention mechanism instead of multi-head attention, which enables gains in efficiency while not sacrificing on performance.

For training our Mega models we used the implementation[2] provided by the authors, which is based on FairSeq (Ott et al., 2019).

3.3 BERT-nar-BERT

The BERT-nar-BERT (BnB) model architecture is similar to BioNART (Asada and Miwa, 2023), composed of a multi-layer Transformer-based encoder and decoder, in which the embedding layer and the stack of transformer layers are initialised with BERT (Devlin et al., 2019). To leverage the expressiveness power of existing pre-trained BERT models, we initialise our encoder and decoder parts with the pre-trained BERT parameters. An overview of BnB architecture is shown in Figure 1.

The encoder part of BnB is the same architecture as the BERT model. We construct latent representations based on token-level representations from the encoder hidden state, and modify the decoder part by leveraging the latent representations and length classification for non-autoregressive generation.

The decoder part is also based on the BERT architecture, and we can directly initialise the decoder with the pre-trained BERT model. Following the BERT2BERT model, the cross-attention mechanism is adopted, and the encoder hidden representation of the final layer is used for cross-attention. Our model differs from the BERT2BERT model in attention masks to enable NAR decoding. In the AR decoding, all target tokens are fed into the decoder with customised attention masks that prevent the decoder from seeing the future tokens during training. Then, in inference, the predicted token is fed to the decoder autoregressively. In our BnB de-

Table 2: Average speedup and inference speed in lines per second on CPU and GPU on average for the four WMT 2023 test sets we participated in.

coder, input representation is constructed without providing any target tokens. The input representation is constructed by summing the corresponding position and type embeddings and the latent embedding from the encoder. The attention masks are the normal masks that give access to all future tokens. The resulting decoder output representations of the final layer are fed to the subsequent generation layer.

3.4 Ablation Study – Retentive Networks

During the submission week of the WMT general machine translation task Sun et al. (2023) proposed a Retentive network (RetNet), with stacked identical blocks, following a similar layout to the Transformer, where each block contains a multi-scale retention module, and a feed-forward network module. Compared to Transformer attention, the retention part removes softmax and enables recurrent formulation, which significantly benefits inference. The authors report significant gains in inference efficiency while maintaining competitive in output quality to the Transformer.

For training our RetNet models we used the implementation[3] provided by the authors, which is based on FairSeq (Ott et al., 2019).

4 Results

Tables 3 and 4 list the progression of our different modelling methods and data selection approaches. We first started with training the Transformer models as our baselines using only non-web-crawled parallel training data and compared it to MEGA models trained on the same data, while the larger Paracrawl corpora were still filtering. Initial results suggested that the Transformer model optimises towards the development data slightly too much while ending up strongly outperformed by the MEGA model on evaluation data. From there on, we opted for using MEGA as our main model, and experimented with adding filtered Paracrawl data to the training mix, which improved translation quality for all directions. We then used these four models (With Paracrawl column in Table 3) to generate back-translated data and distilled parallel training data for BnB. In the final step before submission, we trained MEGA and BnB models on clean parallel + back-translated and distilled + back-translated data respectively. We used ensembles of best and last MEGA model checkpoints to generate our shared task submissions.

As an ablation study of adding another efficient model baseline, after the submission week had ended we trained RetNet models, which were published on arXiv along with code on GitHub during the submission week.

4.1 Automatic Evaluation

According to the unofficial automatic evaluation results (Kocmi et al., 2023) summarised in Table 6, our submitted models are on the lower end, outperforming only two to three out of the 5-10 participants and 7 online systems in the respective translation directions. We manually regenerated the automatic evaluation scores for translations from all of our final models, based on the references released by the organisers.

4.2 Inference Speed

Table 2 compares the inference speed and latency of our chosen models. While loading the models into the memory and model-specific data preprocessing or post-processing steps also take considerable amounts of time, for this comparison we only started measuring the time after the model had been loaded and all data processing – completed. Our BnB model was by far the fastest, outperforming MEGA and Retnet by about 6.4x on the GPU and the Transformer by about 9.3x. On the CPU

its advantage dropped to about 1.9x and 2.8x respectively. Inference speed differences between MEGA and RetNet were minimal, while both still noticabely outperformed the baseline Transformer.

4.3 Post Submission Updates

After the release of the unofficial system rankings and test set references, we manually re-scored all of our models trained on the final back-translated data and noticed that the Transformer and BnB were generating particularly shorter outputs for the document-level EN↔DE test sets than expected. After splitting[4] the English and German source files into sentences, translating them, and combining back into paragraphs for evaluation, the scores improved by several BLEU points (see Table 5). The EN↔JA part did not require any further splitting, as it was already provided at sentence-level.

5 Conclusion

In this paper we described the development process of the AIST AIRC's NMT systems that were submitted for the WMT 2023 shared task on general domain text translation. We compared Transformer models to MEGA, RetNet and BERT-nar-BERT model architectures in search of efficient decoding approaches while still improving upon output quality. We showed that the Transformer models can be outperformed by MEGA and RetNet in both translation quality, as well as inference speed, while BnB remained fastest in inference, but still lowest in quality. We also found that even though modern models should be able to handle long sequences, splitting the English↔German document-level data into separate sentences, translating and recombining them yielded better results. This should, however, be mitigable by training dedicated document-level models with appropriate training data.

In total, output from four systems was submitted to the shared taks by AIRC for the English↔German and English↔Japanese language pairs in both translation directions.

Table 6: Automatic evaluation rankings according to BLEU (nrefs:1|case:mixed|eff:no|tok:13a|smooth:exp|version:2.2.1), chrF (nrefs:1|case:mixed|eff:yes|nc:6|nw:0|space:no|version:2.2.1), and COMET (Unbabel/wmt22-comet-da). The order of the tables from left to right is DE→EN, EN→DE, JA→EN, EN→JA.

In future work, we plan to experiment with replacing the BERT models in BnB with other more efficient pre-trained language models which can be used as encoders/decoders, as well as incorporating document-level training data and modelling longer sequences with available data. In terms of data, we intend to increase vocabulary coverage by adding all known unicode emoji symbols to the vocabulary even if they are not present in the training data, as well as additionally sample paracrawl data where emoji are present.

MUNI-NLP Submission for Czech-Ukrainian Translation Task at WMT23

Pavel Rychlý and **Yuliia Teslia**
NLP Centre, Faculty of Informatics, Masaryk University
pary@fi.muni.cz, 531354@mail.muni.cz

Abstract

The system is trained on officially provided data only. We have heavily filtered all the data to remove machine translated text, Russian text and other noise. We use the DeepNorm modification of the transformer architecture in the TorchScale library with 18 encoder layers and 6 decoder layers. The initial systems for back-translation uses HFT tokenizer, the final system uses custom tokenizer derived from HFT.

1 Introduction

The annual Conference in Machine Translation (WMT) provides an invaluable platform for researchers to showcase their advancements in this domain. This paper serves as the submission from the Natural Language Processing Centre of Masaryk University (MUNI-NLP) team for the Czech-Ukrainian Translation Task at WMT23 (Kocmi et al., 2023).

Central to our approach is a commitment to data quality and we have also done some experiments with different subword tokenizers. Furthermore, we recognize the paramount importance of data filtering, a process that distinguishes signal from noise. To this end, we employ a rigorous data filtering procedure to eliminate machine-translated text, Russian content, and other sources of potential distraction, enabling our model to focus on the genuine linguistic intricacies of Czech and Ukrainian.

In terms of model architecture, we employ the DeepNorm modification (Wang et al., 2022) of the transformer architecture. This modified architecture, integrated within the TorchScale library, boasts 18 encoder layers and 6 decoder layers.

Our approach further delves into the critical aspects of back-translation and tokenization. Initially, we leverage the HFT (High Frequency Tokens) tokenizer for back-translation, harnessing the power of synthetic data to enhance model robustness. In the final iteration of our system, we introduce a custom tokenizer derived from HFT.

2 Data selection and preprocessing

Our system participates in the constrained track, we use only data allowed for this year. We do not use any pretrained models, only selected parallel and monolingual texts.

Many of the provided text are very noisy. We excluded some of them from training completely.

To mitigate the adverse effects of noisy data on our translation system, we conduct a comprehensive analysis of the data problems that emerge from these issues. In subsequent sections of this paper, we delve into the specific strategies and techniques we employ to filter out machine-translated text, Russian content, and other sources of noise. Our data filtering pipeline is designed to rigorously curate the training data set, ensuring that our model is exposed to high-quality, human-generated translations that align closely with the nuances of the Czech and Ukrainian languages. Through these meticulous filtering strategies, we aim to enhance the overall performance and translation quality of our system.

2.1 Parallel data

We use only official Task 1 data downloaded by the `mtdata` command (Gowda et al., 2021). The majority of segments comes from the OPUS corpus (Tiedemann, 2012), the biggest single source is Facebook-wikimatrix (Schwenk et al., 2019).

OPUS-opensubtitles Sometimes contains wrong or missing diacritics in Czech part. We removed segments containing meta data like authors of the subtitles. There are many parts on the Ukrainian side with Russian language instead of Ukrainian. We have removed such segments.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 162–165
December 6–7, 2023.

Source	Used segments	Original segments	Used words
ELRC-acts-ukrainian	130003	130003	2.5M
OPUS-ccmatrix	3916740	3991954	44M
OPUS-opensubtitles	515216	730804	2.7M
OPUS-multiparacrawl	941349	2200276	12M
OPUS-qed	155346	161020	2M
OPUS-tatoeba	2932	2933	11k
OPUS-ted2020	112689	114229	1.6M
Facebook-wikimatrix	824606	848961	9.9M
Total	6602828		

Table 1: The sizes of all sources used for the final system. *Used words* means number of words used in one language, these are almost same for both languages.

In total, almost 30% of segments were removed from this source.

Facebook-wikimatrix Many segments are not aligned, they contains similar texts but the sentences are not translations. We can see such situations in sentences about different sport teams, towns and history persons.

We have removed segments with special formatting options, lines containing *Dostupné online (available online)* and similar strings.

OPUS-wikimedia Removed HTML formatting, notes in tested parenthesis which are not translated anyway.

Removed segments containing URL, references to online sources.

Removed segments with Czech texts in Ukrainian part and vice versa.

OPUS-multiccaligned Excluded from processing.

The Czech part contains almost exclusively a very bad machine translations in domains like: game playing, health recommendations, porn, bitcoins, garden.

Only a few good Czech sentences are copied from Czech Wikipedia.

OPUS-bible Excluded from processing.

It contains very old language with unusual vocabulary and grammar.

OPUS-elrc-5179 Excluded from processing.

The same text as ELRC-acts with some errors (missing characters).

OPUS-eubookshop Excluded from processing.

Contains concatenated words on both sides.

Several sources contains duplicated segment, we keep only the first instance of such duplicates.

The sizes of all parallel sources used for the final system are listed in the Table 1.

2.2 Monolingual data

Statmt-news-crawl-2021-ces Removed time indications at the beginning of lines.

LangUk-* There is no punctuation in text.

We have used simple rules to add probable punctuation marks.

Removed markdown formatting.

We use additional filtering of back-translated segments. We use `filter-acktranslation.py` from (Popel et al., 2022). Unfortunately, there were still some Russian texts at the early stages of development and some Czech sentences were translated into Russian instead of Ukrainian. We filtered such segments out for the final system.

The sizes of monolingual data are listed in Table 2.

3 Tokenization

We use HFT tokenizer (Signoroni and Rychlý, 2022) for all stages. The tokenizer uses special characters to annotate word boundaries and character capitalization, they are listed in Table 3.

An example of tokenized text from the Czech part of the training data is in Figure 1. All uppercase letters are transformed to lower-case and the special characters preserve the original format. White spaces around punctuation marks are annotated explicitly in the same way as in Sentencepiece

```
A on: "Ne, tady jsme už asi rok."
↑¦a¦ ¦on¦ :▁" ↑¦ne¦ ,▁ ¦tady¦ ¦jsme¦ ¦už¦ ¦asi¦ ¦rok¦ ."

Trvalo 17 dní, než US senát zakázal
↑ ¦trvalo¦ ¦17¦ ¦dní¦ ,▁ ¦než¦ Δ¦us¦∇ ¦sen át¦ ¦zak ázal¦

Ona napsala: " MŮJ BANKÉŘ BUDE POTŘEBOVAT PŘEVOD 3 000$.
↑¦ona¦ ¦napsala¦ :▁ "▁ Δ ¦můj¦ ¦bank é ř¦ ¦bude¦ ¦potřebovat¦ ¦převo d¦∇ ¦3¦ ¦000¦ $ .
↑ ¦ona¦ ¦napsala¦ :▁ "▁ Δ ¦můj¦ ¦bank é ř¦ ¦bude¦ ¦potřebovat¦ ¦převo d¦ ∇ ¦3¦ ¦0 0 0¦ $ .
```

Figure 1: Example of the tokenization. The first line of each group is the plain text, the second line is the respective tokenization. The very last line is the modified tokenization used in the final system.

Source	Used segments
Leipzig-news	1M
Leipzig-newscrawl	1M
Leipzig-wikipedia	1M
Statmt-news-crawl.ces	11M
LangUk-ubercorpus	22M
LangUk-news	15M
Total UK	41M
Total CS	15M

Table 2: The sizes of all sources used for back-translation.

¦	<token-delimiter>
↑	<single-uppercase>
▁	<explicit-whitespace>
∇	<all-uppercase>
Δ	<end-of-uppercase>

Table 3: Special characters in the HFT tokenizations.

(Kudo and Richardson, 2018), but spaces between words are assumed as default.

For the final system we have made the following extra changes in tokenization:

- Separate special capitalization symbols from tokens, they are always separate tokens.
- Split numbers into digits.

An example of this changes is displayed on the very last line in the Figure 1, the first token is split into two tokens, the number "3 000" at the end of the line is tokenized into two tokens in the original tokenization and into four tokens in the final one.

For the initial systems for translation we use vocabulary size of 32,000 items. The final translations system use only 12,000 items in the vocabulary on each side.

These modifications in the final system were motivated by an experiment on smaller data where BLEU score increased from 22.4 to 24.9. Separating individual digits is also an option (disabled by default) in the Sentencepiece (Kudo and Richardson, 2018) tokenizer. We will do a detailed evaluation of this modifications in the future.

4 Model

We use the DeepNorm (Wang et al., 2022) modification of the transformer (Vaswani et al., 2017) architecture in the TorchScale library (Ma et al., 2022). Our early experiments with the number of encoder and decoder layers shows with the agreement of Wei et al. (2022) that asymmetric configuration with more encoder layer performs better. We use 18 encoder layers and 6 decoder layers in all our models.

The first stage of the system in CS-UK direction is trained only on parallel data (6.6M segments) for 30 epochs, second stage in UK-CS direction uses also 15M Czech segments and is trained for 17 epochs. The final system uses parallel data and back-translated Ukrainian monolingual data (41M segments). It is trained for only 4 epochs. Checkpoints are created every 2000 updates and the final submission is the average of 8 checkpoints (1 following and 6 preceding) around the top-scoring checkpoint on development data.

The performance of the individual models are detailed in Table 4.

Stage	direction	segments	BLEU
ST1	CS-UK	6.6M	31.17
ST2	UK-CS	19M	34.57
final	CS-UK	48M	35.87

Table 4: Progress of scores

5 Results

Our first submission evaluated by OCELoT system on the test data received very low scores (BLEU 15.6) which don't correlate to the scores on our development set. We noticed Russian sentences instead of Ukrainian in our translations. For the final submission, we have done more filtering of both parallel and monolingual (back-translated) data as described in Section 2. The same system on cleaned data received much better scores (BLEU 28.3)

The official scores of our final system on the test data (Kocmi et al., 2023) are listed in the Table 5.

	final	**first**
COMET	87.0	
chrF	57.0	41.0
BLEU	28.3	15.6

Table 5: Automatic Scores of the final system and the first submission.

6 Conclusion

This paper presents the MUNI-NLP submission to the WMT 2023 General Machine Translation Task. Our results show that it is very important to clean the training data, especially foreign languages.

The paper also introduces a novel tokenization into subwords, a detailed evaluation of it is part of our future work.

Gang Hu
Lan-Bridge / Sichuan (China)
hugang@lan-bridge.com

Abstract

This paper describes Lan-Bridge Translation systems for the WMT 2023 General Translation shared task. We participate in 2 directions: English to and from Chinese. With the emergence of large-scale models, various industries have undergone significant transformations, particularly in the realm of document-level machine translation. This has introduced a novel research paradigm that we have embraced in our participation in the WMT23 competition. Focusing on advancements in models such as GPT-3.5, we have undertaken numerous prompt-based experiments. Our objective is to achieve optimal human evaluation results for document-level machine translation, resulting in our submission of the final outcomes in the general track.

1 Introduction

Recently, large-scale language models, such as GPT-3.5 and GPT-4 (gpt), have emerged as powerful tools in the field of natural language processing. These models have showcased their impressive capabilities in a wide range of tasks, including text generation, question answering, language translation, and more. Language models like GPT-3.5 possess the ability to understand and generate coherent, contextually relevant text, capturing the nuances of language usage and producing high-quality outputs.

In particular, machine translation is an area where these language models have shown tremendous promise. Traditional machine translation models (Yang et al., 2020) used the conventional Transformer architecture (Vaswani et al., 2017) since GPT-3.5 has the potential to revolutionize the translation process by leveraging its massive size and language understanding capabilities. With the advent of large models, the machine translation field has faced new challenges, and utilizing large models for machine translation is a novel attempt.By effectively incorporating prompts and context, GPT-3.5 can produce translations that exhibit fluency, accuracy, and adherence to the source text.

This study focuses on experimenting and evaluating different prompt engineering techniques to further enhance the translation performance of GPT-3.5. By providing more refined and contextually specific prompts, we aim to observe the model's ability to adjust and refine its translations, resulting in improved translation quality. Additionally, we explore the impact of temperature adjustments on the generated translations, allowing us to fine-tune the level of randomness in the output and achieve more deterministic and accurate translations.

Furthermore, we investigate both sentence-level and document-level approaches, examining the effectiveness of GPT-3.5 in handling translations at different granularity levels. These approaches aim to leverage the model's language understanding capabilities to not only produce accurate sentence-level translations but also ensure coherence and consistency at the overall document level.

By delving into these aspects and evaluating the performance of GPT-3.5 in the context of the WMT competition, we aim to contribute to the broader understanding of the capabilities, strengths, and limitations of state-of-the-art language models in the field of machine translation.

The inspiration for this study stems from the outstanding performance exhibited by these large-scale language models, especially in addressing real-world challenges such as major wildfires. GPT-3.5-4k and GPT-3.5-16k, with their increased model capacities, have demonstrated remarkable capabilities in generating high-quality text across various domains. Motivated by these advancements, our study aims to harness the power of these models and explore their potential in the specific domain of machine translation.

By leveraging the robustness and adaptability of GPT-3.5-4k and GPT-3.5-16k, we conduct rigorous

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 166–169
December 6–7, 2023.

experimentation to thoroughly evaluate their translation capabilities. We delve into the nuances of different parameter adjustments, including prompts and temperature, to optimize and enhance the models' performance specifically for translation tasks. By strategically fine-tuning these parameters, we aim to unlock hidden potential and push the boundaries of their translation capabilities.

Real-world challenges, such as major wildfires, require timely and accurate translation of critical information across languages. The effectiveness of machine translation plays a pivotal role in communicating vital updates and ensuring efficient information dissemination during such situations. By investigating the translation capabilities of GPT-3.5-4k and GPT-3.5-16k, we strive to contribute insights that can improve translation efficiency and aid in overcoming language barriers in emergency situations.

With this study, we aim to shed light on the immense potential of large-scale language models, such as GPT-3.5, in addressing real-world challenges through machine translation. By harnessing their capabilities and understanding their performance in various scenarios, we hope to pave the way for more effective and accurate translation systems that can assist in critical situations.

2 Methods

We have designed three prompt schemes:

P1: Translate this sentence from SRC to TGT, do not write any explanations

P2: Translation Request - Sentence-by-Sentence Translation. Language Pair: SRC to TGT. Instructions: 1. Each sentence of the document will be provided individually in the "Original Sentence" section. 2. In the "Translation" section, please provide the corresponding translation for each sentence, considering the context and aiming for faithful translation while minimizing unaligned translations. 3. Avoid including any explanations in the translation. Original Sentence:

P3: Translation Request - Sentence-by-Sentence Translation. Language Pair: SRC to TGT. Instructions: 1. Each sentence of the document will be provided individually in the "Original Sentence" section. 2. In the "Translation" section, please provide the corresponding translation for each sentence, considering the context and aiming for faithful translation while minimizing unaligned translations. 3. Avoid including any explanations in the translation. 4.Please review the translations for verifying that they remain faithful to the original text and provide revised versions accordingly if necessary. If no revisions are needed, provide the translations as they are.

In our study, we conducted several experiments to evaluate the performance of GPT-3.5. The following were the approaches we employed:

- Sentence-to-sentence translation: We used the prompt "Translate this sentence from SRC to TGT, do not write any explanations" to evaluate the model's ability to translate individual sentences accurately.
- Multi-turn dialogue translation: We explored the impact of multi-turn conversations on the performance of GPT-3.5. Using the prompt P1.
- Multi-turn dialogue translation with detailed prompt P3. This experiment aims to test whether GPT-3.5 has the ability to get faithful translations while minimizing unaligned translations.
- Comparison between GPT-3.5-4k and GPT-3.5-16k: We performed separate experiments using both GPT-3.5-4k and GPT-3.5-16k models to observe any differences in translation abilities between the two.
- Adjusting temperature parameter: We varied the temperature parameter (0, 0.3, 0.7) to examine its impact on the translation quality. Changing the temperature can control the randomness of the generated translations.
- Incorporating fake CoT prompt P3. This experiment aims to test whether GPT-3.5 has the ability to automatically reflect and optimize its translations.

3 Result

We conduct experiments to quantify the impact of each component in our system. The evaluation conduct on test set on wmt22 using SacreBLEU (Post, 2018) and COMET (Stewart et al., 2020).

As shown in Table 1, here are the conclusions based on your experimental results:

- From the first and second experiment results, it can be concluded that the performance of GPT-3.5 in multi-turn dialogue is better than

language pair	Prompt	Multi-turn	T	Model	Bleu-A	Bleu-B	Chrf-A	Chrf-B	Comet-A	Comet-B
zh-en	P1	false	0	GPT-3.5-4k	26.6	20.0	57.4	52.5	52.7	43.5
zh-en	P1	true	0	GPT-3.5-4k	27.7	20.7	58.4	53.2	55.8	46.7
zh-en	P3	true	0	GPT-3.5-16k	23.4	18.0	54.4	50.2	54.9	46.1
en-zh	P1	true	0	GPT-3.5-4k	45.7	53.9	41.1	48.5	63.4	71.2
en-zh	P2	true	0	GPT-3.5-4k	44.2	51.4	39.9	46.0	62.1	70.6
en-zh	P2	true	0.7	GPT-3.5-4k	42.8	49.3	38.4	44.1	61.7	68.7
en-zh	P2	true	0.7	GPT-3.5-16k	42.7	49.3	38.3	44.8	63.2	71.1
en-zh	P2	true	0.3	GPT-3.5-16k	44.4	51.5	39.9	46.3	63.8	71.2

Table 1: Bleu/Chrf/Comet score on wmt22 test set. The COMET scores are calculated with the model wmt20-comet-da, the ChrF scores are calculated using all available references and SacreBLEU signature is the default settings. Scores are multiplied by 100. T represents Temperature

single-turn translation. This indicates that context can help improve the translation quality of GPT-3.5 by providing additional prompts.

- Comparing the results of the third experiment with the fourth experiment, it is concluded that the performance of P2 is worse. This suggests that GPT-3.5 does not fully understand the given prompt, which results in difficulty in generating accurate translations.

- Comparing the results of the fourth, fifth, and seventh experiments, it is concluded that lower temperature values yield better translation results. This indicates that reducing temperature parameter leads to more deterministic and high-quality translations.

- Comparing the results of the fifth and sixth experiments, it is concluded that GPT-3.5-16k performs better in translation than GPT-3.5-4k.

- Comparing the results of the seventh experiment with previous results, it is concluded that P3 performs the worst. Additionally, observing the actual revised results, it can be noted that GPT-3.5-16k rarely modifies its translations, indicating that without specific and clear instructions, it is unable to make effective modifications to its own translations.

Based on our previous results, we have chosen GPT-3.5-16k as the final model for our submission. For the WMT23 en-zh/zh-en track, we set the temperature to 0 and utilized P1 as the prompt. Adopting a multi-turn dialogue approach, we submitted our final results with the systerm name "LanBridgeMT". Figure 1 and Figure 2 show the results of our systerm. [1] Additionally, for other language pairs in the general WMT competition, we opted to submit the results generated by our LanMT (Han et al., 2022) engine. This decision was made to assess the engine's performance and determine its scoring capabilities directly in the online evaluation environment.

By taking these approaches, we aim to showcase the effectiveness of GPT-3.5 and demonstrate the performance of our LanMT engine in the respective WMT tracks. These submissions reflect our overarching goal of participating in and contributing to the advancement of machine translation research and development.

4 Conclusion

In this study, we evaluated the translation performance of GPT-3.5 using various experimental approaches. Our findings indicate that incorporating multi-turn dialogue prompts improves the translation quality of GPT-3.5, highlighting the importance of context in guiding the model's translations. Furthermore, we observed that GPT-3.5-16k, compared to GPT-3.5-4k, demonstrates superior translation capabilities in commit scores, indicating its enhanced ability to understand and fulfill user instructions. However, there are marginal differences in the other two metrics, BLEU and ChrF. Additionally, we found that lower temperature values result in improved translation quality, indicating the usefulness of controlling randomness in the generated translations. However, it is important to note that GPT-3.5 may struggle with understanding ambiguous prompts and lacks the ability to autonomously adjust and optimize its translations without explicit instructions. These findings contribute to our under-

Abstract

This paper presents the submission of Huawei Translate Services Center (HW-TSC) to the WMT23 general machine translation (MT) shared task. We participate in Chinese↔English (zh↔en) language pair. We use deep Transformer architecture and obtain the best performance via a Transformer variant with a larger parameter size. We perform fine-grained pre-processing and filtering on the provided large-scale bilingual and monolingual datasets. The model enhancement strategies we used includes Regularized Dropout, Bidirectional Training, Data Diversification, Forward Translation, Back Translation, Alternated Training, Curriculum Learning and Transductive Ensemble Learning. Our submission obtain competitive results in the final evaluation.

1 Introduction

Machine translation (MT) (Brown et al., 1990) refers to the automatic translation of text from one language to another, while the WMT23 general MT shared task focuses on evaluation of general MT capabilities. Compared with the news shared task in previous years, the general MT shared task involves multiple domains. The testsets contain data in news, user generated (social), conversational, and ecommerce domains.

This paper presents the submission of HW-TSC to the WMT23 general MT shared task, in which we participate in zh↔en language pair. Our method is mainly based on previous works (Wei et al., 2022; Wu et al., 2022; Yang et al., 2021). We perform multi-step data cleansing on the provided dataset and only keep a high-quality subset for training. At the same time, several model enhancement strategies are tested in a pipeline, including Regularized Dropout (Wu et al., 2021), Bidirectional Training (Ding et al., 2021), Data Diversification (Nguyen et al., 2020), Forward Translation (Abdulmumin, 2021), Back Translation (Sennrich et al., 2016), Alternated Training (Jiao et al., 2021), Curriculum Learning (Zhang et al., 2019) and Transductive Ensemble Learning (Wang et al., 2020b).

Our system report includes four parts. Section 2 focuses on our data processing strategies while section 3 describes our training details. Section 4 explains our experiment settings and training processes and section 5 presents the results.

2 Data

2.1 Data Source

We obtain bilingual and monolingual data from ParaCrawl v9, News Commentary v18.1, Wiki Titles v3, UN Parallel Corpus V1.0, CCMT Corpus, WikiMatrix, News Crawl and Common Crawl data sources. The amount of data we used is shown in Table 1. It should be noted that in order to obtain better performance in the general domain, we mix the monolingual data from Common Crawl and News Crawl.

language pairs	bitext data	monolingual data
zh↔en	25M	en: 50M, zh: 50M

Table 1: Bilingual and monolingual used for training.

2.2 Data Pre-processing

Our data processing procedure is precisely the same as the previous year (Wei et al., 2021), including deduplication, XML content processing, langid (Lui and Baldwin, 2012) and fast-align (Dyer et al., 2013) filtering strategies. As we use the same data pre-processing strategy as the previous year, we will not go into details here.

2.3 Data Denoising

Since there may be some semantically dissimilar sentence pairs in bilingual data, we use LaBSE (Feng et al., 2022) to calculate the semantic similarity of each bilingual sentence pair, and exclude

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 170–174
December 6–7, 2023.

bilingual sentence pairs with a similarity score lower than 0.7 from our training corpus.

3 System Overview

3.1 Model

We continue using Transformer (Vaswani et al., 2017) as our neural machine translation (NMT) (Bahdanau et al., 2015) model architecture. As we did last year, we only use a 25-6 deep model architecture (Wang et al., 2019). The parameters of the model are the same as Transformer big. We just change the post-layer normalization to the pre-layer normalization, and set encoder layers to 25.

3.2 Regularized Dropout

Regularized Dropout (R-Drop)[1] (Wu et al., 2021) is a simple yet more effective alternative to regularize the training inconsistency induced by dropout (Srivastava et al., 2014). Concretely, in each mini-batch training, each data sample goes through the forward pass twice, and each pass is processed by a different sub model by randomly dropping out some hidden units. R-Drop forces the two distributions for the same data sample outputted by the two sub models to be consistent with each other, through minimizing the bidirectional Kullback-Leibler (KL) divergence (Van Erven and Harremos, 2014) between the two distributions. That is, R-Drop regularizes the outputs of two sub models randomly sampled from dropout for each data sample in training. In this way, the inconsistency between the training and inference stage can be alleviated.

3.3 Bidirectional Training

Many studies have shown that pre-training can transfer the knowledge and data distribution, hence improving the model generalization. Bidirectional training (BiT) (Ding et al., 2021) is a simple and effective pre-training method for NMT. Bidirectional training is divided into two stages: (1) bidirectionally updates model parameters, and (2) tune the model. To achieve bidirectional updating, we only need to reconstruct the training samples from "src→tgt" to "src→tgt & tgt→src" without any complicated model modifications. Notably, BiT does not require additional parameters or training steps and only uses parallel data.

[1] https://github.com/dropreg/R-Drop

3.4 Data Diversification

Data Diversification (DD) (Nguyen et al., 2020) is a data augmentation method to boost NMT performance. It diversifies the training data by using the predictions of multiple forward and backward models and then merging them with the original dataset which the final NMT model is trained on. DD is applicable to all NMT models. It does not require extra monolingual data, nor does it add more parameters. To conserve training resources, we only use one forward model and one backward model to diversify the training data.

3.5 Forward Translation

Forward translation (FT) (Abdulmumin, 2021), also known as self-training, is one of the most commonly used data augmentation methods. FT has proven effective for improving NMT performance by augmenting model training with synthetic parallel data. Generally, FT is performed in three steps: (1) randomly sample a subset from the large-scale source monolingual data; (2) use a "teacher" NMT model to translate the subset data into the target language to construct the synthetic parallel data; (3) combine the synthetic and authentic parallel data to train a "student" NMT model.

3.6 Back Translation

An effective method to improve NMT with target monolingual data is to augment the parallel training data with back translation (BT) (Sennrich et al., 2016; Wei et al., 2023). There are many works expand the understanding of BT and investigates a number of methods to generate synthetic source sentences. Edunov et al. (2018) find that back translations obtained via sampling or noised beam outputs are more effective than back translations generated by beam or greedy search in most scenarios. Caswell et al. (2019) show that the main role of such noised beam outputs is not to diversify the source side, but simply to tell the model that the given source is synthetic. Therefore, they propose a simpler alternative strategy: Tagged BT. This method uses an extra token to mark back translated source sentences, which generally outperforms noised BT (Edunov et al., 2018). For better joint use with FT, we use sampling back translation (ST) (Edunov et al., 2018).

3.7 Alternated Training

While synthetic bilingual data have demonstrated their effectiveness in NMT, adding more synthetic data often deteriorates translation performance since the synthetic data inevitably contains noise and erroneous translations. Alternated training (AT) (Jiao et al., 2021) introduce authentic data as guidance to prevent the training of NMT models from being disturbed by noisy synthetic data. AT describes the synthetic and authentic data as two types of different approximations for the distribution of infinite authentic data, and its basic idea is to alternate synthetic and authentic data iteratively during training until the model converges.

3.8 Curriculum Learning

A practical curriculum learning (CL) (Zhang et al., 2019) method should address two main questions: how to rank the training examples, and how to modify the sampling procedure based on this ranking. For ranking, we choose to estimate the difficulty of training samples according to their domain feature (Wang et al., 2020a). The calculation formula of domain feature is as follows, where θ_{in} represents an in-domain NMT model, and θ_{out} represents a out-of-domain NMT model. One thing to note is that we treat domains including news, user-generated (social), conversational, and e-commerce domains as in-domain, and others as out-of-domain. Specifically, we use the WMT22 test set to fine-tune a baseline model, and then use the baseline model and the fine-tuned model as the out-of-domain model and the in-domain model respectively.

$$q(x,y) = \frac{\log P(y|x;\theta_{in}) - \log P(y|x;\theta_{out})}{|y|} \quad (1)$$

For sampling, we adopt a probabilistic CL strategy that leverages the concept of CL in a nondeterministic fashion without discarding the original standard training practice, such as bucketing and mini-batching.

3.9 Transductive Ensemble Learning

Ensemble learning (Garmash and Monz, 2016), which aggregates multiple diverse models for inference, is a common practice to improve the performance of machine learning models. However, it has been observed that the conventional ensemble methods only bring marginal improvement for NMT when individual models are strong or there are a large number of individual models. Transductive Ensemble Learning (TEL) (Zhang et al., 2019) studies how to effectively aggregate multiple NMT models under the transductive setting where the source sentences of the test set are known. TEL uses all individual models to translate the source test set into the target language space and then fine-tune a strong model on the translated synthetic data, which significantly boosts strong individual models and benefits a lot from more individual models.

4 Experiment Settings

We use the open-source fairseq (Ott et al., 2019) for training, then we use SacreBLEU (Post, 2018)[2] and wmt20-comet-da model (Rei et al., 2020) to measure system performances. The main parameters are as follows: each model is trained using 8 A100 GPUs, batch size is 6144, parameter update frequency is 2, and learning rate is 5e-4. The number of warmup steps is 4000, and model is saved every 1000 steps. The architecture we used is described in section 3.1. We adopt dropout, and the rate varies across different training phases. R-Drop is used in model training, and we set λ to 5.

5 Results

Regarding zh↔en, we use Regularized Dropout, Bidirectional Training, Data Diversification, Forward Translation, Back Translation, Alternated Training, Curriculum Learning, and Transductive Ensemble Learning. The evaluation results of en→zh and zh→en NMT system on WMT22 general test sets are shown in Tables 2.

	en→zh		zh→en	
	BLEU	COMET	BLEU	COMET
BiT R-Drop baseline	45.55	50.24	22.30	22.28
+ DD, FT & ST	49.54	59.69	25.67	33.44
+ AT	54.11	63.99	28.58	37.15
+ CL	56.36	68.90	30.58	44.62
+ TEL	**56.80**	**69.06**	**31.35**	**45.56**

Table 2: BLEU and COMET scores of en→zh and zh→en NMT system on WMT22 general test set.

We observe that DD, FT & ST can stably bring 3-4 BLEU and 1-9 COMET improvement; AT can bring 3-5 BLEU and 4 COMET improvement; and CL can bring 2 BLEU and 5-7 COMET improvement. In addition, TEL can further slightly improve BLEU and COMET scores. Our final en→zh

and zh→en submissions achieve 56.80 and 31.35 BLEU, 69.06 and 45.56 COMET respectively.

6 Official Automatic Evaluation Results

In our final submission, we add post-processing for punctuation correction and entity preservation. WMT (Kocmi et al., 2023) present an automatic evaluation of the systems submitted to the general machine translation task, including the following three different automatic metrics: chrF, BLEU and COMET. We rank the systems according to COMET scores, and unconstrained systems are in a grey background in the tables.

7 Conclusion

This paper presents the submission of HW-TSC to the WMT23 general MT Task. We participate in zh↔en language pair and perform experiments with a series of pre-processing and training strategies. The effectiveness of each strategy is demonstrated. Our experiments show that our model training strategies are effective. Our submission finally achieve competitive results in the evaluation.

Abstract

This paper describes the UvA-MT's submission to the WMT 2023 shared task on general machine translation. We participate in the constrained track in two directions: English ↔ Hebrew. In this competition, we show that by using one model to handle bidirectional tasks, as a minimal setting of Multilingual Machine Translation (MMT), it is possible to achieve comparable results with that of traditional bilingual translation for both directions. By including effective strategies, like back-translation, re-parameterized embedding table, and task-oriented fine-tuning, we obtained competitive final results in the automatic evaluation for both English → Hebrew and Hebrew → English directions.

1 Introduction

Multilingual Machine Translation (MMT) (Johnson et al., 2017) has attracted a lot of attention in recent years because of 1) its high-level efficiency (multiple translation directions within a single model) and 2) the potential for knowledge transfer, especially for low-resource or even unseen directions. In MMT systems, only one additional tag is introduced to indicate the translation direction, compared to the conventional encoder-decoder architecture. In this competition, we explore MMT with a minimal setting, i.e., using one model for bidirectional translations simultaneously.

We leverage all the official parallel data and a substantial portion of the monolingual data generously provided by the WMT23 organizer, as elaborated in Section 2. To elevate the quality of our parallel data, we implemented a comprehensive three-step cleaning procedure. Additionally, for monolingual data, we further trained an n-gram language model to filter out low-quality sentences, with the goal of generating synthetic data as elaborated in Section 4.1.

The backbone of our system is based on a standard transformer (Vaswani et al., 2017). Additionally, we build a re-parameterized embedding table (Wu and Monz, 2023) (see Section 3.2) to enhance the representational word similarity between English and Hebrew, targeting better knowledge transfer for multilingual translation.

The final system involves three stages of training: 1) **Pretraining with synthetic data** (see Section 4.1), where we leverage back-translation (Sennrich et al., 2016) to produce synthetic data, and finally add them as additional data within new translation directions in our MMT system to conduct pretraining. 2) **Training without synthetic data** (see Section 4.2), where we discard the additional synthetic data and further train our system using real bitext only. 3) **Fine-tuning with task-related data** (see Section 4.3), where we copy and fine-tune our system using English → Hebrew and Hebrew → English data for each track respectively. We observe evident improvements for stage 1 and stage 2, while surprisingly performance drops for stage 3.

We report our results, including the offline evaluation and the final online evaluation, in Section 5. Our *constrained* system showed comparable performance to *unconstrained* systems, and outperformed the second-place constrained submission with +10 BLEU.

2 Data

In this section, we provide an overview of our data sources and the data cleaning procedures applied to our English-Hebrew translation task. We utilize both parallel and monolingual data sets provided by the organizers for training our translation systems.

2.1 Parallel Data

We make use of all the available data from the constrained track of the shared task for English-

*Equal contribution.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 175–180
December 6–7, 2023.

Hebrew translation. To enhance the quality of our parallel data, we undergo a thorough preprocessing phase involving three key steps, as outlined below. All steps in the cleaning step 1 are executed using the Moses toolkit[*] (Koehn et al., 2007). Consequently, we reduced the size of the raw bitext data from 70 million to 34 million sentences after completing the three steps of the cleaning process:

- Cleaning Step 1
  - Deescaping special characters in XML.
  - Removing non-printable characters.
  - Normalizing punctuation and tokenizing sentences using Moses.
- Cleaning Step 2
  - Filtering out sentences longer than 256 tokens.
  - Eliminating sentences where over 75% of the words on both the source and target sides are identical.
  - Removing sentences with a source-to-target token ratio exceeding 1.5.
  - Eliminating duplicate sentences.
- Cleaning Step 3
  - Removing off-target sentences using the FastText Language identification tool (Joulin et al., 2016).
  - Excluding sentences exhibiting one-to-many or many-to-one mappings, for example, a single source sentence having multiple different target sentences.

Furthermore, we sampled 10 million parallel sentences to learn a 32k joint unigram (Kudo, 2018) model-based subword vocabulary using SentencePiece (Kudo and Richardson, 2018), which we then utilized across all our models, including the n-gram KenLM model discussed in the next section. However, we encountered a situation where certain emoji tokens were not included in our vocabulary. As a result, we integrated an additional post-processing step in Section 4.4 to address this issue.

2.2 Monolingual Data

To enhance our translation systems further, we incorporate monolingual data to produce synthetic data through back-translation. For our monolingual data, we primarily rely on the official English data provided by the organizers. Note that we did not use any Hebrew monolingual data since it is limited (only 1 million sentences). We combine three official English monolingual datasets: News Discussions 2019, Leipzig News Corpora 2020, and News Crawl (2007-2022) to construct our raw monolingual dataset. Following this, we apply the same Cleaning Step 1 procedure as detailed in the Parallel Data section to preprocess the monolingual data, and this results in 373 million sentences.

Considering the low quality of monolingual data, we additionally filter them by training an n-gram language model, i.e., KenLM (Heafield, 2011), and eliminate the sentences below an LM score threshold. The training data of KenLM is all of the test data in English, including our offline test data Flores, and the official test dataset. We train KenLM at the subword level, where we use the same unigram model (trained upon original bilingual data) to split the training data of KenLM. Then, we use it to score all of the monolingual data. To establish a filtering threshold, we randomly selected 1,000 sentences and labeled them as positive or negative based on criteria such as fluency, naturalness (e.g., avoiding strings of numbers), and relevance to the domain mentioned for WMT23 test datasets. Finally, we chose a threshold that could filter 70% bad cases within the 1,000 sentences, with the cost of monolingual 30% data, resulting in around 250M total sentences.

Lastly, considering the limitation of the computational resource, we sample 32M monolingual sentences (at the same level as the bilingual dataset) from the filtered dataset.

3 Systems

3.1 Backbone and Baseline

In this section, we outline the foundational architecture and adjustments made to our baseline systems. Our baseline model leverages English $\leftrightarrow$ Hebrew translation directions by incorporating the target language token at the beginning of the encoder, denoted as "2he" and "2en". Our implementations are grounded in the Transformer architecture (Vaswani et al., 2017), leveraging the Fairseq toolkit (Ott et al., 2019).

For our baseline model, we utilize a 12-layer Transformer architecture (mT-large) with specific modifications, including pre-norm for both the en-

[*] https://github.com/moses-smt/mosesdecoder/

coder and decoder, and layer-norm for embedding. To enhance stability and performance, we tie the parameters of encoder embedding, decoder embedding, and decoder output. We also introduce dropout and attention dropout with a probability of 0.1, along with label smoothing at a rate of 0.1.

Similar to the approach described by Vaswani et al. (2017), we employ the Adam optimizer with a learning rate of 5e-4, implementing an inverse square root learning rate schedule with 4,000 warmup steps. We set the maximum number of tokens to 10,240, with gradient accumulation every 21 steps to facilitate large-batch training in Tang et al. (2021). We train all of our systems with 4 NVIDIA A6000 Gpus, and to expedite the training process, we conducted all experiments using half-precision training (FP16). Additionally, we save checkpoints every 2000 steps and implement early stopping based on perplexity, with a patience of 5 epochs.

3.2 Re-parameterized Embedding Table

Using a vocabulary that is shared across languages is common practice in MMT. In addition to its simple design, shared tokens play an important role in positive knowledge transfer, assuming that shared tokens refer to similar meanings across languages. This point has been demonstrated by previous works (Pires et al., 2019; Sun et al., 2022; Stap et al., 2023; Wu and Monz, 2023). To enhance word-level knowledge transfer, we follow (Wu and Monz, 2023) to implement a re-parameterized shared embedding table and equipped it with our backbone.

We leverage eflomal (Östling and Tiedemann, 2016) to train and extract subword-level alignments based on all of the bilingual data we used. Then, we build the priors of word equivalence (word alignments) into a graph and leverage GNN (Welling and Kipf, 2016) to re-parameterize the embedding table.

More specifically, For two words v_i and v_j in V, we define an alignment probability from v_j to v_i in corpus D as corresponding transfer ratios $g_{i,j}$ as follows:

$$g_{i,j} = \frac{c_{i,j}}{\sum_{k=1}^{|V|} c_{i,k}}, \quad (1)$$

where $c_{i,j}$ is the number of times both words are aligned with each other across D. The corresponding bilingual equivalence graph G can be induced by filling an adjacency matrix using $g_{i,j}$, G is applied within graph networks to re-parameterize the original embedding table as follows:

$$E' = \rho(EW_1 + GEW_2 + B). \quad (2)$$

To allow the message to pass over multiple hops, we stack multiple graph networks and calculate representations recursively as follows:

$$E^{h+1} = \rho(E^h W_1^h + GE^h W_2^h + B^h), \quad (3)$$

where h is the layer index, i.e., *hop*, and E^0 is equal to the original embedding table E. The last layer representation E^H is the final re-parameterized embedding table, for the maximum number of hops H, which is then used by the system just like any vanilla embedding table.

4 Experiments

We describe the training process of our system in three stages.

4.1 Pretraining with Synthetic Data

Back-translation plays an important role in leveraging monolingual data in machine translation. In this competition, we also apply it to produce synthetic data and include it in our first-stage training.

Specifically, we first train a base MMT model (backbone with re-parameterized embedding tables) using bilingual data. Then, we feed our monolingual English data to produce EN-HE synthetic bitext. Finally, we merge the original bilingual data with the synthetic data together to pre-train our MMT system. We follow Fan et al. (2021) and add an additional language tag "2syn" to differentiate between synthetic and original Hebrew data. Note that, although normally original data (here, it is EN) is used as target side data after back translation, we use synthetic data for both directions.

4.2 Training without Synthetic Data

Considering that the synthetic data may differ from the original bilingual data in terms of data quality, domain difference, and diversity, in the second-stage training, we encourage our system to skew towards the original bilingual distribution. We achieve this by discarding the synthetic data directly and continuing training upon the first-stage system as a kind of full parameter finetuning.

Strategy	Sampled Data		Full Data	
	EN→HE	HE→EN	EN→HE	HE→EN
Bilingual Baseline	24.6	31.1	34.1	46.0
MMT Baseline	24.7	31.6	34.1	45.8
MMT + GM 1-hop	**26.2**	32.3	**34.3**	**46.2**
MMT + GM 2-hop	25.5	**32.7**	-	-

Table 1: Offline evaluation results on sampled and full training data. For sampled data (2M), the backbone is Transformer Base, while for full data (34M) the backbone is Transformer Large as we describe in Section 3.1. MMT + GM means that we equip graph-based re-parameterized embedding tables for our MMT baseline, and hop means how many graph network layers are involved. The best BLEU scores in each column are written in bold.

Strategy	Offline		Online	
	EN→HE	HE→EN	EN→HE	HE→EN
MMT Baseline	34.1	45.8	33.3	50.3
MMT + GM 1-hop	34.3	46.2	33.6	50.7
MMT + GM 1-hop + Stage-1	**35.4**	46.8	**35.0**	50.1
MMT + GM 1-hop + Stage-1,2	34.1	**47.4**	**35.0**	**51.0**
MMT + GM 1-hop + Stage-1,2,3	33.3	44.3	33.3	48.0

Table 2: Final results of three stages training. The best BLEU scores in each column are written in bold.

4.3 Finetuning on Task-Specific Data

Lastly, to encourage the system to focus on one certain language direction, we further fine-tune direction-specific data on the second-stage system. Note, the direction-specific data here, i.e., EN → HE and HE → EN are both from the original bilingual data. The effectiveness is also demonstrated by Ding et al. (2021); Zan et al. (2022) for bilingual translation.

In short, in this three-stage training process, we gradually narrow down the data distribution to focus on task-specific real data.

4.4 Post-Processing

We noticed that some emoji tokens in the official test set were not included in our vocabulary. Thus, we integrated an additional post-processing step to process them. Specifically, we escaped the emoji tokens to their Unicode string* before tokenizing and feeding them to our system to conduct inference, and then convert the Unicode string back for generated predictions.

4.5 Offline Evaluation

We used Flores-200 (Costa-jussà et al., 2022) to evaluate our strategies offline before submissions and Ntrex-128 (Federmann et al., 2022) as the validation set. We show the results in Table 1. Due to resource limitations, we sample 2M of bilingual data to verify whether there is a big performance gap between MMT and bilingual baseline. Meanwhile, we also chose the best hyperparameter for our re-parameterized embedding table, i.e., the hop number, based on the sampled dataset.

As shown in Table 1, on both sampled and full data, the MMT baseline achieves comparable results with bilingual counterparts. Especially for sampled data, it even outperforms 0.5 BLEU for into-English translation.

The model-equipped 1-hop re-parameterized embedding table demonstrates a notable improvement, yielding a 1.5 BLEU gain for the out-of-English direction and a 0.7 BLEU gain for the out-of- and into-English directions, on 2M datasets. It shows that the embedding re-parameterized method (Wu and Monz, 2023) also works for bilingual settings, which is not explored in the original paper. We did not observe evident gains for 2-hop compared with 1-hop on sampled data, hence, we only apply the 1-hop graph networks for the full data training. As shown in the table, the results are consistent with that of small data, where MMT with 1-hop graph networks achieve better performance than MMT baseline.

As above, we chose MMT with the 1-hop setting as our architecture and conducted our three stages of training as described in Section 4.

*For example, the emoji of "Grinning Face with Open Eyes" will convert to a string "U+1F600".

5 Results

Table-2 shows our offline and online evaluation results according to each training stage described in Section 4. We still use Flores-200 to conduct offline evaluations. The online results are reported by WMT23 background BLEU evaluations. Stage-1, -2, and -3 refer to "Pretraining with Synthetic Data", "Training without Synthetic Data", and "Finetuning on Task-Specific Data" respectively.

The results of online and offline evaluations are quite consistent. Both of them achieve best results when training with stage 1 and stage 2. It shows that by step-by-step narrowing training data from mixing with synthetic data to real data distribution, we can further boost our MMT system's performance. However, when we further conduct fine-tuning on direction-specific data, i.e., applying stage 3, there is an evident performance drop. It seems that tuning in a specific direction upon MMT may not be a good practice, at least when the training data are a subset of that for MMT. We leave this point for future exploration.

Our final system achieves 35.0 and 51.0 in EN→HE and HE→EN direction respectively, which are both in the first place for constrained tracks.

6 Conclusion

In this competition, we show that: 1) It is possible to achieve comparable results with conventional bilingual translation by using MMT training fashion to handle two dual translation directions. 2) Previous embedding re-parameterized method (Wu and Monz, 2023) also works for bilingual translation, which is not verified in the original paper. However, when training data scales up to 30+M level, the improvements become marginal. 3) By step-by-step narrowing training data (especially for stage-1 and stage-2) from mixing with synthetic data to real data distribution, we successfully boost the final performance, even in a quite high-resource scenario (30+M).

Achieving State-of-the-Art Multilingual Translation Model with Minimal Data and Parameters

Hui Zeng
LanguageX AI Lab
felix_zeng_ai@aliyun.com

Abstract

This is LanguageX (ZengHuiMT)'s submission to WMT 2023 General Machine Translation task for 13 language directions. We initially employ an encoder-decoder model to train on all 13 competition translation directions as our baseline system. Subsequently, we adopt a decoder-only architecture and fine-tune a multilingual language model by partially sampling data from diverse multilingual datasets such as CC100 and WuDaoCorpora. This is further refined using carefully curated high-quality parallel corpora across multiple translation directions to enable the model to perform translation tasks. As per automated evaluation metrics, our model ranks first in the translation directions from English to Russian, English to German, and English to Ukrainian. It secures the second position in the directions from English to Czech, English to Hebrew, Hebrew to English, and Ukrainian to English, and ranks third in German to English, Japanese to English, and Russian to English among all participating teams. Our best-performing model, covering 13 translation directions, stands on par with GPT-4. Among all 13 translation directions, our multilingual model surpasses GPT-4 in bleu scores for 7 translation directions.

1 Introduction

Since 2023, large language models like ChatGPT (Brockman et al., 2023) have had a profound impact on the field of machine translation, characterized by an ever-increasing scale in terms of parameters and data requirements. Many research institutions and language service providers struggle to keep pace with this computational arms race. For smaller teams, the only viable strategy is to maximize model performance under constrained hardware resources. We participated in the WMT 2023 General Machine Translation task, covering 13 translation directions. Given our limited computational power and time constraints, it was infeasible to craft dedicated models for each translation direction, making a large-scale multilingual translation model our optimal choice. We utilized Fairseq (Ott et al., 2019) to train our baseline multilingual translation model and further employed the Hugging Face Transformers Toolkit (Wolf et al., 2020) to train a multilingual language model. Subsequent fine-tuning with task-specific instructions enabled it to perform multilingual translation tasks effectively.

2 Data Filtering and Selection

We participated in the WMT 2023 General MT task, competing in 13 language pairs including Chinese to/from English, German to/from English (at the document level), Hebrew to/from English (in a low-resource setting), Japanese to/from English, Russian to/from English, Ukrainian to/from English, and English to Czech.

Given the challenge of concurrently training for 13 translation directions, it was imperative for us to judiciously regulate the size of parallel corpora specific to each direction, as well as the parameter count of the multilingual translation model. This was crucial to ensure training completion within a constrained timeline. For the Chinese-English bi-directional translation, our primary sources for parallel corpora were the CCMT Corpus (which can be found at:

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 181–186

http://mteval.cipsc.org.cn:81/agreement/description), genuine internal translation project data, in addition to content extracted and curated from websites and e-books. This rigorous process resulted in a refined collection of approximately 5 million parallel sentence pairs. For other translation orientations, we used the English segments from the derived Chinese-English parallel corpus as foundational data. This seed data enabled the retrieval of analogous language pairs from our comprehensive in-house multilingual parallel corpus, with each translation direction maintaining a parallel sentence count in the ballpark of 5 million.

Given the need to train a decoder-only multilingual model, we primarily utilized public datasets such as Book Corpus (Zhu et al., 2015), CC100 (Conneau et al., 2020), and WuDaoCorpora (Yuan et al., 2021). It was also imperative for us to regulate the data volume for each language and the parameter count of the multilingual model. Table 1 delineates the sources and the respective quantities for monolingual data across different languages. Owing to the extended length of text segments in the WuDaoCorpora (Yuan et al., 2021), the number of extracted text passages is fewer compared to other languages. However, the character count remains substantial.

Language	Data Source	Size in GB	Paragraph Count
Chinese	WuDaoCorpora	6.4	3,980,000
Czech	CC100	4.5	29,630,985
German	CC100	5.1	24,958,540
English	BookCorpus	4.3	20,000,000
English	CC100	3.3	20,000,000
Hebrew	CC100	5.4	30,877,445
Japanese	CC100	5.8	30,985,700
Russian	CC100	5.7	13,928,244
Ukrainian	CC100	4.6	16,818,862

Table 1: Sources and Quantities of Monolingual Data for Each Language.

2.1 Monolingual Data Filtering

The following rules are used to filter parallel corpus.

• Remove duplicated sentence pairs.
• Remove the sentence pairs containing special characters.
• Remove the sentence pairs containing html addresses or tags.

2.2 Parallel Data Filtering Using Rules

The following rules are used to filter parallel corpus.

a. Remove duplicated sentence pairs.
b. Remove the lines having identical source and target sentences.
c. Remove the sentence pairs containing special characters.
d. Remove the sentence pairs containing html addresses or tags.
e. Remove the sentence pairs with empty source or target side.

2.3 Parallel Data Filtering Using Multilingual Language Model

We used a multilingual model - sentence-transformers/paraphrase-multilingual-mpnet-base-v2 (Reimers et al., 2019) that generates embeddings for sentences or paragraphs in various languages. Using these embeddings, we calculated semantic similarity scores for parallel sentence pairs. Based on these scores, we filtered out low-quality parallel sentence pairs.

3 System Description

This section illustrates how the model is trained step by step.

3.1 Data pre-processing

Data pre-processing of multilingual translation model. We utilized the NLLB (NLLB Team, 2022) tokenizer from Hugging Face as the foundation and incorporated additional Chinese tokens to create an enhanced tokenizer specifically for Chinese language processing. This resulted in a final vocabulary size of 266,786 tokens.

To ensure synchronized training across all translation directions and to prevent the model from mastering one translation direction at the expense of another, we evenly blended the multilingual parallel corpora. This involved sequentially placing a fixed number of parallel sentence pairs from different translation directions into the training set, typically set to 100 pairs per direction.

To facilitate the simultaneous training of multiple translation directions within a single large model, we shared the embeddings and vocabulary for both source and target languages. Furthermore, we prefixed the source part of the parallel sentence pairs with specific prompt tokens.

The structure of the parallel sentence pairs is as follows: {engine name} engine. Translation from {source language} to {target language}: {source line} 🐯 {target line} <eos>. 🐯 is the delimiter used for parallel corpora.

To better accommodate the German to/from English (at the document level) translation task, we combined conventional sentence-level German to/from English parallel corpora into paragraph-level corpora based on a specified number of sentences. We then mixed this with the regular sentence-level parallel corpora, ensuring the resultant model is trained to handle a broader range of sequence lengths.

Data pre-processing of multilingual language model. We employed the same tokenizer as used in the multilingual translation model.

Due to the vast size of the CC100 dataset (Conneau et al., 2020), we performed sampling on the data for all languages, with 1,000 lines as the sampling unit. Multiple units were extracted from various parts of the entire dataset to cover it as comprehensively as possible, while keeping the individual language data size at around 5GB.

To mitigate catastrophic forgetting, we uniformly mixed the monolingual data of each language. This ensured that the training process included synchronized training on data from all languages, rather than training on one language first and then training on another.

The structure of the supervised finetuning prompt for translation task is as follows: {engine name} engine. Text in {source language}: {source line} Translation of the previous text to {target language}: {target line} 🥰.

To prevent endless generation and excessive translation, the 🥰 emoji is placed at the end of the translation to signify its completion, signaling the model to cease generation.

3.2 Baseline Translation Model Training

The parallel data prepared in step 3.1 is used to train a multilingual translation model using transformer (Vaswani et al., 2017) architecture as the baseline. Training was conducted using Fairseq (Ott et al., 2019) over the entire dataset for four epochs. The crucial training parameters are as follows:

```
--encoder-layers 12 \
--encoder-attention-heads 16 \
--encoder-embed-dim 1024 \
--encoder-ffn-embed-dim 4096 \
--decoder-layers 6 \
--decoder-attention-heads 16 \
--decoder-embed-dim 1024 \
--decoder-ffn-embed-dim 4096 \
--share-decoder-input-output-embed \
--share-all-embeddings \
--max-source-positions 1024 \
--max-target-positions 1024 \
--lr 5e-4 \
--lr-scheduler inverse_sqrt \
--warmup-updates 4000 \
```

Parameter	Value
Trainable parameters	1,091,315,712
Vocabulary size	266,786
Max length	1024
Embedding Dimension	1536
Decoder layers	24
Attention heads	16
Learning rate	5e-5
Lr scheduler type	linear
Warmup steps	4,000

Table 4: BLEU score comparison between the multilingual model and GPT-4 across all language directions on Newstest 2023.

3.3 Multilingual Language Model Training

We utilized DeepSpeed (Rasley et al., 2020) and Hugging Face transformers (Vaswani et al., 2017) as our training tools and trained the models on the uniformly mixed monolingual data and SFT data prepared in step 3.1 after applying bf16 precision. The specific training parameters are presented in Table 2. The entire training process was completed using four RTX A6000 GPUs. After completing one full pass of the entire dataset, we

terminated the training of the multilingual language model.

3.4 Results

The BLEU (Papineni et al., 2002) scores on Newstest 2023 for all translation directions and different training methodologies are presented in Table 3.

Based on the automated assessment metrics, our system takes the lead in translation directions from English to Russian, English to German, and English to Ukrainian. It claims the runner-up spot for English to Czech, English to Hebrew, Hebrew to English, and Ukrainian to English directions, and occupies the third place for the German to English, Japanese to English, and Russian to English directions among the contenders.

4 Conclusion

This paper describes LanguageX (ZengHuiMT)'s translation system for the WMT2023 General MT task. Initially, we utilize a comprehensive encoder-decoder structure to establish our baseline system by training across all 13 contest translation directions. In the subsequent stages, we embrace a solely decoder-focused design and harness a multilingual language model, drawing samples from multilingual datasets like CC100 (Conneau et al., 2020) and WuDaoCorpora (Yuan et al., 2021). This model is then meticulously fine-tuned using select high-grade parallel corpora from various translation domains, empowering it to execute translation task.

Our best-performing model, covering 13 translation directions, boasts around 1 billion parameters. This is less than one percent of the parameter count of mammoth models like GPT-4 (OpenAI, 2023), which possess hundreds of billions of parameters. In translation evaluations across all languages, our system stands on par with GPT-4 (OpenAI, 2023). Among all 13 translation directions, our multilingual model surpasses GPT-4 (OpenAI, 2023) in bleu (Papineni et al., 2002) scores for 7 translation directions.

Acknowledgments

Thanks to my wife who spends most of her time to take care of our two kids, so that I am able to participate in the contest and complete this paper.

IOL Research Machine Translation Systems for WMT23 General Machine Translation Shared Task

Wenbo Zhang, Zeyu Yan, Qiaobo Deng, Jie Cai, and **Hongbao Mao**
Transn IOL Research, Wuhan, China

Abstract

This paper describes the IOL Research team's submission systems for the WMT23 general machine translation shared task. We participated in two language translation directions, including English→Chinese and Chinese→English. Our final primary submissions belong to constrained systems, which means for both translation directions we only use officially provided monolingual and bilingual data to train the translation systems. Our systems are based on Transformer architecture with pre-norm or deep-norm, which has been proven to be helpful for training deeper models. We employ methods such as back-translation, data diversification, domain fine-tuning and model ensemble to build our translation systems. An important aspect worth mentioning is our careful data cleaning process and the utilization of a substantial amount of monolingual data for data augmentation. Compared with the baseline system, our submissions have a large improvement in BLEU score.

1 Introduction

This paper describes our submissions to the WMT23 General Machine Translation shared task. We participated in two language translations: English-to-Chinese and Chinese-to-English. For both tasks, we built our system in a constrained scenario, using only official training data. Our systems are based on Transformer(Vaswani et al., 2017) architecture with pre-norm or deep-norm(Wang et al., 2022), which has been proven to be helpful for training deeper models. We used rule-based methods, language models, and alignment models to clean bilingual and monolingual data, and then used back-translation(Sennrich et al., 2016), data diversification(Nguyen et al., 2020), and model ensemble(Garmash and Monz, 2016) to leverage large-scale monolingual data to construct our translation systems. We also tried domain fine-tuning and found that this approach still helped in improving the BLEU(Papineni et al., 2002) scores on the WMT23 test set.

The design of the subsequent paper is as follows. We introduce the data source and processing strategy in Section2; Section 3 describes the details of our training procedure; Section 4 presents the experimental settings and results.

2 Data

2.1 Data Source

Bilingual corpus We used all provided bilingual data, including: ParaCrawl v9(Bañón et al., 2020), News Commentary v18.1, Wiki Titles v3, UN Parallel Corpus v1.0(Ziemski et al., 2016), CCMT Corpus, WikiMatrix(Schwenk et al., 2019), and Back-translated news.

English monolingual corpus The used English monolingual data including: News crawl, News discussions, Europarl v10, News Commentary, Common Crawl, Leipzig Corpora(Goldhahn et al., 2012), and English part of other bilingual data for WMT general task.

Chinese monolingual corpus The used Chinese monolingual data including: News crawl, News Commentary, Common Crawl, Leipzig Corpora, and Extended Common Crawl.

2.2 Data Preprocessing

For bilingual data we first filter out noisy sentences according to the rules, the filtering rules are as follows:

- Remove invisible characters.
- Remove sentences containing too more than 300 words or more than 1000 characters or less than 3 characters.
- Remove English sentences containing words exceeding than 40 characters.
- Remove Chinese sentences with a low rate of Chinese characters(less than 0.2).

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 187–191
December 6–7, 2023.

- Remove sentences that contain too many punctuation marks.
- Remove sentences that contain repeated substrings, which refers to a string composed of a single character that repeats more than 10 times, or two or more character that repeat more than 5 times.
- Remove sentences that contain HTML tags.
- Convert full-width characters to half-width characters, Traditional Chinese to Simplified Chinese.
- Remove duplicated sentence pairs.

Then we use fast-align(Dyer et al., 2013) to filter out sentence pairs with low alignment scores (less than 13) or low bilingual alignment ratio (less than 0.6), and use forward and reverse translation models to calculate the perplexity of sentence pairs, removing sentence pairs with high perplexity. For monolingual data we perform filtering using similar rules to bilingual data. At the same time, The KenLM(Heafield, 2011)[1] tool is used to train an n-gram language model to filter sentences with high perplexity scores (more than 10 000). The original parallel data totaled about 64 million sentences, and after cleaning, 46.06 million sentences were retained. Through data cleaning, we obtained 1.4 billion sentences Chinese monolingual data, and 1.2 billion sentences English monolingual data.

We used the Sentencepiece(Kudo and Richardson, 2018) tool to train the unigram model for subword segmentation, and vocabulary sizes for both Chinese and English were set to 36 000.

3 System Overview

We chose Transformer(Vaswani et al., 2017) as our base translation model and used both pre-norm and deep-norm(Wang et al., 2022) variants to help us train deeper models. To improve the quality of translation models, we first pre-trained the translation models from scratch on the synthesized datasets generated by back-translation, then continue training on the datasets generated by data diversification, and finally used domain data for fine-tuning. We also iteratively performed two rounds of data augmentation to improve the quality of the synthetic data. The final synthetic data is generated by the model after training on data diversification data of the first round. We only used domain fine-tuning in the final submission. This method we adopt is a commonly used method in the field of machine translation and has been proven to be effective. In the following sections, We show the specifics of how we use these methods.

3.1 Back-translation

Back-translation(Sennrich et al., 2016) is almost the most well-known data augmentation method in the field of machine translation, which can effectively utilize target monolingual data to improve translation quality, even in high resource situations. We used top-k sampling strategy to generate back-translation data with top-k=10, and used the method in section 2 to filter the generated data. To further increase the diversity of synthetic data, we also employed different back-translation models, such as the R2L model and the L2R model, and models with different structures to perform the back-translation method. Since this task is oriented to a general domain, we only use the cleaned monolingual data to generate synthetic data and do not select according to the domain. Because our systems are first pre-trained on back-translation data, unlike the original approach(Sennrich et al., 2016), the method back-translation in this paper refers to using only back-translation data and does not including the non-augmented corpora.

3.2 Data Diversification

Data diversification(Nguyen et al., 2020) is a data augmentation method by performing back-translation and forward-translation multiple times on the target-side and source-side data of the parallel corpus, respectively. Following this approach, we used different models to generate synthetic data by beam search. However, we not only use parallel data as source language for synthetic data, but also monolingual data. The ratio between monolingual and parallel data is 1:1.

3.3 Model Ensemble

Model ensemble can effectively improve the overall system performance by combining the strengths of multiple individual models. The larger the difference between multiple single models, the larger the improvement the ensemble model can receive. We mainly increase the diversity between single models by using different monolingual data, including different monolingual data in the back-translation

[1] https://github.com/kpu/kenlm

stage and different monolingual data in the data diversification stage.

3.4 Domain Fine-tuning

Although the WMT23 test set contains sentences from multiple domains and the WMT21 test set mainly consists of sentences from the news domain, we found that fine-tuning on the WMT21 test set can still improve the WMT23 test set. Therefore, we still attempted to fine-tune our model using newtest2021 as in-domain data.

4 Experiments

4.1 Experiment Settings

All of our translation models were implemented based on fairseq(Ott et al., 2019) and trained on 8 NVIDIA A100 GPUs. During training, we used the Adam(Kingma and Ba, 2014) optimizer with $\beta 1 = 0.9, \beta 2 = 0.98$, the learning rate scheduling strategy of inverse sqrt, the number of warmup step set to 4000, the maximum learning rate set to 0.0005 and FP16 to accelerate the training process .

We used a 24-encoder, 6-decoder transformer with pre-norm as baseline and the embedding size was set to 1024. It was trained only on a real parallel corpus, with a batch size set at 240,000 tokens. For the data augmentation models, we increased the dimension of the embedding size to 1536 and adjusted the number of the encoder and decoder layers, using equal encoder and decoder layers, or deep encoder layers and shallow decoder layers to increase the model parameter size to approximately 1 billion. The training process for these models used a batch size of 640,000 tokens. Maintaining the diversity of different models is a useful trick for model ensembles, so we trained multiple different models by adjusting the number of layers of different models, using pre-norm or deep-norm, using different synthetic data, with or without domain fine-tuning to improve diversity. Finally, we trained 4 models from Chinese to English and 5 models from English to Chinese for model ensemble.

4.2 Results

All experiments were evaluated using the sacrebleu(Post, 2018) tool to calculate BLEU(Papineni et al., 2002) scores on the WMT21, FLoRes(Goyal et al., 2021), and NTREX-128 test sets(Federmann et al., 2022). We used beam search with beam size=5 to decode all models and converted punctuation to Chinese characters in English-to-Chinese direction. Regarding the final results we submitted, we also used regular expressions for n-gram repetition detection. For translations containing repeated substrings, we set a repetition penalty of 1.5 to retranslate the source sentences. The results of Zh→En and En→Zh are shown in Table 1 and Table 2.

Based on Table 1, we can clearly see that the use of Back-Translation and Data Diversification shows significant improvements on multiple test sets. Compared to the baseline, using both data augmentation methods achieves more than 2 BLEU improvements on each test set. More than 0.5 BLEU improvement is also achieved on each test set with the model ensemble. In the end, we achieved BLEU improvements of +4.4, +3.7 and +2.8 on the three test sets of FLoRes, NTREX-128 and WMT21 respectively. The inclusion of domain fine-tuned models can further improve the WMT 23 test set compared to the model ensemble without domain fine-tuning.

From Table 2, we can see that there is a significant improvement using Back-translation on each test set. After using Data Diversification, only further improvement is achieved on the FLoRes test set, while there is varying degree of decrease on the other two test sets. Due to the decrease in diversity caused by fine-tuning multiple models with similar synthetic data generated by Data Diversification, and Data Diversification did not lead to a consistent improvement on the English to Chinese test set, in the model ensemble stage, 4 out of 5 models were trained on only Back-translation data. Finally, on the three test sets of FLoRes, NTREX-128, and WMT21, we achieve improvements of +6.5, +5.9, and +3.6 BLEUs compared to the baseline, respectively, with the model ensemble contributing the largest improvement. Similar to the results from Chinese to English, further improvements are obtained on the WMT23 test set after adding domain fine-tuning.

5 Conclusion

In this paper, we described IOL Research's submissions to the WMT2023 General Translation shared task. We participated in the English from and to Chinese translation. Our system aims to leverage as much monolingual data as possible to improve the quality of machine translation. Experimental

System	FLoRes	NTREX-128	WMT21	WMT23
Baseline	31.4	30.4	27.6	-
+Back-translation	34.2	33.2	28.4	-
+Data Diversification	35.2	33.2	29.7	-
+Ensemble	35.8	34.1	30.4	26.4
+Fine-tuning	-	-	-	27.2

Table 1: Zh→En BLEU scores on FLoRes, NTREX-128, WMT21, and WMT23 test sets. Due to the limited number of submissions, we only report part results of WMT23.

System	FLoRes	NTREX-128	WMT21	WMT23
Baseline	41.8	33.5	31.9	-
+Back-translation	44.6	37.4	33.9	-
+Data Diversification	45.2	34.5	32.8	-
+Ensemble	48.3	39.4	35.5	56.3
+Fine-tuning	-	-	-	56.9

Table 2: En→Zh BLEU scores on FLoRes, NTREX-128, WMT21, and WMT23 test sets. Due to the limited number of submissions, we only report part results of WMT23.

results show that by increasing the scale of monolingual data in the system through data augmentation and model ensemble, we have achieved substantial improvements on multiple test sets.

Abstract

This paper presents the submission by Global Tone Communication Co., Ltd. and Dalian Univeristy of Technology for the WMT23 shared general Machine Translation (MT) task at the Conference on Empirical Methods in Natural Language Processing (EMNLP). Our participation spans 8 language pairs, including English-Ukrainian, Ukrainian-English, Czech-Ukrainian, English-Hebrew, Hebrew-English, English-Czech, German-English, and Japanese-English. Our systems are designed without any specific constraints or requirements, allowing us to explore a wider range of possibilities in machine translation. We prioritize backtranslation, utilize multilingual translation models, and employ fine-tuning strategies to enhance performance. Additionally, we propose a novel data generation method that leverages human annotation to generate high-quality training data, resulting in improved system performance. Specifically, we use a combination of human-generated and machine-generated data to fine-tune our models, leading to more accurate translations. The automatic evaluation results show that our system ranks first in terms of BLEU score in Ukrainian-English, Hebrew-English, English-Hebrew, and German-English.

1 Introduction

In this study, we utilize fairseq (Ott et al., 2019) as our development tool and adopt the transformer (Vaswani et al., 2017) as the primary architecture. The main ranking index for the submitted systems is BLEU (Papineni et al., 2002), which we also employed as the evaluation metric for our translation system using sacreBLEU[1], consistent with our approach from the previous year.

For data preprocessing, we apply punctuation normalization, tokenization, and Byte Pair Encoding (BPE)(Sennrich et al., 2015) across all languages. Additionally, we applied a truecase model for English, Ukrainian and Czech, tailored to the specific characteristics of each language. In terms of tokenization, we utilized polyglot[2] for Ukrainian and Hebrew, and Moses tokenizer.perl (Koehn et al., 2007) for English and Czech. Moreover, we incorporated knowledge-based rules and a language model to clean parallel data, monolingual data, and synthetic data.

For the multilingual translation model, we amalgamated all languages into a single model and supplemented it with an English to Russian parallel corpus to enrich the language information.

The remainder of this paper is organized as follows: Section 2 introduces the translation task and presents statistics of the dataset. Section 3 describes our baseline systems and the proposed multilingual translation model. The data selection method is elaborated in Section 4. Section 5 presents experiments conducted on all translation directions, covering data filtering, model architectures, back-translation, joint training strategies, adaptations of the multilingual model, fine-tuning, data selection, and ensemble decoding. Section 6 analyzes the results, providing insights into the efficacy of different techniques. Finally, Section 7 concludes the paper.

2 Task Description

The task at hand focuses on bilingual text translation, with the provided data detailed in Table 1, which includes both parallel and monolingual data. For the English-Ukrainian and Ukrainian-English directions, the primary sources of parallel data are ParaCrawl v9 (Bañón et al., 2020), WikiMatrix (Schwenk et al., 2019), the Tilde MODEL corpus (Rozis and Skadiņš, 2017), and OPUS (Tiedemann, 2012). For the Ukrainian-Czech direction, the main parallel data comes

from WikiMatrix, ELRC, and OPUS. In the case of Hebrew-English and English-Hebrew, the parallel data is primarily sourced from WikiMatrix and OPUS. For English-Czech, the data sources include Europarl V10, ParaCrawl V9, Common Crawl corpus, News Commentary v18.1, CzEng 2.0 (Kocmi et al., 2020), Tilde MODEL corpus, WikiMatrix, and OPUS. For English-Russian, the sources are ParaCrawl v9, Common Crawl corpus, News Commentary v18.1, Yandex Corpus, UN Parallel Corpus V1.0(Ziemski et al., 2016), Tilde MODEL corpus, and WikiMatrix. The monolingual data utilized includes: News Crawl (Kocmi et al., 2022) in English, Ukrainian, and Czech; Leipzig Corpora (Goldhahn et al., 2012) in Hebrew, Ukrainian, and Czech; News discussions in English; News Commentary in Czech and English; and Legal Ukrainian. We used the provided development set from newstest2019 for English-Czech, newstest2020 for English-Russian, and the FLoRes101 (NLLB Team, 2022) dataset for the remaining directions.

3 Billingual Baseline Model and Multilingual Translation Model

Bilingual Baseline Model and Multilingual Translation Model: To establish a robust baseline for comparison with our multilingual model, we employed the transformer_wmt_en_de as our Bilingual baseline model, which consists of 12 encoding and 12 decoding layers. The multilingual translation model closely mirrors the GTCOM2022 (Zong and Bei, 2022) model, but this year, the focus is on the X to X model. To achieve superior translation quality, we incorporated Russian as the primary auxiliary language due to its high similarity with Ukrainian. We trained a single multilingual model that encompasses all directions. For all languages in the multilingual model, we applied joint Byte Pair Encoding (BPE) separately.

4 Data Selection

We use source test sets to train a text classification model with RoBERTa (Liu et al., 2019). Specifically, we use the in-domain test set as positive examples, and another same mount of sentence pairs from the out-of-domain test set as negative examples. We fine-tuned RoBERTa on this labeled dataset to obtain a binary classifier, which can effectively distinguish between in-domain and out-of-domain data. We then utilized this classifier to select domain-specific training data from the general training corpus. The selected in-domain training data was used to fine-tune the multilingual neural machine translation model.

We also experimented with an alternative data selection approach based on prompt learning. We constructed a prompt template and leveraged the generative power of ChatGLM-6B (Zeng et al., 2022; Du et al., 2022) to obtain an domain classifier via p-tuning (Liu et al., 2021). The prompt template is displayed in Table 2. Specifically, we extract 1,600 sentences from development set which belong to news, social, e-commerce or conversation domain. We manually select 400 sentences from training set that do not belong to domains above or are of poor quality, considering them as other domain. We then used these 2,000 labeled examples to guide the p-tuning of ChatGLM-6B. The resulting prompt-based classifier can effectively differentiate domains of training data. We consider sentences with predicted labels of "News", "Social", "E-commerce" and "Conversation" as in-domain data, and sentences with predicted labels of "Other" as out-of-domain data.

5 Experiment

This section outlines the step-by-step experiments we conducted, with the entire workflow depicted in Figure 1.

- **Data Filtering:** The data filtering methods largely replicate those we employed last year, encompassing human rules, language models, and repeat cleaning.

Instructions	Please determine the domain to which the given sentence belongs based on the following criteria. 1. Sentence Correctness: If the sentence is incomplete, incoherent, or grammatically incorrect, label it as "Other" domain. If the sentence is complete, fluent, and grammatically correct, proceed to the next step. 2. Domain Identification: Analyze the content of the sentence to identify the possible domain it belongs to. Consider the following domains: News, Social, E-commerce, Conversation, and Other. If the sentence shows clear indications of being from a specific domain, label it accordingly, otherwise label it as "Other" domain. Please label the sentence with the appropriate domain: - If the sentence is from the News domain, label it as "News". - If the sentence is from the Social domain, label it as "Social". - If the sentence is from the E-commerce domain, label it as "E-commerce". - If the sentence is from the Conversation domain, label it as "Conversation". - If the sentence does not fit any specific domain or is incorrect, label it as "Other".
Sentence	Sunday Best: Enter 1880s New York in HBO's "The Gilded Age"
Domain	News

Table 2: Prompt Template. We construct a prompt template <Instructions><Sentence><Label> for ChatGLM-6B p-tuning. Model is asked to label the <Sentence> with the appropriate domain according to <Instructions>. For each language pair in Table 1, we extract 1600 English sentences from development set and label them with given domain. Manually select 400 sentence from the training set that do not belong to specific domain or are of poor quality, and considered them as other domain. By filling <Sentence> and <Domain> with sentences above and corresponding domain, labeled samples for p-tuning can be construct.

- **Baseline:** We constructed our baseline using the transformer big architecture, which consists of 12 encoder layers and 12 decoder layers.

- **Back-translation:** We utilized the best translation model to translate the target sentence to the source side, and cleaned synthetic data with a language model. Here, we translated each language pair included in the multilingual translation model. We mixed the cleaned back-translation data and parallel sentences and trained the multilingual translation model.

- **Joint training:** We repeated the back-translation step using the best model until no further improvement was observed.

- **Multilingual translation model:** We trained a single model for all directions, with each direction having joint BPE and a shared vocabulary. The multilingual translation model comprises 24 encoder layers and 24 decoder layers, using the transformer big architecture.

- **Fine-tuning:** We fine-tuned the multilingual translation model for each direction and bi-direction separately. For instance, we fine-tuned uk2cs on the multilingual translation model and fine-tuned uk2cs and cs2uk on the multilingual translation model for Ukrainian to Czech separately.

- **Data selection:** We use model from section Data Selection to select domain-specific training dataset and fine-tune it on the multilingual translation model.

- **Ensemble Decoding:** We employed the GMSE Algorithm (Deng et al., 2018) to select models to achieve optimal performance.

6 Result and Analysis

Table 3, Table 4 and Table 5 show the BLEU score we evaluated on development set for English to/from Ukrainian, Czech to Ukrainian, English to Czech and English to/from Hebrew respectively. As shown in the above table, back-translation is still the best data augmentation measure to improve translation quality from the data aspect. Multilingual translation model also show solid improvement in all five directions. As ChatGLM only supports Chinese and English, we only perform data selection with prompt learning in

Table 4: The BLEU score of Czech to Ukrainian and English to Czech.

English-sourced language pairs. As shown in Table 6, our prompt learning strategy is still able to improve the BLEU score even after applying all other approaches. Regarding German to English and Japanese to English directions, we generate the task translations using our online system without any specific tuning.

We have noticed a significant improvement, particularly in the low-resource direction of Czech to Ukrainian, when we added Russian (which is a language closely related to Ukrainian) to the multilingual corpus.

model	en2he	he2en

Table 6: The final online automatic evaluation BLEU with/without prompt learning in data selection.

7 Conclusion

This paper presents GTCOM and DLUT's neural machine translation systems for the WMT23 shared general MT task. We applied three major techniques to enhance translation quality: back-translation, a multilingual translation model, and fine-tuning with data selection. By employing these techniques, we achieved significant improvements in automatic evaluation metrics, as demonstrated in Table 7.

RoCS-MT: Robustness Challenge Set for Machine Translation

Rachel Bawden
Inria, Paris, France
rachel.bawden@inria.fr

Benoît Sagot
Inria, Paris, France
benoit.sagot@inria.fr

Abstract

RoCS-MT, a Robust Challenge Set for Machine Translation (MT), is designed to test MT systems' ability to translate user-generated content (UGC) that displays non-standard characteristics, such as spelling errors, devowelling, acronymisation, etc. RoCS-MT is composed of English comments from Reddit, selected for their non-standard nature, which have been manually normalised and professionally translated into five languages: French, German, Czech, Ukrainian and Russian. In the context of the WMT23 test suite shared task, we analyse the models submitted to the general MT task for all from-English language pairs, offering some insights into the types of problems faced by state-of-the-art MT models when dealing with non-standard UGC texts. We compare automatic metrics for MT quality, including quality estimation to see if the same conclusions can be drawn without references. In terms of robustness, we find that many of the systems struggle with non-standard variants of words (e.g. due to phonetically inspired spellings, contraction, truncations, etc.), but that this depends on the system and the amount of training data, with the best overall systems performing better across all phenomena. GPT4 is the clear frontrunner. However we caution against drawing conclusions about generalisation capacity as it and other systems could be trained on the source side of RoCS and also on similar data.

1 Introduction

As the quality of state-of-the-art machine translation (MT) systems is becoming indistinguishable in certain scenarios and domains from that of human translators (Kocmi et al., 2022), the task of tackling the translation non-standard texts is becoming an increasingly realisable aim. A considerable proportion of texts produced today are done so online in informal, unedited settings, e.g. on forums such as Twitter and Reddit, and MT is frequently to make posts accessible to a global audience. However, it has been shown that MT still struggles with user-generated content (UGC) (Gupta et al., 2023), as the type of language can differ considerably from the edited texts that have traditionally been used to train and evaluate MT models.

The RoCS-MT challenge set (Robust Challenge Set for Machine Translation) is designed to provide a test bed for the automatic translation of non-standard UGC phenomena. It contains approximately 2k sentences from the online forum Reddit that have been manually normalised and professionally translated into five languages: French, German, Czech, Ukrainian and Russian. The sentences were selected specifically for the presence of non-standard phenomena, of which we provide manual annotations (e.g. spelling errors, devowelling, capitalisations, acronymisms, etc.). Inspired by other datasets such as the French Social Media Bank (Seddah et al., 2012) and its parallel component (Rosales Núñez et al., 2019), our aim is to provide an evaluation set that is more challenging than certain previous efforts, such as the commonly used MTNT dataset (Michel and Neubig, 2018). We also make different choices from most previous efforts concerning the guidelines for normalisation and translation of the source sentences. We choose to first normalise the source sentences before translation in order to optimise the quality of the translation and to reduce the arbitrariness that may be introduced when transferring non-standard variation to the target language (e.g. on which characters to apply spelling errors, how many characters to duplicate when elongating words). For normalisation, we aim to strike a balance between normalisation as much as possible while making sure that the normalised text remains natural.[1]

In this paper, we describe the creation of the challenge set, and in the context of the WMT23 test suite shared task, we analyse the models submitted

[1] E.g. We choose to not normalise the acronym *lol* 'laughing out loud', as it is rarely/never used in its expanded form.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 198–216
December 6–7, 2023.

to the general MT shared task for the from-English shared task language pairs: English→{Czech, German, Hebrew, Japanese, Russian, Ukrainian, Chinese} (en→{cs, de, he, ja, ru, uk, zh}). Through automatic and manual analysis of system outputs, we find that many of the phenomena remain challenging for most systems (in particular those that create potential out-of-vocabulary or rare words such as phonetically inspired spellings, contractions, devowelling and truncation). However, the difficulty varies depending on the phenomenon, the particular instance (notably how frequent the non-standard word is) and the system, especially with respect to the quantity of training data. The highest performing systems overall generally do better across the board on all phenomena, whereas the weaker systems struggle in particular with certain phenomena. GPT4 has a clear lead over other systems, correctly translating even some of the most challenging examples and sometimes (although inconsistently) reproducing non-standardness in its outputs. However conclusions are limited given that the training data is unknown (as is the case of other unconstrained systems).

We make the challenge set, system outputs, evaluation code and guidelines (for the normalisation, annotation and translation) openly available for research purposes.[2]

2 Related Work

Several parallel UGC datasets exist across different language pairs. While some are extracted automatically from crawled data (Ling et al., 2013; Vicente et al., 2016; Mubarak et al., 2020), a majority are based on monolingual sentences that are then translated into the target language (Sluyter-Gäthje et al., 2018; Michel and Neubig, 2018; Rosales Núñez et al., 2019; Fujii et al., 2020; McNamee and Duh, 2022). The closest to our RoCS-MT dataset are (Michel and Neubig, 2018) and (Rosales Núñez et al., 2019), which were designed to contain challenging non-standard phenomena, whereas many of the existing datasets do not apply any such filter. Like RoCS-MT, the MTNT dataset (Michel and Neubig, 2018) contains texts from Reddit. To target non-standard language, they select sentences that have a low probability using a language model trained on standard data. In practice, and as shown by Rosales Núñez et al. (2019), the amount of non-standard language remains limited with this method. Rosales Núñez et al. (2019) base their parallel dataset on the French Social Media Bank dataset (Seddah et al., 2012), which targets non-standard language by searching for specific non-standard keywords. They show that this leads to a higher level of non-standard language, although the method is by nature more biased towards the keywords and phenomena used for data selection. An error analysis of the dataset was conducted in (Rosales Núñez et al., 2021), showing MT quality (using BLEU) for different UGC phenomena.

Despite significant effort to describe and classify UGC phenomena (Michel and Neubig, 2018; Sanguinetti et al., 2020), there is no consensus as to how texts should be normalised (and indeed translated). One extreme is to normalise all phenomena to standard forms, as is often done in lexical normalisation tasks (Han and Baldwin, 2011; van der Goot et al., 2021), but which in several cases would lead to unnatural outputs (e.g. if *lol* and *lmao*, were systematically normalised to *laughing out loud* and *laughing my ass off*). This makes translation difficult too, as the translations would also be unnatural. At the other end of the spectrum is the choice to not normalise source texts and in addition to attempt to translate the phenomena into the target language, with the disadvantage that some phenomena are language-specific[3] and others would result in arbitrary decisions being made such as to which characters to apply spelling errors. The current datasets targeting particularly non-standard phenomena choose to at least in part transfer some phenomena to the target language, whereas we adopt a higher degree of normalisation (see Section 3.1.1 for more details), producing standard but natural-sounding translations.

3 Challenge Set Creation

3.1 Data Sourcing and Selection

The source sentences are taken from English posts on discussion platform Reddit[4] using the API.[5] We do not target a particular variety of English

[2] https://github.com/rbawden/RoCS-MT

[3] Two examples of this are French *verlan*, which consists in inverting syllables in words (e.g. *louche→chelou* 'bizarre') and English cockney rhyming slang (e.g. *loaf* meaning *head* thanks to its rhyme with the expression *loaf of bread*). However, even phenomena that do exist crosslingually do not necessarily apply to the same words (e.g. the use of digits to replace their homophones as in *2day* 'today', where the translation does not necessarily contain a homophone of a digit in the target language).

[4] www.reddit.com

[5] Using the free version of the API (December 2022).

(e.g. British, American, etc.) and even include some non-native English,[6] although we do not include code-switched texts. We get an initial pool of posts by searching for specific keywords from a manually drawn-up list as in (Sanguinetti et al., 2020), e.g. *ttyl*, *ppl*, *gr8*, *alot*. The full list is given in Appendix A. For each keyword, we crawled both Reddit-wide and 3 specific subreddits (CasualUK, MadeMeSmile and entertainment) to ensure a diversity of informal topics[7] at 6-month intervals between 2017 and 2022.

Once we had the initial pool of examples, in order to reduce the number of posts to manually review, we applied a very coarse-grained in-house 'non-standardness' classifier that we had trained on a small set of manually annotated tweets according to 4 labels (standard, mildly non-standard, moderately non-standard and very non-standard), and look at posts whose title or text was marked as anything other than 'standard'. From those posts, we manually select titles and passages from the text that contain interesting non-standard phenomena, including sentences not containing the initial keyword associated with the post. This means that although our initial search process is biased to our word list, the effect is diminished by taking additional non-standard phenomena. We automatically filter out any 18+ content (using the Reddit meta-information), and manually filter out any content that is sexually inappropriate, insulting or deals with sensitive (potentially triggering) topics such as suicide or drug addiction.

3.1.1 Sentence Splitting and Normalisation

We start by manually splitting the texts into sentences. In many cases, this corresponds to splitting on final punctuation (e.g. full stop, exclamation marks, etc.). However, the non-standard nature of the texts increases the number of cases where texts are split in places that are not marked by punctuation or where punctuation or newlines are added unexpectedly in the middle of what would ordinarily be considered a sentence.

For instance, the sequence *I went grocery shopping I'm down to my last dollars soon (...)* was split into the first sentence *I went grocery shopping* and the second sentence beginning with *I'm down to my last dollars soon*, despite the lack of a final punctuation between *shopping* and *I'm*.

The first author (a native English speaker) manually normalised each of the sentences produced by our manual sentence splitting, seeking help from people knowledgeable in the topics (e.g. video gaming) where necessary. The complete normalisation guidelines with examples can be found in the dedicated Github repository.[8] As with any guidelines for dealing with complex and evolving non-standard phenomena, the decisions made are certainly not bulletproof and are likely to evolve in future work. Our aim was to reach a compromise between (i) normalising as much as possible of the text while (ii) rendering the output natural and realistic and (iii) not over-normalising such as to remove the style of the original text. We therefore normalise words such that the normalised variant could be spontaneously and naturally used.

3.1.2 Translation

Translation of the English sentences was carried out by paid professional translators. They had access to the original posts and both the raw and normalised versions of each sentence. Translation was carried out at the sentence level (following the manual segmentation and using as the source the normalised translation), although the translators had access to surrounding linguistic context, as well as additional context and translation notes provided by the first author during the normalisation step. There were also several exchanges between the first author and the translators in order to provide additional context and to answer questions. In order to preserve author anonymity, translators did not have access to meta-information about the authors (e.g. their gender). A single translation was produced for each sentence (we left the choice of speaker gender to the translators) with the exception of Ukrainian, for which two translations were produced for sentences where the speaker gender has an impact.

The target languages were chosen to cover four of those in the WMT2023 general translation task (Czech, German, Ukrainian and Russian), as well as French, which is an important language for our own research, although we do not analyse the French portion of the data in this article.

Translation Guidelines Translators were provided with guidelines (see Appendix B). They were

[6] We do not have access to any personal information about the post authors, but we know this because some posters apologise for their level of English in the posts included.

[7] The subreddits were chosen to have topics that were informal and could have a reasonable number of posts, although in reality, the number of non-standard posts found from these specific subreddits was limited.

[8] https://github.com/rbawden/RoCS-MT

instructed to translate the normalised versions of each sentence into the target language, using standard language but best matching the intention, naturalness and familiarity level of the sentence, similar to the guidelines set out in (McNamee and Duh, 2022). The decision to use standard language was to avoid the arbitrariness associated with attempting to reproduce non-standard phenomena in translation, which would make comparisons, particularly automatic ones, more difficult (e.g. which characters to alter to reproduce a spelling error, how many characters to repeat in the case of expressive repetition, etc.). They were also instructed to respect the manual segmentation provided,[9] to respect punctuation choices made in the source where appropriate (e.g. conserving full stops) and to preserve English words in meta-linguistic discussions (i.e. where authors are writing specifically about English words). As in the normalisation guidelines, abbreviations, acronyms and simplifications were to be expanded unless the result would not make a natural sentence that could realistically be found. However, abbreviations linked to the names of places and institutions were to be kept as they were if used as such in the target language (e.g. French *OTAN* for English *NATO*). They were requested not to use MT systems to help them translate in order not to bias the translations produced.

3.2 Challenge Set Subsets

We create four subsets of the challenge set to test the impact of sentence segmentation (manual or automatic using spaCy) and of normalisation (manual or none, i.e. the original raw text):

- `manseg-raw`: Manual segmentation with original (raw) text
- `manseg-norm`: Manual segmentation with manual normalisation
- `spacyseg-raw`: spaCy segmentation with original (raw) text
- `spacyseg-norm`: spaCy segmentation with manual normalisation[10]

As shown in Section 3.3, the two different segmentation methods result in different numbers of individual sentences, and automatic segmentation with spaCy differs depending on whether the text has been normalised or not. In practice, in this article, we focus only on the `manseg-raw` and `manseg-norm` subsets, although we also release the system outputs for the `spacyset-` subset. We leave research on these other subsets (i.e. looking at the impact of sentence segmentation) to future work.

3.3 Dataset Characteristics

Some basic quantitative characteristics of the data are given Table 1.

Impact of sentence splitting While the number of sentences is fixed for the manual segmentation, spaCy segmentation is highly dependent on whether the text has been normalised or not, likely due to the tool being less well adapted to non-standard text; when applied to raw text, the resulting number of sentences is far lower than manual segmentation (1660 vs. 1922), whereas the resulting number of sentences is more similar to manual segmentation when applied to the normalised text.

Tokenisation Normalisation impacts the number of tokens in the texts, as well as the number of unique tokens. When comparing the two normalised subsets on the one hand and the two raw subsets on the other (i.e. differing only in the sentence splitting), the number of tokens differs due to the fact that automatic segmentation tends to oversplit sentences on punctuation that in the manual segmentation would remain part of a token in the preceding sentence. The number of unique tokens inevitably drops after normalising, due to the homogenisation of non-standard forms (7175 vs. 6612) for manual segmentation.

Normalisation Types We manually annotated the texts for non-standard phenomena (e.g. spelling errors, acronyms, devowelling, capitalisation, pronoun drop, etc.), with the possibility of there being several types for a single span of text. Our annotations are at the word-level, with some phenomena spanning several words (e.g. capitalisation). Table 2 provides some statistics for the annotations occurring in at least 10 sentences, and some examples are given in Examples 1-4.

4 Translation Systems

In this article, we evaluate the systems submitted to the general translation task at WMT2023. There are both constrained and unconstrained systems, the two settings presenting significant differences in training data that should be taken into account when comparing systems.

Constrained systems Constrained systems followed similar strategies, with many systems doing data filtering/cleaning and data augmentation, using either bilingual or multilingual models and reranking. The constrained systems submitted were AIRC (Rikters and Miwa, 2023), ANVITA, CUNI-Transformer and CUNI-DocTransformer (Popel, 2020) (we refer to these system as CUNI-Trans and CUNI-DocTrans to save space in the results tables), CUNI-GA (Jon et al., 2023), HW-TSC (Wu et al., 2023b), IOL_Research (Zhang, 2023), NAIST-NICT (Deguchi et al., 2023), Samsung_Research_Philippines (Cruz, 2023) (hereafter Samsung_RP), SKIM (Kudo et al., 2023) and UvA-LTL (Wu et al., 2023a).

Unconstrained systems As in previous years of the shared task, translations were produced from anonymised online systems, corresponding in this addition to ONLINE-{A,B,G,M,W,Y} submissions. This year, translations from GPT4 were also produced using 5 few-shot examples (GPT4-5shot).[11] Note that caution should be taken when comparing results from GPT4, given that it is very possible that source sentences from RoCS-MT are included in GPT4's training data. Two systems based on NLLB (Team et al., 2022) were also submitted in the context of the metrics shared task: NLLB_Greedy and NLLB_MBR_BLEU (hereafter NLLB_MBR), which both rely on the same model but differ by the decoding strategy, either standard (greedy) or based on the Minimum Bayes Risk strategy (Freitag et al., 2022). A number of unconstrained systems were also submitted by participants, namely Lan-BridgeMT (Wu and Hu, 2023), KYB , GTCOM (Zong, 2023), (Li et al., 2023), PROMT (Molchanov and Kovalenko, 2023), Yishu

[11]The prompt used is the sentence-level prompt from (Hendy et al., 2023), which is also shown in Appendix C.

(Min et al., 2023) and ZengHuiMT (Zeng, 2023).

5 Evaluation and Analysis

Evaluation of UGC translation is more challenging than standard text; a correct translation can either be standard or non-standard in the target language, and there may be multiple ways of being non-standard that may not all be covered by available references. In our case, we chose to produce standard reference translations (See Section 3.1.2). Any system that produces non-standard language may therefore be underestimated using reference-based metrics.

We test three different metrics (BLEU, COMET and COMET-QE) to evaluate the systems' translations of RoCS-MT, looking at how coherent they are between each other, and whether it is possible to use quality estimation to evaluate MT robustness in order to remove the need for reference translations (Section 5.1). We also look at the MT quality of each system per phenomenon by calculating COMET scores over subsets of the data. Finally, we perform a qualitative analysis, manually looking at how the different systems handle UGC phenomena, and confirming some of the trends using some simple automatic analyses (Section 5.2).

5.1 Automatic evaluation

BLEU (Papineni et al., 2002), as a surface-level metric, is intuitively not robust to variation. It is therefore likely to be particularly ill-adapted to MT robustness evaluation, since MT systems' outputs can display standard or non-standard characteristics. We choose nevertheless to test this here, calculating BLEU scores using the sacreBLEU toolkit (Post, 2018).[12] We compare BLEU to reference-based COMET (Rei et al., 2020)[13] for those language pairs for which we have a reference, and to COMET's reference-less (quality estimation) version, which we refer to as COMET-QE (Rei et al., 2022).[14] We notably aim to test whether it is possible to use COMET-QE for evaluation rather than reference-based COMET, which would remove the dependency on reference translations and make evaluation possible for a wider range of languages.

Ukrainian has two reference translations for sentences for which the speaker's gender results in different translations is ambiguous between male and female. While BLEU is designed to handle multiple references, this is not inbuilt into COMET. For these sentences, we choose to take the best COMET score of the two references. For COMET and COMET-QE, which also use the source sentence, we choose to evaluate system outputs against both the `manseg-norm` and `manseg-raw` source sentences, regardless of which set was translated by the system and take the highest score of all the source-reference combinations. This covers the case where non-standard (i.e. raw) sentences are normalised during the translation process.

We provide full results for COMET and COMET-QE in Table 3 and 4 respectively, and we include results for BLEU in Table 7 in Appendix D.

How coherent are the metrics? The trends of the three metrics are similar but not at all systematic (in terms of rankings) when evaluating translations of the normalised data (`manseg-norm`), with the same systems getting the highest scores across language pairs (amongst the best systems being ONLINE-W, ONLINE-B, GPT4). However, there are some clear inconsistencies between BLEU and the two COMET metrics when evaluating non-standard data (`manseg-raw`). For example GPT4 is ranked above other systems by COMET and COMET-QE, whereas the BLEU scores of other systems (and in particular ONLINE-W and sometimes ONLINE-B) are higher. This indicates that GPT4 outputs are more surfacically different from the reference translations, which could be a result of paraphrasing or non-standard translations rather than a reflection of MT quality, especially given the high scores by COMET.

This confirms that BLEU is poorly adapted to evaluating MT robustness and could even lead to misleading conclusions, confirming previous conclusions drawn by Rosales Núñez et al. (2021) about the inadequacy of BLEU for the evaluation of UGC MT. On the other hand, COMET-QE scores show more similar trends to COMET, suggesting that it could be possible to use it to evaluate without having to produce reference translations. We nevertheless add that COMET remains an automatic metric that does not produce perfect correlation with human judgments, more research would be necessary to stress-test the metric for MT robustness evaluation, particularly in terms of evaluating which of COMET and COMET-QE is better correlated with human judgments.

[12] `case:mixed|eff:no|tok:13a|smooth:exp|v:2.2.1`
[13] We use the default `wmt22-comet-da` model.
[14] We use the default `wmt22-cometkiwi-da`.

Which systems come out on top? The highest performing systems are the unconstrained online systems, with GPT4 getting significantly higher COMET and COMET-QE scores than other systems when translating non-standard (`raw`) text for all languages tested. Other systems that tend to produce high scores are ONLINE-W and to a lesser extent ONLINE-B. Apart from these online models, both NLLB models are the best-scoring ones, which might come from the fact that they are highly multilingual and therefore could be more robust to language variation. The constrained systems, whilst not the highest performing systems, appear to get comparable scores to at least some of the online systems.

Which systems are most robust? This question is linked to the previous question about MT quality on non-standard data. To take into account the base performance of the systems, we look at the difference in score between each system's translation of the non-standard sentences and their normalised versions (also in the previously mentioned Tables 3 and 4. While there is a general trend that the higher performing systems also also have a smaller difference in quality (i.e. they are also more robust), there are some stand-out systems. GPT4 is the system with the lowest quality difference between original and normalised sentences for all language pairs tested. The NLLB models also have a low delta between the two subset, lower than or comparable to some of the more robust online systems. Similarly to the previous question, constrained systems are not the most robust in terms of their score difference. Notably for en–cs and en–de, the score differences are amongst the highest. However, some of the systems do show peformance in the same ballpark as some of the online systems.

Automatic analysis by UGC phenomenon In order to analyse how systems handle different non-standard phenomena, we evaluate sentences by annotation types, by calculating COMET and COMET-QE scores for sentences containing at least one occurrence of a particular normalisation annotation. COMET results are given in Table 5 and we include a fuller analysis for COMET-QE results in Table 8 in Appendix E. Note that we only include annotation types that appear in at least 50 sentences, and that the 'all' column refers to the scores over all sentences and not just the ones annotated for UGC phenomena.

Scores are not directly comparable across annotation type. Performance by annotation type is consistent with previous conclusions, with GPT4 getting the highest scores across the board, and online systems and NLLB also doing well. It is striking that the systems that have higher scores in general tend to do better across the board on all annotation types, whereas the lower-scoring systems struggle with certain non-standard phenomena. They correspond in particular to phonetic distance, where a word is spelt differently according to how it is pronounced (e.g. *HEERE'Z A QWESHCHUN FER YA* 'Here's a question for you'), contractions (e.g. *wud* 'would'), devowelling (e.g. *nvr* 'never'), truncation (e.g. *intro* 'introductory') and spelling errors. These are notably phenomena that could well result in out-of-vocabulary words.

Are certain language pairs more difficult than others? It is tricky to compare across language pairs, since scores are not comparable. However, there are some indications that the en–cs set is more challenging, given the low scores across multiple annotation types for all systems other than GPT4. The fact that GPT4 has high scores for all annotation types listed shows that the lower scores of other models are not due to quality issues in the reference translations, and provides an upper bound against which other systems can be compared, thereby indicating that the systems struggled more.

5.2 Qualitative analysis

Non-standard variants of words Many of the non-standard phenomena that characterise the texts (e.g. acronyms, truncations, contractions, devowelling) represent a similar difficulty to unknown or rare tokens in MT. The treatment of these words differs according to the system used, and inevitably largely on the training data of the model. Many of the constrained systems struggle to translate such words, either copying the words into the translation or omitting them entirely. The degree to which the systems succeed in correctly translating these words appears to depend on how common it is. For example, *tho*, phonetically-inspired spelling of *though*, was translated successfully by multiple systems, although the devowelled word *tmro* 'tomorrow' proved more difficult.

Markers of expressivity It is common for UGC texts to have markers of expressivity such as capitalisation or repetition of letters. We removed these markers in our normalised versions and reference

Table 4: COMET-QE scores of systems on the `manseg-norm` and `manseg-raw` subsets.

translations for consistency. However, there are no guidelines as to how the different systems should translate them: either preserving the markers in the translation or normalising as we do in the reference. What we observe is variable behaviour depending on both the system and on the specific textual instances. Table 6 shows one of the more extreme examples of character repetition. Most of the systems fail to translate the words with character repetition and instead copy them (the case of *moooorrreeee* 'more', *poollliitte* 'polite' and *Discouuurrrse* 'Discourse'). There is greater robustness for the word *neeeeed* 'need', which is translated correctly as *brauchen* by a majority of systems, but not by AIRC, ONLINE-M and ONLINE-W, which is interesting since ONLINE-W obtains very high BLEU scores for en–de. When systems do translate the words, it tends to be the standard form that is generated (i.e. without repetition). The only example here is GPT4, which translates *moooorrreeee* as *viiieeeel* 'viel', conserving the expressivity of the source sentence. What is interesting is that this behaviour is far from consistent for GPT4, with the other non-standard words in the same example not undergoing the same treatment. This could suggest that while the system succeeded in deciphering the

Table 5: COMET scores by normalisation annotation type and averaged over all RoCS-MT sentences ('all').

non-standard English texts, there is no systematic notion of generating non-standard translations; it is possible that an expressive version of *viel* was seen far more often in the training data, thus being a probable translation in this case.

Number of copied words Bearing in mind the fact that unknown source words are often either copied or removed, we apply a simple automatic analysis to judge how often systems copy source words to diagnose a potential problem with out-of-vocabulary words. We calculate how often a sentence's translation contains words that appear in both the source and system's translations (counting occurrences for each sentences and taking the average). We calculate the difference in the average number of copied words for the`manseg-raw` and `manseg-norm` subsets (i.e. how much more are words copied when systems are translating non-standard data). Results are shown in Table 9 of Appendix F. Note that a certain number of 'copied' words is normal, as certain words are expected to be identical in source and target texts (e.g. some named entities, numbers, etc.). There are similar trends across languages: the same systems tend to have relatively fewer/more copied words in raw than norm. GPT4 has the smallest difference in number of copied words between `norm` and `raw` translations. Unsurprisingly, most other systems have more copying in `raw` than in `norm`, indicating a problem handling unknown vocabulary and confirming our previous qualitative analysis.

On a similar note, we also analysed the source-translation length ratios for both `raw` and `norm` subsets. While this could be linked to copying or omit-

	norm/raw	Text
Source	norm	“politics used to be more polite. We need a return to the discourse”

Table 6: Example of character repetition linked to a mark of expressivity for en–de.

ting unknown words (as we have seen), it is more likely to be linked to overgeneration problems, linked to systems encountering text that is out-of-domain, which we occasionally observed in the system outputs. We observed that for all systems, the length ratio between `manseg-raw` translations and their source sentences was greater than those for `manseg-norm`. The effect was even greater for the texts when automatic sentence segmentation was applied (i.e. for `spacyseg-` subsets).

6 Conclusion

We have presented a new resource, RoCS-MT, a robustness challenge set for MT, designed to test MT systems on non-standard UGC. Our automatic and manual analysis show that non-standard texts are still a problem for many of the systems, including the unconstrained ones, and that certain phenomena such as phonetically inspired spellings pose a problem in particular. The comparison of COMET and COMET-QE metrics suggest that it may be possible to draw similar conclusions from automatic scoring without using references, although future work could go into more depth into analysing what is captured by the different metrics.

Limitations

The current test set is available for five from-English directions and it would be interesting to study other language directions, including those not involving English. The current version of the challenge set only contains variants for speaker gender for one of the language pairs, and we plan to add these for the other target languages in a future version.

Finally, a major limitation is one that is becoming widespread nowadays, which is that many of the systems trained and even used in research are trained on an unknown quantity of data for which the sources are unknown. Without being able to verify the fact, GPT4 and potentially some of the other systems are likely to be trained on some of the source sentences in the challenge set, and future models may even be trained on the reference translations we provide, despite it being indicated as a test set. This is a blocking factor for scientific comparison and one that goes beyond this particular resource.

Acknowledgements

This paper was funded by both authors chair positions in the PRAIRIE institute funded by the French national agency ANR as part of the “Investissements d’avenir” programme under the reference ANR-19-P3IA-0001. A Non-standard keywords for sourcing of posts

The full list of keywords we searched for using the Reddit API is as follows: *yyy*, *iii*, *eee*, *ppl*, *btw*, *imo*, *wtf*, *shes*, *hes*, *ima*, *shud*, *wud*, *cud*, *afaik*, *bcuz*, *hahaaa*, *dat*, *wen*, *wot*, *woz*, *bout*, *bro*, *gonna*, *lmao*, *ppl*, *smh*, *yall*, *omg*, *barley*, *fyi*, *beleive*, *seperate*, *lol*, *ttyl*, *muaha*, *mwah*, *air*, *afaik*, *fr*, *fyi*, *idk*, *ikr*, *irl*, *jk*, *nvm*, *plz*, *pls*, *cu*, *tbh*, *ur*, *wth*, *kk*, *2mo*, *2moro*, *tmrw*, *fwiw*, *nvm*, *thx*, *b4*, *ruok*, *m8*, *l8r*, *2nite*, *gr8*, *lk*, *wt*, *w/*, *peeps*, *sooo*, *verry*, *innit*, *wasnt*, *ain't*, *definately*, *yous*, *nae*, *awfull*, *freind*, *untill*, *wierd*, *aweful*, *wether* and *alot*.

The keywords were chosen as they illustrate well known non-standard phenomena, including:

- spelling errors (e.g. *wierd* 'weird', *wether* 'whether', *alot*)
- acronymisation (*nvm* 'never mind', *fyi* 'for your information)
- repetition of characters (e.g. *hahaaa*, *eee*, *sooo*)
- contractions (e.g. *cud*, *gonna*, *shud*))
- dialectisms (e.g. *ain't*, *yous*, *nae*, *innit*, *yall*)
- devowelling (e.g. *tmrw* 'tomorrow', *pls* 'please', *jk* 'joke')
- truncations, including abbrevations (e.g. *peeps* 'people', *w/* "with')
- digit phonetisation (e.g. *2nite* 'tonight', *b4* 'before', *l8r* 'later', *cu* 'see you', *ruok* 'are you ok')
- other phonetic spellings (e.g. *wot* 'what', *thx* 'thanks', *dat* 'that')
- missing whitespace (e.g. *cu* 'see you', *ruok* 'are you ok', both examples also corresponding to phonetic spellings)
- missing punctuation (e.g. *ur* (sometimes) 'you're', *wasnt* 'wasn't')
- etc.

Although the choice of keywords does create a certain bias in the types of language retrieved (especially given that several variants of some keywords are included), these keywords are used to identify posts that likely to contain other non-standard phenomena, so the final selected sentences are not restricted to those containing these keywords.

B Translation Guidelines

These guidelines are included because there are some specific constraints as to how the translations are to be carried out, and some particularities of the dataset to explain. The sentences to be translated are found in the excel spreadsheet in the column "Normalised segment". However, we also provide additional information that can help translation (see below for more information).

Origin of the text The texts to be translated are from the Reddit online forum (extracted using the API), taken from a range of different subreddits (so of different genres of text, e.g. relationship advice, advice about pets, video gaming strategy, etc.). They were selected due to their non-standard nature (spelling mistakes, abbreviations, lack of punctuation etc.).

Preprocessing of the text The texts have been manually pseudo-anonymised (usernames and names other than those representing celebrities and other well-known public figures are replaced with new names), split into "sentences" and normalised. It is the normalised versions of the sentences that are to be translated.

The sentences have been filtered to remove offensive or sensitive content (hate speech, taking drugs, suicide, etc.). However, profanities were kept as they were taken to be illustrative of the sociolect of online language. If however, you do not feel comfortable with translating something, please leave it blank and write a comment indicating that you have not translated it.

Additional context provided to help translation The text is split into short documents with one or several sentences per document. In the excel document, a sentence's document is indicated by the value in the column "Post number", and the cells are also coloured such that it is visually easier to see which sentences belong to the same document (alternating grey and white). A Reddit post is associated with a title and a text with the main content of the post. The documents can contain either the title or a subset of the text or even both. The type of text associated with each sentence is indicated in the column "Text type". Titles are marked in bold to make them visually easier to see. Although the normalised text may be sufficient to carry out the translation, we also give access to the additional information just in case:

- the title of the post
- the entire body of text associated with the post
- the raw version of the sentence (after pseudo-anonymisation and segmentation into sentences)
- some translation notes have been added to provide some context about the posts (e.g. to give an idea of what is the subject of conversation, the meaning of some expressions and abbreviations, etc. in order to make translation easier). Very occasionally there are indications about how to translate (for instance for meta-linguistic questions where people discuss particular words, it is best to keep the English words, e.g. *One word I simply can't say properly is water...* → water should be kept in English in the translation.

Constraints (important) The dataset will be used to evaluate machine translation systems on their ability to handle non-standard texts. This crucially means that: the sentence boundaries that have been defined must not be modified. It is possible to translate a sentence using several sentences if that is what is natural. However, it is not possible to merge several source sentences to produce a single translation of both (i.e. one translation per row). translators should not use machine translation systems or other computational systems to aid translation as this could bias the translations to look like translations produced by Google Translate, DeepL, ChatGPT, etc.

More specific guidelines There are multiple posts that use slang terms (e.g. gaming or general online slang such as *lol*) and it possible that the correct translation will be an English borrowing. It is fine to use an English borrowing in this case, if this is what is generally used online. The punctuation choices should be kept as much as possible, as appropriate for the target language of translation (e.g. conserving full stops, exclamation marks, quotes, etc.). As described above, there are some instances of people talking about English words, and in this case, the English words should be kept as is. Another example: *One says "Let's eat granny" making it seem like someone's going to eat their nan. However, the other example says "Lets eat, granny", implying a different meaning to the sentence.* The phrases *"Let's eat granny"* and *"Let's eat, granny"* should be kept in English. These are indicated in the translation notes.

Use of "non-standard" language:

- Any spelling mistakes that were in the raw sentence should not be reproduced in the translation (i.e. the normalised version should be used as the source sentence to translate).
- Formatting, including things like capitalisation, should (for the same reasons) follow the conventions of the normalised translation.
- Abbreviations, acronyms and simplifications (e.g. in English *wdym* = *what do you mean*, *bc* = *because*, *rly* = *really*, etc.) should be expanded, unless the result would not make a natural sentence that could realistically be found. An example of a non-natural expansion would be *lol* = *laughing out loud*, since this is not practically used.
- However, abbreviations linked to the names of places (e.g. *USA*, *UK*, *UCL* (=*University College London*) should be kept as they are if the acronym is also commonly used in the target language. In other cases, the most frequent equivalent translation should be used. (e.g. English *UN* = French *ONU*, English *NATO* = French *OTAN*).

The overall idea is that the translations should be natural and not contain the types of non-standard language that were normalised in the English versions, although they should match as best possible the style and familiarity.

Additional questions If you have any doubts or questions about the meaning of the sentences, please contact me at rachel.bawden@inria.fr to discuss things further.

C Prompt used for GPT4-5-shot

The prompt used for the GPT4-shot is the one from (Hendy et al., 2023), i.e. the following:

```
Translate this into 1. [target language]:
[shot n source]
1. [shot n reference]
Translate this into 1. [target language]:
[input]
1.
```

D BLEU scores

We provide BLEU scores for language pairs with reference translations in Table 7. The results are provided (as with the COMET scores in the main part of the paper) for the original raw subset (`manseg-raw`) and for its normalised version ((`manseg-norm`)) as well as the difference between the two scores (δ).

E COMET-QE scores by annotation type

We provide in Table 8 COMET-QE scores per annotation type for all from-English language pairs of the shared task.

F Copying analysis

Table 9 shows results for our automatic analysis of the number of source words that are found in the output translations. We calculate the number of such words, averaged over the number of sentences for each of the subsets `manseg-raw` and `manseg-norm` and we calculate the difference between the two. Positive numbers indicate that more copied words are found when systems translate the non-standard output and negative numbers indicate that more copied words are found when systems translated the normalised sentences.

Abstract

Machine Translation Evaluation is critical to Machine Translation researches, as the evaluation results reflect the effectiveness of training strategies. As a result, a fair and efficient evaluation method is necessary. Many researchers have raised questions about currently available evaluation metrics from various perspectives, and propose suggestions accordingly. However, to our knowledge, few researchers has analyzed the difficulty level of source sentence and its influence on evaluation results. This paper presents HW-TSC's submission to the WMT23 MT Test Suites shared task. We propose a systematic approach for construing challenge sets from four aspects: word difficulty, length difficulty, grammar difficulty and model learning difficulty. We open-source two Multifaceted Challenge Sets for Zh→En and En→Zh. We also present results of participants in this year's General MT shared task on our test sets.

1 Introduction

Machine Translation (MT) Evaluation is an indispensable part of MT research, helping researchers verify the effectiveness of proposed training strategies and offering suggestions for future researches. However, automatic machine evaluation has raised a lot of concerns during decades of practices. One research direction is to explore the weakness of available evaluation metrics (Koehn and Monz, 2006; Callison-Burch et al., 2006; Post, 2018; Chen et al., 2022). Another direction is to analyze the soundness of test sets. For example, Freitag et al. (2020) discuss the impact of reference translationese on the evaluation results.

However, to our knowledge, few researches (Ahrenberg, 2018; Isabelle et al., 2017) has been done to discuss the influence of source sentences on the evaluation results. With the advancement of machine translations in recent years, we think that randomly sampled test sets may not be able to reflect the true gaps among models, as you can't test freshman's capability with grade-1 quiz. So we propose a strategy to collect test sentences with high-level of difficulty. The strategy considers a sentence's difficulty level from four dimensions, including word difficulty, length difficulty, grammar difficulty and model learning difficulty.

This paper presents our constructed Multifaceted Challenge Sets[1] for Zh→En and En→Zh language pairs using the strategy mentioned above. Each of the test set contains 2,000 sentences. The source sentences are from the open-sourced English Wikipedia corpus[2] while the translations are provided by our in-house translators. We report the results of participants in this year's General MT shared task on our test sets and hope to gain some insight by comparing our results with the official evaluation results.

2 Challenge Set Construction

2.1 Measuring Difficulty Level of a Test Set

We propose four indexes to measure the difficulty level of a sentence: word difficulty, length difficulty, grammar difficulty and model learning difficulty.

Word Difficulty Word difficulty is measured based on the frequency of a word appeared in the parallel training corpus. In general, the lower the frequency of a word in the training data, the more challenging for neural machine translation (NMT) to translate the word correctly.

We calculate the frequency of all words in the officially provided parallel data for the General MT shared task, and select words with frequency of more than 10 times and less than 99 times as the low-frequency word list. It should be noted that although some words fall into this frequency

Table 1: BLEU, chrF and COMET Scores for the Zh→En translation task. Constrained systems are indicated in bold.

range, they can be divided into high-frequency subwords (e.g. newsagent = news + agent), which certainly does not meet the difficulty requirement. So we manually check the English and Chinese word lists and remove words that are consisted of high-frequency subwords. Finally we use the word lists to match the Wikipedia corpus to collect test sentences.

Length Difficulty Extremely Long and short sentences can be challenging for NMT models. In our daily practice, we find that omission and logic errors are more frequently seen in extremely long sentences. Meanwhile, due to the lack of enough context information, extremely short sentences are also error-prone.

We calculate the length (the number of English words/Chinese characters) of each sentence in the Wikipedia corpus and select 1,000 longest and shortest sentences respectively. We manually check semantics of each sentence and finally select 250 extremely long and 250 extremely short sentences as the test cases. The removed sentences include those that are incomplete, or contains obvious translationese (probably back-translation results from other languages).

Grammar Difficulty Kauchak et al. (2017) propose measuring the grammar difficulty of a sentence using the frequency of the 3rd level sentence parse tree. They employ Berkeley Parser to parse the 5.4M Wikipedia corpus and create 11 frequency bins.

Inspired by their strategy, we use Berkeley Parser to parse all sentences in the Wikipedia corpus and calculate the frequency of each 3rd level parse tree pattern. We exclude patterns that appear only once, which are highly possible to be noisy data. Then we select 1,000 sentences of which their grammar pattern has the lowest frequency as the candidate pool. Finally we manually check the semantics of each candidate and select 500 test sentences.

Model Learning Difficulty Zhao et al. (2019) observe that the translation quality is related to the entropy of the source sentence. The higher the source sentence entropy, the more likely the sentence is under-translated. They propose a formula to calculate entropy of the source sentence: Assume a word s contains K candidate translations, each of which has a probability p_k, the translation entropy for this word can be calculated by:

$$E(s) = -\sum_{k=1}^{k} p_k * \log p_k \quad (1)$$

Using this formula, we calculate the entropy of each sentence in the Wikipedia corpus and select 1,000 sentences with the highest entropy as the candidate pool. Then we manually check the semantics of each sentence and finally select 500 test cases.

Table 2: BLEU, chrF and COMET Scores for the En→Zh translation task. Constrained systems are indicated in bold.

2.2 Test Set Composition

Our Zh→En and En→Zh test sets each contains 2,000 sentences, 500 sentences per category. The source sentences are selected from the open-source Englisjh Wikipedia corpus (version 20230520)[3], using the strategy we mentioned above. The target sentences are translated by our in-house translators, without referring to any machine translation models. We recruit 10 translators whose average working experience in the translation field exceed 5 years.

3 Results and Discussions

3.1 Results on the Multifaceted Challenge Set

Table 1 and Table 2 present the Zh→En and En→Zh results, including sacreBLEU (Post, 2018), chrF (Popović, 2015), and COMET-22 (Rei et al., 2022), as well as corresponding ranks. The ranks are quite different from the official results. However, as we are unable to keep the domain distribution of our test set the same as that of the official test set, we cannot draw a conclusion of whether the ranking difference is due to different levels of source sentence difficulty or domain difference.

If the ranking difference is caused by the different difficulty levels, we can conclude that systems that perform well on average test sets may not perform as well on challenge sets. So we may need a set of test sets at different difficulty levels to comprehensively evaluate model performance. Or if the ranking difference is caused by domain issues, the top-ranked systems on the official test sets may not be so general as the task name, General MT, suggests.

We also report COMET results on each subset (see table 3 and table 4) and try to understand model performance on each dimension. According to table 3, performances of Zh→En systems vary greater under the Word and Length dimensions, as the standard deviation scores are greater than that of other dimensions and the overall result. The result indicates that incorporating low-frequent words and extremely long/short sentences into the test set may better help to significantly differ model performances. The result is similar for En→Zh translation. As shown in table 4, the standard deviation under the Word dimension is much greater than that of the overall result and other dimensions. The standard deviation under the Length category is second largest, although a little bit lower than that of the overall result.

3.2 Towards More Sound Evaluation

Automatic evaluation is still the first option for MT researchers considering its speed and cost. More reliable evaluation metrics, e.g. COMET (Rei et al., 2020), BLEURT (Sellam et al., 2020), now provide more reliable evaluation results that more align with human evaluations. Meanwhile, we believe

there should be a more systematic approach to construct test sets. In addition to domains, we should also put difficulty level into consideration. The randomly sampled test sets represent the average difficulty level in a certain domain, which can reflect the general capability of models. However, to learn the current weakness of MT and push further researches, we need challenge sets.

4 Conclusion and Limitations

This paper presents HW-TSC's submission to the WMT23 MT Test Suites shared task. We propose increasing the test set difficulty level to better measure model performances. We propose a strategy to collect test sets with high difficulty level: word difficulty, length difficulty, grammar difficulty and model learning difficulty. We construct two multifaceted Challenge Sets for Zh→En and En→Zh directions using this strategy and report automatic evaluations of participants in this year's General MT shared task on our test sets.

However, due to time constraints, we do not perform human evaluations on the test results, which we believe will offer more insights on the performance of our challenge sets. For future researches, we will conduct direct assessment (DA) and error annotations to explore the performance of each participants on the challenge sets and compare the result with the official test sets. In addition, we will construct relatively simple test sets in the same domain, and compare the results with these challenge sets, hoping to gain more insights on the role of source sentence difficulty level.

Linguistically Motivated Evaluation of the 2023 State-of-the-art Machine Translation: Can GPT-4 Outperform NMT?

Shushen Manakhimova[1], Eleftherios Avramidis[1], Vivien Macketanz[1], Ekaterina Lapshinova-Koltunski[2], Sergei Bagdasarov[3] and Sebastian Möller[1]

Abstract

This paper offers a fine-grained analysis of the machine translation outputs in the context of the Shared Task at the 8th Conference of Machine Translation (WMT23). Building on the foundation of previous test suite efforts, our analysis includes Large Language Models and an updated test set featuring new linguistic phenomena. To our knowledge, this is the first fine-grained linguistic analysis for the GPT-4 (5-shot) translation outputs. Our evaluation spans German–English, English–German, and English–Russian language directions. Some of the phenomena with the lowest accuracies for German–English are *idioms* and *resultative predicates*. For English–German, these include *mediopassive voice*, and *noun formation(er)*. As for English–Russian, these included *idioms* and *semantic roles*. GPT-4 (5-shot) performs equally or comparably to the best systems in German–English and English–German but falls in the second significance cluster for English–Russian.

1 Introduction

Over the past few years, we have witnessed substantial advancements in Machine Translation (MT) alongside the rapid expansion of Large Language Models (LLMs). These developments have brought translation quality up to par with human capabilities. However, these seemingly perfect translations might contain fine-grained linguistic errors that go unnoticed or get overlooked entirely in automated evaluation. A more structured approach to identifying linguistic issues in the outputs involves the use of *test suites* or *challenge sets* to systematically evaluate the system's performance on specific tasks. The current study focuses on providing a fine-grained evaluation of the translation proficiency of the latest generation of Neural Machine Translation (NMT) against the latest generation of LLMs, exemplified by ChatGPT 4.5. One of the objectives is therefore to assess whether ChatGPT, as an LLM, excels NMT in managing specific linguistic phenomena. Although our focus lies on ChatGPT, we are aware that there might be other LLMS participating in the sub-task.

In this context, we are presenting the results of the test suites analyzing state-of-the-art systems in terms of numerous linguistically motivated phenomena. These test suites[1] were applied to the MT systems submitted for evaluation at the 8th Conference on Machine Translation (WMT23; Kocmi et al., 2023) across multiple language directions: German–English, English–German, and English–Russian.

This paper is structured as follows: Section 2 goes through related work, whereas Section 3 explains how the test suite was created and applied. Section 4 outlines the setup of this year's experiment, whose results are detailed in Section 5. Section 6 concludes the paper with an outlook to future research.

2 Related Work

The origins of test suites can be traced back to the early days of machine translation in the 1990s (King and Falkedal, 1990; Way, 1991; Heid and Hildenbrand, 1991). Several researchers have adopted the use of test suites to achieve their goals. For instance, Guillou and Hardmeier (2016) employed test suites to evaluate pronoun translation. Other studies (e.g. Isabelle et al., 2017; Burchardt et al., 2017) compared different MT technologies, while Avramidis et al. (2018) explored their applicability in Quality Estimation methods.

The Machine Translation test suite track has played a significant role in this context, leading to the creation of test suites focusing on specific translation-related phenomena. For example, the work by Weller-di Marco and Fraser (2022) addressed the translation of morphologically complex

[1]https://github.com/DFKI-NLP/mt-testsuite

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 224–245
December 6–7, 2023.

words from German into English. Additionally, Semenov and Bojar's research delved into document-level translation quality assessment. These test suites, however, focus on one or at most a few phenomena per test suite, including the works by Cinkova and Bojar (2018), Bojar et al. (2018), Burlot et al. (2018), Guillou et al. (2018), Rios et al. (2018), Popović (2019), Raganato et al. (2019), Rysová et al. (2019), Vojtěchová et al. (2019), Kocmi et al. (2020), Scherrer et al. (2020), Zouhar et al. (2020). Test suites, in conjunction with human evaluation, are also instrumental in assessing the quality of machine translation metrics (Freitag et al., 2021; Avramidis and Macketanz, 2022). Our approach enables a comprehensive analysis that spans over a hundred linguistic phenomena across three language pairs (Macketanz et al., 2022a). It incorporates semi-automated human evaluation, combining efficiency with in-depth analysis. Due to our participation in past shared tasks since 2018 (Macketanz et al., 2018b), we are able to analyze the development of machine translation systems over the years.

With the growing interest surrounding LLMs, researchers have been increasingly focused on evaluating ChatGPT's performance in MT. For instance, the paper by Jiao et al. (2023) concludes that ChatGPT performs competitively with commercial translation products on high-resource European languages. A comprehensive evaluation across 18 languages of GPT models versus best-performing WMT-22 systems including human evaluations by Hendy et al. (2023) supports the previous finding. Other research explores these differences in terms of the literalness of translations produced by standard NMT and ChatGPT-3 (Raunak et al., 2023). Castilho et al. (2023) have tested ChatGPT for handling context-related linguistic phenomena such as coreference, terminology, etc. to show that it performed even better than other MT engines. This current paper also places a specific focus on evaluating ChatGPT's performance compared to other systems in the shared task.

3 Method

3.1 Test suite description

This paper focuses on three language pairs: German–English, English–German, and English–Russian. The test suite is built around specific linguistic categories, further divided into more detailed linguistic phenomena. While these categories and phenomena are specific to each language pair or direction, they may overlap across different directions. Although the logic of the test suite does not follow a particular linguistic theory, the categorization is based on linguistic research, established contrastive grammars, and findings from translation studies. The test suite was designed to cover a wide range of potential translation challenges, and its categories and phenomena were internally reviewed for objectivity by linguists and professional translators.

Test set	Test sentences	Categories	Phenomena
De–En	∼5,500	14	106
En–De	∼4,785	13	110
En–Ru	∼1232	12	51

Table 1: Metadata of the language pairs in the test suite.

Table 1 provides an overview of the number of test sentences, categories, and phenomena for each language pair. Notably, our English–Russian test set has more than doubled compared to last year, from 350 sentences (Macketanz et al., 2022b) to 1232. The new categories and phenomena have been added to the English–German direction as well.

To allow the evaluation of test sentences to operate semi-automatically, we have written rules that determine translation correctness. These rules include hand-crafted regular expressions and predefined translation outputs, applied using an internal evaluation tool (Macketanz et al., 2018a). Figure 1 illustrates the workflow of the preparation and application of our test suite.

3.2 Application of the test suite

The details regarding the development and application of our test suite are available in prior publications within the test suite track.(Macketanz et al., 2018c, 2021, 2022b; Avramidis et al., 2019, 2020). In this paper, we present an overview of the complete system. As shown in Figure 1, the building of the test suite follows steps a to c. Once test sentences are input to MT systems (step d), the test suite is applied, and automatic evaluation begins. This is done using predefined rules (step e). These rules are made of regular expressions and fixed strings, indicating correct and incorrect translations based on previous MT system outputs. Regular expressions are designed to evaluate translation accuracy for specific phenomena, possibly excluding unrelated errors. Sentences are flagged with warn-

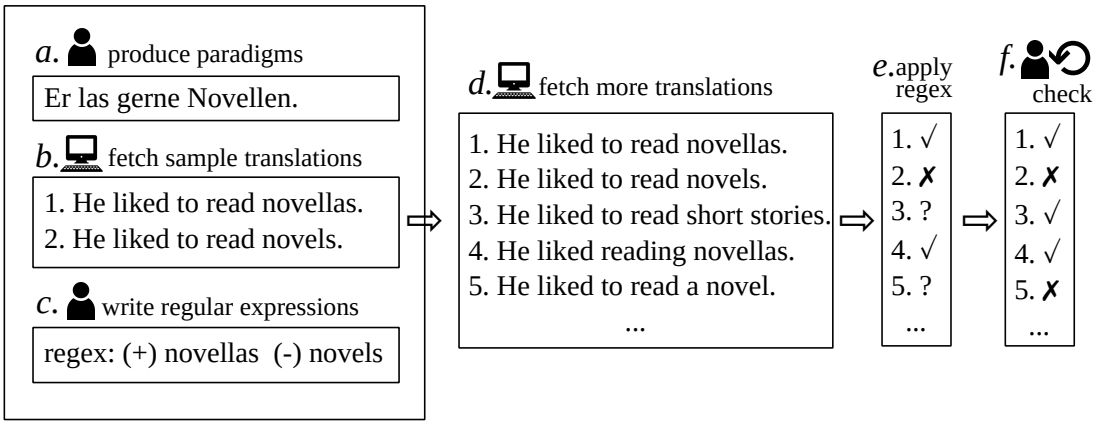

Figure 1: Example of the preparation and application of the test suite for one test sentence

ings when they cannot be automatically sorted as correct or incorrect. Human linguist annotators review and adjust the rules, while sentences with critical language errors unrelated to the phenomena are deemed incorrect.

Subsequently, the translation accuracy specific to the phenomenon is calculated by dividing the number of correctly translated test sentences for that phenomenon by the total number of test sentences for that same phenomenon:

$$\text{accuracy} = \frac{\text{correct translations}}{\text{sum of test items}}$$

Since the goal is to ensure a fair comparison among systems, only the test items that do not have any warnings are included in the calculation. If a test item has at least one unresolved warning, we exclude it from the calculation. Such an approach reduces the total number of test items, which was crucial this year, as there were many problematic outputs.

We begin by identifying the highest-scoring system in each language direction and then compare it to other systems. To do so, we confirm the significance of the comparison with a one-tailed Z-test with $\alpha = 0.95$. Systems that do not significantly differ from the top-performing system are grouped into the first performance cluster, which is indicated with boldface in the respective rows of the tables.

Average scores are computed using three distinct methods to account for variations in the number of test items within each category or phenomenon. The micro-average method aggregates the contributions of all test items to calculate average percentages. Category macro-average computes the percentages independently for each category and then averages them, treating all categories equally. Similarly, the phenomenon macro-average computes percentages independently for each phenomenon and then averages them, treating all phenomena equally.

3.3 Addition of new phenomena

This year, we added some new phenomena and made an effort to make the new test items more challenging for the systems. For instance:

- Some test items are now spanned across multiple sentences. Previously, the *coreference* category had only one sentence test items e.g., *Susan dropped the plate, and it shattered loudly*. This year, some new test items divided into two sentences had been added e.g., *The cat climbed up a tree. It was afraid*.

- There was an effort to include sentences that vary in their length, ambiguity as well syntax complexity. For example, *He was also seen wearing harem-style trousers as he tapped his feet along with his new track* as well as

- to add phenomena that require inventive approach and cultural knowledge e.g., *onomatopoeia*.

4 Experiment Setup

In this paper, we present the evaluation of 37 systems with our test suite. The systems were submitted to the *news translation task* of the Eighth Conference on Machine Translation (WMT23; Kocmi et al., 2023): 13 systems for German–English, 12 systems for English–German, and 12 systems for English–Russian.

This year is the third time that the English–German systems are being evaluated with our test suite and the second time for the English–Russian systems. Every year, manual work is involved upon receiving the system translations as there are usually a number of translation outputs that are not yet covered by the existing rules in the database (the *warnings*). At the beginning of the evaluation process this year, there were on average 10.7 % of warnings for German–English, 15.6 % for English–German, and 70.6 % for English–Russian. The English–Russian test has grown significantly since last year and in comparison with the other sets had more new items that had not been evaluated before. It was also expected that English–German would have a higher amount of warnings than German–English as there were some new categories added to the English–German test suite.

One annotator with extensive linguistic knowledge of the three languages conducted the manual evaluation of the warnings; problematic cases were discussed with several translation experts to exclude subjectivity. The manual evaluation took around three and a half weeks and involved around 55 person-hours. After the manual evaluation, there were on average 7 % of warnings left for German–English, 6.8 % for English–German, and 6.9 % for English–Russian.

As mentioned above, test sentences with at least one warning by one system were excluded from the analysis to achieve a fair comparison between the systems under inspection. As this year, we saw a lot of problematic outputs that could not be properly evaluated, this report deals with a significantly less number of test items than in the previous years. We suspect that some of these can be explained by possible models' hallucinations: a number of the MT outputs this year had some parts of the sentences repeated twice or parts of the test items were not translated at all or seemed out of place altogether. To illustrate, one unevaluated output was from the phenomenon *intransitive-perfect* "Ich bin gerannt" ("I ran" or"I was running") that in the submission of Lan-Bridge (Wu and Hu, 2023) was rendered "I'm a manager".

As a result, our analysis was conducted on 3234 (58.9 %) test sentences for German–English, 3109 (64.8 %) test sentences for English–German, and 909 (73.8 %) test sentences for English–Russian.

5 Results

All result tables can be found in the Appendix.

5.1 System comparison

For **German–English**, ChatGPT 4.5 produced micro and macro scores of 92.5 % and 91.6 % respectively, which puts ChatGPT 4.5 into the cluster of top-performing systems. The highest micro averages ranging from 95.9-93 % were achieved by the systems Online-W, Online-A, and Online-Y. In terms of the macro average, Online-W, Online-A, and Online-B demonstrated the highest scores, ranging from 91.8 % to 92.7 %. The system with the lowest performance on the micro average this year was Lan-Bridge with 81.2 %, while the system with the lowest macro average was AIRC with 74.3 %.

For the **English–German** direction, ChatGPT 4.5 leads with a micro average of 97.8 %, followed closely by Online-Y at 97.4 % and Online-B at 97.2 %. ChatGPT 4.5, on the macro average, displays the highest score 92.9 %, followed by Online-W with 92.6 % and Online-B with 92 %. The system AIRC achieved the lowest scores: 87.1 % for micro and 71 % for macro. On average, systems get micro average of 95.4 % and macro average 86.7 %.

For **English–Russian**, only Online-G and Online-W stand out with the highest scores. Online-G achieves a micro average of 86.9 % and a macro average of 86.3 %, while Online-W achieves 86.8 % and 85.5 % respectively. ChatGPT doesn't end up in the top-performing cluster and ChatGPT gets the same micro average as Online-B 81.7 %. Online-B achieves 81.3 % on macro average and outperforms ChatGPT by 3.4 %. LanguageX and Lan-Bridge as the two systems with the lowest scores achieve micro scores of 65-65.7 % and macro of 61.1 %. Several factors, such as limited training data and substantial structural differences between the languages, contribute to the translation challenges for this language pair, compared to the relatively similar English–German pair.

5.2 Category-level analysis

In **German–English**, a few models achieve 100 % in categories such as *composition*, *named entity & terminology*, and *negation*. This might be attributed to the fact that these categories have well-defined rules that the models have mastered. Categories like *ambiguity* and *false friends* still show varied

results, indicating their complexity. ChatGPT 4.5 excels in many categories, scoring 91.0 % in *ambiguity* and 95.5 % in *ldd & interrogatives*. *Punctuation* is the most difficult category for ChatGPT 4.5 achieving 76 % accuracy. One possible explanation is that GPT translations frequently include punctuation and other content not present in the original text (Hendy et al., 2023).

For **English–German**, the categories with the highest scores are *negation*, *verb tense/aspect/mood*, and *function word*. ChatGPT 4.5 performs well in *function word* (97.6 %) and *ldd & interrogatives*, although NLLBG still outperforms ChatGPT in *ldd & interrogatives*. ChatGPT and NMT models can improve in categories like *subordination* and *verb valency*, where scores are often below 90 %.

For **English–Russian**, the category with the highest average score (89.4 %) is *punctuation*. Categories like *verb semantics* and *lexical Morphology* pose significant challenges. The categories with the lowest accuracy are *ambiguity* with 51.8 %, followed by *coordination & ellipsis*. However, ChatGPT 4.5 achieves the lowest results in the category *false friends* with 61.5 % accuracy. ChatGPT performs best in *function word* (93.1 %) and *verb tense/aspect/mood* (85.9 %). The most challenging phenomenon for ChatGPT is *verb semantics* with a score of 47.1 %.

5.3 Phenomenon-level analysis

For **German–English**, the phenomenon macro-average for ChatGPT is 91.5 % with over 40 phenomena reaching a 100 % accuracy. There are no phenomena that reach 100 % accuracy across all models but some of the easier phenomena for most models include *phrasal verb*, *sluicing*, *polar question*, *ditransitive future I*, *passive voice* and other. The phenomena with the lowest accuracies are *idioms*, *modal negated - pluperfect*, and *resultative predicates*. In terms of *idioms*, ChatGPT performs better than most systems with 57.9 % accuracy.

Table 2 contains example outputs from two different phenomena for German–English. The first example comes from the phenomenon *extended adjective construction*, a frequent construction in German grammar, where the adjective is modified prepositional phrases or attributes. This structure tends to complicate the syntactic structure, making MT more challenging. The first translation is incorrect as it doesn't accurately convey the meaning of the original sentence. The second translation accurately conveys the meaning of the original sentence and uses correct English grammar. The third translation is also inaccurate due to the wrong word order and the incorrect use of an adjective instead of an adverb.

Extended Adjective Construction	
Auf der anderen Straßenseite stand ein laut weinendes Kind.	
On the other side of the street was a noisy child.	fail
A child was crying loudly across the street.	pass
Across the street stood a loud crying child.	fail
Resultative Predicate	
Es regnete die Stühle nass.	
It rained wet the chairs.	fail
It rained and the chairs got wet.	pass
It had a wet effect on the chairs.	fail

Table 2: Examples of German–English linguistic phenomena with passing and failing MT outputs.

The second example contains a *resultative predicate*. The first translation is incorrect because it does not follow the correct word order in English. The word-to-word translation of the German sentence is taken too directly, resulting in an awkward and non-sensical English sentence. The second translation is correct. It accurately conveys the meaning of the original German sentence and uses a natural English construction to do so. The third translation is also incorrect as "having a wet effect" is not typically used to describe things that are "wet" or that "get wet".

For **English–German**, the phenomenon-level macro average is similarly high as for the other language direction with 93 %. The phenomena for which all systems reach near 100 % accuracy include *inversion*, *multiple connectors*, *pied-piping*, *prepositional mwe*, *substitution*, *adverbial clause* and others. Most of the phenomena achieve high accuracies over 85 %, with some exceptions including *stripping*, *topicalization*, *verb semantics*, *mediopassive voice*, and *noun formation(er)*.

Table 3 contains translation examples from English–German. The first example contains a *functional shift*. Functional shift, or conversion, is when a word switches from one word class, or part of speech without changing its form Cannon (1985). In the first output, we can observe a correct structural change with the use of a common German prepositional phrase. In the second output, however, the word "wassappieren" is not a valid German word, resulting in an incomprehensible translation. Similarly, the third translation is also

Functional Shift	
You can whatsapp me on this number.	
Sie können mich per Whatsapp unter dieser Nummer erreichen.	pass
Sie können mich auf dieser Nummer wassappieren.	fail
Du kannst mich auf dieser Nummer aufpassen.	fail
Semantic Roles	
The bike accident broke Sarah's arm.	
Der Fahrradunfall brach Sarah den Arm.	fail
Bei dem Fahrradunfall brach sich Sarah den Arm.	pass

Table 3: Examples of English–German linguistic phenomena with passing and failing MT outputs.

Compound	
He denies that racism is just skin-deep.	
Он отрицает, что расизм — это просто глубинка.	fail
Он отрицает, что расизм поверхностен.	pass
Он отрицает, что расизм сводится только к цвету кожи.	fail
Idiom	
When things look black, there's always a silver lining.	
Когда все выглядит мрачно, всегда есть луч надежды.	pass
Когда все выглядит черным, всегда есть серебряная подкладка.	fail
Когда все выглядит черным, всегда есть худ без добра.	fail

Table 4: Examples of English–Russian linguistic phenomena with passing and failing MT outputs.

not a valid German sentence, it introduces a different verb, "aufpassen", which means "to look after" and doesn't fit the original meaning of the sentence. The second example deals with the problem of *semantic roles* also known as *thematic relations*. English has a broad range of semantic roles in the subject position and while German also allows for non-agentive semantic roles to be expressed as subjects, it may be more restrictive than English. In the incorrect translation, the accident itself is depicted as the direct agent of the action, which is unusual for German. According to the accurate translation, which follows the typical German sentence form, "Sarah's arm broke as a result of the accident".

For **English–Russian**, the phenomenon level macro-average accuracy lies at 77 %. In this year's submission, the following phenomena reached 97-100 % accuracy: *prepositional mwe*, *contact clause*, *object clause*. The two phenomena reaching the lowest accuracies were *idioms* and *semantic roles* with less than 40 % averages. The low accuracy for *idioms* and *semantic roles* are not surprising as t expressions still cause translation errors across all language pairs. ChatGPT 4.5 performs as the fourth-best system in all the averages, showing the lowest result for *semantic roles* as well.

Table 4 covers translation examples in English–Russian. For instance, the translation of a problematic English *compound* "skin-deep" into Russian. The first translation "Он отрицает, что расизм — это просто глубинка" means in Russian "He denies that racism is just a small rural town." "Глубинка" does have the same root as the word "deep" in Russian but has a completely different meaning, which makes this translation incorrect. The second structure is correct as it uses the adjective "поверхностен" or "superficial". The third translation is also incorrect as it means "He denies that racism is only about skin color" and states that the issue of racism is related to skin color, which was not present in the test item. The second example comes from the phenomenon *idiom*. This example includes a very common English non-literal expression "silver lining" meaning that there might be a positive aspect to a situation that may initially appear depressing or hopeless. The first translation correctly interprets the English idiom using a popular expression in Russian, "луч надежды" (ray of hope), reflecting the idea that even in bad times, there is always hope for something positive. The second translation renders the idiom literally. The Russian phrase "серебряная подкладка"(silver underlay) is not commonly used and does not accurately express the original meaning. In the third translation, an appropriate Russian proverb "There is no bad without good" is used to convey the meaning, but there's an error in the Russian expression: instead of "худа", there is a non-existent word "худ", making this translation incorrect.

5.4 Comparison with previous years

The progress of the systems' accuracy for particular categories through the last years can be seen in Table 8 for German–English (since 2018), Table 9 for English–German (since 2021) and Table 10 for English–Russian (since 2022). The calculation has been done based on the common test items without warnings over the years. Compared to last year, the micro- and macro-average scores for the German-English systems included in the comparison have either shown very small improvement or remained the same. For English–German, 3 systems (Online-G, Y, and W) showed an im-

provement, which in some categories sums up to several percentage points. In English–Russian, 5 out of the 7 the systems (Online-A, G, W, Y, and PROMT) showed an improvement which averages to 1-5 %. Whereas we have little information about the development behind the online systems, we can assume that English–Russian is still in active development, English–German has undergone minor improvements, whereas there seems to have been no development for German-English.

Interestingly enough, the Lan-Bridge performance has gotten worse both in micro and macro averages compared to last year. The drop in performance is important in light of Lan-Bridge's own system description. Their approach in the WMT23 competition has been shaped by the shift towards large-scale models and lies on prompt-based experiments. To understand the specific reasons for Lan-Bridge's drop in performance, a detailed analysis of their models, data, experiment designs, and evaluation metrics would be necessary.

6 Conclusions and Outlook

This paper presents a fine-grained, linguistically motivated test suite to evaluate machine translation outputs. The test suite was applied to evaluate and compare the outputs of 37 machine translation systems in three different language pairs: German–English, English–German, and English–Russian.

While the evaluation showed high scores for all language pairs, there was a clear drop in accuracy when dealing with structurally different languages, such as English and Russian. For this language pair, ChatGPT's performance falls in the second significance cluster. Although we didn't observe a systematic significant difference between ChatGPT 4.5 and other systems, it is important to highlight that ChatGPT 4.5 shows competitive results in the context of our evaluation. This indicates that ChatGPT 4.5, a general model, remains competitive in MT and sometimes performs better than some specialized NMT systems. Nevertheless, many linguistic nuances still pose difficulties for these models, demonstrating the continuous need for study and improvement in the field of MT. In terms of linguistic coverage, the current test suite stands out as one of the most extensive available. The semi-automated approach offers a more effective, while still fine-grained analysis in comparison to a typical human evaluation. When paired with other automated metrics or MQM analysis, this method can be seen as a valuable addition offering deeper insights into translation quality. The test suite approach is also highly versatile, allowing for the analysis of various tasks performed by LLMs in different contexts.

Limitations

The current test suite, evolving since 2016, was originally designed to evaluate weaker MT systems and focused on simpler linguistic phenomena. While we've introduced complexity with multi-sentence test items and more intricate sentences, it could be done only for a handful of phenomena and sentences. There are other limitations to consider. Firstly, this analysis is mostly limited to a sentence-level analysis. Secondly, all phenomena and categories are treated equally, although they may vary in their complexity. As mentioned earlier, the current evaluation rules prioritize accuracy in translating specific linguistic phenomena, sometimes at the expense of overall natural fluency, resulting in technically correct but less fluent outputs. To address some of these limitations, we consider including a linguistic acceptability score and an inter-annotator agreement score in future evaluations.

Acknowledgements

This research was supported by the German Research Foundation (Deutsche Forschungsgemeinschaft; DFG) through the project TextQ, by the German Federal Ministry of Education through the project SocialWear (grant num. 01IW20002). We would like to thank Hans Uszkoreit, Aljoscha Burchardt, Ursula Strohriegel, Renlong Ai and He Wang for their prior contributions to the creation of the test suite.

Abstract

This paper summarizes the results of our test suite evaluation on 12 machine translation systems submitted at the Shared Task of the 8th Conference of Machine Translation (WMT23) for English-German (en-de) language pair. Our test suite covers five specific **domains** (*entertainment, environment, health, science, legal*) and spans five distinct **writing styles** (*descriptive, judgments, narrative, reporting, technical-writing*). We present our analysis through automatic evaluation methods, conducted with a focus on domain-specific and writing style-specific evaluations. Our test-suite is available at https://github.com/wmt-conference/wmt23-testsuites/tree/main/submissions/en-de/IIITHYD_TestSuite

1 Introduction

Neural Machine Translation has made significant strides and has achieved a level of quality that proves valuable in numerous everyday scenarios. Nonetheless, various assessment methods for Machine Translation suggest that there is still ample room for enhancement. One such evaluation approach, geared towards identifying translation deficiencies in a more systematic manner, involves the utilization of test suites or challenge sets. Unlike conventional evaluations that draw test sets from random everyday texts, test suites comprise sentences that are carefully curated or selected to assess the MT systems' competence in translating specific linguistic phenomena. In this context, we present the results obtained from applying these test suites, analyzing the performance of state-of-the-art systems concerning numerous linguistically-driven phenomena. These test suites were administered to 12 MT systems submitted during the 8th Conference of Machine Translation (WMT23) (Kocmi et al., 2023) for English–German language pair.

We have developed a comprehensive test suite that encompasses five distinct domains (entertainment, environment, health, science, legal) and spans five different writing styles (descriptive, judgments, narrative, reporting, technical writing). The primary objective of the test suite is not to gauge a system's overall translation performance, as this aspect is already evaluated through manual assessment and various additional metrics within the primary shared task. Instead, the test suite focuses on assessing the translational proficiency across diverse domains and writing styles.

2 Test suite details

Table 1 illustrates the distribution of sentences per domain and per writing style, with a total of 2268 sentences.

2.1 Sentence Selection

In order to ensure diversity and robustness in our test suite, we collected English sentences from a wide array of sources, including BBC NEWS, Children's Stories, Textbooks, Journals, and Legal Datasets. These sentences were then categorized into clusters based on several criteria, such as the count of Noun Phrases (NP), Verb Phrases (VP), Named Entities (NE), Subordinate Clauses (SC), Discourse Markers (DM), Punctuation (P), and Sentence Length (SL).

Within each domain, we chose to include 70% of the sentences from each cluster in our dataset, thereby augmenting the diversity and comprehensiveness of our test suite.

2.2 Evaluation

Our automatic evaluation process for the 12 systems is conducted in three phases. The first phase assesses the overall test suite, the second phase focuses on specific domains, and the third phase examines various writing styles. In addition to these automatic evaluations, we conducted manual

Table 2: System-wise ranking based on COMETKIWI scores. Top five systems are highlighted in bold. Ranks are mentioned in brackets

analyses with the assistance of professional German speakers who aided us in identifying the errors made by the systems, providing valuable insights into their translation quality.

2.3 Experiment Setup

In this paper, we present the evaluation of 12 sysems with our test suite. The systems are part of the news translation task of the Eighth Conference on Machine Translation (WMT23). We cover the system outputs for English-German (en-de) language pair.

2.4 Automatic Evaluation

To evaluate the performance of the 12 submitted MT systems, we utilize COMETKIWI (Rei et al., 2022) scores, which offer quality estimation scores derived from the source sentence and MT output. Using these scores, we determine the system rankings, as outlined in Table 2. We chose COMETKIWI because it performed best among the other reference-free metrics in the recent WMT22 Metrics Shared Task (Freitag et al., 2022).

2.4.1 Domain-wise Evaluation

We have calculated COMETKIWI scores for each domain and presented them in Figure 1.

From this figure, we can deduce that ONLINE-B, ONLINE-Y, ONLINE-W, and ONLINE-A exhibit a high degree of consistency in their performance across all five domains.

However, it is worth noting that GPT4-5shot displayed subpar performance when applied to legal data, while NLLB_Greedy demonstrated comparatively lower performance in the context of environmental data.

Another important evident observation is that the machine translation (MT) systems exhibit a similar trend in both the health and science domains. This similarity may be attributed to the interconnected nature of these domains.

Notably, both ZengHuiMT and AIRC displayed consistently poor performance across all domains.

2.4.2 Writing-Style-wise Evaluation

We have computed COMETKIWI scores for sentence belonging to various writing styles and visualized the results in Figure 2.

ONLINE-W excels in narrative writing style sentences, but its performance declines significantly for technical writing style. In contrast, NLLB_Greedy performs poorly across descriptive, reporting, and technical writing styles.

Both ZengHuiMT and AIRC exhibit subpar performance across all the writing-styles. Additionally, GPT4-5Shot experiences a decline in its performance when it comes to judgments.

ONLINE-G, on the other hand, demonstrates better performance in technical writing and reporting styles.

Indeed, based on COMETKIWI scores, it is clear that both ONLINE-B and ONLINE-Y consistently outperformed other MT systems across a diverse array of writing styles and domains. This consistent

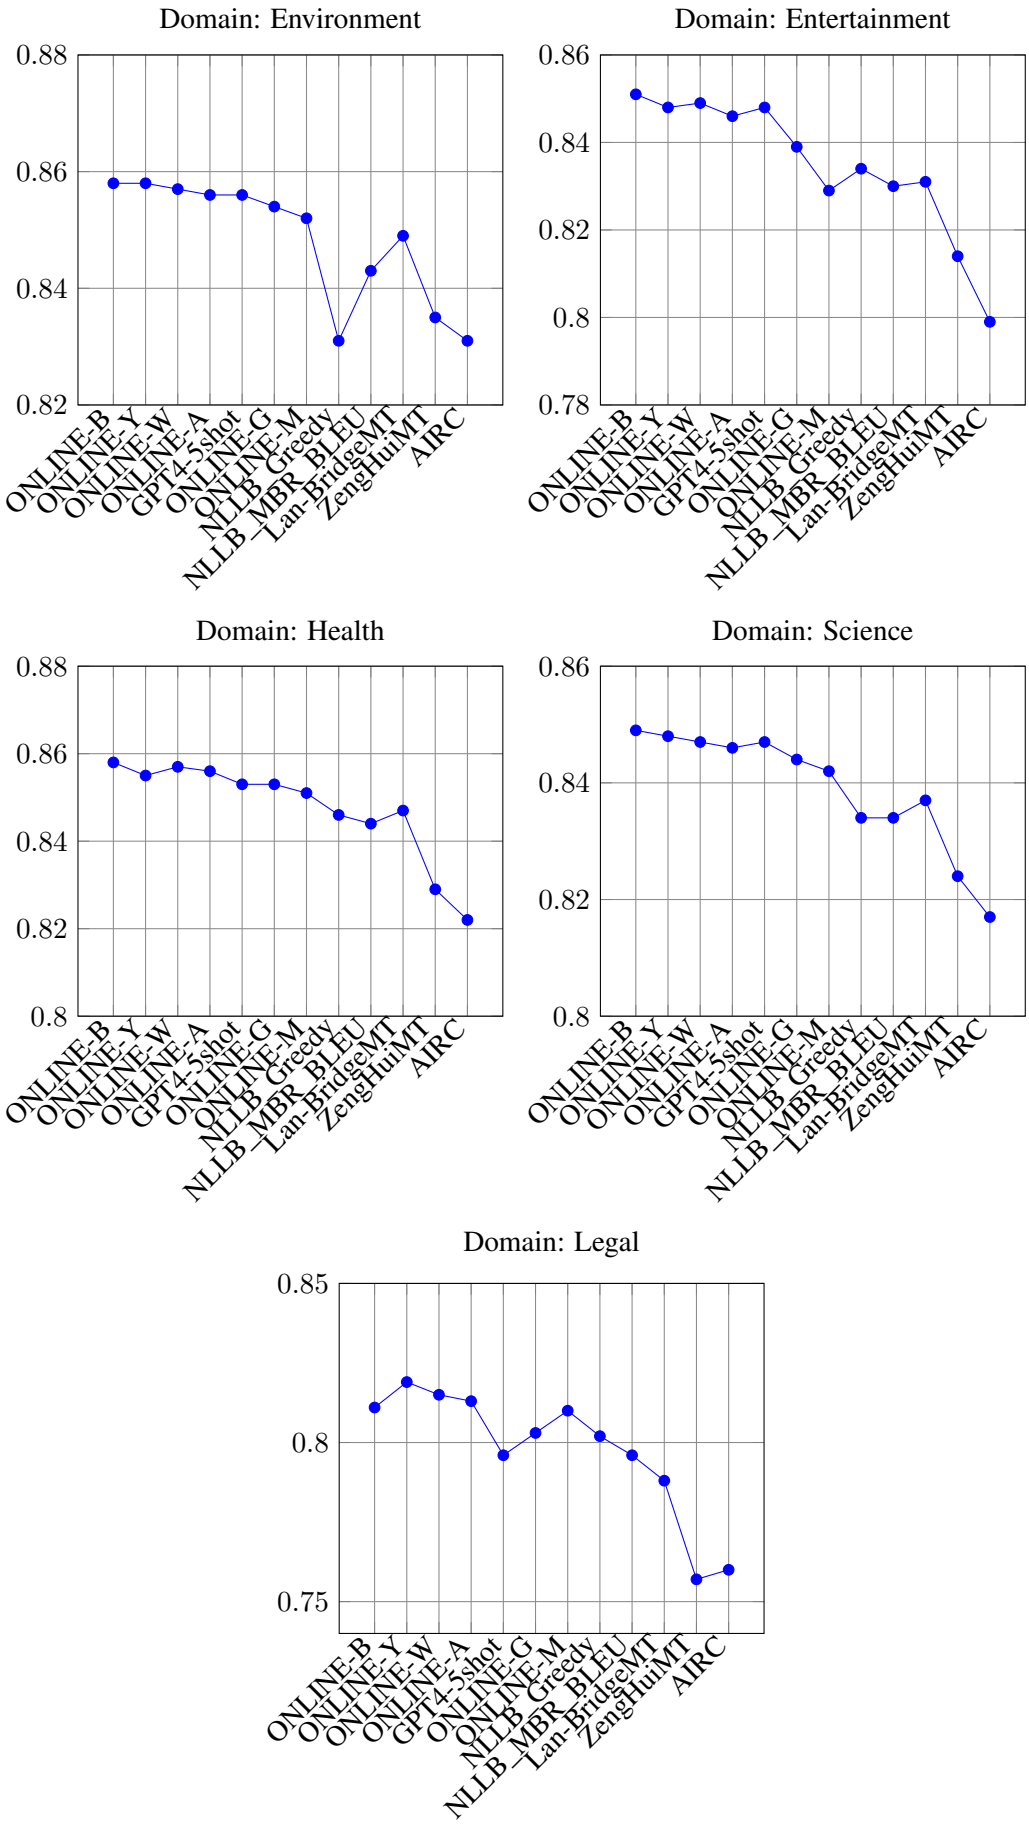

Figure 1: COMETKIWI scores of the systems with respect to domains

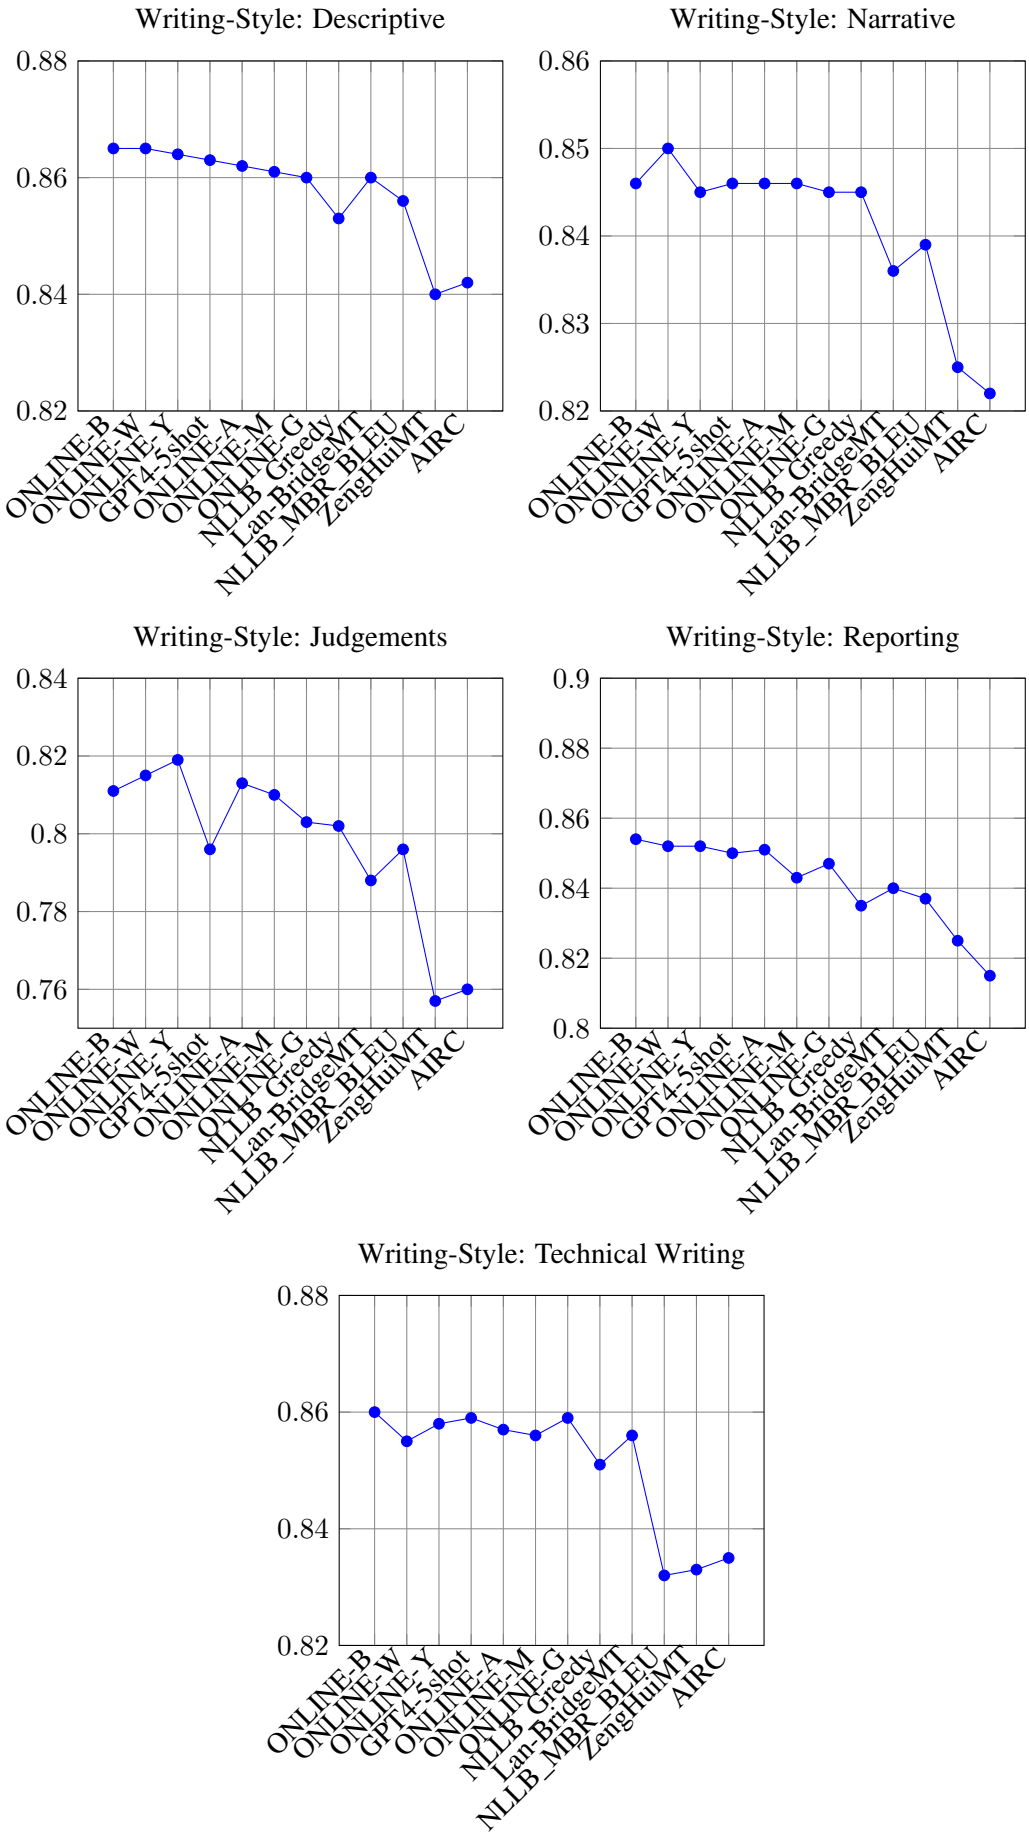

Figure 2: COMETKIWI scores of the systems with respect to writing-styles

superiority in performance suggests that these two MT systems are more robust and versatile, making them strong contenders for a wide range of translation tasks and scenarios.

2.5 Manual Assessments

These manual assessments are carried out voluntarily by professional German speakers who hold graduate-level qualifications and possess good knowledge in the domains covered by our test suite.

2.5.1 Gender-Neutral Pronouns

Machine translation (MT) systems often ascribe gender (sein/ihr $\sim$ his/her) to gender-neutral pronouns (it) in English. For instance, in the sentence '*Its age is not too dissimilar*,' ONLINE-B, ONLINE-M, ONLINE-G, ONLINE-A, ONLINE-W, Lan-BridgeMT, GPT4-5shot, and ZengHuiMT tended to assign the masculine gender 'Sein,' while the remaining systems ONLINE-Y, NLLB_Greedy, NLLB_MBR_BLEU, and AIRC preferred the feminine gender 'Ihr.' However, it's worth noting that in German, 'Sein' is typically used for neutral gender, thus introducing an intriguing linguistic nuance.

2.5.2 Repetition

Another intriguing factor is the phenomenon of Repetition, which is evident in cases like ZengHuiMT, where the translation includes additional information.

English source: a) Doing that amount is enough to reduce the risk of developing heart disease and stroke by 17% and cancer by 7%, the findings suggest.
b) While all living elements — the birds, animals and plants, forests, fisheries etc.— are biotic elements, abiotic elements include air, water, land etc.

Translation by ZengHuiMT: a) Die Ergebnisse deuten darauf hin, dass diese Menge ausreicht, um das Risiko für Herzerkrankungen und Schlaganfälle um 17 % und für Krebs um 7 % zu senken, so die Ergebnisse.
b) Während alle lebenden Elemente - Vögel, Tiere und Pflanzen, Wälder, Fischerei usw. - sind. Sie sind biotische Elemente, abiotische Elemente umfassen Luft, Wasser, Land usw.

Comment: a) The German translation is clear but includes an unnecessary repetition of **so die Ergebnisse** (the findings suggest) at the end.
b) Introduces an unnecessary repetition with **Sie sind biotische Elemente**.

2.5.3 Retention

Retention is another aspect that MT evaluation must consider. When it comes to challenging or complex words, retaining them might be permissible. However, for common or simpler words, retention should be heavily penalized.

Consider an example, "*These issues rarely have simple, single-discipline solutions that can be identified in one-off events or meetings.*" where ONLINE-B, ONLINE-M, GPT4-5shot, Lan-BridgeMT and AIRC MT systems retained the word *meetings* instead of translating it to *treffen*. This highlights the importance of addressing word retention in MT evaluation.

Manual assessments are indeed valuable for identifying gaps in machine translation quality. However, they come with significant drawbacks, including the need for extensive, non-reproducible human effort, time consumption, and high costs. Therefore, in addition to diverse test sets, it is crucial to develop robust automatic evaluation metrics capable of detecting and quantifying translation flaws efficiently and consistently.

3 Conclusion

This paper provides a comprehensive overview of our evaluation of 12 machine translation systems designed for the English-German language pair, all of which were submitted to the Shared Task during the 8th Conference on Machine Translation (WMT23). Our evaluation comprises a robust and diverse test-suite covering five distinct domains and encompassing five diverse writing styles. We conduct our analysis through a combination of automated assessments and manual evaluations, with a particular focus on domain-specific and writing style-specific performance. Based on our automatic evaluation, it is evident that both ONLINE-B and ONLINE-Y consistently surpassed other MT systems in performance across a diverse array of writing styles and domains.

Test Suites Task: Evaluation of Gender Fairness in MT with MuST-SHE and INES

Beatrice Savoldi, Marco Gaido, Matteo Negri, Luisa Bentivogli
Fondazione Bruno Kessler
{bsavoldi,mgaido,negri,bentivo}@fbk.eu

Abstract

As part of the WMT-2023 "Test suites" shared task, in this paper we summarize the results of two test suites evaluations: MuST-SHE^{WMT23} and INES. By focusing on the en-de and de-en language pairs, we rely on these newly created test suites to investigate systems' ability to translate feminine and masculine gender and produce gender-inclusive translations. Furthermore we discuss metrics associated with our test suites and validate them by means of human evaluations. Our results indicate that systems achieve reasonable and comparable performance in correctly translating both feminine and masculine gender forms for naturalistic gender phenomena. Instead, the generation of inclusive language forms in translation emerges as a challenging task for all the evaluated MT models, indicating room for future improvements and research on the topic.

We make MuST-SHE^{WMT23} and INES freely available, respectively at:

https://mt.fbk.eu/must-she/

https://mt.fbk.eu/ines/

1 Introduction

As Machine Translation (MT) has made strides in generic performance, there is an increasing recognition of the need to scrutinize finer, more nuanced aspects that defy assessment through traditional metrics computed on generic test sets. It is within this context that the WMT Test Suites shared task emerges, aiming to provide a dedicated evaluation framework to delve into specific dimensions of MT output with a laser focus. In particular, those representing well-known challenges within the current MT landscape.

In light of the above, our contribution is dedicated to the critical themes of gender bias and inclusivity in translation (Savoldi et al., 2021). Given the large-scale deployment of MT, such aspects are not only relevant from a technical perspective, where gender-related errors negatively impact the accuracy of automatic translation. Rather, biased and non-inclusive systems can pose the concrete risk of under/misrepresenting gender minorities by over-producing masculine forms, while reinforcing binary gendered expectations and stereotypes (Blodgett et al., 2020; Lardelli and Gromann, 2022).

Accordingly, in this paper we present the FBK participation in the Test Suites shared task by conducting evaluations on two newly-created test suites:

1. **MuST-SHE**^{WMT23} for en-de, created as a English→German extension of the already existing multilingual MuST-SHE corpus (Bentivogli et al., 2020). This dataset is designed to allow for fine-grained analysis of (binary) gender bias in MT.

2. **INES** for de-en, designed to assess the ability of MT systems to generate inclusive language forms over non-inclusive ones when translating from German into English.

The MuST-SHE^{WMT23} and INES datasets, as well as their corresponding metrics and evaluations, are respectively discussed in Section 2 and 3. In the evaluations presented in this paper, we obtained translations of our test suites by systems that are part of the standard General Translation Task of the Eighth Conference on Machine Translation (WMT-2023). In particular, we evaluated 11 systems for MuST-SHE^{WMT23} en-de and 13 systems for INES de-en.

2 MuST-SHE^{WMT23}: en-de Evaluation

MuST-SHE^{WMT23} is a test suite designed to evaluate the ability of MT systems to correctly translate gender. It is composed of 200 segments that require the translation of at least one English gender-neutral word into the corresponding

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 252–262
December 6–7, 2023.

Form		Category 1: *Ambiguous first-person references*	Speaker

	REF_{De}	Der andere Hut, den ich bei meiner Arbeit getragen habe, ist **der**<den> **Aktivistin**<Aktivist>...	
Masc.	SRC	I mean, I'm a **journalist**.	He
	REF_{De}	Ich meine, ich bin **Journalist** <Journalistin>.	
		Category 2: *Unambiguous references disambiguated by gender info*	
Fem.	SRC	A college classmate wrote me a couple weeks ago and she said ...	He
	REF_{De}	**Eine**<Ein> **Kommilitonin**<Kommiliton> hat mir vor ein paar Wochen geschrieben und gesagt...	
Masc.	SRC	I decided to pay a visit to **the manager** [...] and he pointed ...	She
	REF_{De}	Also entschied ich mich **den**<die>**Filialleiter**<Filialleiterin> zu besuchen [...]	

Table 1: MuST-SHE annotated segments organized per category. For each gender-neutral word referring to a human entity in the English source sentence (SRC), the reference translation (REF) shows the corresponding gender-marked (Fem./Masc.) forms, annotated with their wrong <gender-swapped> forms. The last column of the table provides information about the speaker's gender.

masculine or feminine target word(s) in German. The test suite is created as an extension of MuST-SHE, a multilingual, natural benchmark built on TED talks data (Bentivogli et al., 2020), which allows for a fine-grained analysis of gender bias in MT and ST. The original MuST-SHE corpus comprises ∼3,000 (*audio, transcript, translation*) triplets annotated with qualitatively differentiated gender-related phenomena for thee language pairs: English→ French/Italian/Spanish. Here, we introduce a newly created **English→ German** textual portion (*transcript, translation*) of the MuST-SHE corpus.

2.1 MuST-SHE^{WMT23} Dataset

Phenomena of Interest. Following the MuST-SHE original design, MuST-SHE^{WMT23} is intended to evaluate the translation of a source English neutral word into its corresponding target gender-marked one(s) in the context of human referents, e.g. en: ***the*** *good* ***friend***, de: ***der/die*** *gute* ***Freund/in***.

To allow revealing a potential gap across the generation of feminine/masculine gender forms, the corpus includes a balanced number of feminine (F) and masculine (M) translation phenomena. Also, the corpus features two categories of phenomena, which differ in the presence/lack of a gender cue to disambiguate the translation. Namely, *i)* **CAT1**: consisting of first-person singular references (i.e. to the speaker), which are to be translated according to the speaker's linguistic expression of gender, e.g., *I am a good friend*. Then, *ii)* **CAT2** consisting of references to any participant, which are be translated according to explicit gender information available in the sentence, like lexically gendered words (*sister*, *Mr*), or pronouns (*He/she is a good friend*). These categories allow differentiating systems' behaviour across ambiguos vs. unambiguos cases.

Dataset creation. In order to create MuST-SHE^{WMT23} we collected a pool of English-German candidate segments by exploiting the same TED-based data sources used to create the other MuST-SHE datasets, namely: the Dev and Common Test sets of the MuST-C corpus, and other parallel sentences extracted from additional TED talks. Then, to target those segments that represented our phenomena of interest, we followed the same automatic procedure used for the original MuST-SHE benchmark, which was aimed to quantitatively and qualitatively maximize the extraction of an assorted variety of gender-marked phenomena. Regular expressions were employed to transform German gender-agreement rules into search patterns to be applied to our pool of candidate sentences. Also, to specifically match a differentiated range of gender-marked lexical items, we also compiled two series of 50 human-referring adjectives in English and German.

Once the automatic step was concluded, the pool of retrieved sentence pairs underwent a manual inspection to: *i)* remove any noise and keep only pairs containing at least one gender phenomenon; *ii)* ensure that the final (*transcript, translation*) pairs were not affected by misalignments resulting from the automatic procedure used to create

MuST-C and the new TED Talks data. Also, we examined the remaining pairs to verify that those to be included in MuST-SHE featured a a balanced distribution of categories, F/M forms, and speakers. Accordingly, since the MuST-C corpus presents a well-known gender imbalance[1], we excluded all of the extracted masculine segments that exceeded the feminine counterpart. Across categories, instead, we were not able to ensure a balanced distribution, as fewer instances from CAT1 could be identified.[2]

The resulting dataset – whose statistics are given in Table 2 – was then manually enriched with different types of information. For each segment, the annotation includes: category (1 and 2), gender form (F and M), and speaker's gender information.[3] Also, for each target gender-marked word in MuST-SHE^{WMT23}, we created a corresponding gender-swapped counterpart in the opposite gender form. As shown in Table 1, these word forms were paired and annotated in the reference translations. As we will describe in more detail in the upcoming Section 2.2, such annotated target gender-marked words are key features of MuST-SHE, which enable gender-sensitive, fine-grained analyses focusing solely on the correct generation of target gender-marked words.

The manual selection of appropriate sentences and their annotation was carried out by two annotators, both students proficient in the German language and with a background in Applied Linguistics.[4] Each annotator worked on half of the corpus independently and then revised the work done by the other. Finally, all the differences found were reconciled to get to the final corpus.

	CAT1	CAT2
Fem.	23	77
Masc.	23	77
Tot.	200	

Table 2: MuST-SHE^{WMT23} sentence-level statistics.

[1]As reported in MuST-Speakers, ∼70% of the speakers in MuST-C are referred to by *He* pronouns.

[2]This is most likely due to the gendered features of the German language, which – unlike es, fr, and it – does not carry gender markings on verbs (e.g., *I went* → de: *Ich bin gegangen* vs it: *Sono andat**a/o***) nor adjective in the nominative case (e.g., *I am good* → de: *Ich bin gut* vs. es: *Soy buen**a/o***.

[3]Such an information is migrated from the MuST-Speakers resource (Gaido et al., 2020), where gender information for each speaker in MuST-C has been labeled based on the personal pronouns the speakers used to describe themselves in their publicly available personal TED section.

[4]Their work was carried out as part of an internship at FBK.

2.2 MuST-SHE^{WMT23} Evaluation

Following the original MuST-SHE evaluation protocol described in Gaido et al. (2020), MuST-SHE^{WMT23} evaluation allows to focus on the gender realization of the target gender-marked forms, which are annotated in the reference translations together with their *wrong*, gender-swapped form (see Table 1). The evaluation is carried out in two steps, and by matching the annotated (*correct*/*wrong*) gender-marked words against the MT output. Accordingly, we first calculate the **Term Coverage** as the proportion of gender-marked words annotated in MuST-SHE (either in the correct or wrong form) that are actually generated by the system, on which the accuracy of gender realization is therefore *measurable*. Then, we define **Gender Accuracy** as the proportion of correct gender realizations among the words on which it is *measurable*. This evaluation method[5] has several advantages. On one side, *term coverage* unveils the precise amount of words on which systems' gender realization is measurable. On the other, *gender accuracy* directly informs about systems' performance on gender translation and related gender bias: scores below 50% indicate that the system produces the wrong gender more often than the correct one, thus signalling a particularly strong biased behaviour.

2.3 MuST-SHE^{WMT23} Results

In Table 3 we present the MuST-SHE^{WMT23} results for the 11 en-de systems that were submitted to the WMT-2023 standard General Translation Task. Starting from coverage results, the scores range between 67.34% (`AIRC`) and 77.07% (`ONLINE-G`), with only 3 systems under 70%. Hence, overall all models produce a good amount of gender-marked words that can be evaluated with regards to the accuracy of their gender realization. Moving onto the overall accuracy scores (All-Acc), we can see that – while there is still room for improvement – all of the evaluated MT systems are reasonably good at translating gender, with `ONLINE-M` emerging as the best model, able to correctly translate gender in 80% of the generated instances. If we go more fine-grained into results disaggregated across gender forms (F and M) and categories (1 and 2), however, we can unveil subtle differences. Indeed, for unambiguous

Table 3: MuST-SHE^{WMT23} results for en-de. Systema are ranked based on overall Gender Accuracy (All-Acc).

gender translation from CAT2, systems perform basically on par across gender forms, with actually slightly higher results for feminine translation. Instead, results on CAT1 unveil a huge gender gap, with systems achieving almost perfect results for masculine translation, whereas feminine accuracy can be as low as 10.53%. In fact, the best ranked systems `ONLINE-M` generates the correct feminine form in 50% of the cases, namely at a random rate.

Overall, results on MuST-SHE^{WMT23} show that the evaluated MT systems are reasonably good at translating gender under realistic conditions, achieving comparable results across feminine and masculine gender translation. However, for ambiguous cases where the input sentence does not inform about the gender form to be used in translation, we confirm a strong skew where all systems favour masculine generation almost by default. This finding calls for further research endeavours and evaluation initiatives to counter gender bias in MT and measure future advances.

3 INES: de-en Evaluation

The INclusive Evaluation Suite (INES) is a test set designed to assess MT systems ability to produce gender-inclusive translations for the German→English language pair. By design, each German source sentence in INES includes an expression that can be rendered by means of either an *inclusive* (`IN`) or *non-inclusive* (`N-IN`) expression in the English target language.

Overall, INES comprises 162 manually curated German sentences, which are annotated with their corresponding (`IN`/`N-IN`) English expressions. As such, it allows to evaluate to what extent MT systems favor the generation of non-inclusive solutions over alternative, valid inclusive translation in their output.

3.1 INES Dataset

Here, we first describe the phenomena of interest included in INES. Then, we proceed by describing its creation methodology.

Phenomena of interest. Despite its comparatively restricted gender grammar, English has traditionally relied on the use of marked forms that treat the masculine gender as the conceptually generic, default human prototype, i.e. as *masculine generics* (Silveira, 1980; Bailey et al., 2022). Exemplary cases of such a phenomenon are man-derivates (e.g., *man-made*, *freshman*) and the use of masculine personal pronouns for generic referents (e.g., "each student must submit *his* form"). Besides, expressions such as "*man* and *wife*" have been identified as depicting skewed representation of genders and gender roles (Stahlberg et al., 2007). Toward the adoption of fairer language for all genders, alternative and inclusive solutions are increasingly promoted by institutions (Höglund and Flinkfeldt, 2023) and recommended in writing (APA, 2020). These include the use of unmarked forms (e.g. *human-made*, *first-year student*) and neutral pronouns (e.g. "each student must submit *their* form") for generic and under-specified referents, as well as more symmetrical formulations that cast men and women in the same role (e.g. "*husband* and *wife*").

On this basis, INES represents translation phenomena where, given a source German sentence, systems are confronted with the generation of a corresponding inclusive or non-inclusive solution. As shown by the examples in Table 4, the German sentences can entail the use of either *i)* a generic masculine form, e.g. *Der Polizist*, or *ii)* a term that does not convey gender, e.g. *Die Menschheit*. Regardless of the source German term, the expected ideal behaviour of the MT system always entails

	German src	English pair
a.	**Der Polizist** half der alten Dame, die Straße sicher zu überqueren.	**police officer**, **policeman**
b.	**Die Menschheit** hat das Potenzial, die Welt zu einem besseren Ort zu machen.	**humankind**, **mankind**
c.	Die **fachmännische** Arbeit des Teams führte zum erfolgreichen Abschluss des Projekts.	**skillful**, **workmanlike**
d.	Die **geschickte** Arbeit des Teams führte zum erfolgreichen Abschluss des Projekts.	**skillful**, **workmanlike**

Table 4: INES source German example sentences with their corresponding annotated English IN and N-IN terms.

the generation of inclusive target words.

Dataset Creation. Since the focus of the INES test suite is to evaluate the ability of MT systems to generate inclusive English translations, we started by compiling a list of well-established pairs of English IN/N-IN terms and expressions. This list was created based on existing collections of paired terms (Vanmassenhove et al., 2021; Amrhein et al., 2023) and integrated with few additional terms retrieved from other inclusive language guidelines from international institutions[6] and universities.[7][8] As a result, we obtained 48 IN/N-IN English pairs, which are shown in Table 5.

Starting from this list, we created the source German sentences that compose INES following a two-step semi-automatic procedure.

In the first step, for each English IN/N-IN term of the pairs, GPT[9] was prompted to generate 3 German sentences containing such term translated into German, for a total of 6 sentences for each English pair.

In the second step, the initial pool of 288 synthetic sentences was manually revised by a linguist proficient in German.[10] The revision was aimed to *i)* correct generation errors and *ii)* select a balanced amount of German sentences for each phenomenon of interest. To this purpose:

- when all the 6 German sentences generated for the two (IN/N-IN) terms of the English pair contained only gender-marked terms (e.g. *police officer –> Der Polizist / policeman –> Der Polizist*) or only gender-neutral terms (e.g. *humankind –> Die Menschheit / mankind –> Die Menschheit*), only 3 sentences out of 6 were kept (see examples a. and b. in Table 4);

IN vs N-IN for job titles	
anchor	anchorman

in the source (see c. and d. in Table 4).

Unfortunately, we found only very few instances of double German realizations, and thus at the end of the manual revision, we remained with 162 German sentences: 21 with an inclusive source term, and 141 with a non-inclusive masculine generic in the source. All the 162 manually-curated German source sentences are included in INES, and provided with their corresponding English IN/N-IN term pair so as to allow for focused evaluations.

3.2 INES Evaluation

To evaluate systems against INES, we can leverage the annotated pairs of English IN/N-IN expressions and match them against the MT generated output. Accordingly, we can perform our evaluation by adopting the same evaluation protocol and metrics defined for MuST-SHE in 2.2. Namely, by *i)* first computing **Term Coverage** as the proportion of IN/N-IN generated by a system, and then *ii)* calculating **Inclusivity Accuracy** as the proportion of IN generated expressions, among all of the generated ones. As a result, all the *out of coverage words* (OOC) are necessarily left unevaluated.

While prior manual assessments of the terms left unevaluated by such an automatic method have been able to confirm the robustness and validity of the accuracy results in the context of binary gender translation (Savoldi et al., 2022b), here we hypothesise a potential limit for evaluating inclusivity in English outputs. Our hypothesis lies on the fact that English, a notional gender language (McConnell-Ginet, 2013), has a restricted repertoire of gender-marked – potentially N-IN – words, whereas most English nouns simply do not convey any gender distinctions (e.g., *doctor*, *secretary*, *president*). In other words, there might be many potential inclusive alternatives and synonyms (e.g. *presenter* and *host* for <*anchor*>) for a single N-IN term (e.g. <*anchorman*>). Thus, whereas OOC words in the context of binary gender present the same distribution assessed automatically in terms of accuracy, this metric might be stringent for inclusivity in English, and overly penalize the generation of alternative terms that differ from those annotated in INES.

In light of the above, we also propose the **Inclusivity Index** metric, defined as:

$$\text{Inclusivity Index} = 1 - \frac{n_{\text{N-IN}}}{N} \quad (1)$$

where $n_{\text{N-IN}}$ is the number of non-inclusive terms annotated in INES that are generated by a system, and N is the size of INES (i.e. total number of sentences to be evaluated).

In what follows, we thus carry out both **Inclusivity Accuracy** and **Inclusivity Index** evaluations,[11] and assess which one better correlates with human judgments.

3.3 INES Results

In this section (Table 6), we present the results obtained on INES by the 13 de-en systems that were submitted to the WMT-2023 standard General Translation Task. Such results are computed and discussed for Inclusivity Accuracy (Table 6a) and Inclusivity Index (Table 6b). Then, based on a manual analysis, we compare such automatic results against the systems ranking obtained with human evaluations (Table 6c).

Automatic Evaluation Results. Table 6a presents coverage and accuracy-based results. Based on such scores, the INES dataset emerges as quite a challenging test suite for current de-en systems. In fact, with the sole exception of the GPT4-5SHOT – which emerges as the best performing system (but see also Sec. 5) – all systems obtain scores that are below 50%, thus suggesting that they generate undesirable N-IN forms in more than half of the (measurable) cases. The lowest accuracy is obtained by NLLB_MBR_BLEU, amounting to 29.41% only.

Moving onto the Inclusivity Index results in Table 6b, from a bird's eye view we can immediately unveil some differences. On the one hand, GPT4-5SHOT and NLLB_MBR_BLEU still emerge as, respectively, the best and worst performing systems. On the other hand, however, there are discrepancies in the overall ranking. For instance, AIRC results as the system that generates the second-best level of inclusive translation according to the Inclusivity Index metrics, whereas it was ranked 7th in terms of accuracy.

Manual Evaluation Results. To verify which of the two automatic metrics yields more reliable results, we proceed with a manual analysis of all MT output sentences that defied the automatic evaluation procedure. Namely, we performed a human evaluation of all OOC terms to determine whether

Table 7: Correlation Coefficients with Human Judgment

the generated expression entailed *i)* an inclusive expression (OOC-in), which simply differed from the `IN` term annotated in INES but was completely acceptable; *ii)* a non-inclusive expression (OOC-not-in) different from the `N-IN` term annotated in INES; and finally *iii)* a translation error (OOC-error), which was not possible to judge in terms of inclusivity.[12] The results of such an analysis across all systems are reported in Figure 1. Such results show that, of all the OOC terms, the vast majority is represented by inclusive terms (e.g., <*business person*>/<*busissnessman*>→ *entrepeneur*). Errors, instead, are quite rare, just like non-inclusive OOC terms, which all correspond to the INES annotated `N-IN` term, but in a different number (e.g., <*freshmen*> → *freshman*).

In light of the above, our initial hypothesis – outlined in Sec. 3.2 – is thus reinforced: we do not find the same inclusivity distribution between evaluated cases in terms of accuracy (see Table 6a) and the OCC instances left unevaluated. Having now collected a complete evaluation of all the sentences, we leverage such information to obtain our official system ranking, which is shown in Table 6c. Results are computed as the proportion of inclusive (`IN` + OOC-in) terms generated by a system among all the terms that could be assessed (i.e. OOC-errors are not measurable, hence excluded).

[12]We underscore that such an analysis only concerns the terms representing the phenomena of our interest, whereas the overall judgement of the whole sentence is not accounted for.

Correlation between Automatic and Human evaluation. On this basis, and to finally verify our hypothesis, in Table 7 we report the correlation coefficients between the automatic metrics and human judgements. Accordingly, while both the Inclusivity Accuracy and Index show a satisfactory correlation with human judgements, the latter consistently emerges as a more reliable indicator of inclusivity. As such, Inclusivity Index is confirmed as the most suited measure to quantify gender-inclusive translation into English.

To conclude, our results in Tables 6 consistently indicate that current MT systems still struggle with the generation of inclusive translations. Within this landscape, GPT4-5SHOT consistently results as the model achieving the highest level of inclusivity, whereas all other models generate a ∼40% or more of non-inclusive translations in their output. This finding highlights that, while on the (binary) gender *bias* side (Section 2.3) MT systems still struggle with specific and particularly challenging ambiguous cases, the limitations of most of them on the gender *inclusion* side are evident and the problem emerges as an urgent topic for future research.

4 Related work

The last few years have witnessed and increasing attention toward (binary) gender bias in NLP (Sun et al., 2019; Stanczak and Augenstein, 2021; Savoldi et al., 2022a). Concurrently, emerging research has highlighted the importance of reshaping gender in NLP technologies in a more inclusive manner (Dev et al., 2021), also through the representation of non-binary identities in language (Lauscher et al., 2022; Ovalle et al., 2023). Foundational works in this area have included several applications, such as coreference resolution systems (Cao and Daumé III, 2020; Brandl et al., 2022) and fair rewriters (Vanmassenhove et al., 2021; Amrhein et al., 2023).

In MT, the research agenda has mainly focused on the improvement of masculine/feminine gender translation into grammatical gender languages (Savoldi et al., 2021). Along this line, different strategies have been devised to improve gender translation and mitigate masculine bias (Costa-jussà and de Jorge, 2020; Gaido et al., 2021; Choubey et al., 2021; Saunders et al., 2022). To test these methods and inspect systems' behaviour, several template-based datasets have been made available – such as WinoMT (Stanovsky et al., 2019) or SimpleGEN (Renduchintala and Williams, 2022) – which are especially intended to target occupational stereotyping. Instead, natural datasets such as the Arabic Parallel Gender Corpus (Alhafni et al., 2022) and GATE (Rarrick et al., 2023) allow for evaluation of gender bias under more naturalistic conditions. Among such type corpora, MuST-SHE (Bentivogli et al., 2020) represents the only multilingual, natural test set designed to evaluate gender bias for both MT and ST. Already available for English→French/Italian/Spanish, here we have contributed to its expansion for the English→German language pair.

As far as the topic of inclusivity and neutral language translation is concerned, research in MT is quite in its infancy. A notable exception is the work by Saunders et al. (2020), who created parallel test and fine-tuning data to develop MT systems able to generate non-binary translations for English→German/Spanish. However, their target sentences are artificial – created by replacing gendered morphemes and articles with synthetic placeholders – thus serving only as a proof-of-concept. Piergentili et al. (2023), instead, are the first to advocate for the use of target gender-neutral rephrasings and synonyms as a viable paradigm toward more inclusive MT when gender is unknown or simply irrelevant. Cho et al. (2019) and Ghosh and Caliskan (2023) investigate the preservation of gender-neutral pronouns for Korean/Bengali→English. Their results, however, show that current MT systems still face serious difficulties on relying on the inclusive, neutral pronoun *they* in translation. Along this line of work, INES – to the best of our knowledge – represents the first test suite designed to asses the use of neutral, inclusive forms beside pronouns for translating into English.

5 Conclusion

This paper summarizes the results of our WMT-2023 Test Suites evaluations, which focus on gender bias and inclusivity in translation. To this aim, we have introduced the en-de expansion of the multilingual MuST-SHE test set (Bentivogli et al., 2020) and the newly created INES dataset for de-en. The former is designed to assess gender bias and translation across a qualitatively differentiated selection of feminine/masculine gender phenomena. INES, instead, measures systems' ability to generate inclusive English translations that do not

rely on the use of masculine generics. Results on MuST-SHE^{WMT23} show that the evaluated MT systems are reasonably good at translating gender under realistic conditions, achieving comparable results across feminine and masculine gender translation. However, for ambiguous cases where the input sentence does not inform about the gender form to be used in translation, we confirm a strong skew where all systems tend to generate masculine forms almost by default. Results on INES, instead, indicate that providing inclusive translations still represents a quite challenging task for current MT systems, in spite of the increasingly widespread use and preference for inclusive language forms in English.

As a final remark, we acknowledge that the phenomena subject to our analysis (gender bias and gender inclusion) are not yet part of the repertoire of phenomena for which MT systems are currently designed. These systems are indeed primarily built with the goal of maximising translation quality in general rather than aspects of the problem, specifically fairness, for which sensitivity is still limited. All in all, however, this experience has allowed us to shed light on these issues, raise the awareness of the MT community and, hopefully, favour future developments.

Limitations

Naturally, this work comes with some limitations. First, both test suites are limited in size and number of language pairs considered. Despite their restricted size, however, both test suites provide a first glimpse into understanding and monitoring systems' behaviour with respect to gender and inclusivity. Additionally, rather than a limitation per se, both INES and MuST-SHE^{WMT23} are designed based on the specific linguistic features of the source and target language taken into account. As such, results in our evaluations intentionally do not aspire to scale and generalize to any language direction. Indeed, such linguistic specificity is also openly accounted for in the introduction of the new Inclusivity Index metric, which considers the morphology of English for a better-suited evaluation of gender inclusivity in MT. We also note that such a metric results as the best one for evaluating inclusivity under the given experimental conditions of this paper, where all the scrutinized systems (those submitted to the WMT General Translation task) are expected to feature generally good overall translation quality and to make few translation errors. As such, future work might be needed to further validate the stability of the Inclusivity Index metric under less optimal conditions and for different target languages, possibly proposing tailored metrics for each case. Finally, to generate the initial pool of sentences in INES we relied on the GPT (gpt-3.5-turbo) closed-source model. This has holds two types of implications. On the one hand, the use of proprietary models such as GPT has reproducibility consequences, since this model is regularly updated, thus potentially yielding future results that differ from those reported in this paper. On the other hand, relying on – even though only partially and post-edited – artificially generated data for testing models, might lead to contamination issues. Indeed, in Sec. 3.2 (Table 6) the GPT4-5SHOT model resulted as the most promising one, achieving the best results for inclusive translation. However, it remains to further verified whether our specific experimental settings and INES benchmark – where we use GPT-derived test data – have advantaged the performance of GPT4-5SHOT.

Ethics Statement

By addressing bias and inclusivity in MT, this work presents an inherent ethical component. It builds from concerns toward the societal impact of widespread translation technologies that reflect and propagate male-grounded and exclusionary language. Still, our work is not without risks either and thus warrants some ethical considerations. In particular, MuST-SHE^{WMT23} only focuses on traditional binary feminine/masculine gender forms. Also, INES investigates neutral, inclusive language in the context of generic, unknown referents and based on inclusive solutions encouraged by institutional guidelines. As such, we do not account for other non-binary solutions (e.g., neopronouns and neomorphemes) that are emerging from grassroots efforts. It should be stressed that the gendered and inclusive strategies incorporated in this MT work are not prescriptively intended. Rather, they are orthogonal to other attempts and non-binary expressions for inclusive language (technologies) (Lauscher et al., 2023; Ginel and Theroine, 2022).

Acknowledgements

Abstract

We have explored the effect of in domain knowledge during parallel sentence filtering from in domain corpora. Models built with sentences mined from in domain corpora without domain knowledge performed poorly, whereas model performance improved by more than 2.3 BLEU points on average with further domain centric filtering. We have used Large Language Models for selecting similar and domain aligned sentences. Our experiments show the importance of inclusion of domain knowledge in sentence selection methodologies even if the initial comparable corpora are in domain.

1 Introduction

This paper describes FJWU's submission to the biomedical translation task. This year the focus of our research was domain specific parallel corpus mining from Wikipedia using Large Language Models, we explored the potential of the mined sentences using two sentence selection schemes. Neural Machine Translation (NMT) (Kalchbrenner and Blunsom, 2013; Sutskever et al., 2014; Bahdanau et al., 2015; Cho et al., 2014) has witnessed great success over the years (Vaswani et al., 2017; Zhang and Zong, 2020). NMT systems train on parallel corpora to produce translations that capture language intricacies and context with enormous precision as compared to the previous counterpart Statistical Machine Translation (SMT) systems.

Machine translation in the biomedical domain is becoming increasingly important due to the critical nature of medical scientific texts. The majority of these texts are published in English, and the goal of Biomedical Machine Translation is to make them accessible in multiple languages. However, this is a complex undertaking due to the extensive nature of this field and the vast and diverse vocabulary it encompasses. This vocabulary includes specialized terms and non-lexical forms (such as dates and biomedical entities) that pose unique challenges. Consequently, the quality of machine translation output fluctuates depending on the availability of biomedical resources tailored to each target language.

Availability of parallel corpora in reasonable amounts has greatly enhanced the performance of NMT systems, especially for the high-resource languages (Bojar et al., 2018). However, its efficacy remains sub optimal for low-resource languages and domain-specific contexts (Zoph et al., 2016; Koehn and Knowles, 2017; Lample et al., 2018; Chu and Wang, 2020). Performance of NMT system degrades as soon as the application domain deviates from training domain. Domain adaptation (Freitag and Al-Onaizan, 2016), transfer learning (Zoph et al., 2016; Khan et al., 2018; Abdul Rauf et al., 2020), model fusion (Gulcehre et al., 2015), back translation (Sennrich et al., 2015; Ul Haq et al., 2020), fine-tuning (Dakwale and Monz, 2017; Huck et al., 2018), data augmentation (Fadaee et al., 2017), data selective training (Van Der Wees et al., 2017; Knowles and Koehn, 2018), decoding strategies (Park et al., 2020), zero-shot translation (Johnson et al., 2017) are some of the techniques used to address this issue. We will be focusing on domain adaptation using data augmentation and fine tuning.

For this years submission we explore the potential of Large-scale Language Models for extracting parallel sentences from Wikipedia[1]. French-English parallel articles are scraped as detailed in Section 4. For learning sentence embeddings of scraped bilingual data, rather than training encoders from scratch, we leverage the potential of LLM in parallel sentence extraction from our bilingual scraped articles. We used LEALLA-Large, a lightweight system developed by (Mao and Nakagawa, 2023) to compute the language-agnostic low-dimensional sentence embeddings for each

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 263–270
December 6–7, 2023.

sentence in the English and French parallel articles. Potential parallel sentences are filtered based on the similarity scores. These sentence are then further domain filtered by comparing the closeness with Medline Titles embeddings computed using Transformers MiniLM. Our experiments show the importance of inclusion of domain knowledge in sentence selection methodologies even if the initial comparable corpora are in domain. Our main contributions include:

- Presenting a methodology for domain inclusion in sentence retrieval tasks by using capabilities of Large Language Models
- Highlighting the importance of inculcation of in domain knowledge in sentence retrieval tasks even when the data source is in domain
- Release of the mined parallel corpora to the research community[2]

The paper is structured as follows: Section 2 presents a brief overview of background and related work, Section 3,4 elaborates the data collection pipeline, Section 5 outline the NMT experiments and results, followed by the conclusion of this study.

2 Related Work

Recent work on parallel sentence extraction has focused on lightweight end-to-end word-level and sentence-level embedding methods (Guo et al., 2018; Artetxe and Schwenk, 2018; Yang et al., 2019a). These embedding-based approaches have gained success (Grégoire and Langlais, 2017; Bouamor and Sajjad, 2018; Schwenk, 2018) as these systems outperformed the large-distributed computationally intensive systems (Uszkoreit et al., 2010; Abdul-Rauf and Schwenk, 2009) used to mine parallel documents. Bilingual sentence embeddings, learned from dual-encoder models, have also been used effectively for parallel corpus mining (Guo et al., 2018). Cross-lingual embeddings encode bilingual texts into a single unified vector space allowing nearest-neighbor search can be used to find potential translation candidates. These embedding approaches produce noisy matches that require a re-scoring step in order to obtain a clean parallel sentence retrieval as addressed by (Yang et al., 2019a) who explored using a bi-directional dual encoder with additive margin softmax (Wang et al., 2018) which results in state-of-the-art performance for sentence filtering. Multilingual sentence embedding approaches (Artetxe and Schwenk, 2018; Chidambaram et al., 2018) also show promising results.

Since language-specific models often demand extensive amounts of labeled data for training and can be limited by their language-specific parameters, language-agnostic sentence embedding(Artetxe and Schwenk, 2019; Yang et al., 2019b; Reimers and Gurevych, 2020; Feng et al., 2020; Mao et al., 2022) align multiple languages in a shared embedding space, facilitating parallel sentence alignment that extracts parallel sentences for training translation systems. Among them, LaBSE (Feng et al., 2020) achieved state-of-the-art performance on various bi-text retrieval. The problem of inference speed and computation overhead of large language models was addressed by (Mao and Nakagawa, 2023) who proposed Learning Leight-Weight Language-agnostic Sentence Embeddings (LEALLA) with Knowledge Distillation (Kim and Rush, 2016). They reported significant reduction in computation overhead and inference speed by providing language-agnostic low-dimensional sentence embeddings. We also use LEALLA in the second phase of our pipeline for parallel sentence alignemnent.

3 Wikipedia as a potential resource for biomedical data

Our primary objective was to collect a comprehensive dataset from the biomedical domain, we explored Wikipedia's key biological categories and selected those having a substantial volume of articles. A brief overview of the selected subdomains is given below:

1. **Biodbs** [3] refers to biological databases and contains links of a variety of biological databases.
2. **Genome Reference Consortium** is an international collaboration dedicated to creating and maintaining the most accurate and up-to-date Human Genome [4] reference sequence.

[2] https://github.com/sabdul111/Biomedical-Parallel-Corpus

[3] https://en.wikipedia.org/wiki/List_of_biological_databases

[4] https://en.wikipedia.org/wiki/Human_genome

Table 1: Scraped Data per subdomain

3. **National Institute of Biomedical Imaging and Bio engineering** plays a central role in advancing biomedical engineering research and provides a wealth of data and resources in the domain of Health Biomedical Engineering [5].

4. **The National Center for Biotechnology Information (NCBI)** [6] is a U.S. government agency that provides an extensive collection of biomedical and genomic resources.

5. **PubMed** [7] is a widely used online database maintained by the National Library of Medicine (NLM) which provides access to a vast collection of biomedical literature.

4 Parallel Corpus Mining

This section presents an overview of our parallel data creation pipeline. Wikipedia has been extensively used as a data resource for corpus development (Chu et al., 2014; Tufiş et al., 2013; Stefanescu et al., 2012; Karimi et al., 2018; Aghaebrahimian, 2018; Schwenk et al., 2019). We also used Wikipedia's inter language links to mine potential parallel sentences by exploring the potential of Large language models for filtering the closet candidates. Our data preparation pipeline involves three main steps; 1) Domain specific web scraping, 2) Candidate sentence scoring and filtering and 3) Domain adapted filtering.

Parallel article scrapping To extract the bilingual data we used Wikipedia's **Interwiki**[8] (also known as inter language links) property (Adafre and De Rijke, 2006; Otero and López, 2010; Chu et al., 2014; Aghaebrahimian, 2018). English Wikipedia has consistently held the distinction of possessing the highest article count among all language editions of Wikipedia. As of August 2023, there are 6,696,071[9] articles in English containing over 4.3 billion words.

We maximized recall in our article selection procedure by choosing English as the base language since it provided wider coverage of topics. Thus, for each unique English article, the corresponding French article (if found) was scrapped. We named the scrapped articles using the title of the English version, distinguishing them with *.en* for English and *.fr* for French files. At this stage, we had to retrieve the parallel articles since many of the English articles did not have the corresponding French articles (see Table 1). For parallel article retrieval, we compiled a list of all French articles and used this list to retrieve parallel English articles which resulted in our parallel French-English articles. The subdomains (see section § 3) had many overlapping articles which were removed and unique articles from each subdomain were selected.
Table 1 shows the amount of URLs, articles, parallel articles and the corresponding unique articles. At this stage we have unique parallel articles from each subdomain.

Parallel sentence filtering We used a lightweight pre-trained large language model LEALLA-Large (Mao and Nakagawa, 2023) which computes sentence embedding of 256 dimensions by distilling knowledge from LaBSE (Feng et al., 2020). It can be used to mine potential parallel sentences by finding the nearest neighbour of each source sentence in the target side according to cosine similarity, and filtering those below a threshold.

Total	42,615	183,594	492,242

Table 3: Bio-Filtered: Parallel sentences from Table 2 selected based on their proximity with Medline titles using MiniLM.

LEALLA Embedding vector is computed for each sentence in the French and English article. Thus for each French(source) sentence we have N potential matching sentences, where N is the number of sentences in English(target) article. The dot-product is then used to compute the similarity between each source and N target candidate sentences. The top 10 candidate sentences are retrieved for each sentence. At this stage we have a sorted list of potential parallel sentences from each subdomain.

It is important to note that these are potential bio med domain sentences since these are mined from in-domain articles. We focus on both precision and recall at this stage. Our sentence retrieval is recall oriented, given that English articles were roughly double the French articles, thus using French sentence as prompt to retrieve the matching English sentences promised a wider search space. For final parallel corpus creations we selected the sentences on similarity threshold. We report three thresholds (thresholds 80, 85, and 90) to retrieve parallel sentences from the retrieved top-10 sentence pairs. We are working on lower threshold sentences. A higher threshold indicates a greater degree of parallelism between the sentences. Table 2 shows the number of parallel sentences retrieved using different thresholds for each subdomain. We call these *LLMfilter* sentences for reference.

In domain filtering We did a second level selection from the *LLMfilter* parallel sentences extracted in the previous step. Even though these sentences come from bio-medical articles and are in-domain but our hypothesis is that there will be many sentences that may categorize as general domain. Our second filter is to ensure collection of purely biomedical sentences. For this we select Medline titles (Jimeno Yepes et al., 2017) as biomedical representative dataset since titles contain the main domain terminologies. An embedding was generated for Medline Titles using sentence transformers `paraphrase-multilingual-MiniLM-L12-v2`[10] which was then used to remove the out-domain sentences, striving to retain an optimal amount of in-domain sentences (pertaining to the biomedical domain). Dot product of each sentence with the Medline titles embedding was used to compute the similarity score(ranging from -1 to 1). We selected thresholds 20, 10, and 0 which correspond to 0.2, 0.1, and 0.0 respectively in the similarity score. Table 3 shows the number of sentences per threshold, we call these *Biofilter* sentences for reference.

Post-processing involved the removal of exceptionally short sentences, special characters, and sentences in languages other than the intended source and target languages. Duplicated and identical sentences were also removed from both English and French sides.

5 Translation performance on retrieved sentences

We used Transformer base (Vaswani et al., 2017) architecture provided by Fairseq (Ott et al., 2019)

Table 4: BLEU scores on fine tuned datasets. B1 and B2 denote the baselines. B1 is trained on the biomedical texts provided by the WMT'23 organizers, while B2 is a big model trained on general domain and biomed data.

as `transformer_iwslt_en_de`. The ReLU activation function was used in all encoder and decoder layers. We optimize with Adam (Kingma and Ba, 2015), set up with a maximum learning rate of 0.0005 and an inverse square root decay schedule, as well as 4000 warmup updates.

All corpora were segmented into subword units using Sentence Piece (Kudo and Richardson, 2018) with a vocabulary of 32K units. We share the decoder input and output embedding matrices. Models are trained with mixed precision and a batch size of 4096 tokens on a single GPU. Systems were trained until convergence based on the BLEU score on the development sets. Evaluation was performed using SacreBleu (Post, 2018). Scores are chosen based on the best score on the development set (Medline 18, 19), and the corresponding scores for that checkpoint are reported on Medline 20 test set.

For fine-tuned systems, the process starts with models trained to convergence, based on BLEU score on dev sets. Training then resumes using a selected portion of the training corpus using the same parameters and criterion as for the base systems.

Baseline We trained a smaller model B1 on the biomedical texts provided by the WMT'23 organizers: Edp, Medline abstracts and titles (Jimeno Yepes et al., 2017), Scielo (Neves et al., 2016) and the Ufal Medical corpus[11] consisting of Cesta, Ecdc, Emea (OpenSubtitles), PatTR Medical and Subtitles. We used a bigger model B2 by (Xu et al., 2021) trained on WMT14 general domain corpus and WMT and supplementary biomed data including B1 data.

5.1 Results and Discussion

Table 4 presents the results using the two data selection methods. *LLMfilter* column shows the BLEU scores on Medline 20 testset for sentences filtered based on the sentence similarity score, whereas *Biofilter* are the sentences which were selected from the *LLMfilter* based on their closeness with the Biomedical Medline titles. Both filters used LLMs for computing similarity as detailed in section 4.

B1 represents a smaller baseline model trained on all biomed data provided by WMT organizers having a BLEU score of 19.52. This was further fine-tuned using each threshold dataset i.e. threshold 90, 85, and 80 (represented by t90, t85, and t80 respectively in 4), and finally with a concatenation of the 3 thresholds. Concatenation refers to the union of t90, t85, and t80. We did this to upsample the higher quality corpora (i.e. t90) to analyze the impact on MT. Evidently, none of the *LLMfilter* sentences improved the initial bio med baseline. The *Biofilter* sentences on the other hand helped improve the scores even when a small amount is added e.g. for t90 and the scores improved consistently with the increase in the number of sentences with SB4 yielding an increase of 1.59 BLEU points from the baseline. For the larger baseline B2, though none of the filtering schemes help improve the initial high score but still the supremacy of *Biofilter* sentences over *LLMfilter* is evident.

Arguably, both *LLMfilter* and *Biofilter* contain in-domain sentences as these have been selected from biomedical articles. The models built using the same thresholds for the two schemes have a difference of more than 2 BLEU points on average

with *Biofilter* systems being superior. Our results demonstrate the importance of inculcation of in-domain knowledge in sentence retrieval tasks even if the data source is in-domain as there are many sentences that do not pertain specifically to the domain and affect the results of domain-centered translation.

6 Conclusion

In this study, we explored the potential of large language models for parallel sentence extraction from domain-adapted bilingual corpus extracted from Wikipedia. On our dataset, we experimented with two data selection schemes and assessed the NMT performance for the biomedical domain. Our findings demonstrate that merely web-mining from in-domain corpus is not sufficient to improve domain-specific NMT performance but there is also a need for further filtering out out-domain sentences to improve the domain-specific NMT systems. Leveraging large language models to extract in-domain parallel sentences resulted in improved NMT performance by outperforming the baseline with 2 BLEU points.

Abstract

This paper presents the domain adaptation methods adopted by Huawei Translation Service Center (HW-TSC) to train the neural machine translation (NMT) system on the English↔German (en↔de) WMT23 biomedical translation task. Our NMT system is built on deep Transformer with larger parameter sizes. Based on the biomedical NMT system trained last year, we leverage Curriculum Learning, Data Diversification, Forward translation, Back translation, and Transductive Ensemble Learning to further improve system performance. Overall, we believe our submission can achieve highly competitive result in the official final evaluation.

1 Introduction

Machine translation (MT) (Lopez, 2008) refers to the automatic translation of text from one language to another. The WMT23 biomedical translation task aims to evaluate the performance of MT systems in the biomedical domain. Due to the lack of sufficient in-domain data, domain adaptation (Chu and Wang, 2018; Wu et al., 2023) has naturally become the main research direction of this task.

This paper presents the domain adaptation methods adopted by HW-TSC to train the NMT (Bahdanau et al., 2015) system on en↔de language pair of the WMT23 biomedical translation task. Our method is mainly based on previous works (Wei et al., 2022, 2021; Yang et al., 2021). We try to train a domain classifier to select biomedical data from general data, then perform multi-step data cleaning on the selected in-domain data and keep only a high-quality subset for training. Based on the biomedical NMT system trained last year, we leverage Curriculum Learning (Zhang et al., 2019), Data Diversification (Nguyen et al., 2020), Forward Translation (Abdulmumin, 2021), Back Translation (Sennrich et al., 2016), and Transductive Ensemble Learning (Wang et al., 2020b) to further improve system performance.

Our system report includes four parts. Section 2 focuses on our data processing strategies while section 3 describes our training details. Section 4 explains our experiment settings and training processes, and section 5 presents the results.

2 Data

2.1 Data Volume

We obtain bilingual and monolingual data from various data sources, except medical database. Then, we use biomedical data and general data to train a domain classifier based on fasttext (Joulin et al., 2016) to select biomedical data from general data. Table 1 lists the final size of the training data.

language pairs	bitext data	monolingual data
en↔de	11.6M	en: 12.3M, de: 10.1M

Table 1: Bilingual and monolingual used for training.

2.2 Data Pre-processing

Our data processing procedure is basically the same as our method last year (Wu et al., 2022), including deduplication, XML content processing, langid (Lui and Baldwin, 2012) and fast-align (Dyer et al., 2013) filtering strategies, etc. As we use the same data pre-processing strategy as last year's, we will not go into details here.

2.3 Data Denoising

Since there may be some semantically dissimilar sentence pairs in bilingual data, we use LaBSE (Feng et al., 2022) to calculate the semantic similarity of each bilingual sentence pair, and exclude bilingual sentence pairs with a similarity score lower than 0.7 from the training corpus.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 271–274
December 6–7, 2023.

3 System Overview

3.1 Model

We continue using Transformer (Vaswani et al., 2017) as our neural machine translation (NMT) model architecture. As we did last year, we use a 25-6 deep model architecture. The parameters of the model are the same as Transformer-big. We just change the post-layer normalization to the pre-layer normalization, and set encoder layers to 25.

3.2 Curriculum Learning

A practical curriculum learning (CL) (Zhang et al., 2019) method should address two main questions: how to rank the training examples, and how to modify the sampling procedure based on this ranking. For ranking, we choose to estimate the difficulty of training samples according to their domain feature (Wang et al., 2020a). The calculation formula of domain feature is as follows, where θ_{in} represents an in-domain NMT model, and θ_{out} represents an out-of-domain NMT model.

$$q(x, y) = \frac{\log P(y|x; \theta_{in}) - \log P(y|x; \theta_{out})}{|y|} \quad (1)$$

For sampling, we adopt a probabilistic CL strategy[1] that takes advantage of the spirit of CL in a nondeterministic fashion without discarding the good practice of original standard training, like bucketing and mini-batching.

3.3 Data Diversification

Data Diversification (DD) (Nguyen et al., 2020) is a data augmentation method to boost NMT performance. It diversifies the training data by using the predictions of multiple forward and backward models and then merging them with the original dataset on which the final NMT model is trained. DD is applicable to all NMT models. It does not require extra monolingual data, nor does it add more computations or parameters. To conserve training resources, we only use one forward model and one backward model when performing DD.

3.4 Forward Translation

Forward translation (FT) (Abdulmumin, 2021), also known as self-training, is one of the most commonly used data augmentation methods. FT has proven effective for improving NMT performance by augmenting model training with synthetic parallel data. Generally, FT is performed in three steps: (1) randomly sample a subset from the large-scale source-side monolingual data; (2) use a "teacher" NMT model to translate the subset data into the target language to construct the synthetic parallel data; (3) combine the synthetic and authentic parallel data to train a "student" NMT model.

3.5 Back Translation

An effective method to improve NMT with target monolingual data is back translation (BT) (Sennrich et al., 2016; Wei et al., 2023). There are many works broaden the understanding of BT and investigates a number of methods to generate synthetic source sentences. Edunov et al. (2018) find that back translations obtained via sampling or noised beam outputs are more effective than back translations generated by beam or greedy search in most scenarios. Caswell et al. (2019) show that the main role of such noised beam outputs is not to diversify the source side, but simply to tell the model that the given source is synthetic. Therefore, they propose a simpler alternative strategy: Tagged BT. This method uses an extra token to mark back translated source sentences, which generally outperforms noised BT. For better joint use with FT, we use sampling back translation (ST).

3.6 Transductive Ensemble Learning

Ensemble learning (Garmash and Monz, 2016), which aggregates multiple diverse models for inference, is a common practice to improve the performance of machine learning models. However, it has been observed that the conventional ensemble methods only bring marginal improvement for NMT when individual models are strong or there are a large number of individual models. Transductive Ensemble Learning (TEL) (Zhang et al., 2019) studies how to effectively aggregate multiple NMT models under the transductive setting where the source sentences of the test set are known. TEL uses all individual models to translate the source test set into the target language space and then fine-tune a strong model on the translated synthetic data, which significantly boosts strong individual models and benefits a lot from more individual models.

[1] https://github.com/kevinduh/sockeye-recipes/tree/master/egs/curriculum

4 Experiment Settings

We use the open-source fairseq (Ott et al., 2019) for training, then we use SacreBLEU (Post, 2018) and multi-eval tool [2] to measure system performances. The main parameters are as follows: each model is trained using 8 A100 GPUs, batch size is 6144, parameter update frequency is 1, and learning rate is 5e-4. The number of warmup steps is 4000, and model is saved every 1000 steps. The architecture we used is described in section 3.1. We adopt dropout (Srivastava et al., 2014), and the rate varies across different training phases. When the training data is higher than tens of millions, the dropout ratio is set to 0.1, otherwise it is set to 0.3.

5 Results

Regarding en↔de, we use Curriculum Learning (CL), Data Diversification (DD), Forward Translation (ft), Back Translation (BT), and Transductive Ensemble Learning (TEL). The evaluation results of en→de and de→en NMT system on WMT22 biomedical test set are shown in Tables 2.

We see that CL can stably bring 3 SacreBLEU and multi-eval improvement, while DD, FT & ST and TEL can further slightly improve SacreBLEU and multi-eval. Our final en→de and de→en submissions achieve 40.48 and 48.75 SacreBLEU, 41.22 and 49.91 multi-eval respectively.

	en→de		de→en	
	SacreBLEU	multi-eval	SacreBLEU	multi-eval
last year's baseline	37.11	37.80	44.45	45.50
+ CL	40.11	40.89	47.77	48.89
+ DD, FT & ST	40.23	41.00	48.60	49.76
+ TEL	**40.48**	**41.22**	**48.75**	**49.91**

Table 2: BLEU scores of en→de and de→en NMT system on WMT22 biomedical test set.

6 Conclusion

This paper presents the submission of HW-TSC to the WMT23 biomedical translation task. We participate in en↔de language pair and perform a series of domain adaptation experiments based on the biomedical NMT system trained last year. The effectiveness of each domain adaptation method is demonstrated. Our experiments show that domain adaptation methods are effective for model training.

Abstract

In the context of this biomedical shared task, we have implemented data filters to enhance the selection of relevant training data for fine-tuning from the available training data sources. Specifically, we have employed textometric analysis to detect repetitive segments within the test set, which we have then used for refining the training data used to fine-tune the mBart-50 baseline model. Through this approach, we aim to achieve several objectives: developing a practical fine-tuning strategy for training biomedical in-domain fr<>en models, defining criteria for filtering in-domain training data, and comparing model predictions, fine-tuning data in accordance with the test set to gain a deeper insight into the functioning of Neural Machine Translation (NMT) systems.

1 Introduction

The objective of our contribution to the biomedical shared task this year is to gain deeper insights into the NMT training pipeline, assess the factors influencing performance, and evaluate the robustness of the training system.

Our training strategy was to build tailor-made fine-tuning data with regard to the test data. We calculated repeated segments (Salem, 1986) in the test data and used a selection of them to extract the corresponding data set from the available training data (as outlined in Section 2.1.1). In order to highlight the "reproducibility", we consistently adhered to the same pipeline with minimum settings presented in Section 2.

While our experience encountered various technical obstacles that likely affected our system's performance, these challenges prompted us to prioritize explainability and comparability. This became especially important when the system produced irrelevant results and hallucinations. We elaborated on this in Sections 3 and 4. The remaining sections of the paper are organized as follows: Section 2 outlines our filtering pipeline, Section 3 delves into our results, and Section 4 provides a discussion of these results. Section 5 explores related research and outlines future work.

2 Optimizing Fine-Tuning Data Selection and Pipeline

For this shared task, we exclusively fine-tuned the "mBart-50 large" baseline model (Tang et al., 2020) over 3-epoch, 5-epoch, and 10-epoch training cycles. Our approach prioritized reproducibility and involved a clear distinction between a "horizontal" dimension (facilitating inter-system analysis, especially in comparison with e-translation[1]) and a "vertical" dimension (examining differences in training strategies within the same system). The fine-tuned setting was established with the following parameters set as a minimum: "num_train_epochs", "train_file", "validation_file", "test_file", "per_device_train_batch_size"[2].

2.1 Raw Training Data

As recommended by the WMT biomedical shared task, we employed the corpora listed in Table 1. The entire corpus, intended for fine-tuning, comprises over 90M words in English and more than 100M in French. It is from these corpora that we extracted the filtered aligned sentences in both source and target languages.

2.1.1 Segmental Proximity Analysis for Training Data Filtering

Our training data filtering strategy is rooted in the theoretical principles of segmental proximity analysis. Repeated segments are sequences that are automatically identified as being repeated within

[1]https://commission.europa.eu/resources-partners/etranslation_fr

[2]Because of hardware constraints, we had to significantly reduce the batch dimension to 4

the same text or across different texts.[4]

The computation of repeated segments (Salem, 1986) is a useful tool in corpus analysis. The computed inventory of repeated segments is of undeniable interest for discourse analysis (Sousa, 2014; Gledhill et al., 2017). This tool facilitates the examination of various discourse phenomena, encompassing the circulation of formulaic expressions, discourse routines, lexico-grammatical patterns, and more. On a cognitive level, the analysis of repeated segments can offer a substantial contribution to the study of knowledge pattern dissemination in specialized discourse. For these reasons, the computation of repeated segments holds substantial value in text profiling, especially in the context of training data selection. Our working hypothesis posits that discerning semantic proximity within a vast dataset can be accomplished through a deliberate selection of repeated segments guided by specific formal criteria, including factors such as frequency and segment length. The method relies on the assumption that related texts share common discourse properties, including phraseology, terminology, and structural patterns. These elements can be effectively "captured" through repeated segments computation and unveiled through segmental proximity analysis (Salem, 1986; Lebart et al., 1997).

The concept of segmental proximity has been thoroughly explored in the work of (Salem, 2006), where the statistical properties of this phenomenon were demonstrated. In this study, Salem (*ibid.*:1) *"considers measures of similarity based on the computation of the frequencies of identical sequences of words among the texts to be compared"*.

In order to identify common sequences within the two sections of a comparable monolingual corpus, it was first necessary to compile a list of segments containing a minimum of four words that were repeated in both parts of the corpus. All segments found exclusively in one part of the corpus were removed from consideration. The sequences that remained were then selected based on their length and their presence in each of the comparable parts of the corpus. By prioritizing relatively longer sequences, we were able to exclude many shorter and more frequent sequences, many of which consisted of common combinations of function words such as "of the" or "by means of."

According to the findings presented in Salem (Salem, 2006), the analysis of lexical distances and proximity indices computed on individual forms (such as the Jaccard index and Chi-square distance) did not reveal any significant affinity between the two sections of the comparable corpus under study. However, when calculations were based on the identification of repeated segments, it became evident that the two parts shared a relatively high number of extended sequences. This methodology enables the study of a range of phenomena related to the circulation of textual units that surpass individual vocabulary items.

Following this line of research, we compiled a systematic inventory of all repeated segments with a length of at least four words, such "acute respiratory syndrome coronavirus", "followed by maintenance therapy", etc. in each test set (English and French), which consisted of texts provided by WMT. We used *iTrameur* (https://itrameur.clillac-arp.univ-paris-diderot.fr) to facilitate this process. We then selected repeated segments with a total frequency of 10 or more. This curated inventory was used for the profiling and filtering of available medical text datasets (training data). We then selected repeated segments having a total frequency

[4]Consortium HN CORpus, Langues et Interactions - Huma-Num: https://corli.huma-num.fr/en/glossaire/repeated-segments/

of 10 or more and used this inventory for profiling and filtering of available medical text sets (training data). This process allowed us to build a dataset that shared common discourse properties and demonstrated semantic similarity with the test set.

2.2 Extraction of Aligned Sentences Containing Filtered Segments

By employing a list of repeated 4-word segments, we implemented a procedure to extract aligned sentences containing these filtered segments (Algorithm 1). To achieve this, we concatenated every delimiter (D) one by one (,;"~ &|#@='-.?!%*$()[]_:+«»§/) of *iTrameur*[5] and every word (g) of each 4-word repeated segment (G) of source language (S, which can be either English or French) to form a regular expression-like pattern GD. We used this pattern to match aligned sentences that contain the segment in both source (S_n, n is the index of matched sentence in raw training corpus of source language) and target (T_n) languages. The extraction result is reported in Table2. The extracted sentences are used to fine-tune the baseline model of mBart50.

Data: segment G, delimiter D and aligned sentences S and T
Result: aligned sentences S_n and T_n containing G

```
for g in G do
    GD ← concatenate(g,D)
    if GD in S_n then
        extract T_n
    end
end
```

Algorithm 1: Filtering and extraction algorithm

3 Results

In the absence of formal evaluation scores, our approach was largely based on textometric browsing techniques (Zimina, 2005) and qualitative analysis of our submitted translations. These translations were produced using a 3-epoch and 5-epoch training for the en-fr corpus, and a 3-epoch training for the fr-en corpus.

For example, Figure 1 shows a parallel section map generated by *iTrameur*, which helps visualize the alignment of parallel sections from two fr-en translations generated by mBart-50 baseline and mBart-50 5-epoch. The map highlights the presence or absence of the token "violence" in both translations. In the contexts displayed below the map, occurrences of repeated segments are underlined. We employ this tool to compare the translation outputs of various systems.

en-fr	Number	Frequency
train set (en)	60	482.144.115
test data (en)	41	98
fr-en	Number	Frequency
train set (fr)	70	176.229.164
test data (fr)	41	109

Table 3: The occurrence of 4-word sequences used for training in the train set corpus and test data (en, fr)

Texts in French	Number	Frequency
mBart50 (3-epoch)	2	9
mBart50 (5-epoch)	2	4
Texts in English	Number	Frequency
mBart50 (3-epoch)	0	0

Table 4: The presence of 4-word sequences (en, fr) in translations generated by our systems

In accordance with our training strategy, which is based on segmental proximity analysis (as described in Section 2.1.1), we expected the test data and the test set to have a substantial number of long sequences in common, assuming that many of the long sequences used for training would be shared. To confirm this, we examined the presence of the 136 four-word sequences (repeated segments) used in training within the test data. The results align with our research strategy, as shown in Table 3): 68% (41 sequences) of the English sequences are found in the en-fr test data and 59% (41 sequences) of the French sequences are present in the fr-en test data.

Continuing along this line of investigation, we examined our submitted translations, yet the analysis revealed that our translated texts had very little overlap with the repeated segments employed in training, as demonstrated in Table 4.

In the following paragraphs, we narrow our focus to two sequences taken from the repeated segments used for training. These examples help illustrate the challenges encountered by our systems and highlight the complexities involved in drawing

[5] https://itrameur.clillac-arp.univ-paris-diderot.fr

Figure 1: Parallel section map generated by *iTrameur*.

significant conclusions from a qualitative analysis of our translations.

With 13 occurrences in the fr-en test data, the sequence *"violence envers les femmes"* presents an intriguing case of terminology. A closer examination of the raw training corpus reveals that several other expressions are commonly employed in French to express the same concept, such as *"violence faite aux femmes"* and *"violence contre les femmes"*, among others. In English, we note a reduced degree of variation, primarily using "violence against women" and, to a lesser extent, "violence directed against women", which is not as prevalent as the former. According to the European Institute for Gender Equality (EIGE), an EU agency, the most accurate translation is "violence against women".[6]. However, in the translations generated by the 3-epoch training, this accurate translation is absent, and the proposed translations ("the women's domestic violence" and "gender-based violence") do not correspond to the same concepts. The medical term "blood flow" appears 10 times in the en-fr test data and is part of one of the repeated segments used for training, specifically "blood flow in dogs." It is also a frequent component in complex noun phrases, including "the dermal blood flow," "regional blood flow," or "auricular dermal blood flow" (with 8 occurrences). Both the 3-epoch and 5-epoch systems encounter challenges when translating this repeated segment and the complex noun phrases. Firstly, there's a high degree of terminological variation in the French texts (*"écoulement sanguin"*, *"débit sanguin"*, *"flux sanguin"*, *"circulation sanguine"*), given the limited occurrences of the term in English. Additionally, we observe instances of hallucinations and incomplete outputs in the 3-epoch system. The 5-epoch system, on the other hand, omits one element in the translation of the complex noun phrase, even though the 3-epoch system accurately translated it.

In a specific case, "regional blood flow," the 5-epoch system incorrectly deduced the semantic relationship between the head and a modifier, yielding "*l'écoulement régional du sang*" instead of the correct "*l'écoulement sanguin régional*", which the 3-epoch system produced.

4 Discussion

4.1 Errors and Inconsistencies Arising From Variations in the Train Set

In general, the output exhibits numerous errors and inconsistencies primarily arising from terminological variations within the train set and the inherent

[6] https://eige.europa.eu/publications-resources/thesaurus/terms

heterogeneity of the selected training data. For instance, the terms "gender-based violence" and "violence against women" are both employed in comparable contexts within the train set, as illustrated by segments like "Many women who experience gender-based violence may never seek any formal help..." and "Violence against women is a global phenomenon" (source: PubMed abstracts, train set: en).

4.2 Hallucinations with mBart-50

Analyzing the translations generated by mBart-50 at different epochs (5 and 10) proves to be an interesting area of research. According to Lee et al. (2018), hallucinations occur when the model produces significantly different and inadequate outputs when the source is subjected to specific noise models. Therefore, we can suggest that there may be instances where the model ceases to translate the source text and instead generates an output composed solely of a continuous sequence of tokens from the present invention. This could be seen as an alternative form of hallucination in epoch 10. Moreover, in epoch 10, there are also examples of incomplete translations produced by the system. Based on our analysis, we observed that these errors tend to be resolved during the training process. Consequently, in mBart-50 (5-epoch) fr-en, there are no "X" tokens present, in contrast to the baseline model translation. This result is highlighted by the calculation of generalized co-occurrence networks conducted using *iTrameur*. Figures 2 and 3 depict co-occurrence networks that represent the most characteristic lexical attractions in the fr-en translations produced by two models: mBart-50 baseline and mBart-50 5-epoch. The numbers on the edges represent the strength of lexical attraction: *Specificity Index* > *9* (Co-frequency > 1).[7] Co-occurrence networks serve as a monitoring tool for tracking changes across various training stages.

5 Related Research and Future Work

Corpus filtering is discussed in many previous and recent works for training data preparation with different approaches : perplexity threshold of text segments(Moore and Lewis, 2010), metric evaluations of raw NMT models' outputs (Duh et al., 2013), acceptability of filtering evaluated by mulitlingual BERT classifier(Zhang et al., 2020), etc. Our approach aims at data relevance between a given test set and in-domain training data.

5.1 Robustness of NMT Models

An essential aspect to consider is that the system generates tokens regardless of whether it possesses the relevant information for translation. However, this raises the need for potential trigger warnings in situations where the system lacks adequate data for accurate translation. This suggests an avenue for developing a confidence index that reflects the system's efforts when generating output. We consider to explore various parameters based on sentence level and on a token level to build such a confidence index, e.g. the scores used by certain large language models to assess the confidence of each token's projection or beam search and the number of competitors for each token to gauge the complexity of a text for translation.
Another aspect to consider is the model's over/underfitting. By plotting our training and test data features in Figure 4, we find out that the model is indeed overfitted from depth 4. That explains partially why the model under-performed and helps us to choose a better data fitting strategy in the future.

5.2 Fine-tuning of mBart-50 and Other Multilingual Systems

For the moment, we only tried to fine-tune mBart-50 as a multilingual large language model, whereas other systems have been developed since, some of them with many more parameters. We may try to replicate or fine-tune experiments with more classical systems such as SYSTRAN Model Studio Advanced (https://u-paris.fr/plateforme-paptan), but also other different multi-lingual large language models such as mT5 (Xue et al., 2020) or Bloom (Scao et al., 2022), a 176-billion parameter language model, in spite of its carbon footprint (at least 24.7 tons of carbon just for the dynamic power consumption) (Luccioni et al., 2022).

Finally, it is worth noting that our fine-tuning efforts were primarily centered around mBart-50, a multilingual large language model. However, since our experiments, various other systems have emerged, some with significantly more parameters. It might be advantageous for us to replicate or fine-tune experiments with more conventional systems based on translation models, such as the SYSTRAN Model Studio Advanced (available at Université Paris Cité: https://u-paris.fr/plateforme-paptan), and explore different multilingual large

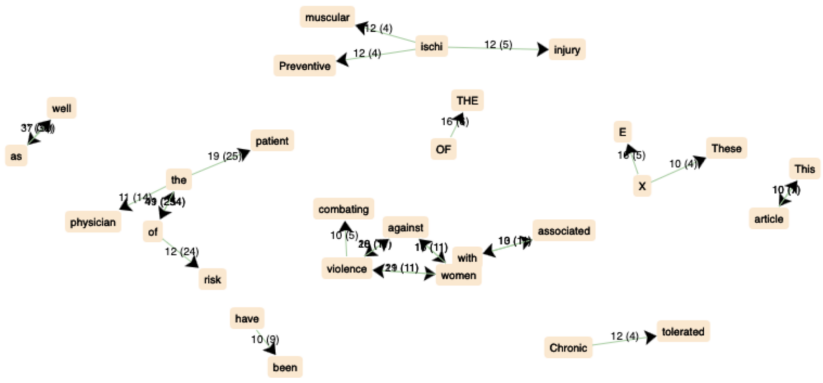

Figure 2: Co-occurrence networks for the baseline.

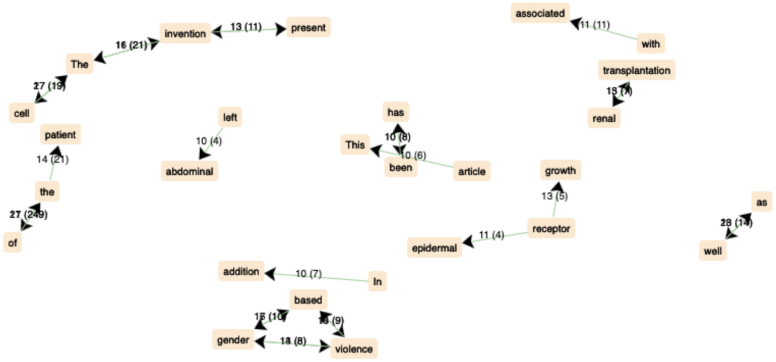

Figure 3: Co-occurrence networks for the 5-epoch system.

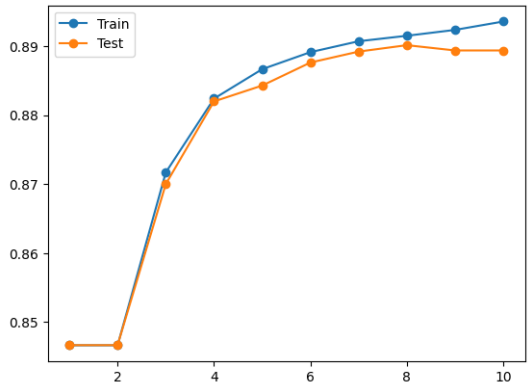

Figure 4: Model's accuracy prediction by training and test data features classification

language models like mT5 (Xue et al., 2020) or Bloom (Scao et al., 2022). Notably, Bloom is a huge 176-billion-parameter language model of major interest, despite its substantial carbon footprint, which amounts to at least 24.7 tons of carbon emissions solely for dynamic power consumption (Luccioni et al., 2022).

6 Conclusion

In this paper, we have described the translation systems used for the submissions in the WMT23 biomedical task6 (our data are available at: https://github.com/lichaozhu/WMT23). Nevertheless, due to certain hardware constraints, we were unable to pinpoint the exact reasons for the model's underperformance.

We also considered our previous participation in the biomedical task. Since 2021, we have recognized that having scores provided in advance and reference texts used for score computation can significantly facilitate our work. These resources enable a more critical evaluation of the translations we generate.

To address the absence of reference translations and evaluation results, translations can undergo

spot checks. In our work, these checks involved the use of qualitative examples to assess the model's successes and failures. Additionally, textometric browsing helped to unveil distinctive features within multiple machine translation outputs.

xuezhema@isi.edu

Abstract

This paper describes MaxLab - Information Sciences Institute (MAX-ISI) Translation systems for the WMT23 shared task. We participated in the discourse-level literary translation task - constrained track. In our methodology, we conduct a comparative analysis between the conventional Transformer model and the recently introduced MEGA model, which exhibits enhanced capabilities in modeling long-range sequences compared to the traditional Transformers. To explore whether language models can more effectively harness document-level context using paragraph-level data, we took the approach of aggregating sentences into paragraphs from the original literary dataset provided by the organizers. This paragraph-level data was utilized in both the Transformer and MEGA models. To ensure a fair comparison across all systems, we employed a sentence-alignment strategy to reverse our translation results from the paragraph-level back to the sentence-level alignment. Finally, our evaluation process encompasses sentence-level metrics such as BLEU, as well as two document-level metrics: d-BLEU and BlonDe.

1 Introduction

This paper introduces our submissions to the WMT23 Shared Task: Discourse-Level Literary Translation (Zh-En), Constrained Track. Our submission comprises three translation systems: a primary system employing a paragraph-level transformer, a first contrastive system utilizing a sentence-level transformer, and a paragraph-level Mega model as the second contrastive system.

Until very recently, the predominant focus of context-aware Neural Machine Translation (NMT) research has been on parallel datasets that align at the sentence level, such as IWSLT17 (Cettolo et al., 2017) and OPUS (Tiedemann, 2012). More recent research endeavors have concentrated on literary translation, which is typically more intricate and requires the models to be able to capture long-range context for high-quality translations. For example, Thai et al. (2022) introduced the first multilingual paragraph-aligned dataset PAR3, sourced from public-domain non-English literary works.

We use Transformer as the baseline model. In order to assess whether a more advanced model can excel in modeling long-range sequences using literary data, which contains richer contextual information, we also include the MEGA (Ma et al., 2023) model for comparison. The foundational model architectures we employ are introduced in Section 2.

In Section 3, we provide an extensive explanation of our systems. Within this section, Section 3.1 outlines the data pre-processing step. In this phase, we construct both sentence-level data, which comprises the filtered original data, as well as paragraph-level data. It's worth noting that aligning sentences in literary translation is not always feasible due to the possibility of sentence merging or truncation during the translation process. At the paragraph level, language models can adeptly exploit document-level context, resulting in a reduction of translation errors at the discourse level, as corroborated by human evaluations (Karpinska and Iyyer, 2023). Building on these encouraging findings, we created a dataset aligned at the paragraph level by aggregating multiple sentences from the provided literary dataset. Then, we propose three systems and evaluate those systems with both sentence-level and document-level metrics.

Section 4 presents the results that culminate in our final submissions. Additionally, we discussed challenges we encountered regarding discourse-level translation in Section 5.

*Equal contribution.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 282–286
December 6–7, 2023.

2 Model Architectures

We select the following two model architectures for our systems, taking into account their strong performance in the context of context-aware machine translation.

Transformer The Transformer architecture, as introduced by Vaswani et al. (2017), utilizes an encoder-decoder framework, leveraging a self-attention mechanism. This mechanism enables each position within a given sequence to interact with every other position, facilitating the computation of a comprehensive representation for the entire sequence.

In all our experiments, we employ the Transformer `base` version which consists of 6 encoder layers, 6 decoder layers, a model dimension of 512, and a FFN hidden dimension of 2048.

MEGA The recently unveiled MEGA (Moving Average Equipped Gated Attention) (Ma et al., 2023), addresses two longstanding limitations of the conventional Transformer model, which have impeded its performance on tasks involving long sequences. These limitations pertain to a weak inductive bias and a quadratic computational complexity.

MEGA employs a multi-dimensional, damped exponential moving average (Hunter, 1986) (EMA) in conjunction with a single-head gated attention mechanism to preserve inductive biases. Importantly, MEGA can replace the attention mechanism within the Transformer framework. Additionally, MEGA is of comparable size to the Transformer.

In total, the Transformer architecture is around 75M parameters; the MEGA architecture is around 77M parameters.

3 System Overview

3.1 Data Preprocessing

We first perform the following filtering steps on the training data:

- Remove translators' notes.
- Merge dialogues with tags "#<#" and "#>#" into one instance.
- Combine blank lines with their following line.

We construct sent-level and paragraph-level datasets separately.

Sentence-level dataset is constructed using the sentence alignment information, which is thoughtfully provided.

Paragraph-level dataset Considering the critical role played by context, particularly in literary translation, we further construct a paragraph-aligned corpus. This corpus is established based on the sentence alignment, allowing us to leverage context more effectively in our translations.

Data for each language pair is then encoded and vectorized with byte-pair encoding (Sennrich et al., 2016) using the `SentencePiece` (Kudo and Richardson, 2018) framework. We use separate vocabularies of size 32K for each language Zh and En.

Full corpus statistics are in Table 1.

Subset	Sent-level	Paragraph-level
Train	1742150	290315
Valid1	711	154
Valid2	810	148

Table 1: Instance counts across train and valid subsets.

3.2 System Architectures

Transformer-256 Our primary system employs a `Transformer-base` model at the paragraph level. Prior to tokenization, we structured the data into paragraphs, each with a maximum length of 256 characters on the source side (Zh). The model is subsequently trained and utilized for decoding on the paragraph-aligned corpus mentioned above.

Transformer-Sent In contrast, we conduct training for the transformer-base model using the sentence-level corpus.

MEGA-256 We adopted our proposed paragraph-aligned data as it demonstrates competitive efficacy in comparison to conventional Transformers across established benchmarks, including the LRA dataset, all while maintaining a significantly leaner parameter configuration.

3.3 Training

We train all models on the `fairseq` framework (Ott et al., 2019). All models were trained on 4 NVIDIA A40 GPUs. Following Vaswani et al. (2017); Fernandes et al. (2021), we use the Adam optimizer with $\beta_1 = 0.9$ and $\beta_2 = 0.98$, a linear decay learning rate scheduler with an initial value of 10^{-4},

System	Subset	BLEU	d-BLEU	BlonDe				
				all	pron.	entity	tense	d.m.
Transformer-Sent	VALID1	**26.40**	**26.40**	37.87	74.40	36.95	69.98	67.22
	VALID2	**16.40**	16.10	29.89	67.34	**49.05**	70.76	52.78
Transformer-256	VALID1	21.90	26.20	**40.92**	**84.17**	**40.47**	**78.72**	**72.71**
	VALID2	13.60	**16.30**	**33.50**	**79.72**	46.44	**81.57**	**68.80**
MEGA-Sent	VALID1	25.00	25.00	37.03	73.55	36.32	68.81	66.55
	VALID2	16.20	15.80	29.54	67.18	47.30	69.95	54.21

	VALID2	13.20	15.80	32.90	77.37	48.17	81.13	66.80

Table 2: Automatic metric results on the valid1 and valid2 sets. All reported BlonDe scores are F1s; pron. stands for pronoun, d.m. stands for discourse marker.

System	Sent-Level				Doc-Level	Human Annotator
	BLEU	chrF	COMET	TER	d-BLEU	Average
Transformer-256	34.1	53.3	78.24	**62.4**	**45.1**	73.59
Transformer-Sent	**34.5**	**54.7**	**79.14**	62.7	44.9	✗
MEGA-256	33.1	52.4	77.84	63.6	44.4	✗

Table 3: Automatic metric results of our submissions on the test set and the average score by different annotators on one sampled document. (Wang et al., 2023).

and increasing to $5e^{-4}$ during a warm-up phase of 4000, and a dropout of 0.2. We run inference on the validation set and save the checkpoint with the best BLEU score.

3.4 Post-processing

Since the final submission requires that each line must be aligned with the corresponding input line in the output files, we add this post-processing step to reverse our paragraph-level translation result to sentence-level alignment. We will discuss this further in the conclusion part.

Sentence-Alignment

1. Use the translated results at the sentence level as a reference

2. Calculated the similarity between each sentence in the translated paragraph and the *M* nearest sentences in the sentence-level translation

3. Align each sentence to the most similar one using Jaccard similarity on N-gram overlap as the similarity metric

3.5 Evaluation

To evaluate the discourse-level translation ability of three systems, we compute three metrics:

BLEU (Papineni et al., 2002) sentence-level BLEU is the most commonly used metric to evaluate the quality of machine-generated translations. We report the standard BLEU score calculated using `sacreBLEU` (Post, 2018)[1] in our systems.

d-BLEU (Liu et al., 2020) document-level sacreBLEU is computed by matching n-grams in the whole document. Note that all evaluations are case-sensitive

BlonDe (Jiang et al., 2022) is introduced as a document-level automatic metric that calculates the similarity-based F1 measure of discourse-related spans across four categories (*pronoun, entity, tense and discourse marker*).

4 Results

The results of our experiments are presented in Table 2. We evaluate our models on the provided two validation sets and list model performances

[1]The sacreBLEU signature is BLEU+case.mixed+lang.src-tgt+numrefs.1+smooth.exp+{test-set}+tok.13a.

on three automatic metrics, i.e., BLEU, d-BLEU, and BlonDe. Given that BLEU scores compare n-grams on a sentence-level basis, we extend our evaluation to encompass d-BLEU and BlonDe metrics, providing a comprehensive assessment of the models' proficiency in discourse-level translation. The results of the test set are presented in Table 3.

Transformer *vs.* MEGA As per the outcomes presented in Table 2, Transformer models slightly surpass MEGA models in both sentence-level and paragraph-level translations. While MEGA demonstrates superior capabilities in long-range sequence modeling, its limited enhancement may be attributed to the fact that current data are not lengthy and doesn't capture sufficient useful context (Jin et al., 2023). Furthermore, the discrepancy in BLEU scores is more pronounced than the variation in BlonDe scores.

Sent-level *vs.* Paragraph-level Based on the results presented in Table 2, there is a discrepancy between BLEU and BlonDe evaluations. Specifically, it is observed that sentence-level translation exhibits a better performance in terms of the BLEU metric, whereas paragraph-level models demonstrate a substantial improvement when assessed using the BlonDe metric.

As delving into the four distinct categories in BlonDe, a consistent trend of enhancement emerges across each category with the adoption of paragraph-level translation. Particularly, marked improvements are observed within the pronoun and tense categories. This can be attributed to the inherent reliance of pronouns and tenses on contextual information. These empirical results demonstrate that paragraph-level data provides more useful contextual signals than sentence-level data.

5 Discussion

Limitation of sentence alignment Literary texts often rely on context that spans beyond individual sentences, making strict sentence alignment impractical. As evidenced in our results, paragraph-level translation excels in preserving contextual information, like pronouns and tenses. However, the insistence on maintaining sentence-level alignment imposes constraints on model selection, hindering flexibility and adaptability.

Limitation of evaluation metrics The current evaluation metrics are not capable enough of measuring document-level machine translation. The most commonly used metric, BLEU, and its variant, d-BLEU, may struggle to fully capture the context awareness and coherence that is crucial at the document level translation.

6 Conclusion

This paper describes the submission to the WMT23 literary translation shared task - constrained track. We compare traditional Transformer models to the newer MEGA model, integrating paragraph-level data into both. Transformer models outperform MEGA in both sentence and paragraph translation on this literary dataset. We observe a discrepancy between BLEU and BlonDe evaluations, with the latter favoring paragraph-level translation. These results emphasize the challenges of document-level translation and the importance of more context-aware evaluation metrics.

Abstract

This paper describes the MAKE-NMT-Viz's submission to the WMT 2023 Literary task. As a primary submission, we fine-tune the mBART50 model using Train, Valid1, and Test1 as part of the GuoFeng corpus (Wang et al., 2023b).We followed similar training parameters to (Lee et al., 2022) when fine-tuning mBART50. For our contrastive1 submission, we used a context-aware NMT system based on the concatenation method (Lupo et al., 2022). The training was performed in two steps: (i) a traditional sentence-level transformer (Vaswani et al., 2017) was trained for 10 epochs using GeneralData, Test2, and Valid2; (ii) second, we fine-tuned such Transformer using document-level data, with 3-sentence concatenation as context, for 4 epochs using Train, Test1, and Valid1 data. We then compared the three translation outputs from an interdisciplinary perspective, investigating some of the effects of sentence- vs. document-based training. Computer scientists, translators and corpus linguists discussed the remaining linguistic issues for this discourse-level literary translation.

1 Introduction

In order to analyse literary translations, we have gathered an interdisciplinary team of translators, linguists and computational scientists. We used this opportunity to explore neural machine translation of literary texts as a test set for test suites and unsolved issues for MMT literary translations, especially for the Chinese-English language pair. While the topic of literary machine translation has gained momentum in the last years, there have still been few attempts to customize systems to literary data, although this idea is also drawing attention (Kenny and Winters, forthcoming). Indeed, research has been carried out on this subject, notably on Catalan (Toral and Way, 2018), but also on Slovenian (Kuzman et al., 2019), German and Russian (Matusov, 2019), and on French (Besacier and Schwartz, 2015), where research suggests that MT systems can be further fine-tuned on specific genres and individual translator styles (Hansen and Esperança-Rodier, V.2023).

Of course, these very attempts bring about many issues concerning textual ownership, copyright, translator status and livelihood, possibly lowered quality, cognitive friction, etc. (Taivalkoski-Shilov, 2019). It is therefore important to include these ethical aspects into the research and clarify its objectives: for instance, whether MT should serve as a reading aid (Oliver González, 2017), or as a post-editing tool that may decrease the effort needed to translate (Kolb, 2020) and constrain creativity (Guerberof-Arenas and Toral, 2022).

Part research has also focused on evaluating the use of existing tools for literary texts. In the context of Chinese to English, attention has been paid to some of the specific shortcomings of MT systems, such as the translation of adjectival possessive pronouns (Jiang and Yu, 2017), or theme-rheme progressions (Jiang and Niu, 2022). Such limitations can indeed have a drastic impact on readers' acceptance, which Shih (2016) explores in the context of online folktales, confirming that the text's function plays a large role in this respect.

Lastly, Thai et al. (2022) have also pointed the incompatibility of MT metrics, document-level or otherwise, for literary texts, concluding that "hu-

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 287–295
December 6–7, 2023.

man expert evaluation is currently the only way to judge the quality of literary MT".

The rest of the paper is organised as follows: Section 2 details our approaches to the task and the training data of our experiments, Section 3 presents the results and Section 4 discusses them.

2 Data and Tools Used

This section details the toolkits we used and our training data for the three submissions authorised for the task. We first used part of the training data proposed by the organisers (Wang et al., 2023a) to observe the translations from mBART50 from Chinese into English before fine-tuning mBART (primary submission). We then used a fine-tuned context-aware concatenation-based Transformer trained at document level (contrastive1 submission) and a traditional sentence-level Transformer (contrastive2 submission).

2.1 Primary model: mBART50 fine-tuning

As a primary submission, we used GuoFeng corpus (Wang et al., 2023a) to fine-tune the mBART50 model with Chinese-English data, using the Train set for training, Test1 as test set, and Valid1 as validation set. We followed similar training parameters to (Lee et al., 2022) when fine-tuning mBART50. As (Lee et al., 2022), we trained for 3 epochs, using gelu as an activation function, with a learning rate of 0.05, dropout of 0.1 and a batch size of 16 (we parallelised two A100 GPUs with batch size 8 per device). We decoded using a beam search of size 5.

2.2 Contrastive models

We submit two contrastive models, the first is a context-aware model (*contrastive1*) built on the second system, a sentence-level model (*contrastive2*).

For our contrastive1 submission, we used a context-aware NMT system based on the concatenation method (Lupo et al., 2023). The training was performed in two steps: (i) a sentence-level transformer (Vaswani et al., 2017) was trained for 10 epochs[1] using General Data as train set, Test2 as test set, and Valid2 as validation set ; (ii) second, we fine-tuned at document-level using 3-sentence concatenation for 4 epochs[2] using Train as train set, Valid1 as validation set and Test1 as test set. During the fine-tuning, we used ReLU as an activation function, with an inverse square root learning rate decay, dropout of 0.1, and a batch size of 64. We decoded using a beam search of size 4. For our contrastive2, we used the model trained at step (i) (sentence-level). The training parameters were an inverse square root learning rate decay, a dropout of 0.1, and a batch size of 64. We decoded using a beam search of size 4.

[1]We used only 10 epochs because of time constraints

[2]We used only 4 epochs because of time constraints

2.3 Evaluation Metrics

To evaluate our models, we use the BLEU score metric (Papineni et al., 2002) as implemented in the Moses package.

We performed a human annotation of errors in the translation obtained by our primary submission. 109 segments were selected and annotated by three evaluators that are Chinese native speakers. To measure the inter-annotator agreement, we used Fleiss' kappa (Fleiss et al., 1971). The score is calculated to measure the inter-rater reliability of the annotations as the following equation

$$\kappa = \frac{P_o - P_e}{1 - P_e}$$

where $P_o - P_e$ measures the real concordance of annotations that are not achieved above chance, while $1 - P_e$ measures the achievable concordance of annotations above chance. In our case, we computed errors by type as well as error types by segment (6 types and 109 segments, cf4.3.2).

3 Experiments and Results

We provide a human analysis of the primary model by discussing the improvements observed with the mBART fine-tuning with respect to the baseline. Additionally, we report the BLEU scores of our three systems.

3.1 Baseline of primary model: mBART50

During the training phase of the competition, with the standard HuggingFace implementation of mBART50, we observed the following issues when we translated Test1 from Chinese to English, which was part of the data provided for training by the organisers:

- hallucinations
- discrepancy between the Chinese input and the English translations
- tense concord
- co-referentiality issues for pronouns

Most textual discrepancies between the sizes of the sentences in the two languages were fixed by the fine-tuning as well as hallucinations and Chinese characters in the English translations. We nevertheless noticed a certain number of Chinese characters in the mBART50 translations, which decreased after our fine-tuning, and we only found 18 examples for all the 16,742 sentences, mostly for the fantasy genre, when referring to named entities or specific attributes of the universe (*Skills: Blade Technique, Wing Protection,*).

3.2 Fine-tuning with Literary Data

In this section, we analyse the outputs qualitatively. This analysis consists of an initial description of the baseline and fine-tuned outputs, followed by a deeper examination of the syntactic and semantic functions of the produced outputs by both models.

Instances of hallucinations were observed in the outputs of our baseline model. The hallucinated elements are present in the source text, so they are not elements which are not present in the source text. According to Lee et al. (2018), hallucinations can be defined as the model producing a vastly different and inadequate output when the source is perturbed under a specific noise model. Thus, we may suggest that there exist other instances where the model ceases translation of the source text and proceeds with generating output punctuated solely by a sequence of continuous commas (,,,,,,,,,), which may represent an alternative manifestation of hallucination. Interestingly, it is noteworthy that the fine-tuned outputs did not exhibit any instances of hallucination. However, it should be mentioned that few Chinese tokens were observed in the fine-tuned outputs. In the Chinese source text, the equivalent of the word "businessmen" is placed at the left periphery of the sentence, having a pragmatic effect that involves topic introduction or re-introduction, based on the context. Both the baseline and fine-tuned models take the left dislocated element to the right periphery of the sentence, thereby inducing an alternation in the sentence's intended meaning. As we observed, the baseline models chunk the sentences and use commas instead of employing coordinations, relative clauses, or more complex structures. In this example, the baseline model produces "Ten minutes later. consciousness is exhausted. scattered" by separating each chunk or even token with a period. In contrast, the fine-tuned model generates "Ten minutes later, his consciousness was exhausted and dissipated.", using coordination to form a united sentence. This represents another instance of the fine-tuned model's proficient manipulation of structures, wherein it employs a relative clause "which" to interconnect the sentences. Ex: "Wang lived in the 413 bedrooms of the West school district, Lins lived in the 413 bedrooms of the East school district." Fine-tuned: 09primary: "Wang Yicheng stayed in 413, which was in the West campus. Lin Sisi stayed in 413, which was in the East campus." Furthermore, the choice of tense seems to be different in the two models: As for the fine-tuned model, a preference for the past tense becomes evident. Conversely, as for the baseline model, an over-use of the present tense is observed in its outputs. We may also add that baseline models tend to favour the indicative mood, which indicates assertion, as seen in an example like "What's wrong with the game?". On the other hand, fine-tuned models have been *trained* to produce sentences in moods that exhibit a reduced level of assertiveness, as evidenced by constructions like "Could there be a problem with the game?".

3.3 BLEU scores

In this section, we report the results of our primary, constrastive1, and contrastive2 in terms of BLEU score computed using Test1 and Test2 datasets at the end of the full training process of each model. The official results of the competition on test3 were not computed as the reference translations were not provided (at the time of writing this article).

Model	Test1	Test2
primary	22.31	–
contrastive1 (document-level)	19.03	17.58
contrastive2 (sentence-level)	22.31	18.22

Table 1: BLEU score for primary, contrastive1 and contrastive2 systems.

Table 1 shows that our primary system achieves the same BLEU score as contrastive2[3], the sentence-level transformer implementation. We notice that the document-level system (contrastive1) is not better than the sentence-level model. This

[3]Primary and contrastive2 scores on Test1 are identical due to coincidence.

might be explained by the few epochs used for training.

4 Discussion

4.1 Lexical Complexity

To appreciate the relative complexity of the terms used in the translations we first qualitatively compared the translations and contrastive2 seemed to be more elaborate, so we tested this impression with more quantitative means. We investigated the vocabulary growth curves of the three translations using the functions available from the languageR package (Baayen and Shafaei-Bajestan, 2019) to find out that the number of different types progress on the same rhythm for the different translations. In this type of representation, the horizontal axis corresponds to the expansion of the translation corpus (number of tokens) and the vertical axis corresponds to the number of types. The first lower series of curves corresponds to the number of hapaxes. As can be seen in Figure 1, the progression is very similar for the different translations we produced, while the mBART fine-tuning translation (primary) seems to be more verbose as the translation contains pore tokens than the two contrastive translations. The difference between our different models is clearly not lexical.

4.2 Challenging Literary Aspects of the Test Set

The first challenge was the size of the testing data, which resorted to different text genres, but was 30 times bigger than other challenge datasets like for the biomedical task in 2021. An additional difficulty was the paucity of metadata for the 14 genres or for chapter attributions (22 announced and 12 found).

4.3 Translation Quality analysis based on Error Annotation

4.3.1 Quality overview

In total, 109 sample segments were randomly selected from the twelve translated texts generated by the fine-tuned mBART50 model. Based on these sample segments, each translated text was assigned an overall grade individually by three annotators on a scale of 1 to 10, with 1-3 denoting "Very Poor", 4-6 denoting "Poor", 7-8 denoting "Moderate", and 9-10 denoting "Good". The annotators are native Chinese speakers with near native level of English competence. They work in the domain of translation training and linguistics with an advanced proficiency of Chinese-English translation. The three grades given by the annotators for each text were then averaged to obtain a relative ranking of each translation. Overall, the twelve translations achieved an average score of 5 out of 10 in general, with a standard deviation of 0.87. Specifically, seven subgenres were identified among the twelve texts, namely: fantasy (4 texts), ancient romance (2 texts), military (1 text), thriller (1 text), modern romance (2 texts), sci-fi (1 text), and online games (1 text). All the sub-genres are typical in contemporary web novels. Notably, there is not a clear cut between different sub-genres and this categorisation is for analytical purposes only. Among the identified subgenres, the ranking from high to low quality is as follows: thriller (6.0 out of 10), fantasy (5.7), online games (5.4), sci-fi (5.0), ancient romance (4.7), modern romance (4.6), and military (3.8). While subgenre types might be a factor in influencing the quality of the translation given their language styles (e.g., the proportion of conversational segments, terminologies, formality, etc.), this line of discussion requires further evidence. Among the sample segments, the quality and language style of individual source text seem to play a more vital role in the overall quality of the translations. Several prominent error types linking to the stylistic features of the texts were identified, as detailed below.

4.3.2 Error typology

To obtain a more detailed insight into the quality of these translations, the sample segments were annotated based on the error typology introduced by (Hansen and Esperança-Rodier, V.2023). The original typology was further categorized for the Chinese - English language pair and inter-rater validation purposes. Specifically, six level-one error types were identified:

- semantic errors (SEM): errors that directly affect the meaning of the text, involving issues like omission, addition, or wrong translation of content/nuance of content;
- logical, structural and cohesion errors (LSC): errors related to the logical flow and coherence of the text, affecting how different parts relate to each other;
- grammatical errors (GRM): errors related to

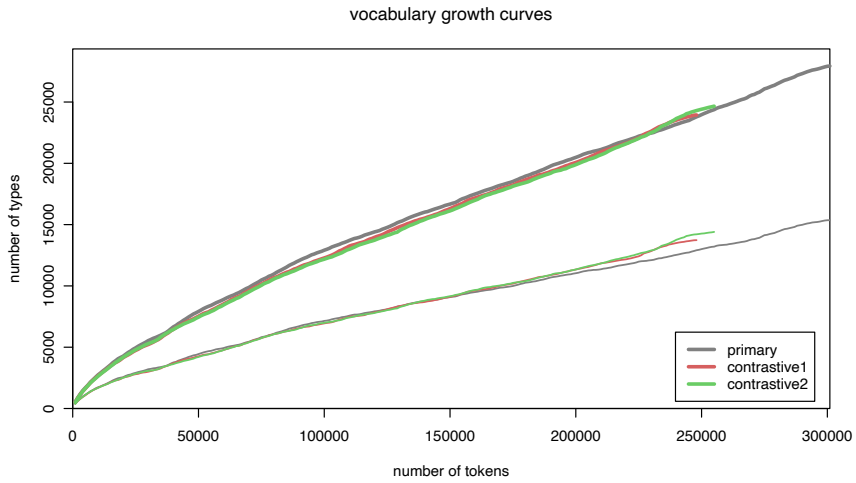

Figure 1: Vocabulary growth curves of our three translations (primary, contrastive1, contrastive2). The lower series of curves corresponds to the hapaxes for primary, ontrastive1 and contrastive2.

the rules of language such as gender, number, tense, and person etc.;

- stylistic errors (STY): errors regarding the style, tone, and appropriateness of the language used;
- stuttering (STU): words repeated for no apparent reason by the MT system;
- non-translation (NTR): source term left untranslated in the target.

Each level one error type contains specific level two and sometimes level three error types. The complete error typology tailored for this task can be found in the appendix.

We use Fleiss' kappa to measure the Level 1 error type inter-rater agreement, and the overall Fleiss' kappa score is 0.288, which can be interpreted as "Moderate agreement" according to (Landis and Koch, 1977)'s classifications. . Fleiss' kappa of Level 1 subgenre annotations is presented in Table 2.

Among all annotated segments, 30.58% segments are considered error-free. 47.71% of them belong to the SEM error type, with the remainder of 11.31% on STY, 4.89% on LSC, and 3.98% on GRM.

4.3.3 Prominent Error Types

Understanding the text in its original language is the basis for literary translation, which requires multi-faceted considerations pinned by context, literary style and cultural nuance. The fine-tuned system attempts to address the greater-than-sentence-level textual features. However, human annotation results have shown that it continues to struggle with contextual analysis, which leads to prominent errors such as non-translation, mistranslation and inconsistent translation or reference of proper nouns and terms, mistranslation of idioms, etc.

Subgenre	**Score** ↑
Modern Military	0.534
Science Fiction	0.344
Ancient Romance	0.321
Fantasy	0.283
Modern Romance	0.283
Thriller	0.152
Online Game	0.143

Table 2: Fleiss' kappa of subgenres. $\kappa = 1$ is perfect concordance, $\kappa = 0$ is no concordance between annotators.

Transliteration is the main way of addressing the character names from Chinese into English (in this case, standard Pinyin is used). Surprisingly, the system failed to maintain consistency of reference to name entities, for example, "宋扶" (song fu) was translated as "Song Fu", "Song Fudge" and "Song Yidao" at places. The character "宋扶" is also mentioned as "宋师弟" or "宋师兄", which were translated literally (see examples in table 3, hand-annotated in bold). Given the nature of fantasy (xianxia) novels, "师兄" (senior brother) or "师弟" (junior brother) is a common way of addressing

王子法一脸惊讶道：“师兄此话怎讲？”	"What do you mean, senior brother?" Prince Charming asked in surprise.
郑金龙笑眯眯道：“师弟，你是在跟我装糊涂吗？宋师弟的死，你们不准备给师门一个交代？”	"Junior brother, are you playing dumb?" Zheng Jin Long said with a smile.“You don’t want to give your sect an account for **Junior brother Song**’s death?"
王子法面容一肃，沉声道：“宋师兄差点坏我蓝玉门好事，宋扶该死！再给我们一次机会，我们还是会这样做！”	"**Senior Brother Song** almost ruined our Lanyu Sect’s business. **Song Fudge** deserves to die! Give us another chance, and we’ll still do this!" the prince said solemnly.

Table 3: Examples for illustration

people under the same sect. Literal translation in this particular context might reduce textual cohesion and such inconsistent reference might confuse target language readers given the numerous consecutive mentions of “brother” in the text. The same issue was observed in the document-level model (contrastive1) result too.

It is difficult for the system to identify a named entity if the name itself or part of the name can be used as a proper noun. For example, “王子法” (wang zi fa) was mistranslated as “Prince Charming”, which was because the system misidentified the first two Chinese characters “王子” (wang zi, literal meaning: prince) as a named entity.

Other inconsistency regarding proper nouns lies in the formality of presentation, i.e., case error, meaning translation going against previous choices regarding the capitalization of series-specific terms. In fantasy novels, sect names and martial arts techniques are prominent terms. However, the capitalization of these terms was not always consistent.

It is challenging for the current system to capture ideas or emotions in culturally specific expressions. For example, the idiom “天下没有不散的宴席” is translated as “there is no such thing as a banquet in the world”. As a literal translation, it omitted the important part of the idiom “不散的” (literal meaning: non-separable / never-ending), which leads to the failure of conveying its figurative meaning “All good things must come to an end”. On the contrary, it did well in translating “哑巴吃黄连” (literal meaning: a mute person eats bitter melons) as “speechless”. The discrepancy between the translation quality of idioms shows that more culture-specific training data is needed to improve the accuracy and idiomaticity of literary machine translation.

4.4 Sentence- vs. Document-based Training Strategies

An important aspect of the competition was the choice to use full chapters with contextualised successive sentences instead of (more) limited contexts usually retained for translation competitions. This resulted in a much bigger dataset than for more standard competitions (in the vicinity of 400 sentences for biomedical tasks). We submitted 2 models based on a similar architecture: *Contrastive1* and *Contrastive2*.

We used as *Contrastive2* a context-agnostic sentence-level transformer model as in (Vaswani et al., 2017) trained on 10 epochs.

We used as *Contrastive1* an on-context transformer model with the exact same architecture as *Contrastive2* but that adopts sliding windows of 3 concatenated sentences pre-trained on 10 epochs to the sentence-level and trained on 4 epochs with concatenated sentences.

Concatenation of 3to3 implies that the source sentence is concatenated to the two previous sentences using end-of-sentence tokens between each of them. A *sliding windows* is when sliding-KtoK model encodes the source windows sentences x_K^i using the end to sentence tokens <*eos*> and a special token <*S*> used to mark sentence boundaries in the concatenation then decode the translation y_K^i

$$x_K^i = x^{i-K+1}\text{<S>}x^{i-K+2}\text{<S>}...\text{<S>}x^i\text{<eos>}$$

$$y_K^i = y^{i-K+1}\text{<S>}y^{i-K+2}\text{<S>}...\text{<S>}y^i\text{<eos>}$$

Another Contrastive model was trained, but unfortunately too late for the submission, based on (Lupo et al., 2022) it has the same specificity than *Contrastive1* with a context discount of 0.01. Context-discount means that the loss function is defined as :

$$\mathcal{L}_{CD}(x_K^j, y_K^j) = CD \cdot \mathcal{L}_{context} + \mathcal{L}_{current}$$

After the submission period, we continued training our contrastive systems. After 55 epochs

of sentence-level pre-training and 14 epochs of document-level training, the system achieved a BLEU score of 21.46 on Test1 test set.

5 Further Research

5.1 Related Research

This subsection discusses related papers.

For fine-tuning mBART, we replicated the parameters tested by (Lee et al., 2022), namely retraining for three epochs. With the same parameter, (Namdarzadeh et al., 2023) have fine-tuned Persian→English and Persian→French with a single short story but nevertheless observed dramatic improvement for Persian→French translations in terms of elimination of hallucinations, English words and morpho-syntactic correction. We have not tried other multilingual Large Language Models such as mBERT (Wu and Dredze, 2019) (based on BERT), mT5 (Xue et al., 2020), XLM-R (Conneau et al., 2019) based on RobertA or the more recent (and bigger) Bloom model (Scao et al., 2022).

For concatenation Transformer, we used some parameters tested by (Lupo et al., 2022) that translated English→German and English→Russian to observe dramatic improvement on Contrapro set (Müller et al., 2018) and English→Russian set (Voita et al., 2019) although with only a slight improvement in BLEU score.

5.2 Future Research

This first collaboration between several universities and backgrounds has discussed English input and was an opportunity to discuss the findings of the competition on literary data and also our insights into the fine-tuning of mBART50 with literary data. We aim to replicate this analysis on Farsi data, as Farsi is one of the 50 languages of mBART50. As is often the case in competitions, we did not train as much as we expected. For the fine-tuning of mBART, we managed to train for three epochs, which is what we found in previous studies (Lee et al., 2022), but for two other submissions, we were training from scratch and could only manage to train for 10 epochs for constrastive2 (sentence-level) and fine-tune for 4 epochs for contrastive1 (document-level). This impacted our results. Evaluating our BLEU score on Test1, we got 22.31 BLEU score for both primary and contrastive2 meanwhile 19.03 BLEU score for constrative1.

6 Conclusion

This paper presented the MAKE-NMTViz system description for the WMT2023 Literary Shared Task. We participated in the Chinese-to-English task with a model trained at sentence level and at document level. We only used the data provided by the organisers but also analysed the translations produced with mBART50 before our submissions. As we did not receive scores from the organisers of the task, we mostly focused on the qualitative analysis of our translations. We resorted to a typology of translation errors and highlighted prominent error types that remained in our translations.

Limitations

During this translation task, we met one limitation with respect to the document-level translation system. In this case, we did not adapt the system to process in Chinese→English language pair. We employed the same setup described in previous works, where the system was trained for English→Russian, English→German and English→French languages.

Acknowledgements

This paper emanated from research partly supported by the MAKE-NMTVIZ project, funded under the 2022 Grenoble-Swansea Centre for AI Call for Proposals/ GoSCAI - Grenoble-Swansea Joint Centre in Human Centred AI and Data Systems (MIAI@Grenoble Alpes (ANR-19-P3IA-0003)), and by a 2021 research equipment grant from the Scientific Platforms and Equipment Committee (PAPTAN project) under the ANR grant (ANR-18-IDEX-0001, Financement IdEx Université de Paris). Abstract

This paper details the submission from the DUTNLP Lab for the WMT23 Discourse-Level Literary Translation in Chinese to English translation direction under unconstrained conditions. Our primary system aims to harness a large language model with various prompt strategies, allowing for a comprehensive exploration of the potential capabilities of large language models in discourse-level neural machine translation. Moreover, we apply detailed data preprocessing methods to filter bilingual data, which proves to be beneficial. Additionally, we assess a widely used discourse-level machine translation model, G-transformer, using different training strategies. In our experimental results, the method employing large language models achieves a BLEU score of 28.16, whereas the fine-tuned method scores 25.26. These findings indicate that selecting appropriate prompt strategies based on large language models can significantly enhance translation performance compared to traditional model training methods.

1 Introduction

The DUTNLP Lab is actively participating in WMT23 Discourse-Level Literary Translation, focusing on Chinese to English translation direction. As observed, prompting large language models (LLMs) has led to outstanding performance across a range of natural language processing (NLP) tasks (Chowdhery et al., 2022; Goyal et al., 2023; Chung et al., 2022). So our research involves experimenting with various prompts and in-context learning strategies, utilizing large language models. Additionally, we conduct experiments to explore the impact of sentence length and data preprocessing methods on translation results.

Our research is primarily anchored in the gpt-3.5-turbo model (Brown et al., 2020), renowned for its outstanding language generation capabilities spanning various domains, from writing to conversations. This model excels at producing natural and fluent text with simple prompts, making it accessible even to individuals without extensive technical knowledge.

Intriguingly, for crafting effective prompts to stimulate the machine translation capability of the large model, we take inspiration from gpt-3.5-turbo. We actively interact with it to derive prompts that can boost translation performance, resulting in the identification of three candidate translation prompt templates. Our evaluation of these prompts in the discourse-level translation task indicates their overall effectiveness, with minor performance variations.

Recognizing the substantial impact of data quality on translation performance, we employ cleaner development corpora for our main experiments. When utilizing large pre-trained models, we conduct a data filtering process through off-the-shelf tools and manual rule-based approaches. Further details will be seen in Session 2.

Given the inherent randomness and flexibility in translations generated by large models, aligning the output with the source text can be challenging. To tackle this challenge, we develop scripts to identify segments with alignment errors and subsequently apply manual corrections for rectification.

To sum up, our contributions can be outlined as follows:

- We have carefully crafted a prompt that has led to a notable performance of 28.16 BLEU (Papineni et al., 2002) on our dataset. This accomplishment suggests a significant improvement over standard document-level machine translation models, including the G-transformer model (Bao et al., 2021), trained with various strategies.
- We have conducted a series of meticulously controlled experiments to systematically in-

Figure 1: Prompts advised by gpt-3.5-turbo for machine translation.

vestigate the impact of different prompt strategies, batch sentence quantities, and tokenizer methods on the performance of the gpt-3.5-turbo model when apply to the Chinese-to-English discourse-level translation task.

This paper is structured as follows: Section 2 describes the data pre-processing strategies, followed by the details of our method in Section 3. Section 4 presents the experimental results and analysis, and we draw conclusions in Section 5.

2 Data Processing

Contrary to the conventional fine-tuning approach on large language models, our method utilizes a large pre-trained language model combined with prompts. In other words, Our primary experiment do not require further model training. Therefore, we conduct experiments using only a small portion of the development dataset.

Since the data quality significantly impacts our final translation performance, we adopt both traditional data processing methods and manual rules for filtering. The pre-processing strategies are as follows:

- Extract the discourse-level data from the text data with HTML tags and filter out duplicated sentence pairs.
- Filter out sentences containing illegal and invisible characters, like certain emoji symbols, as they may cause alignment issues.
- Normalize punctuation using Moses scripts (Koehn et al., 2007) for English and Chinese. Chinese text is separately segmented by Jieba tool.
- For Chinese, convert full-width format to half-width format and traditional Chinese characters to simplified ones.

	Translation Prompt
TP1	Translate the following sentences "[Insert text here]" from [SRC] to [TGT].
TP2	These sentences "[Insert text here]" are in [SRC] and can be translated to [TGT] as follows:
TP3	Please provide translations of these sentences "[Insert text here]" into [TGT].

Table 1: Candidate translation prompt.

3 Method

To unlock the full potential of large language models, we introduce an innovative approach by seeking guidance from gpt-3.5-turbo for the creation of effective machine translation prompts (Jiao et al., 2023). Specifically, we pose the following query: 'Provide ten concise prompts or templates that can prompt translation.'

The obtained results are shown in Figure 1. Upon observation, we note that the generated prompts are reasonable and similar. Consequently, we consolidate them into three sets of candidate templates, as illustrated in Table 1, where [SRC] and [TGT] represent the source and target language of translation.

In previous studies concerning discourse-level machine translation, it is evident that factors such as varying discourse lengths (Wang and Cho, 2019; Raffel et al., 2019) and different segmentation granularities (Koehn, 2005; Sennrich et al., 2016) can significantly impact translation performance. Consequently, we design a series of comparative experiments to investigate these aspects. Specifically, we segment the document texts into sizes of k and analyze the effects of different text lengths on machine translation performance in our experimental results.

During the segmentation of document text, our goal is to achieve an equitable distribution of text segments and prevent a situation where only a few isolated sentences remain at the end of a document. To address this, we devise a text segmentation algorithm that preserves the data while also ensuring that the number of text portions between segments is as uniformly distributed as possible. The aim is to minimize variance in sentence counts, as illustrated below.

The main strategy is as follows: for a document containing n lines of text, it undergoes slicing based on a specified size of m lines, where the quotient is denoted as p and the remainder as q. If there is a remainder ($q \neq 0$), it indicates the need to slice the text into $n/p + 1$ segments. This results in a new quotient, k, and a new remainder, t. Consequently, the last t segments are allocated a line count of $k + 1$, while the rest of the segments maintain a line count of k.

In traditional machine translation experiments, it is well-recognized that varying segmentation granularities can significantly influence translation quality, particularly in languages like Chinese where clear word boundaries are often absent (Zhao et al., 2013). Therefore, we conduct additional experiments to assess the impact of segmentation granularity on translation performance. Our experiments involve three different segmentation granularities for model input in both Chinese and English datasets: unsegmented, Chinese segmented using the 'Jieba' tool, and Chinese-English segmented using the 'MOSS' tool.

Finally, we compare the performance of our system with commonly used document-level machine translation models. Detailed findings will be presented in the subsequent section.

Translation Prompt	BLEU
TP1	27.92
TP2	27.19
TP3	27.54

Table 2: The results of three candidate translation prompts.

Split the document into k segments	BLEU
k=5	27.73
k=10	27.92
k=15	27.94
k=20	28.08
k=25	27.88
k=30	N/A

Table 3: The results of TP1 with different segment lengths.

4 Results

4.1 Score Analysis

In the discourse-level translation task, we evaluate the performance of three different candidate prompts, as shown in Table 2. Considering these candidate prompts, TP1 yields the highest BLEU score. Therefore, in the subsequent comparative experiments, we consistently employ TP1 as the foundational prompt.

We initially include additional theme information in TP1 based on a suggestion from gpt-3.5-turbo. The theme is related to novels, and we use it to translate the provided sentences from Chinese to English. Surprisingly, the resulting BLEU score is only 27.02, which is even worse than the three base candidate prompts. Consequently, we decide to remove this additional theme information.

For text fragment segmentation, we do experiment with different values of k, including 5, 10, 15, 20, 25, and 30. However, when we set $k = 30$, we encounter errors due to the input being too lengthy for the model to handle. Therefore, we obtain results for the five groups, as shown in Table 3.

We observe that, with the same prompt, varying the length of text segments indeed has an impact on translation performance. When the number of sentences reaches 30 and the token count exceeds 4,096, the system can no longer perform translation. Conversely, when the text length is relatively short ($k = 5$), the model cannot gather enough informa-

Word segmentation granularity	BLEU
unsegmented	27.88
segmented with jieba	**28.16**
segmented with moss	27.53

Table 4: The results of TP1 with different Word segmentation granularity.

exp_randinit	21.21
exp_finetune	24.46
exp_mBART	25.26

Table 5: The results of G-transformer with different training modes.

tion, leading to the lowest translation performance. Conversely, overly long text segments ($k = 25$) also weaken performance of the model, potentially introducing noise. Therefore, we choose $k = 20$ as the base for our experiments.

As shown in Table 4, the granularity of text significantly affects the performance of machine translation. Experimental results demonstrate that unsegmented Chinese and English texts are impacted due to the lack of alignment between words, resulting in a slight reduction in translation effectiveness. However, the 'MOSS' segmentation granularity leads to the worst result. We infer that the word segmentation results are too dispersed, making it challenging for the large language model to precisely integrate contextual information for word translation.

Before the widespread use of effective prompts for large-scale models, fine-tuning on pre-trained language models is a common approach to enhance translation performance in specific domains. Therefore, for the comparison experiments, we select a state-of-the-art (SOTA) model designed for document-level machine translation. G-transformer is a straightforward extension of the standard Transformer architecture (Vaswani et al., 2017), using group tags for attention guiding, and introducing locality assumption as an inductive bias to reduce the hypothesis space of the attention from target to source. And we train the G-transformer model using the training corpus provided in the task. This training process involved random initialization, fine-tuning initialization, and fine-tuning on mBART (Liu et al., 2020). The results of these experiments are presented in Table 5.

Comparing the experimental results, it becomes evident that conducting targeted fine-tuning experiments on large language models can enhance machine translation performance. However, it is important to note that this approach falls significantly short of the effectiveness achieved by using prompts on large language models.

4.2 Discourse Analysis

In the context of a document translation (S, T), Lyu et al. (2021) argues that translation consistency should be maintained at the target end if a lexical word w occurs multiple times (two or more times) at the source end.

Due to constraints on time and resources, we conduct manual discourse-level analysis on a limited amount of text. Specific operations are as follows: First, we use a co-reference identification tool (Gardner et al., 2018) to identify all co-reference chains in the target-side documents. We perform data cleaning to extract multiple entity co-reference chains and then compare whether the entity words in the co-reference chains maintain translation consistency.

An example is provided in Table 6. Given that the three candidate prompts exhibit similar discourse characteristics, we choose the large language model gpt-3.5-turbo with prompt TP1 as an example for our analysis. We also introduce the model fine-tuned on the large model mBART for comparison.

Upon observing the result, we notice that even excellent models like ChatGPT may face challenges in addressing certain issues of discourse consistency and coherence. This could be attributed to the extensive training data and the challenge of ensuring coverage of test datasets. On the other hand, fine-tuning strategies, owing to their training on domain-specific data, result in more targeted translations and facilitate the maintenance of translation consistency. This underscores a demand for higher quality document-level translation and could potentially indicate a direction: the need to capture more contextual dependencies.

5 Conclusion

We have presented our experimental study on gpt-3.5-turbo for machine translation, covering translation prompts and robustness. Through careful observation and analysis of the experimental

Table 6: The analysis of discourse phenomenon on different translation models.

results, we have noted that the utilization of the large language model with prompts achieves a significant improvement, nearly 3 points higher than the baseline. It even surpasses the currently widely used mBART+fine-tune approach for discourse-level machine translation. We also attempt to enhance translation performance by incorporating in-context information, but this lead to a negative impact. Our future work may include investigating the impact of historical context on translation results and iterative refinement of translation. Simultaneously, we will focus on the recognition and translation of discourse phenomena for large language models.

Abstract

This paper introduces HW-TSC's submission to the WMT23 Discourse-Level Literary Translation shared task. We use standard sentence-level transformer as a baseline, and perform domain adaptation and discourse modeling to enhance discourse-level capabilities. Regarding domain adaptation, we employ Back-Translation, Forward-Translation and Data Diversification. For discourse modeling, we apply strategies such as Multi-resolutional Document-to-Document Translation and TrAining Data Augmentation.

1 Introduction

Transformer architectures (Vaswani et al., 2017) have achieved outstanding performance on sentence-level machine translation tasks, but still have some shortcomings when it comes to discourse-level machine translation. Particularly, for machine translation scenarios that are highly discourse-dependent, such as novel translation and conversation translation, the performance is unsatisfactory.

This paper presents the submission of HW-TSC to the WMT23 Discourse-Level Literary Translation shared task. We utilize an effective data cleaning pipeline summarized in our previous works (Wei et al., 2022; Wu et al., 2022; Yang et al., 2021) to process the training data. We employ Regularized Dropout, Forward Translation, Back Translation, Data Diversification to train a strong baseline. On top of the baseline, we apply strategies including Multi-resolutional doc2doc Translation (MR-doc2doc), TrAining Data Augmentation (TADA) to enhance discourse-level translation capabilities.

The general translation model does not work well in novel translation. We found that the biggest factor affecting the quality of translation is domain adaptation; however, domain adaptation cannot solve the consistency of named entity such as names, addresses, and zero pronoun in novel translation. The consistency needs to be optimized by using strategies such as MR-doc2doc and TADA.

2 Data

2.1 Data Source

We use the same training data as that for the general MT shared task to train a sentence-level baseline. Then We use GuoFeng Webnovel Corpus[1] (Wang et al., 2023) and web-crawled novel data for domain adaptation and discourse-level capability enhancement. The data size is shown in Table 1.

	Bilingual	Source	Target
General MT	25M	50M	50M
GuoFeng Webnovel Corpus	1.9M	-	-
web-crawled novel data	10M	100M	400M

Table 1: Bilingual and monolingual data used for training.

2.2 Data Pre-processing

The data preprocessing pipeline follows our previous work (Wei et al., 2021), including deduplication, XML content processing, langid (Lui and Baldwin, 2012) and fast-align (Dyer et al., 2013) filtering strategies, etc. We will not repeat the details here.

3 System Overview

3.1 Sentence-level baseline

We directly employ the model we trained for the general MT shared task as the sentence-level baseline in this task. The following is the strategy we use to train the sentence-level baseline.

[1] http://www2.statmt.org/wmt23/literary-translation-task.html

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 302–306
December 6–7, 2023.

3.1.1 Regularized Dropout

Regularized Dropout (R-Drop) (Wu et al., 2021) improves performance over standard dropout, especially for recurrent neural networks on tasks with long input sequences. It ensures more consistent regularization while maintaining model uncertainty estimates. The consistent masking also improves training efficiency compared to standard dropout. Overall, Regularized Dropout is an enhanced dropout technique that often outperforms standard dropout.

3.1.2 Data Diversification

Data Diversification (DD) (Nguyen et al., 2020) is a simple but effective strategy to boost neural machine translation (NMT) (Bahdanau et al., 2015) performance. It diversifies the training data by using the predictions of multiple forward and backward models and then merging them with the original dataset on which the final NMT model is trained. This method is more effective than knowledge distillation and dual learning.

3.1.3 Forward Translation

Forward translation (FT) (Abdulmumin, 2021) uses source-side monolingual data to improve model performance. The general procedure of FT involves three steps: (1) randomly sampling a subset from large-scale source monolingual data; (2) using a "teacher" NMT model to translate the subset into the target language, thereby constructing synthetic parallel data; and (3) combining the synthetic and authentic parallel data to train a "student" NMT model.

3.1.4 Back Translation

Augmenting parallel training data with back-translation (BT) (Sennrich et al., 2016; Wei et al., 2023) has been shown effective for improving NMT using target monolingual data. Numerous works have expanded the understanding of BT and investigated various approaches to generate synthetic source sentences. Edunov et al. found that back-translations obtained via sampling or noised beam outputs tend to be more effective than those via beam or greedy search in most scenarios. For optimal joint use with FT, we employ sampling back-translation (ST) (Edunov et al., 2018).

3.1.5 Alternated Training

While synthetic bilingual data has been shown effective for NMT, adding more synthetic data may deteriorate performance as synthetic data inevitably contains noise and errors. To address this issue, alternated training (AT) (Jiao et al., 2021) introduces authentic data as guidance to prevent model training from being disturbed by noisy synthetic data. AT views synthetic and authentic data as two types of different approximations for the authentic data distribution. The key idea is to iteratively alternate between synthetic and authentic data during training until convergence. Authentic data provides guidance to overcome noise in synthetic data. By alternating data types, AT ensures the usage of a large amount of synthetic data while prevents model deterioration from noisy data.

3.1.6 Curriculum Learning

A practical curriculum learning (CL) (Zhang et al., 2019) approach for NMT should address two key issues: ranking training examples by difficulty, and modifying the sampling procedure based on ranking. For ranking, we estimate example difficulty using domain features (Wang et al., 2020). The domain feature is calculated as:

$$q(x,y) = \frac{\log P(y|x;\theta_{in}) - \log P(y|x;\theta_{out})}{|y|} \quad (1)$$

Where θ_{in} is an in-domain NMT model, while θ_{out} is an out-of-domain model. The novel domain is treated as in-domain.

We fine-tune the model on the valid set to get the teacher model and select top 40% of the highest scoring data for finetuning.

3.2 Domain Adaptation

We found that the translation style of novel translation and general domain translation is completely different, so domain adaptation is very important. So we finetune the sentence-level baseline model with bilingual/monolingual novel data. For web-crawled novel data, we use 100M Chinese monolingual data and 400M English monolingual data to construct FT and ST corpus respectively, and use GuoFeng Webnovel Corpus bilingual 1.9M, web-crawled novel data bilingual 10M, finally mix the four parts data together and shuffle them.

3.3 Discourse Modeling

Although the translation quality has improved with domain adaptation, it still unable to solve document-level translation problems such as NE

consistency and zero pronoun translation. MR-doc2doc and TADA need to be used to solve the problem. It is expected to further improve the ability of discourse-level translation on the basis of section 3.2. We employ monolingual and bilingual novel data, and reconstruct them according to the method of discourse-level translation.

3.3.1 Multi-resolutional doc2doc

Multi-resolutional doc2doc (MR-doc2doc) (Sun et al., 2020) is a document-level neural machine translation approach that operates on different granularities of the document. It utilizes both sentence-level and document-level information during translation to improve context modeling and overall translation quality. Specifically, we split each document averagely into kparts multiple times and collect all the sequences together. For example, a document containing eight sentences will be split into two four-sentences segments, four two-sentences segments, and eight single sentence segments. Finally, fifteen sequences are all gathered and fed into sequence-to-sequence training. In this way, the model can acquire the ability to translate long documents since it is assisted by easier, shorter sentences and paragraphs. By doing so, the model can acquire discourse-level translation capabilities.

3.3.2 TrAining Data Augmentation

The key idea of TrAining Data Augmentation (Ailem et al., 2021) is to use tags to mark words or phrases that needs to be constrained in the source sentence during translation. When the model encounters a tagged token in the source, it is biased towards directly copying the expected lexical constraint following the tagged source word into the target output. This allows enforcing lexical constraints without changing the core NMT architecture, simply by using tags in the source. The model learns this copy behavior during training when exposed to tagged source sentences and the expected lexical constraints in the target. Thus, the approach can easily guide NMT to satisfy terminology constraints by just tagging the source sentence appropriately. It provides a simple and efficient way to constrain NMT output lexicons by merely adding tags on the source side. We use this method to ensure consistent translation of named entities (such as person names, location names, etc.) at both inference and training phases.

4 Experiments

4.1 Experiment Settings

We use SacreBLEU (Post, 2018) to measure system performances. The main parameters are as follows: the model is transformer-big with 25 encoder layers and 6 decoder layers. It trained using 8 A100 GPUs, batch size is 8192, parameter update frequency is 1, and learning rate is 5e-4. The number of warmup steps is 4000, and the model is saved every 1000 steps. We adopt dropout, and the rate varies across different training phases. R-Drop is used in model training, and we set λ to 5. We use fairseq (Ott et al., 2019) for training.

4.2 Testing Datasets

4.2.1 Simple Set

Simple Set[2] (Wang et al., 2023) contains unseen chapters in the same web novels as the training data.

4.2.2 Difficult Set

Difficult Set[3] (Wang et al., 2023) contains chapters in different web novels from the training data.

5 Results

As shown in Table 2, each step is fine-tuned based on the model from the previous step. In the Domain Adaptation stage (ST, ST & FT & AT & DD, CL), we observe significant s-BLEU improvement, while d-bleu is also improved. In the Discourse Modeling stage, MR-doc2doc can improve both s-bleu and d-bleu. TADA works well on NE consistency, but does not significantly improve d-BLEU and leads to a slight decrease in s-bleu.

As shown in Table 3, We extracted 75 NEs by W2NER (Li et al., 2022) from the test set, which occurred 1241 times in total. We count the word frequency of consecutive and identical NEs as an indicator to evaluate the consistency. We found that the TADA strategy can bring significant improvements in NE consistency.

6 Conclusion

It was believed that algorithm enhancement can make the model handle long inputs so that discourse-level translation would be improved. However, it can only achieve slight improvement.

TJUNLP:System Description for the WMT23 Literary Task in Chinese to English Translation Direction

Shaolin Zhu and Deyi xiong*
College of Intelligence and Computing, Tianjin University, Tianjin, China
{zhushaolin, dyxiong}@tju.edu.cn

Abstract

This paper introduces the overall situation of the Natural Language Processing Laboratory of Tianjin University participating in the WMT23 machine translation evaluation task from Chinese to English. For this evaluation, the base model used is a Transformer based on a Mixture of Experts (MOE) model. During the model's construction and training, a basic dense model based on Transformer is first trained on the training set. Then, this model is used to initialize the MOE-based translation model, which is further trained on the training corpus. Since the training dataset provided for this translation task is relatively small, to better utilize sparse models to enhance translation, we employed a data augmentation technique for alignment. Experimental results show that this method can effectively improve neural machine translation performance.

1 Introduction

Machine translation, as a core branch of natural language processing, has experienced significant development and received widespread attention in the past few years. Propelled by deep learning and neural networks, architectures like the Transformer(Vaswani et al., 2017) and its derivative models, such as BERT (Devlin et al., 2019) and GPT (Brown et al., 2020), have become mainstream methods for achieving efficient machine translation. These models, by learning underlying representations of language, are able to capture complex relationships and rich semantic information between texts.

Although neural machine translation with dense models has a promising future, it still faces many challenges. One of the main issues with the standard Transformer-based dense multilingual neural machine translation model is the model's capacity bottleneck(Zhu et al., 2021; Fedus et al., 2022b; Cheng et al., 2021). While increasing the model's depth and breadth can effectively enhance its capacity, it severely reduces the model's execution efficiency and increases the hardware requirements for training the model. This often results in the need for large GPU devices, limiting the model's applications. Therefore, in recent years, multilingual neural machine translation based on Mixture-of-Experts (MOE) (Fedus et al., 2022a) has been proposed. Compared to dense models, MOE-based multilingual machine translation activates only a portion of the network parameters during model training and inference (Lepikhin et al., 2021), giving it excellent computational efficiency. Under the same hardware conditions, it can achieve greater model capacity (compared to dense models, capacity can be increased by several tens of times) (Shazeer et al., 2017) and shorter computation time. Therefore, in this translation task evaluation, our basic model framework is based on the MOE Transformer. Furthermore, when there is limited available data, overfitting can easily occur (Wang et al., 2022; Pan et al., 2021). Combining the knowledge of multiple experts can often provide more accurate predictions than a single model. During model training, by allocating experts to focus on different input subsets, MOE can help alleviate the overfitting issue (Szymanski and Lemmon, 1993).

In this paper, we primarily focus on the WMT23 Chinese to English machine translation task. To enhance the model's capacity while maintaining a high computational efficiency, we employ a neural machine translation model based on the MOE Transformer framework. This model can effectively expand the model parameters. Moreover, since it's a domain-specific translation task with limited translation data corpus, we employed a strategy to initialize MOE using dense models effectively. The rest of this paper is organized as follows. In Section 2, we will present the models and methods we designed. Section 3 primarily

*Corresponding author.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 307–311

showcases the experimental results and discusses and analyzes the outcomes. Section 4 concludes the paper and provides an outlook.

2 Method Description

To evaluate machine translation from Chinese to English, we need to construct a machine translation model. Therefore, in section 2.1, we first introduce the model's design and initialization strategy. In section 2.2, we primarily discuss the data alignment augmentation method, aiming to further utilize the data to enhance the model's performance. Finally, we introduce the model's training strategy.

2.1 Model Design

Compared to the MOE model, dense models perform better in bilingual settings (Costa-jussà et al., 2022). Given that the WMT23 machine translation evaluation task has relatively limited corpora, in order to enhance the model's performance, we first pretrain a dense model. Then, we use this dense model to initialize the MOE model. The framework of the model is illustrated in the Figure 1.

We first employ a 6x6 Transformer-based encoder-decoder framework to train the dense model. We can then use the parameters of this pretrained model to initialize the MOE-based translation model. The difference between the dense model and the MoE model lies in the fact that some FFN layers are replaced with MoE layers (Lin et al., 2020), while the rest of the structure remains identical. Therefore, we can directly initialize the embedding, Self-Attention, and Cross-Attention using the dense model. As for the MoE layer, it has a routing module and multiple FFN layers of the same size. We take the FFN layer parameters from the corresponding layer in the dense model (Komatsuzaki et al., 2023), add noise to increase the diversity of the initializing parameters, and then use these noisy FFN layer parameters to initialize each FFN in the MoE layer one by one. For the routing module, we initialize it randomly.

Specifically, our model in this paper adopts three stages. First, we train a basic multilingual neural machine translation model using the Transformer model. Upon successfully training the multilingual machine translation model, we select all of its parameters to initialize the MoE model. We need to create multiple expert sub-networks, and each expert sub-network will replicate the parameters of the corresponding FFN layer.

Next, we use the MoE model for self-supervised learning. Self-supervised learning is an unsupervised learning method that generates its own labels. For the machine translation task, one method of self-supervised learning is to use the original language text as input and then predict its translation. We mask 35% of the input text at random on a per-line basis. Ultimately, we compare the predicted text with the original text, compute the loss, and then update the model parameters. Finally, we use the MoE model, which has undergone self-supervised learning, to initialize a new MoE machine translation model. The expert sub-networks of the new model will replicate the parameters of the self-supervised learning model (Koishekenov et al., 2023). We then continue to train the new model until it meets our performance criteria.

2.2 Training Strategy

We preprocess all the data, removing special characters and standardizing punctuation marks. We uniformly apply SentencePiece (spm) (Kudo and Richardson, 2018) tokenization and construct a unified vocabulary with a size of 32,000. Additionally, we use the fairseq tool (Ott et al., 2019) for binarization. During training and decoding, the vocabulary is shared. We chose the Transformer as the foundational architecture and made improvements upon it to train bilingual models, multilingual dense models, and multilingual MOE models. We uniformly divided the data into training and validation sets. Since there is no test set, the final results are evaluated on the validation set. The model employs Adam (Kingma and Ba, 2015) as the optimizer to update model parameters. Every 30k steps, the model's performance is evaluated using the validation set. We use Polynomial Decay to dynamically adjust the learning rate, with the basic idea being to gradually decrease the learning rate as training progresses. For the dense model, it is trained for 100k steps. For the self-supervised model, we initialize the MOE model parameters using the dense model. We set the number of experts to 32, frequency to 4, expert capacity size to 1.0, and train for 50k steps. For the MOE model, we initialize the MOE model parameters using the self-supervised model. We set the number of experts to 32, frequency to 4, expert capacity size to 1.0, and train for 70k steps. During decoding, we adopt the beam search strategy, and the evaluation metric used is sacrebleu (Post, 2018)

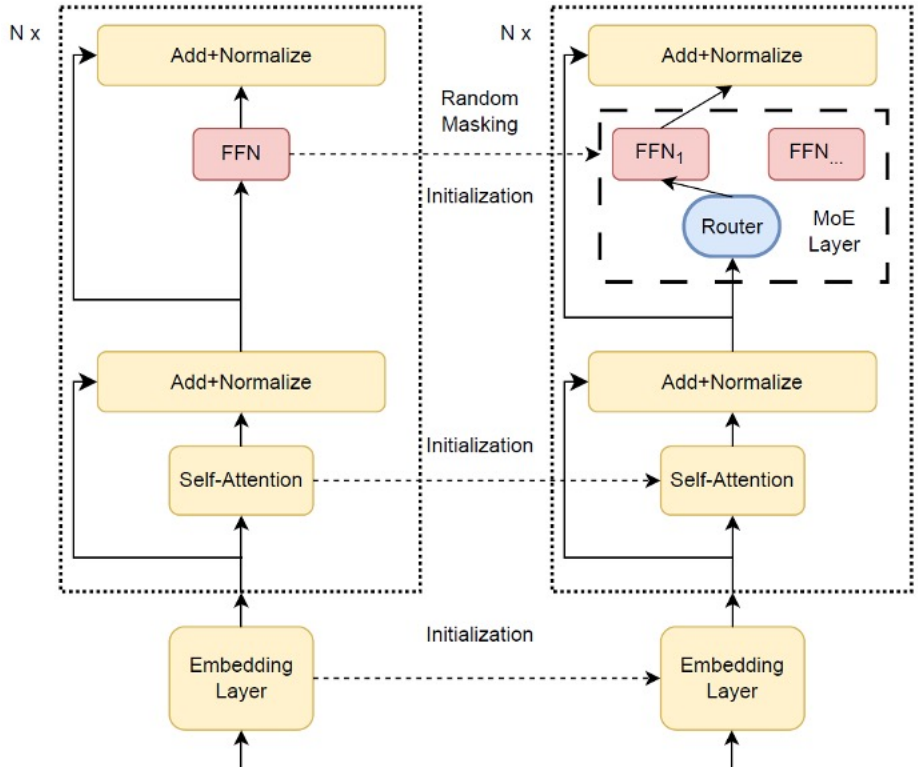

Figure 1: Taking the encoder as an example, the initialization process from the pretrained dense model to MOE is described. The process for the decoder is the same.

3 Experimental Results and Analysis

We first introduce the parameter settings of our trained models, and then analyze the experimental results.

Model	Dense-MOE	Dense
Test1	21.59	19.08
Test2	17.89	15.48

Table 1: Evaluation Results for Dense-MOE and Dense.

3.1 Setting

The model is improved upon fairseq (MoE version) [1]. The training precision is uniformly set to fp16. Both the encoder and decoder are set to 6 layers with 8 attention heads each. The word embedding size is 512, and the hidden layer size is 1024. The loss function used is the cross-entropy function, and the optimizer is Adam, with beta1 set to 0.9 and beta2 set to 0.98. During the pretraining phase, the learning rate is set to 2e-4. A polynomial learning rate scheduling strategy is employed to optimize the learning rate, with warmup set to 4000. Dropout is set to 0.1. Each batch has a maximum of 4096 tokens, and gradients are updated every 4 accumulated batches.

3.2 Experimental Results

For this evaluation task, we did not compare our system with the current state-of-the-art NMT systems. The reason is that the organizers fixed the training data and system configurations to ensure a fair comparison among all participants.We use the Test1 and Test2 provided by the organizers as evaluation targets.

In the experiments, we used sacrebleu as the evaluation metric. From Table 1, we can first observe that the method we employed in this paper achieved better performance compared to the dense model. After training, the dense model has already learned the basic patterns of the dataset. Using these parameters to initialize the MOE model allows the MOE model to start from a more optimal initial state, thereby converging quickly. Using the parameters of the dense model as initial values ensures that the MOE model has already grasped the basic features of the data at the onset of training. This provides a stable starting point for the MOE model, reducing the risks of instability and overfitting during training. Each expert in the MOE model can specifically handle certain distinct patterns or features in the

[1] https://github.com/facebookresearch/fairseq/tree/moe

data. By utilizing the pretrained dense model parameters, each expert in the MOE model can more rapidly identify its area of expertise, leading to a more efficient decomposition of model tasks. Even on the same dataset, due to its structural characteristics, the MOE model can capture more complex patterns in the data. With the initialization from the dense model's parameters, the MOE model can further optimize on this foundation, enhancing the model's expressive capability.

4 Conclusion

This paper introduces the main techniques and methods used for the WMT23 Chinese to English neural machine translation evaluation task. We employ a multilingual neural machine translation model based on the MOE Transformer framework. This model effectively achieves a vast and efficient parameterization. Moreover, given that it's a domain-specific translation task with limited translation data corpus, we utilized an effective strategy of initializing the MOE model using a dense model. This ensures that the MOE model has already grasped the fundamental features of the data at the start of training, providing a stable foundation for the MOE model and reducing the risks of instability and overfitting during training. Experimental results demonstrate that these methods can significantly improve the translation quality of neural machine translation.

Abstract

Currently, there is no usable machine translation system for Nko [1], a language spoken by tens of millions of people across multiple West African countries, which holds significant cultural and educational value. To address this issue, we present a set of tools, resources, and baseline results aimed towards the development of usable machine translation systems for Nko and other languages that do not currently have sufficiently large parallel text corpora available. (1) Fria||el: A novel collaborative parallel text curation software that incorporates quality control through copyedit-based workflows. (2) Expansion of the FLoRes-200 and NLLB-Seed corpora with 2,009 and 6,193 high-quality Nko translations in parallel with 204 and 40 other languages. (3) nicolingua-0005: A collection of trilingual and bilingual corpora with 130,850 parallel segments and monolingual corpora containing over 3 million Nko words. (4) Baseline bilingual and multilingual neural machine translation results with the best model scoring 30.83 English-Nko chrF++ on FLoRes-devtest.

1 Introduction

The Manding languages, including Bambara, Maninka, Mandinka, Dyula, and several others, are generally mutually intelligible and spoken by over 40 million people across West African countries including Mali, Guinea, Ivory Coast, Gambia, Burkina Faso, Sierra Leone, Senegal, Liberia, and Guinea-Bissau. Nko, which means 'I say' in all Manding languages, was developed as both the Manding literary standard language and a writing system by Soulemana Kanté in 1949 for the purpose of sustaining the strong oral tradition of Manding languages (Niane, 1974; Conde, 2017; Eberhard et al., 2023).[2] Nko thus serves a role for the Manding languages somewhat akin to Modern Standard Arabic for Arabic languages. It adequately transcribes their essential features such as vowel length, nasalization, and tone (Oyler, 2002; Conde, 2017; Donaldson, 2017) and enables the development of a shared literature.

Since its invention, the use of Nko has been growing. It is taught by literacy promotion associations, and used in newspapers, social media, and electronic communication (RFI, 2016; Rosenberg, 2011; Donaldson, 2019; Diane, 2022). Given that students learn best in their native language (Soh et al., 2021), Nko is particularly valuable for elementary native language education. Unfortunately, Nko and more generally West African languages remain marginalized in West African academic institutions (Kotey, 1975; Bryant, 2020). As a result, and despite the efforts of its courageous community, few academic resources are available in Nko.

Amongst numerous other benefits, computer-assisted translation could be used to facilitate the translation of academic content between Nko and other languages and facilitate projects such as Nko Wikipedia, which currently contains less than two thousand articles, in contrast with French and English Wikipedia with over 2 and 6 million articles respectively (Wikimedia, 2023). Unfortunately, to date, there isn't any usable machine translation (MT) system for Nko, in part due to the unavailability of large text corpora required by state-of-the-art neural machine translation (NMT) algorithms.

Nko is a representative case study of the broader issues that interfere with the goal of universal machine translation. Thousands of languages still don't have available or usable MT systems, mainly due to the unavailability of high-quality parallel text corpora. Recent corpora curation efforts have also resulted in sub-standard data quality for some languages. Some issues reported by (NLLB Team

*moussa@cs.stanford.edu

[1] Also spelled N'Ko, but speakers prefer the name Nko.

[2] ISO-639 code: nqo; ISO-15924 code: Nkoo.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 312–343
December 6–7, 2023.

et al., 2022) and others that we address in this work (see Section 3.3, and 3.6) could have been avoided with the use of an adequate parallel text corpus curation system, which did not previously exist.

This work aims to bootstrap the development of MT systems for Nko and, in the process, to contribute open-sourced resources and tools applicable to other languages. Our main contributions include:

Novel Parallel Text Curation Software. Our first contribution is Fria||el (pronounced Friallel), a cloud-based collaborative parallel text curation software that helps human translators orchestrate copy-editing processes resulting in high-quality corpora. Fria||el is presented in Section 2.

Extension of FLoRes-200 and NLLB-SEED. Our second contribution is the extension of FLoRes-200 and a multilingually aligned version of the NLLB-SEED (NLLB Team et al., 2022) corpora with high-quality Nko translations performed by Nko native speaker experts. Both FLoRes-200 and NLLB-SEED match our educational objective fairly well. Both are built over sentences drawn from Wikipedia, with NLLB-SEED, in particular, covering various fields of human knowledge and activity. They are therefore more diverse than other common parallel texts, such as religious texts.

Language Resource from the Nko Community. Our third contribution is the *nicolingua-0005* corpus, a collection of mono-, bi-, and trilingual corpora curated from data files donated by Baba Mamadi Diané, Solo Farabado Cissé, Djibrila Diané, Nafadji Sory Condé, and Kalo Mory Diané.

Baseline Machine Translation Results. Our fourth and last contribution consists of baseline NMT experiments from English, French, and Bambara transcribed in Latin script to Nko and vice versa. We present bilingual and multilingual transformer-based NMT systems (Vaswani et al., 2017) built using the fairseq toolkit (Ott et al., 2019). At present, results remain quite modest, with the best *eng_Latn* → *nqo_Nkoo* system scoring 30.83 chrF++ on FLoRes-devtest.

All presented software and tools have been publicly released to facilitate further progress on machine translation for Nko and other languages.[3]

2 Fria||el: Collaborative Parallel Corpus Curation System

Recent efforts on collecting multilingual parallel corpora involved sets of data file exchange between various translation teams (Federmann et al., 2022). This process is error-prone as it doesn't allow the systematic tracking of individual corpus entries through a curation quality process. Other recent similar efforts such as NLLB-SEED (NLLB Team et al., 2022), unnecessarily resulted in bi-text data rather than the intended multi-text because the reference files ended up being modified and re-ordered by various translation teams (see Section 3.3). Adequate software could have helped avoid such issues.

We propose Fria||el, a collaborative system designed to help distributed translation teams produce large multilingually aligned high-quality parallel text corpora. The system design particularly emphasizes suitability for use in various contexts, supporting web and mobile device usage and use in an offline mode. Its design goals include: itemized curation, automatic work organization, collaborative copyediting, and localization to translators' preferred user-interface language and preferred source languages to translate from (Figure 1).

2.1 Previous Tools and Multilingual Parallel Corpora Creation Processes

Masakhane Similarly to (Nekoto et al., 2020), this work is an effort towards African language technology development. Our work is participatory in the sense that we are a diverse team of computer scientists, linguists, and native speakers of Nko and other West African languages. We expect that our approach, and the parallel text curation software we release with this paper, Fria||el, will be valuable for MT technology development for other languages.

ParaText ParaText (SIL International & United Bible Societies, 2023) is specialized software for Bible translation projects. Its features include team management, task assignments, notes, collaborative document editing, multilingual dictionaries, and various biblical resources. It also allows a side-by-side comparison of biblical passages from various sources or in various languages. Paratext is not suited for general-purpose parallel corpus curation for MT. There is no indication that ParaText or any such software was used in the curation process of recent multilingual parallel corpora such as NLLB-SEED, FLoRes-200, and NTREX-128.

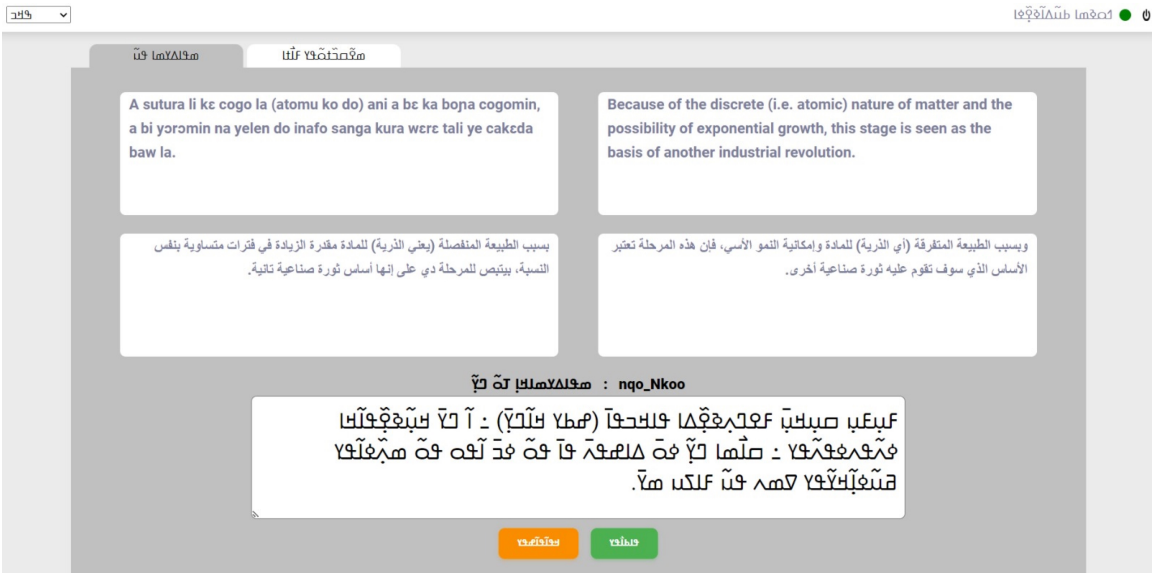

Figure 1: Fria||el's user interface for a Nko translator simultaneously inspecting multiple parallel variants of the same segment from the Multitext-NLLB-SEED corpus. All labels are localized to Nko. The source language fields are also localized to their own language's writing direction: LTR for Bambara in Latin script and English; and RTL for Moroccan Arabic and Egyptian Arabic. The translated text is localized to Nko's writing direction (RTL).

NLLB-SEED and FLoRes-200 The curation process of FLoRes-200 involved teams of translators and reviewers who underwent a vetting process. The QA team reviewed a 20% subset of data files with 3000 entries produced by translation teams. Data files falling below the 90% quality threshold were returned for rework. NLLB-SEED underwent a less rigorous quality control process. The curation process was English-centric. Translators were required to be proficient in English. Translation to the majority of languages was also done from English, with the following exceptions: In NLLB-SEED, Ligurian, was translated from Italian, In FLoRes-200, some Arabic languages were translated from Modern Standard Arabic. As noted by the authors, there are qualified translators who may not speak English, and several languages may be easier to translate from non-English sources.

NTREX-128 NTREX-128 (Federmann et al., 2022) was curated as follows. The English reference file was sent to a translation provider that produced translations. Source-based direct assessment was performed on the translated files by a different provider using the Appraise platform (Federmann, 2018) to generate segment-level quality scores. Segments with a score below a specified threshold were returned for correction. The translation process and quality control method of the translation provider were not specified.

Fria||el is a collaborative parallel text curation software system that tracks individual segments through a translation and copyedit workflow. Each segment is translated by one translator, and subsequently sequentially copyedited by other translators. Fria||el allows translators to simultaneously inspect variants of the source segment in multiple languages. This results in segments translated and copyedited in the context of different subsets of source languages. In addition to the final parallel corpus, Fria||el also yields copyedit logs, which could be valuable in various modeling scenarios.

2.2 Design Goals

Fria||el was designed with the following goals:

Itemized Curation Each corpus segment is individually tracked through the curation process in which it is translated to the target language and subsequently reviewed and copyedited several times.

Automatic Task Assignments Translation and copyediting tasks are automatically assigned to translators with fixed lease periods. Uncompleted tasks are automatically reassigned upon expiration.

Collaborative Copyediting Each segment is translated once and copyedited two or three times, following the workflow in Figure 2. Segments for which the first or second verification results in edits are copyedited a third time. A given translator can only perform a task on a given segment once.

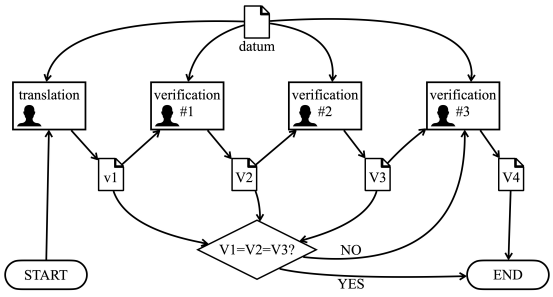

Figure 2: Translation workflow for a multilingual segment (datum). The initial translation (*v1*) is approved or copyedited by two other translators (*v2*) and (*v3*). If any copyediting occurs, a third copyediting task is assigned to a fourth translator who either approves the current translation or performs a final copyedit (*v4*).

Multilingual Sources While performing translation and copyediting tasks, translators can simultaneously inspect segments in several languages configured according to their preferences.

Machine-Generated Sources Datasets can be augmented with additional machine-generated variants of segments such as machine translations, transliterations, and detransliterations.

Responsive Web Design Fria||el is a web application that automatically adapts the layout of its component to the user's screen size. This makes it usable on desktop and laptop computers as well as on mobile phones and tablets.

Resilience to Connectivity Disruptions Translators who temporarily lose their internet connectivity can seamlessly keep working offline on their currently assigned translation and verification tasks. Their work is automatically synchronized with the central database when their connectivity is restored.

Internationalization and Localization Fria||el is internationalized (i18n) in that all user-facing strings are externalized into a translatable resource file, and the writing direction and text alignment of translation source and target languages are configurable. As a result, the user interface is localized (L10n) to the translator's preferred user-interface language, and to each source language (Figure 1).

2.3 Software Components

This section provides details on Fria||el's software components that collectively realize the design goals specified in Section 2.2.

2.3.1 Workflow Manager

Both the Workflow and Task Managers are implemented as Firebase cloud functions that are triggered at fixed time intervals. A workflow entity is inserted for each parallel segment with an initial *active* state. The Workflow Manager periodically inspects workflow entities and (1) creates the next task if needed, and per the workflow management rules, (2) moves the workflow to the *completed* status if all related tasks have been completed and there is no need to create additional tasks or (3) nothing, if the workflow has an uncompleted task.

2.3.2 Task Manager

When triggered, the Task Manager revokes all expired task assignments and assigns unassigned translation and copyedit tasks to users according to their roles. The maximum number of tasks assigned to each user is fixed. A given user is never assigned a task related to a segment on which they have previously completed a task. The Task Manager also ensures that a copyedit task is only assigned to a user with the appropriate verification skill level (*L1*, *L2*, or *L3*) for the first, second, and third copyedit rounds. Each translator account is configured with specific verification skill levels.

2.3.3 Data Model and Storage

Google Firestore, a document-oriented NoSQL database, is used for data storage. The central application database is accessed by data import/export scripts, the WorkflowManager, the Task Manager, and the user interface. It contains the following collections of documents:

datasets: One collection per imported dataset. Each document represents a multilingual segment and contains all available translations of the segment, each annotated with its language and writing system. See Figure 10.

workflows: Each document represents a prioritized workflow entity. The WorkflowManager (Section 2.3.1) periodically inspects workflow entities by priority order and creates task entities as per the workflow management logic.

annotation-tasks: Each document is a task of a specific type (translation or copyedit) related to a specific multilingual segment. Each task has a status (unassigned, assigned, completed). Tasks are assigned to translators by the Task Manager.

users: Each document represents a translator and specifies whether they can be assigned translation (*isActiveTranslator*) and copyedit (*isActiveV-*

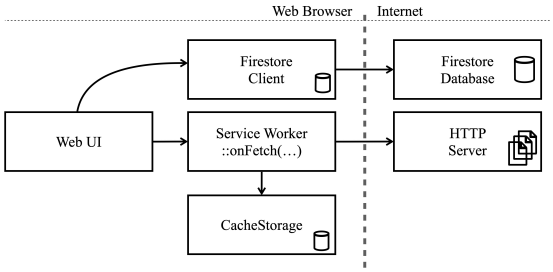

Figure 3: The software uses Firestore's client library's offline mechanism and *cached-aside* HTTP resources to be resilient to intermittent internet disruptions.

erifier) tasks. Translator documents also store the source languages the translator prefers to translate from, subject to availability in the source corpus. User documents also specify a *verifierLevel*, which indicates the maximum copyediting round the translator can participate in for a specific segment.

config: Contains language writing direction configuration. Languages are assumed to be left-to-right unless explicitly marked right-to-left.

2.3.4 User Interface

The user interface is a responsive web application that is usable on a variety of devices, including mobile phones, tablets, desktops, and laptops (Figure 1). It directs authenticated translators to their workspace where they can perform translation (first tab) and copyediting (second tab) tasks that are assigned to them. The task assignment process is transparent to translators. One task is displayed at a time. The prioritized list of tasks assigned to the current translator is kept in a cache for resilience to intermittent internet disruptions. The connection status is indicated by the green circle (top-right).

When performing translation tasks, translators simultaneously inspect the source segment in several languages (top four text fields) and write a translation in the target language text field (bottom). When the 'submit' button (green) is selected, the translation is recorded and the next task is displayed. Translators can also skip the current task by selecting the 'skip' button (orange). When performing copyediting tasks, the bottom text field is initialized with the latest version of the translated segment (Figure 2). The translator may leave the translation intact or copyedit it before submitting.

2.3.5 Offline Mode

The software is a web application designed to be resilient to intermittent internet disruptions. This is achieved with Google Firebase's client library (Google, 2023), which supports offline read and write operations by leveraging a client-side *eventually consistent* (Burckhardt et al., 2014) LRU cache, and *cached-aside* (Pamula et al., 2014) HTTP resources, implemented with two web APIs supported by the majority of web browsers: CacheStorage and ServiceWorker (w3.org, 2022; Mozilla, 2023b,a). After the initial loading of the web application in a web browser, a ServiceWorker is registered to intercept HTTP fetch events. If the remote web server is reachable, the ServiceWorker fetches remote HTTP resources (e.g., HTML, CSS, javascript, image files) and stores them in a CacheStorage before returning them to the caller; otherwise, cached resources are served. The entire process is transparent to the user. See Fig 3.

2.3.6 Translator Copyedit Logs

In addition to the final version of the translated segments, the data Fria||el also outputs their initial translation (*v1*), and the versions of the same entries after the first, second, and third copyediting rounds (*v2*, *v3*, *v4*) – see the workflow in Figure 2. Copyediting logs can be valuable in developing language and machine translation models.

2.3.7 Data Import and Export

Fria||el includes the following administrative Python scripts for importing and exporting parallel corpora and other reports. `load_dataset.py` imports a new parallel corpus from its original data files. Pre-processing may be required to adapt to various original dataset formats. `create_translation_workflows.py` creates active translation workflows for an imported dataset. `system_report.py` displays the number of workflows and tasks by status by dataset. `export_dataset.py` exports translations and translator edits for a curated dataset in a csv file. Post-processing may be required to adapt to a desired format. `accounting_statements.py` generate completed tasks by user by dataset by month. This data can be imported into an accounting system to generate payroll for translators.

2.4 Qualitative User Study

Nko translators used Fria||el to translate FLoRes-200 (dev, devtest) and Multitext-NLLB-SEED to nqo_Nkoo, and to copyedit each segment two or three times. The following sections present an analysis of their responses to a survey questionnaire

(Figure 6). Quantitative measures on their copy-editing logs are also discussed in Section 2.4.6.

2.4.1 Usability

Nko translators praised the simplicity of the user interface. They appreciated the automatically organized itemized copyediting-based data curation process. They highlighted the localization features, particularly, the fact that the user-interface is available in Nko and that the presentation was adequate for both right-to-left and left-to-right source languages and the target language. They valued the offline functionality that allowed them to temporarily continue working without an internet connection. Furthermore, they found the task counters displayed on the user-interface helpful. They noted two usability-related limitations: First, it was not possible to directly go back to a task after submitting it. Second, although the software allowed them to continue working offline, it did not allow them to perform the initial authentication while offline.

2.4.2 Translation Process

Nko translators found the fact that source segments were visible in multiple languages beneficial. They said that the ability to inspect the same segment in multiple languages facilitated its translation to Nko. They also mentioned that the itemized translation tasks, which presented one segment at a time, decreased the likelihood of translation mistakes.

An improvement they requested is the addition of a translation memory including dictionary entries and previously translated expressions.

2.4.3 Copyediting Process

Nko translators found Fria||el's multi-pass copy-editing process effective for finding and correcting translation mistakes. They mentioned that the fact that segments were consecutively assigned to different translators for copyediting led to higher-quality translations as it is easy to overlook one's own mistakes. Because each translator had a different translation source language configuration, Nko segments were translated from and copyedited against their versions in different sets of languages, which Nko translators found enriching.

2.4.4 Mistranslations

Types of mistranslations Nko translators noted during the copyediting process included typos, omitted words, grammatical errors, incorrect word sense translations, incorrect translations of named entities, and punctuation errors. They noted that word sense was sometimes hard to disambiguate without the full context of segments. For instance, the English word *state* maps to different Nko words based on the sense of the word (political community vs. a particular condition of a person, place, or thing). They also noted punctuation errors, particularly the use of the Arabic comma (U+060C) instead of the Nko comma (U+07F8), and spacing around that punctuation. Finally, they reported that translators using different source languages would sometimes disagree on named entity translations.

2.4.5 Disagreements

Nko translators reported few disagreements on language standards. They also reported using existing English-Nko and French-Nko dictionaries for consistency. During the translation of FLoRes-200, NLLB-SEED to Nko, translators participated in weekly team meetings and routinely consulted each other over video conferences and phone calls. They deferred the few cases of disagreement and perplexing questions to the most senior translator.

2.4.6 Copyediting Metrics

Table 1 summarizes the size of the translated corpora in segments and Nko words, as well as the percentage of segments that were edited in each verification round, and the related edit magnitudes, computed as edit distances. The number of edited segments and related edit magnitudes generally decreased as copy-editing rounds progressed.

3 Nko Corpora for Machine Translation

This section discusses the extension of FLoRes-200 and NLLB-SEED to Nko, which included the multilingual alignment of NLLB-SEED, and the use of Fria||el to translate those corpora to Nko. This section also introduces *nicolingua-0005*, a collection of monolingual corpora and bi- and trilingual parallel corpora donated by Nko community members.

3.1 Translation of FLoRes-200 and NLLB-Seed to Nko

Nko native speaker experts Baba Mamadi Diané, Solo Farabado Cissé, and Djibrila Diané, used Fria||el to translate Multitext-NLLB-SEED, FLoRes-dev, and FLoRes-devtest to Nko. They worked from Cairo (Egypt), Banankoro (Guinea), and New York (USA), and with the rest of the team, participated in weekly video conference meetings.

corpus	segments	words	$v1 \rightarrow v2$ edited	$v1 \rightarrow v2$ edit distance	$v2 \rightarrow v3$ edited	$v2 \rightarrow v3$ edit distance	$v3 \rightarrow v4$ edited	$v3 \rightarrow v4$ edit distance
FLoRes-dev	997	27,361	83%	38.75 ± 1.55	67%	50.48 ± 2.10	71%	11.74 ± 0.65
FLoRes-devtest	1,012	29,503	87%	61.74 ± 1.81	93%	9.69 ± 0.64	24%	2.79 ± 0.15
NLLB-SEED	6,193	184,138	48%	45.97 ± 1.11	35%	38.94 ± 1.16	35%	11.96 ± 0.48

Table 1: Percentage of edited Nko segments, and related mean± standard error of edit magnitudes (edit distance) resulting from the translation of FLoRes-dev, FLoRes-devtest, NLLB-SEED to Nko

3.2 Translation Process

The initial translations of FLoRes-dev, which our translators performed using spreadsheets, were imported into Fria||el after our software engineers completed its development. The copyediting tasks for FLoRes-dev, and the translation and copyediting tasks for FLoRes-devtest and Multitext-NLLB-SEED were entirely performed using Fria||el. The system was designed not to allow translators to copyedit their own translations or previous copyedits. This constraint made the proposed translation workflow impossible given the size of our team of translators. As a workaround, an additional user account was created for the two most experienced translators to allow third copyediting rounds.

Each segment was translated once and copyedited two or three times. The resulting curated Nko data files are summarized in Table 2. The multilingually aligned NLLB-SEED dataset (Multitext-NLLB-SEED), FLoRes-dev, and FLoRes-devtest, all extended with Nko translations along with copyedit logs, collectively make up common-parallel-corpora ver. 2023-06-19 summarized in Table 3.

3.3 Multilingual Alignment of NLLB-SEED

The original NLLB-SEED dataset consists of pairwise parallel corpora between English and each other language but suffers from the complication that many of the source English sides are slightly different from each other, variously due to minor copyediting, and reordered and added entries.

Multitext-NLLB-SEED is a multilingually aligned version of NLLB-SEED that fixes this limitation. It was created as follows: A consensus *eng_Latn* reference file was manually edited by human comparison of all existing reference *eng_Latn* files. The lines of each *eng_Latn* file were matched (binary assignment matrix $M_{i,j}$) to the lines of the consensus *eng_Latn* file by minimizing the sum of the edit distances $E_{i,j}$ between matched lines (Equation 1). The optimal

Translations		
lines	words	file
6193	184138	SEED/nqo_Nkoo

Table 2: Extensions of FLoRes-200 (dev, devtest) and Multitext-NLLB-SEED to Nko. The *nqo_Nkoo* data files are parallel with 40 other languages in NLLB-SEED, and 204 other languages in FLoRes-200. FLoRes-test, which is not publicly available, was not translated.

CPC subset	lines	langs.	tr. edits langs.
Multitext-NLLB-SEED	6193	41	1
FLoRes-dev	997	205	1
FLoRes-devtest	1012	205	1

Table 3: Summary of common-parallel-corpora version 2023-06-19. All entries are parallel across all languages. Translator edits are only available for nqo_Nkoo.

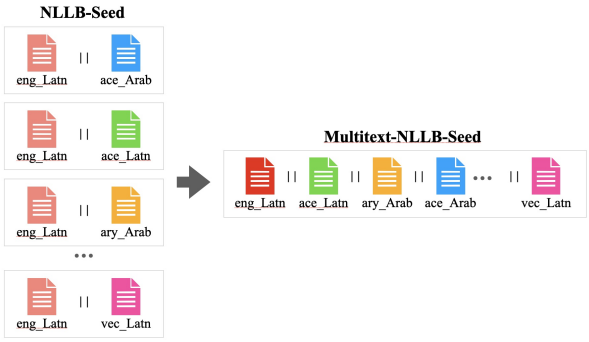

Figure 4: Multitext-NLLB-SEED is a multilingually aligned version of the original NLLB-SEED dataset.

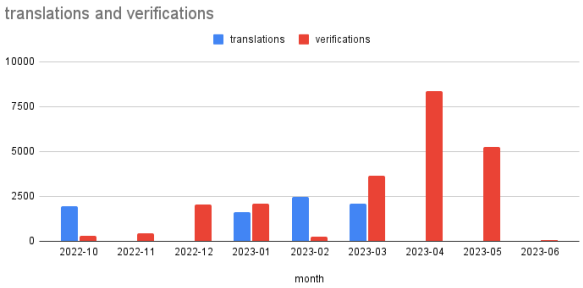

Figure 5: From October 2022 to June 2023, 8,202 translations and 22,426 verifications/edits were performed to produce high-quality translations of FLoRes-200 and Multitext-NLLB-SEED to Nko.

line matching M^*, obtained using the scipy package (Virtanen et al., 2020), was used to re-order each non-English language file to match the order of the consensus *eng_Latn* file. Two unmatched lines from (*eng_Latn*, *kas_Deva*) and one from (*eng_Latn*, *lij_Latn*) were discarded.

$$M^* = \arg\min_{M} \sum_{i,j} M_{i,j} E_{i,j} \quad (1)$$

The resulting re-ordered non-English language files and the consensus eng_Latn file constitute the Multitext-NLLB-SEED corpus, containing 40 parallel language files; see Figure 4. Multitext-NLLB-SEED was loaded in Fria||el in lieu of the original NLLB-SEED corpus, enabling translators to inspect each segment in multiple languages, and resulting in an expanded multilingually aligned corpus.

3.4 Translation Source Languages

Source languages were configured in Fria||el according to the preferences of each translator. Collectively, they translated from *fra_Latn*, *eng_Latn*, *ary_Arab*, *arz_Arab*, and *bam_Latn*. Note that *fra_Latn* is not available in NLLB-SEED. *bam_Nkoo* was detransliterated from *bam_Latn* using a neural detransliterator (Doumbouya, 2022); however, translators did not find this source useful and preferred not to enable it in their configuration.

3.5 Further Notes on Manding languages

Nko was developed as a standardized form of the Manding languages. The aim was a standardized language and writing system, which could serve a similar role to Modern Standard Arabic with respect to various regional Arabic languages. Manding languages, which include Mandinka and Bambara, are a subgroup of the Mande language family and are generally mutually intelligible to speakers. Bambara, written in a Latin script, is currently the best-supported Manding language, available in Google Translate and in NLLB-SEED. Our Nko translators are also fluent in Bambara.

3.6 Quality of bam_Latn in NLLB-SEED

Our Nko translators noted the following quality issues with NLLB-SEED's *bam_Latn* data: (1) The data contains too much French vocabulary not enough Manding vocabulary. (2) Some entries do not match their English counterpart at all. (3) Some entries are entirely in French; examples are shown in Figure 11. (4) The *bam_Latn* data completely lacks tonal marks, which are important in Manding languages (e.g., many nouns are indistinguishable without tonal marks, such as *bird*, *belly*, *inside*; the definite and indefinite inflections of nouns cannot be distinguished without tonal marks (*I saw a person* vs. *I did not see any person*); and nouns that can be used as a verb and their verb form cannot be distinguished (*get out!* vs. *to get out*). *bam_Nkoo*, detransliterated from *bam_Latn* was included in the corpus; however, some Nko translators did not find it useful and preferred to not enable it as a source.

3.7 *nicolingua-0005* Corpus

nicolingua-0005 is curated from files donated by Nko community members for the purpose of developing machine translation for Nko. It is comprised of 3.9 million Nko words with 25K (Nko, English, French) parallel segments, 59K (Nko, English) parallel segments, 45K (Nko, French) parallel segments, and a monolingual corpus of 3.3 million Nko words. Included datasets were curated from files provided by Baba Mamadi Diané, Solo Farabado Cissé, Djibrila Diané, Nafadji Sory

type	languages	segments	nqo words
trilingual	*nqo_Nkoo*, *eng_Latn*, *fra_Latn*	25 848	256 934
bilingual	*nqo_Nkoo*, *eng_Latn*	59 442	283 279
bilingual	*nqo_Nkoo*, *fra_Latn*	45 560	129 789
monolingual	*nqo_Nkoo*	N/A	3 291 371
total		130 850	3 961 373

Table 4: Summary of *nicolingua-0005*

Condé, and Kalo Mory Diané. See Table 4 and Appendix D for more details on the constitution of the corpus. A datasheet questionnaire based on (Costa-jussà et al., 2020) is presented in Appendix E.

4 Baseline Machine Translation Experiments

This section describes Transformer (Vaswani et al., 2017) based encoder-decoder neural machine translation models built using the fairseq toolkit (Ott et al., 2019). Both bilingual and multilingual translation models are explored. At present, results remain quite modest, with the best model achieving a 30.83 *eng_Latn* → *nqo_Nkoo* chrF++ score on the CPC/FLoRes-devtest corpus.

Eight models were trained: The bilingual unidirectional models 200.11 and 200.16, the multilingual model 201.16, and its variant that is trained to also autoencode Nko segments 202.16, and Models 206.19, 207.19, 208.19 and 209.19, which explore three different ways of specifying language tokens.

4.1 Datasets

common-parallel-corpora (CPC) and *nicolingua-0005*, described in Section 3 are used to build baseline NMT models for the following translation directions: *nqo_Nkoo* ⇄ *eng_Latn*, *nqo_Nkoo* ⇄ *fra_Latn*, and *nqo_Nkoo* ⇄ *bam_Latn*. The subsets of those corpora used to train, validate, and test the models are specified in Tables 11 and 12.

4.2 Tokenization

Byte-pair encoding (BPE) (Sennrich et al., 2016) is employed to perform sub-word tokenization. In each training experiment, the BPE model is trained on a token corpus constructed by concatenating all data files containing the languages of interest in the training set. In all cases, the BPE model is trained to produce 15K sub-word units.

4.3 Models

Eight models were trained. The first two, 200.11 and 200.16, are unidirectional bilingual *nqo_Nkoo* ⇄ *eng_Latn* models. The last six, 201.16, 202.16, 206.19, 207.19, 208.19, and 208.19 are multilingual *nqo_Nkoo* ⇄ *eng_Latn*, *nqo_Nkoo* ⇄ *fra_Latn*, and *nqo_Nkoo* ⇄ *bam_Latn* models.

4.3.1 Bilingual Models

200.11 is the baseline bilingual *nqo* ← *eng* model. 200.16 differs from 200.11 in terms of model architecture and hyper-parameters. 200.16 and the multilingual models 201.16 and 202.16 have identical architectures and training hyper-parameters.

Model 200.11 is a Transformer-based (Vaswani et al., 2017) encoder-decoder sequence-to-sequence model consisting of 5 encoder and 5 decoder layers, each with a 512-dimensional token embeddings and 2048-dimensional feed-forward networks, 2 attention heads per layer, and a layer normalization module before each layer. Its architecture and training hyper-parameters are identical to the baseline system of the AmericasNLP 2021 Shared Task on Open Machine Translation (Mager et al., 2021), except for the following differences: (1) encoder and decoder embeddings are not shared, (2) Subword Regularization (Kudo, 2018) and BPE-dropout (Provilkov et al., 2020) are not employed in BPE tokenizer training, (3) larger batches are employed during training, (4) gradient clipping is applied during training.

Model 200.16 This model is only different from 200.11 in that it is deeper (6 encoder layers and 6 decoder layers), and that it is trained with a higher token dropout probability (0.6 instead of 0.4).

4.3.2 Multilingual Models

Our multilingual models are trained on parallel corpora obtained by concatenating all available (*nqo* ⇄ *eng*, *nqo* ⇄ *fra*, *nqo* ⇄ *bam*) bitext and prefixing the source segments with language tokens as introduced by (Johnson et al., 2017). Similarly to (Wicks and Duh, 2022), models 206.19, 207.19, 208.19, and 209.19 compare the effect of various approaches to constructing source-side prefixes.

Model 201.16 is the baseline multilingual model. It has the same architecture and training hyperparameters as the bilingual model 200.16, but it is trained on multilingual data and it employs target language token prefixes (Table 5).

Model 202.16 employs target language tokens just like 201.16, but its training set also contains *nqo* → *nqo* pairs where each side is the same sentence from monolingual Nko corpora in *nicolingua-*

model	prefix
200.11 200.16	(none)
201.16 202.16 206.19	<to_tgt_Lang>
207.19	<from_src_Lang> <to_tgt_Lang>
208.19	<from> <src_Lang> <to> <tgt_Lang>
209.19	<from_src_Lang_to_tgt_Lang>

Table 5: Specification of source sequence language token prefixes used in our multilingual translation models.

0005. Consequently, 202.16 performs simultaneous multilingual translation and monolingual sequence autoencoding. Positive results from such a strategy were found in (Luong et al., 2016).

Models 20x.19 also perform simultaneous translation and monolingual sequence auto-encoding. However, their architecture is different from 202.16, and they explore different language token prefixing strategies. Compared to 202.16 models, in 20x.19 models, the encoder and decoder layers use 8 attention heads instead of 2. Also, the encoder's input embeddings and the decoder's input and output embeddings are all shared. Finally, the source and target token dictionaries are also shared.

Models 20x.19 explore four approaches of source-side prefix specification (Table 5). As an example, a source segment to be translated from English to Nko is prefixed as follows per model:
206.19: "<to_nqo_Nkoo> "
207.19: "<from_eng_Latn> <to_nqo_Nkoo> "
208.19: "<from> <eng_Latn> <to> <nqo_Nkoo> "
209.19: "<from><eng_Latn><to><nqo_Nkoo> "

4.4 Training

During training, dropout is used with the following probabilities: input token embedding dropout 0.4 (xxx.11) or 0.6 (xxx.16, xxx.19), attention dropout 0.2, ReLU dropout 0.2. The label-smoothed cross-entropy loss function is used with a smoothing rate of 0.2. Optimization is performed using Adam with a weight decay of 0.0001. The inverse squared root learning rate scheduler is used with an initial rate of 1e-7 and 4000 warm-up updates. Gradient clipping is employed with a norm threshold of 1. Effective batches of up to 65,536 tokens are used to train all models. Gradients are accumulated for 1 batch of up 65,536 tokens on A100 GPUs and 4 batches of up to 16384 on Titan XP GPUs before each update.

4.5 Model Selection and Stopping Criteria

Trainings are stopped when BLEU scores on the validation step do not improve after 20K gradient updates. Checkpoints with the highest BLEU scores on the validation set are selected. The average BLEU score across all supported translation directions is used for multilingual model selection.

4.6 Evaluation

CPC/FLoRes-dev and CPC/FLoRes-devtest are respectively used as validation and test sets. For each model, their subsets with languages of interest are considered (see Tables 12 and 11). The chrF++ score, which has been shown to align well with human assessments, especially for morphologically rich languages (Popović, 2017), is used as the main evaluation metric. The Sacre BLEU library (Post, 2018) is used to compute BLEU and chrF++ scores.

4.7 Results

Table 6 shows the test and validation BLEU and chrF++ scores for each model and supported translation direction. The best performing model 208.19 scores 26.00 mean chrF++ on the test set.

Layer Count and Regularization: Compared to 200.11, 200.16 with one extra encoder and decoder layer, and a higher token embedding dropout rate, scored $+0.34$ *nqo* $\leftarrow$ *eng* chrF++.

Multilinguality: Compared to 200.16, the multilingual model 201.16, which has the same architecture and training hyperparameters, scored -0.92 *nqo* $\leftarrow$ *eng* chrF++.

Monolingual Autoencoding: Compared to 201.16, 202.16, which performs simultaneous multilingual translation and monolingual autoencoding, scored $+0.14$ *nqo* $\leftarrow$ *eng* chrF++

Attention Heads and Shared Embeddings: Compared to 202.16, 206.19 which uses 8 attention heads in the encoder and decoder layers, and which shares all input and output embeddings and dictionaries scores $+1.59$ mean chrF++.

Language Token Prefixing: Compared to 206.19, which only specifies target language tokens in the source sequence, 207.19, which specifies the source and target languages as two separate tokens, scored $+0.08$ mean chrF++. 209.19, which specifies the source and target languages as a single

token, scored +0.06 mean chrF++. 208.19, which specifies the source and target languages in a four-token clause scored +0.15 mean chrF++.

5 Discussions

5.1 Fria||el

Improving Usability: As noted by Nko translators, the usability of Fria||el could be improved by: (1) Allowing translators to review their recently submitted tasks before the Workflow Manager proceeds to the next stage of the curation process. (2) Implementing an offline authentication mechanism.

Adding a Translation Memory: Adding a translation memory could increase the productivity, accuracy, and consistency of translators. However, the effect of such a tool on the general quality of translations, including the diversity of synonyms and expression styles should not be overlooked.

Extensibility: Alternate copyediting workflows can be implemented in Fria||el by extending the Workflow Manager and Task Manager. The task presentation user interface can also be adapted to other text curation tasks, such as syntax annotation.

5.2 Parallel Corpora

Handling Short Sequences: The segments in *nicolingua-0005* are, on average, significantly shorter than those in FLoRes and NLLB-SEED. Despite being short, sequences such as ones from the Nko-Français dictionary and Unicode CLDR files, are too valuable to discard. To prevent biasing models towards shorter sequence lengths, we repeated the *(nqo_Nkoo, eng_Latn)* data from CPC/NLLB-SEED five times in the training set. A more principled approach should be considered.

Punctuations, Case and Diacritical Marks: Our models showed sensitivity to minor changes in Latin case, and punctuation as well as Nko diacritical marks (see Appendix G). Including augmented data with lowered case and stripped punctuation and diacritical marks in source sequences in the training corpora may help address this issue.

Learning from Translator Edits: Translator edits, as recorded by Fria||el throughout the copy-edit process, could be useful for various modeling and quality estimation tasks. This data could also be used for an auxiliary copy-edit reconstruction task that may improve the accuracy of a multitask NMT

		Intl. BLEU		chrF++

model. Finally, translator edit data can be used to train and align translators on consistency standards.

5.3 Neural Machine Translation

Tokenization: Subword regularization, as discussed in (Kudo, 2018) and the dropout-based approach presented by (Provilkov et al., 2020), may lead to increased translation performance for Nko.

Language Token Prefixes: The choice of source-side prefixing strategy had a marginal impact on translation accuracy. Our best model employs a four-token prefix, consisting of source and target language tokens joined with the '<from>' and '<to>' tokens. Our results and those of (Wicks and Duh, 2022), suggest that the specification of translation directions as source-side prefixes in multilingual NMT models merits further investigation.

Learning from Monolingual Data: The use of monolingual Nko data in 202.16 led to marginal improvements in most translation directions. Additional unsupervised tasks such as masked language modeling and denoising should also be explored.

Data Augmentation: Back-translation-based data augmentation, and the generalized data augmentation method in (Xia et al., 2019) could significantly increase NMT performance for Nko.

International BLEU Our BLEU scores are computed with sacreBLEU using international tokenization because sacreBLEU's current default tokenizer (v13a) is inappropriate for Nko; it doesn't properly interpret the Nko Unicode block, particularly its punctuations, to detect word boundaries.

BLEU vs chrF++ The BLEU scores of our models are rather low. This was surprising given the training data size and given Nko translators' feedback on generated translations. This observation is in line with (Popović, 2017)'s hypothesis that chrF++ correlates better with human judgment than BLEU for morphologically rich languages.

6 Conclusion

This work presented Fria||el, a collaborative parallel text curation system with copyediting-based quality workflows. Fria||el enabled the extension of existing multilingual corpora, FLoRes-200 and NLLB-SEED with high-quality Nko translations. Those, and a new corpus we introduced, *nicolingua-0005*, served to build baseline bilingual and multilingual NMT systems for Nko, with the best model achieving the accuracy of 30.84 *eng_Latn* → *nqo_Nkoo* chrF++. We have released Fria||el to facilitate the development and extension of multilingual parallel corpora to more languages. We have also released resources and tools to enable the reproducibility of our results, and further progress towards usable MT systems for Nko.

Acknowledgements

Sources of support that made this project possible include: A generous unrestricted research gift from Meta Platforms, Inc., the Stanford Graduate Fellowship (SGF), the Stanford Natural Language Processing (NLP) group, FriaSoft, and Nko USA Inc. We extend our deep gratitude to FriaSoft for selflessly donating numerous software engineering hours and to Nko USA Inc. for providing Nko language expertise and resources. The commitment of Nko USA Inc. and FriaSoft to advancing West African language technology was instrumental in realizing this project. We thanks to John Hewitt and Tolúlọpẹ́ Ògúnrèmí for giving invaluable feedback. We are grateful to Asmaou Diallo, Nantenin Camara, Koulako Camara, Moussa Thomas Doumbouya, and Ibrahima Doumbouya for creating a supportive environment conducive to the execution of portions of this work in Conakry, Fria, and Boké.

Appendices

A Fria||el User Study Feedback Questionnaire

The feedback questionnaire sent to N'Ko translators appears in Figure 6.

Parallel Data Curation Software Feedback

1. Usability of the software
    a. Is the software useful? Why?
    b. What are your favorite features of the software?
    c. What are some improvements that would make the software better?
2. Translation
    a. Did the software make the translation effort easier? How?
    b. How does the software compare to previous systems you used for translation?
    c. What are some difficulties that you encountered when performing translation tasks?
    d. What are some improvements that would make the software better for translation?
3. Verification
    a. Was the software helpful for performing verification tasks? How?
    b. How does the software compare to previous systems you used for verification?
    c. What are some difficulties that you encountered when performing translation tasks?
    d. What are some improvements that would make the software better for verification?
4. Mistranslations
    a. When performing verifications, what are some frequent types of translation mistakes you found?
    b. Why were these types of mistakes frequent?
    c. Did you communicate with other translators about those types of mistakes?
5. Disagreements
    a. Were there any disagreements regarding language standards?
    b. How were those disagreements resolved?

Figure 6: Survey questions sent to translators after they translated flores-200, nllb-seed, and ntrex-128 to N'Ko

B Fria||el Software Engineering Diagrams

On the next three pages appear:

- Workflow and task management sequence diagrams
- Workflow and Task State-Transition Diagrams
- Logical Data Model
- Physical Data Storage Model in Google Firestore

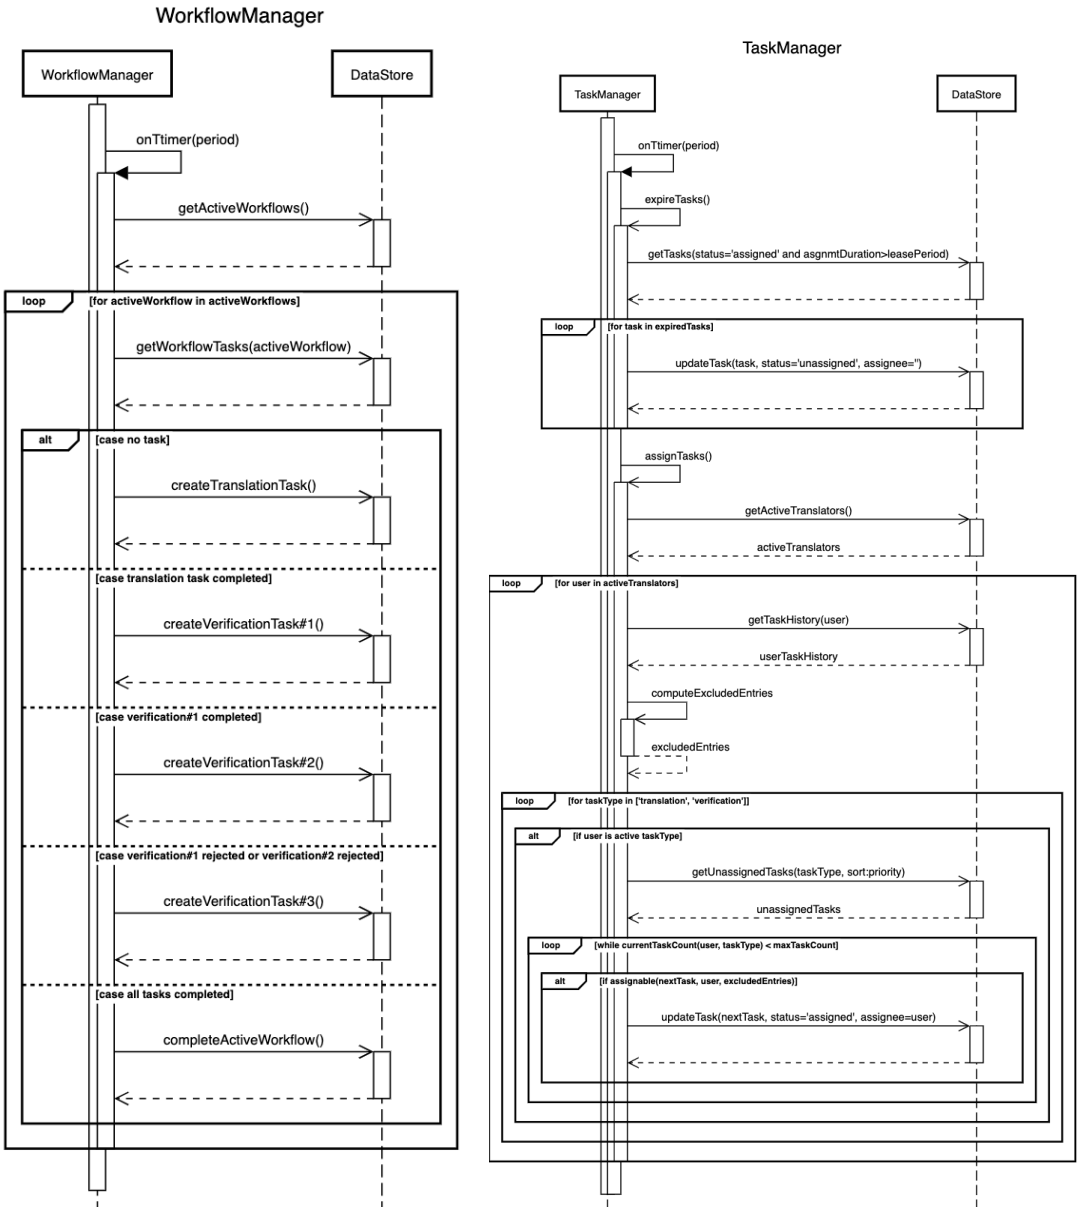

Figure 7: Sequence Diagram: Workflow Manager and Task Manager

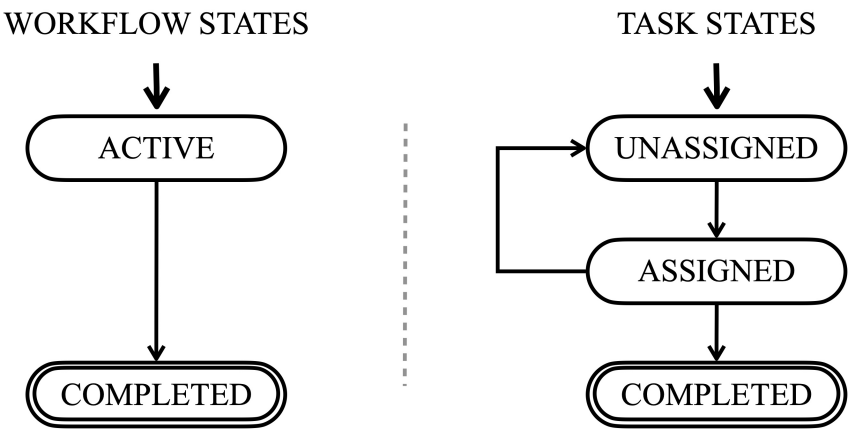

Figure 8: State Transition Diagrams for Tasks and Workflows. A translation workflow entity in the *active* state is created for each dataset entry. The workflow manager creates related *unassigned* tasks as needed, per the rules of the workflow. The Task Manager assigns tasks to users as appropriate. Uncompleted tasks are moved back to the *unassigned* status when not completed within the lease period. The workflow manager moves workflows to the *completed* status when all related tasks are *completed* and there is no need to create additional tasks.

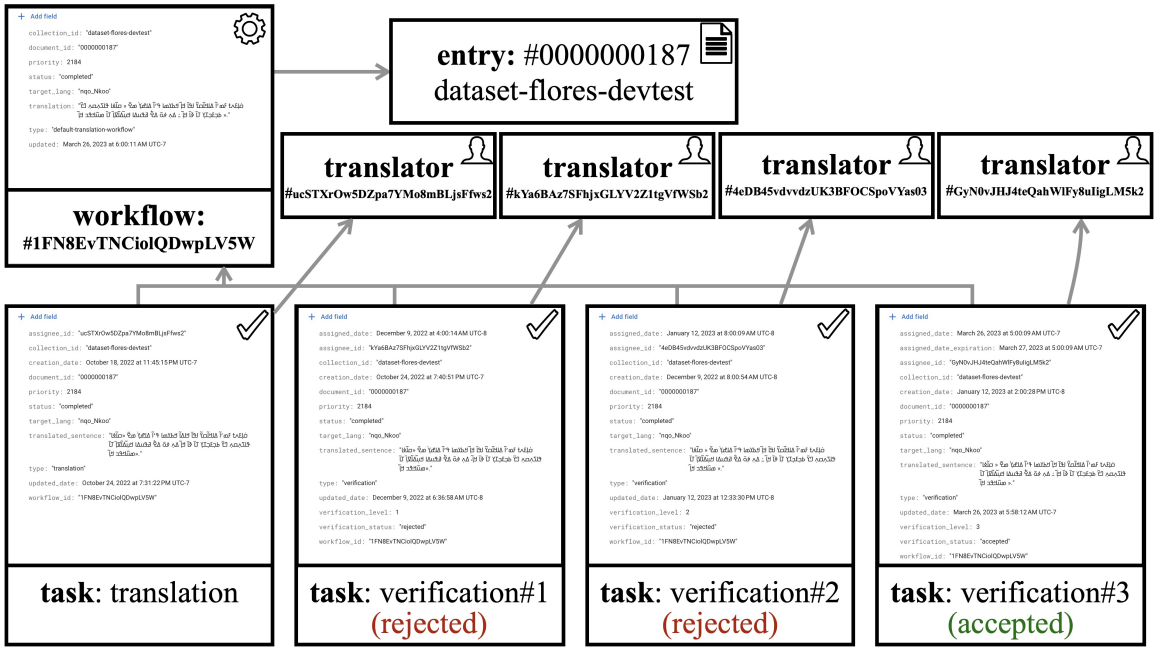

Figure 9: Logical model of entities involved in the curation process of entry#187 of the FLoRes-devtest dataset. Each entity is stored as a document in the Firestore database. The Workflow Manager created one translation task, and three verification tasks, each assigned to a different translator. The third verification task was created because at least one of the previous two resulted in translator edits. Arrows point from referencing to referenced documents.

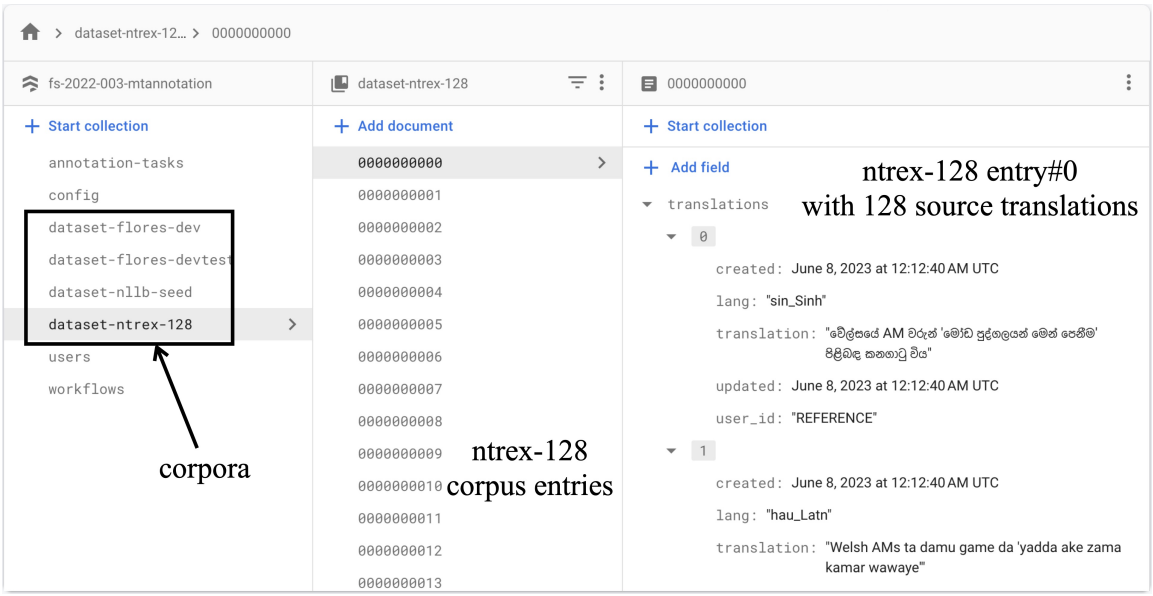

Figure 10: Data Storage in Google Firestore. Each corpus is stored as a collection of documents (left), each of which is identified by its position in the original data files (middle). Each entry contains an array of source translations. Each translation is labeled with its language and script codes (ISO-639_ISO-15924) (right). The system also uses the *users*, *config*, *workflows* and *annotation-tasks* for user, configurations, and data curation workflow management.

C NLLB-SEED *bam_Latn* Quality Issues

Examples of quality issues in NLLB-SEED *bam_Latn* data file appear on the following page.

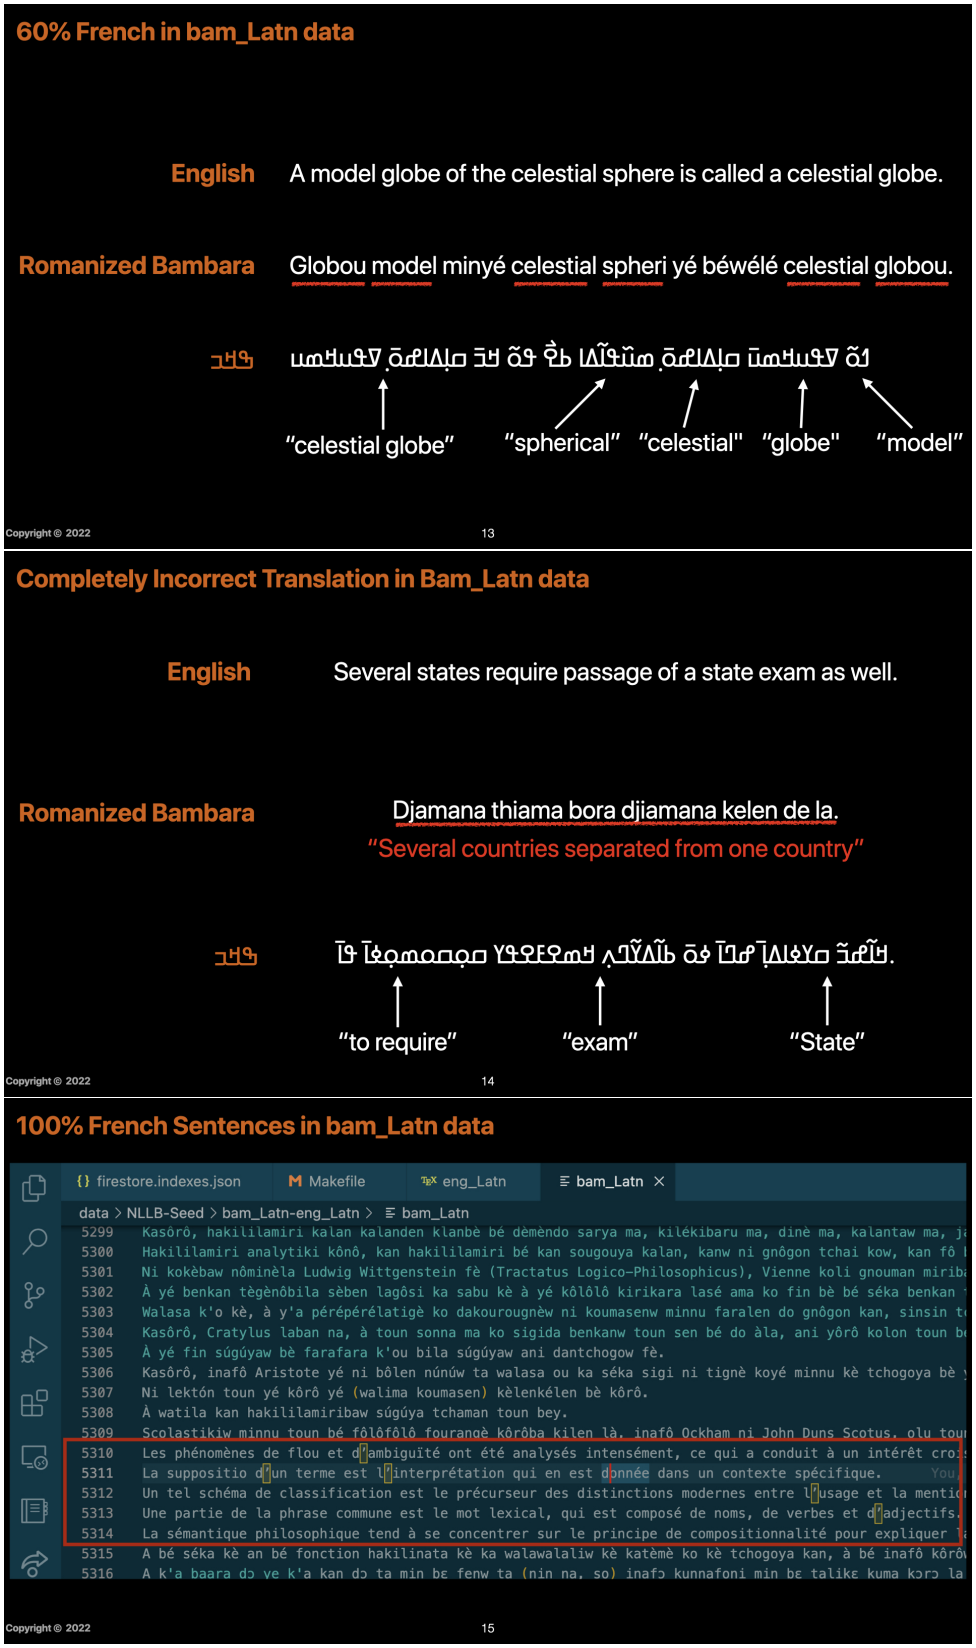

Figure 11: Examples of quality issues in NLLB-SEED *bam_Latn* data file. (1) Sentence with 60% borrowed French words. (2) Incorrect translation. (3) a block of sentences entirely in French. Notice that tonal marks are missing from *bam_Latn* text.

D nicolingua-0005 details

This section provides details on the monolingual, bilingual and trilingual parallel corpora, donated by Nko community members, collectively making up the nicolingua-0005 corpus.

D.0.1 Trilingual Corpora
$(nqo\_Nkoo, eng\_Latn, fra\_Latn)$

baba_mamadi_diane_parallel_002 This corpus is composed of parallel Quran translations in Nko (Diane, Baba Mamadi, 2021), English (International, Saheeh, 2022), and French (International Center, Noor, 2018). The Quran's translation in Nko was originally performed by Baba Mamadi Diane for Islamic education purposes.

kalo_mory_diane_parallel_00{1,2,3} This corpus contains various short phrases collected and translated by Kalo Mory Diane for the purpose of machine translation system development.

solo_farabado_cisse_parallel_002 This corpus contains various short phrases collected and translated by Solo Farabado Cisse for the purpose of machine translation system development.

solo_farabado_cisse_parallel_001 Nko localization strings from the Unicode Common Locale Data Repository (CLDR) (Unicode, 2023a) to which Solo Farabado Cisse and Baba Mamadi Diane contributed (Unicode, 2023b). Corresponding CLDR strings in Nko, English, and French were compiled to make this trilingual parallel corpus.

D.0.2 Bilingual Corpora
(nqo_Nkoo, eng_Latn)

baba_mamadi_diane_parallel_003 This corpus contains segments manually chunked from the Quran and translated by Baba Mamadi Diane specifically for the purpose of creating a corpus usable for machine translation system development.

baba_mamadi_diane_parallel_004 This corpus contains the localization strings of a custom Android build translated by Baba Mamadi Diane.

djibrila_diane_parallel_003 This corpus contains short phrases collected and translated by Djibrila Diane. The phrases also include some basic scientific terminology. The corpus was originally created for education purposes only.

djibrila_diane_parallel_001 This corpus contains short phrases in various tenses collected and translated by Djibrila Diane to serve of MT system development.

djibrila_diane_parallel_002 This corpus contains various short phrases composed and translated by Djibrila Diane for the purpose of MT system development.

D.0.3 Bilingual Corpora
(nqo_Nkoo, fra_Latn)

baba_mamadi_diane_parallel_001 Nko-French dictionary authored by Baba Mamadi Diane for education purposes. Dictionary entries in french with multiple forms (e.g. gender) were automatically expanded using regular expressions.

nafadji_sory_conde_parallel_001 This corpus contains various short phrases composed and translated by Nafadji Sory Conde for the purpose of machine translation system development.

nafadji_sory_conde_parallel_003 This corpus contains phrases from Camara Laye's 1953 novel "L'enfant Noir" (Camara, 1953). The translation was originally done by Nafadji Sory Conde for the purpose of expanding available literature in Nko.

nafadji_sory_conde_parallel_002 This corpus contains various phrases related to Guinean society and sociology. It was created by Nafadji Sory Conde for the purpose of MT system development.

nafadji_sory_conde_parallel_004 This corpus contains segments extracted from the Guinean constitution. It was originally translated by Nafaji Sory Conde for education purposes.

D.0.4 Monolingual Corpora (nqo_Nkoo)

nafadji_sory_conde_monolingual_001 This corpus, composed by Nafadji Sory Conde and his collaborators, contains extracts of books and newspapers in Nko. A substantial part of the corpus was harvested from Kanjamadi.com. This corpus may overlap with the Maninka Reference Corpus (Vydrin et al., 2016).

baba_mamadi_diane_monolingual_00{1,2} These corpora were extracted from various Nko books and articles in various domains including history, religion, philosophy, literature and Science. The corpora were originally composed by Baba M. Diane for the purpose of auto-completion algorithm development for Nko.

E Datasheet Questionnaire for *nicolingua-0005*

E.1 Motivation

E.1.1 Who created the dataset(e.g., which team, research group) and on behalf of which entity (e.g. company, institution, organization)?

nicolingua-0005 was curated by Moussa Doumbouya (Stanford University). Its constituent corpora were provided by the following members of Nko USA Inc: Baba Mamadi Diane, Solo Farabado Cisse, Djibrila Diane, Nafadji Sory Conde, Kalo Mory Diane.

E.1.2 Did they fund it themselves? If there is an associated grant, please provide the name of the grantor and the grant name and number.

Nko community members voluntarily composed the included corpora.

E.1.3 For what purpose was the data set created? Was there a specific task in mind? If so, please specify the result type (e.g. unit) to be expected.

Some included corpora were composed specifically for the development of MT systems while others were originally created for educational purposes. See Appendix D for details.

E.1.4 Could any of these uses, or their results, interfere with human will or communicate a false reality?

Not to the best of our knowledge.

E.1.5 What is the antiquity of the file? Provide, please, the current date.

July 19 2023.

E.1.6 Has there been any monetary profit from the creation of this dataset?

No.

E.2 Composition

E.2.1 Is there any synthetic data in the dataset? If so, in what percentage?

The corpus doesn't contain any synthetic data.

E.2.2 Are there multiple types of instances or is there just one type? Please specify the type(s), e.g. Raw data, preprocessed, symbolic.

The corpus contains monolingual and parallel text corpora.

E.2.3 What do the instances (of each type, if appropriate) that comprise the data set represent? (e.g. documents, photos, people, countries).

The instances represent segments of text in Nko, English, and French.

E.2.4 How many instances (of each type, if appropriate) are there in total?

See Tables 4, 7, 8, 9 and 10

E.2.5 Does the dataset contain all possible instances or is it just a sample of a larger set? i.e. Is the dataset different than an original one due to the preprocessing process? In case this dataset is a subset of another one, is the original dataset available?

This dataset is a collection of corpora from various sources. Some sources were integrally sampled (e.g. quran), while other sources were composed by individual translators.

E.2.6 Is there a label or a target associated with each of the instances? If so, please provide a description.

The multilingual subsets of the corpora are matching segments of text in multiple languages.

E.2.7 What is the format of the data? e.g. .json, .xml, .csv .

The files are text files encoded in UTF-8 that have the following extensions matching the iso standard code of the language and writing system they contain: .nqo_Nkoo, .eng_Latn, .fra_Latn.

E.2.8 Is any information missing from individual instances? If so, please provide a description, explaining why this information is missing (e.g. because it was unavailable). This does not include intentionally removed information, but might include, e.g. redacted text.

There is no missing information to report.

E.2.9 Are there any errors, sources of noise, or redundancies in the dataset? If so, please provide a description. Do not include missing information here.

The sentences were benevolently translated by various individuals. A minimal quality control process was adopted during the curation phase. The data may contain some errors. The corpus baba_mamadi_diane_parallel_003 was created by sampling Quran phrases from baba_mamadi_diane_parallel_002. Some parallel Nko segments may be repeated in the monolingual Nko corpora.

E.2.10 Is there any verification that guarantees there is not institutionalization of unfair biases? Both regarding the dataset itself and the potential algorithms that could use it.

no.

E.2.11 Are there recommended data splits, e.g. training, development/validation, testing? If so, please provide a description of these splits explaining the rationale behind them.

The corpora are intended to be used to train natural language processing algorithms.

E.2.12 Is the dataset self-contained, or does it link to or otherwise rely on external resources? e.g., websites, tweets, other datasets. If it links to or relies on external resources, a) Are there any guarantees that they will exist, and remain constant over time? b) Are there official archival versions of the complete dataset? i.e. including the external resources as they existed at the time the dataset was created. c) Are there any restrictions (e.g. licenses, fees) associated with any of the external resources that might apply to a future user? Please provide descriptions of all external resources and any restrictions associated with them, as well as links or other access points, if appropriate.

nicolingua-0005 is self-contained.

E.2.13 Does the dataset contain data that might be considered confidential? e.g. data that is protected by legal privilege or by doctor-patient confidentiality, data that includes the content of individuals non-public communications. If so, please provide a description.

Not to the best of our knowledge.

E.2.14 Does the dataset contain data that, if viewed directly, might be offensive, insulting, threatening, or might otherwise cause anxiety? If so, please describe why.

Not to the best of our knowledge. Notes: (1) *nicolingua-0005* contains religious text that some people may find offensive or threatening. (2) Some words contained in *nicolingua-0005*, such as the name of certain human body parts included in the Nko-Francais dictionary, may be considered vulgar or offensive.

E.2.15 Does the dataset relate to people? If so, please specify a) Whether the dataset identifies subpopulations or not. b) Whether the dataset identifies indivual people or not. c) Whether it contains information that could vulnerate any individuals or their rights. c) Any other verified information on the topic that can be provided.

The data includes news articles that may reference specific people and people groups. The data also includes literature relating to West African people and people groups and their history.

E.2.16 Does the dataset cover included languages equally?

No. The sizes of various parallel and monolingual subsets have been specified in Table 4.

E.2.17 Is there any evidence that the data may be somehow biased? i.e. towards gender, ethics, beliefs.

The data includes religious texts, articles, and books that may reflect various types of biases. The data may contain biases inherent in historical and current Manding culture such as work organization between men and women, young and old people. Nko doesn't have masculine vs. feminine noun classes. Therefore genders are not distinguished in

Nko nouns and pronouns, which may reduce the potential for gender-based bias.

E.2.18 Is the data made up of formal text, informal text or both equitably?

The data mostly contains formal text.

E.2.19 Does the data contain incorrect language expressions on purpose? Does it contain slang terms? If that's the case, please provide which instances of the data correspond to these.

Not to the best of our knowledge. The dataset may contain unintentional errors.

E.3 Collection Process

E.3.1 Where was the data collected at? Please include as much detail; i.e. country, city, community, entity and so on.

Most data was collected in Conakry, Guinea, and Banakoro, Guinea. Some contributors also worked in Bamako, Mali (Solo F Cisse, Baba M Diane), Egypt (Baba M Diane) and USA (Djibrila Diane) while collecting the datasets.

E.3.2 If the dataset is a sample from a larger set, what was the sampling strategy? i.e. deterministic, probabilistic with specific sampling probabilities.

N/A

E.3.3 Are there any guarantees that the acquisition of the data did not violate any law or anyone's rights?

Not to the best of our knowledge.

E.3.4 Are there any guarantees that prove the data is reliable?

No.

E.3.5 Did the collection process involve the participation of individual people? If so, please report any information available regarding the following questions: Was the data collected from people directly? Did all the involved parts give their explicit consent? Is there any mechanism available to revoke this consent in the future, if desired?

The dataset authors are authors of this paper. They gave their explicit consent.

E.3.6 Has an analysis of the potential impact of the dataset and its use on data subjects been conducted? i.e. a data protection impact analysis. If so, please provide a description of this analysis, including the outcomes, as well as a link or other access point to any supporting documentation.

No.

E.3.7 Were any ethical review processes conducted?

No.

E.3.8 Does the data come from a single source or is it the result of a combination of data coming from different sources? In any case, please provide references.

The data was curated from a combination of different sources.

E.3.9 If the same content was to be collected from a different source, would it be similar?

Not Applicable.

E.3.10 Please specify any other information regarding the collection process. i.e. Who collected the data, whether they were compensated or not, what mechanisms were used. Please, only include if verified.

E.4 Preprocessing/Cleaning/Labelling

E.4.1 Please specify any information regarding the preprocessing that you may know (e.g. the person who created the dataset has somehow explained it) or be able to find (e.g. there exists and informational site). Please, only include if verified. i.e. Was there any mechanism applied to obtain a neutral language? Were all instances preprocessed the same way?

The data was normalized with Unicode normalization form NFC: Canonical Decomposition followed by Canonical Composition. Non-Nko characters were stripped from monolingual Nko text. Extra punctuations were removed from some sources. Some entries in Baba Mamadi Diane's Nko-Francais dictionary were expanded using regular expressions so that separate forms of the same

words (e.g. gendered, plural) were repeated as separate entries.

E.5 Uses

E.5.1 Has the dataset been used already? If so, please provide a description.

The data was used to build baseline neural machine translation algorithms for Nko. See Section 4.

E.5.2 Is there a repository that links to any or all papers or systems that use this dataset? If so, please provide a link or any other access point.

`https://github.com/mdoumbouya/nicolingua-0005-nqo-nmt-resources`
`https://github.com/mdoumbouya/nicolingua-0005-nqo-nmt-resources`

E.5.3 What (other) tasks could the dataset be used for? Please include your own intentions, if any.

Any natural language processing tasks including language modeling and machine translation.

E.5.4 Are there tasks for which the dataset should not be used? If so, please provide a description.

Not to the best of our knowledge.

E.6 Distribution

E.6.1 Please specify the source where you got the dataset from.

The datasets came from the following individuals:

E.6.2 When was the dataset first released?

July 19 2023.

E.6.3 Are there any restrictions regarding the distribution and/or usage of this data in any particular geographic regions?

No.

E.6.4 Is the dataset distributed under a copyright or other intellectual property (IP) license? And/or under applicable terms of use (ToU)? Please cite a verified source.

The dataset is openly available under the Attribution-ShareAlike 4.0 International (CC BY-SA 4.0) license.

E.7 Maintenance

E.7.1 Is there any verified manner of contacting the creator of the dataset?

The authors of this paper can be contacted via email.

E.7.2 Specify any limitations there might be to contributing to the dataset. i.e. Can anyone contribute to it? Can someone do it at all?

The dataset is openly available under the Attribution-ShareAlike 4.0 International (CC BY-SA 4.0) license.

E.7.3 Has any erratum been notified?

No.

E.7.4 Is there any verified information on whether the dataset will be updated in any form in the future? Is someone in charge of checking if any of the data has become irrelevant throughout time? If so, will it be removed or labeled somehow?

The dataset will be maintained on GitHub. Any updates will be made available in the same GitHub repository.

E.7.5 Is there any available log about the changes performed previously in the dataset?

Any future modifications will be tracked in GitHub's version control.

E.7.6 Could changes to current legislation end the right-of-use of the dataset?

Not to the best of our knowledge.

E.7.7 Are there any lifelong learning updates, such as vocabulary enrichment, automatically developed?

No.

F Train, Valid and Test Subset Details

Details on the training, validation, and test subset composition for each model appear on the following page.

Abstract

We describe TTIC's submission to the WMT 2023 Sign Language Translation shared task on the Swiss-German Sign Language (DSGS) to German track. Our approach explores the advantages of using large-scale self-supervised pre-training in the task of sign language translation, over more traditional approaches that rely heavily on supervision, along with costly labels such as gloss annotations. The proposed model consists of a VideoSwin transformer for image encoding, and a T5 model adapted to receive VideoSwin features as input instead of text. On WMT-SLT 22's development set, this system achieves 2.03 BLEU score, a 59% increase over the previous best reported performance. On the official test set, our primary submission achieves 1.1 BLEU score and 17.0 chrF score. It also achieves the highest human evaluation score among all the participants.

1 Introduction

Sign language translation (SLT) is the task of translating a signed language to a written language, typically the lingua franca of the region the signed language is utilized. In recent years, SLT has received increased attention from the natural language processing (NLP) and computer vision (CV) communities.

The best-performing SLT models primarily rely on glosses (Zhou et al., 2021; Chen et al., 2022), a combination of morpheme translations into the target language along with differentiating phonological features like handshape and location. However, annotating glosses is expensive (Müller et al., 2023b), and recent research has begun to move away from gloss-based translation (Shi et al., 2022a; Uthus et al., 2023; Lin et al., 2023), particularly in regimes where larger datasets are available.

In this paper, we study large-scale self-supervision and noisy supervision for Swiss-German Sign Language (DSGS from the German *Deutschschweizer Gebärdensprache*) to German SLT, as part of the WMT-SLT 23 shared task (Müller et al., 2023a). Given recent findings on self-supervised transformers' perfomance on isolated sign recognition and feature extraction (Sandoval-Castañeda et al., 2023), we utilize a VideoSwin (Liu et al., 2022) visual feature extractor with BEVT pre-training (Wang et al., 2022). Additionally, we use T5 (Raffel et al., 2020) as a sequence-to-sequence translation model into German because of its state-of-the-art performance on American Sign Language (ASL) to English SLT with pose input (Uthus et al., 2023). Depending on the generation algorithm, our model achieves either the highest BLEU score (Papineni et al., 2002) or the highest chrF (Popović, 2015) in the task's leaderboard. With top-k beam sampling, it achieves 0.8 BLEU and 17.3 chrF, and with diverse beam search (Vijayakumar et al., 2016), it achieves 1.1 BLEU and 17.0 chrF.

2 Method

Our model follows the most common gloss-free translation architecture, composed of a visual encoding backbone and a transformer-based model for sequence modeling. Our visual backbone is a Video Swin Transformer (VideoSwin) and our sequence-to-sequence model is a Text-to-Text Transfer Transformer (T5).

2.1 VideoSwin

VideoSwin is an architecture proposed as an extension of the shifted-window transformer (Liu et al., 2021), a hierarchical vision transformer that relies on windowed self-attention for computational efficiency. We pre-train a VideoSwin using video-only BEVT pre-training (Wang et al., 2022) on OpenASL (Shi et al., 2022a), using the codebook from a discrete variational autoencoder (dVAE) (Ramesh et al., 2021) to produce the labels in the self-supervision objective. Though OpenASL is originally a sign language translation dataset, we ig-

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 344–350
December 6–7, 2023.

nore the English translations and train exclusively on the dataset's videos. Then, we fine-tune on the gloss-based version (Dafnis et al., 2022; Neidle and Ballard, 2022) of WLASL2000 (Li et al., 2020) for supervised isolated sign language recognition.

Given a video with dimensions $16 \times 224 \times 224$, that is, 16 frames of height 224 pixels and width 224 pixels, VideoSwin first divides the input into patches of shape $2 \times 4 \times 4$ and produces a 128-dimensional vector representation for each patch, producing a tensor of shape $8 \times 56 \times 56 \times 128$. After the first two windowed self-attention blocks, patch representations are divided into non-overlapping groups of four spatially contiguous patches, which are then projected into a single 256-dimensional vector each. This is done again after two windowed self-attention blocks, and once more after eighteen windowed self-attention blocks. The resulting tensor after these patch merging steps has dimensions $8 \times 7 \times 7 \times 1024$.

For translation, we pad the video at the end such that the number of frames is a multiple of 16, divide it into non-overlapping segments of 16 contiguous frames, and run each segment independently through the model. The visual features extracted from the model are the output of the last windowed self-attention block from VideoSwin for each video segment. Then, we concatenate them across the time dimension, and remove the model's outputs that correspond to the padding frames. This is done both during training and during inference. More formally:

$$f_{1:\lceil T/2 \rceil} = M^v(I_{1:T}) \quad (1)$$

where $I_{1:T}$ is a sequence of T image frames, M^v is our VideoSwin model, and $f_{1:\lceil T/2 \rceil}$ is the resulting sequence of visual features, with dimensions $\lceil T/2 \rceil \times 7 \times 7 \times 1024$.

2.2 T5

T5 is a standard encoder–decoder text transformer (Raffel et al., 2020). Recent research has found that T5 pre-trained on English and fine-tuned for ASL to English translation produces state-of-the-art results using pose input (Uthus et al., 2023). We use a T5 model pre-trained on the German Colossal Cleaned Common Crawl (GC4) corpus, which is a cleaned and pre-processed German-only corpus based on Common Crawl. We take pre-trained checkpoints[1] from HuggingFace (Wolf et al., 2020).

[1] https://huggingface.co/GermanT5

Since our sequence of visual features $f_{1:\lceil T/2 \rceil}$ has dimensions $\lceil T/2 \rceil \times 7 \times 7 \times 1024$, we project these into a single vector per timestep, $\lceil T/2 \rceil \times 1024$. To this end, we use a simple convolutional layer with kernel size $1 \times 7 \times 7$. We replace the word embeddings layer from the T5 model with this convolutional layer. This is the only component trained from scratch in our DSGS to German translation model.

2.3 Training Loss

We use cross-entropy loss for BEVT pre-training, isolated sign language recognition (ISLR) fine-tuning, text-to-text pre-training, and features-to-text translation.

2.4 Inference

We expand on the effect of generation algorithms in Section 4.5. For our primary submission, our generation algorithm of choice is diverse beam search (Vijayakumar et al., 2016), with 5 beams, 5 beam groups, and a diversity penalty of 1.

3 Experimental Setup

3.1 Data

We use both last year's and this year's WMT-SLT datasets. Last year's training dataset is composed of data from FocusNews and SRF, both news TV programs, consisting of 17,207 manually aligned DSGS–German pairs, for a total of 35 hours. German text is obtained from the subtitles that correspond to the original spoken German content, and DSGS video is obtained from live translators. Manual alignment is necessary to ensure that each translated sentence in the video is assigned the correct German sentence. In contrast, this year's dataset consists of 231,834 DSGS–German pairs without any manual alignment, for a total of 437 hours, of only SRF data. Last year's SRF data is a subset of this year's dataset, with the key difference that the superset does not contain manually aligned and verified German translations.

Additionally, we use OpenASL (Shi et al., 2022a), a dataset consisting of 288 hours of ASL-English pairs, for the self-supervised pre-training of our visual encoder. In this pre-training we also employ the labels produced by the codebook of a dVAE, which was separately trained on Conceptual Captions (Sharma et al., 2018). For the second stage of pre-training of our visual encoder,

we fine-tune the pre-trained model on the gloss-based version of WLASL2000 (Li et al., 2020), a 14-hour dataset consisting of 19,673 isolated sign ASL videos and 1535 gloss labels (Neidle and Ballard, 2022).

Lastly, the checkpoint we use for T5 is pre-trained on the GC4 corpus. GC4 is a German-only corpus that contains 40.8 billion tokens in total. This is a subset of Common Crawl where the primary language is German extracted between 2015 and 2021.

3.2 Training

Our visual backbone is VideoSwin's base version. It consists of 88.1 million parameters, and is composed of 2 windowed self-attention blocks with 128 hidden dimensions at stage 1, 2 with 256 hidden dimensions at stage 2, 18 with 512 hidden dimensions at stage 3, and 2 with 1024 dimensions at stage 4. We pre-train it in two stages. First, we train it for 150 epochs on OpenASL via video-only BEVT where the labels are produced by the codebook of a dVAE, with a learning rate of 0.0005 on a cosine schedule with 10 warmup epochs and batch size of 128 across 8 GPUs. We use AdamW (Loshchilov and Hutter, 2019) as the optimizer, with $\beta_1 = 0.9$ and $\beta_2 = 0.999$ and 0.05 weight decay. In the second stage, we train it on gloss-based WLASL2000[2] for classification for 120 epochs, this time with a learning rate of 0.0003 on a cosine schedule with 2.5 warmup epochs and a batch size of 256 across 8 GPUs. Again, we use AdamW as our optimizer, with $\beta_1 = 0.9$ and $\beta_2 = 0.999$ and 0.001 weight decay. Our VideoSwin backbone is then frozen for the rest of our model's training.

For translation, we adapt T5's efficient-large (Tay et al., 2022) version using a convolutional layer to project our representations. This model is composed of 1.09 billion parameters, with 36 self-attention blocks in the encoder and 36 self-attention blocks in the decoder. To tokenize the target translations, we use a SentencePiece tokenizer trained on the same data as the German-only T5, with a vocabulary size of 32,128. We train it in two stages, using both WMT-SLT 22 and WMT-SLT 23 data. WMT-SLT 23 translations are weakly supervised labels, since there is no guarantee of alignment between the video and the corresponding text translations. Therefore, our pipeline uses it as a large, noisy dataset to train the model which will be eventually further fine-tuned with WMT-SLT 22, which has manually verified labels. First, we train it for 8500 steps on WMT-SLT 23's dataset, with a learning rate of 0.001 on a linearly decreasing schedule and a batch size of 64 across 8 GPUs. We use Adafactor (Shazeer and Stern, 2018) as the optimizer. For the second stage, we train the model for 1500 steps on WMT-SLT 22's dataset, with a learning rate of 0.0002 on a linearly decreasing schedule with a batch size of 64 across 8 GPUs. We also use Adafactor at this stage.

3.3 Evaluation

We evaluate our systems and compare them with last year's submissions, since we use the same validation set, using BLEU-1, BLEU-2, BLEU-3 and BLEU-4.

4 Experimental Results

Table 1 shows the performance of our model on WMT-SLT 22's development set, compared to the highest reported BLEU-4 scores reported on the test set by human evaluation (Müller et al., 2022). We also include MSMUNICH's model based on AV-HuBERT (Shi et al., 2022c), since it achieved the highest BLEU-4 score on the development set. Our model performs at least 81% better than the others in all metrics, and 99% better in BLEU-4, which is the metric used in the challenge's leaderboard.

We additionally perform several ablations to quantify the impact of our model's several moving parts. Our ablations are performed using T5's efficient-base configuration with 619 million parameters for time efficiency, unless otherwise specified.

4.1 Visual Backbone

We first evaluate the effect of our choice of visual backbone and pre-training tasks. We compare our VideoSwin backbone with two other models. First, we take a standard I3D model (Carreira and Zisserman, 2017) trained on the ISLR component of the BBC-Oxford British Sign Language dataset (Albanie et al., 2020), called BSL5K (Varol et al., 2021), since I3D is the most commonly used backbone for SL translation. Previous literature suggests that diversity of isolated signs leads to

[2]The original data can be downloaded here: https://dxli94.github.io/WLASL/ And the gloss-based labels can be downloaded here: https://dai.cs.rutgers.edu/dai/s/aboutwlasl

Model	Backbone	Translation Data	B1	B2	B3	B4
MSMUNICH (Dey et al., 2022)	AV-HuBERT	WMT-SLT 22	–	–	–	1.28
MSMUNICH (Dey et al., 2022)	I3D	WMT-SLT 22	–	–	–	0.77
UZH (Müller et al., 2022)	OpenPose	WMT-SLT 22	–	–	–	0.59
TTIC (Shi et al., 2022b)	I3D	WMT-SLT 22	8.36	2.92	1.55	1.02
Ours	**VideoSwin**	**WMT-SLT 22 + 23**	**15.19**	**5.62**	**3.06**	**2.03**

Table 1: Performance of our model on WMT-SLT 22's development set compared to WMT-SLT 22's highest reported scores. B1, B2, B3, and B4 stand for BLEU-1, BLEU-2, BLEU-3, and BLEU-4, respectively.

better representations for downstream tasks like translation, and BSL5K is the largest and most diverse ISLR dataset to our knowledge. We also include an I3D model trained on WLASL2000 for comparison. Second, we also include a version of our pipeline where we replace OpenASL with the WMT-SLT 23 training data without translations for self-supervised pre-training. However, we do not include WLASL2000 fine-tuning for this model, given the language differences between DSGS and ASL.

As Table 2 shows, There is significant deterioration from shifting our self-supervised BEVT VideoSwin backbone to any of the fully supervised I3Ds. Similarly, despite being pre-trained in a different language, OpenASL pre-training performs much better than WMT-SLT 23 pre-training, despite being the smaller training set (288 vs. 437 hours). This is likely a product of OpenASL's far superior diversity in backgrounds, which are masked in WMT-SLT 23, topics (social media content vs. news), and signers (220 vs. 4).

Backbone	Data	B1	B2	B3	B4
I3D	ASL	12.15	2.96	1.31	0.79
I3D	BSL	12.79	2.80	1.12	0.59
BEVT	DSGS	12.43	3.34	1.72	1.16
BEVT	**ASL**	**15.16**	**5.20**	**2.75**	**1.82**

Table 2: Impact of visual backbone and training data on our model's performance. I3D refers to Inception3D models and BEVT refers to BEVT VideoSwin models. We group our pre-training data by language: BSL refers to BSL5K, DSGS refers to WMT-SLT 23, and ASL refers to OpenASL (if BEVT) and WLASL2000.

4.2 Translation Pre-Training

We also consider different combinations of our two DSGS to German translation datasets. In our training set-up, the model is first trained on WMT-SLT 23's weakly supervised labels, and then fine-tuned on WMT-SLT 22's manually aligned labels. We compare this to settings where we use either only WMT-SLT 23 data or only WMT-SLT 22 data. Using only WMT-SLT 22 data is equivalent to WMT-SLT 22's challenge.

From Table 3, we can see that despite the possible misalignments in WMT-SLT 23, training on a larger set of translation pairs is superior to using only WMT-SLT 22 data. However, the best performance we obtain comes from first training on the potentially noisy but large WMT-SLT 23, and then fine-tuning on WMT-SLT 22 for fewer steps.

W22	W23	B1	B2	B3	B4
✗	✓	14.28	4.33	2.27	1.58
✓	✗	13.47	4.30	2.19	1.42
✓	✓	**15.16**	**5.20**	**2.75**	**1.82**

Table 3: Impact of weak supervision translation labels on our model's performance. W22 refers to training on WMT-SLT 22 data and W23 refers to training on WMT-SLT 23 data. Where both are used, the model is trained on WMT-SLT 23 first and then on WMT-SLT 22.

4.3 Sequence-to-Sequence Model

In addition to T5, we also adapt Whisper (Radford et al., 2023) for DSGS to German translation and test it. The intuition behind it is that audio and video both have a time dimension that corresponds to seconds, whereas text does not. We adapt it in a similar fashion to T5, with the addition of a $4\times$ bicubic interpolation step right before the convolutional layer. We do so because Whisper receives input with 50 tokens per second, whereas our VideoSwin features produce one representation every two frames, for 12.5 every second, since the video is at 25 frames per second.

Results in Table 4 suggest that using a text-to-text model performs significantly better than a speech-to-text one.

Model	B1	B2	B3	B4
Whisper	15.08	4.26	2.04	1.29
T5	**15.16**	**5.20**	**2.75**	**1.82**

Table 4: Impact of sequence-to-sequence component of our model on translation performance.

4.4 Model Size

Next, we consider model size in Table 5. Due to computational and time constraints, we only evaluate T5-efficient-small, T5-efficient-base, and T5-efficient-large, with 142 million, 619 million, and 1.09 billion parameters respectively. As expected, larger models correspond to better performance.

Size	Params	B1	B2	B3	B4
Small	142m	15.43	5.13	2.47	1.52
Base	619m	15.16	5.20	2.75	1.82
Large	**1.09b**	**15.19**	**5.62**	**3.06**	**2.03**

Table 5: Impact of model size on our model's performance.

4.5 Decoding Algorithm

Last, we evaluate the effect of different choices of decoding algorithm on test set performance, using our best performing model, T5-efficient-large. We compare the results generated from the following algorithms: greedy decoding, top-k sampling (Fan et al., 2018), beam search, top-k beam sampling, and diverse beam search (Vijayakumar et al., 2016), with $k = 50$ and beam width set to 5. Table 6 shows our results from this experiment, revealing that diverse beam search and top-k beam sampling represent the most significant improvements from the greedy decoding baseline. We choose diverse beam search for our primary submission to the challenge, as it is the only one that improves both BLEU and chrF scores from our baseline.

Generation Algorithm	B4	chrF
Greedy Decoding	0.9	16.0
Top-k Sampling	0.8	16.3
Beam Search	0.9	17.2
Top-k Beam Sampling	0.8	17.3
Diverse Beam Search	**1.1**	**17.0**

Table 6: Impact of generation algorithm for our best model in WMT-SLT 23's test set.

5 Conclusion

Our experiments evaluate a hierarchical vision transformer on the task of sign language translation for the first time, and demonstrate superior performance over I3D-based translation models. We also show the benefits of using large datasets and self-supervised models for sign language translation, outperforming all previous fully supervised approaches to this task. Our final model achieves highest BLEU-4 score, highest chrF score, and highest human evaluation score among all participants of the task. However, translation quality remains extremely low.

Abstract

Sign Language Translation (SLT) is a complex task that involves accurately interpreting sign language gestures and translating them into spoken or written language and vice versa. Its primary objective is to facilitate communication between individuals with hearing difficulties using deep learning systems. Existing approaches leverage gloss annotations of sign language gestures to assist the model in capturing the movement and differentiating various gestures. However, constructing a large-scale gloss-annotated dataset is expensive and impractical to cover multiple languages, and pre-trained generative models cannot be efficiently used due to the lack of textual source context in SLT. To address these challenges, we propose a gloss-free framework for the WMT23 SLT task. Our system primarily consists of a visual extractor for extracting video embeddings and a generator responsible for producing the translated text. We also employ an embedding alignment block that is trained to align the embedding space of the visual extractor with that of the generator. Despite undergoing extensive training and validation, our system consistently falls short of meeting the baseline performance. Further analysis shows that our model's poor projection rate prevents it from learning diverse visual embeddings. Our codes and model checkpoints are available at https://github.com/HKUST-KnowComp/SLT.

1 Introduction

Machine translation has significantly improved thanks to the development of pre-trained language models (Mohammadshahi et al., 2022; Huang et al., 2023). While translation within a single modality has been extensively studied, translation involving multiple modalities remains challenging and less explored (Lin et al., 2023). Sign Language Translation (SLT), which translates sign gestures into spoken language, remains an exceedingly complex task due to two fundamental challenges. Firstly, sign languages are visual-gestural languages that rely on manual signs, facial expressions, and body movements to convey information. This fundamental distinction sets them apart from written languages, which consist of word characters and symbols. Consequently, translation models must be able to accurately interpret visual signals and gestures and develop a deep understanding of the semantics involved in producing prompt translations. However, the multimodal nature of sign languages poses a significant challenge for models, requiring them to learn and generalize these complex interactions effectively. Moreover, sign languages are typically represented as exceedingly lengthy sequences of frames, surpassing the number of tokens in a standard sentence (Guo et al., 2018). This requires translation models to grasp the prolonged dependencies within the video to accurately capture the information conveyed through these visual signals.

To tackle these challenges, methods have been proposed that utilize pre-training a visual backbone based on gloss annotations (Camgöz et al., 2020). These approaches have demonstrated exceptional performance in various multimodal translation tasks. Nevertheless, the acquisition of extensive gloss annotations comes with significant cost and practical constraints, making it impractical to cover a wide range of multilingual translation directions (Müller et al., 2023).

In this paper, we propose a gloss-free framework for the SLT task. Our approach combines a pre-trained visual backbone model (Varol et al., 2021), which has been trained to recognize sign gestures, with a GPT2-based language model (Radford et al., 2019) to generate the translated sentence. To align the embedding space between both models, we utilize an embedding alignment block inspired by ClipCap (Mokady et al., 2021). The final translation is produced using converted visual embeddings and text embeddings (Section 3). Despite

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 351–358
December 6–7, 2023.

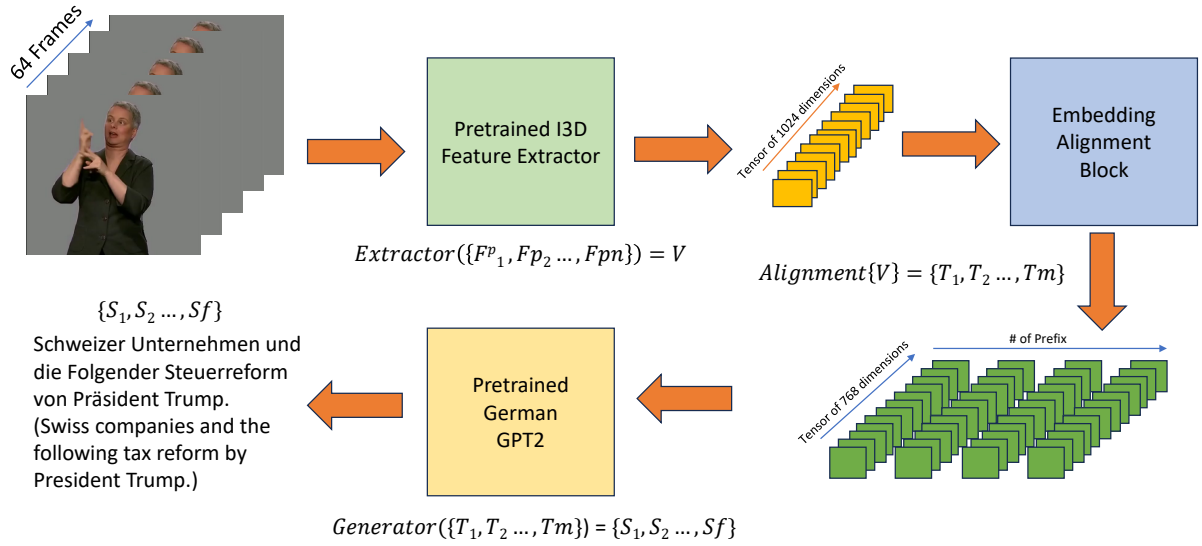

Figure 1: An overview of our framework. We first downsample video data and feed them into the visual feature extractor to obtain the visual embeddings. The embeddings are then passed into the alignment block to project them into embedding inputs of the `German-GPT2`. They are used as the prefix of the GPT2 model to generate the final translation results.

conducting extensive experiments with our system, we consistently achieved a BELU score of 0.1 and a chrF score of 7.6 on the testing set of the SRF dataset, which is below the baseline performance. Further analysis reveals that the embedding alignment block fails to differentiate between different embedding inputs from the visual encoder. As a result, our generation often produces repeated and nonsensical outputs. We will make all codes and results publicly available upon acceptance of this paper.

2 Preliminary

2.1 Task Definition

The objective of the Sign Language Translation (SLT) task (Fang et al., 2017; Kan et al., 2021) is to utilize the model's video understanding ability and language modeling ability to translate meaningful gesture sequence into spoken language (Varol et al., 2021; Hu et al., 2023). Formally, our objective is to learn a conditional probablity $P(S|F^r)$ of generating a natural spoken language, denoted as $\mathcal{S} = \{S_1, S_2..., S_m\}$ with m tokens given the raw sign language video $\mathcal{F}^r = \{F_1^r, F_2^r..., F_n^r\}$ with n frames.

To better elaborate our proposed model, we hereby set some notions for convenience. The aforementioned $\mathcal{S}$ and $\mathcal{F}^r$ refer to the translated spoken language and the sign language video before preprocessing. We use $\mathcal{F}^p = \{F_1^p, F_2^p..., F_n^p\}$ to denote the preprocessed video frames. In our proposed model, we endeavor to optimize the alignment block to yield better translation results while parameters in other modules are frozen for training efficiency.

Dataset	#raw data	#processed data
SRF	771	354901

Table 1: Statistics of the SRF dataset. # raw data refers to the number of videos, and # processed data is the amount of data after video slicing.

2.2 Dataset

We use the datasets provided by Müller et al. (2023) as our primary training and evaluation benchmarks. Our model is exclusively trained on the SRF dataset (Jiang et al., 2023b), while the SignSuisse dataset (Jiang et al., 2023a) is solely utilized for zero-shot evaluation purposes. Both datasets consist of sign language videos accompanied by their corresponding translation text in German. The statistical information for the SRF dataset can be

found in Table 1.

The SRF (Jiang et al., 2023b) dataset comprises videos from Standard German daily news (Tagesschau) and Swiss German weather forecast (Meteo) episodes broadcast. They are further interpreted into Swiss German Sign Language by hearing interpreters via Swiss National TV. In the SRF dataset released by Müller et al. (2022), there are a total of 354901 video slices covering episodes from 2014 to 2022.

The SignSuisse (Jiang et al., 2023a) dataset contains 18221 lexical items in Swiss German Sign Language, French Sign Language of Switzerland, and Italian Sign Language of Switzerland, represented as videos with corresponding spoken language translations.

The BSL-1k (Albanie et al., 2020) is a large-scale sign language recognition dataset constructed based on British Sign Language(BSL) signs. The authors leverage the observation that signers often mouth the word they are signing simultaneously, providing additional visual cues. They use visual keyword spotting to detect the mouthings and align them with the subtitles to determine whether and when a keyword of interest is uttered by a talking face using visual information. The dataset is then used to train a strong sign recognition model for co-articulated signs in BSL and serves as excellent pretraining for other sign languages and benchmarks. Thus, in our paper, it is reasonable for us to use a model pretrained on BSL-1k as our visual feature extractor and expect it to yield meaningful and informative video representations for the model to utilize.

3 Method

This section introduces our proposed framework, which is depicted in Figure 1. While previous systems (Dey et al., 2022; Shi et al., 2022; Tarres et al., 2022) primarily employ an encoder-decoder paradigm and train their models from scratch to address this task, we distinguish ourselves by being the first to utilize a pre-trained language model for this task, as these language models possess strong natural language understanding and generation ability (Wang et al., 2023c, 2022; Fang et al., 2021b,a, 2023; He et al., 2022; Bai et al., 2023a,b). Specifically, we leverage the pre-trained I3D model provided by Varol et al. (2021) as our visual extractor backbone and employ a German-GPT2 model (Schweter, 2020) as the generator's backbone.

3.1 Video Extractor

We use the Two-Stream Inflated 3D ConvNets (I3D; Carreira and Zisserman, 2017) that is pre-trained on the BSL-1k (Albanie et al., 2020) dataset as our visual extractor backbone. I3D was first proposed by Carreira and Zisserman (2017) aiming to mitigate the 2D convolution network failure to capture the temporal information behind the video data. To overcome this, I3D directly expands the original 2D convolution network, which yields significant success in 3-dimensional space by expanding extra dimension to the kernel and pooling layer. When the kernel and pooling layers are extended to 3D in I3D, these layers are initialized using the pre-trained weights from the corresponding 2D image classification networks. Overall, the I3D model offers a powerful framework for action recognition by leveraging the strengths of both image classification architectures and spatio-temporal feature extraction in videos. For the SLT task, we ask the model to transform a 64 frames ($\mathcal{F}_p$) video into a 1024-dimensional tensor ($\mathcal{V}$), denoted as:

$$\text{Extractor}(\{F_1^p, F_2^p ..., F_n^p\}) = \mathcal{V}$$

3.2 Embedding Alignment Block

Inspired by the success of ClipCap (Mokady et al., 2021), we then train an embedding alignment block to project the obtained visual embeddings $\mathcal{V}$ into textual embeddings T for further processing by German-GPT2. ClipCap was originally designed by Mokady et al. (2021) to tackle the task of image captioning (Ou et al., 2023). In the paper, the authors utilized the expressive power of an image feature extractor and a generative language model. By adding an alignment layer in between, the representation of the visual modality can be projected to the text modality for the language model to generate meaningful captions. The extraordinary ability shown by this innovative architecture makes it reasonable for us to adopt it in our framework. We implement the alignment block by stacking six transformer encoder layers together. Two fully connected neural networks are also placed before and after the alignment block to extend the visual embeddings into a sequential format and densify the aligned embeddings into prefix embeddings of German-GPT2, respectively. Formally, this process can be denoted as:

$$\text{Alignment}(\mathcal{V}) = \{T_1, T_2 ..., T_m\}$$

	BLEU			chrF			BLEURT		
Submission	all	SS	SRF	all	SS	SRF	all	SS	SRF
Baseline	0.09±0.03	0.15±0.06	0.10±0.05	12.4±0.4	12.2±0.5	12.5±0.5	0.072±0.003	0.083±0.005	0.060±0.005
KnowComp	0.07±0.05	0.06±0.02	0.11±0.09	7.6±0.3	8.2±0.4	7.2±0.4	0.083±0.005	0.084±0.007	0.081±0.007

Table 2: The experiment result of our proposed model comparing to the baseline released by the shared task organizer. Although our model was trained only on SRF, we still shown stronger performance on BLEURT than the baseline model in domain of SS and all. SS dataset is OOD and all is partially OOD for our model.

3.3 Text Generator

Finally, we leverage a pre-trained `German-GPT2` model as the text generator to generate the final translations by feeding the previously acquired textual prefix embeddings as the input. The German-GPT2 is trained on a large German corpus GC4 and can generate fluent german sentences. This step can be finally denoted as:

$$\text{Generator}(\{T_1, T_2..., T_m\} = \{S_1, S_2..., S_f\}$$

4 Experiments

4.1 Experiment Setup

We first describe our data preprocessing procedure and experiment settings.

4.1.1 Data Preprocessing

We first preprocess the raw data by dividing the video into smaller segments, or video slices, and match them with their corresponding ground truth German translations. To address a potential issue with the video extractor's encoding capacity, we adopt a downsampling strategy. Specifically, we select the first frame from every three frames in each video slice. Doing so reduces the number of frames and alleviates encoding challenges. Additionally, we encounter cases where certain video slices have fewer than 64 frames. To maintain consistency in video length, we append pure black frames to the end of these slices. To ensure compatibility with the video feature extractor's training environment, we resize each video frame to 224×224 dimension. This step guarantees that the model functions effectively within its designated parameters.

4.1.2 Experiment Setting

To enhance training efficiency, the parameters of the two backbone models are frozen, while the parameters of GPT2 are unfrozen after a certain iteration. This ensures that the randomly initialized transformer encoder does not compromise the language modeling ability of the GPT2 model. In our experiment, we set the batch size to 4, the learning rate to 5e-6, and changed the training parameters at iteration 66000. We employ an Adam (Kingma and Ba, 2015) as our optimizer and save the model checkpoint every 1000 iterations. The input and output lengths of GPT2 were fixed at 20, as we observed that most of the ground truth lengths were 20 or less, making this maximum length setting cover a significant portion of the training data. We set the number of heads in the multi-head attention to 8 and the prefix length for GPT2 to 4. Before feeding the embedding to the alignment block, the sequence length for translating the visual embedding was adjusted to 2×4, where 4 represents the GPT2 model's prefix number. Our model consists of 6 stacked encoder layers forming the alignment block. All experiments were conducted on NVIDIA GeForce GTX 1080 Ti with 11G memory.

4.2 Results

After extensive training and evaluation, our system achieves a BLEU (Papineni et al., 2002) score of 0.1 and a Chrf (Popovic, 2015) score of 7.6 in this shared task. These results are obtained from the official result submission platform. We present our experimental findings in comparison to the baseline model provided by the organizers, as shown in Table 2. Despite training our model solely on SRF, we outperform the baseline regarding the BLEURT (Sellam et al., 2020) score in SignSuisee and a combination of both datasets, which are considered out-of-domain evaluations for our model. However, it is important to note that our system falls significantly below the baselines and systems from other submissions. One potential explanation for this discrepancy could be that our system has not yet reached its optimal state, as the alignment block is trained from scratch, which could be quite challenging to converge. We conduct a fine-grained analysis in the following section to further investigate this hypothesis.

Table 3: Examples of our generated subtitles with their corresponding ground truth subtitles. We observe that 4 out of 5 of our generated sentences generate the same token for the first one and keep generating the same token at the end of its sentence. We try to analyze the reason for this in the following section.

4.3 Analysis

To analyze the reasons behind the failure of our system and its tendency to generate repetitive words in translations, we conduct a tSNE plot analysis of the visual embeddings before and after passing through the embedding alignment block. The results are presented in Figure 2. Upon examining the plot, we observe that the orange markers, representing the embeddings before alignment, were scattered, occupying a large area in the plot. In contrast, the blue crosses, corresponding to the embeddings after alignment, are densely concentrated in the middle of the plot. This stark contrast proves that the model loses its ability to differentiate between different visual features after projecting the embeddings from the I3D embedding space to the German-GPT2 embedding space. One potential explanation for this is that the embedding alignment block has not been effectively trained under the current training protocol. Further investigation is required to understand the underlying causes and devise appropriate solutions.

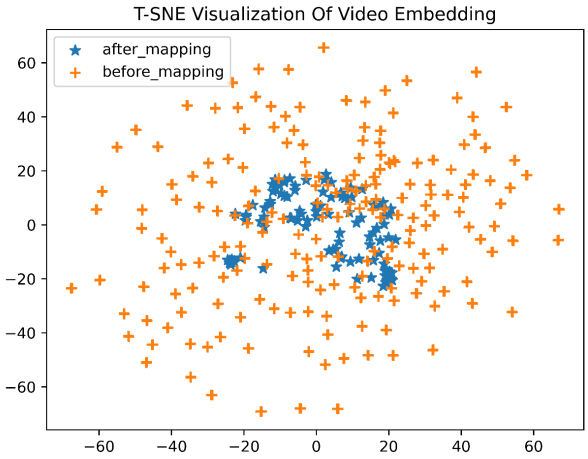

Figure 2: The tSNE comparison plot of the video embeddings before and after the embedding alignment block. We observe that the embeddings of different videos are dispersely distributed. However, they exhibit a denser distribution after alignment, which challenges generating coherent natural language descriptions.

4.4 Case Study

In Table 3, we present several instances of our generation using the data from the SRF dataset. The left column displays the ground truth sentences with a pad token appended at the end. In the right column, we showcase the generated sentences. Notably, 4 out of 5 of these sentences begin with "Der," and some consistently produce the same token, particularly in the final few positions. This further illustrates the subpar performance of our model. One possible explanation for this issue is the concentration of embeddings after the alignment block, which increases the likelihood of generating similar tokens. In the future, large-scale pertaining and appropriately leveraging large language models (OpenAI, 2023; Chan et al., 2023; Yu et al., 2023) and large multimodal foundation models (Zhu et al., 2023) may also be considered to improve the performance of this task further.

5 Conclusions

In conclusion, this paper presents the KnowComp system for the WMT23-SLT Sign Language Translation Shared Task. Our system utilizes two pretrained backbone models for visual feature extraction and translation text generation. However, this architecture fails, resulting in unsatisfactory perfor-

mance across all evaluation datasets. Our system's performance is significantly below the baseline's performance. We have identified a critical weakness in our model through further analysis, including embedding t-SNE plots and case studies. The embedding alignment block unexpectedly densifies all visual embeddings together, leading to the generator generating repeated tokens. To enhance our model's performance in future work, an appropriate data augmentation technique (Wang et al., 2023b,a; Gowda et al., 2022) can be implemented to help the alignment block distinguish different input features more efficiently. Also, future works can focus on whether further increasing the model capacity could help to mitigate the issue shown in the analysis section considering the advancing computation resources.

Abstract

The effectiveness of a machine translation (MT) system is intricately linked to the quality of its training dataset. In an era where websites offer an extensive repository of translations such as movie subtitles, stories, and TED Talks, the fundamental challenge resides in pinpointing the sentence pairs or documents that represent accurate translations of each other. This paper presents the results of our submission to the shared task WMT2023 (Sloto et al., 2023), which aimed to evaluate parallel data curation methods for improving the MT system. The task involved alignment and filtering data to create high-quality parallel corpora for training and evaluating the MT models. Our approach leveraged a combination of dictionary and rule-based methods to ensure data quality and consistency. We achieved an improvement with the highest 1.6 BLEU score compared to the baseline system. Significantly, our approach showed consistent improvements across all test sets, suggesting its efficiency.

1 Introduction

Neural Machine Translation (NMT) has revolutionized the field of machine translation by utilizing deep learning algorithms to learn from large amounts of data and generate high-accurate translations (Sennrich et al., 2016; Vaswani et al., 2017). However, the success of NMT models heavily depends on the quantity and quality of data used for training. On low-resource language pairs, the NMT architectures perform poorly (Koehn and Knowles, 2017; Khayrallah and Koehn, 2018) and are more sensitive to noisy data than statistical machine translation (SMT) methods (Belinkov and Bisk, 2017; Koehn et al., 2018). Therefore, access to vast cleaned corpus can significantly improve the performance of NMT models, allowing them to learn and produce more accurate translations (Bojar et al., 2017).

Fortunately, very large text sources offer a massive collection of data for various types of content, including movie subtitles, stories, and TED Talks. These resources have not been fully exploited for NMT training due to the lack of alignment between the source and target languages. Furthermore, the parallel data which movie subtitles also could be noisy with poor accuracy (Khayrallah and Koehn, 2018). To address this challenge, WMT2023 introduced a shared task on Parallel Data Curation for the Estonian-Lithuanian (et-lt) language pair, focusing on finding the best possible training data set within the web-crawled data to train a downstream NMT model (Sloto et al., 2023).

Among the popular solutions, Thompson and Koehn (2019) introduced using Vecalign to embed sentences and compute the cosine similarity of sentence pairs. Following this method, the shared task provides participants with extensive cosine similarity files and LASER embeddings generated by the LASER model (Heffernan et al., 2022). Participants are tasked with identifying the most optimal parallel data to train the MT models. Although this approach performs efficiently in many cases, Zhou et al. (2022) has shown that the cosine similarity has several limitations. Because the sentence representation in vector space could be impacted by word frequency. To tackle this problem, we build a pipeline to improve the quality of the parallel corpus. Our contributions focus on:

- using the phrased base dictionary to distill the high-quality sentences.
- making the pipeline to re-ranking the top-K cosine similarity.
- analyzing the influence of cosine similarity thresholds on corpus size and MT Models.

The related work is presented in section 2. The detail of our method is described in section 3, experi-

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 359–365
December 6–7, 2023.

ments and results are shown in section 4. Finally, the analysis is presented in section 4.5.

2 Related work

The WMT2023 shared task builds upon previous shared tasks focused on document alignment (WMT 16) and sentence filtering (WMT 18, 19, 20) (Buck and Koehn, 2016; Koehn et al., 2018, 2019, 2020). Previously, several researchers proposed a method to align documents, such as Gomes and Pereira Lopes (2016) used the phrase table to align in the search space and then fill in and refine alignments. Moreover, Thompson and Koehn (2019) employed the Vecalign to gain the sentence embeddings. Nevertheless, Sentence alignments based on cosine similarity have some limitations because the cosine scores could be dense in the range of 0.5 to 1 (Zhou et al., 2022). And with the same query sentence, the higher score could not determine the quality of the parallel sentence.

In addition, for the filtering shared task, participants applied filtering rules to eliminate noisy data, including removing too long/short sentences, using language identification for source and target (Kejriwal and Koehn, 2020) or fine-tuning pre-trained models such as BERT, XLM to re-score sentence pairs (Yang et al., 2019; Bernier-Colborne and Lo, 2019; Açarçiçek et al., 2020). Besides, Xu and Koehn (2017) created artificially noisy data by generating inadequate and nonfluent translations. They used this noisy data to train a classifier to distinguish between high-quality and low-quality sentence pairs within a corpus containing noise.

We found the related ideas from (Lu et al., 2020; Xu et al., 2020). Both of these approaches only focus on the alignment rules and adopt the other pre-trained models. Junczys-Dowmunt (2018) trained an NMT model to filter data and became standard for the high-resource case. Nevertheless, when training an original NMT model with low or noisy resources, the NMT model could face certain limitations. In our work, we utilize the phrase table to compute *edit distance* and extract the superior sentences. Furthermore, we introduce a pipeline to re-rank sentences based on their top-K cosine similarity scores and extract the best compact corpus for training purposes. The detail of our method is presented in section 3.

3 Methodology

3.1 LASER Similarity Scores

The LASER2 similarity scores are produced for the WMT23 shared task. These files are an intermediate output from our baseline submission. The laser embeddings applied L2 normalization and added them to a flat inner product index, such that the resulting scores are equivalent to cosine similarity. And query each index with all L2 normalized embeddings in the target sentences and store the top-8 results (locally, per chunk). Finally, the data is aggregated and meticulously sorted across unique IDs.

3.2 Building Dictionary

Our proposed method incorporates several innovative techniques to enhance the accuracy and efficacy of the filtering process. Initially, we train a phrased table based on MGiza++[1] (Gao and Vogel, 2008), a widely utilized algorithm for learning phrase tables from parallel corpora. Given a source string $X^I = \{x_1...x_i...x_I\}$ and a target string $Y^J = \{y_1...y_j...y_J\}$. In the context of statistical alignment, the probability of a source sentence given a target sentence is formulated as follows:

$$P(X^I|Y^J) = \sum_{i=1}^{J} P_\theta(X_i^I, a_i^J|Y_i^J), \qquad (1)$$

Where a_i^J represents the alignment of the sentence pair. The parameters θ can be estimated using maximum likelihood estimation (MLE) on a training corpus to represent the statistical probability with the best alignment of the sentence pair:

$$a_1^J = \arg\max_{a_1^J} p_\theta(x_i^I, a_i^J|y_i^J), \qquad (2)$$

These steps enable us to establish connections between words in the source and target languages. After that, we extract the dictionary from the phrase base table. This stage helps to remove unnecessary or redundant words and sentences, streamlining the dictionary and improving its quality.

3.3 Edit Distance

In this work, we utilized the dictionary to translate source sentences to target sentences called candidate strings. To identify sentences where the source and target are similar, we compute the edit

[1] https://github.com/moses-smt/mgiza

distance between a pair of candidate and reference sentences.

$$score = \sigma(C_i^I, Y_i^J), \quad (3)$$

Here, C_i^I is the candidate sentence and Y_i^J indicates the target sentence. The σ function employs the Damerau-Levenshtein distance (Miller et al., 2010). We set each insertion, deletion, and substitution as one step, but the transposition (swapping) of two words is computed as $\frac{1}{2}$ step. We opted for option $\frac{1}{2}$ in the swapping step due to the limitation of using a dictionary to translate strings, which neglects word positions. Finally, we choose the sentences that have scores greater than or equal to $\frac{N}{2}$, with N being the max length of the candidate sentence and target sentence.

3.4 Accumulative Filtering

Because the word frequency impacts the cosine score, we produce a filtering pipeline to improve the corpus quality and apply it to the larger corpus. The implementation method is described in Algorithm 1.

Algorithm 1: Accumulative Filtering

Data: The raw parallel corpora: $(X^I, Y^J) \in D$, dictionary, and threshold_values in range {0.7-0.9}
Result: The cleaned data: $(X_f, Y_f) \in D$
`/* Initialize the NMT model` θ `*/`
$t \leftarrow 0.9$;
$X, Y \leftarrow filter(D, t)$;
`/* Filter data via top1 cosine score with the threshold of t */`
$C' \leftarrow translate(X, dictionary)$;
`/* Translate source using dictionary */`
$X_f, Y_f \leftarrow select(C', Y)$;
`/* Select sentences based on edit-distance score */`
$\theta \leftarrow train(X_f, Y_f)$;
`/* Loop t with the step as 0,5 */`
for $t \in threshold\_values$ **do**
  $X, Y \leftarrow filter\_topK(D, t, 8)$;
  $X' \leftarrow translate(X, \theta)$;
  $X_f, Y_f \leftarrow select(C', Y)$;
  $\theta \leftarrow train(X_f, Y_f)$;
end

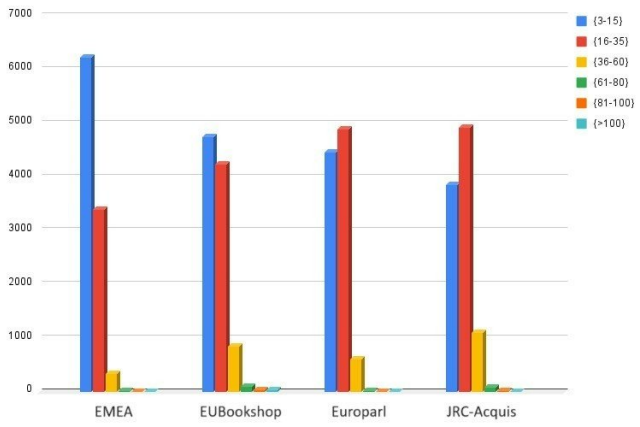

Figure 1: The statistics of the sentence length of each test set are used to evaluate the cleaned corpus. We separate the length of sentences into five levels, with 3-15 as the total sentences exhibit lengths that fall within the 3 to 5 range. The 16-35, 36-60, 61-80, 81-100, and >100 are the 16 to 35, 36 to 60, 61 to 80, 81 to 100, and greater 100 correspondingly.

4 Experiments

In this section, we describe the experimental setup for our system, including the data, training tools, and baseline system.

4.1 Data

In this shared task, the corpus was gathered from a recent snapshot of CommonCrawl[2].

Training Data

From the crawled data, the data is smoothed to some steps such as extracting plain texts from HTML documents, using the identifier language to hold the Estonian and Lithuanian documents, and removing the unsafe and offensive content. Besides, each sentence is assigned a distinct, randomly generated unique ID. These identifiers are uniform within their language datasets but diverge between two languages. This allows quick access and operation with data. Table 2 depicts the total number of collected data.

Testing Data

To assess the quality of the cleaned corpus, we train NMT models and evaluate them in four test sets, including EMEA, EU-Bookshop, Europarl, and JRC-Acquis. The statistics of the sentence length of each test set are exhibited in Figure 1, with the

Table 2: The statistics of sentences are available in the corpus for the Estonian-Lithuanian.

total number of sentences in each test set being 10,000.

4.2 Training Tools

We utilize the training scripts[3] provided by organizers to run the evaluation for the Shared Task. To observe the effect of filtered datasets, we use the same hyper-parameters for the whole experiment to compare results equally. In more detail, the Transformer architecture (Vaswani et al., 2017) is used in the training tool with the default 8 heads, 6 layers, and the model size is 512. Besides, the training pipeline employs the subword segmentation tool provided by (Sennrich et al., 2016) for tokenization. We use the sacreBLEU (Post, 2018) and ChrF++ (Popović, 2015) score to evaluate whole experiments.

4.3 Baseline

Following scripts provided by organizers, we present briefly how to create a simple baseline. Firstly, we collect the whole provided cosine similarity files. Secondly, we extract sentence alignments with the threshold of 0.9 and only select the top highest similarity scores. And finally, we run the end-to-end evaluation to produce BLEU scores from the extracted data.

4.4 Our system

In the first place, we obtain the cosine files that are computed from Laser embeddings. From these files, We extract the sentence pairs by considering the highest cosine similarity score, specifically the top-1 score, and we set a threshold of 0.9. In the following phase, we remove longer sentences having 200 tokens and more and utilize the dictionary to perform word-by-word translation of these source sentences into the target language. After that, we compute the edit distance and eliminate poor-quality sentences. Finally, we employ the cumulative filtering algorithm discussed in section 3.4 to acquire the expanded corpus, opting for thresholds of 0.9, 0.85, and 0.8, respectively.

4.5 Results

In this section, we present the results obtained through a comparative analysis of different methods within the context of our works. Table 1 illustrates the results attained in the development system while preparing the submission. The system responsible for generating the scores for our final submission is shown in underline. We consider the reported results as the LASER baseline, and the outperforming results are indicated in bold.

Our investigation reveals that the LASER baseline provides a starting point for evaluation and moderate levels of performance across a range of metrics. However, the Accumulative Filtering approach, particularly when applying lower threshold values (0.85, 0.8, and 0.75), showcases significant improvements in various metrics. Notably, the choice of threshold within the Accumulative Filtering method influences performance, with lower thresholds yielding higher results. These findings

	top1_0.95	top1_0.9	top1_0.85	top1_0.8	top1_0.75	top1_0.7
Corpus size	173,239	1,230,810	4,194,132	12,918,719	27,811,424	32,568,712
BLEU	16.8	23.9	25.1	25.4	25.0	24.4

Table 3: The influence of sentences on the corpus size and BLEU score. The evaluation of the BLEU score is conducted specifically on the JRC-Acquis test set. Sentence selection is based solely on the cosine score threshold, with additional criteria involving the removal of excessively short or long sentences.

underscore the importance of threshold selection and methodological considerations in achieving optimal outcomes. Further analysis and task-specific considerations are required to determine the most suitable approach for our specific research objectives. We analyze the impact of the cosine similarity score thresholds on the corpus size and quality of NMT models. The details are described in section 4.5.

5 Analysis

In this section, we delve deeply into our approaches and the scale of our data corpora. Firstly, we conduct some experiments to find the best threshold when selecting the top-K highest cosine similarity score. For every source sentence, our approach involves selecting a single target sentence from a set of eight candidates based on the highest cosine similarity score provided. Table 3 illustrates the impact of different sentence selection criteria, denoted by the cosine similarity thresholds (top1_0.95, top1_0.9, top1_0.85, top1_0.8, top1_0.75, top1_0.7), on both the corpus size and BLEU score. The corpus size varies significantly depending on the threshold, ranging from 173,239 sentences to 32,568,712 sentences. Simultaneously, the BLEU score, evaluated on the JRC-Acquis test set, fluctuates, with the highest score of 25.4 achieved at the top1_0.8 threshold. These findings underscore the delicate balance between corpus size and translation quality, highlighting the importance of threshold selection in the context of machine translation evaluation.

Secondly, we conduct a statistical analysis to determine the number of sentence pairs that achieve the highest cosine score but are not considered parallel sentences. Table 4 shows the statistics for the number of sentences that do not have the highest cosine similarity score but are regarded as parallel sentences. The table indicates a total of 5,981,148 sentences in cleaned data and 353,642 sentences are considered re-ranking parallel sentences.

No.	Cleaned Data	Re-ranking
Num of Sents	5,981,148	353,642

Table 4: Number of sentences that are not in top-1 cosine similarity score, but are considered parallel sentences.

6 Conclusion

In conclusion, our study has provided valuable insights into the performance of different methods employed in our research on WMT2023 parallel data curation shared tasks. Our findings reveal that while the LASER baseline and using the dictionary method exhibited moderate and consistent performance across several metrics, the accumulative filtering approach, particularly when adopting lower threshold values (0.85, 0.8, and 0.75), demonstrated notable improvements in various aspects. Notably, the selection of the threshold played a pivotal role in influencing performance outcomes. Furthermore, our analysis also encompassed the identification of sentence pairs that exhibit parallel characteristics, even if they may not always possess the highest cosine similarity scores. In the future, further investigation and task-specific considerations will be essential in finding the smallest possible set of training data and achieving the highest result.

A Sentence Alignment Approach to Document Alignment and Multi-faceted Filtering for Curating Parallel Sentence Pairs from Web-crawled Data

Steinþór Steingrímsson

Reykjavik, Iceland
steinthor.steingrimsson@arnastofnun.is

Abstract

This paper describes the AST submission to the WMT23 Shared Task on Parallel Data Curation. We experiment with two approaches for curating data from the provided web-scraped texts. We use sentence alignment to identify document alignments in the data and extract parallel sentence pairs from the aligned documents. All other sentences, not aligned in that step, are paired based on cosine similarity before we apply various different filters. For filtering, we use language detection, fluency classification, word alignments, cosine distance as calculated by multilingual sentence embedding models, and Bicleaner AI. Our best model outperforms the baseline by 1.9 BLEU points on average over the four provided evaluation sets.

1 Introduction

The aim of the Shared Task on Parallel Data Curation at the Eighth Conference on Machine Translation (WMT23) is to evaluate parallel data curation methods (Sloto et al., 2023). The goal is to find the best machine translation (MT) training data within a provided pile of web-crawled data.

The language pair chosen for the task is Estonian-Lithuanian. The provided data is extracted from a single snapshot of CommonCrawl,[1] which according to the task organizers should contain enough training data to train a reasonable Estonian → Lithuanian MT model, even with limited compute. As well as providing the data, the organizers release pre-computed intermediate steps from a baseline, so participants can choose whether to focus on one or more aspects of the task. We describe the provided data and the baseline in Section 3.

In our submission we experiment on two aspects of parallel data curation. Initially we try to to identify parallel documents in the two languages. We then align sentences in the documents using our own sentence alignment tool, SentAlign[2] (Steingrímsson, 2023; Steingrímsson et al., 2023b), and train an MT system on the resulting sentence pairs. SentAlign is a sentence aligner that uses LaBSE (Feng et al., 2022) to score all possible alignment combinations for a document pair, selects the highest scoring one, but then re-evaluates the results by looking at each individual alignment and their closest neighbours to see if localized scores can be raised. This is to counteract an effect of dynamic programming with cosine similarity, which often favours many-to-many alignments over 1-to-1 alignments (see e.g. Thompson and Koehn (2019). Steingrímsson et al. (2023b) show that this approach outperforms other aligners on two evaluation sets, as well as on a downstream task. The other aligners include aligners such as the length based Gale-Church (Gale and Church, 1991), MT-based Bleualign (Sennrich and Volk, 2010) and Vecalign (Thompson and Koehn, 2019) which is the most similar to SimAlign, using LASER embeddings (Artetxe and Schwenk, 2019b) to calculate cosine similarity of alignment candidates, and a recursive approximation to reduce the search space, as opposed to evaluating all possibilities as SentAlign does. We describe our approach to document alignment in Section 4.1. Subsequently, we try to identify parallel sentence pairs in all the other provided data and run a number of different filters to remove sentence pair candidates that we deem likely to be detrimental or useless for MT training. Our filtering approaches are described in Section 4.2

2 Related Work

Khayrallah and Koehn (2018) show that incorrect translations, untranslated target text, misalignments, and other noisy segments in a parallel corpus have a detrimental effect on the output quality of neural machine translation (NMT) systems trained on that corpus, as measured by using BLEU (Papineni et al., 2002). They specify five general

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 366–374
December 6–7, 2023.

classes of noise commonly found in a German-English version of the ParaCrawl corpus: misaligned sentences, disfluent text, wrong language, short segments, and untranslated sentences. They find this distinction to be useful to give a general idea of which types of errors seem to have the least impact on MT systems (short segments, untranslated source sentences and wrong source language) and which have the most dramatic effect (untranslated target sentence). Misalignments, misordered words, and wrong language, in source or target texts, are also shown to be harmful, but not as harmful.

The Conference on Machine Translation, WMT, hosted three annual shared tasks on parallel corpus filtering (Koehn et al., 2018, 2019, 2020), focusing on filtering noisy web-crawled corpora. Submitted systems include the ones by Chaudhary et al. (2019) and Artetxe and Schwenk (2019a), who introduce approaches based on cross-lingual sentence embeddings trained from parallel sentences. Both papers use cosine similarity and consider the margin between a given sentence pair and its closest candidates to normalize the similarity scores.

Bicleaner (Sánchez-Cartagena et al., 2018; Ramírez-Sánchez et al., 2020) uses a set of handcrafted rules to detect flawed sentences and then proceeds to use a random forest classifier based on lexical translations and several shallow features such as respective length, matching numbers and punctuation. It also scores sentences based on fluency using 5-gram language models. The tool ranked highly on the first two parallel corpus filtering tasks at WMT. Bicleaner AI (Zaragoza-Bernabeu et al., 2022) is a fork of Bicleaner using a neural classifier. It has been shown to give significant improvements in translation quality as measured by BLEU when used for filtering training data for multiple language pairs, as compared to the previous version of the tool.

In contrast to tools that apply a single method for parallel corpus filtering, Aulamo et al. (2020) implement multiple different filters in the OpusFilter toolbox. These include heuristic based filters, language identification, character-based language models and word alignment tools. The toolbox can furthermore be extended with custom filters.

Herold et al. (2022) revisit the noise classes specified by Khayrallah and Koehn (2018) to investigate how accurately two strong filtering approaches, cross entropy (Rossenbach et al., 2018) and LASER (Artetxe and Schwenk, 2019b) can filter out different noise classes. They find that for a common language pair, German→English, most types of noise can be detected with over 90% accuracy, although misalignments and poor synthetic translation can only be detected with an accuracy of less than 70%. For a less common language pair, Khmer–English, the performance of the filtering system degraded significantly and the accuracy of identifying noise was lowered by 8–19%, depending on the type of noise, indicating that results can vary dramatically depending on the languages.

3 Data and Baseline

The provided data is retrieved from the 2023-06 snapshot of Common Crawl. The organizers have extracted plain text from HTML documents and used the Fasttext (Joulin et al., 2017) language identification model to remove documents not classified as Estonian or Lithuanian by the model, based on the first 2,000 characters of the document. Unsafe and offensive content has been removed. Documents from host names in the following lists in the blocklist project[3] where removed: *abuse, basic, crypto, drugs, fraud, gambling, malware, phishing, piracy, porn, ransomware, redirect, scam, torrent*. Documents were split into paragraphs based on line breaks, and then into sentences using Mediacloud Sentence Splitter.[4] Each sentence was assigned a unique sentence id and classified using the Fasttext language identification model. The data is provided in TSV format.

The task organizers provide LASER2 sentence embeddings (Heffernan et al., 2022) for all sentences in the correct language, as classified by the Fasttext model. They index the embeddings and query each index to retrieve the top-8 results for each sentence, based on cosine similarity. We use these results as a starting point for our filtering approaches, as described in Section 4.2. The baseline simply takes top-1, i.e. the highest scoring sentence pair for each sentence, provided the score exceeds a threshold of 0.9. This results in a set of 2,654,090 parallel pairs for training a baseline model.

A script for training the baseline model using Sockeye (Hieber et al., 2022) was provided. We use the script and Sockeye for training all models on a single Nvidia GeForce RTX 3090 GPU card.

[4] https://github.com/mediacloud/sentence-splitter

4 System Architecture

In this section we describe our approaches to the parallel data curation problem. First, we try to identify parallel documents in the two languages and align them on the sentence level. Second, we use the provided sentence pair candidates, eight for each sentence in each language, and filter using a number of different approaches to remove possibly detrimental pairs from our training set. The sentence pairs from the aligned documents and the filtered sentence pairs are combined to compile our final dataset.

4.1 Document identification by Sentence Alignment

Bilingual document alignment is a matching task that considers documents in two languages and estimates the likelihood of the documents being a translation of each other. In the Bilingual Document Alignment Shared Task at WMT 2016 (Buck and Koehn, 2016), the submitted systems used a variety of approaches. Some of these include Gomes and Pereira Lopes (2016), who used a phrase table from a phrase-based statistical machine translation (SMT) system to compute coverage scores. Dara and Lin (2016) use MT to find corresponding documents based on n-gram matches, assisted by document length ratio, and Mahata et al. (2016) use text matching based on sentence alignment and word dictionaries. Thompson and Koehn (2020) present a document alignment method that uses information on sentence order both when generating candidates and when re-scoring the candidates. For re-scoring the candidate pairs they perform sentence alignment and score the alignment based on semantic similarity of the resulting sentence pairs.

In this paper, we use sentence alignment and average cosine distance as measured by LaBSE (Feng et al., 2022) to determine whether documents can be aligned. The provided dataset contains sentences scraped from the web, information on the web domain and an order of sentences within documents on the websites. We recreate documents, most likely to have a corresponding translation in the other language, using this information. In order to reduce the need for compute we only consider texts from the same domain to be possible candidates for document alignment.

Our approach is the following:

1. We start by collecting a list of all web domains common to both languages.
2. From these domains, we recreate all documents that contain more than five sentences. The recreated documents have one sentence in each line.
3. Using SentAlign, for each domain we align the recreated documents in Estonian to all the recreated documents in Lithuanian, and vice versa. SentAlign outputs all aligned sentence pairs, as well as the LaBSE score for the pair.
4. If more than half of the sentences in either language does not get an alignment, the document pair is discarded.
5. If the average LaBSE score for all sentence alignments for a given document pair is below a threshold of 0.6, the document pair is discarded.
6. We calculate an alignment ratio using Equation 1:

$$\frac{1}{2}\left(\frac{et_{aligned}}{et_{total}} + \frac{lt_{aligned}}{lt_{total}}\right) \quad (1)$$

Where $et_{aligned}$ is the number of Estonian sentences that obtain an alignment to a Lithuanian sentence, and et_{total} is the total number of Estonian sentences in the document. $lt_{aligned}$ and lt_{total} are the corresponding numbers for Lithuanian.

From a pool of documents for each web domain, a greedy algorithm selects the document pair with the highest alignment ratio, and if multiple pairs have the highest ratio, one of those with the highest average LaBSE score. The selected documents are then removed from the pool and the process repeated until all acceptable pairs have been collected for that domain.

The sentence alignment approach to identifying aligned documents in (Thompson and Koehn, 2020) uses Vecalign (Thompson and Koehn, 2019) and LASER embeddings to perform sentence alignment and judge sentence similarity. While we use a different aligner and embeddings, our approach follows the same general strategy, with the main difference being that language identification is part of their scoring function while we simply require over half the sentences in each document to obtain an alignment. We can do this as the provided data set we work with has been selected based on

language identification, so we can assume the sentences we work with are generally in the correct language.

Our process results in 4,372 document pairs, containing 160,787 sentence pairs after deduplication. We remove all sentence pairs that have less than three tokens in either language, disregarding all numbers and other non-alphabetical symbols. Furthermore, we remove all sentence pairs that obtain a LaBSE score lower than 0.4. While we do not have any statistics on what the ideal LaBSE threshold should be for this language pair, Steingrímsson et al. (2023a) show that for Icelandic-English over half the sentence pairs are acceptable when the LaBSE score exceeds 0.4, and we base our threshold on that. Our approach results in a set of 120,756 sentence pairs obtained from parallel documents, with 114,301 of those used for training after we have removed sentences that may overlap with test and development datasets.

4.2 Filtering Sentence Pair Candidates

Having extracted sentence pairs from aligned documents, we have yet to consider most of the data in the provided dataset. We experiment with various filtering filtering approaches and as a starting point we simply use the sentence pair candidates provided by the tasks organizers, eight Lithuanian sentences for each Estonian sentence and eight Estonian sentences for each Lithuanian sentence, as described in Section 3. To extract the best sentence pairs, we apply a number of diverse filtering approaches to these sentence pair candidates.

We start by filtering the sets of Estonian and Lithuanian sentences separately:

1. To start with, we have 142,516,521 sentences in Estonian and 210,914,146 sentences in Lithuanian. We deduplicate these sets, giving us 53,228,455 Estonian sentences and 63,536,939 Lithuanian sentences.

2. Although the Fasttext language detection model has been applied to the data, it still contains sentences that are in different languages. In order to remove these we run two additional language detection tools, lingua[5] and langdetect (Shuyo, 2010). From both of these tools we acquire a language classification for each sentence. We then remove all sentences that do not obtain the expected classification by at least two of the three classifiers that have been applied. This leaves us with 33,500,758 Estonian sentences and 43,173,412 lithuanian sentences.

3. In order to remove sentences that may be disfluent we use two pre-trained GPT-2 (Radford et al., 2019) models, one for each language,[6] to classify the sentences. For that we use the approach described in (Steingrímsson et al., 2023a): We collect two sets of sentences for each language, one containing sentences that are presumably fluent and the other one containing sentences that are likely to be disfluent. To train the classifiers, we selected 15,000 sentences randomly for each language from the Leipzig Corpora Collection (Goldhahn et al., 2012) for the fluent examples and 15,000 random sentences from the provided data we had already discarded in the previous step. The classifier uses the GPT-2 model to calculate perplexity for the sentences, and chooses potential thresholds as the average between two adjacent perplexity values. It then uses a maximization function to decide on a threshold that yields the most accurate prediction based on the training set. After classifying the remaining sentences, and removing the approximately 120 thousand sentences included in the document alignment data previously acquired, we are left with 31,298,451 Estonian sentences and 29,498,886 Lithuanian sentences.

Next, we consider the provided sentence pair candidates as calculated using LASER2. We have two candidate lists, one with eight candidates for each Estonian sentence and another with eight candidates for each Lithuanian sentence. We remove all pairs containing sentences not in our filtered sentence lists. We then take an intersection of the resulting sets. The intersection thus only contains sentence pairs where the Lithuanian sentence is one of the top 8 candidates for the Estonian sentence, and vice versa. This gives us a list of 36,250,870 sentence pairs, 35,720,955 after we have excluded all pairs containing sentences that overlap with sentences in the evaluation or development data sets. It should be noted that at this stage some sentences

[5] https://pemistahl.github.io/lingua-py

[6] Lithuanian model: https://huggingface.co/DeividasM/gpt2_lithuanian_small; Estonian model: https://huggingface.co/tartuNLP/gpt-4-est-base

are found in multiple sentence pairs. We proceed to filter this set of sentence pairs:

4. For each Estonian sentence we select only the Lithuanian sentence that gives the highest LASER2 score, and for each Lithuanian sentence we likewise select only the Estonian sentence with the highest score. This reduces the candidate list to 24,735,722 sentence pairs.

5. The sentences comprising the pairs are tokenized. We then run fast-align (Dyer et al., 2013) to obtain word alignments for each sentence pair. These word alignments are used to calculate a word alignment score, WAScore, a word alignment-based score devised to measure word-level parallelism, introduced in Steingrímsson et al. (2021). Steingrímsson et al. (2023a) show that when WAScore is low, very few sentences are good mutual translations. We remove all sentence pairs that have a WAScore lower than 0.15, indicating that 40% or fewer tokens in either sentence obtained an alignment on average. After that our candidate list contains 21,387,140 sentence pairs.

6. We calculate a LaBSE score for all the pairs. If the LaBSE score is higher than 0.9, we accept the sentence pair for our final training set without further processing. These are 891,313 sentence pairs. We also set a minimum threshold of 0.6, as suggested by Feng et al. (2022). This gives us 13,289,869 sentence pairs to processed further, and the rest is discarded.

7. Next, we train Bicleaner AI (Zaragoza-Bernabeu et al., 2022) to classify the Estonian-Lithuanian language pair. For training Bicleaner we need monolingual corpora and parallel corpora. For monolingual data we collected 5 million sentences in each language from the Leipzig Corpora Collection and used 100 thousand parallel pairs randomly selected from the set of sentence pairs extracted from the document alignment step described in Section 4.1. Our Bicleaner AI model gives low scores and we accept sentence pairs with scores over the threshold of 0.05. We run the model on all unfiltered sentences, removing over 20 million and leaving us with 14,988,586 sentence pairs, as shown in Table 1.[7] We later take an intersection of this set and the set obtained by applying other filters, as shown in Table 2.

8. Finally, we use the LASER2 scores, LaBSE scores, WAScore and NMTScore (Vamvas and Sennrich, 2022) with a classifier to predict whether a sentence pair contains a mutual translation. NMTScore is based on translation cross-likelihood, the likelihood that a translation of segment *A* into some language, could also be a translation of segment *B* into the same language. We used OPUS-MT models to translate the segments. We use a logistic regression (Cox, 1958) classifier trained on the same data as the GPT-2 classifiers described above. The classifier accepts as valid mutual translations, 2,967,348 sentence pairs out of the 13,289,869 marked for further processing in (6). When these are added to the set of previously accepted sentences from the aligned documents and the ones having very high LaBSE scores, we have 3,902,740 in our final training set, before applying the Bicleaner AI filter, as shown in Table 2.

5 Results

In addition to the baseline models described in Section 3, we trained eleven MT models using data sets at different stages of the compilation process and evaluated on the provided test sets, using BLEU[8] and chrF[9]. Table 1 shows the results after each filtering step until the logistic regression filter, and Table 2 shows the final sets after filtering and an ablation study on the effects of combining the sets acquired using different approaches. Our best model (**K**) was trained on a combination of sentence pairs from the aligned document pairs (**G**), sentence pairs with a LaBSE score over 0.9 (**H**) and the sentence pairs accepted by our logistic regression filter (**I**).[10]

[7] Our model is available at Github: `https://github.com/steinst/BicleanerAI-models`

[8] Sacrebleu signature: BLEU+nrefs.1+case.mixed+eff.no+tok.3a+smooth.exp+version.2.3.1

[9] Sacrebleu signature: chrF2+nrefs.1+case.mixed+eff.yes+nc.6+nw.0+space:no+version.2.3.1

[10] We submitted dataset *L* to the shared task, which has somewhat lower scores than dataset *K* and was the dataset that was used to train our second best model. This was due to an error in our training script used for selecting a dataset to submit. The script did not remove sentences overlapping with evaluation data, giving us incorrect results. This error has been rectified in all results given in this paper and when we talk about our best model we are always referring to the model trained on dataset *K*.

Data Filters	No. sent.	Bleu				ChrF			
		EMEA	EUB	EP	JRC	EMEA	EUB	EP	JRC
A. Unfiltered	35,720,955	16.2	14.8	15.1	18.2	45.0	43.3	45.9	45.8

L. K ∩ B	2,684,931	20.4	19.7	18.4	25.1	51.4	52.5	51.8	54.9

Table 2: Datasets created using different approaches and an ablation study for investigating the effect of each dataset on MT quality as measured by BLEU and ChrF. The logistic regression dataset is created by applying our logistic regression classifier on dataset E in Table 1. We evaluate on the four provided test sets.

Our best model outperforms the baseline by approximately 1.9 BLEU on average. We find that the sentence pairs from the aligned documents, only 114,301 pairs, improve the BLEU on average by 1.0 BLEU. This indicates that these sentence pairs are useful and that identifying document alignments in web-scraped data is worth the effort. We also find that the sentence pairs having high LaBSE scores, over 0.9, give much better results on their own than over three times more sentence pairs with LaBSE scores in the range 0.6 to 0.9, even though they have been filtered further using additional methods. As shown in Table 2, combining these two sets raises the scores substantially. Furthermore, while the Bicleaner AI model we trained seemed to give decent results in earlier stages, using it to filter the dataset we acquired using other approaches actually decreased the scores. This indicates that the Bicleaner AI model is rejecting too many useful sentence pairs. It could be useful to try to investigate further which of these rejected sentences are useful for MT training and which are truly detrimental, but we leave that for future work.

6 Conclusions and Future Work

Our alignment and filtering approach resulted in an improvement over the baseline in terms of BLEU score for the four evaluation sets. We identified 4,372 document pairs in the provided dataset, which we aligned on sentence level and used the resulting data set for training. We then combined a number of filtering approaches for determining which sentence pair candidates from a provided candidate list would be likely to be useful, these included an ensemble approach for language detection, using three different tools, a GPT-2 based classifier to determine whether sentences are fluent or disfluent, a logistic regression classifier based on word alignment scores and two sentence embedding based scores, LaBSE and LASER2, and finally a Bicleaner AI classifier.

Working in a similar vein, many different paths could be taken for future work on this problem. Steingrímsson et al. (2023a) show that it can be beneficial to inspect how different filters suit a given translation direction. A filtering method giving an optimal results for $\text{lang}_a \rightarrow \text{lang}_b$ is not necessarily the optimal filtering approach for $\text{lang}_b \rightarrow \text{lang}_a$.

In this work we did not try to evaluate the filtering approaches with regards to translation direction. For translating only from Estonian to Lithuanian, removing incoherent and ungrammatical Estonian sentences may not be as important as removing such sentences in Lithuanian, as it is more important that the target language data contains coherent and well written examples. Different levels of filtering for the different languages could thus be useful in order to add more useful examples.

The aim of our filters is to remove sentences likely to be detrimental in MT training. While we do know about some of the qualities that reduce translation quality, as discussed in Section 2, more fine-grained classifications may be useful. For example, we could designate different levels of misalignments, which include partial alignments defined as sentence pairs where a part of one or both sentences is not represented in the other sentence. Steingrímsson et al. (2023c) argue that extracting mutual translations from such pairs, while discarding the extraneous data, may improve the quality of MT models trained on the data, and show that for one parallel corpus. If that holds in general, it could be useful when working with web-scraped data to identify when misalignments become detrimental and when they can be useful, as well as helping to come up with effective ways to refine such sentence pairs.

Table 2 shows that the datasets compiled from the aligned documents and the one comprising sentence pairs with very high LaBSE scores are very useful as additional training data. We presume that this is an indication of these sets containing higher-quality data. While not suitable for the shared task, it would be an interesting experiment to use a curriculum learning approach for training models on web-scraped corpora such as the one we are using by training a model first on a large set of possibly useful sentences and then fine-tuning the model on the higher-quality data.

Finally, it should be noted that the training times for these models varied considerably. While our best model reached the optimal checkpoint in approximately 20 hours and the second best in 12 hours, the models trained on the larger datasets listed in Table 1 took between 50 and 80 hours of training, using the same settings, while still resulting in lower quality models. It shows that careful curation of training data for MT is not only important for improving model quality in terms of better translations, it also allows for much faster training resulting in a lower carbon footprint.

Abstract

Despite the known limitations, most machine translation systems today still operate on the sentence-level. One reason for this is, that most parallel training data is only sentence-level aligned, without document-level meta information available. In this work, we set out to build context-aware translation systems utilizing document-level monolingual data instead. This can be achieved by combining any existing sentence-level translation model with a document-level language model. We improve existing approaches by leveraging recent advancements in model combination. Additionally, we propose novel weighting techniques that make the system combination more flexible and significantly reduce computational overhead. In a comprehensive evaluation on four diverse translation tasks, we show that our extensions improve document-targeted scores substantially and are also computationally more efficient. However, we also find that in most scenarios, back-translation gives even better results, at the cost of having to re-train the translation system. Finally, we explore language model fusion in the light of recent advancements in large language models. Our findings suggest that there might be strong potential in utilizing large language models via model combination.

1 Introduction

Machine translation (MT), the automatic translation of text from one language to another, has seen significant advancements in recent years, primarily driven by neural machine translation (NMT) models (Bahdanau et al., 2015; Vaswani et al., 2017). These models have demonstrated remarkable capabilities in capturing complex linguistic patterns and producing high-quality translations (Wu et al., 2016; Hassan et al., 2018). Nevertheless, most models to-date operate on sentence-level, i.e. translate sentences independently without the context of the surrounding document. Without access to such context, it is impossible for these MT systems to account for discourse-level phenomena such as resolution of ambiguous words and coherence. Unsurprisingly, automatic translations are perceived as much worse, when they are evaluated on entire documents rather than just at the sentence-level (Läubli et al., 2018, 2020; Maruf et al., 2022).

An obvious solution to this problem is to utilize context-aware MT models (Tiedemann and Scherrer, 2017). While document-level NMT models have been thoroughly studied in recent years, sentence-level MT remains the standard despite its inherent limitations. One of the main reasons for this is that most of the document-level approaches rely on parallel training data with document-level metadata. Most releases of large parallel training corpora lack this information and remain purely sentence-level (Bañón et al., 2020; Schwenk et al., 2021). In contrast, large amounts of document-level monolingual data are readily available for almost all domains and languages.

In this work, we strive to build a context-aware MT system that does not rely on any parallel document-level training data. Instead, we use monolingual documents to train a document-level language model (LM), which we fuse with an existing sentence-level MT model during translation. While existing work on LM fusion shows that the fused model is able to incorporate document-level context (Jean and Cho, 2020; Sugiyama and Yoshinaga, 2021), these approaches can be improved. Our work aims to do so in two main directions.

First, we acknowledge that NMT models implicitly learn the language modeling task during training. Recently, Herold et al. (2023) showed that estimating and neutralizing this internal LM can improve translation quality for sentence-level MT. We adapt their approach to document-level LM fusion and demonstrate that this also improves discourse modeling.

Second, the contribution of the fused MT model,

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 375–391
December 6–7, 2023.

the document-level LM and the internal LM must be balanced by a set of fusion scales. Existing work defines the fusion scales as static hyperparameters which are tuned on a validation set via an extensive grid search (Gülçehre et al., 2015; Jean and Cho, 2020; Sugiyama and Yoshinaga, 2021). In our work, we provide two simple alternatives to grid search which allow for automatically tuned context-dependent fusion scales. Our approaches eliminate the need for expensive tuning and further improve discourse-modelling.

The contributions of this work are as follows:

1. We propose multiple extensions to the existing approaches on document-level LM fusion for MT.

2. We compare our methods against two strong baselines: Back-translation, the to-date most popular way to utilize monolingual data for MT, and a task-specific LM re-ranking baseline for pronoun disambiguation. The comparison takes place over four diverse translation tasks in terms of general translation quality as well as specific context-dependant phenomena.

3. We present first results on fusing a large language model (LLM) with a sentence-level MT system.

2 Related Works

Most works on document-level NMT rely on parallel document-level data for system training.

Tiedemann and Scherrer (2017) propose to concatenate adjacent sentences on source and target side and input this into the NMT model which has the exact same architecture as the vanilla sentence-level transformer (Vaswani et al., 2017). Later, many works have proposed modifications to the architecture to better accommodate the additional context (Jean et al., 2017; Bawden et al., 2018; Zhang et al., 2018; Voita et al., 2018; Kuang and Xiong, 2018; Miculicich et al., 2018; Maruf and Haffari, 2018). However, it has been shown that the simple concatenation approach performs as good, if not better than these more complicated variants (Lopes et al., 2020; Sun et al., 2022).

Maybe the biggest challenge for document-level NMT is that most of the parallel MT training data is not document-level (Esplà-Gomis et al., 2019; Schwenk et al., 2021). Recently there has been some effort to restore document-level meta information from existing sentence-level corpora but this is a very time consuming and error-prone process (Ghussin et al., 2023). Therefore, approaches to document-level NMT have been proposed that utilize document-level monolingual data, of which typically large amounts are readily available.

One direction is to back-translate the document-level monolingual data to create synthetic parallel document-level data. The reverse system used for back-translation can be either sentence-level (Junczys-Dowmunt, 2019; Saleh et al., 2019; Post and Junczys-Dowmunt, 2023) or document-level (Sugiyama and Yoshinaga, 2019; Huo et al., 2020). A downside of this approach is that the final MT system has to be re-trained to incorporate the new synthetic data.

Another line of work uses document-level language models in combination with sentence-level translation models. Gülçehre et al. (2015) were the first to propose a log-linear combination of sentence-level language and NMT models, coining the term 'shallow fusion'. Recently, it was shown that the shallow fusion approach for sentence-level NMT can be improved by compensating for the implicitly learned internal language model of the NMT system (Herold et al., 2023). Regarding the integration of a document-level LM, earlier approaches simply use the LM for re-ranking the hypothesis of the sentence-level NMT model (Stahlberg et al., 2019; Yu et al., 2020). Several works have proposed to employ a log-linear combination between sentence-level NMT system and document-level LM (Garcia et al., 2019; Jean and Cho, 2020; Sugiyama and Yoshinaga, 2020). Both Jean and Cho (2020) and Sugiyama and Yoshinaga (2020) propose to also include the probabilities of the LM without context information in order to mitigate the influence of the current sentence on the LM probabilities. While our approach also uses the output of a sentence-level LM, it is conceptually different from the previous works in that we want to mitigate the influence of the internal LM from the NMT model, resulting in a different final formulation. To further improve LM incorporation, Jean and Cho (2020) propose to use subword-dependent fusion scales instead of a single scale per model.

Apart from back-translation and LM integration there exist some other ways to utilize additional monolingual document-level data for MT. Voita et al. (2019) train a document-level automatic post

editing system on the monolingual data and use it to improve the hypotheses from a sentence-level NMT system in a two-pass approach. Several works utilize the additional data in a multi-task learning approach (Junczys-Dowmunt, 2019) or for pre-training (Zhu et al., 2020; Chen et al., 2021b; Liu et al., 2020; Chen et al., 2021a).

Very recently, LLMs have shown their potential for the task of document-level NMT (Wang et al., 2023). However, it is unclear how much parallel training samples were seen during the large scale pre-training on trillions of tokens.

3 Document-level Language Model Fusion

The sentence-level MT model translates a source sentence F into a target sentence $E := e_0^I$ of subwords e_i. In the document-level LM fusion approach, we additionally provide the k previous target-side sentences E_{-k}^{-1} as context[1].

3.1 Internal Language Model Neutralization

As the translation model already implicitly learns probabilities that are source-independent, directly fusing the MT model and the document-level LM overvalues the source-agnostic probabilities. Therefore, we estimate the internal LM of the MT model and in total combine three models during generation:

- the existing sentence-level MT model $p_{\text{TM}}(e_i) := p_{\text{TM}}(e_i \,|\, e_0^{i-1}, F)$,
- the LM $p_{\text{LM}}(e_i) := p_{\text{LM}}(e_i \mid e_0^{i-1}, E_{-k}^{-1})$ trained on monolingual documents with access to the previous target sentences E_{-k}^{-1},
- and a second LM $p_{\text{ILM}}(e_i) := p_{\text{ILM}}(e_i \,|\, e_0^{i-1})$ which estimates the internal LM probabilities implicitly learned by the MT model. We train this LM separately on the target-side of the MT training data, as we found that this approach works best for document-level MT when compared to other approaches presented by Herold et al. (2023). This comparison can be found in Appendix A.3.

We multiply the model output probabilities and normalize them. The resulting probability distribution is now conditioned on both the source sentence F and the target-side context E_{-k}^{-1}:

$$p(e_i) := p(e_i \,|\, e_0^{i-1}, F, E_{-k}^{-1}) := \frac{p_{\text{TM}}^{\lambda_0}(e_i) \cdot p_{\text{LM}}^{\lambda_1}(e_i) \cdot p_{\text{ILM}}^{-\lambda_2}(e_i)}{\sum_{e'} p_{\text{TM}}^{\lambda_0}(e') \cdot p_{\text{LM}}^{\lambda_1}(e') \cdot p_{\text{ILM}}^{-\lambda_2}(e')}. \quad (1)$$

Each model is weighted with a scalar $\lambda_0, \lambda_1, \lambda_2 \geq 0$, the internal LM is included with a negative exponent. We tune these fusion scales on the validation set for BLEU via a grid search over $\lambda_0, \lambda_1, \lambda_2 \in \{0, 0.1, \ldots, 1\}$.

Existing work on document-level LM fusion uses a similar formulation as our approach, but instead of neutralizing the internal LM of the MT model, it accounts for the sentence-level probabilities $p_{\text{LM}}(e_i \,|\, e_0^{i-1})$ of the document-level LM (Jean and Cho, 2020; Sugiyama and Yoshinaga, 2021). In the particular case where there are no previous sentences available, this approach simply falls back to using only the sentence-level MT model probabilities. Our approach on the contrary can also leverage the gains obtained from sentence-level LM fusion and is theoretically more expressive.

3.2 Context-dependent Fusion Scales

Choosing appropriate fusion scales $\lambda_0, \lambda_1, \lambda_2$ in Equation 1 is crucial. Conventionally, the scales are tuned via grid search. This is problematic in three aspects:

1. Grid search is expensive. Testing e.g. ten possible values for each of the three model scales already requires translating the validation set 1000 times.
2. The tuning process depends on the tuning data, its domain and the tuning objective. E.g., the scales that optimize document-targeted metrics differ from the ones that maximize sentence-level translation quality (Sugiyama and Yoshinaga, 2021).
3. Fusion scales obtained by a hyperparameter grid search must be constant. Document-level context however is not uniformly useful for all predicted subwords.

In the following, we propose two simple alternatives to obtaining fusion scales with grid search that overcome the aforementioned issues.

[1] At the beginning of the document we only provide as many sentences as available.

3.2.1 On-the-fly Fusion Scales

During decoding, the next subword e_i is chosen to maximize the fused probability (Equation 1). We propose to also choose the fusion scales in a similar fashion and define them to maximize the fused model scores:

$$(\lambda_0, \lambda_1, \lambda_2) \coloneqq \underset{(\lambda_0,\lambda_1,\lambda_2)}{\operatorname{argmax}} \frac{p_{\text{TM}}^{\lambda_0}(e_i) \cdot p_{\text{LM}}^{\lambda_1}(e_i) \cdot p_{\text{ILM}}^{-\lambda_2}(e_i)}{\sum_{e'} p_{\text{TM}}^{\lambda_0}(e') \cdot p_{\text{LM}}^{\lambda_1}(e') \cdot p_{\text{ILM}}^{-\lambda_2}(e')}. \quad (2)$$

Our model maximizes over the discrete set $\lambda_0, \lambda_1, \lambda_2 \in \{0, 0.1, \ldots, 1\}$. This approach obviates the need for separate scale tuning entirely and only has a small overhead during generation.

3.2.2 Automatically Learned Fusion Scales

Alternatively, we propose to learn the fusion scales automatically using a small amount of training examples (F, E, E_{-k}^{-1}) with document-level context, similarly to Jean and Cho (2020). We obtain the training data by back-translating the monolingual data (see Section 5). Automatic learning allows us to implement subword-dependent fusion scales: We introduce a set of learnable parameters $\lambda_0(e), \lambda_1(e), \lambda_2(e)$ for each subword e from the target vocabulary and learn them automatically by optimizing the cross-entropy loss

$$(\lambda_0, \lambda_1, \lambda_2) \coloneqq \underset{\lambda\colon V \to \mathbb{R}^3}{\operatorname{argmax}} \sum_{(F,E,E_{-k}^{-1})} \sum_i \log \frac{p_{\text{TM}}^{\lambda_0(e_i)}(e_i) \cdot p_{\text{LM}}^{\lambda_1(e_i)}(e_i) \cdot p_{\text{ILM}}^{-\lambda_2(e_i)}(e_i)}{\sum_{e'} p_{\text{TM}}^{\lambda_0(e')}(e') \cdot p_{\text{LM}}^{\lambda_1(e')}(e') \cdot p_{\text{ILM}}^{-\lambda_2(e')}(e')}. \quad (3)$$

Scale learning uses the same optimization parameters as the MT model was originally trained with. The scale parameters are initialized with a small variance around zero while all other parameters are frozen.

4 Document-level Language Model Pronoun Re-ranking

Besides consistency, the main problem of discourse-modelling are ambiguities. E.g. translating the English pronoun 'it' to German requires access to the noun that it refers to, which might only be found in a preceding sentence (Müller et al., 2019).

We propose an approach specific to the En→De language pair that directly targets the pronoun translation problem by re-ranking sentence-level hypotheses using a document-level LM. We first translate each sentence independently using the sentence-level MT model. Each sentence-level translation is expanded to a set of candidates by replacing the pronouns with all alternatives ('er', 'sie', 'es'). All candidate translations are then scored in context of the preceding sentences using a document-level LM, and we select the pronoun for which the LM score is highest.

This approach is very much tailored to the specific pronoun translation problem for this specific language pair. While it is theoretically possible to extend this approach to cover more cases, this will require extensive human effort and is probably not feasible in most scenarios. However, we include it here, because it serves as a reasonable baseline for this popular pronoun translation benchmark.

5 Document-level Back-translation

The to-date most popular way of utilizing monolingual data for MT is to create synthetic parallel training data via back-translation (Sennrich et al., 2016). We train a sentence-level backwards MT system on the parallel data and use it to translate the document-level monolingual data back into the source language. The sentence-level translations are concatenated to obtain synthetic parallel documents (Junczys-Dowmunt, 2019; Saleh et al., 2019; Sugiyama and Yoshinaga, 2019; Huo et al., 2020; Post and Junczys-Dowmunt, 2023).

To train the final systems we combine the authentic sentence-level parallel and the synthetic document-level data. Combining both data sources is not straightforward, because of their varying size and the difference between sentence/document-level context. Therefore, we first oversample the data accordingly to have roughly the same number of sentences in both parts. Secondly, we turn the authentic sentence-level parallel data into 'pseudo-documents' by concatenating them in a random order (Junczys-Dowmunt, 2019; Jean et al., 2019). This ensures that all training data has the same context size. We found this procedure to perform best when incorporating synthetic document-level data. For a detailed comparison, see Appendix A.5.

6 Experiments

6.1 Tasks

We evaluate our approaches on four different tasks of varying data conditions and domains. Three

tasks are on publicly available data and a fourth task is based on a large scale internal dataset in the e-Commerce domain. All tasks include (sentence-level) parallel training data and document-level monolingual data from the same domain. The exact data conditions are provided in Appendix A.1.

The *News En→De* data consists of news articles while the *TED En→It* task consists of scientific talks. Both are low resource with less than 1M training samples in total. The *Subtitles En→De* data consists of subtitles from various TV shows and is medium size. Finally, the *e-Commerce En→De* task is about translating item descriptions from e-Commerce listings and the training data is large scale with more than 100M examples.

While the parallel training data for the three academic tasks does provide document-level metadata, our approaches do not make use of this information and we assume that the parallel training data is sentence-level for most experiments. We only make use of this information to provide a direct comparison against the setting where document-level parallel data is assumed to be available. As ParaCrawl, like most other large-scale web-crawled parallel datasets, is not a document-level corpus, we can not conduct these experiments for the e-Commerce task.

We preprocess each corpus with byte-pair encodings (Sennrich et al., 2016) using the SentencePiece toolkit (Kudo, 2018) learned on the parallel dataset with a shared vocabulary of 32k subwords (13.6k for TED). For the e-Commerce task we additionally use inline casing (Berard et al., 2019; Etchegoyhen and Gete, 2020).

6.2 Settings

We train transformer MT models in the 'base' configuration (Vaswani et al., 2017), implemented in Fairseq (Ott et al., 2019). For the LMs we use a similar architecture but without the encoder. Our document-level models use the same architecture as the sentence-level models, we simply include context sentences by concatenating the previous two source and target sentences to all training examples, separated by a reserved symbol (Tiedemann and Scherrer, 2017).

Details on the optimization algorithm are given in Appendix A.1. The final model is selected based on the validation set perplexity. We then perform beam search with beam size 12 and length normalization. Document-level decoding uses the 'last sentence' search strategy as described in Herold and Ney (2023b).

The document-level LMs are trained on a combination of target-side of the sentence-level parallel and document-level monolingual data. Regardless of the task, we train the LMs for 300k update steps with batch size 90k, 10 % dropout, and 10 % label smoothing.

For the LM fusion experiments with non-static fusion scales, we restrict the search space to only consider scale combinations where $\lambda_0 = 1$ and $\lambda_1 = \lambda_2$. A direction comparison is given in Appendix A.4. For back-translation, we use beam search with beam size 4 and increase the training time proportionally to the new data size.

6.3 Evaluation

Document-level evaluation is challenging, as intersentential context usually is only relevant for a small fraction of words. Further, conventional metrics like BLEU (Papineni et al., 2002) or COMET (Rei et al., 2020) do not appropriately measure how well document-level context is considered for those words where context does matter (Läubli et al., 2018, 2020; Maruf et al., 2022). However, we still report BLEU using Sacrebleu (Post, 2018) and COMET[2] on the task-specific in-domain test sets to evaluate the general MT quality.

To better evaluate the improvements from the document-level approaches, we focus on selected sentences for which document-level context is known to be important. Here, we report on two test sets focusing on ambiguities. The En→De *pronouns* test set released by Müller et al. (2018) was curated from OpenSubtitles shows and contains 12k examples. Most examples require previous sentences as context to properly translate the English pronoun 'it' with German 'er', 'sie' or 'es'. Further, the *gender-referring professions* test sets released as contextual part of MT-GenEval (Currey et al., 2022) are available for various target languages and focus on a wider range of ambiguous words, e.g. whether 'the teacher' should be translated with 'die Lehrerin' or 'der Lehrer' in German. Again, context from the previous sentences is required to determine the correct translation. We use these test sets for En→De and En→It which both comprise approx. 1.1k examples that were created by translating Wikipedia articles.

Computing BLEU and COMET on these chal-

[2] Using the `wmt22-comet-da` model (Rei et al., 2020)

lenge test sets better reflects how well a MT system handles document-level context. An even more specific metric can be obtained by focusing only on the ambiguous words. Previous work commonly reports an accuracy metric that is based on contrastive scoring, which is computed by comparing the model probabilities of the reference against a set of contrastive examples (Müller et al., 2018). This metric however can be misleading, as it not based on the generated translation but rather just on scoring. MT systems with high contrastive scores often perform poorly when their generated hypothesis is evaluated (Post and Junczys-Dowmunt, 2023). Instead, we focus on translation-based document-targeted metrics.

On the pronouns test set, we compute a pronoun F1-score as proposed by Herold and Ney (2023a). This metric directly compares the pronouns of the hypothesis and the reference and is based on the BLONDE metric (Jiang et al., 2022). On the professions test set, we report the translation-based accuracy metric suggested by their curators (Currey et al., 2022). Further, for the Subtitles system we also report a formality F1-score on its test set as proposed by Herold and Ney (2023a).

6.4 Results

We evaluate our approaches to utilize monolingual document-level data on the four MT tasks. We apply them in two settings where a) we assume that all parallel data is purely sentence-level, and b) also the parallel data is document-level.

In an effort to compare to previous work, we re-implement LM fusion with static scales without subtracting the internal LM which was independently proposed by Jean and Cho (2020) and Sugiyama and Yoshinaga (2021). These works subtract the intersentential probabilities of the external LM instead. Further, we also re-implement the non-static scales predicted with a 'merging module' learned on parallel document-level data as proposed by Jean and Cho (2020).

We first evaluate our approaches on conventional metrics to measure their general MT performance. Then, we focus on the document-targeted challenge sets to quantify how well they utilize document-level context.

6.4.1 Conventional Metrics

We start by evaluating on the in-domain test sets of the four MT tasks using the conventional MT metrics. Here, we do not expect to see much improvements coming from the document-level context. The results are presented in Table 1.

Adding monolingual data gives the largest improvements on News and small improvements on the e-Commerce task. On these two tasks, the monolingual data is in-domain and the improvements are likely because of the domain. On Subtitles and TED we do not see any improvements as Subtitles already has a large amount of in-domain parallel data and the TED monolingual data is slightly out-of-domain. We verified the domain effect by training sentence-level LMs on equal amounts of data from the target-side of the parallel and monolingual corpora and comparing their perplexities on the test sets. Details are provided in Appendix A.2.

None of the presented approaches significantly decreases translation performance in terms of conventional metrics. The only exception is the back-translation which when added to the Subtitles and TED document-level baseline performs worse in BLEU. In COMET however, this decrease is less prevalent.

6.4.2 Document-targeted Metrics

The results on the document-targeted test sets are shown in Table 2. First we discuss the scenario without access to document-level parallel training data.

LM fusion. Adding monolingual documents to the sentence-level baseline with the existing approaches from Jean and Cho (2020) and Sugiyama and Yoshinaga (2021) improves scores only marginally by on average +0.5 % absolute F1 score on the pronouns test set and no improvements on the professions set. In comparison, our approach on LM fusion with the neutralization of the internal LM performs better: E.g., the variant with on-the-fly scales on average improves the pronoun F1 score by +2.4 % and the professions ac-

[3] External baseline by Herold and Ney (2023b)

[4] External baseline by Huo et al. (2020)

[5] Re-implementation of LM fusion with neutralization of the intersentential LM probabilities instead of the internal LM, as introduced by Jean and Cho (2020) and Sugiyama and Yoshinaga (2021)

[6] Re-implementation of the 'merging module' approach by Jean and Cho (2020). This approach uses parallel document-level data for scale learning.

Table 2: Document-targeted evaluation of the different approaches utilizing document-level monolingual data. We report the pronoun F1 score (Herold and Ney, 2023a), gender-referring professions accuracy (Currey et al., 2022) and the formality F1 score on the Subtitles test set (Herold and Ney, 2023a), all given in percentage. Best results for each column are highlighted.

curacy by +0.9 %. Compared to static scales, both on-the-fly and automatically learned scales yield small improvements and further do not involve the expensive grid search.

LM re-ranking pronouns. Our LM re-ranking approach was specifically tailored towards the pronouns test set. We see most improvements on this test set, while the document-targeted metrics on the other test sets remain mostly unchanged. For both the Subtitles and the e-Commerce task, LM re-ranking is the best approach of utilizing document-level monolingual data for this specific test set in the absence of document-level parallel data. On News however, the gains are less prevalent: Our analysis finds that even though the LM in this case can predict the pronouns correctly, the general translation quality of the baseline on this test set is low and therefore this model often fails to generate any pronouns at all. This again highlights the discrepancy between scoring- and generation-based metrics.

Back-translation. In a direct comparison to LM fusion, back-translation outperforms LM fusion despite our improvements over the existing work. Back-translation on average improves the pronouns F1 score by +4.8 % and the professions accuracy by +4.9 % over the sentence-level baseline. This may also highlight the importance of source-side document-level context as the LM based approaches do not have access to this. Still, both back-translation and LM fusion can be combined and this yields further improvements: The best performing approach not relying on document-level parallel data is to use both document-level back-translation and then LM fusion with on-the-fly scales, this method achieves on average +6.2 % F1 score on the pronouns and +6.0 % professions accuracy.

Parallel document-level data. The three baselines trained on parallel document-level data perform much better than the sentence-level baseline: The document-level baselines score on average +18.0 % better on the pronouns F1 score and +4.2 % better on the professions accuracy than their sentence-level counterparts. In addition, the systems trained on parallel documents also perform better than the sentence-level systems with additional monolingual documents in almost all cases. This concludes that on these three tasks, having access to parallel document-level data is much more effective than utilizing monolingual document-level data, even though our monolingual corpora are much larger than the parallel ones.

Method	contrastive pronoun acc.		
	News	Subtitles	e-Comm.
sentence-level baseline	49.0	46.4	46.1
(Jean, 2020; Sugiyama, 2021)[5]	53.4	48.8	47.4
(Jean, 2020)[6]	49.2	46.8	45.5

back-translation	56.5	57.9	47.3
+ LM: static	57.7	61.6	47.5
+ LM: on-the-fly	57.9	61.1	54.3
+ LM: auto. learned	56.7	59.0	54.1
document-level baseline	**67.9**	**84.0**	n.a.

Table 3: Scoring-based, contrastive accuracies on the pronouns test set (Müller et al., 2018) for the three En→De tasks, reported in percent.

Further including monolingual document-level data to the document-level baselines does not generally give additional improvements. In particular, LM pronoun re-ranking decreases performance in this setting as the MT model itself is already better at predicting the correct pronoun than the LM trained on the document-level monolingual data.

Contrastive scores. Previous work on document-level MT commonly evaluates document-level MT systems using contrastive scoring (e.g., Jean and Cho, 2020; Sugiyama and Yoshinaga, 2021). As a direct comparison, we report the contrastive accuracies on the pronouns test set in Table 3. The trend is often similar to the translation-based metrics in Table 2, however scoring-based improvements are much more pronounced. Our experiments also show that strong contrastive accuracies do not necessarily lead to improvements on the generated hypothesis. For example, on the News task, the contrastive scores of the LM pronoun re-ranking approach and the document-level baseline are similar but their translation-based scores differ strongly (c.f. Table 2).

6.4.3 Computational Cost

We have shown that both the on-the-fly scales and the automatically learned scales improve document-targeted scores over static scores obtained via grid search. Another downside of grid search is that the tuning process is quite expensive. In Table 4, we illustrate that a grid search with 11^3 parameters (as is used in this work) on a single GPU can easily take multiple days. The on-the-fly scales do not

Method	Time	
	Preparation	Search
LM: static	7187 min	5.4 min
LM: on-the-fly	0 min	6.5 min
LM: auto. learned	8.3 min	5.4 min

Table 4: Total time necessary to tune different fusion scale variants on a single GPU, as well as the time spent during translation. We measure the time used to translate the News validation set.

LM	perplexity		contrastive acc.	
	news	e-comm.	pron.	proff.
NewsCrawl	17.0	44.5	62.8	**63.4**
LLaMA	**9.2**	**11.8**	**80.0**	62.3

Table 5: Comparing the small in-domain LM trained on NewsCrawl against the LLM LLaMA.

require any preparation time as they are obtained entirely during search, in which the overhead is small. The automatically scales on the other hand can be learned in just a few minutes and do not have any overhead in decoding.

6.4.4 Large Language Model Integration

Recently, large language models (LLMs) which are trained on large corpora and long context sizes received a lot of attention (e.g., Brown et al., 2020; Touvron et al., 2023). In particular, they have also been able to perform document-level MT (Zhang et al., 2023; Hendy et al., 2023; Karpinska and Iyyer, 2023; Wang et al., 2023). This raises the natural question whether LLMs can improve document-level LM fusion.

We experiment on the News task and compare our own small LM with 35M parameters trained on 2.2B tokens from the in-domain German NewsCrawl corpus against the 13B parameter version of LLaMA (Touvron et al., 2023), which was trained on a total of 1000B tokens. LLaMA's training data includes various domains and languages. Only a small fraction of its data is German. The small LM provides two sentences context while we query the LLM with 200 tokens context. We re-train our MT model and the small LM using the LLaMA tokenizer. This leads to slightly worse performance compared to our previous experiments as the LLaMA tokenization was learned on general-domain English data. For decoding we use a beam size of 4.

Table 5 shows the perplexities of both LMs and their contrastive scores on the document-targeted test sets[7]. Both LMs use the same vocabulary and thus their perplexities are comparable. Because it is in general unclear whether test sets are or are not included in LLM training data, we also include the e-Commerce test set which was translated by ourselves for the purpose of cross-validation. On both test sets, the LLM perplexities are much better than the ones of the small in-domain LM. LLaMA's contrastive scores are also much better on the pronouns test set.

LM Fusion		news		e-Commerce	
LM	Scales	BLEU	COMET	BLEU	COMET
(none)	-	31.2	81.3	13.6	70.5
NewsCrawl	static	33.2	83.0	14.4	72.5
	on-the-fly	33.2	82.8	14.3	72.2
LLaMA	static	**34.6**	**84.2**	**16.5**	**75.0**
	on-the-fly	33.4	83.9	13.7	72.9

Table 6: Comparing fusion with a small LM and a LLM on general test sets.

Table 6 shows the performance of LM fusion with the two LMs in BLEU and COMET. Both LMs notably improve translation, but the LLM translation quality is best. Fusion with LLaMA yields +3.4 % absolute improvements on the in-domain test set. Improvements on the e-Commerce test set are similar, indicating that the gains are not an effect of data leakage of the test set into the training data. While the on-the-fly scales and the static scales perform similarly for the small LM, on-the-fly scales do not perform as well for the LLM.

The improvements measured on the in-domain test sets are likely not because of document-level context but rather due to the increased amount of data. Therefore, we continue our evaluation with the document-targeted scores. Table 8 depicts the results. On these metrics, the LLM outperforms the small LM by an even larger margin. In general, the improvements are correlated to their contrastive scores (c.f. Table 5).

6.5 Extended Analysis on Automatically Learned Fusion Scales

In our experiments we use the validation set of the News task to find the best working methods. We share some insights in the following.

How are the automatically learned scales distributed? Figure 1 shows the distribution of the au-

[7] The professions test set was released without target-side context, which we therefore created ourselves by translating the source-side context with a commercial MT system.

Fusion Scales Learning			λ	valid set		doc.-targeted	
Scales	Crit.	Train Set		BLEU	COMET	pron.	proff.
none	-	-	0.0	24.5	80.9	45.1	65.9
subword-agnostic	grid search	valid set	0.40	25.4	81.8	46.5	65.1
	CE	valid set	0.34	25.5	81.7	46.4	65.0
		synthetic	0.46	25.3	81.6	**47.1**	65.2
subword-dependent	CE	valid set	-	**26.6**	**81.8**	46.1	65.0
		synthetic	-	25.4	81.6	46.9	65.4

Table 7: Automatically learning subword-dependent and -agnostic fusion scales on the News task. We employ the restriction $\lambda_0 := 1$, $\lambda := \lambda_1 = \lambda_2$.

LM Fusion		document-targeted		
LM	Scales	pron.	proff.	form.
(none)	-	44.5	65.7	33.4
NewsCrawl	static	46.3	66.3	34.7
	on-the-fly	47.4	66.7	34.3
LLaMA	static	**51.6**	66.9	**36.1**
	on-the-fly	48.2	**68.9**	35.2

Table 8: Fusion with a small LM against a LLM, reporting the translation-based scores on the document-targeted test sets.

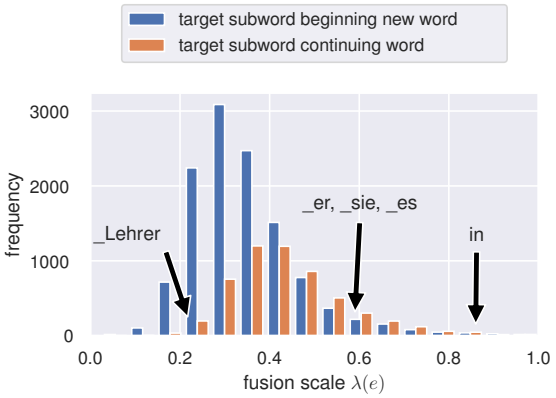

Figure 1: Distribution of the automatically learned LM fusion scales for different target-side subwords on the News task. Subwords for which document-level context is often necessary, such as the German pronouns '_er', '_sie', '_es', and the suffix 'in' marking female professions, have learned higher scales than nouns like '_Lehrer'.

tomatically learned scales for the News task. The learned LM scale of subwords that continue another subword are in general higher than the ones that begin a new word. This is intuitive as continuing a subword is an LM task while beginning a new word requires information about the source sentence.

How much data is needed for automatically learning scales? The static fusion scales are usually tuned on a small validation set via grid search. Table 7 shows that it is also possible to use automatic differentiation to learn static scales only on the validation set. The automatically learned subword-agnostic scales have similar values as the ones tuned via grid search and therefore also their translation performance is similar. Learning subword-dependent scales automatically on the validation set on the other hand improves performance on this set, but does not generalize which indicates overfitting.

7 Conclusions

This work presents multiple extensions to document-level LM fusion, a technique of utilizing document-level monolingual data for context-aware MT. In comparison to existing work, our extensions significantly improve discourse-modeling across four MT tasks and furthermore are computationally more efficient. We conduct evaluations against two baselines: document-level back-translation and a task-specific LM re-ranking method. Despite our extensions, back-translation in general still outperforms document-level LM fusion. Nevertheless back-translation can be effectively combined with LM fusion, further improving translation performance. On very specific test sets, the LM re-ranking performs best. However, our experiments also show that systems trained on document-level parallel data outperform the best systems trained with monolingual documents only.

Finally, this work is the first to explore document-level LM fusion with LLMs. First findings demonstrate that fusion with an LLM outperforms a small LM trained on in-domain data and open the path for future investigations.

Limitations

The experiments in this work were limited to four MT tasks, from which two are low-resource and three are translating from English into German. Apart from the experiments with the LLM, we did not conduct any experiments on a large-scale dataset of multi-domain monolingual documents. The LLM in our experiments only has 7B parameters, while much larger LLMs exist (e.g., Touvron et al., 2023).

Further, our work focuses only on one specific architecture for document-level MT and uses only two sentences target-side context. Various other architectures exist and may entail different properties. This work further does not investigate the behavior of larger translation models.

Another limitation lies in the evaluation of document-level MT models. The document-level targeted metrics we used are all reference-based and limited to the translation of pronouns, gender-referring professions or salutation forms. Other discourse phenomena like e.g. cohesion exist (Maruf et al., 2022) but were not studied in our work. It is unclear how well automated metrics actually correlate with the actual document-level translation quality (Currey et al., 2022), and this work did not perform any qualitative analysis.

A Appendix

A.1 Model Training

Data. The *News En→De* task comprises 330k parallel sentences from NewsCommentary v14[8], which we combine with document-level monolingual data from NewsCrawl[9] (70M sentences[10]). Our *Subtitles En→De* data consists of a total of 39M monolingual movie show subtitles from OpenSubtitles, from which a subset of 22.5M sentences has been aligned to English sentences and forms our parallel training data (Lison et al., 2018). For *TED En→It* we use 230k parallel sentences from scientific TED talks released as part of the IWSLT17 multilingual task (Cettolo et al., 2017) which we combine with 2.2M sentences of talks from the European parliament (Koehn, 2005). Finally, the *e-Commerce En→De* task is about translating item descriptions from e-Commerce listings. We use 326M parallel sentences of out-of-domain parallel training data from the ParaCrawl v9 corpus (Esplà-Gomis et al., 2019) which we combine with 128k parallel sentences in-domain data. The monolingual data was sampled from item descriptions and is entirely in-domain (119M sentences).

The sizes of our training corpora are shown in Table 10.

On each task, we use a validation set for selecting the best checkpoint, tuning the fusion scales and for finding which method works best. For the final comparison in Table 1 we then report on an unseen test set of the same domain.

The News validation set is `newstest2015`, and `newstest2018` as test set. For Subtitles, our validation and test sets were sampled from the training corpus. The precise document IDs for the validation set are: 1995/254, 1997/165, 2000/313, 2002/461, 2005/441, 2007/781, 2010/273, 2012/757, 2015/1488, 2017/525 for the validation set; and for our test set: 1997/310, 2002/40, 2007/189, 2012/1085, 2017/644. The test set is the same as used in Huo et al. (2020). For TED, we concatenate `dev2010` and `tst2010` and use `tst2017.mltlng` as test set. For e-Commerce, we create the validation and test set ourselves by translating English e-Commerce item descriptions into German: Our validation set comprises 85 documents (2882 sentences) and the test set 100

[8] https://data.statmt.org/news-commentary/v14/

[9] https://data.statmt.org/news-crawl/

[10] To reduce training time, our back-translation experiments on this task utilize only the first 2M sentences.

	mono.	6k	2.2M	54.6M
e-Commerce	parallel	n.a.	326M	9.6B
	mono.	1.5M	119M	3.1B

Table 10: Training data statistics.

documents (2520 sentences).

As the pronouns test set (Müller et al., 2018) was extracted from the OpenSubtitles corpus, we remove these sentences from the Subtitles training data. The professions test set (Currey et al., 2022) was curated from Wikipedia articles and is not part of our training corpora.

Models. We train the News, Subtitles and TED models with a shared embedding and projection matrix. Th resulting MT models for News and Subtitles have 60M parameters, 51M parameters for TED and 90M for e-Commerce. For model training we use eight Tesla V100-SXM2-32GB GPUs. Training the baselines takes approximately 7h for News, 21h for Subtitles, 5h for TED, and 30h for e-commerce. Due to resource constraints, we report only a single run for each experiment.

Optimization. For optimization we use Adam (Kingma and Ba, 2015) and a batch size of 22k subwords. The low-resource MT models (News, TED) are trained for 100k update steps with 30 % dropout, 20 % label smoothing and weight decay, while the high-resource models (Subtitles, e-Commerce) are trained for 300k updates with 10 % dropout, 10 % label smoothing and no weight decay.

A.2 Domain Effects

In an effort to estimate how well the domain of the training data matches the test sets, we train LMs on the target-side part of the parallel and the monolingual training data. Within each task, the LMs are trained with the same parameters and the same vocabulary. We then report the perplexities on the task-specific test sets and the document-targeted challenge sets in Table 9.

For News, the monolingual data is more in-domain for all test sets. Similarly the domain of the e-Commerce monolingual data is closer to the task-specific test set. For Subtitles, the domains of parallel and monolingual data are more or less equal and on TED, the monolingual data is slightly out-of-domain.

This domain effect explains the improvements in BLEU and COMET on the task-specific test sets that we reported in Table 1 on News and on e-Commerce.

Approach	valid set		doc.-targeted	
	BLEU	COMET	pron.	proff.
baseline	24.5	80.9	45.1	**65.9**
LM fusion	24.8	81.2	45.0	65.8
+ (Jean, 2020; Sugiyama, 2021)[5]	24.9	81.2	46.0	65.0
+ ILM: separate	**25.8**	**82.1**	**47.3**	65.2
+ ILM: $h = 0$	25.5	82.0	43.8	64.7
+ ILM: mini self-att.	**25.8**	**82.1**	44.6	65.1

Table 11: Document-level LM fusion (a) without subtracting any LM, (b) subtracting the sentence-level probabilities of the external LM (Jean and Cho, 2020; Sugiyama and Yoshinaga, 2021), and (c) subtracting different approximations of the internal LM (ILM) learned by the MT model, reported on the News task.

A.3 Comparing Internal Language Model Estimations

Herold et al. (2023) propose several ways of approximating the internal LM learned implicitly by the MT model in the context of sentence-level MT. We evaluate three of their approaches for document-level LM fusion and compare them against the existing document-level LM fusion approach that subtracts the sentence-level probabilities of the external LM (Jean and Cho, 2020; Sugiyama and Yoshinaga, 2021). Table 11 shows the results: Subtracting the internal LM substantially improves LM fusion over existing work. Estimating it by training a separate LM on the same data as the MT model works best.

Fusion Scales		valid set		doc.-targeted	
Approach	Restriction	BLEU	COMET	pron.	proff.
none	-	24.5	80.9	45.1	65.9
static	-	**25.8**	**82.1**	47.3	65.2
	$\lambda_0 = 1, \lambda_1 = \lambda_2$	25.4	81.8	46.5	65.1
on-the-fly	-	22.3	78.3	43.4	69.3
	$\lambda_0 = 1, \lambda_1 = \lambda_2$	25.6	81.8	**48.0**	65.5
auto. learned	-	24.8	80.7	44.7	**69.4**
	$\lambda_0 = 1, \lambda_1 = \lambda_2$	25.3	81.5	46.7	64.9

Data		valid set		doc.-targeted	
parallel	mono.	BLEU	COMET	pron.	proff.
sent.	-	24.5	80.9	45.1	65.9
sent.	sent.	27.0	**83.2**	46.7	65.7
sent.	doc.	26.9	82.4	47.8	**80.7**
pseudo-doc.	doc.	**27.1**	83.0	**48.7**	80.5

Table 13: Effect of back-translation on the News task.

A.4 Fusion Scale Restrictions

The three LM fusion scales $\lambda_0, \lambda_1, \lambda_2$ in Equation 1 balance the contribution of the MT model and the two LMs. In our experiments the optimal scales usually lie at $\lambda_0 \approx 1$ and $\lambda_1 \approx \lambda_2$. This is plausible as the internal LM (λ_2) should neutralize the external LM (λ_1) to the same degree. For the non-static fusion scales however, we find that searching over the three-dimensional search space of independent $\lambda_0, \lambda_1, \lambda_2$ finds unintuitive scale combinations and that this causes bad performance. Therefore in our experiments we restrict the search space of fusion scales to the one-dimensional slice where $\lambda_0 = 1$ and $\lambda_1 = \lambda_2$. Table 12 gives a direct comparison.

A.5 Document-level Back-translation

In Table 13 we compare back-translation using document-level data against sentence-level back-translation.

Sentence- and document-level back-translation gives the same performance improvements in BLEU and COMET, however only back-translation on document-level improves the document-targeted metrics. For document-level back-translation we find that creating pseudo-documents from the parallel data is necessary to achieve the same BLEU and COMET scores as sentence-level back-translation.

ChatGPT MT: Competitive for High- (but not Low-) Resource Languages

Abstract

Large language models (LLMs) implicitly learn to perform a range of language tasks, including machine translation (MT). Previous studies explore aspects of LLMs' MT capabilities. However, there exist a wide variety of languages for which recent LLM MT performance has never before been evaluated. Without published experimental evidence on the matter, it is difficult for speakers of the world's diverse languages to know how and whether they can use LLMs for their languages. We present the first experimental evidence for an expansive set of 204 languages, along with MT cost analysis, using the FLORES-200 benchmark. Trends reveal that GPT models approach or exceed traditional MT model performance for some high-resource languages (HRLs) but consistently lag for low-resource languages (LRLs), under-performing traditional MT for 84.1% of languages we covered. Our analysis reveals that a language's resource level is the most important feature in determining ChatGPT's relative ability to translate it, and suggests that ChatGPT is especially disadvantaged for LRLs and African languages.

1 Introduction

Despite the majority of the world's languages being low-resource, current MT systems still perform poorly on them or do not include them at all. Some commercial systems like Google Translate[1] support a number of LRLs, but many systems do not support any, and in either case the majority of LRLs are largely neglected in language technologies.

In recent years, generative LLMs have shown increasingly impressive translation abilities (Radford et al., 2019; Brown et al., 2020). Even more recently, LLM tools like ChatGPT have become popular and accessible to end users. This marks an important shift, since a majority of LLM users are now consumers rather than researchers. The prospect of LLM translation is exciting, since theoretically, generative LLMs could support more languages than commercial systems like Google's.[2] But only beginning steps have been made to test this hypothesis. While some studies outlined in §4 have evaluated MT with recent LLMs, evaluation is still lacking for many languages. This brings up important questions, such as: *Can end users in need of MT for a variety of languages use ChatGPT? Are ChatGPT and other LLMs reliable translators? For which languages are they reliable?* Initially we hypothesize that LLMs translate HRLs better than LRLs. But due to limited information about the training data and methods for powerful LLMs like ChatGPT (**GPT-3.5** and variants) and GPT-4, hypotheses like this must be experimentally verified.

We significantly expand experimental verification for such hypotheses by testing ChatGPT's performance on the FLORES-200 benchmark (NLLB Team et al., 2022), containing 204 language varieties. We emphasize that, rather than optimizing LLM MT for a few languages, we focus on helping end users of various language communities know how and when to use LLM MT. We expect that our contributions may benefit both direct end users, such as LRL speakers in need of translation, and indirect users, such as researchers of LRL translation considering ChatGPT to enhance specialized MT systems. In summary, we contribute:

1. MT scores on 203 languages for ChatGPT and comparisons with GPT-4, Google Translate, and NLLB (NLLB Team et al., 2022)
2. Evidence that LLMs are competitive with traditional MT models for many HRLs but lag for LRLs (with baselines outperforming ChatGPT on 84.1% of languages evaluated)
3. Evidence that few-shot prompts offer

marginal benefits for LLM translation

4. A decision tree analysis of language features' correlation with LLM effectiveness in MT, suggesting ChatGPT is especially disadvantaged for LRLs and African languages

5. A cost comparison across MT systems

Our experiments are motivated by the interests of LLM users speaking a variety of languages. In addition to evaluating a large language set (§3), we chose to analyse language features (§3.4), to draw generalizations for even more LRL speakers. We compare MT costs because they impact end users (§3.7). We keep ChatGPT central to our analyses because of its current popularity among consumers.

2 Methodology

We used data for 204 language varieties from FLORES-200 (NLLB Team et al., 2022). We used the 1012 *devtest* sentences for our main experiments and the 997 *dev* sentences for follow-up experiments. We queried the OpenAI API[3] to translate our test set from English into the target languages. We explored ENG→X translation only because the FLORES-200 English data was taken from Wikipedia. Thus OpenAI's GPT models were likely trained on those exact English sentences, making fair X→ENG evaluation infeasible.

2.1 Experimental setup

We evaluated ChatGPT's (`gpt-3.5-turbo`) MT for our full language set. We compared with NLLB-MOE (NLLB Team et al., 2022) as our baseline, as it is the current state-of-the-art open-source MT model that covers such a wide variety of languages. NLLB is a discriminative transformer trained on supervised bi-text data (the traditional MT paradigm). We obtained scores for NLLB outputs of ENG→X translation into 201 of the language varieties in our set (as reported by NLLB Team et al. (2022)).

We used both zero- and five-shot prompts for ChatGPT MT. (See §2.3.) Previous studies (Hendy et al., 2023; Gao et al., 2023; Moslem et al., 2023; Brown et al., 2020; Zhu et al., 2023) suggest that few-shot prompts produce slightly (albeit not consistently) better translations. But zero-shot prompts are more convenient and affordable for users.

We also compare with results for subsets of our selected languages from two other MT engines. Google Translate API was an important baseline for our analysis because it is popular among end users. We also included it to represent commercial MT systems in our study. Because Google's API does not support all 204 of the FLORES-200 languages, we obtained results only for the 115 non-English languages it supports.

Lastly, we obtained MT results from GPT-4, since it is a popular LLM and has been shown to outperform ChatGPT on MT (Jiao et al., 2023; Wang et al., 2023). Because the cost of GPT-4 use exceeds that of ChatGPT by 1900%, our resources did not permit its evaluation on all 203 non-English languages. Instead we selected a 20-language subset by picking approximately every 10th language, with languages sorted by chrF++ differentials between ChatGPT and NLLB ($chrf_{GPT} - chrf_{NLLB}$). We chose this criterion in order to have 20 languages with a range of relative ChatGPT performance and a variety of resource levels. We used only five-shot prompts for GPT-4.

2.2 Implementation details

We conducted all LLM experiments with `gpt-3.5-turbo` (ChatGPT) and `gpt-4-0613` (GPT-4). We used `top_p` 1, `temperature` 0.3, `context_length` −1, and `max_tokens`[4] 500.

To evaluate the outputs, we used:[5]

spBLEU: BLEU (Papineni et al., 2002) is standard in MT evaluation. We find spBLEU scores (Goyal et al., 2022) via sacreBLEU (Post, 2018) with the SPM-200 tokenizer (NLLB Team et al., 2022).

chrF2++: We use sacreBLEU's implementation of chrF++ (Popović, 2017). We adopt it as our main metric, as it overcomes some of BLEU's weaknesses, and refer to it as *chrF* for brevity.

2.3 Zero- and few-shot prompts

Previous works (Gao et al., 2023; Jiao et al., 2023) investigated LLM prompting to optimize MT performance. We adopt Gao et al. (2023)'s recommended prompts for both zero- and few-shot MT (Table 1). We are interested in multiple n-shot prompt settings because, as mentioned in §2.1, they

[3] `https://platform.openai.com`

[4] Although some languages had higher token counts than others (see §3.4), we found that adjusting `max_tokens` had a minimal effect on MT performance. We thus decided to maintain the same value of `max_tokens` across all languages for experimental consistency.

[5] We excluded learned MT metrics like COMET (Rei et al., 2020) and BLEURT (Sellam et al., 2020), since they do not support many LRLs.

Shot	Prompt
zero	This is an English to [TGT] translation, please provide the [TGT] translation for this sentence. Do not provide any explanations or text apart from the translation. [SRC]: [src-sentence] [TGT]:

Do not provide any explanations or text apart from the translation. [SRC]: [src-sentence] [TGT]:

Table 1: Prompts used for zero- and five-shot settings

present different benefits to LLM users. We explored zero-shot (no in-context example), one-shot (1 example), and five-shot (5 examples). We employed both zero- and five-shot prompts in our main experiments over 203 languages, and we analyzed all three n-shot settings for a subset of languages on FLORES-200 *dev* sets.

The languages in FLORES-200 represent 22 language families. To experiment with multiple n-shot settings, we selected one language from each of the 12 families containing at least two members in the set. We chose four HRLs ($\geq$1M Wikipedia pages[6]), four LRLs (25K-1M pages), and four extremely LRLs ($\leq$25K pages). These languages also employ a variety of scripts. See Table 2.

Language	Code	Family	Script	Wiki. #

Google	115	**52.2**	**34.6**

Table 3: Languages evaluated, average chrF, and average BLEU for each MT system. Best scores are **bold**.

3 Results and Analysis

3.1 Traditional MT generally beats LLMs

Table 3 shows the number of languages we evaluated for each MT system, as noted in §2.1, with average chrF and BLEU scores across those languages. The best performing model on average was (1) Google, then (2) NLLB, (3) GPT-4, and (4) ChatGPT. Unabridged results are in Table 11 in Appendix A. Supplementary materials can also be browsed on our repository.[7] (Also see the interactive score visualizer on our Zeno browser.[8])

Table 4 shows chrF for the 20 languages evaluated on both LLM systems. Of the 11 languages evaluated on all four systems, Google performed best for 9 of them. Notably, GPT-4 surpassed NLLB in five languages and Google in one[9] (Mesopotamian Arabic, acm_Arab).

On the 20 languages for which we tested it, GPT-4 improved over ChatGPT by 6.5 chrF on average. The standard deviation of performance difference with NLLB ($chrF_{GPT} - chrF_{NLLB}$) was 8.6 for GPT-4, compared with ChatGPT's 12.7 for the same languages, suggesting a more consistent advantage across language directions. GPT-4 offered larger improvements for LRLs, whereas HRL performance plateaued between the LLMs. Previous studies have found GPT-4 improving multilingual capabilities over ChatGPT on a range of tasks (Xu et al., 2023; Zhang et al., 2023; OpenAI, 2023). This may account for its superior MT performance.

Google Translate outperformed all other systems in chrF on 100 of the 115 languages for which we evaluated it, with an average improvement of 2.0 chrF points over the next best system for each language. (See Appendix A for unabridged results.)

[7]https://github.com/cmu-llab/gpt_mt_benchmark

[8]https://hub.zenoml.com/project/cabreraalex/GPT%20MT%20Benchmark

[9]Our language identification analysis in §3.6 and manual inspection suggest that GPT models only output one Arabic variety: Modern Standard Arabic (MSA). It seems the LLMs' high performance on some Arabic varieties is due simply to incidental high token overlap with MSA targets.

Table 4: chrF (↑) scores across models for all languages we used to evaluate GPT-4. Best scores are **bold**. ChatGPT scores here are 5-shot, to compare with GPT-4.

Google's was the best performing MT system overall, though NLLB has broader language coverage.

NLLB outperformed ChatGPT in chrF on 169 (84.1%) of the 201 languages for which we obtained scores for both, with NLLB scoring an average of 11.9 chrF points higher than the better n-shot ChatGPT setting for each language. This trend is corroborated by Zhu et al. (2023). Table 5 has both BLEU and chrF scores from both systems for the five languages with the most negative chrF deltas ($chrF_{GPT} - chrF_{NLLB}$) on top, followed by the five languages with the highest positive deltas on bottom. For many of the subsequent sections of this paper we focus on comparing ChatGPT and NLLB, since we evaluted them on the most languages.

	ChatGPT		NLLB

Table 5: Lowest (top) and highest (bottom) chrF differences between zero-shot ChatGPT and NLLB. Best scores for each metric in **bold** (with BLEU **blue**).

3.2 ChatGPT under-performs for LRL

Using NLLB Team et al.'s (2022) resource categorization, we find that ChatGPT performs worse on LRLs than HRLs, corroborating findings of previous works (Jiao et al., 2023; Zhu et al., 2023). There is a strong positive correlation between ChatGPT and NLLB chrF scores, but the correlation is higher for HRLs (ρ=0.85) than LRLs (ρ=0.78), indicating that ChatGPT struggles to keep up with NLLB for LRLs.

Figure 1 shows scatter plots where dots represent languages, with ChatGPT's (positive or negative) *relative improvement* over NLLB chrF ($\frac{chrf_{GPT} - chrf_{NLLB}}{chrf_{NLLB}}$) on the y-axis. When languages are grouped by family or script, some trends are apparent (in part because we ordered groups by descending average scores). For example, ChatGPT fairs better with Uralic and Indo-European languages and clearly worse with Niger-Congo and Nilo-Saharan languages. However, the clearest natural correlation appears when languages are grouped by resource level, approximated by number of Wikipedia pages (Figure 1, bottom). Note the *relative improvement* (y-axis) is typically negative since ChatGPT rarely outperformed NLLB.

In the five-shot setting, ChatGPT outperformed NLLB on 47% of the HRLs designated by NLLB Team et al. (2022), but only on 6% of the LRLs. These findings contrast with what is commonly observed in multilingual MT models (Liu et al., 2020; Fan et al., 2020; Siddhant et al., 2022; Bapna et al., 2022; NLLB Team et al., 2022), where LRLs benefit the most. This highlights the need to investigate how decoder-only models may catch up with encoder-decoder models in low-resource applications. It underscores the importance of MT-specialized models when larger multitask models cannot overcome low-resource challenges.

3.3 Few-shot prompts offer marginal improvement

Our main experiments suggested that n-shot setting had only a modest effect on MT performance. We conducted a more concentrated study of n-shot prompts using dev sets for the 12 languages in Table 2. Results in Table 6 show five-shot prompts performing best. For some LRLs, this was simply a result of ChatGPT's failure to model the language. In Santali's case, for example, zero-shot ChatGPT was unable to produce the Ol Chiki script at all. In the five-shot setting, it was able to imitate the script

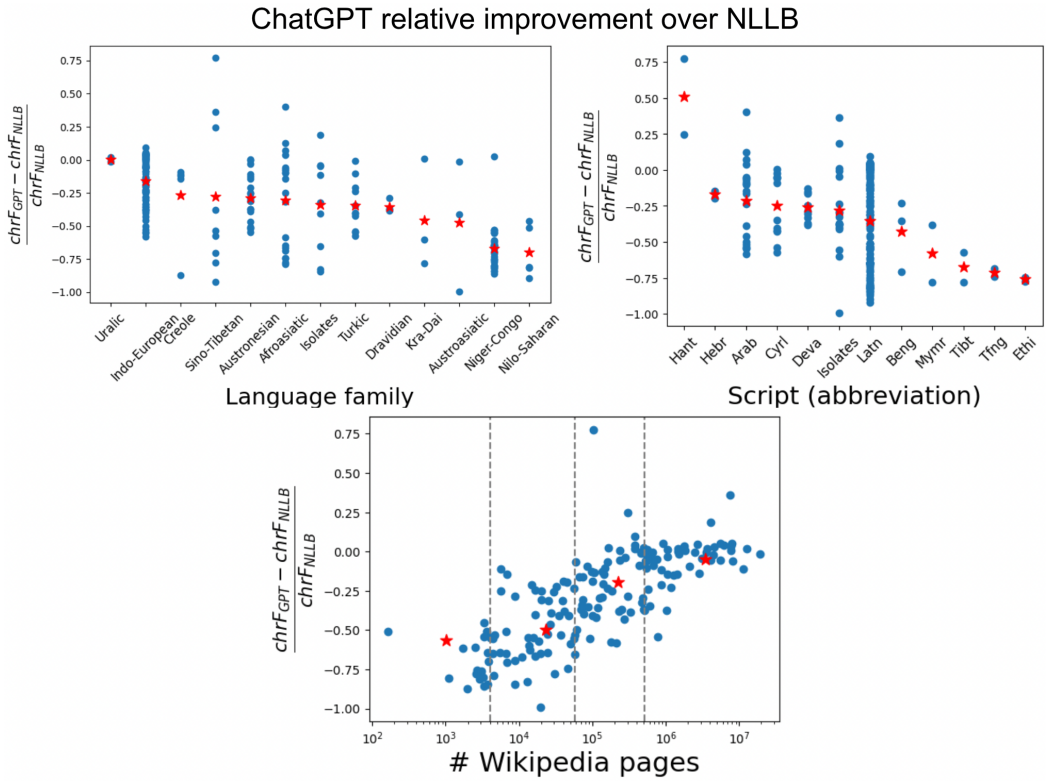

Figure 1: ChatGPT *relative improvement* over NLLB chrF, with languages organized by family, script, and number of Wikipedia pages. Red stars represent averages per group. In the bottom plot, languages are grouped into quartiles of equal size (with dotted lines at the Q1, median, and Q3). More expansive visualizations with language labels for each value can be found in Appendix C.

characters from the context, but without any coherence or accuracy. Excepting Santali as an outlier, five-shot settings offered generally marginal improvements over zero-shot (the most cost-effective of the settings), with an average improvement of only 1.41 chrF across all 12 languages (0.31 if we exclude Santali). Zero-shot prompts actually produced the best chrF score for six of the 12 languages. The one-shot setting performed worst. We noted this trend of few-shot contexts offering only meager and inconsistent improvements throughout our experiments, with five-shot MT improving on zero-shot by only 0.88 average chrF across all 203 language directions. (See Appendix A.)

3.4 Importance of language features

We were interested in which language features determined LLMs' effectiveness compared to traditional MT. Analyzing this may reveal trends helpful to end users deciding which MT system to use, especially if their language is not represented here but shares some of the features we consider. In this section we focus on comparing ChatGPT and NLLB, since we evaluated the most languages with them. We focus on zero-shot ChatGPT, as it is the most common and convenient setting for end users.

Table 6: Three n-shot settings for 12 diverse languages

We encoded each of the 203 languages in our set as a *feature vector*. In these language *feature vectors* we included **four numerical features**: number of Wikipedia pages in the language (`wiki_ct`), size of the language's bi-text corpus in the Oscar MT database[10] (`oscar_ct`) (Abadji et al., 2022), percentage of ASCII characters[11] in the FLORES-

[10] https://oscar-project.org

[11] Percentage of characters with an encoding between 0 and

200 *dev* set for the language (`ascii_percentage`), and average number of tokens per *dev* set sentence in FLORES-200 with ChatGPT's tokenizer (`token_ct`). We also included **two categorical features**: language family (`family`) and script the language was written in (`script`); and **one binary feature**: the FLORES resource designation of the language—with 1 for high-resource and 0 for low-resource (`hi/lo`). Before analysis, we one-hot encoded the two **categorical features** into 48 binary features like `family_Niger-Congo` and `script_Latn`.

We selected `token_ct` as a feature because we observed languages in low-resource scripts having many tokens. For example, ChatGPT's tokenizer encodes multiple tokens for every character in Ol Chiki script. This tendency for GPT models with low-resource scripts has been noted in previous studies (Ahia et al., 2023).

We fit a decision tree with these *feature vectors* to regress on ChatGPT's *relative improvement* over NLLB in chrF ($\frac{chrf_{GPT} - chrf_{NLLB}}{chrf_{NLLB}}$), for each of the 201 languages with NLLB scores. When we used `max_depth` 3, the tree in Figure 2 was learned. Languages are delimited first by `wiki_ct`; then LRLs are separated into Niger-Congo languages and others, while HRLs are delimited by `token_ct`. The only group where ChatGPT beat NLLB is of languages with more than 58,344 Wikipedia pages, fewer than 86 tokens per average sentence, and less than 15.5% ASCII characters. This group contains some East Asian HRLs. The group where ChatGPT was least advantaged contains Niger-Congo languages with fewer than 3,707 Wikipedia pages.

We also fit a random forest regressor with the same features and labels to find feature importance values. Only ten features had importance ≥ 0.01, shown in Table 7. The most important feature by far was `wiki_ct`. (This feature correlates strongly with ChatGPT's *relative improvement*, $\rho = 0.68$.) `family_Niger-Congo` was much more important than any other family feature. No script feature had an importance exceeding 0.01. In general, features for resource level and tokenization were more important than family or script.

ChatGPT has a blind spot not only for Niger-Congo languages, but for African languages in general. Figure 1 shows ChatGPT is least advantaged for the two exclusively African families, Niger-Congo and Nilo-Saharan; and the two exclusively African scripts, Tifinagh (`Tfng`) and Ge'ez (`Ethi`).

feature	importance
`wiki_ct`	0.514
`token_ct`	0.157
`ascii_percentage`	0.104
`family_Niger-Congo`	0.054
`oscar_ct`	0.040
`family_Afroasiatic`	0.025
`family_Indo-European`	0.025
`family_Sino-Tibetan`	0.022
`family_Creole`	0.012
`family_Nilo-Saharan`	0.011

Table 7: Ten most important language features to predict ChatGPT's effectiveness relative to NLLB

3.5 Impact of script

Prior research suggests that ChatGPT output quality is sensitive to language script (Bang et al., 2023). Our own analysis in §3.4 actually suggests that script is the least important language feature in predicting ChatGPT's MT effectiveness. However, differences in performance are clear when comparing scripts used for the same language. Table 8 shows one script typically outperforming the other, by an average of 14.3 chrF points for zero-shot. Five-shot contexts narrowed the gap slightly to 12.0. Although transliteration is a deterministic process for many languages, these performance gaps suggest that ChatGPT has not implicitly learned it as part of a translation task. We hypothesize that ChatGPT's observed sensitivity to script in earlier studies may be particular to the languages and tasks evaluated.

	BLEU		chrF

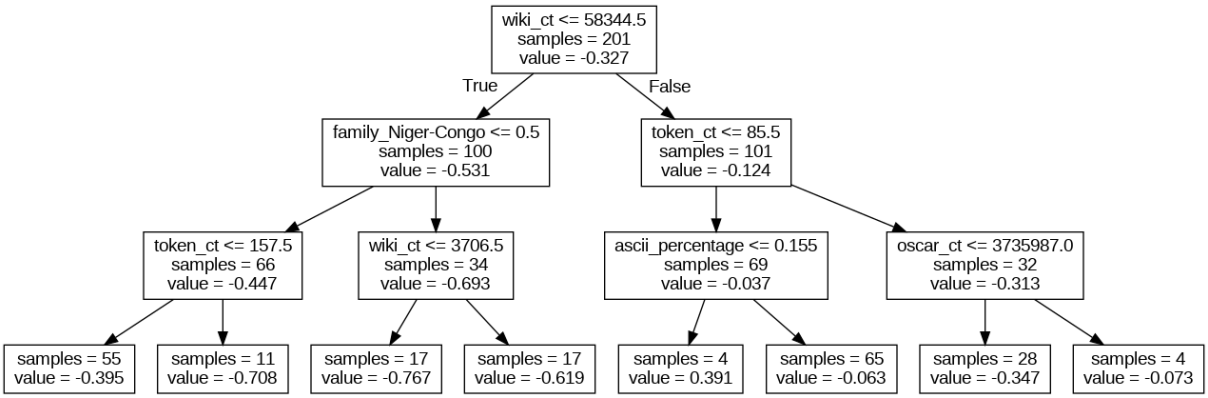

Figure 2: Decision tree predicting ChatGPT *relative improvement* over NLLB chrF, from language features.

3.6 LLMs often get the language wrong

LLMs' performing worse than NLLB may be due in large part to their translating into the wrong language. Using FLORES-200's *dev* data, we trained a logistic regression language identifier for 100 epochs. Language identification accuracies for four of the models we evaluated are in Table 9. Zero-shot ChatGPT only translated on target 72% of the time. This expectedly improved with five-shot prompts, and GPT-4 performed even better, still just shy of NLLB. LLMs' tendency to translate off target is corroborated by Zhu et al. (2023).

model	lang. ID acc.
ChatGPT (0-shot)	72%
ChatGPT (5-shot)	83%
GPT-4 (5-shot)	90%
NLLB	91%

Table 9: Proportion of the time each model translated into the correct target language

3.7 Cost comparison

Our results suggest that GPT-4 is a better translator than ChatGPT. However in considering the needs of MT end users, it would be remiss not to consider the respective costs of the systems evaluated. GPT-4's high cost (roughly 2000% that of ChatGPT's) prohibited us from evaluating it on all FLORES-200 languages. In general, using few-shot prompts for LLMs is more costly than zero-shot prompts, since users are charged for both input and output tokens. And for this same reason, some languages are more costly than others in LLM MT. Previous work has found that Google Translate has associated costs comparable to those of five-shot ChatGPT (Neubig and He, 2023). NLLB is the least expensive system we evaluated.

We estimated cost values for each MT system and language: the expense, in USD, of translating the full FLORES-200 *devtest* English set into the language. We estimated GPT model costs using the prompts employed in our experiments, the tiktoken tokenizer[12] used by both models, and inference prices posted by OpenAI.[13] Conveniently, Google Translate costs nothing for the first 500K input characters. But since frequent MT users may have already expended this allowance, we calculated costs from their rates beyond the first 500K.[14] As the NLLB-MOE model (54.5B parameters) is difficult to run on standard computing devices, NLLB Team et al. (2022) also provided a version with only 3.3B parameters that achieves similar performance. Since users commonly opt for the smaller model, and since the performance difference does not impact our estimates significantly, we estimated the costs to run the 3.3B-parameter NLLB model using a single GPU on Google Colab. Details of our estimation method are in Appendix B.1. Table 10 contains the average cost for each system across the languages we evaluated with it.

model	cost
NLLB	$0.09
ChatGPT (0-shot)	$0.35
ChatGPT (5-shot)	$1.32
Google	$2.66
GPT-4 (5-shot)	$25.93

Table 10: Estimated cost in USD to translate FLORES-200 *devtest* ENG→X with each system, averaged across all languages we evaluated with each

Figure 3 displays chrF scores for the 11 languages on which we evaluated all four MT sys-

[12] https://github.com/openai/tiktoken

[14] https://cloud.google.com/translate/pricing

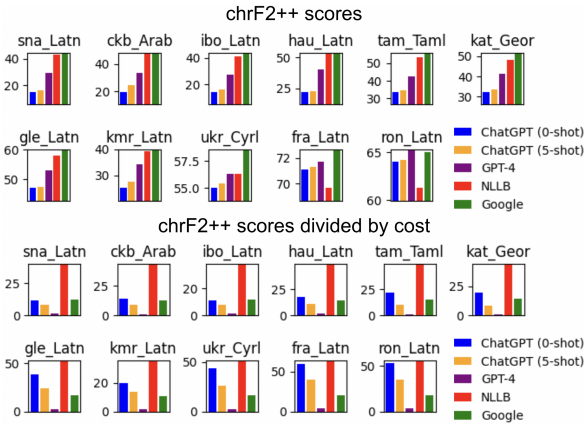

Figure 3: chrF scores for the 11 languages on which we evaluted all MT systems (top), followed by the same scores divided by the estimated cost of each system for each language (bottom)

tems (top), and the same scores divided by the approximate cost of each model (bottom). Bars for GPT-4 drop significantly in the bottom chart because of its high cost. Note from the top chart that Google Translate scores the best, but the bottom chart shows that NLLB has the best scores for its price. Zero-shot ChatGPT also tops five-shot in the bottom chart, suggesting that while few-shot prompts provide modest score improvements, they may not be worth the extra cost. See Appendix B for fuller visualizations with all 203 languages.

4 Related Work

We are not the first researchers to explore LLM MT. However, most existing studies do not provide benchmarks for a large number or languages. Wang et al. (2023) studied GPT model discourse MT, but only for four languages. Gao et al. (2023) studied prompt engineering for GPT model MT, a helpful precursor to our work, but only for three languages. Moslem et al. (2023) probed the abilities of GPT models for adaptive and domain-appropriate MT and term extraction, only including six languages in five directions. Jiao et al. (2023) produced MT benchmarks for ChatGPT and GPT-4, but only for five languages, none of them LRLs.[15] They corroborated our findings that GPT models lag behind traditional MT models, but that GPT-4 outperforms ChatGPT. Hendy et al. (2023) explored 18 language pairs in a similar study, including four LRLs, but they focused more on MT performance across text domains, in-context learning, and reasoning than on multilingual benchmarks.

In all the heretofore mentioned works combined, researchers explored only 18 languages, including five LRLs. This few-language approach does not address the needs of LLM users seeking to translate any languages other than the small few represented. In a work most comparable to our own, Zhu et al. (2023) attempted to address this issue. They provided benchmarks comparing LLMs and traditional MT models across 102 languages, including 68 LRLs. Their results corroborate our own conclusions that LLMs lag behind traditional MT models, especially for LRLs. However, their analysis focuses primarily on few-shot learning and prompt engineering, including some topics somewhat removed from end user needs (such as the viability of nonsensical prompts in few-shot settings). Our work differs from existing studies in our focus on end users. We include more languages than any existing work (**204** languages, including **168** LRLs), to address the needs of various LRL communities. Our analysis suggests which language features predict LLM effectiveness, to help end users make hypotheses even about languages not represented in our study. We evaluate monetary costs, since they are a concern for LLM users.

5 Conclusion

We provide benchmarks for LLM ENG→X MT performance across 203 languages, with comparisons to state-of-the-art commercial and open-source MT models. For many HRLs, LLMs like ChatGPT perform competitively with these traditional models. But for LRLs, traditional MT remains dominant, despite LLMs' increased parameter size. Our decision-tree analysis reveals language features that predict ChatGPT's translation effectiveness relative to NLLB, finding that ChatGPT is especially disadvantaged for LRLs and African languages, and that the number of Wikipedia pages a language has is a strong predictor of ChatGPT's effectiveness in it. We present evidence that few-shot learning offers generally marginal improvements for ENG→X MT, which may not justify its additional cost. We provide MT users with scores and cost estimates for four LLM and traditional MT systems, to help them determine which to use for their languages.

Future work may include more translation directions (X→ENG and non-English-centric), document-level MT, and human evaluation of LLM

[15] In this section, we define LRLs as languages having fewer than 1M Wikipedia pages.

outputs to reveal trends along fluency and accuracy dimensions. We open-source software and outputs of the models we evaluated on our repository.

Limitations

We acknowledge limitations of using ChatGPT models for research. Since they are closed-source models, there is much we do not know about their architectural and training details, which can impact our understanding of their capabilities and biases. For instance, OpenAI's implementation of mechanisms to prevent the generation of harmful or toxic content may inadvertently impact the quality of the model's output. This can be a concern when evaluating the reliability and accuracy of the results. OpenAI continuously updates and deprecates models behind the ChatGPT API, so our assessment may not be immaculate for future versions. Future work may mitigate these concerns by evaluating white-box LLMs, such as BLOOM (Scao et al., 2022) or MPT (Team, 2023), or LLMs not tuned for instruction, like GPT-3 (Brown et al., 2020).

While FLORES-200 is large and diverse, it is likely not representative of the vast array of languages worldwide. Some low-resource sets within FLORES-200 may contain noisy or corrupted data, potentially affecting the validity of the automatic metrics we employ in our reporting of scores. Additionally, FLORES-200 sets were translated from English Wikipedia. We avoided any X→ENG translation directions, since it is likely that GPT models were trained on English Wikipedia. However, the semantic proximity of the other language sets to the original English source could potentially provide an advantage to these models in generating them. We also acknowledge the absence of non-English-centric translation directions from this study; we leave this for future work.

Lastly, the unavailability of semantic MT evaluation techniques like COMET (Rei et al., 2020) or BLEURT (Sellam et al., 2020) for LRLs hinders our ability to conduct comprehensive semantic evaluations and may leave some aspects of the translation quality unexplored. Future researchers may gain additional insights by evaluating LLM COMET scores for the target languages in which they are available. Human evaluation (which we leave for future work) may also reveal much in this area. These limitations surrounding model transparency, representative data, and evaluation should be taken into account when interpreting the findings of this work. Future studies may benefit from addressing these challenges to enhance the robustness and reliability of MT conclusions.

Ethics Statement

The new prominence of LLMs in language technologies has numerous ethical implications. This study makes it apparent that even powerful LLMs like ChatGPT have significant limitations, such as an inability to translate a large number of low-resource languages. It also suggests that although these LLMs are trained on large and diverse data sets, they still have implicit biases, such as a clear disadvantage in MT for African languages. We hope to stress the importance of acknowledging and publicizing the limits and biases of these LLMs. This is especially relevant because a majority of LLM users may not be familiar or experienced with artificial intelligence (AI) engineering practices, and the commercial entities providing LLMs often have a monetary incentive to deliberately downplay the models' limitations. This can lead to unethical exploitation of users, who may attempt to use LLMs in applications where their limitations and biases can cause harm. Part of our goal in this work is to bring these discussions to the forefront of AI research. Ethical considerations like these should be a top concern for AI researchers, especially when many recent AI advancements are piloted by powerful commercial corporations.

We hope also to acknowledge some of the ethical considerations involved in our own research. As we strive to develop improved open-source and accessible translation systems, it is essential to acknowledge that some language communities may have reservations about having their languages translated. Another crucial point is that utilizing the FLORES-200 test set in this research may inadvertently contribute to its incorporation into OpenAI's training data. OpenAI's current position is that API requests are not used for training (Schade, 2023), but if this position were altered or disregarded, it could compromise the reliability of this test set for future GPT iterations. (This is a consideration for many commercial LLMs, though we only used OpenAI's in the current work.) This scenario has a potential negative impact on the MT community, since many researchers depend on FLORES-200 and other MT benchmarks for large, diverse, high-quality data to conduct system comparisons.

A Unabridged Result Table

In Table 11 we report full results for 203 target languages in ENG→X translation directions, across four MT systems: two LLMs (ChatGPT and GPT-4, with two n-shot settings for ChatGPT), one open-source encoder-decoder MT model (NLLB), and one commercial system (Google). We order in them in increasing order of performance, with zero-shot ChatGPT performing the worst and Google performing the best overall. We obtained scores for 203 target languages with ChatGPT, 201 with NLLB, 115 with Google Translate, and 20 with GPT-4. Our scores are spBLEU (Goyal et al., 2022) using the SPM-200 tokenizer (NLLB Team et al., 2022) and chrF2++ (Popović, 2017). All results are also available on our repository, and interactive visualizations and histograms can be browsed on our Zeno browser.

B Unabridged Bar Charts and Cost Estimation

See Figures 4 and 5 for chrF and BLEU scores across all MT systems and languages. Google Translate and NLLB are generally the best performers in both metrics, though GPT-4 and ChatGPT are occasionally best. An "x" indicates where we did not evaluate one of the systems for a language. Figures 6 and 7 display chrF and BLEU scores divided by the estimated cost of each MT system. The cost value is measured as the amount in USD that it would cost to translate the entire FLORES-200 *devtest* set for each language.

These visualizations are also available on our repository. (Also see our Zeno browser for interactive visualizations of our results.) We also include cost estimates and scores divided thereby for all languages and MT systems in Table 14. We exclude cost estimates by language for NLLB and Google because there is very little variation between languages. Our estimated cost of translating FLORES-200 *devtest* ENG→ is approximately $0.09 for every target language. And the respective estimate for Google Translate is roughly $2.66 regardless of the target language, since Google's API only charges for input characters.

B.1 Details about estimating NLLB cost

To estimate the cost of running NLLB's 3.3B-parameter model for translation, we used one GPU from Google Colab to translate the full FLORES-200 *devtest* set from English into six languages representing six high- and low-resource scripts–Burmese (`mya_Mymr`), Simplified Chinese (`zho_Hans`), Standard Arabic (`arb_Arab`), Hindi (`hin_Deva`), Armenian (`hye_Armn`), and French (`fra_Latn`)–and measured the time for each. We assumed that runtime t is determined by an equation with unknown coefficients x_1, x_2, and x_3:

$$t = x_1 n_{input} + x_2 n_{output} + x_3 \quad (1)$$

where n_{input} represents the number of input tokens and n_{output} is the number of output tokens. In this case, x_1 represents the rate at which the encoder processes input tokens, x_2 represents the rate at which the decoder undergoes inference, and x_3 is the amount of time to perform all other computations, independent of the number of tokens. We estimated x_1, x_2, and x_3 via a least-squares solution to the linear system defined by the six languages for which we obtained runtime t:

$$\begin{bmatrix} n_{input} & n_{output}(\texttt{mya}) & 1 \\ n_{input} & n_{output}(\texttt{zho}) & 1 \\ n_{input} & n_{output}(\texttt{arb}) & 1 \\ n_{input} & n_{output}(\texttt{hin}) & 1 \\ n_{input} & n_{output}(\texttt{hye}) & 1 \\ n_{input} & n_{output}(\texttt{fra}) & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} t_{\texttt{mya}} \\ t_{\texttt{zho}} \\ t_{\texttt{arb}} \\ t_{\texttt{hin}} \\ t_{\texttt{hye}} \\ t_{\texttt{fra}} \end{bmatrix}$$

where n_{input} is the number of tokens in the English *devtest* set, and n_{output} for each language is the number of tokens in the NLLB-MOE model output provided by NLLB Team et al. (2022). (We used the same tokenizer that we had used for GPT model cost estimation, for simplicity.) After estimating x_1, x_2, and x_3, we used them in Equation 1 to estimate t values for all 201 languages for which we obtained NLLB MT scores. We then used Google Colab's estimated rate of $0.35/hour for use of one GPU to estimate costs for each language.

C Visualizations Comparing ChatGPT and NLLB

See Figures 8 and 9. They are also posted on our repository. (Also see our Zeno browser for interactive visualizations of our results.)

D Estimating Wikipedia Page Counts

As mentioned in §2.3, we used the "Total pages" count from `https://en.wikipedia.org/wiki/List_of_Wikipedias`, accessed 7 August 2023,

as a proxy for the resource level of a language (refered to as `wiki_ct` in §3.4). We had to make some decisions regarding macrolanguage and microlanguage matches when making these estimates. Many of the languages in FLORES-200 (NLLB Team et al., 2022) are in fact microlanguages of a macrolangauge not included in the dataset. In some cases this microlanguage was did not have a listed Wikipedia page count, so we used the macrolanguage page count instead. Table 12 lists all the languages for which we used the Wikipedia page count of a macrolanguage (with a different ISO 639-3 code), based on our best judgment. In every case this was because the FLORES-200 microlanguage was not listed.

There were also cases where we decided to list zero for a microlanguage's `wiki_ct`, even if its macrolanguage was listed with a nonzero number of pages. This was in cases where we could reasonably assume that the macrolanguage's Wikipedia pages were likely (either all or predominantly) in another microlanguage or dialect. We list the languages that we considered in this manner in Table 13.

We also made some decisions regarding `wiki_ct` assignment based on the script of a language. We recorded zero Wikipedia pages for `kas_Deva` and 13,210 for `kas_Arab` (all of the Kashmiri pages) because a majority of Kashmiri pages seem to be in Perso-Arabic script. (There may be a few in Devanagari, but we simplify by assuming none are.) We also recorded zero pages for `mni_Beng` because, although Wikipedia has pages in Meitei, they appear to be in the Meitei `Mtei` script, not Bengali `Beng`. Lastly, we assigned Wikipedia's count for 'Classical Chinese' (`zh-classical`) to `zho_Hant` and its count for 'Chinese' to `zho_Hans` (though it is possible that some of the 'Chinese' pages may be in the Traditional Chinese (`Hant`) script).

In all other cases, if a language did not have a listed number of Wikipedia pages, we took this to mean it had zero.

Table 11: BLEU and chrF results on ENG→X directions. “0-shot" and “5-shot" are ChatGPT with zero- and five-shot settings, respectively. “NLLB" is the NLLB-MOE model, and “Google" is Google Translate. We used five-shot settings only for GPT-4. Models are listed in order of their effectiveness in MT (with zero-shot ChatGPT performing the worst and Google Translate performing the best).

Figure 4: chrF scores across all MT systems and languages

Figure 5: BLEU scores across all MT systems and languages

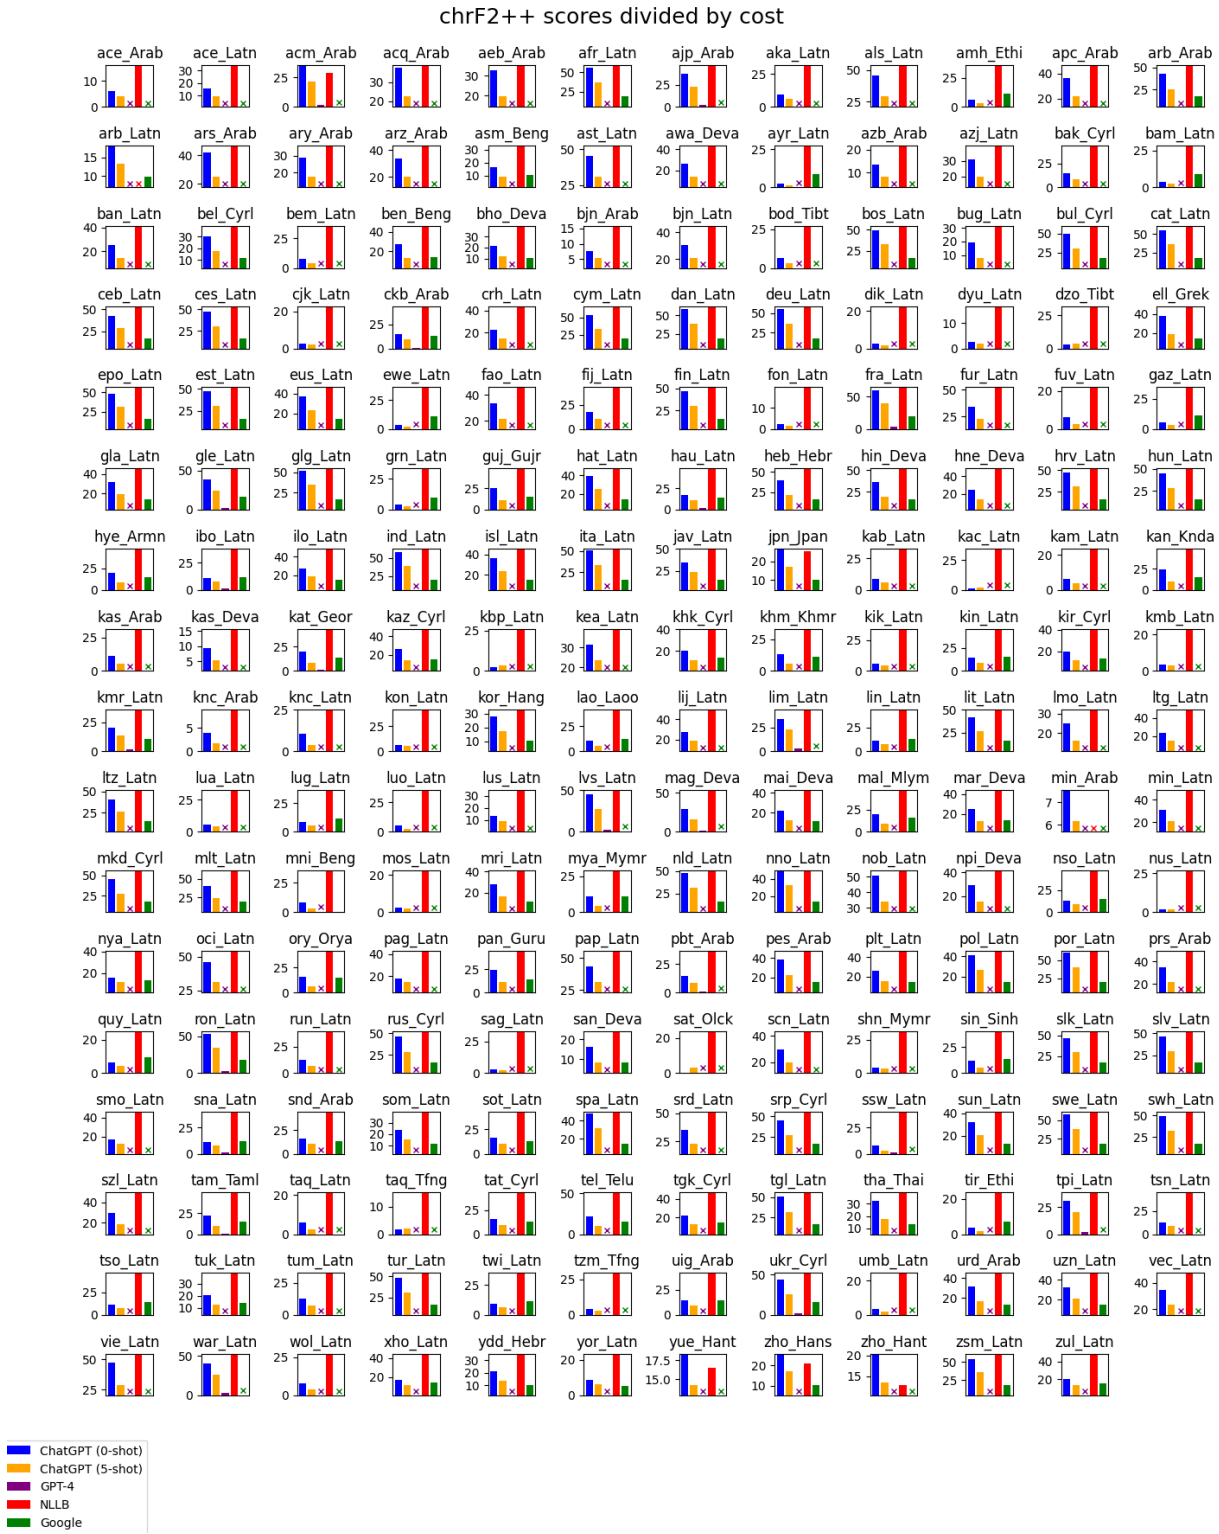

Figure 6: chrF scores divided by the estimated cost of each MT system, across all MT systems and languages

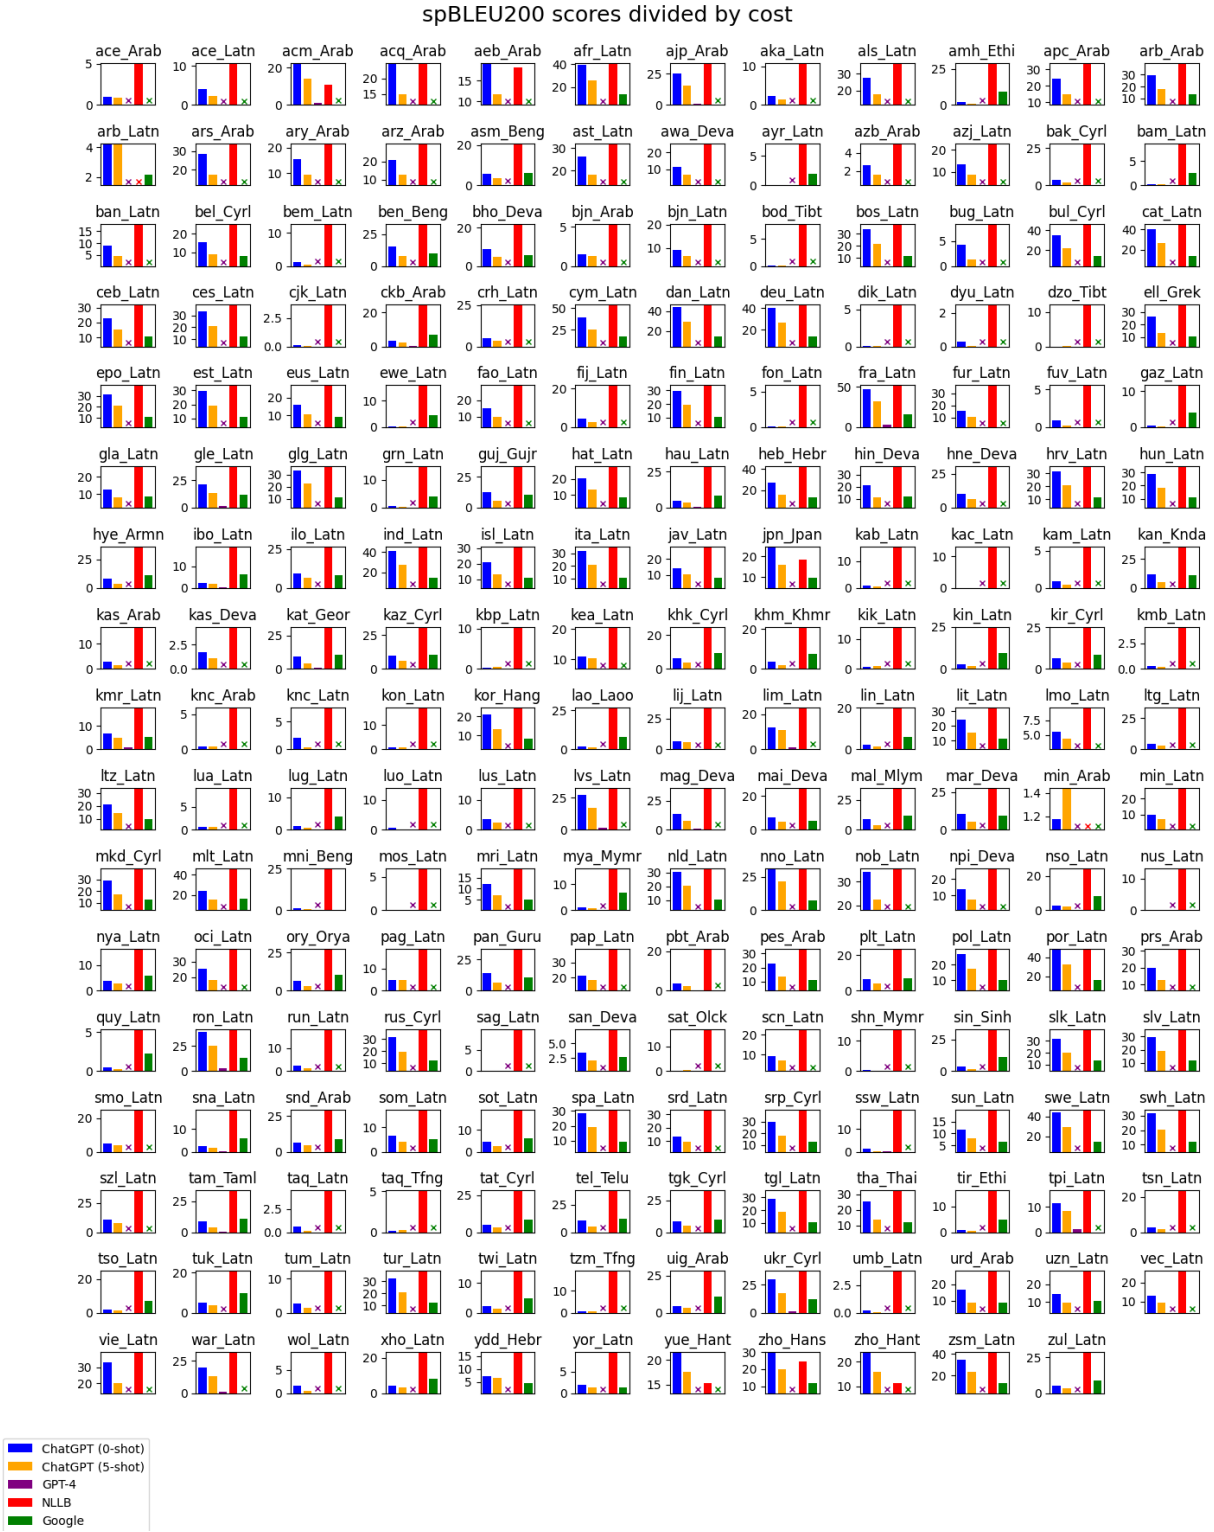

Figure 7: BLEU scores divided by the estimated cost of each MT system, across all MT systems and languages

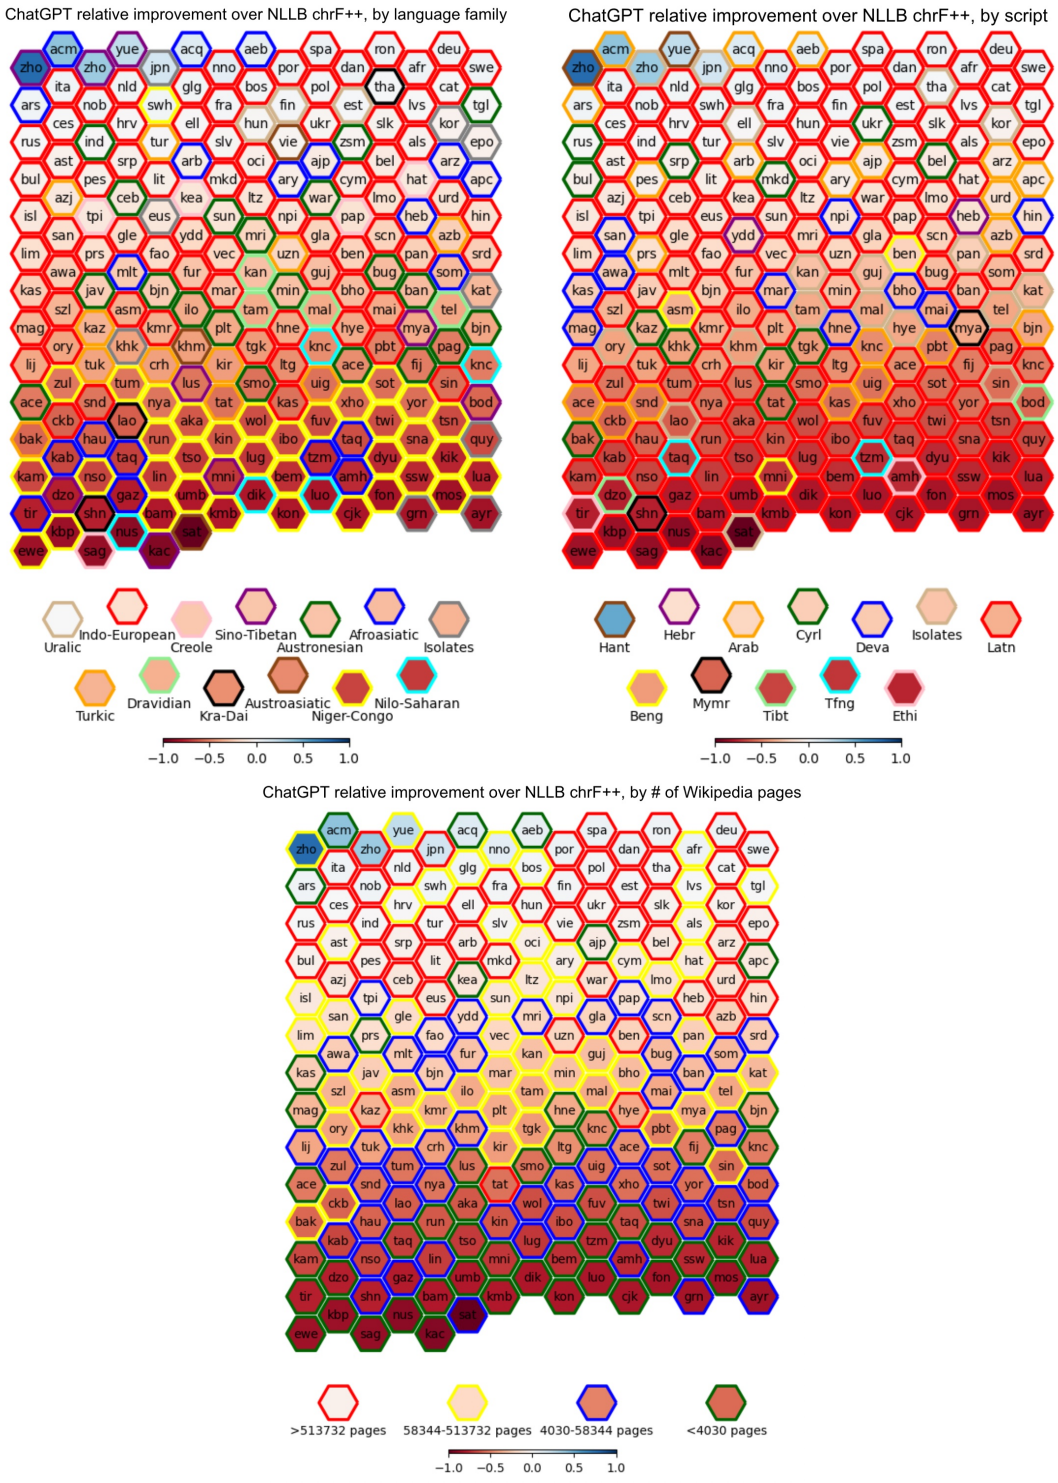

Figure 8: ChatGPT *relative improvement* over NLLB chrF (color scale), with languages organized by family, script, and number of Wikipedia pages (divided in quartiles). Hexagons (one per language) are displayed in descending order across rows, with the highest ChatGPT relative improvement over NLLB chrF2++ at the top left, and the lowest at the bottom right. Group hexagons at the bottom of each plot display the average color for each group and are organized in like manner.

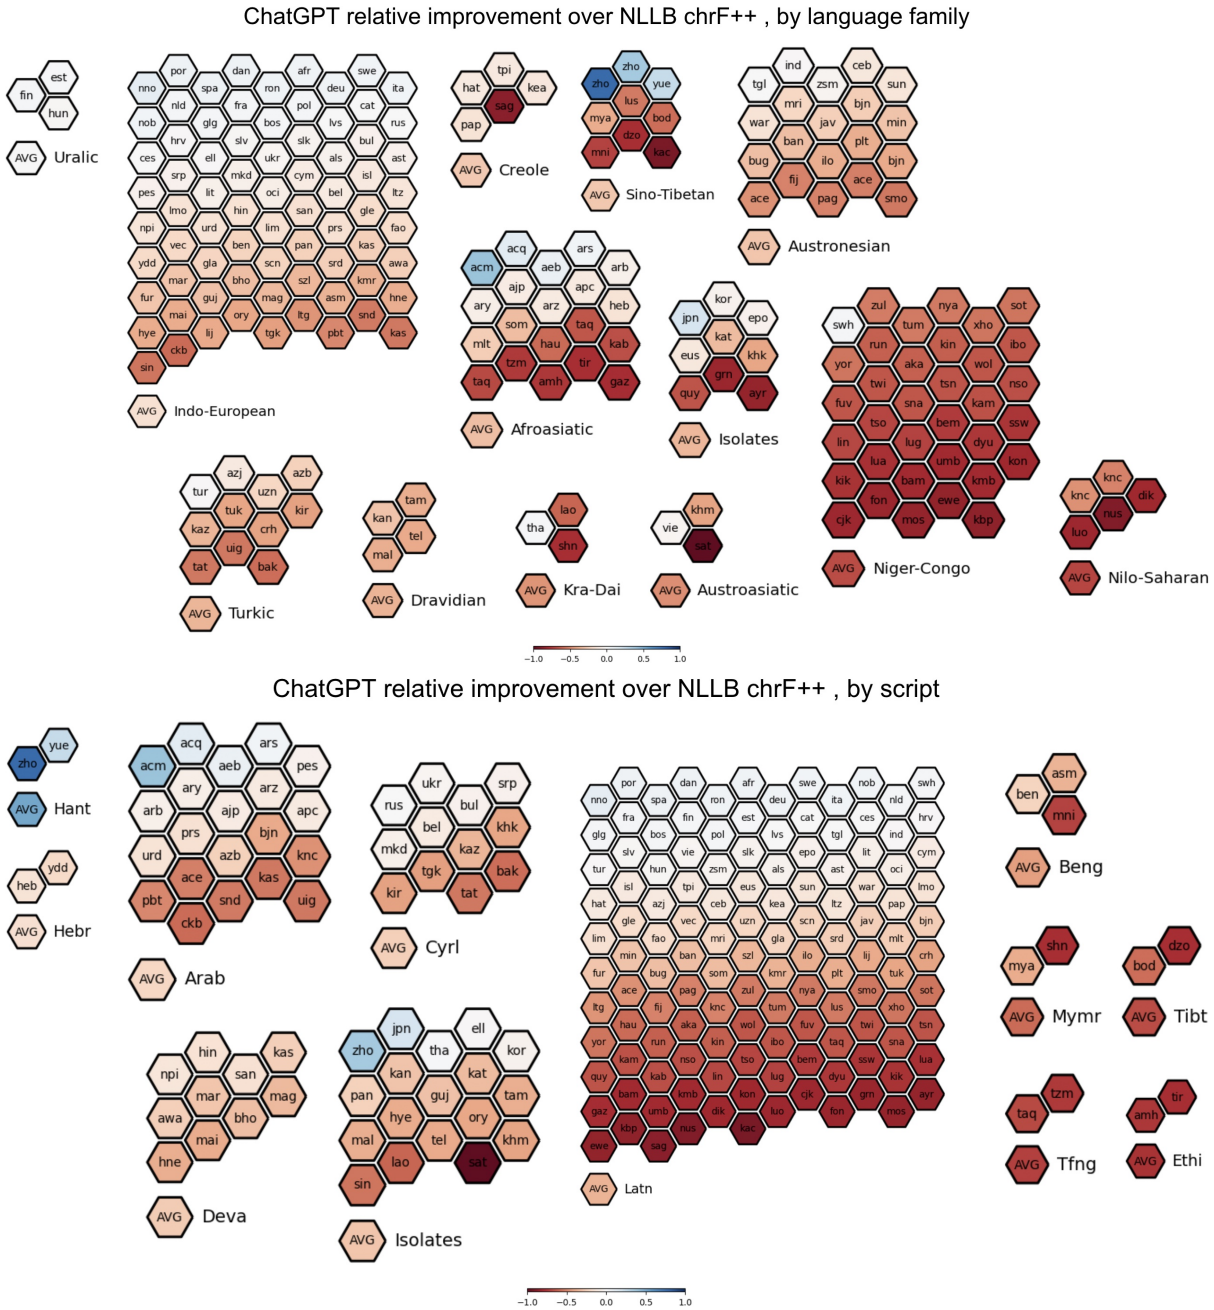

Figure 9: Alternative visualizations to those in Figure 8. Groups and languages are organized the same here: from top left to bottom right in descending order of the ChatGPT *relative improvement* over NLLB (using averages for the groups).

FLORES lang.	substitution for wiki_ct
arb	Used macrolanguage ‘Arabic’ (ara) because ‘Standard Arabic’ (arb) not present
bho	Used macrolanguage ‘Bihari’ (bih) because ‘Bhojpuri’ (bho) not present
dik	Used macrolanguage ‘Dinka’ (din) because ‘Southwestern Dinka’ (dik) not present
fuv	Used macrolanguage ‘Fula’ (ful) because "Nigerian Fulfulde" (fuv) not present
knc	Used macrolanguage ‘Kanuri’ (kau) because ‘Central Kanuri’ (knc) not present
lvs	Used macrolanguage ‘Latvian’ (lav) because ‘Standard Latvian’ (lvs) not present
plt	Used macrolanguage ‘Malagasy’ (mlg) because ‘Plateau Malagasy’ (plt) not present
khk	Used macrolanguage ‘Mongolian’ (mon) because ‘Halh Mongolian’ (khk) not present
gaz	Used macrolanguage ‘Oromo’ (orm) because ‘West Central Oromo’ (gaz) not present
pes	Used macrolanguage ‘Persian’ (fas) because ‘Western Persian’ (pes) not present
pbt	Used macrolanguage ‘Pashto’ (pus) because ‘Southern Pashto’ (pbt) not present
quy	Used macrolanguage ‘Quechua’ (que) because ‘Ayuacucho Quechua’ (quy) not present
als	Used macrolanguage ‘Albanian’ (sqi) because ‘Tosk Albanian’ (als) not present
uzn	Used macrolanguage ‘Uzbek’ (uzb) because ‘Northern Uzbek’ (uzn) not present
ydd	Used macrolanguage ‘Yiddish’ (yid) because ‘Eastern Yiddish’ (ydd) not present
zsm	Used macrolangauge ‘Malay’ (msa) because ‘Standard Malay’ (zsm) not present

Table 12: FLORES-200 languages for which we used the Wikipedia page count associated with a macrolanguage of another ISO 639-3 code

FLORES lang.	reason for assigning wiki_ct = 0
acm	Macrolanguage ‘Arabic’ (ara) appears to be in ‘Standard Arabic’ (arb), not ‘Mesopotamian Arabic’ (acm)
acq	Macrolanguage ‘Arabic’ (ara) appears to be in ‘Standard Arabic’ (arb), not ‘Tai’izzi Arabic’ (acq)
aeb	Macrolanguage ‘Arabic’ (ara) appears to be in ‘Standard Arabic’ (arb), not ‘Tunisian Arabic’ (aeb)
ajp	Macrolanguage ‘Arabic’ (ara) appears to be in ‘Standard Arabic’ (arb), not ‘South Levantine Arabic’ (ajp)
apc	Macrolanguage ‘Arabic’ (ara) appears to be in ‘Standard Arabic’ (arb), not ‘North Levantine Arabic’ (apc)
ars	Macrolanguage ‘Arabic’ (ara) appears to be in ‘Standard Arabic’ (arb), not ‘Najdi Arabic’ (ars)
mag	Macrolanguage ‘Bihari’ (bih) appears to be in ‘Bhojpuri’ (bho), not ‘Magahi’ (mag)
prs	Macrolanguage ‘Persian’ (fas) appears to be in ‘Western Persian’ (pes), not ‘Dari’ (prs)

Table 13: FLORES-200 languages for which we used assigned wiki_ct to be zero, despite the existence of Wikipedia pages in a corresponding macrolanguage

Table 14: Estimated costs in USD to translate the FLORES-200 *devtest* set ENG→X for each targe language and MT system, along with BLEU and chrF scores divided by the cost estimates, where applicable. The cost is roughly $0.09 for NLLB and $2.66 for Google Translate for all target languages.

Large language models effectively leverage document-level context for literary translation, but critical errors persist

Marzena Karpinska **Mohit Iyyer**

Abstract

Large language models (LLMs) are competitive with the state of the art on a wide range of *sentence-level* translation datasets. However, their ability to translate paragraphs and documents remains unexplored because evaluation in these settings is costly and difficult. We show through a rigorous human evaluation that asking the GPT-3.5 (`text-davinci-003`) LLM to translate an entire *literary* paragraph (e.g., from a novel) at once results in higher-quality translations than standard sentence-by-sentence translation across 18 linguistically-diverse language pairs (e.g., translating into and out of Japanese, Polish, and English). Our evaluation, which took approximately 350 hours of effort for annotation and analysis, is conducted by hiring translators fluent in both the source and target language and asking them to provide both span-level error annotations as well as preference judgments of which system's translations are better. We observe that discourse-level LLM translators commit fewer mistranslations, grammar errors, and stylistic inconsistencies than sentence-level approaches. With that said, critical errors still abound, including occasional content omissions, and a human translator's intervention remains necessary to ensure that the author's voice remains intact. We publicly release our dataset and error annotations to spur future research on the evaluation of document-level literary translation.[1]

1 Introduction

Large language models (LLMs) such as ChatGPT (OpenAI, 2022) demonstrate remarkable performance as stand-alone translation systems, rivaling and sometimes surpassing commercial models on sentence-level benchmarks (Vilar et al., 2022; Hendy et al., 2023; Jiao et al., 2023). Furthermore, LLMs are increasingly being deployed for *document-level* translation (Book Maker, 2023; Pawlak, 2023), a scenario for which there are currently no reliable automatic evaluation methods. In this paper, we hire human translators to conduct a rigorous fine-grained evaluation of GPT-3.5's ability to translate **paragraph-level** texts from **literary works** across 18 different language pairs. Our results (Figure 1) demonstrate that GPT-3.5[2] effectively leverages discourse-level context to produce higher-quality translations than when translating sentences in isolation.

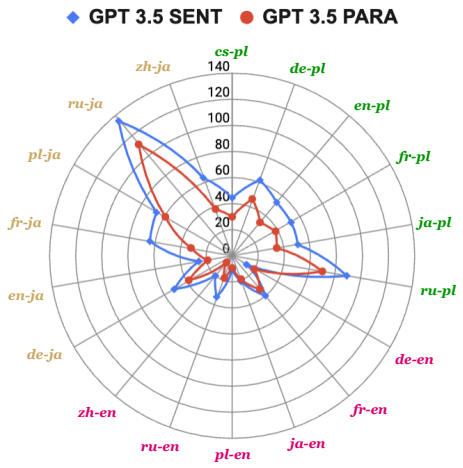

Figure 1: A plot of the total number of errors annotated in sentence-level (SENT) and paragraph-level (PARA) translations produced by GPT-3.5 across 18 different language pairs. In all cases, PARA produces fewer errors than SENT, which demonstrates that GPT-3.5 takes advantage of discourse context during translation.

Why literary texts? Translating works of literature poses unique challenges due to the intricate nature of creative work and the importance of capturing the author's voice and contextual nuances. Translators thus apply a wide range of transla-

[2] We completed our annotations on translations from the `text-davinci-003` checkpoint obtained prior to the API release of ChatGPT and GPT-4. Nevertheless, we include a preliminary analysis of GPT-4's translations in §F.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 419–451
December 6–7, 2023.

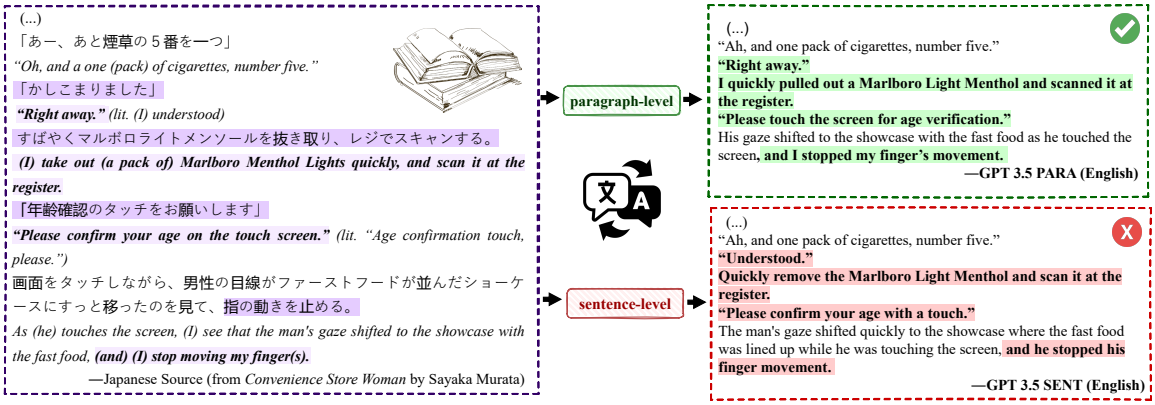

Figure 2: An example of paragraph-level (PARA) and sentence-level (SENT) translations of the same Japanese paragraph into English. Sentence-level translation results in a range of erroneous translations, from worse word choice ("understood" vs "right away") to incorrect pronouns ("he" vs "I"); these errors are corrected by PARA.

tion techniques (Chesterman, 1997; Molina and Hurtado Albir, 2004), from simple shifts in grammatical categories to more complex stylistic or content-based rearrangements that often cross sentence boundaries. Translators may also merge or split sentences and paragraphs, which renders the traditional sentence-level pipeline insufficient for capturing the full scope of the original text (Toral and Way, 2015; Taivalkoski-Shilov, 2019b; Post and Junczys-Dowmunt, 2023; Jiang et al., 2023).[3] Taken together, these properties make literary texts a good testbed for document-level machine translation (Thai et al., 2022); in our work, we focus on the *paragraph*[4] as a minimal discourse-level unit.

Why human evaluation? The absence of rigorous document-level evaluations of LLM translators is striking but also somewhat understandable given the unreliability of automatic metrics (Thai et al., 2022) and the difficulty of properly conducting human evaluations (Castilho, 2021). Furthermore, evaluations of LLM translators are especially difficult due to data contamination (Aiyappa et al., 2023; Chang et al., 2023), as it is unclear whether the models are pretrained on existing benchmarks (e.g., from WMT). We fill this gap by first collecting paragraphs from recently-published literary translations. Then, we provide human translators with two candidate machine translations of a given source paragraph and ask them to (1) mark error *spans* and categorize them based on a predefined schema inspired by MQM (Lommel et al., 2014b; Freitag et al., 2021), (2) make preference judgments of which of the two translations is of higher quality, and (3) provide free-form justifications of their preference judgments. In total, we collect such annotations on **720** pairs of translated paragraphs across **18** different language pairs (using three diverse target languages of English, Japanese, and Polish), which we then leverage for a fine-grained analysis of the behavior of different LLM translation methods.

LLMs produce better translations when provided with paragraph-level context: Our evaluations reveal that using GPT-3.5 to translate complete paragraphs via few-shot prompting (PARA) yields translations of significantly higher quality than both the sentence-by-sentence GPT-3.5 methods (SENT, PARA_SENT) as well as Google Translate. Our detailed analysis of annotated translation errors and free-form comments shows that PARA exhibit increased coherence, better preservation of literary style, and improved handling of context-dependent expressions (see Figure 2). That said, PARA makes many critical mistranslations and other errors across different language pairs, which shows that LLM-based translators still have significant room to improve, particularly when translating contextually-rich literary texts.

2 Background

Before describing our dataset and evaluation, we first contextualize our work within the recent body of research on translation via large language models. We also survey the broader body of document-

[3] At least 55% of the reference target paragraphs used in our study split or merge sentences from the source text (measured with an automatic sentence tokenizer).

[4] We broadly define a paragraph as a distinct passage within the novel, focusing on a single theme.

level[5] MT research in §A.

Translation with large language models: LLM-based translation is attractive because a single model, without training or fine-tuning on *large* parallel corpora, can produce high-quality translations across many language pairs.[6] Recent work explores LLMs' capabilities in this space (Wang et al., 2023) spanning paragraph-level post-editing with LLMs (Thai et al., 2022), translating sentence-level inputs (Vilar et al., 2022; Jiao et al., 2023), analyzing hallucinations in LLM-generated translations (Guerreiro et al., 2023), and employing LLMs to evaluate machine translation (Kocmi and Federmann, 2023). Simple sentence-level English prompt templates have been found effective for paragraph translations (Zhang et al., 2023), and automatically-generated dictionaries can assist LLM-based translation (Ghazvininejad et al., 2023; Lu et al., 2023) along with selecting high-quality demonstrations (Vilar et al., 2022). To the best of our knowledge, the only prior work other than ours that evaluates LLMs for paragraph-level translation is Hendy et al. (2023), who conduct *automatic* evaluation of context-aware sentence-by-sentence translation; in contrast, we perform a fine-grained *human* evaluation of paragraph-level translation.

3 Data & methods

Our work differs from existing research on translating with large language models in two key ways: we focus on translating *literary* text at the *paragraph level*. In this section, we describe and motivate the paragraph-level translation dataset used in our study, which covers 18 unique language pairs (three target languages) and is sourced from recently-published novels. Then, we outline the different ways in which we leverage GPT-3.5 to translate these paragraphs at both the sentence and paragraph levels.

3.1 Dataset collection

Literary texts (e.g., novels or short stories) pose unique challenges for translators due to their complex nature. Translators must interpret and honor the author's voice with no objective reality to measure against, which can result in several equally valid translations (Sager, 1998). For machine translation systems, these challenges exacerbate the need for discourse-level context (Thai et al., 2022): an author's intended meaning or style is often unclear from just a single sentence.

Selecting paragraphs from novels: How good are machines at translating literary paragraphs? To answer this question, we extract **20** paragraphs (dialogues and narrative texts) each from **18** recently-published translations of novels, and we manually align these paragraphs with corresponding paragraphs in the source novel[7] (see Table 8 in §B). Almost all of the translations were published after 2021 (see Table 7 in §B), which is important to avoid data contamination with LLM pretraining data (Aiyappa et al., 2023; Chang et al., 2023). In sum, we obtain **360** aligned source-target paragraphs, which we use for all of the experiments described in the rest of the paper.

Data memorization issue: In order to investigate the extent to which `text-davinci-003` may have memorized the novels in our dataset, we employ the prompts from (Chang et al., 2023) and assess the model's ability to produce masked characters' names. For this purpose we select 171 translation paragraphs, which contained character's names, resulting in an average of 8 out of 20 paragraphs used per book. In nearly all instances, the model was unable to accurately produce the correct names, with three exceptions. Two of these were names of well-known historical figures, "Napoleon Bonaparte" and "Simonides of Ceos." A closer examination revealed that these names could likely be inferred from the context, rather than being a result of the model's memorization. In the third instance the model produced the correct name but in diminutive instead of augmentative form ("Kasia" instead of "Kaśka").[8]

Additionally, we tested `text-davinci-003` with a randomly selected subset of paragraphs from our dataset. In these cases, the model was unable to generate accurate completions.

[5] Note that the term "document-level" has been used in MT research to denote both multi-sentence passages as well as complete documents.

[6] That said, parallel data is almost certainly included in LLM pretraining data, at least for high-resource languages (Briakou et al., 2023).

[7] We purchase the source ebook and its corresponding translation before extracting aligned paragraphs.

[8] Kasia/Kaśka" are both forms of "Katarzyna," the second most common female name in Poland as of January 2023. This raises a question of whether the model's response was due to memorization or an educated guess based on the name's popularity (`https://www.statista.com/statistics/1089014/poland-most-popular-female-names/`).

Paragraph length: All paragraphs consist of at least two sentences, and the majority of them are between four to nine sentences long (mean=7.45, std=4.14).[9] As automatic sentence tokenizers are not always reliable for all of the languages considered in our study, we manually perform sentence tokenization to enable a direct comparison of sentence and paragraph-level translation systems. For more details about the dataset statistics, including token and sentence counts, see §B, which also includes data on sentence numbers obtained using a sentence tokenizer.

Source and target languages: As source languages, we select eight languages that belong to different language families, have varied morphological traits, and employ different writing systems: English (*en*), Polish (*pl*), Russian (*ru*), Czech (*cs*), French (*fr*), German (*de*), Japanese (*ja*), and Chinese (*zh*). As target languages, we select English, Japanese, and Polish, as they also vary greatly in their morphology, grammar, and writing systems. The detailed rationale can be found in §B.

3.2 Translation with large language models

In this paper, we focus on translating the literary paragraphs in our dataset using large language models. More specifically, we use the GPT-3.5 `text-davinci-003` checkpoint, which has been further tuned to follow instructions based on human feedback (Ouyang et al., 2022). Hendy et al. (2023) demonstrate that GPT-3.5 produces translations of reasonable quality, though their focus was mainly at the sentence level. Since many LLMs, including GPT-3.5, are only accessible via black-box APIs, we adapt the model for translation via in-context learning (Brown et al., 2020).

Demonstration examples: We use few-shot prompting, in which a model is provided with a prompt consisting of five demonstrations. We manually curate the five demonstrations from literary texts for each of the 18 language pairs, resulting in 90 total demonstration examples. These demonstrations are sourced from novels that are *not* part of our translation dataset, resulting in potential differences in topic and style (see Table 9 in the §B for details). We further ensure that each set of five demonstrations includes both dialogues and narrative texts.

Prompting for translation: We consider the following three prompting strategies for GPT-3.5 that allow us to compare the model's abilities to translate with and without discourse-level context (see Table 1 for templates and §C for the exact prompts):

- **GPT-3.5 sentence-level translation without context (SENT):** Each sentence of the paragraph is translated in isolation of the others. To maintain consistency, we provide the same five *sentence*-level examples[10] in each prompt for the given source-target language pair.[11]
- **GPT-3.5 sentence-level translation *with* context (PARA_SENT):** Each sentence of the paragraph is translated in context. The model is provided with the entire source paragraph as input, where the sentence to be translated is wrapped in `<translate>` and `</translate>` tags, in addition to a partially-translated target paragraph. The demonstrations are also presented with the same tags. For each demonstration in the prompt, a sentence in a different position was chosen (e.g., from the beginning, middle, and end of the paragraph).
- **GPT-3.5 paragraph-level translation (PARA):** The entire source paragraph is passed into the model, and the output target paragraph is generated conditioned on this input (i.e., without any sentence tokenization). Demonstrations in the prompt are also *paragraphs*[12] of translations from the respective source language into the target language in question.[13]

[9] A paragraph with fewer sentences is not necessarily short: for example, in the German novel "An Inventory of Losses," sentences can be as long as 70 to 80 words, with the longest reaching 117 words. The distribution of sentences in paragraphs is provided in Figure 7 in §B.

[10] Sentence-level demonstrations for SENT are sampled from the demonstrations for paragraph-level translation.

[11] To ensure consistent quotation mark usage and enable a fair comparison with paragraph-level translations, quotation marks in sentence-level translations were manually adjusted.

[12] The examples for PARA and PARA_SENT configurations are necessarily lengthier. Due to the GPT-3.5 maximum context size, it is not always possible to include all five examples within the prompt. Consequently, around 10% of the data was translated using four or fewer examples.

[13] Initially, we experimented with GPT-3 by translating between two non-English languages using English as a pivot, as it is the primary language of the model. The model had access to the source text and its English translation. After manual evaluation and comparison to translations without a pivot language, we found no significant benefit in using English as the pivot. Consequently, we directly translated paragraphs into the target language. Refer to §H for details and results of this preliminary study.

SENT Demonstration Template
Original text in [SRC LANG]: source sentence Translation into [TRG LANG]: target sentence
PARA_SENT Demonstration Template
Original text in [SRC LANG]: source sentence 1 <translate> source sentence 2 </translate> source sentence 3 Translation into [TRG LANG]: target sentence 1 <translated> target sentence 2 </translated>
PARA Demonstration Template

Table 1: Prompt templates for SENT, PARA_SENT, and PARA. The source text to translate and expected target outputs are underlined.

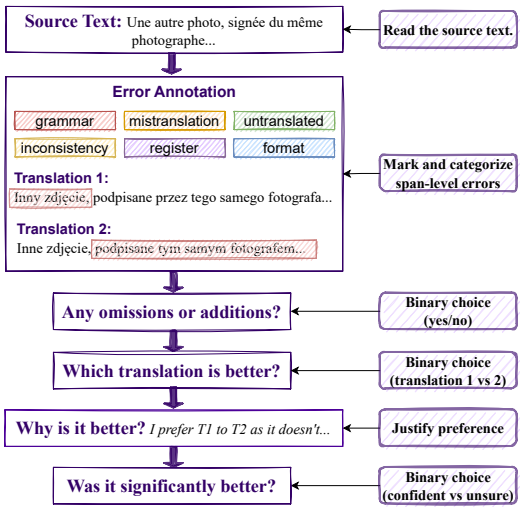

Figure 3: A description of the annotation process for a pair of candidate translations given a source paragraph. Note that our hired translators go through this pipeline for *three* different pairs per source paragraph, comparing PARA with SENT, PARA_SENT, and GTR.

Using Google Translate (GTR) as a baseline: In order to compare commercial-grade translation systems to LLM translators, we also translate all paragraphs in our dataset using Google Translate.[14] We opt for an off-the-shelf commercial system instead of a state-of-the-art system from, for instance, WMT competitions for two primary reasons. First, our experiments focus on *literary* translations. Given that WMT systems are predominantly evaluated on the news domain, it is uncertain which system would perform best, and some language pairs may not even be supported. Second, our main research question revolves around LLMs' ability to incorporate contextual information, rather than merely comparing their performance with state-of-the-art translation systems. We employ GTR as a reasonably robust baseline to assess the extent to which context can enhance MT quality, rather than asserting that LLMs outperform *all* traditional MT systems.

4 Evaluating document-level literary translation

How do we compare the translation quality of the systems described above? Automatic metrics such as BLEURT and COMET are untested on document-level inputs as well as literary texts, and as such we do not consider them reliable, although we do report them in §G.[15] Human evaluation is equally problematic, as direct assessments of translation quality (e.g., "rate the quality of this translation from 0-100") suffer from calibration issues that are exacerbated with longer texts (Karpinska et al., 2021). Thus, we opt for a human evaluation inspired by Multidimensional Quality Metrics (Lommel et al., 2014b, MQM), in which annotators mark and classify error spans within the translation. Specifically, for each of the 18 language pairs studied in this work, we hire translators to identify all span-level errors in two competing translations. For each evaluated pair, the annotators were also asked to choose the better translation and provide a free-form rationale. For each source paragraph, the translators make three binary judgments of which translation is higher quality: SENT vs PARA, PARA_SENT vs PARA, and GTR vs PARA.

Recruiting annotators: As our task is complex and requires fluency in both the source and target language, we hire *translators* to provide the annotations. We recruit 13 translators via the Upwork freelancing platform,[16] each of whom is a native speaker of English, Polish, or Japanese.[17] One

[14] All paragraphs were translated in January 2023 using the `GoogleTranslate` API. The system was provided entire paragraphs, which it likely partitioned and translated sentence-by-sentence.

[15] Automatic metrics developed specifically for document-level MT are also insufficient as they either work best with one-to-one sentence level alignments (Vernikos et al., 2022; Hendy et al., 2023) or are available only for English (Jiang et al., 2022).

[16] https://www.upwork.com/

[17] The annotators for Czech-Polish and Russian-English were both native speakers of the respective source languages

translator, hired directly, was a bilingual speaker of English and Polish with advanced knowledge of German; as such, she performed the *pl-en*, *de-en*, and *de-pl* evaluations. Evaluation of *ja-pl*, *pl-ja*, and *pl-en* texts was done by the first author in a collaboration with native speakers of Polish/Japanese to avoid any potential bias. Each translator was paid $2 per evaluated pair of candidate translations, with an additional $5 bonus to cover the time spent familiarizing themselves with the instructions. We asked them to compare three pairs of system translations (PARA vs. SENT, PARA vs. PARA_SENT, PARA vs. GTR) for 10 paragraphs per language pair[18]; as such, 180 total source paragraphs were used in our evaluations. Altogether, we paid approximately $12 per hour, with a total cost of $955.

Annotation task: First, we tasked the hired translators[19] with annotating a subset of MQM translation errors identified through a pilot analysis and annotation of the system's outputs. Specifically, we ask them to highlight spans within the candidate translations that contain errors belonging to any of the following error categories:

- **mistranslation:** [20] accuracy errors that occur when the wrong target word or phrase is chosen to represent content from the source text. In addition to canonical mistranslations, we also include *overly literal* translation errors that occur when systems nonsensically translate word-by-word into the target language.
- **grammar:** grammatical errors, such as errors in conjugation, declension, or wrong prepositions.
- **untranslated:** words or phrases that should have been translated into the target language but were either left in the source language or just transliterated into the target language.
- **inconsistency:** use of different terms to refer to the same entity, or different words where the same word should be used for stylistic reasons (e.g., "Kasia" and "Kate," "coat" and "jacket," or "bad" and "awful").
- **register:** a clear violation in the use of formal and informal language within the same text, only annotated in Japanese.[21]
- **format:** incorrect usage of punctuation (e.g., "." instead of "。").

After the span-level annotation is complete, we then ask the translators to further identify if any of the candidate translations contains significant content **additions** or **omissions** in relation to the source text.[22] Finally, they are asked to **choose the better translation** and provide a justification for their choice in two to five sentences. We instruct them to additionally mark whether their chosen translation is significantly superior, or if the decision was difficult because both translations are of roughly comparable quality (see Figure 3 and §D for details).

5 Results

In this section, we compare our different literary translation methodologies using both automatic metrics and aggregate statistics from the human evaluations. Overall, we observe that the PARA configuration outperforms competing methods across all evaluations and language pairs. These results demonstrate that GPT-3.5 effectively leverages paragraph-level context to produce better translations than sentence-level methods, and also that the less efficient sentence-by-sentence translation with context is (PARA_SENT) is unnecessary to achieve high translation quality.

5.1 Human evaluation also favors PARA

Figure 5 contains human preference results comparing PARA to SENT, PARA to PARA_SENT, and

and highly proficient in their respective target languages. They collaborated with native speakers of the target languages, who possessed a basic understanding of the source language, to complete their annotations.

[18]These paragraphs were randomly sampled from the 360 paragraphs. The entire set of 360 paragraphs was used for the automatic evaluation described in §G.

[19]They were presented with guidelines in their native language. The annotation task was performed using the Label-Studio annotation tool (Tkachenko et al., 2020-2022). See Figure 11 for the screenshot of the interface.

[20]We note that mistranslations in literary text are often not as grave as, for instance, in news articles. Human translators hold *poetic license*, which allows them to change some details to make the text more enjoyable for the reader. Is changing "bonito" into "tuna" incorrect? Or can it be perceived as a way to accommodate an English-speaking readership that is likely more familiar with the latter?

[21]We only annotate cases where the level of formality changes abruptly within the same paragraph. It is possible that a given character would be more likely to use formal language but an informal language is being employed. As long as this is consistent we do not consider it an error as this cannot be fully determined from the paragraph context.

[22]Note that this task was simplified to a binary choice – either there were serious omissions/additions or not. We did not ask the annotators to further annotate them due to the time restrictions.

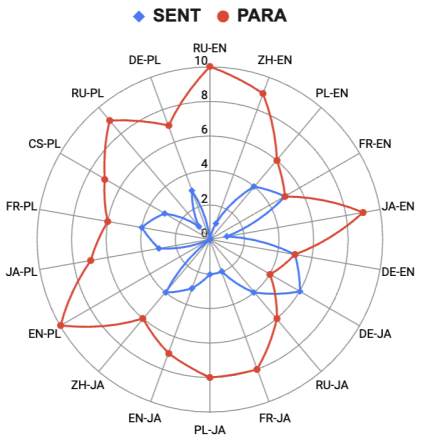

Figure 4: The distribution of translator preference judgments between sentence-level translation (SENT) and paragraph-level translation (PARA). PARA is preferred (i.e., more votes) in every language pair except *de-ja*, *fr-en* and *de-en*.

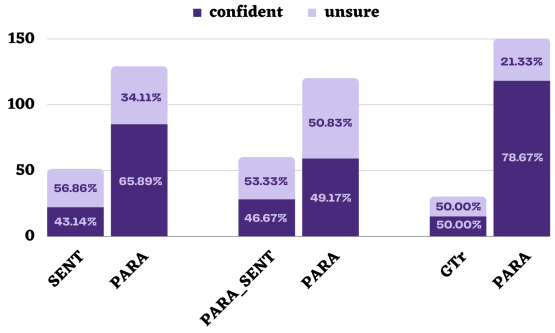

Figure 5: The number of votes for SENT vs PARA, PARA_SENT vs PARA, and GTR vs PARA along with rater confidence (*confident* or *unsure*). PARA is preferred to all competing methods. All differences are statistically significant at $p<.001$ (binomial test).

PARA to GTR, aggregated across all 18 language pairs studied in this paper (i.e., 180 votes per system comparison). Table 11 breaks down these results for each language pair, and we observe the same trends for the vast majority of pairs. Overall, the translators significantly favored PARA translations over the alternatives ($p<.001$, binomial test). Table 2 contains specific information about grammar and mistranslation errors split across the three target languages (see Table 16 and Table 17 for details), which we refer to in the discussion below.

PARA is clearly better than SENT: PARA is preferred by translators over SENT at a rate of 71.67% ($p<.001$, 95% CI [0.645, 0.781]). Additionally, when translators preferred PARA, they were usually confident in the decision (i.e., it was clearly better than SENT); even if we exclude all "unsure" votes, the preference for PARA translations remains significant at 79.44% ($p<.001$, 95% CI [0.705, 0.866]). The only language pair in which SENT is favored over PARA is *de-ja* (see Figure 4).[23] Overall, SENT produces 31% more mistranslations, 48.6% more grammar errors, 15 times more inconsistencies, and 3.5 times more register errors (Table 2).

PARA is clearly better than GTR: PARA translations are overwhelmingly preferred over those from Google Translate (GTR), with an 83.33% preference rate ($p<.001$, 95% CI [0.771, 0.885]). In the *fr-ja*, *pl-ja*, *zh-ja*, and *cs-pl* language pairs, PARA received *all* of the ten votes over GTR. Overall, GTR translations result in 58.18% more mistranslations, 35.24% more grammatical errors, over seven as many inconsistency errors, and ten times more register errors (see Table 2). §E contains more fine-grained comparisons of these two systems.

PARA is slightly preferred over PARA_SENT: Our evaluations show that PARA is better than PARA_SENT, but the gap is smaller than it is for the other two methods. PARA is still preferred at a 66.67% rate ($p<.001$, 95% CI [0.593, 0.735]). Both PARA and PARA_SENT produce a comparable number of mistranslations (*483* vs 462), grammar errors (*105* vs *113*), and inconsistencies (*2* vs *3*) (see Table 2). While PARA_SENT leaves around 22% more words untranslated, it appears to leverage the contexts and even occasionally selects better equivalents in the target language, as evidenced by translator comments. One major issue with PARA_SENT is that it occasionally repeats sentences, whereas PARA never does so.

6 Analyzing translation errors

The aggregate statistics from the previous section confirm that PARA-level translation via GPT-3.5 is the strongest literary translator of the methods that we study. Translations produced by PARA are favored by both automatic metrics and human translators, and it makes fewer errors than competing methods. In this section, we dive deeper into specific *types* of errors that are made within each high-level category (e.g., grammar, mistranslation), and we present examples of errors associated with

[23] This could be because the German novel *An Inventory of Losses* in our dataset contains the longest sentences of any book (45 tokens per sentence), and thus the intra-sentence context is likely more informative than in other books.

Type	Trg Lang	Para	Sent	Para_Sent	GTr
Mistranslation	En	88	109	82	155
	Ja	224	295	223	334
	Pl	171	229	157	275
	Total	*483*	*633*	*462*	*764*
Grammar	En	5	20	9	18
	Ja	43	49	38	65
	Pl	57	87	66	59
	Total	*105*	*156*	*113*	*142*
Inconsistency	En	0	5	0	1
	Ja	1	7	2	7
	Pl	1	19	1	7
	Total	*2*	*31*	*3*	*15*
Untranslated	En	13	5	14	6
	Ja	23	30	33	24
	Pl	23	16	25	4
	Total	*59*	*51*	*72*	*34*
Register	En	0	0	0	0
	Ja	7	25	13	71
	Pl	0	0	0	0
	Total	*7*	*25*	*13*	*71*
Format	En	0	*n/a*	*n/a*	1
	Ja	0	*n/a*	*n/a*	117
	Pl	0	*n/a*	*n/a*	8
	Total	*0*	*n/a*	*n/a*	*126*

Table 2: Total counts of all of the types of mistakes made by each of the four systems from our annotation. Overall, models with access to paragraph-level context commit fewer translation errors.

lack of context understanding made by Sent and GTr that are fixed by Para.

6.1 Language-specific grammatical errors

We analyze the types of grammatical errors that are made by the studied translation methods in all three target languages.[24] In summary, although GPT-3.5 is primarily trained on English, it is competitive with GTr at Polish and Japanese grammar proficiency. In fact, Para generates the fewest grammatical errors of any system, with a total of *97* for both languages, in contrast to *136* errors made by Sent, *101* errors by Para_Sent, and *122* errors by GTr (see Table 2). That said, *none* of these systems delivers translations devoid of grammatical inaccuracies, even for English.

English: Perhaps not surprisingly, translations into English contain fewer grammatical mistakes than Japanese or Polish (see Table 2). The most prominent mistakes in English are incorrect articles, which is most frequent with Sent and GTr. This is to be expected, as the choice between the definite and indefinite article in English depends heavily on the context. Other mistakes include wrong or omitted prepositions, wrong parts of speech, and incorrect word order (see Table 17).

[24]There are some differences in the paragraph lengths between the three target languages that should be taken into consideration when analyzing raw numbers. However, the general tendencies remain intact.

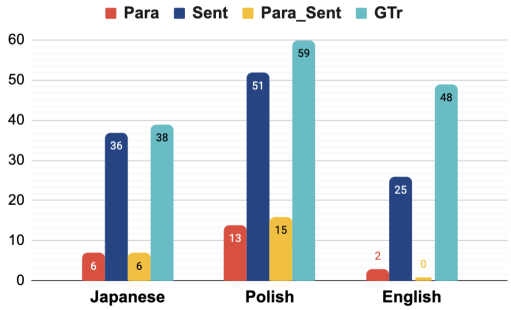

Figure 6: Quantification of mistranslations resulting from missing or misinterpreted paragraph-level context in Para, Sent, Para_Sent, and GTr systems, organized by the target language (Japanese, Polish, and English).

Japanese: Translations into Japanese contain considerably more mistakes. Most notably, the systems struggle with the correct choice of particle: Para and Sent produce twice as many mistakes in this regard than Para_Sent and GTr (see Table 17). Other mistakes include incorrect tense, verb finite form within the sentence, or incorrect word order, the latter of which is much more frequent in GTr than any of the GPT-3.5 translations.

Polish: GPT-3.5 exhibits more difficulty with Polish grammar than English or Japanese across all prompting strategies (see Table 2). It frequently generates incorrect gender, case, or prepositions (see Table 17). We also observe instances in which GPT-3.5 alters the gender of a noun, such as producing *grilla*, a non-existent feminine form, in place of the masculine *grill*, while accurately modifying all adjectives and verbs to match the novel feminine noun.[25]

6.2 Context-related errors

We manually classify *all* annotated mistranslations (2,324 instances) into subcategories, several of which include instances where the absence of discourse-level context is clearly a contributing factor (see Table 16 for detailed classification).[26] We also further analyze *all* translations in terms of content-related issues. Overall, we observe that context is indeed incorporated into the translations

[25]It is worth noting that *grilla* can also be also the genitive form of the masculine noun *grill*; however, the agreement of surrounding verbs and adjectives with the feminine noun suggests that the system likely treated the word as feminine.

[26]The initial classification was conducted on the first version of the dataset. After incorporating small corrections, we identified 18 more mistranslations that were not part of this analysis.

Type	Source	GPT-3.5 Sent Translation	GPT-3.5 Para Translation	Comment
Pronouns	Романы, как известно, печатались на разной бумаге [*paper*]. И гореть она [*she*] может по-разному. —Russian Source (from *Manaraga*)	Romany, jak wiadomo, drukowano na różnym papierze [*paper*]. I może ona [*she*] tęsknić na różne sposoby. —GPT-3.5 Sent (Polish)	Jak wiadomo, powieści drukowano na różnym papierze [*paper*]. I może on [*he*] palić się na różne sposoby. —GPT-3.5 Para (Polish)	"Paper" is a feminine noun in Russian and referred to as "she," whereas it is a masculine noun in Polish and should be referred to as "he," as in Para. The absence of context in Sent leads to an incorrect translation.
Cultural Nuances	「気が付かなくてすみません」「いやいや、(...). 古倉さんは毎日勤務なのに手を抜かないからねー！」 [lit. *Ms. Furukura works every day*] —Japanese Source (from *Convenience Store Woman*)	"I'm sorry I didn't notice." "No, no, (...). Furukura-san works hard every day without taking any shortcuts!" —GPT-3.5 Sent (English)	"I'm sorry I didn't notice." "No, no, (...). You work every day, but you never slack off!" —GPT-3.5 Para (English)	"Furukura-san" or "Miss Furukura" in the last source sentence is used instead of the second-person "you" as per Japanese convention. Translating this sentence without context into English results in a confusing translation (Sent) that implies that the speaker refers to some other "Furukura" rather than their listener. Para correctly translates "Furukura" as "you."
Ellipsis	„Ne, teď uděláš nádobí!" [*(you) will do the dishes!*] „Neudělám!" [*(I) won't do!*] „Uděláš!" [*(You) will do!*] —Czech Source (from *Crows*)	— Nie, teraz zrobisz zmywanie! [*(you) will do the washing*] — Nie zrobię! [*(I) won't do!*] — Zrobisz to! [*(You) will do it!*] —GPT-3.5 Sent (Polish)	— Nie, teraz umyjesz naczynia [*(You) will wash the dishes*]! — Nie umyję [*(I) won't wash*]! — Umyjesz [*(You) will wash*]! —GPT-3.5 Para (Polish)	Czech uses the same collocation as English, "*do* the dishes," which is invalid in Polish. Hence, the ellipses in the last two sentences in the source text require a broader context to be translated correctly. Para does it properly, translating both as "wash," while Sent unsurprisingly fails to choose the correct collocation.
Subject Ellipsis	When we were done, the lipstick went back into some mother's Fendi handbag. We watched her apply it, unaware. —English Source (from *A Children's Bible*)	Gdy skończyliśmy, szminka wróciła do jakiejś torebki Fendi należącej do matki. Patrzyliśmy, jak to robi, nieświadomi [*unaware (we)*] tego. —GPT-3.5 Sent (Polish)	Kiedy skończyliśmy, szminka wróciła do torebki Fendi jakiejś matki. Patrzyliśmy, jak ją nakłada, nieświadoma [*unaware (she)*] naszych działań. —GPT-3.5 Para (Polish)	Only from the broader context we can deduce that "unaware" refers to the mother, not the "we" (referring to children) watching her. Para correctly attributes the state of being "unaware" to the mother, which is exhibited by its usage of the singular feminine form of the adjective. In contrast, Sent mistranslates it using the plural masculine form of the adjective "unaware," which implies that it refers to "we" rather than the "mother."
Consistency	Alles zu vergessen, ist gewiss schlimm [*bad*]. Noch schlimmer [*worse*] ist, nichts zu vergessen (...). —German Source (from *An Inventory of Losses*)	すべてを忘れることは確かに悲惨な[*tragic*]ことです。さらに悪い[*worse*]のは、何も忘れないことです。 —GPT-3.5 Sent (Japanese)	すべてを忘れることは確かに悪い[*bad*]ことです。もっと悪い[*worse*]ことは、何も忘れないことです。 —GPT-3.5 Para (Japanese)	The German source translates into English as "To forget everything is *bad*, certainly. *Worse* still is to forget nothing." It is arguably important for the translation to repeat the same word which is an equivalent of the German "schlimm" ("bad"). Para does it well, translating both as 悪い, or "bad," while Sent uses two different words, "tragic" and "bad" which results in inconsistent translation.
Polysemy	Все прошло хорошо. Книга прочитана идеально – не быстро и не медленно, минимум дыма. Классика. Я был в форме [*in shape*]. —Russian Source (from *Maranaga*)	Wszystko poszło dobrze. Książka została przeczytana idealnie – nie szybko i nie wolno, minimalna ilość dymu. Klasyka. Byłem w mundurze [*in uniform*]. —GPT-3.5 Sent (Polish)	Wszystko poszło dobrze. Książka przeczytana idealnie – nie szybko i nie wolno, minimalna ilość dymu. Klasyka. Byłem w formie [*in shape*]. —GPT-3.5 Para (Polish)	The ambiguity stems here from multiple meanings of the Russian noun форма , which can mean either "shape" or "uniform." Since one can be "in shape" as well as "in a uniform", only from the context it becomes clear which meaning was intended by the author. Para translates it correctly as "shape" while Sent mistranslates it as "uniform."
Appropriateness	「あー、あと煙草の５番を一つ」「かしこまりました」 [lit. *(I) understood*] —Japanese Source (from *Convenience Store Woman*)	"Ah, and one pack of cigarettes, number five." "Understood." —GPT-3.5 Sent (English)	"Ah, and one pack of cigarettes, number five." "Right away." —GPT-3.5 Para (English)	This conversation is between a clerk and a customer. The Japanese expression かしこまりました is an honorific that literally means "understood." However, when choosing the best equivalent, the translator needs to consider the situation at hand to best reflect its meaning in the target language. "Understood" in Sent is technically correct, but it is an unfortunate word choice for the clerk to employ. On the other hand, "right away" in Para fits much better in the context of this conversation.

Table 3: Examples of different context-related issues observed in Sent translations, which are fixed in the corresponding Para translations. Phrases that exemplify these issues are highlighted in purple, and English glosses are provided in [*square brackets*].

for both Para and Para_Sent outputs, which results in fewer context-dependent issues (see Figure 6). More specifically, we observe that Para produces translations that leverage the context resulting in mostly correct translations of pronouns, ellipsis, cultural nuances, and polysemous words and phrases; Table 3 contains specific examples and discussion of each. Para is also more consistent and appropriate in vocabulary usage than Sent. All cases are further analyzed in §E.2.

7 Conclusion

In this paper, we demonstrate that LLMs leverage paragraph-level context to produce translations that are more coherent and enjoyable than sentence-by-sentence translation while containing fewer mistranslations and grammatical issues. Our evaluations reveal that professional translators prefer paragraph-level translations over both sentence-level translations produced by the same language model, and also to those generated by an off-the-shelf commercial system (GTr). We release our dataset and error annotations to help facilitate the development of new evaluation methodologies and automatic metrics for document-level machine translation. Finally, a full-length novel extends far beyond the confines of paragraph-level translation. In future work, we will focus on integrating individual paragraphs into cohesive chapters, which can then be expanded to encompass the entire novel.

8 Limitations

So far, we have shown that GPT-3.5 leverages paragraph-level context to produce translations that

are better than those produced by sentence-level counterparts (SENT vs PARA). However, there are still many issues with PARA's translations. From the annotations and translators' comments, we observe that PARA suffers from occasional omissions of content from the source paragraph to a greater extent than SENT and GTR (see §D). Moreover, PARA still makes a sizeable number of mistranslations and grammatical errors, though fewer than SENT or GTR. These issues seem to be only partially mitigated by employing GPT-4 (see §F). Finally, it is important to acknowledge that the languages covered in the current study are either mid or high-resource. Performance might be much worse when translating from or into a low-resource language such as Zulu or Armenian.[27]

Ethical considerations

Translating with LLMs: The rise of large language models has also brought many ethical concerns to the forefront of NLP research (Blodgett et al., 2020; Bender et al., 2021). LLMs encode biases and exhibit toxicity, and these behaviors can be exacerbated by unconstrained prompting (Gehman et al., 2020; Costa-jussà et al., 2022). Further ethical concerns arise in the context of machine translation, particularly *literary* translation, where multiple stakeholders – the author, the translator, and the audience – are involved (Taivalkoski-Shilov, 2019a). Low-quality output can influence the perception of the author's work, impair the reader's linguistic abilities, and hinder the transfer of ideas to the target language, while overrelying on machine translation can possibly threaten the role of human translators (Drugan, 2013; Ning and Domínguez, 2016; Taivalkoski-Shilov, 2019a). On the other hand, machine translation employed *responsibly* as an auxiliary tool holds the potential to alleviate the translator's cognitive burden (O'Brien, 2012) and make the author's work accessible to a broader audience more swiftly (Besacier, 2014). Contrary to the predictions in Eloundou et al. (2023), we do not view large language models as a substitute for human translators, but rather as a means to assist translators in their work.

Human Evaluation: The experiments involving human translators were reviewed by the IRB, and all involved translators gave their written consent to disclose their annotations, comments, and preference choices. In recognizing contributions, our acknowledgments only include the names of those translators who explicitly gave their consent to be acknowledged by their full name in this publication.

Data Copyrights: We use and make public only about 2% of the text from each of the original novels. This number was determined after consulting domain experts at the HathiTrust (https://www.hathitrust.org/) and qualifies as fair use (up to 10% of a text can generally be considered fair use).

[27] For instance, our initial experiments with translations into low-resource languages show that GPT-3.5 (ChatGPT) suffers from repetition when translating into Hausa.

Acknowledgements

First and foremost, we would like to express our gratitude to the translators hired mostly on Upwork: Malgorzata Szymczak (*fr-pl*), Kinga Przekota (*ru-pl*), Michal Sikora (*cs-pl*), Paula Kurzawska (*de-pl*, *de-en*, *pl-en*), Kristy Darling Finder (*fr-en*), Timothy Shostak (*ja-en*), Shun Enoki (*zh-ja*), Takanori Kurokawa (*fr-ja*), Yoshiko Kikawa (*en-ja*), Shinnosuke Kasahara (*ru-ja*), and all those who wish to remain anonymous. We encourage any machine translation researchers working on these language pairs to contact these translators for human evaluations.

We would also like to show our appreciation to Jan Wislicki, Tom Gally, Nader Akoury, Kalpesh Krishna, Simeng Sun, Katherine Thai, and the entire UMass NLP group for insightful discussion, which helped to shape this project.

Furthermore, we would like to express our gratitude to the reviewers for their constructive feedback and valuable suggestions.

Finally, we would like to thank Sergiusz Rzepkowski (*pl*), Paula Kurzawska (*pl, en*), Hiroshi Iida (*ja*), Grégory Fleurot (*fr*), Peyton Bowman (*en*), Simeng Sun (*zh*), Igor Zapala (*pl, de*), Marvin Hoffmann (*de*), Kinga Przekota (*pl, ru*), and Yuki Mori (*ja*) for further consultations on their respective native languages.

This project was partially supported by awards IIS-1955567 and IIS-2046248 from the National Science Foundation (NSF) as well as an award from Open Philanthropy.

Appendix

A Background

In this section of the appendix, we survey the existing approaches to document-level machine translation, which do not involve prompting LLMs.

Existing approaches to document-level translation: Before the rise of neural machine translation, several attempts were made to incorporate discourse-level phenomena into statistical machine translation systems (Hardmeier, 2012; Carpuat and Simard, 2012; Hardmeier et al., 2013; Ding et al., 2014). Neural MT systems condition sentence-by-sentence translation on discourse-level context via concatenation models (Tiedemann and Scherrer, 2017; Jean et al., 2017; Agrawal et al., 2018; Junczys-Dowmunt, 2019; Lopes et al., 2020), hierarchical models (Miculicich et al., 2018; Tan et al., 2019; Chen et al., 2020; Zheng et al., 2020), multi-pass models (Mansimov et al., 2021), dynamic context models (Kang et al., 2020), multi-source models (Zhang et al., 2018; Feng et al., 2022), and transfer learning approaches (Zhang et al., 2022). Despite sometimes obtaining clear gains from discourse-level context (Voita et al., 2019), the machine translation community has not made much progress on this problem, particularly for non-English language pairs, due largely to the scarcity of parallel document-level corpora (Zhang et al., 2022). This problem has been partially addressed by introducing a pivot language (Cohn and Lapata, 2007; Utiyama and Isahara, 2007), but this approach can also lead to substantial information loss.

B Dataset

In this section of the appendix, we first discuss the rationale for the source and target language selection. Then we provide more details on the selection of the paragraphs. Finally, we provide details about the number of tokens and sentences in the source text and different translations.

Target language selection: We select English, Japanese, and Polish as the target languages of our study, as these languages differ considerably in many linguistic aspects. English is an analytic language that is widely spoken and extensively studied in the field of natural language processing, and it serves as the primary pretraining language of most large language models, including GPT-3.5.[28] In contrast, both Japanese and Polish are comparatively under-explored. Japanese is an agglutinative language that employs three distinct writing systems: Kanji, Hiragana, and Katakana. As a high-context language, the translation of Japanese texts necessitates a profound comprehension of context and cultural nuances, rendering it a compelling choice for testing the limits of LLMs' translation capabilities. Polish, on the other hand, is a fusional language characterized by a rich morphological system. Its complex word forms, grammatical gender, conjugation, and declension make it an apt choice for testing the accuracy and robustness of LLMs.[29]

Source language selection: As source languages, we select English (*es*), Polish (*pl*), Russian (*ru*), Czech (*cs*), French (*fr*), German (*de*), Japanese (*ja*), and Chinese (*zh*). These languages belong to a diverse array of language families – Indo-European (Romance, Germanic, Slavic), Sino-Tibetan, and Japonic – each with distinctive morphological traits – fusional, agglutinative, and analytic. Moreover, they employ a variety of writing systems such as the Latin alphabet, the Cyrillic alphabet, Hanzi, and Kanji/Hiragana/Katakana (see Table 4 for details). Finally, we carefully select source-target language pairs to ensure that our study encompasses both linguistically similar and dissimilar languages. For example, we paired *cs-pl*, as these languages are characterized by only 10% lexical distance[30] and have similar syntactic structures (Jágrová and Avgustinova, 2023). Conversely, we also include *ja-pl*, as the two languages have very little lexical overlap, vastly different grammars, and utilize distinct writing systems.

Choosing paragraphs: The selection of a particular paragraph was semi-random, with certain considerations in mind during the sampling process. We prioritized the following criteria: (1) for each

[28] As of 2020, the reported distribution of languages featured in the present study within the GPT-3 training data was as follows: English – 92.647% (1st), French – 1.818% (2nd), German – 1.469% (3rd), Russian – 0.188% (9th), Polish – 0.155% (11th), Japanese – 0.111% (15th), Chinese – 0.099% (17th), Czech – 0.071% (18th) (see https://github.com/openai/gpt-3/blob/master/dataset_statistics/languages_by_word_count.csv). The current GPT-3.5 `text-davinci-003` model is reported to incorporate data up to June 2021 and it is unclear what texts or languages were added to the original training data https://platform.openai.com/docs/models/gpt-3-5.

[29] The first author is fluent in all three target languages.

[30] i.e., the percentage of non-cognates in the language pair.

source language we sample paragraphs so that there is a combination of dialogue and narrative texts; (2) the paragraph should be reasonably intelligible to a human translator without additional context; and (3) alignment between the source paragraph and human translation should be feasible, meaning no major content rearrangement *across* paragraphs.

Nonetheless, meeting all these requirements was not always possible. For instance, the source text of *Convenience Store Woman* (*ja*) is mostly written in the first-person narrative. Since Japanese does not encode the speaker's gender in the verb forms, it is often impossible to determine whether the narrator is a male or a female. In cases where it was impossible to determine the gender of the character we instructed translators to accept *either* option, provided that the translation remained consistent within the given paragraph (i.e., the gender did not change within the paragraph).

Dataset statistics: The dataset used for this study contains 360 source paragraphs with their corresponding human translations.[31] We further report the following statistics: (1) the number of sentences in the source text, as per manual sentence tokenization, along with the number of tokens in the sources and text and each translation (Table 5), (2) the number of sentences in the source text, human translation, and each machine translation as tokenized with SpaCy (Table 6), and (3) the distribution of sentences in paragraphs (Figure 7).

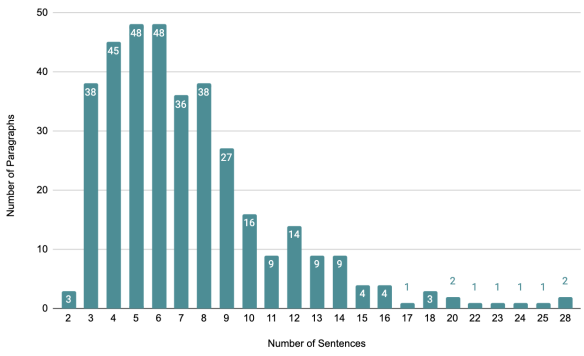

Figure 7: Distribution of sentences in the sampled paragraphs. The paragraphs were sentencized manually.

C Prompting for Translation

D Human Evaluation

In this section, we provide some further details about the human evaluation with a focus on the error annotation. First, discuss the issue of subjectivity in error annotation. Next, we explain some choices we had to make when annotating "inconsistency" and "format" errors. Finally, we present some details about the translators hired for the evaluation task.

Error annotation: Annotating and classifying errors in translations is inherently subjective (Lommel et al., 2014a; Han, 2020). For instance, translating French "corsage" ("bodice") as a "blouse" can be seen as either a mistranslation or a permissible deviation from the original text; this is, in fact, how the "corsage" was translated by the human translator in our data.

Furthermore, sometimes there are multiple ways of annotating errors (Thomson et al., 2023). Consider the following example:

> (1) We had to hide the running, though, in case our haste betrayed us, so truer to say we slipped out quietly. When one of my parents appeared, my technique was: pretend to catch sight of someone in the next room. **Move in a natural manner toward this figment of my imagination, making a purposeful face.**
>
> —English Source (from *A Children's Bible*)

The translation of the last sentence in (1) into Polish as an imperative can be considered a mistranslation. We would hypothesis that the system misinterpreted the source as an imperative form. However, using the infinitive form of the verb in the translation is less clear and raises questions about whether it is a mistranslation or a grammatical error. The distinction between the two lies in the point at which the mistake was made. If the original sentence was understood correctly but the resulting translation was ungrammatical, then it is a grammatical error. On the other hand, if the use of the infinitive form resulted from interpreting "move" as an infinitive, it may be considered a mistranslation as well.

Inconsistency: For marking the "inconsistency" errors we decided to the take *minimal* approach. For instance, is the same person is referred to in the translation as both "Piotr" and "Peter" we would

[31] See Table 7 for the list of novels included in the dataset and Table 8 for examples of aligned paragraphs.

LANGUAGE	LANGUAGE FAMILY	MORPHOLOGICAL FEATURES	WRITING SYSTEM

Table 5: Number of sentences in the source text sentencized manually (#SENT) along with the number of tokens in the human reference (HUM) and different machine translations (PARA, SENT, PARA_SENT, GTR). All translations were tokenized using SPACY[32] with the large model for each of the three target languages (Polish, Japanese, and English). All source texts were tokenized with STANZA (Qi et al., 2020) as SPACY does not include models for all target languages.

Original text in Japanese:
「そういうのは実際には起こらないの？」

Translation into Polish:
– To się w rzeczywistości nie zdarza?

(...)

Original text in Japanese:
「いらっしゃいませ！」

Translation into Polish:

TOTAL	**2,580**	**2,785**	**2,764**	**2,782**	**2,740**	**2,742**

Table 6: Number of sentences in the source text and each translation. The data was sentencized with SPACY. As evident from the data and manual inspection of translations the translations may result in a very different number of sentences as a result of splits and merges. We observe that about 55% of the data potentially lacks one-to-one correspondence.

Original text in Czech:
V hospodě U kalicha seděl jen jeden host. Byl to civilní strážník Bretschneider, stojící ve službách státní policie. **<translate>**Hostinský Palivec myl tácky a Bretschneider se marně snažil navázat s ním vážný rozhovor.**</translate>**

Translation into Polish:
W gospodzie „Pod Kielichem" siedział tylko jeden gość. Był to wywiadowca Bretschneider, będący na służbie policji państwowej. **<translated>**Gospodarz Palivec zmywał podstawki, a Bretschneider daremnie usiłował wyciągnąć go na poważną rozmowę.**</translated>**

(...)

Original text in Czech:
„Je to fakt dobrý," řekl mi Frodo, když se na můj výkres koukal. **<translate>**A skoro to vypadalo, že je z toho obrázku překvapenej.**</translate>** Pak se ptal, jestli maluju i doma, tak jsem odpověděla, že jo. Nejradši bych mu řekla i to, že chci být malířkou, ale mamka pořád opakuje, že je to blbost, že člověk musí dělat něco pořádnýho, jako třeba ona dělá knihovnici v knihovně, tak jsem raději mlčela, aby si nemyslel, že mám blbý nápady. Chvíli na výkres ještě koukal a otáčel ho ze všech stran a pak šel dál a koukal na obrázek Lindy, která nakreslila takový docela pěkný jabko.

Translation into Polish:
– To jest naprawdę dobre – powiedział Frodo, patrząc na moją pracę. **<translated>**

Figure 9: An example of prompt for PARA_SENT translations with one demonstration and a text to translate.

mark only the one that is less frequent. If "Piotr" appears *once* in the paragraph, while "Peter" is used *twice*, "Piotr" would be annotated as being inconsistent. The same strategy was applied for "register" errors, such as when both polite and casual forms were acceptable, but the translation used them randomly.

Format: We did not label "format" errors for the SENT and PARA_SENT translations, as we manually corrected the quotation marks during post-processing of the translations. This manual correction was done to ensure that SENT and PARA_SENT could be compared to PARA without relying too heavily on simple heuristic (i.e., incorrect usage of the quotation marks).

Translators: The translators in this study were hired on a freelancing platform, Upwork. We interviewed all translators prior to the task to assure

Table 7: Details of the translated novels used in our study. In cases where the same novel is used for multiple target languages (e.g., "The Years"), identical source paragraphs are extracted to enable comparisons across language pairs. These novels exhibit distinct differences beyond just their source languages. For instance, "What Can You See From Here" presents a philosophical exploration of life and death, while "Sword of Destiny" is a fantasy story part of "The Witcher" saga.

Original text in Japanese:
直子は立ちどまった。僕も立ちどまった。彼女は両手を僕の肩にあてて正面から、僕の目をじっとのぞきこんだ。彼女の瞳の奥の方ではまっ黒な重い液体が不思議な図形の渦を描いていた。そんな一対の美しい瞳が長いあいだ僕の中をのぞきこんでいた。それから彼女は背のびをして僕の頬にそっと頬をつけた。それは一瞬胸がつまってしまうくらいあたたかくて素敵な仕草だった。

Translation into Polish:
Naoko zatrzymała się. Ja też stanąłem. Położyła mi ręce na ramionach i zajrzała uważnie w oczy. W jej ciemnych jak atrament źrenicach tworzyły się przedziwne wirujące wzory. Te piękne oczy długo badały moje serce. Potem wyprostowała się i przytuliła policzek do mojego. To był cudowny ciepły gest, aż mi serce na chwilę zamarło.

(...)

Original text in Japanese:
店長は30歳の男性で、常にきびきびとしている。口は悪いが働き者の、この店で８人目の店長だ。２人目の店長はサボり癖があり、４人目の店長は真面目で掃除好きで、６人目の店長は癖のある人で嫌われ、夕勤が全員一気に辞めるというトラブルになった。８人目の店長は比較的アルバイトからも好かれ、自分が体を動かして働くタイプなので、見ていて気持ちがいい。７人目の店長は気弱すぎて夜勤になかなか注意ができずに店がぼろぼろになってしまったので、少し口が悪くてもこれくらいのほうが働きやすいと、８人目の店長を見ると思う。

Translation into Polish:

Figure 10: An example of prompt for PARA translations with one demonstration and a text to translate.

that they were qualified to evaluate the translations. All translators were highly proficient in the source language and most of them were native speakers of the target language with some being bilingual.[33] Only one translator reported familiarity with the book, which translation she evaluated. All translators were instructed to evaluate each paragraph in isolation without relying on any prior knowledge about the book and to allow for *all* possible interpretations based on the given part of the source text. They were asked to evaluate five translations first and received feedback on their work before moving forward. Details about the translators are reported

[33]We consider a translator bilingual only if they were raised using both languages; i.e. both can be consider their *native* languages (e.g., *ru-pl* translator was raised in Poland while speaking Russian at home). In the broader sense of this word, all of the translators are bilingual with some of them being trilingual. For the cases where the hired translator was *not* a native speaker of the target language, the annotations were verified by a native speaker of the target language in consultation with the translator.

Book	Lang Pair	Source	Target
An Inventory of Losses	de-ja	Natürlich hatte ich schon davor andere bemerkenswerte Begräbnisstätten besucht: die Toteninsel San Michele etwa, wie sie mit hohen, roten Backsteinmauern aus dem blaugrünen Wasser der Lagune von Venedig emporragt gleich einer uneinnehmbaren Festung, oder das grelle Jahrmarktstreiben des Hollywood Forever Cemetery am alljährlich von der mexikanischen Bevölkerung begangenen Día de los Muertos mit den orange-gelb geschmückten Gräbern und den von der fortgeschrittenen Verwesung auf ewig zum Grinsen verdammten Totenschädeln aus bunt gefärbtem Zucker und Pappmaché. Doch keine hat mich so berührt wie der Friedhof jener Fischersiedlung, in dessen eigentümlichem Grundriss — einer Art Kompromiss aus Kreis und Quadrat ich nichts anderes als ein Sinnbild der ungeheuerlichen Utopie zu erkennen glaubte, die ich dort verwirklicht sah: mit dem Tod vor Augen zu leben. Lange Zeit war ich überzeugt, an diesem Ort, dessen dänischer Name »kleine Insel« oder »vom Wasser umgeben« bedeutet, sei man dem Leben näher, gerade weil seine Bewohner die Toten wortwörtlich in ihre Mitte geholt hatten, anstatt sie wie sonst in unseren Breitengraden üblich — aus dem Innersten der Gemeinden vor die Stadttore zu verbannen, auch wenn der urbane Raum sich die Gräberstätten durch sein ungehemmtes Anwachsen oft nur wenig später wieder einverleibt hat.	もちろんそれ以前にもいくつか特筆すべき墓所を訪れたことはあった。たとえばヴェネツィアの干潟の青緑色の水中から、赤煉瓦の高い壁に囲まれて難攻不落の要塞のようにそびえたつ死者の島、サン・ミシェル。あるいはメキシコ系住民が毎年にぎやかに死者の日を祝う、ハリウッド・フォーエバー墓地。墓はオレンジと黄色の花で飾られ、カラフルな砂糖菓子や張り子細工の頭蓋骨は、腐敗が進んで永遠の笑顔を浮かべているようだ。けれども、この漁師町の墓地ほどに私の心を動かす墓所はなかった。まるで円と四角の間の妥協のようなその独特の輪郭に、私はまさにユートピアの象徴を見たように思った。死を目の前にしつつ生きるというユートピアが、そこに実現されていた。長いこと私は確信していた。デンマーク語で「小さな島」とか「水に囲まれた」という意味の名前を持つこの場所に住む人々は、同じくらいの緯度の国々で通常行われているように、共同体の内部から市門の外へと死者たちを追放する代わりに、死者たちを文字通り町の中心に迎え入れた。だからこそ、より生に近いのだと。もっとも都市空間もまた人口膨張のために、ほとなくして墓地をふたたび内部へと取り込まざるを得なくなるのだけれど。
A Children's Bible	en-pl	The lady urinated. "Oh, poor old thing, she has a nervous bladder!" exclaimed someone's chubby mother. "Is that a Persian rug?" Whose mother was it? Unclear. No one would cop to it, of course. We canceled the performance. "Admit it, that was your mother," said a kid named Rafe to a kid named Sukey, when the parents had filed out. Some of their goblets, highball glasses, and beer bottles were completely empty. Drained. Those parents were in a hurry, then. "No way," said Sukey firmly, and shook her head. "Then who is your mother? The one with the big ass? Or the one with the clubfoot?" "Neither," said Sukey. "So fuck you."	Dama się posikała. – Och, biedactwo, ma wrażliwy pęcherz! – wykrzyknęła czyjaś pulchna matka. – Zaraz, to perski dywan? Czyją matką była? Nie wiadomo. Oczywiście nikt nie chciał się przyznać. Odwołaliśmy przedstawienie. – No dawaj, to twoja – powiedział chłopiec imieniem Rafe do dziewczynki imieniem Sukey, kiedy rodzice sobie poszli. Zostawili po sobie kieliszki, wysokie szklanki i butelki po piwie. Niektóre były zupełnie puste. Do ostatniej kropelki. Tym z rodziców się zatem spieszyło. – W życiu – odparła Sukey stanowczo i pokręciła głową. – To która? Ta z wielkim dupskiem? Czy ze szpotawą stopą? – Ani jedna, ani druga. Spierdalaj.

Table 8: Examples of aligned reference source and target paragraphs from our dataset, including both a narrative (*An Inventory of Losses*) and a dialogue (*A Children's Biblie*). Our PARA approach takes as input the entire source paragraph and outputs a paragraph-level translation.

in Table 10.[34]

E Results

In this section of the appendix, we provide more detailed analysis of the results of the human evaluation. We start with providing more details about the GTR vs PARA evaluation. Next, we include an in-depth discussion of the context-related errors in SENT which were corrected in the PARA translations. Finally, we include some comments from the translators. In the next section (§F), we also provide more information about the issues still present in the PARA translations along with the preliminary analysis of paragraph-level translation by GPT-4.

E.1 PARA is clearly better than GTR

PARA translations are overwhelmingly preferred over those from Google Translate (GTR), with an 82.8% preference rate (p<.001, 95% CI [0.765, 0.880]). Even after removing the "unsure" votes, the preference for PARA remains significant at 88.0% (p<.001, 95% CI [0.812, 0.930]). In the *fr-ja*, *pl-ja*, *zh-ja*, and *cs-pl* language pairs, PARA received *all* of the ten votes over GTR. Part of this advantage may be attributed to GTR sometimes using English as a pivot language, which can result in information loss. Our Czech translator observed that mistakes in GTR translations suggest the text was first translated into English.[35]

[34]Three language pairs (*pl-ja*, *en-pl*, *ja-pl*) were annotated by the first author of this paper.

[35]For the *cs-pl* language pair, we separately annotated mistranslations arising from pivot translation. These errors accounted for over 50% of all mistranslations in that language pair. The elimination of the need for parallel data may therefore be beneficial for translating between lower-resource

Overall, GTR translations result in 57.7% more mistranslations, 37.3% more grammatical errors, over twice as many inconsistency errors, and ten times more register errors (see Table 2). Additionally, GTR produced 125 format errors while PARA produced perfect outputs in this regard. Finally, it is worth noting that GTR left fewer words untranslated, though this is inflated by the fact that in one German text, the word "Bauer" ("farmer") was untranslated 14 times in the PARA translation.

E.2 Context-related errors

Here we present examples of context-related issues present in SENT while correctly translated by PARA.[36]

Pronouns: Unsurprisingly, the absence of discourse context results in the incorrect translation of pronouns. Consider the following example, with English glosses of important words provided in [brackets]:

(2) И ветер [*wind*] то начинал шуметь в голых деревьях, то замолкал, так же как и я прислушиваясь к течению ночи. Но он [*he*] не уходил, он [*he*] был здесь.
—RUSSIAN SOURCE (from *The Story of a Life*)

a. The wind would start to rustle in the bare trees and then fall silent, just as I listened to the flow of the night. But he didn't leave, he was here.
—GPT-3.5 SENT (ENGLISH)

b. The wind would start to rustle in the bare trees, then die down, just like me, listening to the flow of the night. But it didn't go away, it was still here.
—GPT-3.5 PARA (ENGLISH)

In Russian, nouns have grammatical gender. "Wind" in the first sentence of the source text is a masculine noun, so it is later referred to as "he" in (2). Without access to the context, the SENT model incorrectly translates it as "he" into English (2a), while the PARA translation correctly modifies the pronoun to "it" (2b).

When translating from Russian into Polish, another language with grammatical gender, we observe issues when the gender of Russian and Polish nouns differs. Consider the following example:

(3) Романы, как известно, печатались на разной бумаге [*paper*]. И гореть она [*she*] может поразному.
—RUSSIAN SOURCE (from *Manaraga*)

a. Romany, jak wiadomo, drukowano na różnym papierze [*paper*]. I może ona [*she*] tęsknić na różne sposoby.
—GPT-3.5 SENT (POLISH)

b. Jak wiadomo, powieści drukowano na różnym papierze [*paper*]. I może on [*he*] palić się na różne sposoby.
—GPT-3.5 PARA (POLISH)

Although both Russian and Polish nouns possess grammatical gender, "Paper" in (3) is feminine in Russian and referred to as "she," whereas it is a masculine noun in Polish and should be referred to as "he," as in (3b). The absence of context in SENT leads to an incorrect translation in (3a).

Cultural nuances: Assigning appropriate pronouns without context becomes even more challenging when translating from languages like Japanese, in which speakers frequently refer to the listener (or themselves) in the third person rather than using second-person personal pronouns such as "you" in English. Consider the following example:

(4) 「気が付かなくてすみません」
「いやいや、(...)。古倉さんは毎日勤務なのに手を抜かないからねー！」
[lit. *Ms./Mrs./Mr. Furukura works every day*]
—JAPANESE SOURCE (from *Convenience Store Woman*)

a. "I'm sorry I didn't notice."
"No, no, (...). Furukura-san works hard every day without taking any shortcuts!"
—GPT-3.5 SENT (ENGLISH)

b. "I'm sorry I didn't notice."
"No, no, (...). You work every day, but you never slack off!"
—GPT-3.5 PARA (ENGLISH)

From the context of this conversation, a Japanese listener can easily infer that "Furukura-san" or "Miss Furukura"[37] in the last source sentence (4) is used instead of the second-person "you" as per Japanese convention. Translating this sentence without context into English, a language in which third-person reference is not common,[38] results in a confusing translation (4a) that implies that the speaker refers to some other "Furukura" rather than their listener. However, when translating the sentence in context, the model correctly changes "Furukura" into "you" (4b), which makes it clear whom the speaker refers to in English.

languages where sufficient parallel data is often unavailable necessitating the pivot translation.

[36]Note that PARA also suffers from context-related issues. However, at a much lesser extent than SENT.

[37]Note that the gender of neither character is apparent from the fragment alone.

[38]While third-person reference can be used in English, it is only used in rare circumstances e.g. when addressing children.

Language Pair	Sent	Para	Para_Sent	Para	GTr	Para

Table 11: The number of votes for Sent vs Para, Para_Sent vs Para, and GTr vs Para in human evaluation by the language pair. The winning counts are highlighted in purple.

Ellipsis: Another example where context helps is the translation of elliptical constructions. Consider the following example:

(5) „Ne, ted' uděláš nádobí!“ [*(you) will do the dishes!*]
„Neudělám!“ [*(I) won't do!*]
„Uděláš!“ [*(You) will do!*]
—Czech Source (from *Crows*)

a. — Nie, teraz zrobisz zmywanie! [*(you) will do the washing*]
— Nie zrobię! [*(I) won't do!*]
— Zrobisz to! [*(You) will do it!*]
—GPT-3.5 Sent (Polish)

b. — Nie, teraz umyjesz naczynia [*(You) will wash the dishes*]!
— Nie umyję [*(I) won't wash*]!
— Umyjesz [*(You) will wash*]!
—GPT-3.5 Para (Polish)

Czech uses the same collocation as English, "*do* the dishes" (5), which is invalid in Polish. Hence, the ellipses in the last two sentences in (5) require broader context to be translated correctly. Para does it properly, translating both as "wash" (5b), while Sent unsurprisingly fails to choose the correct collocation (5a).

Subject ellipsis: Similarly, context may be needed to attribute a state or an action to the correct character due to the subject ellipsis. This is an obvious issue for languages like Japanese, which tend to omit the subject of the sentence and do not encode any relevant information in the verb form, but it can also arise in English. Consider the following example:

(6) When we were done, the lipstick went back into some mother's Fendi handbag. We watched her apply it, unaware.
—English Source (from *A Children's Bible*)

a. Gdy skończyliśmy, szminka wróciła do jakiejś torebki Fendi należącej do matki. Patrzyliśmy, jak to robi, nieświadomi [*unaware (we)*] tego.
—GPT-3.5 Sent (Polish)

b. Kiedy skończyliśmy, szminka wróciła do torebki Fendi jakiejś matki. Patrzyliśmy, jak ją nakłada, nieświadoma [*unaware (she)*] naszych działań.
—GPT-3.5 Para (Polish)

From the second sentence alone it is not clear who is "unaware" (6) – the mother or the "we" (referring to children) watching her. Only from the

broader context can we confidently deduce that it is in fact the mother, not the children, who is "unaware." PARA (6b) correctly attributes the state of being "unaware" to the mother, which is exhibited by its usage of the singular feminine form of the adjective. In contrast, SENT (6a) mistranslates it using the plural masculine form of the adjective "unaware," which implies that it refers to "we" rather than the "mother."

Consistency: Context is sometimes critical for preserving the overall consistency of the text. The simplest cases include referring to the same entity – a place or a person – in the same way. More interesting cases pertain to style and can enhance the reader's experience. Consider the following example:

(7) Alles zu vergessen, ist gewiss schlimm [*bad*]. Noch schlimmer [*worse*] ist, nichts zu vergessen (...).
—GERMAN SOURCE (from *An Inventory of Losses*)

a. すべてを忘れることは確かに悲惨な[*tragic*]ことです。さらに悪い[*worse*]のは、何も忘れないことです。
—GPT-3.5 SENT (JAPANESE)

b. すべてを忘れることは確かに悪い[*bad*]ことです。もっと悪い[*worse*]ことは、何も忘れないことです。
—GPT-3.5 PARA (JAPANESE)

The German source in (7) translates into English as "To forget everything is *bad*, certainly. *Worse* still is to forget nothing."[39] It is arguably important for the translation to repeat the same word which is an equivalent of the German "schlimm" ("bad"). PARA does it well, translating both as 悪い "warui," or "bad" (7b), in the exact same way as the human Japanese translator. SENT, on the other hand, uses two different words, "tragic" and "bad" (7a), which while technically correct omits the intentional repetition that is meant to introduce an unexpected conclusion.

Polysemy: The absence of context makes it difficult to interpret words or expressions that have multiple meanings in the source language. Consider the following example:

(8) Все прошло хорошо. Книга прочитана идеально – не быстро и не медленно, минимум дыма. Классика. Я был в форме [*in shape*].
—RUSSIAN SOURCE (from *Maranaga*)

a. Wszystko poszło dobrze. Książka została przeczytana idealnie – nie szybko i nie wolno, minimalna ilość dymu. Klasyka. Byłem w mundurze [*in uniform*].
—GPT-3.5 SENT (POLISH)

b. Wszystko poszło dobrze. Książka przeczytana idealnie – nie szybko i nie wolno, minimalna ilość dymu. Klasyka. Byłem w formie [*in shape*].
—GPT-3.5 PARA (POLISH)

The ambiguity stems here from multiple meanings of the Russian noun форма "forma" (8), which can mean either "shape" or "uniform." Since one can be "in shape" as well as "in a uniform", it is unclear from the sentence alone which meaning was intended by the author. From the preceding context, it is clear that "everything went well" for the narrator, who mastered the art of "book'n'grill," a unique form of expression exclusive to this fictional world. Based on this, we can infer that in this instance, the term "forma" signifies "shape," as in (8b), rather than "uniform," as in (8a).

Appropriateness: Finally, context may help to choose the more appropriate equivalent for the given situation. Consider the following example:

(9) 「あー、あと煙草の５番を一つ」
「かしこまりました」 [lit. *(I) understood*]
—JAPANESE SOURCE (from *Convenience Store Woman*)

a. "Ah, and one pack of cigarettes, number five."
"Understood."
—GPT-3.5 SENT (ENGLISH)

b. "Ah, and one pack of cigarettes, number five."
"Right away."
—GPT-3.5 PARA (ENGLISH)

The conversation above is between a clerk and a customer. The Japanese expression かしこまりました "kashikomarimashita" (9) is an honorific that literally means "understood." However, when choosing the best equivalent, the translator needs to consider the situation at hand to best reflect its meaning in the target language. "Understood" in SENT (9a) is technically correct, but it is an unfortunate word choice for the clerk to employ. On the other hand, "right away" in PARA (9b) fits much better in the context of this conversation. Had this been a series of commands (e.g., in a military context) "understood" would be the more favorable option.

E.3 What do translators think about PARA?

To wrap up this section, we provide a qualitative analysis of the free-form comments written by translators to justify their preference judgments. Overall, the translators praise PARA for its *more skillful use of rhetoric devices*, and *surpas[ing]*

[39] Excerpt taken from the official English translation by Jakie Smith (2020).

SENT *as a literary rendition*. They also mention that PARA *uses more of a poetic license but this makes it stylistically much smoother* than SENT. Furthermore, translators state that PARA *clearly better reflects the content and style of the original* when compared to GTR, and that it *stays consistent within the paragraph*. Inevitably, translations are not flawless, and there are instances where both compared systems fall short, as highlighted by one of the translators when assessing PARA against SENT: *Nightmare, a mistake upon mistake (...) Despite all these mistakes, I can understand the* [PARA] *translation better but they are equally miserable.*

F Limitations

In this section of the appendix, we delve deeper into the unresolved issues in the PARA translations. First, we discuss the omissions present in the translations. Next, we highlight some mistranslations that persist in the PARA translations. To conclude, we briefly discuss our initial experiments utilizing GPT-4 for paragraph-level translation.

Omissions: One thing we ought to discuss is the omission issue. Upon examining translations and annotator feedback, we observe that PARA occasionally omits details, which are crucial to the storyline. Preliminary investigation indicates that PARA translations are more prone to omissions compared to SENT and GTR. Although PARA_SENT appears to mitigate this problem to some extent, it still results in a higher number of omissions than the sentence-level approach while at the same time introducing some repetition issues (see Table 12).[40]

Mistranslations: Moreover, PARA still makes a sizeable number of mistranslations and grammatical errors, though fewer than SENT or GTR. We observe that PARA occasionally merges sentences with two distinctive subjects attributing all states and/or actions to one of them. Very rarely, we also find cases where context possibly confuses the model, resulting in an incorrect translation. The following example illustrates this issue:

(10) Le bois du bureau amplifie les battements de mon cœur. Le vieux mobilier Art déco conduit bien les émotions et les fatigues. Ruhlman ? Leleu ? Il [*he*] en a tant vu.

—FRENCH SOURCE (from *Dear Reader*)

a. 机の木材が私の心臓の鼓動を増幅している。古いアール・デコ家具は感情や疲労をうまく導いてくれる。ルールマン？レルー？彼ら [*they*] はそんなに多くを見てきた。

—GPT-3.5 PARA (JAPANESE)

In the French text, the narrator wonders whether the brand of the desk was Ruhlman or Leleu, with both proper nouns possibly referring to a person. In the last sentence, the French text uses "il" or "he" (10), as a desk is a masculine noun in French ("le bureau"). PARA, on the other hand, appears to be confused by the two preceding names and incorrectly translates the singular pronoun as 彼ら, or "they."

Furthermore, we observe (very few) cases where the paragraph-level translation disregards the context. Most representative of this class of errors is when the model struggles to translate from Japanese in cases where the subject is omitted. The following example illustrates this issue:

(11) ミホ [*Miho*] は、今では結婚して地元に中古の一戸建てを買っていて、そこに友達がよく集まっている。明日もアルバイトなので億劫に思う時もあるが、コンビニ以外の世界との唯一の接点であり、同い年の「普通の三十代女性」と交流する貴重な機会なので、ミホの [*Miho's*] 誘いにはなるべく応じるようにしている。

—JAPANESE SOURCE (from *Convenience Store Woman*)

a. Miho [*Miho*] wyszła za mąż i kupiła stary, jednorodzinny dom w swoim rodzinnym mieście. Przychodzą tam często jej znajomi. Mimo że Miho ma [*Miho has*] jutro pracę w konbini, zazwyczaj chętnie odpowiada [*(she) responds*] na jej [*her*] zaproszenia, bo to jedyna okazja, by spotkać się z innymi kobietami w jej [*her*] wieku.

—GPT-3.5 PARA (POLISH)

b. Miho is now married and has bought an old house in her hometown, where her friends often gather. Though she often finds it a chore to work tomorrow, it is her only connection to the world outside the convenience store, and a valuable opportunity to interact with other "normal thirty-something women" her age, so she tries to accept Miho's invitations as often as possible.

—GPT-3.5 PARA (ENGLISH)

Both Polish (11a) and English (11b) translations of the same source text (11) share a common issue. The narrator begins the paragraph by talking about Miho and then proceeds to describe her

[40] Note that although ask the annotators to report both omissions *and* additions, based on their comments and our analysis of the translations, we conclude that omissions are the predominant issue. In version two of our data (currently on https://github.com/marzenakrp/LiteraryTranslation), we further annotate any repetition as a separate type of error (i.e. error with 'repetition' label) rather than counting it as an addition. This annotations resulted in eight repetition errors in PARA_SENT translations.

Language Pair	PARA	SENT	PARA_SENT	GTR
Russian-English	0	0	1	0
Chinese-English	1	0	1	0
Polish-English	0	0	0	0
French-English	1	0	2	0
Japanese-English	2	1	2	3
German-English	0	0	0	0
German-Japanese	8	2	6	8
Russian-Japanese	10	4	6	4
French-Japanese	3	1	4	4
Polish-Japanese	4	1	3	0
English-Japanese	2	2	1	0
Chinese-Japanese	2	0	0	1
English-Polish	0	1	2	0

Russian-Polish	1	1	1	0
German-Polish	0	0	0	0
Total	**37**	17	32	22

Table 12: Count of omissions reported by the translators for each translation method.

own (the narrator's) feelings about the situation, although the gender of the narrator is never revealed in the Japanese text. The second sentence should be written from a first-person perspective, particularly since it directly references Miho towards the end (blue text). However, both the Polish and English translations produced by PARA are confused by this: by using the third-person's perspective ("she," "her"), both translations incorrectly imply that Miho is the subject of the second sentence. SENT and GTR translate this passage accurately, albeit with some clumsy phrasing.

GPT-4 does not magically solve all of these issues! Our preliminary experiments indicate that GPT-4 (OpenAI, 2023) sometimes generates better paragraph-level translations than those of GPT-3.5. For instance, it seems to have a better grasp of the inverted word order in German, though no broader conclusions should be made without further testing. Nevertheless, it does not resolve all of the issues discussed in our paper. Mistranslations and grammatical errors are still abundant across many language pairs. GPT-4 produces the following translation when fed the previous example paragraph (11) as input; note that all of the issues still remain:[41]

(12) Miho is now married and has bought a used single-family home in her hometown where her friends often gather. Although she sometimes finds it a drag to work a part-time job the next day, she makes an effort to respond to Miho's invitations because it's a valuable opportunity to interact with "normal" women in their thirties like herself, apart from her convenience store job.

—GPT-4 PARA (ENGLISH)

PARA translations hold the potential to captivate readers, especially if LLMs continue to improve at their current pace. Indeed, some of our translators mentioned that they genuinely enjoyed the task, though integrating these paragraphs into a coherent novel still poses a considerable challenge. With all that said, literary translation involves more than just overall "correctness" or mere entertainment value. A translation that is perfectly "correct" and enjoyable might still fail to convey the author's intentions or meaning skillfully hidden behind a simple phrase. Our *fr-en* translator shares her thoughts on this matter:

[41] Although the given paragraph is already comprehensible for a human reader, we also attempt to enhance the translation by incorporating three additional preceding paragraphs for context. Intriguingly, when provided with this extended context, both GPT-3.5 and GPT-4 generated accurate translations.

System	Comet	Bleurt	BertScore	Comet-QE
Para	**0.785**	**0.485**	**0.840**	**0.038**
Sent	0.779	0.469	0.839	-0.052
Para_Sent	0.780	0.480	0.838	-0.062
GTr	0.735	0.443	0.832	-0.156

Table 13: Results of automatic evaluation. A higher number indicates better scores.

Metric	Acc	τ	Acc (*conf*)	τ (*conf*)
Comet	67.41%	0.348	72.78%	0.456
Comet-QE	64.44%	0.289	70.64%	0.413
Bleurt	61.30%	0.226	66.36%	0.327
BARTScore	58.52%	0.170	63.91%	0.278

Table 14: Correlation of automatic metrics with human judgments from our human evaluation. We evaluate the metrics performance on *all* human judgments as well as on the *subset* of judgments where the translator indicated that the chosen translation was visibly better (*conf*). We report both the percentage of agreement (Acc) and Kendall's Tau (τ). Data reported on v1 of the dataset.

> *Both translations* [Sent and Para] *translate the words without the feeling; the original author's voice is lost.*
>
> —French to English Translator

G Automatic Evaluation

In this section of the appendix, we present the results of automatic evaluation. First, we discuss the scores assigned to the translations by automatic metrics.[42] Then we provide the statistical analysis. Finally, we present the correlation of each metric with human judgments for the 180 paragraphs used in the human evaluation.

Automatic metrics favor Para: We assess the translation from all four systems using the reference-based Comet (Rei et al., 2022), Bleurt (Sellam et al., 2020), and BertScore (Zhang et al., 2020) metrics, as well as the reference-free Comet-QE (Rei et al., 2021)[43] metric. Although these metrics were not explicitly designed for evaluating paragraph-level outputs and their results should be interpreted with caution, they prove more reliable than string-based metrics like Bleu, especially for literary translations (Thai et al., 2022; Karpinska et al., 2022; Gehrmann et al., 2022). Table 13 shows the effectiveness of the Para translation method: a statistical analysis with linear mixed-effects models (Baayen et al., 2008) demonstrates that Para significantly outperforms Sent and GTr based on Comet, Bleurt, and Comet-QE scores (p<.001), and surpasses GTr based on the BertScore results (p<.001). We discuss the details of this statistical analysis in the next section.

Statistical Analysis: We employ the linear-mixed effect models (Baayen et al., 2008) to analyze the scores produced by automatic metrics. We fitted the model in `R` using the `lme4` package (Bates et al., 2015); the p-values were obtained with the `LmerTest` package (Kuznetsova et al., 2017). Linear-mixed effects models contain both *fixed-effects* and *random-effects* (random *intercept* and/or *slope*). The fixed effect here is the translation setup (Para, Sent, Para_Sent, GTr) with the source paragraph being coded as the random effect (random intercept). We inspect the residual plots to ensure that the variance across the fitted range is relatively constant. The results from the fitted model are presented in Table 18 (Bleurt), Table 20 (Comet), Table 22 (Comet-QE), and Table 24 (BertScore).[44]

We further perform a post hoc analysis using the `emmeans` package (Lenth, 2023) to obtain p-values for the pairwise comparison. The results of the post hoc analysis are presented in Table 19 (Bleurt), Table 21 (Comet), Table 23 (Comet-QE), and Table 25 (BertScore).

Correlation with Human Judgements: We investigate the correlation of automatic metrics with human judgments in our evaluation. We consider (1) all the judgments, as well as (2) a subset of all judgments where the annotator stated that they were sure that one translation is *clearly* better than the other. We compute both *accuracy* (i.e., the percentage of cases where the metric agrees with human judgment), and a correlation coefficient Kendall's Tau which is defined as follows:

$$\tau = \frac{\text{Concordant} - \text{Discordant}}{\text{Concordant} + \text{Discordant}}$$

[42] This analysis is done on the entire dataset excluding only the paragraphs which were too long as per each metric's token limit.

[43] We use the newest `wmt22-comet-da` checkpoints for Comet, `Bleurt-20` checkpoints for Bleurt, `wmt20-comet-qe-da` checkpoints for Comet-QE, and the HuggingFace implementation which employs `roberta-large` for BertScore.

[44] It should be noted that, while significant, the analysis is underpowered. It is possible that analyzing more examples would provide a more reliable analysis.

SOURCE	TARGET	PARA	PARA_PIVOT
Czech	*Polish*	11	9
German	*Japanese*	13	7
German	*Polish*	12	8
French	*Japanese*	9	11
French	*Polish*	11	9
Japanese	*Polish*	10	10
Polish	*Japanese*	3	17
Russian	*Japanese*	10	10
Russian	*Polish*	8	12
Chinese	*Japanese*	9	11
	TOTAL	*96*	*104*

Table 15: The results of pairwise comparison for the paragraph-level translations with (PARA_PIVOT) and without (PARA) English as a pivot language.

Table 14 shows the correlation of automatic metrics with the human judgments obtained in this study. COMET exhibits the highest agreement with human judgments both in terms of the *accuracy* (64.04% for all data, 72.78% for confident votes only) and Kendall's Tau (0.341 for all data, 0.456 for confident votes only).

H Pivot Pilot

In this section of the appendix, we discuss the results of the preliminary study where we translated the paragraphs using English as a pivot language. Table 15 shows the results of this pilot study. The evaluation was done by the first author on *all* 20 passages for every language pair that did not include translation from or into English, as these do not require any pivoting.[45] A total number of 200 pairs was evaluated employing simple preference judgments.

During the PARA_PIVOT translation process, the model utilized both the source text and its corresponding English translation (`text-davinci-003`, top-p=1.0, temp=0.3). This approach has the potential to mitigate the limitations associated with pivoting translations, where some information may be lost. For example, both Czech and Polish encode the gender information in the past tense form of the verb. English does not, so this information is lost and will most likely result in an erroneous translation. Indeed, we notice that adding the source text helps the model to overcome this shortcoming, however, we do not observe a clear gain from using English as a pivot language. Consider the following example:

(13) Taťka mě zase zmlátil. Byl hrozně naštvanej, protože mamka řvala. On mě vždycky mlátí, když ona řve. Že prej jsem pořádně neudělala nádobí. Ale já vím, že jsem je udělala dobře. I ten hrnec jsem vydrhla pořádně. A ještě jsem to všechno utřela před koupáním. Ale možná jsem nevyždímala hadr.
—CZECH SOURCE (from *Crows*)

a. Tata mnie znowu zbił. **Był wściekły**, bo mama krzyczała. On zawsze mnie bije, kiedy ona krzyczy. Że niby nie **umyłam** dobrze naczyń. Ale ja wiem, że **umyłam** je dobrze. I garnek też dokładnie **wypolerowałam**. I jeszcze wszystko **wytrzepałam** przed kąpielą. Ale może nie **wyciśniłam** ręcznika.

b. Tata mnie znów uderzył. **Był wściekły**, bo mama krzyczała. On zawsze mnie bije, kiedy ona krzyczy. Że niby nie **umyłam** dobrze naczyń. Ale ja wiem, że **umyłam** je dobrze. Nawet garnek dokładnie **wytrzepałam**. I jeszcze wszystko przed kąpielą **wytrzepałam**. Ale może nie **wyżągnęłam** mopa.
—GPT-3.5 PARA_PIVOT (POLISH)

In each instance, the emphasized verbs could potentially be mistranslated when translated through English as the pivot language, as the speaker's gender information would be lost. For instance, the past tense verb "washed" remains unchanged in English regardless of the gender of the speaker, with such details encoded only in the source (*Czech*) and target (*Polish*) languages. In this case, all verbs have been translated accurately with respect to grammatical gender, implying that incorporating the source language into the pivot pipeline does indeed improve the translation. However, PARA_PIVOT still selects less suitable verbs (highlighted in red) resulting in slightly more errors in this particular paragraph.

The only pair where pivoting seems to help is *pl-ja*. While it is unclear why this happens, it is possible that this outcome is due to the specifics of the Polish novel employed for the translation. *Sword of Destiny* by Andrzej Sapkowski uses a very distinct language with many archaic expressions. It is possible that translating into English, a language the GPT models were trained on, helps the model deal with these difficult phrases.

Since we do not observe any apparent gains from performing the translation via English as a pivot

[45] The author is fluent in English, Japanese, and Polish with a limited proficiency in other source languages.

language (p=0.62, 95% [0.448, 0.591]) and doing so reduces the number of examples one can fit into the prompt, we continue our experiments with a direct translation.

Type	Description	Trg Lang	Para	Sent	Para_Sent	GTr
Context (sentence)	A mistranslation that results most likely from lack of "understanding" the sentence-level context (e.g., translating "guide" as "doradca," or "adviser" instead of "przewodnik," or "guide"). This can include translating a word or a phrase into one that is semantically related but does not convey the intended meaning, or translation which appear to be an outcome of translating a word semantically related to the source word, instead of the source word itself.	Japanese	114	118	107	158
		Polish	64	67	49	82
		English	30	36	44	59
Context (paragraph)	A mistranslation that results from lack of a beyond-sentence context. This include issues such as polysemy, employment of correct pronouns, or translating elliptical expressions.	Japanese	6	36	6	38
		Polish	13	51	15	59
		English	2	25	0	48
Minor Issue	A minor issue which does not significantly affect the text and can be disputable, such as translating "barked" as "howl."	Japanese	34	25	26	16
		Polish	33	26	16	13
		English	18	11	12	9
Surface Similarity	A translation by word which is similar to the correct translation on the surface level, but has a different meaning (e.g., "Wilczak," a Polish surname, instead of "wilczarz," a "wolfhound").	Japanese	8	6	7	2
		Polish	14	13	16	5
		English	5	5	6	2
Word-by-Word	A translation of longer phrase which is overly literal resulting in confusing and incorrect translation.	Japanese	15	52	34	84
		Polish	17	23	18	33
		English	7	13	5	20
Unrelated Word	A translation with unrelated word such as "klnie" ("swear") instead of "zapuka" ("knock") where no apparent semantic relation could be found.	Japanese	3	2	5	4
		Polish	5	14	10	12
		English	1	3	1	2
Subject Changed	Change of subject. In the case of Para, it occurs mostly due to merging two sentences with two distinctive subjects where all states and/or actions are then assigned to one of them.	Japanese	5	2	2	0
		Polish	6	0	5	3
		English	7	2	5	1
Factuality	A translation that results in change in factuality, such as translating affirmative sentence as negation or translating word by its antonym.	Japanese	4	11	5	7
		Polish	0	2	1	3
		English	1	2	1	1
Non-word	A translation by a non-existent (made up) word. Some examples include skillfully constructed words like 火炎棒 which was generated instead of a "torch." While this word does not exist in Japanese (or Chinese) it follows the compositionality rules of these languages and is fully intelligible to a native speaker (火炎 "fire" and 棒 "stick.")	Japanese	1	2	2	0
		Polish	6	8	9	3
		English	0	0	0	0
mood	Change in the grammatical mood with regard to the source text. Note that the sentence here is *still* grammatically correct but does not reflect the meaning intended by the author.	Japanese	4	9	1	3
		Polish	1	3	4	2
		English	0	0	0	0
Unnecessary Translation	A translation of text which should be left untranslated such as some proper names.	Japanese	0	0	0	0
		Polish	0	3	0	2
		English	1	1	1	1
Language Mismatch	A translation into a language different than the target language (e.g., Chinese instead of Japanese). Note that leaving the word in the source language classifies as an "untranslated" error.	Japanese	2	3	3	2
		Polish	2	0	2	0
		English	0	0	0	0
Number/Time	A translation which changes number or time expression, such as translating 1h15min as 1h30min. Note that these rarely affect the overall meaning of the text. We have not observe cases where this would be a critical issue.	Japanese	3	2	4	3
		Polish	0	0	0	0
		English	5	2	1	3
Pivot Translation (Czech)	A mistranslation that stems from pivoting on English (annotated for cs-pl language pair).	Polish	0	0	0	43
other	Other issues which do not fit into any of the above.	Japanese	24	26	27	17
		Polish	9	14	10	13
		English	10	4	5	4
		Total (*Japanese*)	223	294	229	334
		Total (*Polish*)	170	224	155	273
		Total (*English*)	87	104	81	150
		Total (*All*)	**480**	**622**	**465**	**757**

Identifying Context-Dependent Translations for Evaluation Set Production

Rachel Wicks[1,2] and **Matt Post**[1–3]

Abstract

A major impediment to the transition to context-aware machine translation is the absence of good evaluation metrics and test sets. Sentences that require context to be translated correctly are rare in test sets, reducing the utility of standard corpus-level metrics such as COMET or BLEU. On the other hand, datasets that annotate such sentences are also rare, small in scale, and available for only a few languages. To address this, we modernize, generalize, and extend previous annotation pipelines to produce CTXPRO, a tool that identifies subsets of parallel documents containing sentences that require context to correctly translate five phenomena: gender, formality, and animacy for pronouns, verb phrase ellipsis, and ambiguous noun inflections. The input to the pipeline is a set of handcrafted, per-language, linguistically-informed rules that select contextual sentence pairs using coreference, part-of-speech, and morphological features provided by state-of-the-art tools. We apply this pipeline to seven languages pairs (EN into and out-of DE, ES, FR, IT, PL, PT, and RU) and two datasets (OpenSubtitles and WMT test sets), and validate its performance using both overlap with previous work and its ability to discriminate a contextual MT system from a sentence-based one. We release the CTXPRO pipeline and data as open source.[1]

1 Introduction

Neural machine translation (NMT) systems can produce high-quality, fluent output which are nearly indistinguishable from human translations, when evaluated at the sentence level. This human-level parity has been shown to disappear, however, when evaluated in context (Läubli et al., 2018; Toral et al., 2018). This is unsurprising, because sentences are nearly always written by humans in some contextual setting, and are translated by translators in the same fashion. Dismissing this context may create ambiguities that do not exist in the document as a whole, and in some cases, may make it impossible to correctly interpret the sentence.

	GENDER	AUXILIARY	INFLECTION	FORMALITY	ANIMACY	LANGS

Table 1: This work expands evaluation set coverage to new document phenomena and languages. (*) Note that Nadejde et al. (2022) does not include contextual information. (†) Currey et al. (2022) focuses on natural, rather than grammatical, gender.

Translation to another language must address ambiguities where the semantic or grammatical granularity of two sentences is imbalanced or mismatched. Probably the most widely-known of these is grammatical gender, i.e., when translating referential pronouns from a grammatically non-gendered language to a gendered one. For example, when translating from English to French, the pronoun *it* must be translated to *il* or *elle* depending on the grammatical gender of the antecedent noun, which may not be available in the same sentence.

The obvious path forward in addressing these issues is to move to contextual machine translation, in which sentences are no longer translated in isolation but with their source-side context. Recent work has shown that transformers (Vaswani et al., 2017) are capable of handling longer sequences and improving performance on context-based evaluation (Sun et al., 2022; Post and Junczys-Dowmunt, 2023). However, general contextual translation has

	*Well, uh, I was an obstetrician before, and I most definitely owe **you.***	(es) *Bueno, era obstetra antes, y definitivamente se **los** debo.*

Table 2: An example of the extracted ambiguities with their preceding contexts for each language pair. The ambiguous sentence is denoted in *italics* and the ambiguous word is **bolded**. Note the dialectal use of the "usted" accusative form "los". Language denoted in parentheses.

a number of obstacles, foremost is the lack of available evaluation resources. There are essentially two kinds of contextual evaluations: general metrics, which can theoretically be applied to any test set, and fixed test sets. There is relatively little work in the former setting (Vernikos et al., 2022; Jiang et al., 2022), and while they correlate with human judgments, they have not been proven capable of discriminating sentence-based from known-high-quality contextual systems. For the latter, a number of high-quality evaluation sets exist (Müller et al., 2018; Lopes et al., 2020; Bawden et al., 2018; Voita et al., 2019, Table 1), but they are limited both in language coverage and scope of phenomena.

In this work, we address this lack of evaluation data by extending coverage of existing datasets to more languages and contextual phenomena. We:

- develop a pipeline that makes use of broad-language-coverage annotation tools and hand-developed rules to identify context-based phenomena in any test set;
- construct rules for five context-based phenomena (§ 2) and seven language pairs (§ 3): DE, ES, FR, IT, PL, PT, and RU with EN; and
- apply this toolchain to multiple datasets.

We show that this dataset, called CTXPRO, is capable of discriminating high-quality contextual systems from sentence-level ones.

2 Contextual phenomena

A number of context-based phenomena which create ambiguities are common. We display some examples in Table 2. Humans easily handle these ambiguities during translation, which nearly always takes place in context, so a machine translation system which ignores these issues will never reach human-level parity. Some, such as lexical cohesion or fluency, are hard to quantify, while others, for example pronoun translation accuracy or word sense disambiguation, are easier. These phenomena all present difficulties and even impossibilities to systems that translate sentences in isolation. Our goal is to identify as many of these phenomena we can in a general way, such that we can create a general pipeline for isolating them, that can be reliably applied to any test set.

We describe each phenomena for comprehension and then provide our extraction methodology in order to identify when these ambiguities arise.

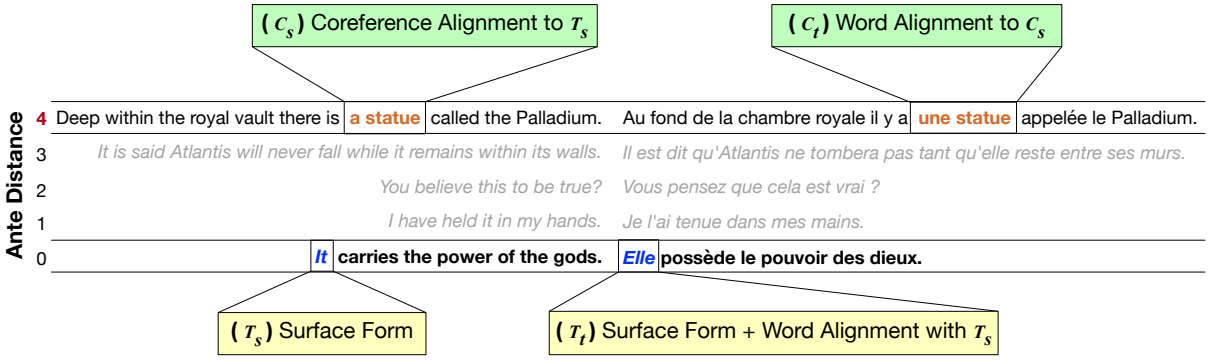

Figure 1: A diagram showing how the four key words for GENDER identification are identified. The antecedent distance is determined by what sentence C_e is found in. In order to be considered, T_e, T_t, C_e, C_t would also have to pass morphological feature tests similar to those shown in Table 3.

2.1 Anaphoric pronouns

Pronouns are a general descriptor that function as a placeholder for a noun phrase, providing the speaker with a more succinct form instead of repeatedly identifying an established referent.

In grammatical contexts, anaphora refers to the use of a pronoun to refer to a previously mentioned word or entity. Pronouns for which the referent noun can be found in preceding contexts are called *anaphora*; in contrast, *cataphora* denotes situations where the referent noun follows the pronoun. We do not consider cataphora in this paper.

2.1.1 Gender

Languages with gendered nouns require agreement with the appropriate gendered pronoun. English, which makes no such distinction for inanimate objects, will use the pronoun "it." In order to correctly translate "it" into Spanish, it is necessary to know what "it" refers to. If "it" refers to a school, it would be translated differently (*una* escuela) than if it refers to a heart (*un* corazón).

Apart from a few exceptions, English does not make use of grammatical gender. Machine translation often centers around translating either into or out of English with most of the paired languages expressing genders (masculine, feminine, and neuter), so there is a clear need to evaluate the translation of gender. Further, removing English from the equation does not resolve the problem. Gender assignment of inanimate objects is arbitrary which means that translating between two gendered languages is non-trivial. In extreme cases, a language may exhibit *"noun classes"* which behave similarly to gender, but may correlate more heavily with meaning. A noun in Swahili is not grouped via an arbitrary *gender* assignment, but is instead somewhat assigned to groups based on other labels such as *animacy, items, plants*, or *tools*. These classes affect morphological agreement in ways that English does not express. In any case, translating a pronoun that refers to a previously mentioned noun requires resolving this coreference in order to correctly generate the new pronoun.

2.1.2 Animacy

Humans and animals are often treated differently grammatically than inanimate objects. As stated, English makes no gender distinction for inanimate objects, though it does have gendered pronouns for *animate* objects. *She* and *he* are English pronouns used for humans and often animals but are rarely used to refer to inanimate objects.[2] This results in an ambiguity when translating pronouns into English from languages that do not make this distinction. For example, in English, *she is in the kitchen* clearly refers to a person while *it is in the kitchen* refers to a non-person. In French, the word *elle* would be used in both situations, requiring an MT system to make a choice.

2.1.3 Formality

Social expectations dictate language usage. In many languages, this is explicitly lexicalized with different second-person pronouns and verb conjugations that distinguish intimate or familiar relationships from formal ones. Examples include the *tu/vous* distinction in French and *du/Sie* in German.

Over time, English has lost its formal register in pronouns (often called the T-V distinction) which other languages frequently employ. A common sentence "Where are you?" may have multiple

[2]A small exception occurs when inanimate objects are personified. A frequent example is boats, which are often referred to as *she* in English.

interpretations determined by the addressee, but subtle cues in preceding context may indicate the level of formality or familiarity of the speaker—a "sir", the domain, or profession mentioned can clarify this. When translating this sentence into French, the system must choose a register to produce either "Où êtes-vous?" or "Où es-tu?" There is often insufficient information to make the correct choice from just a single sentence.

2.2 Verb Phrase Ellipsis

Verb phrases can be dropped for emphasis, style, or brevity. The manner in which they are ellipsed will follow the rules of syntax of the specific language.

2.2.1 Isolated Auxiliaries

English auxiliaries ("do", "will", "would") can occur as standalone verbs by taking the place of a verb phrase. The question "Will you walk with me?" can be answered with a short "I will." Many target languages require translation of the original head of the verb phrase rather than the modal or auxiliary. Simply, "I will" must be translated as "I will walk" or rather "I walk" inflected in the future tense. We limit this work to the aforementioned auxiliaries as they rarely have direct translations.

2.2.2 Inflection of Verb-less Nouns

Extreme ellipsis may remove entire portions of a sentence and render it a *phrase*. English word order conveys grammatical role of nouns. When elements of the original sentence, such as the verb, are ellipsed, it may be impossible to infer the grammatical case of any remaining nouns which have no inflection. Translation into languages with case systems suffers. Voita et al. (2019) exemplifies using the phrase: "You call her your friend but have you been to her home? Her work?" To translate this phrase into Russian, it is necessary to know that "her work" has the same grammatical case as "her home" in the previous sentence.

3 Extraction Pipeline

Our pipeline functions by identifying up to four key tokens and ensuring each token matches a set of predefined criteria. The four components are: (1) The source (English) token defined as T_s, the target (non-English) token defined as T_t, the source token which conveys the contextual information required to resolve the ambiguity defined as C_s, and the target token aligned to C_s defined as C_t. These relationships are illustrated in Figure 1. Contextual information is defined by a contextual relationship, Q, which has an associated solver. The predefined criteria is a set of rules, R.

We can identify ambiguous sentences by:

1. For each source–target sentence pair, apply word alignment. Each aligned pair of words forms a potential T_s–T_t pair.
2. Ensure T_s meets all criteria R_{T_s}
3. Ensure T_t meets all criteria R_{T_t}
4. Apply a solver for the contextual relationship, Q to the English token T_s and its preceding context to identify C_s.
5. Ensure C_s meets all criteria R_{C_s}.
6. Identify the target token C_t via word alignment to C_s. If translation conveys semantic symmetry, this token *also* has a contextual relationship with T_t.
7. Ensure C_t meets all criteria R_{C_t}

Consider the ambiguity of pronoun resolution. Müller et al. (2018) first proposed a pipeline for extracting ambiguous translations of English "it" to German nominatives ("er", "es", and "sie"). We can explain their methodology[3] via the aforementioned definition. The following identifies all ambiguities where the English "it" is translated as "sie."

1. For each source-target sentence pair, apply word alignment. Each aligned pair of words forms a potential T_s–T_t pair.
2. Ensure T_s is the word "it"
3. Ensure T_t is the word "sie"
4. The contextual information to resolve the ambiguity is its antecedent—expressed via a coreference relationship. Apply a coreference resolver (Q) to identify C_s.
5. Ensure C_s is a noun (not another pronoun).
6. Identify C_t via word alignment.
7. Ensure C_t is a feminine, singular noun.

The same criteria could be enumerated for the masculine and neuter equivalents, appropriately changing gender and surface form checks.

To extract a specific phenomenon and language, a "rule" (R) must be written which specifies features that T_s, T_t, C_s, and C_t must have. These features can range from part-of-speech, lemma, gender, case, plurality or others. The manner in which

[3] Müller et al. (2018) performs an extra coreference check on the target side that we do not.

Table 3: German criteria for all pronouns. We expand from Müller et al. (2018) to consider more cases (Accusative and Dative). English case is not used since the German annotations are more precise (English does not label Dative). PNOUN check in some cases is required to eliminate determiners (possessive adjectives instead of possessive pronouns)

	English (T_e)	French (T_t)
Rule	Lemma	Illegal Lemmas
DO.ELL	do	faire, aller
WOULD.ELL	would	faire, pouvoir
WILL.ELL	will	aller, faire

Table 4: French ellipsis Rules. English must have specified lemma. French alignment cannot have a lemma in the specified list.

these four components are identified creates the adaptability for each phenomena.

Gender Following previous works, we retrieve T_s and T_t based on surface form and word alignment. C_s is a noun discovered via coreference chain. If the coreference is a noun phrase, the head of the phrase is used. C_t is retrieved via word alignment. C_t must match the same morphological features present in T_t (e.g., gender and number).

Animacy As explained in Section 2.1.2, the animacy ambiguity that we consider occurs when translating from the gendered languages *into* English (whereas the gender ambiguity occurs when translating *out-of* English). To extract these examples, we use the same rules as GENDER, but we reverse the language direction for inference.

Formality The distinction of formality is the lack of a consistent or discrete C_s which informs the level of formality. Translating between English and a T-V language is always ambiguous with respect to the second person so we forgo using a contextual resolver Q to identify the appropriate context.

Auxiliary T_s is extracted from a pre-constructed list of auxiliaries—similar to those mentioned in Section 2.2.1. T_t, identified via word alignment, cannot occur in a pre-constructed list of forbidden translations. These translations are meant to prevent valid translations of auxiliaries, rather than the ambiguous ellipsed forms. For example, "to do" translated as a form of "faire" in French, is a direct translation, and is likely not representative of an ellipsed form. Contrarily, "to do" translated as a form of "savoir" in French is not a direct translation and is indicative of a previous occurrence of English "to know." C_t can be identified by finding the most recent occurrence of the same verb T_t, and C_s is retrieved from word alignment with C_t.

Inflection T_s and T_t can be of any form and any case. Any aligned noun pair (T_s and T_t) that occurs without an accompanying verb is ambiguous. C_t is identified as the most recent occurrence of *any noun* occurring in the same case as T_t. We assume the verb phrase surrounding C_t was ellipsed when generating T_t. We align C_t to find C_s.

We use FastCoref (Otmazgin et al., 2022) to perform English coreference resolution, simalign (Jalili Sabet et al., 2020) to perform cross-lingual

(*) ANIMACY was created by reversing a subset of the GENDER class so it is not used to calculate EXTRACTED because of the overlap.

word alignment, and SpaCy[4] to extract all other morphological features. We provide a larger list of our criteria in Appendix A.

3.1 Application to OpenSubtitles

We apply our extractor to the OpenSubtitles2018 dataset (Lison and Tiedemann, 2016) following previous work (Müller et al., 2018; Lopes et al., 2020). It comprises conversational dialog extracted from film and television subtitles. The conversational nature means plenty of context-based phenomenon occur. In Table 5, we present the total number of instances we extracted from Open Subtitles.

The fraction of the dataset that contains the phenomenon we target varies from language to language. This stems from the number of forms in each language, the number of genders, as well as translation standards. German, for instance, has very few AUXILIARY examples. We speculate this is due to German having similar auxiliary features as English so many examples were filtered out due to our "forbidden translation" criteria.

Some categories are extremely common. FORMALITY is invoked every time the second-person is used, which is frequent in conversational speech. INFLECTION also has high occurrences since there was relatively little filtering on the extracted examples. GENDER and AUXILIARY are *very rarely* extracted—less than 1% of the time in all languages. A 1% error rate is extreme when deploying at scale. Further, test sets, in nature, are small. If only 1% of the test set challenges contextual models, the results may be insignificant.

To form the dev, devtest, and test splits, we apply the following approach. For each label within a category, we ensure there are at least 100 examples. If there are fewer, we keep all examples for test. If there are more, we split the most recent years of OpenSubtitles into a 1:1:5 ratio for dev:devtest:test, limiting the test set's maximum size to 5000 examples per label. One label is roughly one surface form, but corresponds to one "rule" (a set of criteria R) or one row as shown in Table 3.

4 Quantitative Evaluation

Our goal is to show that our test sets can usefully discriminate between sentence-level and context-aware systems. An impediment to this goal is the lack of contextual machine translation models across languages for use in comparison and evaluation, and the difficulty in building them. Consequently, we turn to a commercial system, DeepL, which is alone among commercial providers in advertising contextual translation.[5] We translate with document-context by providing DeepL with context when translating, and compare to the same model translating without context at the sentence level. We show that a contextual system appropriately benefits from the additional context and gains significance performance on this test set.

Many works release their evaluation sets with the assumption of contrastive evaluation (Müller et al., 2018; Lopes et al., 2020; Voita et al., 2019), where the test is whether a model assigns a higher score to correct data than to linguistically-manipulated counterparts. This assumption ignores the fact that machine translation is a generative problem and should be evaluated as such. Recent work (Post and Junczys-Dowmunt, 2023) confronts this problem

Table 6: Generative evaluation percent accuracy scores (left section) evaluation ability to produce expected form; COMET scores (right section) evaluate the translation quality of this model; *sent.* denotes that no additional context was given while *doc.* was given five consecutive sentences for context. All translations made using DeepL commercial API. ANIMACY is *into* English. All others are *out of* English

and proposes generative evaluation as an alternative, showing a wide gap between contextual and sentence-level systems that is only observed under generative evaluation. Translations are counted as correct if the *expected surface form* is present anywhere in the model's output—matching the entire word and not simply a substring. We follow this approach in our evaluation.

We validate our data by showing it (1) adequately addresses context-based phenomena and (2) is sufficiently challenging. We demonstrate the former by showing that a context-aware translation model consistently outperforms a context-less equivalent. We see the latter is true as the contextual model does not solve the problem. There is still significant context-aware work to be done.

4.1 Accuracy

We begin by translating sentences both with and without context, using at most five sentences of context. To limit API calls, we run a subsample of our produced evaluation sets. We limit each category (GENDER, ANIMACY, FORMALITY, AUXILIARY, and INFLECTION) to approximately 10k total examples, divided evenly amongst the categories labels. To extract the final sentence for scoring purposes, we apply segmentation using the ERSATZ segmenter (Wicks and Post, 2022).

The results in Table 6 clearly show that the DeepL model with additional context *far outperforms* its sentence-level equivalent.[6] Many of these evaluation examples have specific preceding context that needs to be used in order to correctly translate the ambiguity. FORMALITY is a slight exception. There is little to no guarantee that explicit cues are given to convey the nature of the relationship between the speaker and addressee, yet preceding context still benefits an average of 9 percentage points across all languages. AUXILIARY is a task of translating verbs. A random guess would equate to sampling from the distribution of verbs in a language–which results in low success rates. Translating AUXILIARY with context increases from nearly never correct to a roughly 50% accuracy rate. Translating ANIMACY has higher sentence-level baselines than some of the other categories. We attribute this to other semantic cues towards ANIMACY which are less arbitrary than something such as GENDER assignment. For instance, if a noun *talks*, it is likely animate, while a noun that *is thrown* is likely inanimate. Similarly, INFLECTION may have some sentence-internal cues. Certain nouns may have a majority class, or preceding prepositions ((“with”, “for”, “in”, etc.) may indicate case. This is similar to the intrasentential coreference found with pronouns, which makes some occurrences easier than oth-

[6] Ideally we would make the same comparison between document- and sentence-level translation with other commercial systems, but there is no way to prevent them from applying sentence-level segmentation to the document-context string.

ers. Nonetheless, additional context aids the model. In every category, the context-aware model shows consistent gains over its context-less variant.

4.2 Automatic metric

We also present COMET scores (Rei et al., 2020) in Table 6. Across all categories and language pairs, COMET shows improvement when the system leverages additional context. The consistent improvement in COMET reinforces the trends we see with the generative evaluation metric. The one exception is the FORMALITY class which has minimal differences between the sentence-level and contextual inputs. COMET rewards synonyms and we suspect formal and informal surface forms have more similar encodings in COMET models than these other grammatical forms. A surface-based metric would better capture the gains that can be seen from the accuracy scores, which is indeed what we find (Table 18 in Appendix A).

5 Qualitative Evaluation

Our extraction pipeline relies on handbuilt rules applied to the outputs of automatic tools. As a result, the process is noisy and may be susceptible to errors. The previous section showed that a contextual system does better on our test sets than its sentence-based counterpart, and there is no reason we can think of to suspect that errors would systematically benefit the contextual system. However, in the interest of completeness, we took a more qualitative look at the data. This includes a systematic manual review (§ 5.1), direct comparison with prior work (§ 5.2), and an error analysis (§ 5.3).

5.1 Manual review

Previous work in automatic test set production has not typically included a manual analysis of rule quality. To build confidence in these automatic extraction methodologies, we sampled 100 random test examples from the extracted English–French GENDER set and manually reviewed and annotated them for errors. We find that 92 of the extracted examples are correct. Three more were questionably incorrect—with correct translations and alignments—yet had atypical coreference resolutions that were difficult for our human reviewer to understand. Of the remaining five, two had a non-referential pronoun. One such example "What is it?" was used in the sense of "What's wrong?" rather than "What is that?" In the former, "it" has no valid antecedent, yet it was extracted.

We present the remaining three errors in Table 7, where they demonstrate where errors arise at each step in the pipeline. The Coreference Error is a clear mistake. "They don't want us to know what they're working on" refers to the people being talked to, and not "these guys"—who instead seemed to be criminals who broke into a company. The Alignment Error is an unfortunate combination of a bad alignment and inconsistent translation. "the discipline" is aligned to the word "espionnage." "discipline" in French is a feminine noun, while "espionnage" is masculine. The French "il" is masculine, and thus has "espionnage" as an antecedent despite the English having "the discipline." This coincidental error caused this example to still be extracted. Lastly, one of these examples seemed to have a typo in the English transcript. The word "signatures" seemed to be incorrect. We suspect the correct transcription word was "serial killers." Given the inconsistent context on the English side, we suspect the neural coreference model had difficulties resolving this.

5.2 Comparison with prior work

Since our extraction framework is largely based on that of Müller et al. (2018), we expect to have a similar quality of extracted rules (or better, since the underlying annotations tools have improved). We thus undertake a comparison to the data that they released. When applying our pipeline to the German–English OpenSubtitles data, we extract 147,211 sentences that have ambiguous pronoun usage. Müller did not report their raw extraction numbers, but their release includes 12,000 examples, balanced across gender (but not distance). We therefore focus our analysis on this subset.

Since their pipeline contained a target-side coreference check that we do not have, one might think their pipeline would be a stricter selection process, but we find the opposite to be true. Our pipeline's selection overlaps with only half of ContraPro (6,003 sentences), rejecting the other half (5,997 sentences). An analysis of this rejected portion of ContraPro turns up some explanations. ContraPro extracts three categories of German pronouns corresponding to neuter, masculine, and feminine genders. For *er* and *sie*, we rejected roughly 25% of the ContraPro examples; however, we rejected over 75% of the neuter examples from ContraPro. Upon review, we found a substantial number of

Error Type	English	French
Coreference	We got any ideas what these ***guys*** were after?	Une idée de ce que voulaient ces ***gars***?
	No, CEO is on his way down to talk to us now.	Non, le PDG arrive pour nous le dire.
	So far, everyone we've talked to hasn't really given us much.	Tous ceux à qui on a parlés ne nous ont rien appris.
	Makes sense.	C'est logique.
	They don't want us to know what they're working on here.	***Ils*** ne veulent pas qu'on sache ce qu'ils font.
Alignment	As you know the ***discipline*** of media espionage is a new one.	Comme vous le savez, l'***espionnage*** médiatique est une nouvelle discipline.
	Oh yes, ***it*** is everywhere.	***Il*** est partout.
Translation	You know more about ***signatures*** than most of ***them*** put together.	Vous en savez plur sur ces ***tueurs*** (`en: killers`) qu'***eux*** tous réunis

Table 7: In a sample of 100 extracted items, 8 errors were found. This table shows 3 of these errors made by the extraction pipeline on the French Gender set. The ***indicated*** words show the pronouns in French and English, as well as their antecedents. Some examples fit into multiple categories, but these show the most evident error type. `en:` indicates the English translation of French word.

non-referential instances. These examples include sentences such as "It was your duty.", "It would have been all right if it wasn't for you." and "It was one of those California Spanish houses" that all have either a non-specified referent or have a passive construction. The inclusion of these examples points to inaccurate coference chains, likely explained by their use of older corefence tools.

Our extraction employs strict criteria to find the head of a span during coreference and alignment. The head is used for the gender, person, and number checks included in the definition of R (§ 3). From our understanding of Müller's work, they did not include this check. Mistakes are inherent to any automatic process, and likely persist in our dataset as well. Our analysis here lends some confidence to the belief that tighter selection criteria and improved underlying tools result in better data.

5.3 Model analysis

Absent sufficient information, the translation of ambiguous words will regress to their proportions in the training data. For pronouns, this would be the neuter or masculine class; for auxiliaries, the direct translation (the "Illegal Lemma" in R).

We examine the English–German model outputs. Our evaluation sets have balanced counts across genders, so a correct model would produce a neuter pronoun roughly one-third of the time. Instead, this sentence-level model produces either "es" or "ihm" (the German neuter pronouns) closer to two-thirds of the time. This contextual model has better performance producing the neuter pronouns about 40% of the time. This problem is well-known, but other issues are not as well documented.

The auxiliary category had the worst scores, both in terms of how low the sentence-level model was performing as well as the absolute increase from adding context. The cause of these scores becomes obvious as we examine the model outputs. To generate the rules for the AUXILIARY class, we enumerated illegal lemmas that represent the most common direct translations of English modals as described in Section 3. Ideally, a model would never generate these verbs for our evaluation set unless part of a larger verb phrase construction. We find the sentence-level model generates a translation that contains a form of one of these lemmas approximately two-thirds of the time. Conversely, the contextual model generates these closer to one-third of the time.

6 Analysis of WMT test sets

As previously earlier, this pipeline is easily applied to new data and test sets. We demonstrate this by applying it to the 2019–2022 WMT newswire test sets (Barrault et al., 2019, 2020; Akhbardeh et al., 2021; Kocmi et al., 2022). In so doing, we find

	DE	RU	PL
GENDER	135	64	13
FORMALITY	540	416	4
AUXILIARY	1	0	0
INFLECTION	-	14	1
WMT # LINES	6454	7038	1000

Table 8: Counts on the number of extracted examples from WMT 2019-2022 (when available) test sets.

phenomena in a similar proportion of sentences to OpenSubtitles, but with a different distribution; there is a higher rate of GENDER but smaller of FORMALITY and AUXILIARY. In Table 8, we present the total number of examples discovered in WMT 2019-2022 in `en-de`, `en-ru`, and `en-pl` (when available). The newswire text hardly ever contains the AUXILIARY type of ambiguity. Formality comprises the bulk of the examples, and upon further inspection, we find a severe bias towards the formal register, with a 1 to 7 ratio of informal to formal—likely due to the characteristics of the domain. Further, we suspect the sparseness in contextual ambiguities is important to consider when evaluating these systems.

7 Related Work

Work in contextual machine translation can be divided into three categories: (1) the publication of resources, similar to this work; (2) alterations on the training paradigm via architecture or data input; (3) evaluation metrics.

This work largely follows the path set forth by those who have previously published resources on the detection of gender, pronouns, and formality (Guillou and Hardmeier, 2016; Müller et al., 2018; Bawden et al., 2018; Voita et al., 2019; Lopes et al., 2020). (Currey et al., 2022) produces a gender-based evaluation dataset using human annotators, but covers the complement of this work: gender assigned to humans rather than inanimate objects. In addition to the manual pipelines, recent work has been done to promote the automatic detection of these phenomena. Nadejde et al. (2022) implements a cross-lingual mutual information metric that tags words as needing additional context. The tags were found to often overlap with the variety discussed in this work. Fernandes et al. (2023) also use a mutual-information based score to select data that is then used to derive a similar rule-based extraction approach, but do not release evaluation sets.

A substantial amount of work has been done to allow traditional neural models to handle additional input. Some approaches involve more complex architectures or modifications to training paradigms incorporate longer sequences (Miculicich et al., 2018; Bao et al., 2021), but Sun et al. (2022) showed that unaltered Transformers can handle longer sequences. Other work has focused on leveraging and cleaning the available data, since large-scale document bitext is lacking (Junczys-Dowmunt, 2019; Post and Junczys-Dowmunt, 2023).

Lastly, many have realized that BLEU, COMET, or other sentence-level metrics will not address the distinction in document-level performance. Vernikos et al. (2022) proposed a new method for adjusting current methods to adjust for document-level inputs. Jiang et al. (2022) proposed BlonDe, an entirely novel metric for document-level evaluation. We hope this work complements these works and serves to further the field in its aspirations towards true context-aware translation.

8 Summary

Machine translation systems face a performance ceiling that can't be overcome so long as they continue to operate at the sentence level. A major obstacle to that transition is the unavailability of test sets in many languages and for many contextual phenomena. The goal of this work has been to help address that problem. The extraction pipeline proposed in this paper can be used to identify and generate new test sets which contain linguistic phenomena that can only be consistently translated by contextual systems. The application of our pipeline to the OpenSubtitles dataset in seven languages provides a new set of evaluation sets including a wider set of languages and phenomena than were available before. Further, we hope that the extensibility of our pipeline to new phenomena and languages allows for others to build upon this work to expand resources and coverage. The CTXPRO datasets and extraction pipeline are available as open source from `https://github.com/rewicks/ctxpro`.

Abstract

While large language models have made remarkable advancements in natural language generation, their potential in machine translation, especially when fine-tuned, remains underexplored. In our study, we conduct comprehensive experiments, evaluating 15 publicly available language models on machine translation tasks. We compare the performance across three methodologies: zero-shot prompting, few-shot learning, and fine-tuning. Central to our approach is the use of QLoRA, an efficient fine-tuning method. On French-English, QLoRA fine-tuning outperforms both few-shot learning and models trained from scratch. This superiority is highlighted in both sentence-level and document-level translations, with a significant BLEU score improvement of 28.93 over the prompting method. Impressively, with QLoRA, the enhanced performance is achieved by fine-tuning a mere 0.77% of the model's parameters.

1 Introduction

The rapid advancement of large language models (LLMs) is reshaping the field of natural language processing (NLP), marking a potential paradigm shift in future development (Zhao et al., 2023). Instead of crafting dedicated task-specific systems, a growing interest has been focusing on quickly adapting LLMs to specific tasks simply through prompting (Liu et al., 2023; Sanh et al., 2022). So far, studies have shown that prompting LLMs can match or even rival the performance of specialized systems on numerous NLP tasks (Radford et al.).

Among all the NLP tasks, the application of LLMs to machine translation (MT) is understudied. The optimal way to harness LLMs for MT remains an open question. While encoder-decoder-based LLMs (Xue et al., 2021; Liu et al., 2020; Costa-jussà et al., 2022) are inherently designed for the sequence-to-sequence demands of MT, the approach for leveraging decoder-only models is less straightforward.

Although there are initial attempts in this direction (Sia and Duh, 2022; Hendy et al., 2023; Moslem et al., 2023; Zhu et al., 2023), these studies mainly concentrate on prompting and few-shot learning, not exploiting the availability of bitext. Additionally, most work focus on exceptionally large LLMs like GPT3 (Brown et al., 2020) with its staggering 175 billion parameters, which are beyond the reach of non-commercial research groups for local training. This poses a significant hurdle for institutions with constrained computational resources, rendering the findings less applicable and relevant to many researchers.

In this paper, we aim to investigate the performance of LLMs on MT tasks, with a particular focus on decoder-based LLMs, a category less charted for MT applications. Our research focuses on a range of publicly available medium-sized LLMs. This includes models pretrained on English-centric datasets, such as GPT-Neo (Black et al., 2021), OPT (Zhang et al., 2022), LLaMA2 (Touvron et al., 2023), as well as those on multilingual datasets such as XGLM (Lin et al., 2021) and BLOOMZ (Muennighoff et al., 2022). We evaluate various versions of these models, with their parameter sizes spanning from 1.3 billion to 13 billion, totaling 15 models.

In our experiments, we explore zero-shot prompting, few-shot learning, and fine-tuning, where our emphasis on fine-tuning fills the gap in previous studies. For the fine-tuning process, we employ the QLoRA method (Dettmers et al., 2023), which enhances efficiency and minimizes memory usage by quantizing the model to 4-bit precision and limiting the number of trainable parameters. To the best of our knowledge, this is the first instance of QLoRA being applied to fine-tuning LLMs for MT tasks.

We also evaluate the performance of LLMs in document-level translation. Standard sequence-to-sequence MT models focus on translating one sentence at a time, overlooking discourse phenom-

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 468–481
December 6–7, 2023.

ena and the broader context. Existing methods for document-level translation often pivot toward architectural modifications (Tu et al., 2018; Tan et al., 2019; Xu et al., 2021), leading to specialized models that need unique designs. Our objective is to evaluate the capability of LLMs in preserving long-term contextual coherence and to explore their potential in facilitating the development of a robust document-level translation system.

We demonstrate the effectiveness of fine-tuning on a French-English dataset – this language pair is selected due to its accessibility for LLMs, positioning it as an ideal starting point for research in this domain. Our experimental results, complemented by thorough analysis, reveal that:

- LLMs, when subjected to fine-tuning, are potent MT models. Through fine-tuning, they consistently outperform their zero-shot prompting counterparts, achieving an average improvement of 8 BLEU for sentence-level translation and 16.33 BLEU for document-level translation. Notably, the model *opt-13b* even sees a remarkable boost of 28.93 BLEU (from 4.56 to 33.49).

- There is a large variation in the performance across different LLMs. LLaMA 2 consistently outperforms others for both prompting and fine-tuning. BLOOMZ, initially lagging behind in prompting, ascends to top-tier models after fine-tuning. However, some models, despite benefiting from fine-tuning, either match or fall short of the performance of models trained from scratch. It is also noteworthy that larger models don't invariably outshine their smaller counterparts.

- When prompted, LLMs demonstrate superior performance in sentence-level translation. However, the application of fine-tuning yields more substantial enhancements in document translation, as reflected by both the BLEU and COMET scores. Notably, LLaMA 2 surpasses its performance in sentence-level translation when trained on documents.

- QLoRA accelerates the fine-tuning process without compromising model performance. To attain an equivalent BLEU score, it necessitates 21 times less training time and reduces the trainable parameters by 1370-fold compared to conventional fine-tuning.

2 Related Work

2.1 LLM Applications

Leveraging LLMs across a spectrum of downstream natural language processing (NLP) tasks is now a prevailing approach. However, the optimal strategies for utilizing these models both effectively and efficiently remain an open question. Broadly speaking, there are three primary methods to build applications based on LLMs:

- **Zero-shot prompting.**[1] This involves querying LLMs with a prompt that hasn't been seen in the training data of the model. Such prompts typically provide specific task instructions along with the main query. Given the sensitivity of LLMs to the structure and content of prompts, careful prompt engineering is crucial to achieve optimal performance.

- **Few-shot learning.** Often referred to as in-context learning, few-shot learning is a technique where LLMs are provided with a handful of examples to guide their responses. Zero-shot prompting can be considered a subset of this, where no examples are given. In few-shot learning, these examples are integrated into the prompt template, serving as context to instruct the model on how to respond.

- **Fine-tuning.** The two methods above allow for task adaptation without the need for further training on the LLMs. In contrast, fine-tuning involves extending the training of the LLMs using additional, task-specific data. This is particularly beneficial when such tailored datasets are available.

Yang et al. (2023) survey the 'use cases' and 'no use cases' of LLMs for specific downstream tasks, considering the three aforementioned methods, and conclude that LLMs excel in most NLP tasks.

2.2 LLMs for MT

Recent literature has begun to explore the application of LLMs for MT, an area that remained relatively under-explored until now. Both Hendy et al. (2023) and Moslem et al. (2023) underscore the superiority of GPT3 (Brown et al., 2020), GPT3.5 and ChatGPT (Bawden and Yvon, 2023) in MT

[1]Throughout this paper, we refer to 'zero-shot prompting' simply as 'prompting'.

using prompting. However, the former also indicates that these models may not consistently outperform SOTA MT systems and commercial translators. In a comparative study, Zhu et al. (2023) experiment with various LLMs, including GLM-7.5B (Lin et al., 2021), OPT-175B (Zhang et al., 2022), BLOOMZ-7.1B (Muennighoff et al., 2022), and ChatGPT. Their findings suggest that while these decoder-only LLMs are competitive, they still lag behind when compared to the encoder-decoder-based multilingual language model NLLB (Costa-jussà et al., 2022). Briakou et al. (2023) studied the impact of LLM data on MT.

Prompting strategies for MT are studied by Vilar et al. (2023) for PaLM (Chowdhery et al., 2022) and Zhang et al. (2023) for GLM-130B (Zeng et al., 2022). They reveal several challenges associated with MT prompting, such as issues with copying, mistranslation of entities, and hallucination. These challenges are echoed by Bawden and Yvon (2023), which identify similar constraints with prompting on BLOOM (Scao et al., 2022). However, they show these limitations can be mitigated in a few-shot learning setting. Sia and Duh (2022) investigated a light-weight tuning method akin to prefix tuning (Li and Liang, 2021). Sia and Duh (2023) and Wang et al. (2023) expand the evaluation to document-level translation.

While prior studies have highlighted the potential of LLMs in MT, their focus has been primarily on in-context learning. A significant gap remains in the exploration of fine-tuning LLMs specifically for MT tasks. Additionally, there is an evident absence of research that provides a comprehensive comparison among prompting, few-shot learning, and fine-tuning methodologies. Recognizing this oversight, the primary objective of this paper is to address and bridge this research gap.

3 QLoRA

QLoRA (Dettmers et al., 2023) is an efficient fine-tuning approach that reduces the memory usage of training without compromising the 16-bit task performance. The approach involves quantizing a pre-trained model to 4-bit precision. Subsequently, a compact set of learnable Low-rank Adapter (LoRA, Hu et al. (2021)) weights are added, which can be tuned through backpropagation.

LoRA Motivated by the empirical findings of Li et al. (2018) and Aghajanyan et al. (2020), which suggest that LLMs possess a notably low intrinsic dimension for their parameters, LoRA hypothesizes a similar low intrinsic rank for weights during model adaptation. Thus, LoRA introduces a reparameterization aimed at reducing dimensions. Specifically, it employs a low-rank decomposition to represent the pretrained weights, resulting in newly-added adapter weight matrices, with the rank r anticipated to be considerably smaller than the original weight matrices' dimension. During fine-tuning, the pretrained weights are frozen, with only the newly incorporated adapter updated via back-propagation. A key observation is that as the rank r is reduced, there is a corresponding decrease in the number of adaptable parameters.

4 Experimental Setup

4.1 Datasets

In this study, we focus on the translation direction from French to English due to its significant demand for high-quality translation and the availability of substantial parallel data. Our fine-tuning set includes the commonly used Europarl (Koehn, 2005) and News Commentary dataset from WMT14[2]. The dev and test sets are the newstest2013 and newstest2014 datasets, respectively, from WMT14. These datasets are constructed from documents, thus enabling a natural evaluation of document-level translation. Table 1 summarizes the statistics of the datasets.

	#sents	#docs	avg.sents/doc
train	2,366,117	21,430	144
dev	3000	126	24
test	3003	169	18

Table 1: Dataset statistics.

4.2 Baseline

We compare the performance of systems built upon LLMs against an NMT model trained from scratch using the Amazon Sockeye framework (Hieber et al., 2022). The model architecture is a 12-layer transformer with a model size of 1024, 16 attention heads, and 4096 hidden units in the feed-forward layers. We employ byte pair encoding (BPE, Sennrich et al. (2016)) separately for each language, setting the number of BPE symbols to 30k for both languages. The model is trained with a batch size of 4096, an initial learning rate of 0.0002, and a

[2]https://www.statmt.org/wmt14/translation-task.html

Model	Release Time	Data	Size (B)
GPT-Neo (Black et al., 2021)	Mar, 2021	English-centric	1.3; 2.7
OPT (Zhang et al., 2022)	June, 2022	English-centric	1.3; 2.7; 6.7
LLaMA2 (Touvron et al., 2023)	July, 2023	English-centric	7; 13
XGLM (Lin et al., 2021)	Nov, 2022	Multilingual	1.7; 2.9; 4.5; 7.5
BLOOMZ (Muennighoff et al., 2022)	Nov, 2022	Multilingual	1.7; 3; 7.1

Table 2: Overview of evaluated LLMs.

plateau-reduce learning rate scheduler. Additionally, we apply a dropout and label smoothing of 0.1, use the Adam optimizer with a warm-up of 10k steps, and set the checkpoint interval to 4000. Training is halted if there is no improvement in performance on the dev set for 32 consecutive checkpoints. The model has 4 billion parameters and is trained on a single NVIDIA V100 with 32G GPU memory.

This is a relatively standard NMT model, devoid of advanced techniques such as back translation, knowledge distillation, or ensembling, which could potentially elevate the model to state-of-the-art performance (Kocmi et al., 2022). However, the primary objective of this study is to compare the efficacy of using an off-the-shelf machine translation toolkit, which is widely accessible and requires minimal effort for machine translation practitioners, against building MT systems using LLMs. Importantly, both methods demand similar levels of effort in development, making this a fair comparison to ascertain the most efficient approach for practitioners and researchers alike.

4.3 Pretrained LLMs

We investigate a varied collection of pretrained LLMs accessible on HuggingFace (Wolf et al., 2020), all based on the transformer architecture. This collection comprises five distinct LLMs, each trained on either English-centric or multilingual data and available in multiple versions with varying parameter sizes. This results in a comprehensive assortment of 15 models, with parameter sizes ranging from 1.3 billion to 13 billion. Table 2 summarizes the models included in our study.

- **GPT-Neo** - a GPT-2 (Radford et al.) like causal language model trained on the Pile dataset (Gao et al., 2020), an 825 GiB English corpus.
- **OPT** - a suite of causal language models, where the largest one, OPT-175B, exhibits performance comparable to GPT-3 (Brown et al., 2020).
- **LLAMA 2** - pretrained on 2 trillion tokens of English-centric data. We used a fine-tuned version of the model, referred to as *LLAMA 2-CHAT*. This fine-tuned version demonstrates superior performance compared to open-source chat models across a wide range of benchmarks.
- **XGLM** - a multilingual language model trained on a balanced corpus covering 30 diverse languages with 500B tokens. The XGLM 7.5B outperforms GPT-3 on the FLORES-101 (Goyal et al., 2022) machine translation benchmark in few-shot learning scenarios.
- **BLOOMZ** - a multilingual BLOOM model (Scao et al., 2022) fine-tuned with the xP3 dataset (Muennighoff et al., 2022), which consists of multilingual datasets with English prompts, totaling 95 GiB of text.

The selection of these models enables us to assess the impact of various factors on translation performance, including the type of model (English-centric vs. multilingual) and model size. Additionally, the chosen sizes reflect the computational resources typically available to research institutes with limited GPU resources, such as university labs. This consideration ensures that our findings are applicable and accessible to a broad range of machine translation researchers and practitioners.

4.4 Prompted Tuning

We fine-tune LLMs using examples that include specifically formatted prompts (French: [fr sent] English:) and their corresponding responses ([en sent]). The dev set is also formatted in the same way. This approach customizes the model for the French-English machine translation task.

Sentence-level Prompts The inputs at the sentence level are formatted as follows:

French: [fr sent] English: [en sent] <eos>

We append the special token <eos> at the end of each sample to regulate the length of the text generated by the model. Without this, LLMs tend

to generate text continuously until they reach a predetermined length limit.

Document-level Prompts We use the given document boundaries to concatenate parallel sentences into document-level sequences. These parallel documents comprise an equal number of sentences in both languages. Our goal is to ensure that the models generate the same number of output sentences per document as the number of input sentences provided, facilitating sentence-level evaluation. We adopt the document mark-up used in Junczys-Dowmunt (2019), incorporating symbols for document start (<BEG>) and end (<END>), as well as sentence separators (<SEP>). In instances where documents exceed our sentence limit of 10, we substitute the <END> symbol with a break symbol (<BRK>) and commence the subsequent sequence with a continuation symbol (<CNT>) instead of <BEG> . Below is an example of a document input:

French: <BEG> [fr sent1] <SEP> [fr sent2] <SEP><END> English: <BEG> [en sent1] <SEP> [en sent2] <SEP><END>

4.5 Fine-tuning Setup

We configure the learning rate to 2e-4 and employ the Adam optimizer for the training process. A batch size of 32 is used, and the evaluation is performed every 1000 steps. The fine-tuning process is halted if there is no improvement in the model's performance over 16 consecutive checkpoints. For the LoRA configurations, the rank for the low-rank approximation is set to 64, and the scaling factor for the low-rank adaptation is set to 32. The trainable parameters are limited to the self-attention layers of the model. Additionally, a dropout rate of 0.05 is applied in the LoRA layer. The model weights are quantized to 4-bit precision to reduce memory requirements, and mixed-precision training is enabled, using a combination of float16 and float32 data types to accelerate the training process. Models with less than 3 billion parameters are trained on a single NVIDIA RTX GPU with 24GB of memory, while models with more than 3 billion but less than 7 billion parameters are trained on a single NVIDIA V100 GPU with 32GB of memory. For models with an even larger number of parameters, we employ multiple V100 GPUs and enable model parallelism by setting device_map="auto" . This is facilitated by the Accelerate library from Hugging Face, which automatically distributes the model across the available GPUs.

4.6 Evaluation Metrics

We use **BLEU** and **COMET** (Rei et al., 2020) as evaluation metrics to assess the performance of our models. For BLEU we use the SacreBLEU (Post, 2018) implementation, which standardizes tokenization and facilitates reproducibility.

On the other hand, unlike BLEU, which depends on the n-gram overlap between the machine-generated translation and the reference translation, COMET models are trained on a comprehensive dataset comprising human translations and human quality assessments. This dataset is used to predict translation quality while also taking the source side into account. This approach enables COMET to provide a more holistic evaluation that includes fluency, adequacy, and preservation of meaning. We employ the latest model, *Unbabel/wmt22-comet-da*, for our evaluation. This model scales the scores between 0 and 1, where a score approaching 1 indicates a high-quality translation.

By employing both BLEU and COMET, we can ensure that our evaluation is robust and comprehensive, accounting for not only the lexical similarity between the translations and the references but also the overall quality and preservation of meaning in the translations. Moreover, COMET may serve as a superior evaluation metric when assessing the zero-shot performance of LLMs compared to BLEU. As we demonstrated in Section 7, the outputs from LLMs often excel in preserving meanings but might receive a low score if evaluated solely based on n-gram matching.

5 Sentence-level Translation

In this section, we assess the sentence-level translation performance of pretrained LLMs using prompting versus fine-tuned LLMs (Section 5.1). We investigate the effects of incorporating or not incorporating QLoRA during the fine-tuning process (Section 5.2). Additionally, we analyze the impact of varying QLoRA hyperparameters (Section 5.3), including the rank of the low-rank approximation (Section 5.3.1), and the trainable parameters (Section 5.3.2). We also conduct experiments with different sizes of fine-tuning data and compare the results of fine-tuned LLMs with the baseline NMT model (Section 5.4). Lastly, we explore few-shot learning with varying numbers of shots and diverse prompts (Section 5.5).

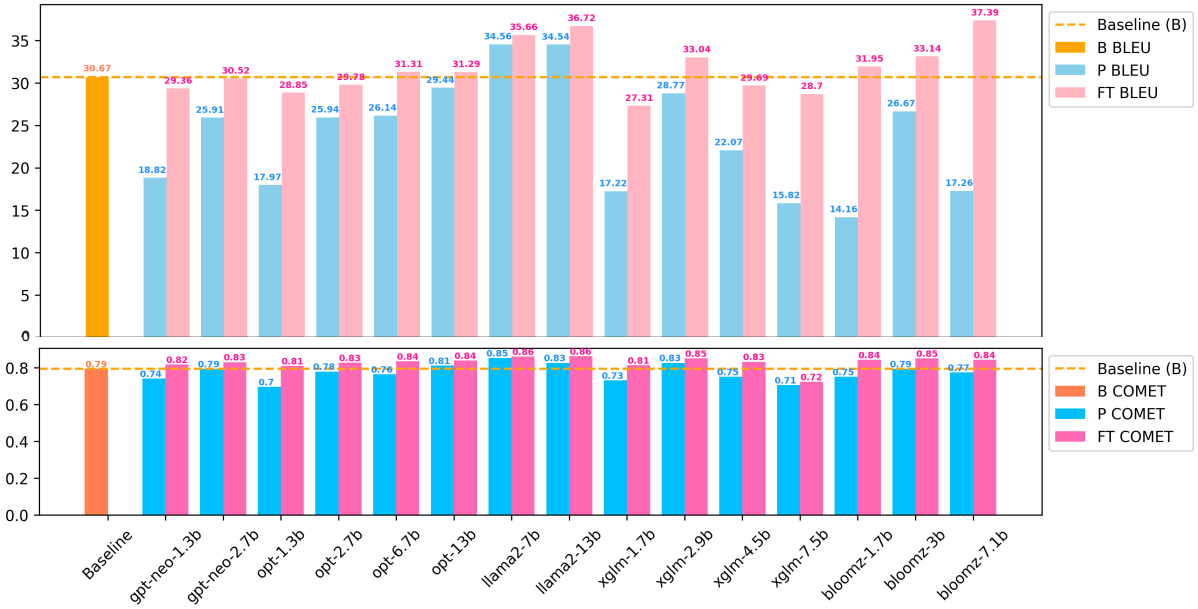

Figure 1: Prompting (*P*) vs. QLoRA fine-tuning (*FT*) on sentence-level translation using various pretrained LLMs. *Baseline* is the NMT system described in Section 4.2. Rank r for QLoRA is set to 64.[3]

5.1 Main Results

We present the results of prompting and QLoRA fine-tuning in Figure 1. Key observations are:

- While there is a significant disparity in BLEU scores, the same is not observed in COMET. All models exhibit comparable COMET scores. The top-performing fine-tuned model, *llama2-13b*, outperforms the *baseline* from 0.837 to 0.862. This indicates that while all models produce semantically coherent translations, their lexical choices, which affect BLEU scores, might differ.
- In terms of BLEU, the *baseline* model surpasses most prompted LLMs, with the exception of *LLAMA 2*. Specifically, *llama2-7b* achieves the highest performance at 34.56 BLEU, marking a 3.89 BLEU improvement over the *baseline*.
- 8 out of the 15 fine-tuned LLMs exceed the *baseline*. This includes both English-centric and multilingual models. The standout model is *bloomz-7.1b* achieving a BLEU score of 37.39, a 6.72 BLEU enhancement compared to the *baseline*.
- Fine-tuning invariably boosts LLM performance on average by 8 BLEU points, with *bloomz-7.1b* witnessing the most substantial leap of 20.13 BLEU.
- No clear advantage is discerned when contrasting prompted multilingual models with English-centric ones. For instance, the multilingual *bloomz-1.7b* scores the lowest at 14.16 BLEU. Yet, when evaluating the fine-tuning gains over prompting, multilingual models average an 11.32 BLEU improvement, surpassing the 5.02 BLEU of their counterparts.
- Bigger models do not consistently outshine their smaller counterparts. For instance, after fine-tuning, *bloomz-1.7b* trumps the larger *opt-13b* (31.95 vs. 31.29 BLEU). Within the same architecture, models with more parameters typically fare better, but there are exceptions, like with *XGLM*, where the *4.5b* and *7.5b* versions lag behind the *2.9b* variant.

In conclusion, while directly prompted LLMs do not universally outperform train-from-scratch MT models, certain LLMs, such as LLAMA 2, defy this trend. Moreover, fine-tuning consistently proves beneficial, with the potential to elevate even underperforming LLMs, like *bloomz-7.1b*, to top-tier performance.

	params(%)	**#GPUs**	**time(hrs)**
No QLoRA	27.40	4	52
QLoRA	0.02	1	10

Table 3: Fine-tuning *xglm-2.9b* with and without QLoRA to achieve the BLEU score of 30.05.[4]Only the self-attention layers are tuned. The rank r for QLoRA approximation is set to 2.

[3]We also report TER in Appendix A.

[4]We train the model without QLoRA for 96 hours in total, and 30.05 is the BLEU score obtained at the best checkpoint.

r	2	4	8	16	32	64	128	256	512
train params(%)	0.02	0.05	0.09	0.19	0.39	0.77	1.53	3.01	5.85
BLEU	31.69	31.72	32.28	32.52	32.80	**33.04**	30.60	30.09	30.31
COMET	0.845	0.846	0.847	0.848	0.849	**0.850**	0.837	0.835	0.836

Table 4: QLoRA fine-tuning results on XGLM 2.9B with various rank r choices. All the weights except for self-attentions are frozen.

5.2 QLoRA vs. No QLoRA

To assess QLoRA's efficacy, we contrast it with the original approach, a more resource-intensive choice: fine-tuning without QLoRA, which excludes both quantization and low-rank adaptation. We train the *xglm-2.9b* model using its native 32-bit precision, necessitating the use of 4 NVIDIA v100s. This is compared against a model fine-tuned with QLoRA set at $r = 2$. For consistency, only the self-attention layers are unfrozen in both models. The comparative results are presented in Table 3.

Achieving a BLEU score of 30.05, the model fine-tuned without QLoRA requires 52 hours across 4 GPUs, totaling 208 GPU hours. In contrast, the QLoRA-enhanced model completes in just 10 hours, marking a 21-fold acceleration and utilizing 1370 times fewer trainable parameters (0.02% compared to 27.4%).

5.3 QLoRA Hyperparameters

We investigate the impact of selecting different ranks for LoRA and the unfrozen parameters for fine-tuning. We present the results for XGLM 2.9B.

5.3.1 Rank r

The rank r of the decomposition matrices influences the number of trainable parameters, with a larger r resulting in more trainable parameters. We assess the performance associated with different choices of r, ranging from 2 to 512, in Table 4, while only unfreezing the self-attention layers.

With $r = 64$, the model attains its optimal performance. However, either reducing or increasing the number of trainable parameters adversely affects the model's performance. Interestingly, when $r = 512$, the performance deteriorates even more than when $r = 2$, despite the fact that the latter converges more quickly due to a smaller number of trainable parameters.

5.3.2 Trainable Parameters

Next, we aim to determine which part of the model should be fine-tuned. To do this, we unfreeze the parameters in different layers of the XGLM 2.9B model. As illustrated in Table 5, we experiment with unfreezing parameters from various layers, including the self-attention layers, embedding layers, fully-connected feed-forward layers, and the LM head layers. The results indicate that fine-tuning only the self-attention layer is sufficient to yield the best performance.

Params	a	a+e	a+e+f	a+e+f+l
BLEU	**31.69**	30.09	30.30	28.39
COMET	**0.845**	0.837	0.834	0.826

Table 5: QLoRA fine-tuning results on XGLM 2.9B with different trainable parameters. *a*: self-attentions; *e*: embeddings; *f*: fully-connected feed-forward layers; *l*: lm head. Rank r is set to 2.

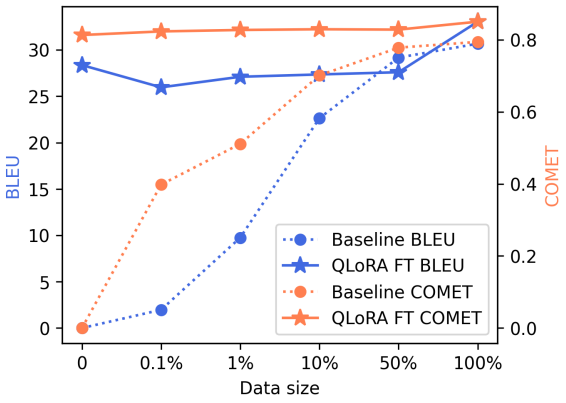

Figure 2: The performance of the *baseline* system and fine-tuned XGLM 2.9B trained with different amounts of data.

5.4 Data Curves

The performance of a traditional MT model is closely tied to the volume of its training data, as highlighted by (Koehn and Knowles, 2017). However, for LLMs, which have already benefited from vast training datasets, does this correlation still hold? To investigate, we compare the responses of both MT model types to varying training data sizes. We incrementally adjust the dataset size from 0.1% (2,366 examples) to its entirety and then train the

Table 7: Few-shot learning results on XGLM 2.9B.

baseline model and fine-tune the LLMs. The outcomes of this experiment are depicted in Figure 2.

The *baseline* curve validates the assumption that performance improves with increased data availability. In contrast, LLMs make a robust debut; even without additional training data, they achieve a BLEU score comparable to the *baseline* trained on half the dataset. Yet, their performance does not consistently improve with more data. In fact, fine-tuning with less than 50% (1.2 million examples) of the data seems counterproductive, diminishing performance until the full dataset comes into play.

5.5 Few-shot Learning

In this section, we evaluate the few-shot learning performance of LLMs. Few-shot learning is also denoted as **K**-shot, with **K** representing the number of examples provided before the query, where in our case, examples are randomly sampled from the training set. We also compare the impact of 5 slightly varied prompts, detailed in Table 6. The results of the experiments are presented in Table 7.

When **K** $>=$ 1, the model consistently outperforms the 0-shot scenario. For *prompt 5*, 1-shot dramatically enhances the model's capability, elevating the BLEU score from 11.82[5] to 28.76. However, the performance does not exhibit a linear growth with increasing **K**; it plateaus. In the case of *prompt 4*, augmenting **K** even diminishes the performance.

In our experiments, the choice of prompt is particularly impactful for 0-shot performance, especially when comparing *prompt 5* to the others. However, this impact seems to lessen when examples are presented before the query.

6 Document-level Translation

In this section, we delve into the proficiency of LLMs in document-level translation. Our primary observations, contrasting the prompted and fine-tuned LLMs, are detailed in Section 6.1. Additionally, we explore the influence of document length, measured by the number of sentences per document, in Section 6.2.

6.1 Main Results

Figure 3 presents the results for document-level translations. Key takeaways include:

[5]We observed many empty generations when prompting with **Prompt 5**. One hypothesis is that the prompt is ambiguous and the model is confused about what to translate.

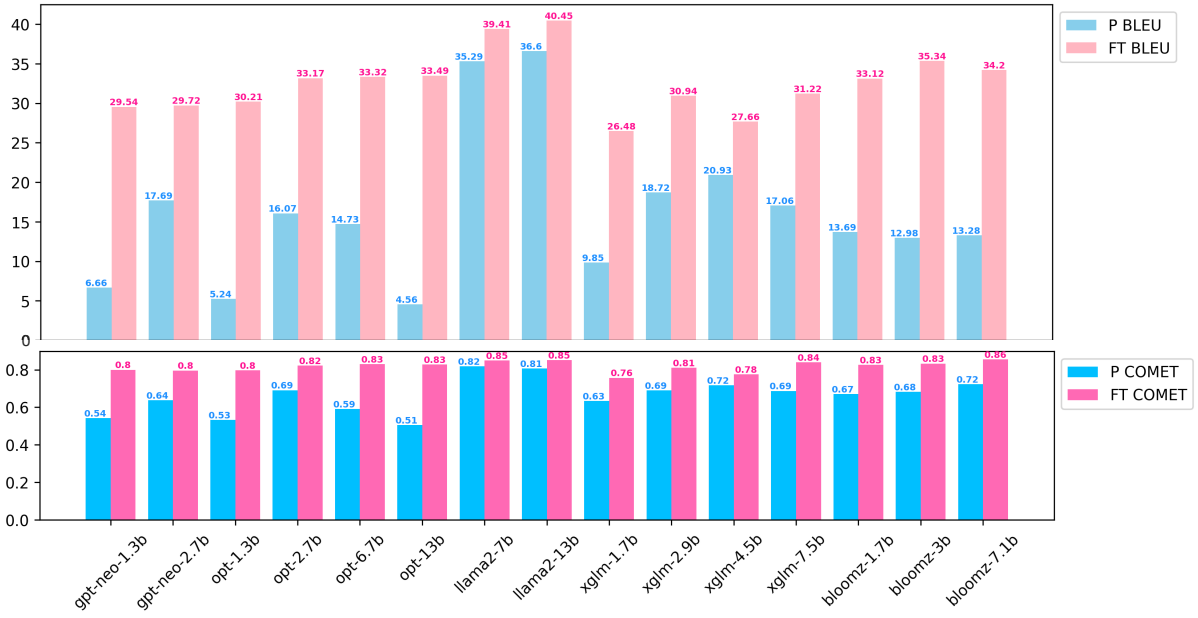

Figure 3: Prompting (*P*) vs. QLoRA fine-tuning (*FT*) on document-level translation using various pretrained LLMs. Rank r for QLoRA is set to 64.

- In contrast to sentence-level translation, prompted LLMs face challenges with document-level translation. 4 out of the 15 LLMs register BLEU scores below 10. However, consistent with sentence-level findings, *LLAMA 2* continues to stand out in zero-shot performance, with the *7b* and *13b* versions achieving impressive BLEU scores of 35.29 and 36.6, respectively.
- Fine-tuning demonstrates significant promise for document-level translations, enhancing the BLEU scores of their prompted counterparts by an average of 16.33. The most notable improvement is seen in *opt-13b*, which witnesses a BLEU increment of 28.93 (from 4.56 to 33.49).
- Unlike sentence-level translation, where COMET scores remain consistent across all models, document-level translation displays a more pronounced variance. This variability is particularly evident in prompted models but diminishes in fine-tuned ones.
- Trends observed in sentence-level translation (Section 5.1) persist in the document-level context: (1) Both English-centric and multilingual models deliver comparable performance. (2) Larger models do not consistently surpass their smaller counterparts. (3) Top-performing models in sentence-level translation, such as *LLAMA 2* and *BLOOMZ*, maintain their dominance in document-level translation.

6.2 Input Lengths

We construct the examples for fine-tuning by merging sentences from an original document, as described in Section 4.4. By varying the number of sentences per document – specifically, 5, 10, and 15 – we present our findings in Table 8. Notably, fine-tuning with sets of 10 consecutive sentences yields the optimal performance, registering a 30.94 BLEU and a 0.811 COMET score.

#sents	5	10	15
BLEU	29.07	**30.94**	28.32
COMET	0.781	**0.811**	0.742

Table 8: QLoRA fine-tuning on documents composed of different numbers of sentences[6]. XGLM 2.9B systems are fine-tuned with $r = 64$, and self-attentions and embeddings as trainable parameters.

7 Qualitative Analysis

Figure 4 shows translations of two French sentences using various LLMs. In the first example, when prompted, *bloomz-7.1b* replicates the source sentence verbatim, neglecting to translate. While this does not occur for every test set sample, as shown in the second example, similar behavior is noted in other prompted LLMs. On the other hand,

[6]We match the length of text documents to that of train documents.

Figure 4: Translations from prompted (**P**) and fine-tuned (**FT**) LLMs.

the translation using *llama2-13b P*, though not mirroring the reference verbatim, retains the original sentence's meaning. Both fine-tuned LLMs produce proper translations with the initial segment of the generated sequences. *Bloomz-7.1b* appends a <eos> token post-translation, while *llama2b-13b* reiterates its translation multiple times. Both outputs necessitate post-processing, specifically truncating the output at the first occurrence of the <eos> token.

In the second example, the LLM-generated translations retain the meaning of the reference translation, showcasing LLMs' potential in the translation tasks.

8 Conclusions

In this study, we investigate the capabilities of LLMs in performing machine translation tasks. Through comprehensive experiments, we assess the effectiveness of prompting, few-shot learning, and fine-tuning using QLoRA for French-English translation. Our key findings are:

1. The proficiency of LLMs in machine translation varies. While **LLAMA 2** consistently outperforms its counterparts, other models, when relying solely on few-shot learning, often lag behind models trained from scratch.
2. Fine-tuning invariably enhances performance, particularly for models that struggle with few-shot learning and for translating documents. It can transform a seemingly inadequate model into a top-tier translation model, as seen with *bloomz-7.1b*.
3. QLoRA, due to its efficiency, can be a superior alternative to original fine-tuning methods.
4. Fine-tuning LLMs with QLoRA can be a promising and new paradigm for machine translation practice.

In the future, we are interested in exploring two primary avenues. (1) While our current study demonstrates the promise of LLMs trained on English-centric data for French-to-English translations, it raises intriguing questions: Would these results hold true for other language pairs, especially for low-resource languages? And would there be a noticeable difference in performance between English-centric and multilingual LLMs in such scenarios? (2) Our experiments are confined to decoder-based LLMs. Moving forward, we are also interested in comparing these models against their encoder-decoder counterparts, such as mT5(Xue et al., 2021), mBART (Liu et al., 2020), NLLB (Costa-jussà et al., 2022).

Limitations

Single dataset and language pair Our experiments are confined to a single dataset and the French-English language pair. It remains unclear if our findings are generalizable to other datasets and language pairs.

Medium-sized LLMs We have only experimented with medium-sized LLMs due to computational resource constraints. The necessity of fine-tuning for significantly larger LLMs remains an open question.

A TER on Sentence-level Translations

The Translation Edit Rate (TER) is a metric introduced by Snover et al. (2006) to quantify the amount of human editing required to align a system's output with a reference translation. Specifically, TER is calculated as the ratio of the total edits made to the length of the reference translation. Such edits encompass insertions, deletions, single-word substitutions, and shifts in word sequence. A lower TER indicates better alignment with the reference. As illustrated in Figure 5, when evaluated using TER, LLMs do not exhibit a noticeable improvement over the baseline model.

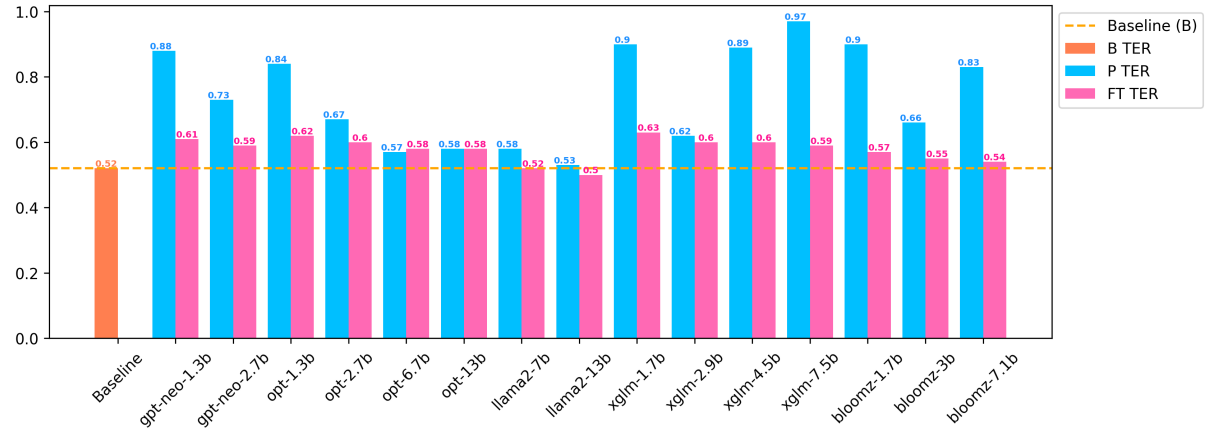

Figure 5: Prompting (*P*) vs. QLoRA fine-tuning (*FT*) on sentence-level translation using various pretrained LLMs. *Baseline* is the NMT system described in Section 4.2. Rank r for QLoRA is set to 64.

Towards Effective Disambiguation for Machine Translation with Large Language Models

Vivek Iyer **Pinzhen Chen** **Alexandra Birch**
School of Informatics, University of Edinburgh
{vivek.iyer, pinzhen.chen, a.birch}@ed.ac.uk

Abstract

Resolving semantic ambiguity has long been recognised as a central challenge in the field of Machine Translation. Recent work on benchmarking translation performance on ambiguous sentences has exposed the limitations of conventional Neural Machine Translation (NMT) systems, which fail to handle many such cases. Large language models (LLMs) have emerged as a promising alternative, demonstrating comparable performance to traditional NMT models while introducing new paradigms for controlling the target outputs. In this paper, we study the capabilities of LLMs to translate "ambiguous sentences" - i.e. those containing highly polysemous words and/or rare word senses. We also propose two ways to improve their disambiguation capabilities, through a) in-context learning and b) fine-tuning on carefully curated ambiguous datasets. Experiments show that our methods can match or outperform state-of-the-art systems such as DeepL and NLLB in four out of five language directions. Our research provides valuable insights into effectively adapting LLMs to become better disambiguators during Machine Translation. We release our curated disambiguation corpora and resources at https://data.statmt.org/ambiguous-europarl.

1 Introduction

While the field of NMT has advanced rapidly in recent times, the disambiguation and translation of ambiguous words still remain an open challenge. Notably, Campolungo et al. (2022) created a benchmark named DiBiMT to study the behaviour of state-of-the-art (SOTA) NMT systems when translating sentences with ambiguous words.[1] They reported that even the best-performing commercial NMT systems yielded accurate translations only 50-60% of the time,[2] while other open-source multilingual models like mBART50 (Tang et al., 2021) and M2M100 (Fan et al., 2021) performed much worse. This was found to be due to biases against rare and polysemous word senses inherited during pretraining. Table 1 shows an example from the DiBiMT benchmark where DeepL[3] mistranslates an ambiguous word while the LLM BLOOMZ resolves the word to its correct in-context meaning.

Source	The horse had a blaze between its eyes.
DeepL	那匹马的两眼之间有一团火焰。 (There is a flame between the horse's eyes.)
BLOOMZ (176B)	这匹马的眼睛之间有一道白线。 (There is a white line between the horse's eyes.)

Table 1: An example of English-to-Chinese translation involving an ambiguous term "blaze". For BLOOMZ, we use 1-shot prompting to obtain the translation.

In this paper, we explore whether LLMs can indeed perform better at translating "ambiguous sentences" – i.e. those containing highly polysemous and/or rare word senses. The motivation behind this is that while NMT models can potentially learn biases from noisy or narrow domain parallel data, hurting their ability to detect and translate rare word senses, LLMs can potentially be pretrained on a wider variety of monolingual text – though they might also prefer fluency over accuracy. Still, LLMs have shown many emergent abilities due to scale (Brown et al., 2020; Chowdhery et al., 2022; Wei et al., 2022a) and moreover, have demonstrated great potential for Machine Translation (MT) (Vilar et al., 2023; Zhang et al., 2023).

We comprehensively examine how these trends extend to the specific task of translating ambiguous sentences. We select a diverse set of foundational and instruction-tuned LLMs, of different

[1] https://nlp.uniroma1.it/dibimt/public/leaderboard

[2] Subsequent iterations of these commercial models have improved, but large margins still remain.

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 482–495
December 6–7, 2023.

sizes and with varying combinations of languages in the pre-training data. We then compare how these LLMs match up against several widely used NMT models on the DiBiMT test set, which covers translation from English to five languages: Spanish, Italian, German, Russian and Chinese. We find that, with only 1-shot in-context learning (Brown et al., 2020), LLMs – in particular, BLOOMZ 176B (Muennighoff et al., 2023) and LLaMA 65B (Touvron et al., 2023) – match or outperform top-performing open-source and commercial MT systems, and set a new SOTA in two of the five languages we tested. Furthermore, we propose two methods for adapting LLMs for ambiguous translation: 1) in-context learning with sentences having the same word sense, and 2) fine-tuning on curated ambiguous parallel corpora. We show that these methods are highly effective and can further improve performance by up to 15 points in DiBiMT accuracy in the best case.

Our work thus makes three key contributions:

1. We evaluate the performance of LLMs compared to top-performing NMT systems in the challenging task of translating ambiguous sentences. We report SOTA scores on 2 of the 5 languages tested, and comparable performance otherwise.

2. We also show that our suggested techniques of similar sentence in-context learning and targeted disambiguation fine-tuning significantly outperform naive few-shot prompting

3. We conclude our work by evaluating LLMs on the FLORES200 test sets, and confirm that improvements in disambiguation accuracy correlate strongly with those in overall MT quality.

2 Background

2.1 Ambiguity in machine translation

Resolving ambiguity in the source sentence was historically framed as one of the most fundamental challenges in MT (Weaver, 1952). In an effort to address this challenge, traditional works integrating Word Sense Disambiguation in Statistical Machine Translation (Carpuat and Wu, 2007; Chan et al., 2007) were followed by those integrating it in NMT architectures in various ad-hoc ways (Choi et al., 2017; Liu et al., 2018; Pu et al., 2018). Later, with the introduction of the Transformer (Vaswani et al., 2017), it was shown that higher layer encoder representations are robust enough to handle disambiguation (Tang et al., 2019) without any explicit handling of word senses.

However, more recent research creating challenging evaluation benchmarks has called the purported abilities of NMT systems into question once again. Following the proposal of the MuCoW benchmark for testing WMT19 (Raganato et al., 2019) and WMT20 (Scherrer et al., 2020) systems, Raganato et al. (2020a) showed how Transformer-based NMT models, in general, underperform when translating rare word senses. Campolungo et al. (2022), who experimented with SOTA commercial (Google Translate, DeepL) and open-source systems (mBART50, M2M100, OPUS-NMT (Tiedemann and Thottingal, 2020), etc.), arrived at the same conclusion when they proposed the DiBiMT benchmark for evaluating MT systems between English and 5 languages (Spanish, Italian, German, Russian, and Chinese). They found similar biases against low-frequency and highly polysemous word senses. They also noted the accuracies of these systems were much lower than the then SOTA WSD system, ESCHER (Barba et al., 2021) – indicating significant room for improvement. In this work, we explored whether foundational and instruction-tuned LLMs could bridge this gap with minimal supervision (i.e. few-shot prompting).

2.2 LLMs and machine translation

Previous research has found that LLMs can perform machine translation without being specifically fine-tuned (Radford et al., 2019). In order to elicit a translation, research in this direction follows the paradigm of LLM prompting:

1. Zero-shot prompting, where an LLM is directly asked to translate a source input into the target language (Radford et al., 2019).

2. Few-shot prompting, also called in-context learning, where an LLM is supplied with demonstrations of input and output pairs from the same task it is performing, before being queried an input (Brown et al., 2020).

3. Chain-of-thought (CoT), where an LLM is prompted to reason to gain relevant knowledge about the input before producing an output (Wei et al., 2022b; Kojima et al., 2022).

Besides training-free approaches, another route is instruction tuning, which optimizes an LLM on a

mixed range of downstream tasks and fine-tunes the model to understand and respond to user intention through natural language (Wei et al., 2021).

It was observed that LLMs might not surpass Transformer models solely trained to translate, especially for non-English and low-resource translation directions (Vilar et al., 2023; Hendy et al., 2023). Nevertheless, LLMs have been shown to achieve superiority in tasks requiring in-depth understanding and manipulation of text, primarily due to them being pretrained on very large corpora. For example, without fine-tuning, LLMs are good at adapting to word alignments (Moslem et al., 2023), translation evaluation (Kocmi and Federmann, 2023), idiom translation (Raunak et al., 2023), iterative refinement (Chen et al., 2023), and interactive translation via CoT (Pilault et al., 2023; He et al., 2023). Related to our work is Pilault et al. (2023)'s proposal of using interactive question answering as a CoT process for LLMs to disambiguate source words. As an alternative approach, we aim to generate translations in a single pass by leveraging SOTA WSD systems to provide contexts that guide LLMs to disambiguate better.

3 Methodology

3.1 Preliminaries

A word sense is a concept in a Knowledge Base (in this work, BabelNet by Navigli et al. (2021)) that denotes a distinct meaning of a word in the context of a sentence. The polysemy degree of an ambiguous word is defined as the total count of all possible senses that a particular word can have. The sense frequency is defined as the occurrence count of that particular sense in a disambiguated training corpus.

In this work, we define an ambiguous word as a polysemous term with multiple possible, and likely related, meanings – with the correct sense inferable only from the sentence-level context. We then refer to a sentence with an ambiguous word as an "ambiguous sentence" for brevity and ease of explanation. By definition, the DiBiMT test set (Campolungo et al., 2022) contains only one ambiguous word per sentence.

Word Sense Disambiguation (WSD) is the process of linking an ambiguous word in a sentence to its appropriate word sense in the Knowledge Base. We use ESCHER-WSD (Barba et al., 2021) in this work, a high-performing WSD system that had achieved the SOTA for English.

3.2 *K*-shot prompting

Given a test sentence X and a Large Language Model to prompt for translations, we construct a query with k demonstrations, i.e. parallel sentence pairs $\{(X_1, Y_1), (X_2, Y_2) \dots (X_k, Y_k)\}$ as examples, followed by the test sentence. As shown in Figure 1, for foundation LLMs, we frame the prompt as a text completion task, while for instruction-tuned LLMs (like BLOOMZ) we structure the last phrase as a question, in order to conform to the latter's question answering format. In the naive setting, we choose our demonstrations randomly from the development set.

3.3 In-context learning with similar ambiguous contexts

LLMs can effectively gain knowledge relevant to the test domain through prompting, and this process is named in-context learning (ICL). We leverage ICL to help LLMs ingest information on translation of ambiguous sentences, by providing related sense translations as examples in the prompt. To achieve this, we first identify the most polysemous word in the input sentence by disambiguating it with a WSD system, and then calculate the polysemy degree of all disambiguated senses with respect to a large development set. We choose the most polysemous word sense[4] and search for other occurrences of the same sense in the same development set. Finally, we randomly sample k source-target pairs including such a sense to use as demonstrations in k-shot prompting, instead of using random pairs. This technique seemed to return enough examples for our purposes in most cases – for 5-shot prompting, given a corpus of 1.8M sentences, we observed that we got all 5 matches 92.5% of the time.

3.4 Low-rank fine-tuning

Apart from providing relevant examples through prompting, another conventional approach is to optimize the model parameters in a domain adaptation fashion for disambiguation. Considering the computational cost, our work experiments with instruction fine-tuning via low-rank adaptation (LoRA). This technique appends trainable lower-rank decomposition matrices to giant matrices in an LLM

[4]Currently, we only explore the case of one ambiguous word per sentence, due to the nature of the benchmark. One could extend our approach to multiple ambiguous words by separately sampling examples for each polysemous word and conducting higher-shot prompting - but further research would be needed to find the optimal way to combine these examples.

```
Translate the following sentence from {src_lang} to {tgt_lang}: {src_demo_1}
The translation in {tgt_lang} is: {tgt_demo_1}
                              ⋮
                              k demonstrations
                              ⋮
Translate the following sentence from {src_lang} to {tgt_lang}: {src_demo_k}

that can remain frozen during fine-tuning (Hu et al., 2021). By sacrificing a little performance, this fine-tuning method achieves great parameter efficiency. We aim to adjust LLMs to perform the translation task specifically. In order to maximise an LLM's capability to disambiguate when translating, we follow a careful data selection procedure to identify the most ambiguous sentences in our corpus.

Given the size of LLMs, it would be infeasible to fine-tune them on a large parallel corpus, so we opt to curate a smaller dataset that suits the ambiguous translation task. We would like a balanced mix of sentences with highly polysemous words as well as those with rare senses of a given word. This is to ensure fine-tuning reduces both polysemy degree-related and sense frequency-related biases, as discovered by Campolungo et al. (2022) and consequently, maximises disambiguation performance. We, thus, sort our corpora in two ways: one, by the maximum polysemy degree (greatest first) and two, by the minimum sense frequency (rarest first) of all word senses in a given sentence, disambiguated with ESCHER-WSD. We take the top $N/2$ sentences from each set and interleave them to create our final fine-tuning corpus of size N. We release our fine-tuning corpus, along with the ESCHER-WSD disambiguation outputs for public use.[5]

Once the data is chosen, we follow the fine-tuning paradigm of Alpaca (Taori et al., 2023): the model is prompted with an instruction specifying the source and target languages, as well as the test sentence as an input, and the model is expected to respond with the translation.[6]

4 Experiments

In this section, we seek to answer the following research questions:

1. **RQ1:** How do LLMs perform at translation of ambiguous sentences compared to traditional high-performing NMT systems? (Section 4.3)
2. **RQ2:** What methods could one use to adapt LLMs for this task and improve performance over naive few-shot prompting? (Section 4.4)
3. **RQ3:** How do these disambiguation-adapted LLMs fare in terms of overall translation quality? (Section 4.5)

4.1 Models

To ensure reproducibility, we pick four well-known and high-performing open-source LLMs,[7] of which we sample seven versions for experimentation:

- BLOOM (Scao et al., 2022): A fully open-source, multilingual, foundation LLM that supports 46 languages. To establish the range of its capabilities, we explore both the smallest (7.1B) and the largest (176B) versions.
- BLOOMZ (Muennighoff et al., 2023): BLOOM instruction-tuned on a multilingual prompting set. Again, we choose the smallest (7.1B) and the largest (176B) versions.
- LLaMA (Touvron et al., 2023): The popular LLM trained by Meta AI, on gigantic datasets ranging up to 1.5T tokens. We evaluate the smallest (7B) and the largest (65B) versions.

[7] at the time of experiment formulation

- Alpaca (Taori et al., 2023): A LLaMA model instruction-tuned on a 52K dataset generated using Self-Instruct (Wang et al., 2023).

To effectively position these open-source LLMs against traditional NMT systems, we compare them against the best-performing and the most widely used commercial and open-source models:

1. DeepL Translator[8]: a SOTA commercial NMT system (accessed on 24th July 2023).
2. Google Translate[9]: Probably the most widely used commercial NMT system (accessed on 24th July 2023).
3. OPUS (Tiedemann and Thottingal, 2020): Small, bilingual, Transformer-based NMT models trained on the OPUS parallel corpora.
4. mBART50 (Tang et al., 2021): Multilingual NMT models pretrained on monolingual corpora from 50 languages, and fine-tuned on the translation task. We report performances of both the English-to-many and many-to-many fine-tuned models.
5. M2M100 (Fan et al., 2021): A massive multilingual NMT model that was trained on 2200 translation directions to support many-to-many translation among 100 languages in total. We compare both the base (418M) and the large (1.2B) versions.
6. NLLB-200 (NLLB Team et al., 2022): It is the current SOTA in many low-resource pairs, scaling to 200 languages. We experiment with all its variants, where the largest is a mixture-of-experts (MoE) model with 54B parameters. We also benchmark its smaller checkpoints at 1.3B and 3.3B, as well as distilled versions at 0.6B and 1.3B.

We take the results for mBART50, M2M100, and OPUS directly from the DiBiMT leaderboard.[10] We use Hugging Face[11] for accessing and inferencing all other models – except for Google Translate and DeepL, which are accessed using their respective APIs. Despite their presence on the leaderboard, we re-evaluate these systems since they are being constantly updated.

Fine-tuning corpus	100K	100K

Table 2: Statistics of data used in our experiments, in terms of parallel sentence count.

4.2 Experimental setup

Datasets In this study, we use the DiBiMT test set for evaluation and measure accuracy across all five translation directions: English to Spanish, Italian, Chinese, Russian, and German, respectively. For validation, we use the development set from FLORES 200 (NLLB Team et al., 2022) in our base setting. To search for similar ambiguous contexts (Section 3.3), we require a larger development set to find relevant examples and also to accurately estimate polysemy degree. Hence, we use the Europarl corpus (Koehn, 2005), disambiguated with ESCHER-WSD. We also use the same disambiguated corpus for fine-tuning, however, we first follow the filtering procedure described in Section 3.4 to create a small corpus full of ambiguous sentences. Validation during fine-tuning is done using 500 randomly sampled sentences from this corpus and the rest is used for training. We detail the data statistics used for these experiments in Table 2.

LLM prompting setup Due to memory constraints, and to compare all models fairly, we load LLMs in 8-bit and use a batch size of 1. For generation, we set both beam size and temperature to 1. To prevent repetition in LLM output, we set `no_repeat_ngram_size` to 4. From the LLM's response, we filter out the sentence before the first newline character as the output translation.

LoRA fine-tuning We inject LoRA modules into all query, key, and value matrices. We set rank to 8, alpha to 8, and dropout to 0.05. For training, we set the effective batch size to 32, the learning rate to 3e-4, and the maximum length to 256. The total training budget is 5 epochs, and we pick the best model checkpoint based on cross-entropy loss on the validation set. The training data is shuffled after every epoch. Inference is done with a beam size of 3, and a maximum generation length of 150.

4.3 LLMs vs NMT systems on DiBiMT

We show our results in Table 3. For the subsequent discussion, we note that LLaMA was not intentionally trained on Chinese and is, thus, an 'unseen'

Table 3: Accuracies on DiBiMT test for establish NMT systems and LLMs, using naive k-shot prompting. For Alpaca, we can only use 0-shot prompting due to its particular prompt template. We highlight the top three scores per language in bold, with the best underlined as well, the 2nd best as is, and the 3rd best italicized. We indicate scores for unseen languages (ie. not intentionally included in pretraining) with a †.

language. Similarly, for BLOOM, Chinese and Spanish are "seen" and the rest are "unseen". We share our key observations below:

1. **LLMs usually match or beat massive MT models on seen languages.** Except for the very rich-resourced En-De, where supervised MT systems appear to have an edge, LLaMA 65B mostly matches the SOTA NMT systems (namely DeepL and NLLB-200). Furthermore, BLOOMZ sets a new SOTA in its seen languages, Spanish and Chinese, and outperforms DeepL by margins of 7.3% and 12.2% respectively. These improvements against such strong, supervised massive NMT systems are particularly remarkable since our corresponding setup for inferencing the LLMs is quite cheap – as we noted previously, this is only naive few-shot prompting of an 8-bit quantized model, with a beam size of 1.

2. **LLMs perform relatively worse for unseen languages, but they can still be much better than some supervised MT models.** We note that relative to seen languages, LLaMA underperforms in translation to Chinese. Similarly,

BLOOM performs worse for its' unseen languages of German, Italian, and Russian. Still, LLMs yield reasonable performance here that is still much better than some supervised NMT systems. For example, BLOOMZ-7B achieves 40.68% accuracy in English-Italian, which is about 35.9% more than OPUS, 52.8% more than mBART50 and 75% more than M2M100-1.2B. While NLLB-200 does outperform BLOOMZ-7B, our results just highlight the power of pretraining at scale.

3. **Scale helps improve performance for ambiguity translation**. Continuing from the last point, similar to NMT models that improve with scale (e.g. NLLB-200), we observe that LLMs too perform consistently better at ambiguous translation on scaling up to their larger variants. This applies to the translation of both seen and unseen languages. That said, the lighter models, such as LLaMA 7B or BLOOM 7B, also perform quite well and in many cases, 1-shot prompting of these LLMs is almost as good as NLLB translations.

4. **LLM performance does improve on average with more demonstrations, but this is not uniform.** On average, we observe that 5-shot prompting works best, followed by 3-shot and then 1-shot, though some outliers exist for LLaMA 7B. Moreover, when looking at the performance of individual language pairs, we note that the improvement trend is not uniform, and it is possible a 3-shot translation outperforms a 5-shot one. This aligns with the finding of Zhang et al. (2023), who reach the same conclusion regarding overall MT quality. Nonetheless, as we show in Section 4.4.1, accuracy does significantly improve when we provide relevant and helpful examples – suggesting quality of demonstrations matters more than quantity.

5. **General-purpose instruction-tuned LLMs consistently outperform foundation LLMs.** Interestingly, we observe that 1-shot prompting of a general-purpose instruction-tuned LLM like BLOOMZ often significantly outperforms 5-shot prompting of BLOOM, even on the very specific task of ambiguity translation. In fact, even with 0-shot prompting, models like Alpaca 7B, BLOOMZ 7B and BLOOMZ 176B perform reasonably well, matching some supervised MT systems. We observed that this did not work for foundation LLMs like BLOOM 165B and LLaMA 7B, and 0-shot prompting of these models yielded hallucinations in many cases.

Lastly, we include a qualitative comparison of DeepL and BLOOMZ 176B translations for the En-Zh pair in the Appendix (see Table 8) – where we observe that BLOOMZ generates more contextual translations, relatively speaking, while its counterpart tends to translate literally in many cases.

4.4 Adapting LLMs for ambiguous MT

This section reports experiments with two proposed strategies to enable LLMs to disambiguate better and improve performance on the ambiguous translation task. While both methods are shown to significantly improve performance, we include a discussion of the relative tradeoffs between the techniques in Appendix A.2.

4.4.1 Improving In-Context Learning by leveraging similar ambiguous contexts

Rather than selecting our examples randomly as in our naive setting, we employ the data selection procedure described in Section 3.3 to discover other examples that contain the same word sense as the most polysemous sense in the input sentence. We report our scores in Table 4, and our findings below:

1. **Similar contexts yield more improvements as the example count increases** We observe that for 1-shot prompting, similar contexts perform comparably or slightly better than random examples. However, the gains increase substantially as we move towards 3-shot and 5-shot prompting. We can understand this from the intuition that 1-shot prompting likely just guides the LLM towards generating a reasonable translation, whereas with more relevant examples, it learns to disambiguate better and translate in context accordingly.

2. **Larger models observe greater and more consistent gains than smaller LLMs** Compared to LLaMA 7B, the other LLMs (LLaMA 65B, BLOOM 176B and BLOOMZ 176B) yield much larger accuracy improvements on a more uniform basis. This is probably because scaling up allows LLMs to model polysemous words better in their semantic space, facilitating effective in-context learning of disambiguation capabilities.

(b) English-Italian

Table 4: 1-shot, 3-shot and 5-shot results for En-Es and En-It prompting with randomised examples (`Rand.`) versus similar contexts (`Sim.`). The best-performing systems from Table 3, i.e. DeepL and NLLB-200 are chosen as baselines. For LLMs, for each setting, the better-performing baseline between `Rand.` and `Sim.` is highlighted in bold. The overall best score (among all LLMs) is underlined as well, while the best NMT system is also italicized.

4.4.2 Fine-tuning with ambiguous corpora

We fine-tune Alpaca 7B, BLOOM 7B and BLOOMZ 7B in En-Es and En-It directions using the data described in Section 4.2. We show our results when prompting these fine-tuned LLMs in Table 5. We make the following observations:

1. **Fine-tuning generally improves performance.** We observe that fine-tuned LLMs significantly outperform their non-finetuned versions in most cases. The biggest improvement is observed for BLOOM 7B in En-It, where accuracy increases by as high as 47.73%, indicating the effectiveness of our method. The only exception to this is when the LLM is already strong, such as BLOOMZ 7B at En-Es, and then the improvements are marginal. But even so, strong instruction-tuned LLMs like BLOOMZ still gain significantly from fine-tuning on the En-It pair – where it was originally weaker due to Italian being an unseen language during pretraining.

2. **Best Cross Entropy does not necessarily translate to best disambiguation accuracy.** Looking at Table 5, we note that the checkpoints with the best cross-entropy fall short of the topline with the best DiBiMT accuracies, suggesting the former is not an optimal metric for this task. Future work could benefit from using disambiguation-specific metrics for validation, leveraging other ambiguous test sets like MuCoW (Raganato et al., 2020b).

3. **Fine-tuning for 2-3 epochs is sufficient.** We plot the DiBiMT accuracy versus epoch curves in Figure 2 where the performance is evaluated after each epoch. We observe that in all cases, accuracy peaks between the 1st and the 3rd epoch, after which it mostly plateaus or dips slightly - suggesting that one does not need to fine-tune these LLMs for too long.

4. **Fine-tuning improves LLM performance until about 65K training samples.** We now try to answer the Research Question of how many training samples we need for fine-tuning these LLMs, to get optimal performance. We plot the Accuracy vs corpus size graph in Figure 3, where we indicate corpus size by the number of parallel sentences. We observe that accuracy increases non-monotonically with an increase in corpus size, but peaks anywhere between 36K-63K training samples, which seems to depend on the pre-existing capabilities of the LLM. For a raw foundation LLM like BLOOM 7B, relatively more fine-tuning data (54K-63K) appears to be beneficial. Alpaca 7B, which has been instruction-tuned on an English-only dataset, also seems to benefit from further fine-tuning—especially for En-Es, accuracy peaks after 63K training samples. However, for a powerful LLM like BLOOMZ that has been instruction-tuned on a large multilingual dataset like xP3 (Muennighoff et al., 2023), fine-tuning on smaller datasets (at most 36K sentences, in our case) appears to suffice.

4.5 Overall MT performance of disambiguation-adapted LLMs

Lastly, for completeness, we evaluate the overall translation quality of the key LLMs used in this work, since we are interested in noting how well the reported disambiguation accuracies extend to overall MT performance. For our test set, we want to choose one recently released (ideally within the

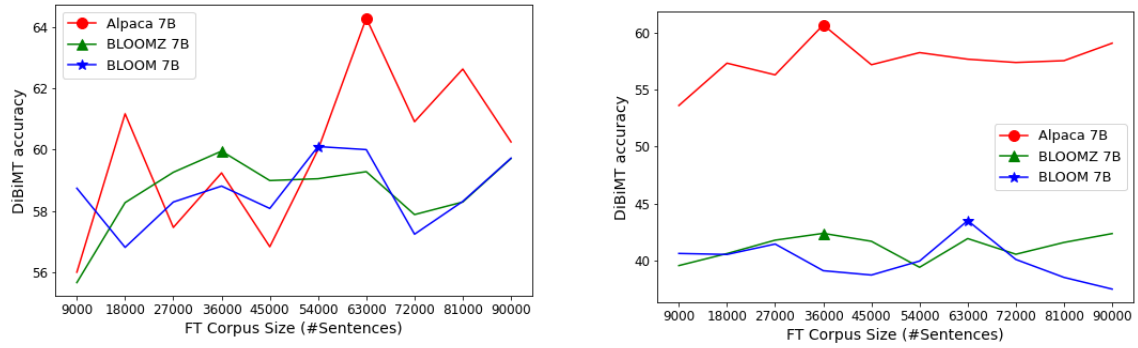
Figure 2: DiBiMT accuracy at the end of every epoch, for the LoRA fine-tuned LLMs



(a) English-Spanish (b) English-Italian

Figure 3: DiBiMT accuracy vs fine-tuning (FT) corpus size in terms of parallel sentence count. These results are obtained from evaluating checkpoints at every 300 steps in the 1st epoch - which roughly corresponds to about 9K sentences, since we use a batch size of 32.

last year) to minimize the chances of its inclusion in the pretraining corpora of LLMs. We, thus, use FLORES 200 (NLLB Team et al., 2022) as our test set since it satisfies this criterion and also supports all our languages of evaluation. We use spBLEU[12] (Goyal et al., 2022), chrF++[13] (Popović, 2017) and COMET22 (Rei et al., 2022) using the `wmt22-comet-da` model as metrics. In this setting, we evaluate Alpaca with 0-shot prompting, while LLaMA 7B, LLaMA 65B and BLOOM 176B use the 1-shot setup. NLLB-200 is our primary supervised NMT baseline. We also evaluate LoRA fine-tuned versions of Alpaca 7B and BLOOM 7B, from section 4.4.2, on the English-Spanish and English-Italian pairs. We exclude BLOOMZ from this evaluation since it is instruction-tuned on FLORES200. We report our results in Table 6.

We observe trends similar to those of our DiBiMT experiments. BLOOM 176B performs well in translation of seen languages, performing comparably to NLLB-200 in English-Spanish and outperforming it in English-Chinese. This is particularly the case for COMET22 scores, a metric which has shown high correlations with human

Table 6: FLORES 200 results for k-shot prompting of some key LLMs used in this work, compared with the NLLB-200 baseline. We also include results for the LoRA fine-tuned models, for the En-Es and En-It pairs. Same as the previous notation, we indicate all unseen language results with a †. We observe similar trends in all standard MT metrics, as those observed with DiBiMT accuracy.

	spBLEU w/ acc.	ChrF++ w/ acc.	COMET22 w/ acc.
ρ	0.83	0.56	0.76
p-value	0.0001	0.0039	0.0010

Table 7: Pearson's correlation ρ (Benesty et al., 2009) between DiBiMT accuracy and spBLEU, chrF++, and COMET22 respectively, together with p-values.

evaluation, ranking second in the WMT22 Metrics shared task (Freitag et al., 2022). For the other languages, LLaMA 65B usually performs better than BLOOMZ, but in the 1-shot prompting setup, it is unable to beat the NLLB-200 54B MOE. We also notice that the fine-tuned versions of Alpaca 7B and BLOOM 7B consistently outperform their vanilla counterparts – suggesting our techniques to improve disambiguation performance also boost overall translation quality.

Thus, while we evaluate key LLMs to verify consistency in trends, we avoid re-running all our baselines on FLORES200. Instead, we try to answer a broader question: how well does DiBiMT disambiguation accuracy correlate with standard MT metrics? We conduct a Pearson's correlation test (Benesty et al., 2009) between the accuracy metric and spBLEU, chrF++, and COMET22 respectively. We report our results in Table 7, and find that all MT quality metrics correlate positively with accuracy—with p-values of the two-sided alternative hypothesis being much lesser than 0.05 in all cases. We discover that spBLEU and COMET22 exhibit higher correlations than chrF++. We hypothesize that this could be due to the character-level chrF++ being less sensitive to word-level senses. Overall, the results of Tables 6 and 7 suggest that the significant accuracy improvements noted earlier are not at the cost of translation quality, and in turn, could yield improvements in overall MT scores too.

5 Conclusion

In this work, we studied the capabilities of LLMs to handle ambiguity during machine translation. We choose seven of the most widely used foundation and instruction-tuned LLMs and compare accuracy with SOTA commercial and open-source NMT systems on the DiBiMT translation benchmark. Out of 5 language directions, we report scores comparable to the SOTA on two (En-Ru, En-It) and set a new SOTA on two others (En-Zh, En-Es). We then present two techniques that significantly improve disambiguation accuracy: in-context learning with similar contexts, and fine-tuning on an ambiguous corpus. We end the paper with an evaluation of overall MT quality. We hope the methods and findings shared in this work could guide future researchers studying ambiguity in translation.

Limitations

In this work, we attempt to note overall trends in LLM performance as compared to conventional NMT systems and, based on our results, suggest methods that generally improve performance. That said, there are exceptions to these trends - prompting with similar contexts can, at times, degrade performance and so can increasing the number of demonstrations (see Table 4). But there is some consistency here too that these observations mostly apply to smaller LLMs (such as LLaMA 7B) while the larger LLMs benefit more significantly. Also, as noted in Section 4.4.1, in a small percentage of cases (7.5%), we are unable to find 5 matches when attempting 5-shot prompting with similar contexts. In such cases, it might be worthwhile, from a performance perspective, to use random demonstrations; nonetheless, since we are interested in verifying the utility of similar contexts and also since there are only a few cases where it might be pertinent, we do not explore this.

Table 8: Manual inspection on English-to-Chinese translation focused on the disambiguation of "head", corresponding to the first five test instances in DiBiMT. The baselines are DeepL and BLOOMZ 176B, the highest performing NMT system and LLM for this pair (from Table 3). The reported annotations are obtained from a native Chinese speaker who was invited to label the sense of the translated ambiguous word.

A Appendix

A.1 Qualitative comparison: BLOOMZ vs DeepL

We choose the best-performing LLM and the SOTA MT system from Table 3 – focusing on the En-Zh pair since LLMs seem to yield the highest gains there. With the help of a native Chinese speaker, we got hypotheses from these two systems annotated, for the first 5 sentences of the DiBiMT test set. We observe that although there are cases where DeepL gets it right over BLOOMZ (example 4) or where both are correct (Example 5), in many instances BLOOMZ appears to generate more contextual (and less literal) translations. We hypothesize that this could potentially be due to the former's powerful language modelling abilities

A.2 Trade-off between prompting and fine-tuning

We show in Section 4.4 that both prompting with similar contexts through In-Context Learning (ICL) and LoRA fine-tuning can significantly improve performance. However, depending on the use case, it might be better to favour one over the other. For instance, in production environments, LLMs that are LoRA fine-tuned on ambiguous text can provide powerful disambiguation performance, while also being more feasible to deploy and run at scale. In contrast, ICL with k-shot prompting, especially for higher values of k, can significantly increase query size and memory consumption, necessitating reduced batch size and thus, throughput.

However, conducting ICL with similar ambiguous contexts can be used to query LLMs as large as LLaMA 65B and BLOOMZ 176B and yield performance comparable to SOTA MT systems (see Table 4). The preprocessing cost overhead of such a method, namely disambiguating the test set, is also low - it took us about 13 seconds to disambiguate a test set of about 500 sentences on 1 Nvidia GeForce RTX 3090. In contrast, the one-time cost of fine-tuning can be quite expensive—for instance, it took us 44 hours to fine-tune an Alpaca 7B with LoRA on a single Nvidia Tesla A100 40G. Thus, in GPU-scarce settings where the costs of LoRA fine-tuning are prohibitive, it might be favourable to use ICL to query massive LLMs and obtain SOTA performances. In contrast, production environments are likely to prefer the fine-tuned LLMs, since the one-off fine-tuning costs can be amortized.

A Closer Look at Transformer Attention for Multilingual Translation

Abstract

Transformers are the predominant model for machine translation. Recent studies also showed that a single Transformer model can be trained to learn translation for multiple different language pairs, achieving promising results. In this work, we investigate how multilingual Transformer models pay attention when translating different language pairs. To achieve this, we first conduct automatic pruning to eliminate a large number of noisy heads and then assess the functions and behaviors of the remaining heads in both self-attention and cross-attention. We find that different language pairs, in spite of having different syntax and word orders, tend to share the same heads for the same functions, such as syntax heads and reordering heads. However, the different characteristics of different language pairs can clearly cause interference in function heads and affect head accuracies. Additionally, we reveal an interesting behavior of the Transformer cross-attention: the deep-layer cross-attention heads work in a cooperative way to learn different options for word reordering, which may be caused by the nature of translation tasks having multiple different gold translations in the target language for the same source sentence.[1]

1 Introduction

For traditional statistical machine translation, such as phrase-based translation (Koehn et al., 2003), the translation process is very clear: source phrases are translated into target phrases according to translation rules and then target phrases are reordered to ensure the fluency of the target sentence. However, in state-of-the-art neural translation models (Bahdanau et al., 2014; Vaswani et al., 2017; Chen et al., 2018), how the model learns to translate is substantially less obvious. The behavior of the Transformer model (Vaswani et al., 2017) remains particularly hazy, as it contains many different self- and cross-attention heads in different layers.

A number of existing studies conducted analyses of functions and behaviors of attention heads in Transformer translation models. Voita et al. (2019b) found that the Transformer attention is noisy, as most of the Transformer heads can be pruned away without significant loss in translation quality. They also identified three important functions of self-attention in the Transformer encoder, such as heads focusing on syntax. Ferrando and Costa-jussà (2021) demonstrated that the cross-attention of the Transformer model frequently attends to uninformative source words to balance the contribution of source and target context for predicting the next word. Chen et al. (2020) showed that some cross-attention heads learn alignment for the current target word, achieving higher accuracies than cross-attention heads that learn alignment for the next target word. However, these methods only analyzed attention in bilingual models, not for multilingual Transformer models.

Multilingual translation, i.e., training a single Transformer to learn translation for multiple different language pairs, has received much attention in recent years and obtained promising results (Wang et al., 2020; Kim et al., 2021; Pires et al., 2023). A number of studies investigated how a multilingual Transformer learns to translate different language pairs. Several of these (Lin et al., 2021; Wang et al., 2020; Xie et al., 2021) learned language-dependent weight masks to identify language-dependent subnetworks. Pires et al. (2023) trained the multilingual Transformer to learn language-specific layers and improved translation quality. Chiang et al. (2022) and Kim et al. (2021) assessed how different language pairs share important heads in multilingual Transformer models.

However, prior work has not yet studied the specific functions and behaviors of different attention heads in multilingual Transformer models. In this

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 496–506
December 6–7, 2023.

paper, we investigate functions and behaviors[2] of both self-attention and cross-attention for multilingual translation. We find that different language pairs with different syntax and different word orders tend to share the same heads for the same functions (such as syntax heads and reordering heads), but the different characteristics of different language pairs can clearly cause interference in function heads and affect head accuracies compared to bilingual models. We further obtain an interesting finding about how the Transformer learns word reordering: different cross-attention heads in deep layers work in a cooperative way to learn different options for reordering. This may result from the fact that there are multiple different gold translations (reorderings) in the target language for the same source sentence[3].

2 Related Work

There are a number of studies on analyzing layer representations of different Transformer layers. Voita et al. (2019a) used canonical correlation analysis and mutual information estimators to study how information flows across Transformer layers for different learning objectives. Kudugunta et al. (2019) used Singular Value Canonical Correlation Analysis (SVCCA) to analyze how representations evolve in a multilingual translation model. Xu et al. (2021b) analyzed how word translation evolves in Transformer layers and showed that translation already happens progressively in encoder layers and even in the input embeddings, by measuring word translation accuracy of different Transformer layers. These methods did not analyze the specific functions of attention heads.

Other prior work analyzed Transformer attention to better understand a particular aspect of the translation process. Tang et al. (2021) analyzed Transformer attention for negation translation and showed that negation is often rephrased during training, which can make it more difficult for the model to learn a reliable link between source and target negation. Tang et al. (2018) analyzed Transformer cross-attention for learning word sense disambiguation (WSD) and showed that cross-attention is likely to distribute more attention to the ambiguous noun itself rather than context tokens, in comparison to other nouns, which suggests that the Transformer learns to encode contextual information necessary for WSD in the encoder hidden states. Additionally, Tang et al. (2018) also noticed that, from shallow layers to deep layers, the cross-attention accuracy for aligning the next target word first increases and then decreases. However, we our study is the first to reveal the cooperative behavior of cross-attention heads.

There is also prior work that studied representation sharing in multilingual translation. Firat et al. (2016) proposed a multiway, multilingual model with language-specific encoders and decoders and showed result quality improvements over models trained on only one language pair. Several authors (Zhang et al., 2021; Bapna and Firat, 2019; Zhu et al., 2021) considered language-dependent gating and adaptation for layer representations. Xu et al. (2021a) proposed parallel encoder and decoder layers with language-dependent weighted layer aggregation. Wang et al. (2019) presented a universal representer to replace both encoder and decoder models to enable parameter sharing between encoder and decoder and they made the representer sensitive for specific languages using language-sensitive embedding, attention, and discriminator. Zhu et al. (2020) incorporated a language-aware interlingua into the encoder–decoder architecture, which enables the model to learn a language-independent representation from the semantic spaces of different languages, while still allowing for language-specific specialization of a particular language pair. Additionally, Shaham et al. (2023) showed that controlling the proportion of each language pair in the training data can balance the amount of interference between languages in multilingual models. Yuan et al. (2023) developed a detachable model by assigning each language (or group of languages) to an individual branch that supports plug-and-play training and inference with a novel efficient training recipe. Xu et al. (2023) investigated how to utilize intra-distillation to learn more language-specific parameters and then showed the importance of these language-specific parameters. However, these methods did not investigate the head functions in multilingual models.

[2]Following Voita et al. (2019b)'s work, we use a weight-based method for analyzing attention head behaviors. It is also possible to use a norm-based method (Kobayashi et al., 2020), which may provide a more detailed interpretation of the inner workings of Transformers compared to weight-based methods in some cases.

[3]In the training data of translation models, it is rather rare that the same source sentence has multiple different translated target sentences, but it is very common that the same source phrase has multiple different translated target phrases. Therefore, translation models are able to learn to translate a source sentence into different target sentences.

3 How Do Transformers Pay Attention for Multilingual Translation?

3.1 Methodology and Experimental Setup

Bilingual Baseline. We used the original Transformer model in its base setting (Vaswani et al., 2017) (i.e., the same model parameters, training parameters and inference parameters) as our bilingual baseline model and conducted translation experiments for six translation directions[4]: German↔English (De↔En), French↔English (Fr↔En), and Romanian↔English (Ro↔En). For each translation direction (such as De→En), we trained a Transformer model using the training data and validation data for this translation direction as shown in Table 2.[5] Following Vaswani et al. (2017), we trained each model for 100k training steps. However, because our training data size for a single translation direction is smaller than in their work, 100k training steps caused overfitting in our models. Therefore we computed the validation loss after each training epoch and then chose the best validation checkpoint for evaluation. Translation results on the test sets are given in Table 1 as R-bi.

Multilingual Translation. For multilingual translation, we trained a single Transformer to learn translation for all six translation directions. We combined all training data in Table 2 together and added a special token at the beginning of each source sentence to indicate which target language we desire the model to generate, following Johnson et al. (2017). We used the same base setting of the original Transformer with 100k training steps for our multilingual model. During training of the multilingual model, we computed the validation loss for the combined validation data after each training epoch and found that the validation loss continuously decreased, so we used the final checkpoint of the multilingual model for evaluation. The evaluation results of the multilingual model are given in Table 1 as R-multi. In the results, we can observe that the multilingual model obtained comparable or higher translation quality compared to our bilingual baseline for different language pairs.

Finetuning. We then finetuned[6] the multilingual model for each translation direction using direction-

[4]We chose these language pairs because parallel sentences with gold-standard word alignments are available (Zhang and van Genabith, 2021) for these language pairs, which can be used to analyze target-to-source attention (alignment).

[5]For subword segmentation, we applied byte pair encoding (Sennrich et al., 2016) and learned a joint vocabulary of size 32k for all languages in our experiments.

[6]Finetuning a multilingual model for a given translation direction (i.e., multilingual pretraining) is very popular for low-resource language pairs and can significantly improve translation quality. We find that finetuning generally did not change the functions of different heads (see Figure 1) but did improve the accuracies of function heads for the given translation direction (see Table 12).

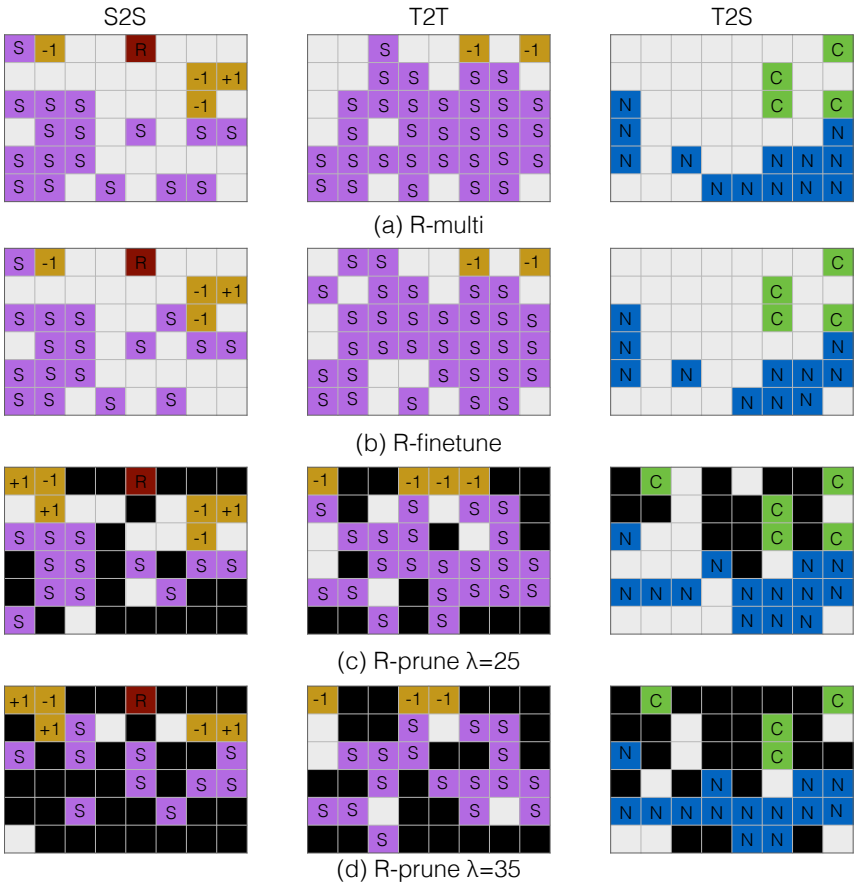

Figure 1: Functional heads (red: rare word head (R); yellow: positional head (-1 and $+1$); purple: syntactical head (S); green: C-alignment head (C); blue: N-alignment head (N)) contained in (a) the multilingual model (R-multi); (b) finetuned models (R-finetune); (c) pruned models with $\lambda = 25$; (d) pruned models with $\lambda = 35$. From left to right, the three columns of figures represent S2S, T2T, and T2S attention. Each figure shows attention heads from the first layer to the last layer (top-down) and each layer contains 8 heads. Black denotes heads that are pruned away.

specific training and validation data.[7] During finetuning, we set the maximum number of finetuning steps to 50k and computed the validation loss after each training epoch, and finally used the best validation checkpoint for evaluation. We found that models for all six directions converged during finetuning (the best validation checkpoint is not the last checkpoint). The results of the finetuned models are given in Table 1 as R-finetune. As shown in Table 1, finetuning a pre-trained multilingual translation model for a specific translation direction can improve the translation quality for the given translation direction (i.e., R-finetune $>$ R-multi). Table 1 also shows that the finetuned models can achieve higher translation quality compared to the bilingual models (R-bi) for all translation directions in our experiments.

Head Pruning. As shown by Voita et al. (2019b), Transformer attention is noisy, i.e., many attention heads carry no important function and can be pruned away without significant loss in translation quality. Following them, we conduct automatic pruning to identify important heads and analyze their functions. For each translation direction, we continue to finetune the already converged model (R-finetune) with a regularization loss (Louizos et al., 2017) along with the original translation loss to prune away useless heads. With the regularization loss, the model learns a 0/1 gate for each head. Heads with a 0 gate are pruned away. A weight λ is assigned to the regularization loss to control the amount of heads to be pruned, i.e., a higher weight for the regularization loss will result in more heads being pruned away. Translation results after head pruning are given in Table 1 and the number of remaining heads for each translation direction is

[7] For example, when we finetuned the multilingual model for the De→En direction, we only used training and validation data with German in the source and English in the target.

	DeEn	FrEn	RoEn	EnDe	EnFr	EnRo

listed in Table 3.[8] At $\lambda = 35$, roughly $2/3$ of all heads were pruned away and the average BLEU only decreased by 0.28. Table 3 also shows that different language pairs tended to share important heads, as most of the remaining heads remained for all six translation directions.

3.2 Head Function Analysis

We analyzed the behavior of the remaining heads to understand their functions.

Source-to-source Rare-word Heads. We find that one source-to-source (S2S) attention head in the first encoder layer tends to attend to the most infrequent word of the input sentence, which agrees with the bidirectional findings of Voita et al. (2019b). The maximum weight of this head is assigned to one of the least two frequent words in the input sentence roughly 30% of the time, as shown in Table 4 for most language pairs. We also find that this behavior of attending to rare words does not occur in target-to-target (T2T) and target-to-source (T2S) attention, as all T2T and T2S heads achieved less than 10% accuracy at attending to the two least frequent words. The S2S rare word head is marked in red in Figure 1.[9]

Self-attention Positional Heads. We find that some self-attention heads in both the encoder and the decoder tend to attend to neighbors ($+1$ or -1 position). We call a self-attention head "positional" if its maximum attention weight is assigned to neighbors at least 80% of the time. For example, if the maximum weight of a head is assigned to the -1 relative position more than 80% of the time, then this head is identified as a positional -1 head, as shown in Figure 1. Table 5 shows positional heads found in the finetuned models (R-finetune). We find that different language pairs generally share the same positional heads, and positional heads only occur in shallow encoder and decoder layers. As shown in Figure 1, positional heads essentially remain unchanged during finetuning. However, during pruning, some positional heads are eliminated and some new positional heads emerge, mostly because positional attention is easy to learn and therefore this function tends to migrate from one head to another during automatic pruning.

nsubj	1	1	2	1
advmod	1	1	1	1
amod	1	-1	-1	1

Table 6: The highest-probability relative distance for different dependency relationships (forward direction).

Self-attention Syntactical Heads. We find that some self-attention heads in both the encoder and the decoder learn syntactical dependencies, i.e., the maximum attention weight is assigned to a syntactically related word of the current word. We call a self-attention head "syntactical" if it learns a dependency relationship with an accuracy at least 10% higher than the baseline accuracy of this relationship. The baseline accuracy of a dependency relationship is the accuracy of a fictional head that always attends to the most likely relative position of this relationship. For example, for the obj dependency relationship in English, the correct dependency typically is encountered at the -2 relative position (38% of cases), which is the most likely relative position for this relationship. Hence, a fictional head that always attends to the -2 relative position will achieve 38% accuracy for this relationship, and 38% can serve as the baseline accuracy for the English obj relationship. For different languages, the most likely relative position of the obj relationship is different, as shown in Table 6. We look at four important dependency relation-

[8] The base Transformer model contains 144 attention heads in total: 48 self-attention heads in the encoder, 48 self-attention heads and 48 cross-attention heads in the decoder. Cross-attention and self-attention in both the encoder and the decoder have 6 layers and each layer contains 8 heads.

[9] Figure 1 shows functional heads identified for at least one translation direction. For example, all syntactical heads identified for different translation directions as shown in Table 7 and Table 9 are marked as S heads in Figure 1. Black heads are heads that were pruned away for all translation directions during automatic pruning.

ships[10]: obj (v→o), nsubj (v→s), advmod (v→a), and amod (n→a). For each of these 4 relationships, we consider both the forward and the backward directions. Ultimately, we thus investigate whether a head learns any of the 8 relationships obj-f, obj-b, nsubj-f, nsubj-b, advmod-f, advmod-b, amod-f, and amod-b. We find a head can learn different dependency relationships, as shown in Tables 7 and 9. The most important dependency relationship learned by the Transformer is obj, as more than half of all syntactical heads mainly learn the obj relationship. Tables 7 and 9 further show that some translation directions share some syntactical heads (e.g., DeEn, RoEn, and EnDe share the

Table 10: Accuracy of C-alignment heads.

S2S "4:2" head for the `obj-f` relationship in Table 7), but not all translation directions share all syntactical heads. For a more direct overview of how different translation directions share syntactical heads, Table 8 gives the accuracy of different S2S heads for the `obj-f` relationship, which clearly shows that the "2:2" head mainly learns `obj-f` for EnDe, EnFr, and EnRo, while the "4:2" head mainly learns `obj-f` for DeEn, FrEn, and RoEn. Meanwhile, the S2S "2:2" head acquires nearly 0 `obj-f` accuracy for the DeEn direction, although this head is the most accurate `obj-f` head for EnDe, EnFr, and EnRo.

Cross-attention C-alignment Heads. We find that some cross-attention heads in the shallow layers learn word alignment for the current target word, i.e., the maximum weight is assigned to the source word aligned to the current target word. If a head achieves more than 80% accuracy for aligning the current target word, we call such a head a "C-alignment" head. When we calculate the alignment accuracy[11], we only consider situations when the current target word is a content word[12], as function words generally do not have clear alignments between different languages. By attending to the contextualized representation of the source word aligned to the current target word, C-alignment heads can help to retrieve the full context of the current target word (both the left-side and right-side context), in contrast to target-to-target self-attention, which can only attend to the left-side context of the current target word. Table 10 gives the accuracy of C-alignment heads in the finetuned models (R-finetune), showing that C-alignment heads generally learn the current word alignment for all translation directions, while the highest-accuracy C-alignment head for different directions may differ.

[11]We use human-annotated word alignments (Zhang and van Genabith, 2021) as the ground truth label for computing word alignment accuracies.

[12]For each language, we judge whether a word is a function word or a content word using a list of stopwords from NLTK, https://www.nltk.org/

5:6	0.66	0.71	0.66	0.68	0.61	0.65

Table 11: Accuracy of N-alignment heads.

Cross-attention N-alignment Heads. We further find that some cross-attention heads in the deep layers learn word alignment for the next target word, i.e., the maximum weight is assigned to the source word aligned to the next target word. As the next word is unknown at the current decoding step, N-alignment heads are rather learning to predict the next target word than just aligning the next target word. Therefore, the N-alignment accuracies are generally lower than the C-alignment accuracies. We identify "N-alignment" heads as heads that achieve more than 70% accuracy for aligning the next word. When we calculate the N-alignment accuracy, we again only consider situations when the next target word is a content word, as before for the C-alignment accuracy. Figure 1 shows that C-alignment heads occur in shallow layers and N-alignment heads occur in deep layers, which indicates that the Transformer decoder appears to first use C-alignment heads to obtain the context of the current target word, and then, based on the context of the current target word, predicts which word to generate next. Table 11 gives the accuracy of N-alignment heads in the finetuned models (R-finetune), which shows that different language pairs generally shared N-alignment heads, which is surprising since the purpose of N-alignment heads is learning word reordering and different language pairs should have different reordering rules. Table 11 also shows that the highest-accuracy N-alignment heads are most likely from the 4th layer, i.e., the N-alignment accuracy first increases and then decreases as the layer number increases.

3.3 Head Behavior Analysis

We provide a further analysis of head behavior by comparing head accuracies in different multilingual and bilingual models. Table 12 gives the highest

Table 12: Highest accuracy for syntactical (obj), C-alignment (C-a), and N-alignment (N-a) heads in different models. $^{\times}$ means the accuracy is not high enough to be identified as function head. △ (▽) means finetuning increased (decreased) the head accuracy (i.e., R-finetune $>$ ($<$) R-multi).

accuracy of different types of function heads in the multilingual and bilingual models. As shown in Table 12, finetuning a multilingual model for a specific translation direction tended to increase accuracies of function heads (e.g., the syntactical obj heads and C-alignment heads) for the given translation direction, which is unsurprising. However, Table 12 indeed shows two interesting head behaviors in multilingual and bilingual models.

Cooperative Behavior of N-alignment Heads. First, we find the highest N-alignment accuracy tended to decrease instead of increasing during finetuning (the average accuracy of N-alignment heads also decreased). The fact that finetuning decreased N-alignment accuracies is surprising, considering N-alignment heads are crucial for predicting the next target word. We hypothesize that this is because N-alignment heads work in a cooperative way. Since there are multiple different gold translations (reorderings) in the target language for one source sentence, the Transformer uses different heads to learn different options for predicting (aligning) the next target word. Thus, the accuracy of a single N-alignment head is less important. Table 13 gives the accuracy of at least one head from the 4th layer (the most important N-alignment layer) correctly aligning the next target word. The results show that when we consider the whole layer, the next word alignment accuracy is fairly high and the layer accuracy generally increased during finetuning. The fact that the accuracy of any individual

R-f	**96.8**	96.8	**96.0**	96.4	95.4	**95.2**

Table 13: Layer accuracy (4th layer) for N-alignment. R-b: R-bi; R-m: R-multi; R-f: R-finetune.

N-alignment head nevertheless tended to decrease during finetuning while the overall N-alignment layer accuracy tended to increase during finetuning indicates that N-alignment heads work in a cooperative way to collect different options for word reordering.

Multilingual Interference for Head Accuracy. Second, we find that, although finetuning generally improved the accuracies of function heads, the finetuned models (R-finetune) still tended to have lower accuracy than the bilingual baseline models (R-bi), especially the C-alignment accuracy and N-alignment layer accuracy for our high-resource language pairs De↔En and Fr↔En, as shown in Tables 12 and 13. This is surprising considering that R-finetune achieved higher translation qualities compared to R-bi, and suggests that language interference tends to cause an accuracy decrease for function heads and can be an important disadvantage of multilingual models compared to bilingual models. Regarding the reason why R-finetune generally had lower head accuracies but higher translation quality compared to R-bi for De↔En and Fr↔En tasks, it could be that the multilingual

pretraining helps the model to learn better representations (word embeddings) for less frequent words via the shared vocabulary.

4 Conclusion

This paper analyzes attention head functions and behaviors in multilingual Transformer translation models. We find that different language pairs, in spite of having different syntax and word orders, tend to share the same heads for the same functions, such as syntax heads and reordering heads. However, the different characteristics of different language pairs clearly cause interference in function heads and affect head accuracies, which can be an important disadvantage of multilingual models compared to bilingual models. Additionally, we reveal an interesting behavior of the Transformer cross-attention: the deep-layer cross-attention heads work in a cooperative way to learn different options for word reordering, which can be caused by the nature of translation tasks having multiple different gold translations (reorderings) in the target language for one source sentence.

Limitations

Our study focuses on models trained for particular source to target language pairs. It covers six translation directions with limited typological diversity in the considered languages, due to the need for ground truth word alignments. In future work, multilingual models covering many more languages with more linguistic diversity can be investigated following our methodology.

Abstract

Position-based token-mixing approaches, such as FNet and MLPMixer, have shown to be exciting attention alternatives for computer vision and natural language understanding. The motivation is usually to remove redundant operations for higher efficiency on consumer GPUs while maintaining Transformer quality. On the hardware side, research on memristive crossbar arrays shows the possibility of efficiency gains up to two orders of magnitude by performing in-memory computation with weights stored on device. While it is impossible to store dynamic attention weights based on token-token interactions on device, position-based weights represent a concrete alternative if they only lead to minimal degradation. In this paper, we propose position-based attention as a variant of multi-head attention where the attention weights are computed from position representations. A naive replacement of token vectors with position vectors in self-attention results in a significant loss in translation quality, which can be recovered by using relative position representations and a gating mechanism. We show analytically that this gating mechanism introduces some form of word dependency and validate its effectiveness experimentally under various conditions. The resulting network, rPosNet, outperforms previous position-based approaches and matches the quality of the Transformer with relative position embedding while requiring 20% less attention parameters after training.[1]

1 Introduction

The Transformer (Vaswani et al., 2017) revolutionized the field of neural machine translation before its wide adoption in numerous other tasks (Dong et al., 2018; Devlin et al., 2019; Chen et al., 2021; Dosovitskiy et al., 2021). Using self-attention (Vaswani et al., 2017), the Transformer computes high-level representations for each token as a weighted sum of the entire sequence, where the weights depend on the pairwise content interactions. However, recent work argues that results similar to the Transformer can also be achieved by modeling self-attention weights based on positional instead of content information (Wu et al., 2019; You et al., 2020; Tolstikhin et al., 2021; Liu et al., 2021; Lee-Thorp et al., 2022). Often, these position-based methods are used with some form of gating mechanism that precedes or wraps the token-mixing operation (Wu et al., 2019; Liu et al., 2021; Kim et al., 2023).

Position-based self-attention alternatives often speed up the computation on commercial computing devices like GPU, but they can become more attractive from the perspective of using memristive crossbar arrays (Chua, 1971; Strukov et al., 2008). Recent advances in analog in-memory computation with memristive crossbar arrays have shown impressive efficiency improvements in the inference of deep learning models (Hu et al., 2018; Wang et al., 2019; Kataeva et al., 2019; Yao et al., 2020; Xue et al., 2021), up to 110 times better energy efficiency and 30 times better performance density compared to a Tesla V100 GPU (Yao et al., 2020). However, such efficiency is obtained by storing weights of matrix-vector multiplications in the device rather than calculating them on the fly, which excludes the possibility of using attention to compute the weight matrix.

With the goal of finding self-attention alternatives for machine translation that can be more easily used with memristive crossbar arrays, we compare existing position-based approaches and observe a significant quality loss when they use no form of gating. Additionally, by scoring with a diverse set of metrics, we show that, even with gating, no existing approach can consistently match Transformer results. While the role of gating to guide the information flow of neural networks is known (Srivastava et al., 2015; Dauphin et al., 2017), its

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 507–521
December 6–7, 2023.

importance for the performance of position-based approaches has yet to be explored.

In this paper, we propose aPosNet and rPosNet, two position-based networks that leverage gating and compute self-attention weights based on the interactions of **a**bsolute and **r**elative position representations. Both differ slightly from the Transformer baseline with relative position embeddings (Shaw et al., 2018), which enables us to deliver insights into gating and its dependency on position information. In summary, we provide the following contributions:

- Analytically, we derive that wrapping the weighted sum of tokens with a gating mechanism introduces latent content-dependent token-mixing weights (Section 3).
- We provide an inference-time matrix precomputation for positional attention that can be easily stored in device (Section 4).
- rPosNet outperforms existing position-based methods and performs on par with the Transformer with relative position embeddings while saving 20% of the self-attention parameters (Section 6).
- We show that increasing the expressiveness of token-mixing weights reduces the usefulness of gating, coherently with the idea that it enables content-based interactions (Section 7.1).
- We observe experimentally that rPosNet is less effective when used in cross-attention. Our gating reformulation suggests one probable reason, but we leave detailed investigations for future work (Section 7.2).

2 Background

Neural machine translation is typically modeled with an encoder-decoder sequence-to-sequence (Sutskever et al., 2014) Transformer, which mainly consists of multi-head attention and feed-forward sub-layers. In the following, we introduce our notation, position-based token-mixing alternatives and the gating mechanism commonly used in modern architectures.

2.1 Multi-head attention

Given a source sequence representation $\mathbf{x} \in \mathbb{R}^{M \times D}$ and target sequence representation $\mathbf{y} \in \mathbb{R}^{N \times D}$, the multi-head attention mechanism (Vaswani et al., 2017) mixes the elements in $\mathbf{x}$ for every element in $\mathbf{y}$. If $\mathbf{y}$ and $\mathbf{x}$ refer to the same sequence, it is called self-attention. The multi-head concept derives from performing the following operations on H parallel splits of the feature dimension D. In this work, we drop the head indices for simplicity of notation. To calculate the unnormalized mixing weight, referred to as attention energy, of y_n and x_m, those are projected into query and key and combined using the dot product:

$$\hat{\alpha}_{nm} := \frac{(W^Q y_n)(W^K x_m)^\top}{\sqrt{D}}. \tag{1}$$

Since $\hat{\alpha}_{nm}$ is computed from token contents, we say that attention captures token-token interactions. The attention weight is then calculated by the softmax normalization of the attention energy:

$$\alpha_{nm} := \frac{\exp \hat{\alpha}_{nm}}{\sum_{m'} \exp \hat{\alpha}_{nm'}}, \tag{2}$$

and used as the token-mixing weight in the weighted sum over projected input tokens $\mathbf{x}$, denoted value vectors:

$$c_n := \sum_m \alpha_{nm} \cdot (W^V x_m). \tag{3}$$

We will refer to the result c_n as context vector. Finally, the context vectors of each head are concatenated and mixed with a linear projection, called output projection.

2.2 Position-based token mixing

We briefly overview how existing position-based token-mixing approaches propose to modify the attention weights and provide the corresponding Equations in Appendix A for comparison.

FNet Proposed for language understanding, FNet (Lee-Thorp et al., 2022) applies a 2D Fourier transform over the spatial and feature dimension of $\mathbf{x}$. However, this formulation performed poorly in preliminary experiments, which is why our FNet implementation, denoted FourierNet, applies a 1D Fourier transform along the spatial dimension and employs value and output projections. We will show in our results that, despite its claimed good quality for natural language understanding, the translation quality achieved by FourierNet is significantly lower than Transformer.

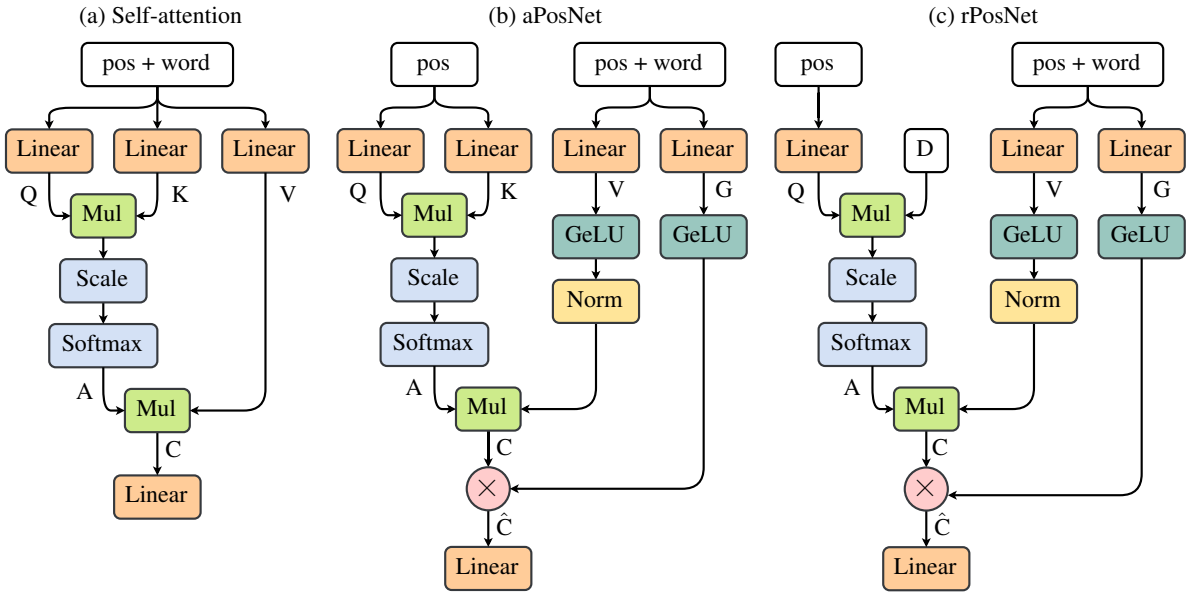

Figure 1: Flowchart representation of (a) self-attention, (b) gated absolute position-based attention (aPosNet), and (c) gated relative position-based attention (rPosNet). While self-attention provides word and position information to queries (Q) and keys (K), we omit word information to calculate the attention weights of PosNet. In rPosNet, we model relative positions using relative position representations (D). In addition, we employ the gating mechanism presented in Section 2.3, which applies GeLU activation and layer normalization on the values (V) and elementwise multiplies the context vector (C) with the GeLU activated gate (G) resulting in the gated context vector (Ĉ).

GaussianNet Proposed for machine translation, You et al. (2020) hardcode self-attention weights as a Gaussian distribution. They report similar performance to the Transformer when GaussianNet is applied for self-attention but a significant degradation if extended to cross-attention.

LinearNet Tolstikhin et al. (2021) propose mixing tokens with a learnable spatial projection, effectively representing α. It has been proposed, together with other architecture changes, for image classification and natural language understanding with minor degradations to the Transformer.

LightConv For machine translation and other tasks, Wu et al. (2019) introduce a lightweight form of depthwise convolution, which shares the kernel weights W across the feature dimension of a head and the outputs while additionally softmax normalizing them.

gLinearNet Liu et al. (2021) combine the spatial projection of LinearNet with the gating mechanism of Section 2.3. They propose their architecture for image classification and masked language modeling and report significant improvements over Tolstikhin et al. (2021).

2.3 Gating mechanisms

Various formulations of gating mechanisms have been proposed to control the information flow in neural networks (Hochreiter and Schmidhuber, 1997; Cho et al., 2014; Srivastava et al., 2015; van den Oord et al., 2016; Dauphin et al., 2017). They all have in common an elementwise multiplication between two vectors where one, the gate, is bounded in the $[0, 1]$ interval. The gating mechanism we consider here has been proven effective with position-based token-mixing approaches (Liu et al., 2021; Kim et al., 2023) and differs from other gating mechanisms in that the gate is GeLU activated (Hendrycks and Gimpel, 2016) and thus only lower bounded. This gating mechanism modifies the weighted sum of Equation 3 by applying layer normalization (Ba et al., 2016) on the value vector $v_m = W^V x_m$ and elementwise multiplying the context vector with the gate $g_n = \sigma_g(W^G y_n)$:

$$\hat{c}_n := \Big[\sum_m \alpha_{nm} \cdot \mathrm{Norm}\big(\sigma_g(v_m)\big)\Big] \odot g_n, \quad (4)$$

where σ_g refers to the GeLU function and $\hat{c}_n$ to the gated context vector. In general, gating can be applied with any formulation of α. However, we will show experimentally in Section 7.1 that its benefits

strongly depend on the information incorporated within α.

3 Reformulating the Gating Mechanism

To better understand the implications of gating, we reformulate Equation 4. We omit layer normalization for simplicity and will show in the Appendix B that the general reformulation is unaffected if we apply layer normalization on v_m. Additionally, we leverage the GeLU approximation $\sigma_g(v_m) \approx v_m \sigma_s(1.702 v_m)$, where σ_s refers to the Sigmoid function, and rewrite Equation 4 as

$$\hat{c}_n \approx \sum_m \alpha_{nm} \beta_{nm} \odot v_m. \tag{5}$$

Equation 5 shows that gating the context vector introduces the latent weights $\beta_{nm} \in \mathbb{R}^D$:

$$\beta_{nm} = g_n \odot \sigma_s(1.702 v_m), \tag{6}$$

which consists of the two independent factors $\beta'_n = g_n$ and $\beta'_m = \sigma_s(1.702 v_m)$. While the multiplication of β'_n and β'_m, in general, allows for token-token interactions, the independence of these factors poses a limitation: for a given query token y_n, the ratio between the weights assigned to x_m and to $x_{m'}$ is independent of y_n:

$$\frac{\beta_{nm}}{\beta_{nm'}} = \frac{\beta'_m}{\beta'_{m'}}. \tag{7}$$

In other words, the ratios of token-mixing weights for a query y_n as computed by β are predetermined by the ratios across $\beta'_{1\ldots M}$. While we show in Section 6 that this limitation is not problematic for self-attention, it may be part of the reason gating and relative position-based attention are not effective in cross-attention (see Section 7.2).

4 Position-based Attention

In this Section, we propose position-based attention, which determines the token-mixing weight connecting tokens x_m and y_n solely based on the position-position interactions between n and m. We pair position-based attention with the gating mechanism of Section 2.3.

4.1 Absolute position-based attention

In absolute position-based attention we compute the attention energy as the dot product between the two projected position embeddings $\tilde{n}$ and $\tilde{m}$:

$$\hat{\alpha}_{nm} := \frac{(W^Q \tilde{n})(W^K \tilde{m})^\top}{\sqrt{D_h}}. \tag{8}$$

While $\tilde{n}$ and $\tilde{m}$ are shared across all layers, W^Q and W^K are layer-specific. We refer to the combination of Equation 8 and the gating mechanism of Section 2.3 with aPosNet.

Pre-computing the attention energies The query and key inputs $\tilde{n}$ and $\tilde{m}$ are independent of the word representations y_n and x_m and are constant after training. Since the attention energy values $\hat{\alpha}_{nm}$ only depend on $\tilde{n}$ and $\tilde{m}$, we can pre-compute $\hat{\alpha}$ and obtain a matrix of the form $(H \times N \times M)$ that can be used during inference. In the following theoretical complexity discussions we set $N = M$ for simplicity of notation.

Theoretical complexity Apart from the gating overhead, aPosNet has similar theoretical complexity as attention. However, by pre-computing $\hat{\alpha}$, we can skip the dot-product and key query projections, reducing[2] the number of parameters from $5D^2$ to $HN^2 + 3D^2$ and the number of operations from $2N^2D + 5ND^2$ to $N^2D + 3ND^2$. We compare theoretical complexities in Appendix C.

Relation to gLinearNet With the pre-computed attention energy matrix, aPosNet becomes similar to gLinearNet except that α of gLinearNet is not normalized and has been trained directly.

4.2 Relative position-based attention

To model position interactions with relative position-based attention, we borrow the relative position representations $\tilde{d}_{nm}$ from Shaw et al. (2018), which we use in the dot product with the projected position embedding $\tilde{n}$:

$$\hat{\alpha}_{nm} := \frac{(W^Q \tilde{n})(\tilde{d}_{nm})^\top}{\sqrt{D_h}}. \tag{9}$$

Similarly to Shaw et al. (2018), the distance embedding $\tilde{d}$ is clipped to a maximum unidirectional context size K:

$$\tilde{d}_{nm} := \text{Embedding}_{\text{rel}}\Big(\text{clip}\big(\lfloor \gamma n \rfloor - m, K\big)\Big). \tag{10}$$

However, in contrast to Shaw et al. (2018), we extend relative position-based self-attention to be compatible with cross-attention by multiplying n with the length ratio $\gamma := \frac{M}{N}$ which we determine similar to You et al. (2020) by measuring the average length ratio on the training set. We refer to the

[2] Typically in sentence-level machine translation we have $N \ll D$.

Table 1: Dataset statistics.

Dataset	Vocab. Size		Train Pairs	Test Pairs	Valid Pairs
	Src	Tgt			
DE→EN	10k		160k	6750	7283
EN→DE	44k		4M	3003	40k
EN→FR	46k		36M	3003	27k
EN→ZH	32k	45k	17M	2001	13k

combination of Equation 9 and the gating mechanism of Section 2.3 with rPosNet. In Figure 1, we illustrate the operations performed by aPosNet and rPosNet in comparison to multi-head self-attention.

Pre-computing the attention energies Similar to aPosNet, we can pre-compute $\hat{\alpha}$ of rPosNet after training, which summarizes the interactions between query and relative position representations into a matrix of shape $(H \times \hat{K} \times N)$, where $\hat{K} = 2K + 1$. While the attention energy matrix of aPosNet grows quadratically with the length of the sequence, rPosNet's matrix grows linearly due to the constant size $\hat{K}$ of the relative position representations.

Theoretical complexity Pre-computing $\hat{\alpha}$ after training reduces the number of parameters from $\hat{K}D + 4D^2$ to $H\hat{K}N + 3D^2$ and operations from $\hat{K}ND + N^2D + 4ND^2$ to $N^2D + 3ND^2$. Inserting the Base model configuration of Section 5 ($D = 2048$, $\hat{K} = 33$) and the maximum sentence length $N = 128$, this pre-computation of $\hat{\alpha}$ saves 23% of attention parameters.

Relation to LightConv After pre-computing $\hat{\alpha}$, rPosNet differs from LightConv in that rPosNet's weights have global context and depend also on the absolute query position, and as such are not shared across y_n. We provide an ablation study in Section 7.3 to understand the importance of these differences.

5 Experimental Setup

5.1 Datasets & evaluation

We perform our comparison on four datasets of varying sizes: IWSLT14 German-English (Federico et al., 2014), WMT14 English-{German, French} (Bojar et al., 2014), and WMT18 English-Chinese (Bojar et al., 2018). We split each dataset into train and validation pairs and evaluate DE→EN models on the test sets TED-{dev10,dev12, test10, tst11, tst12}, EN-{DE, FR} models on newstest14 and EN→ZH models on newstest17. An overview of the dataset statistics is shown in Table 1. We preprocess all datasets using Byte Pair Encoding (BPE) (Sennrich et al., 2016) and lowercase the text for the DE→EN direction.

We report BLEU (Papineni et al., 2002), BLEURT (Sellam et al., 2020), and COMET (Rei et al., 2020) for each evaluation. All scores are calculated on detokenized text. To calculate BLEU scores, we use sacreBLEU[3] and its internal tokenizations[4][5]. For BLEURT and COMET, we use the official implementations[6][7] and the models *BLEURT-20* and *wmt20-comet-da*, respectively. To summarize results, we will refer to the translation quality difference between two approaches as their relative difference averaged across all metrics and datasets.

5.2 Model architectures

Our Base and Big Transformer architectures follow the implementation of Vaswani et al. (2017), whereas, for the Small models, we halve the feed-forward dimension to 1024 and increase dropout to 0.3. We compare position-based token-mixing approaches by leveraging the respective formulations instead of encoder/decoder self-attention while leaving the rest of the Transformer architecture unchanged. We make an exception for FourierNet, which cannot be straightforwardly extended to the decoder because it has an explicit dependency on the sequence length. Instead, FourierNet uses multi-head attention within decoder self-attention.

In preliminary experiments, we found that aPosNet works best with sinusoidal positional embeddings (Vaswani et al., 2017) and rPosNet with learnable embeddings (Gehring et al., 2017). All other position-based token-mixing approaches use sinusoidal positional embeddings. Similar to Shaw et al. (2018), our implementation of rPosNet and LightConv use a unidirectional context window $K = 16$ for the Base and $K = 8$ for the Big model.

5.3 Training setup

Our training setup closely follows the configuration of Vaswani et al. (2017). Similarly, we use

[3] https://github.com/mjpost/sacrebleu

Table 2: Base model results on EN→DE, EN→FR, and EN→ZH. We calculate statistical significance (p-value $\leqslant 0.05$) using paired bootstrap resampling with respect to the Transformer (†) and to Shaw et al. (2018) (‡). Note that this scoring differs from Vaswani et al. (2017) in that they split German compound words, which usually increases the BLEU score, and from You et al. (2020) in that we use sacreBLEU's default tokenizer, not 'intl'. We ensured that our baseline system and reimplementation of You et al. (2020) match in BLEU when evaluating similarly.

the Adam optimizer (Kingma and Ba, 2014) and a warmup learning rate schedule with 4000 steps. We group batches by sentence length and train the Small models for 30k steps, the Base models for 150k, and the Big models for 300k.

The final model is an average over the best checkpoint and its following if there are enough checkpoints to average, or else we take an average over the last checkpoints. We determine the best checkpoint by its perplexity on the validation set. For DE→EN, we consistently average 30 checkpoints with a checkpoint period of 300 steps; for the Base models, we average 7 checkpoints with 1000 steps each; for the Big models, 20 checkpoints with 600 steps each.

The Small models use an effective batch size of approximately 16000 target tokens while the Base and Big models accumulate approximately 27000 target tokens per step. The source and target sentence lengths are restricted to 128 tokens. We use beam search with a beam size of 12 for all models. All models in this work are implemented in PyTorch (Paszke et al., 2019). The Small models are trained on a single 2080 TI graphics card, the Base models on two, and the Big models on four.

6 Results

We compare translation quality of the Base model configurations in Table 2, and Small and Big model configurations in Table 3.

Gated position-based attention In all experiments, we observe rPosNet performing as well or slightly better than the Transformer with an average translation quality increase of 0.7% across

all test sets and metrics. It shows that the self-attention weights of rPosNet, consisting of content-dependent β and position-dependent α, achieve sufficient expressiveness for machine translation. aPosNet cannot match this expressiveness and underperforms the Transformer with an average relative degradation of 1.8%. In the Small setup on DE→EN, this reaches an absolute degradation of 2.9 points in COMET and 0.8 points in BLEURT. The significant difference between aPosNet and rPosNet highlights the importance of relative position information in α.

The results of gLinearNet and LightConv further emphasize the strong modeling capabilities of absolute (query) and relative position (key) interactions in rPosNet. In comparison, token-mixing weights in gLinearNet solely model absolute position interactions and in LightConv relative position interactions. Both cannot match rPosNet's translation quality, with gLinearNet on average lacking behind by 1.3% relative and LightConv by 2.4%. Note that in contrast to Wu et al. (2019), we do not match parameters between LightConv and the Transformer. Most prominent in the Base setting on EN→DE, rPosNet outperforms gLinearNet by 0.6 BLEURT and 1.9 COMET points. While aPosNet cannot match Transformer results, rPosNet consistently outperforms other position-based methods and is on par with Shaw et al. (2018) and the Transformer across most model sizes and data conditions.

Hard-coded token-mixing weights Our results show that hard coding encoder self-attention weights as the twiddle factors of the Fourier transform (FourierNet) leads to poor results for machine translation and, on average across all datasets and metrics, degrades translation quality relative to the Transformer by 13.2%. In GaussianNet, weights are manually designed to follow the normal distribution of Transformer self-attention patterns, which significantly reduces the degradation to 6.3%. However, the translation quality is still considerably worse than LinearNet's, the weakest model with trainable self-attention weights. The difference between LinearNet and GaussianNet is negligible in BLEU but made visible with BLEURT and COMET, which correlate better with human judgment (Kocmi et al., 2021). In particular, we confirmed by manually analyzing a sample of translations (see Appendix E) that the semantic metrics discriminate better between translation hypotheses when they all have little overlap with the references

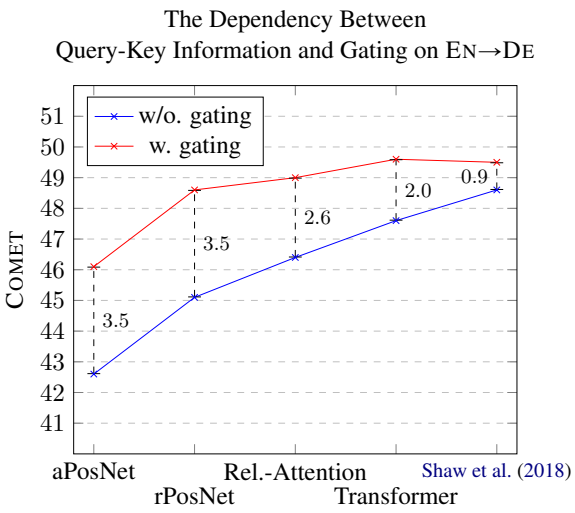

Figure 2: Approaches depicted on the x-axis differ in the provided information to queries and keys. On the y-axis we depict COMET, which is the most accurate metric according to Kocmi et al. (2021), and provide the full Table showing BLEU, BLEURT, and COMET in Appendix D. If position information is provided to queries and keys, gating has a significant positive impact on translation quality that diminishes with the usage of content information.

or changing a single word alters the meaning of the sentence. Thus, approaches with learnable token-mixing weights, such as rPosNet, are considerably better than hard-coded approaches.

7 Analysis

7.1 The impact of gating and query-key information

The gating mechanism is known to guide the learning of cross-token patterns (Tu et al., 2017; Dauphin et al., 2017). In Section 3, we mathematically showed that by gating the context vector, these patterns are captured within the latent token-mixing weights β. Since the products of β and α form the actual token-mixing weights, we analyze in this Section how content information in α impacts the usefulness of gating. For that, we compare the utilization of position versus content information in the query and key input of self-attention, with and without gating. The results are visualized in Figure 2, where we depict COMET scores on the y-axis and the query and key input on the x-axis.

The formulation of position-based attention without gating primarily[8] differs from the Transformer in the provided information within queries and

[8]The position embeddings may also differ between approaches.

keys. Relative attention uses the relative position representations of Shaw et al. (2018)'s approach but without the query-key dot product of multi-head attention. Thus, relative attention differs from rPosNet in that content information is provided to the queries and is equal to dynamic convolutions (Wu et al., 2019) with global context (Chang et al., 2021). In total, the x-axis of Figure 2 depicts position-position interactions for aPosNet and rPosNet, token-position interactions for relative attention, token-token interactions for the Transformer, and token-token + token-position interactions for Shaw et al. (2018). We sort these approaches on the x-axis in order of their attention weight expressiveness.

Figure 2 shows that the gating mechanism of the position-based attention approaches aPosNet and rPosNet increases COMET by 3.5 points. On the other hand, content-based approaches leverage gating with a lower absolute COMET increase of 2.6 points for relative attention, 2 points for the Transformer and only 0.9 points for Shaw et al. (2018). Thus, gating is less helpful if α can capture content-dependent patterns, and increasing the expressiveness of those patterns diminishes the usefulness of gating. Since gating introduces an additional projection matrix of size D^2 per self-attention layer, content-based mixing approaches may just leverage the additional parameters, but we leave further investigation for future work. In contrast, approaches that do not incorporate content information within the attention weights can benefit from token-token interactions captured in β. Additionally, the comparable performance of rPosNet and relative attention with gating suggests that gating makes the content information within relative attention redundant for translation quality.

7.2 Comparing the usage of rPosNet across attention layers

While the aforementioned experiments concentrated on self-attention, we also consider cross-attention in this Section and analyze how the usage of rPosNet affects translation quality compared to multi-head attention. In Table 4, we depict the translation quality on EN→DE when combinations of encoder self-attention (enc-self), decoder self-attention (dec-self), and decoder cross-attention (dec-cross) employ multi-head attention (✗) or rPosNet (✓). The model using rPosNet only for cross-attention while all other layers employ multi-head attention (row 4) significantly decreases translation quality by 5.7% relative to the Transformer. The result suggests that content-dependent patterns incorporated by β cannot sufficiently capture source-target token interactions. We hypothesize that part of the reason is the inability of β to express varying relations across source tokens (see Section 3). While this may be a significant limitation of gating, we leave the exploration of this and other possible reasons to future work.

Table 4: A translation quality comparison of all combinations in which encoder self-attention (enc-self), decoder self-attention (dec-self), and/or decoder cross-attention (dec-cross) use either multi-head attention (✗) or rPosNet (✓). We conduct the experiments on EN→DE and report BLEU, BLEURT, and COMET.

rPosNet Layers			EN→DE		
enc-self	dec-self	dec-cross	BLEU	BLEURT	COMET
✗	✗	✗	26.3	71.1	47.6
✓	✗	✗	26.4	71.2	48.1
✗	✓	✗	26.1	71.1	47.2
✗	✗	✓	24.6	69.2	43.8
✓	✓	✗	**26.6**	**71.4**	**48.6**
✓	✗	✓	24.8	69.8	45.2
✗	✓	✓	24.3	69.0	42.8
✓	✓	✓	24.9	69.3	43.5

However, utilizing rPosNet within all self-attention layers (row 8), so that rPosNet is the only token-mixing method, does not lead to further degradation of translation quality with a relative degradation to the Transformer of 5.5% (5.3% relative in BLEU). Although the loss is substantial, rPosNet improves upon You et al. (2020)'s relative BLEU degradation of 12.3%[9]. Additionally, Table 4 shows that using rPosNet within decoder self-attention is only beneficial if encoder self-attention leverages rPosNet, whereas the usage within encoder self-attention always positively impacts translation quality.

7.3 From LightConv to rPosNet

With the similarities between LightConv and rPosNet, we want to understand what features of rPosNet are responsible for its better translation quality. While Wu et al. (2019) propose LightConv initially

[9]As reported by You et al. (2020)

Table 5: Starting from LightConv and progressively implementing the features of rPosNet.

Model	Params	EN→ZH		
		BLEU	BLEURT	COMET
Light Convolution	101M	33.2	63.4	40.6
+ GLU [LightConv]	104M	33.0	63.5	41.1
+ GeLU Gating	104M	33.5	63.7	42.4
+ Global Context	104M	33.6	63.9	42.4
rPosNet	104M	**33.8**	**64.2**	**43.1**

with the GLU mechanism (Dauphin et al., 2017) (see Equation 14), we differentiate between LightConv with and without GLU since the effect of gating is a central component of our analysis. We start with LightConv without GLU, denoted Light Convolution, and progressively implement the features of rPosNet. In Table 5, we show the translation quality on EN→ZH of the models leveraging the respective position-based approach instead of self-attention. Light Convolution (row 1) shows similar translation quality to LightConv (row 2). Replacing GLU gating with the gating mechanism of Section 2.3, denoted GeLU gating (row 3), increases translation quality noticeably by 0.5 points in BLEU, 0.2 points in BLEURT, and 1.3 points in COMET. Additionally, adding global context (row 4) by spreading the outer kernel weights across the whole sequence increases translation quality slightly by 0.1 BLEU and 0.2 BLEURT (no improvement in COMET). The remaining difference to rPosNet (row 5) is the different training scheme and rPosNet's unshared kernel weights across query positions. Together they add additional 0.2 points in BLEU, 0.3 in BLEURT, and 0.7 in COMET. The results show that all differences between LightConv and rPosNet are responsible for their translation quality difference. While the global context seems negligible for machine translation, GeLU gating, training scheme, and unshared token-mixing weights are the most important.

8 Related Work

The question of how to represent position and integrate it into the Transformer architecture has been a vast research field that we briefly want to overview and connect to our approach. An extensive line of research focuses on improving position embeddings (Kitaev et al., 2020; Liu et al., 2020; Kiyono et al., 2021) and their integration into the word vectors (Neishi and Yoshinaga, 2019; Wang et al., 2020). This direction is mainly orthogonal to our approach, and many ideas and methods can be leveraged with position-based attention. We leave these investigations for future work and restricted to learnable (Gehring et al., 2017) and sinusoidal (Vaswani et al., 2017) embeddings.

A different line of research focuses on integrating position within the attention mechanism (Shaw et al., 2018; Dai et al., 2019; Dufter et al., 2020; Huang et al., 2020; Raffel et al., 2020; Ke et al., 2020; He et al., 2021; Wu et al., 2021). They all improve over Transformer models for various tasks by modifying word and position interactions within the attention matrix and introducing relative position representations as a scalar or vector. While they still rely on content-dependent attention weights, they showed the importance of relative position representations, which we also used in rPosNet. However, we are interested in studying purely position-based self-attention approaches and how they can perform at least on par with the (content-based) Transformer. Additionally, we compare with Shaw et al. (2018) as an upper bound since it leverages token-token interactions and was proposed for machine translation.

9 Conclusion

We have introduced the gated token-mixing approaches aPosNet and rPosNet in order to find a high-quality self-attention alternative for machine translation whose attention weights can be pre-computed at inference time. Although their token-mixing weights are position-based, the gating mechanism introduces content dependency in the form of latent weights β, as shown by our analysis. These weights capture token-token interactions and are crucial for the results of rPosNet. In our experiments, we have compared aPosNet and rPosNet with existing position-based token-mixing approaches and found that rPosNet outperforms all the position-based alternatives and performs on par with (Shaw et al., 2018) on most benchmarks while saving more than 20% of the self-attention parameters. Moreover, the possibility of pre-computing rPosNet's token-mixing weights paves the way for high-quality machine translation on specialized hardware accelerators.

Limitations

The goal of this paper is to find alternatives for self-attention with minimal or no quality loss that

can pre-compute token-mixing weights at inference time. We have compared numerous approaches across many data conditions and model sizes to show the validity of our results. However, we can identify the following limitations in our work:

- rPosNet's position-based attention is an effective replacement of Transformer's self-attention, but its usage in cross-attention leads to quality loss;
- We did not have enough computational resources to run our numerous experiments multiple times, so we relied on the consistent results we obtained across different conditions and metrics.
- While our work is motivated by future use in memristor-based devices, we have no experiments in that specific hardware because i) it is still experimental and hard to find, and ii) our proposed models still contain operations that cannot be performed naively in the analog domain.

A Formulas describing related position-based token-mixing approaches

In the following, we provide the formulas describing how the position-based token-mixing approaches from Section 2.2 formulate the context vector.

FNet

$$c_n := \mathcal{R}\Big(\sum_m \exp\big[-2\pi j \frac{n \cdot m}{M}\big] \cdot \mathcal{F}_h(x_m)\Big) \tag{11}$$

GaussianNet

$$c_n := \frac{1}{\sigma\sqrt{2\pi}} \sum_m \exp\Big[\frac{-(m-\mu(n))^2}{2\sigma^2}\Big] \cdot (W^V x_m) \tag{12}$$

LinearNet

$$c_n := \sum_m W_{nm} \cdot (W^V x_m) \tag{13}$$

LightConv

$$c_n := \sum_{k=0}^{2K} \frac{\exp W_k}{\sum_{k'=0}^{2K} \exp W_{k'}} \cdot \sigma_{\text{GLU}}(W^V x_{n+k-K}) \tag{14}$$

B Reformulating the gating mechanism with layer normalization

Substituting $z_m = \sigma_g(v_m)$ we rewrite the gating mechanism of Equation 4 as

$$\hat{c}_n := \Big[\sum_m \alpha_{nm} \cdot \text{Norm}(z_m)\Big] \odot g_n. \tag{15}$$

Similar to Section 3, we aim to rediscover the weighted sum over v_m. For this, we utilize the definition of layer normalization:

$$\text{Norm}(x) := a \odot [f_1(x)x - f_2(x)] + b, \tag{16}$$

Table 6: Comparing how different attention approaches leverage gating.

Model	Gating	Params	EN→DE		
			BLEU	BLEURT	COMET
Transformer	✗	66.5M	26.3	71.1	47.6
	✓	69.7M	26.6	71.6	49.6
Shaw et al. (2018)	✗	66.7M	26.3	71.4	48.6
	✓	69.9M	26.7	71.8	49.5
Rel. Self-Attention	✗	63.6M	25.7	70.4	46.4
	✓	66.7M	26.5	71.3	49.0
aPosNet	✗	61.8M	25.4	69.4	42.6
	✓	65.0M	25.9	70.6	46.1
rPosNet	✗	60.8M	25.3	70.1	45.1
	✓	63.9M	26.6	71.4	48.6

with gain $a \in \mathbb{R}^D$, bias $b \in \mathbb{R}^D$, $f_1(x) = \frac{1}{\sqrt{\sigma_x}}$ and $f_2(x) = \frac{\mu_x}{\sqrt{\sigma(x)}}$. The insertion into Equation 15 gives us:

$$\begin{aligned}\hat{c}_n \approx a \odot \sum_m \alpha_{nm} \underbrace{f_1(z_m) \cdot g_n \odot \sigma_s(v_m)}_{\beta_{nm} \in \mathbb{R}^D} \odot v_m \\ - a \odot \sum_m \alpha_{nm} \cdot f_2(z_m) \cdot g_n + \sum_m \alpha_{nm} b \odot g_n.\end{aligned} \tag{17}$$

Utilizing the normalization property $\sum_m \alpha_{nm} = 1$ we can simplify Equation 17 to:

$$\begin{aligned}\hat{c}_n \approx a \odot \sum_m \alpha_{nm}\beta_{nm} \odot v_m \\ + g_n \odot \Big[b - a \sum_m \alpha_{nm} f_2(z_m)\Big],\end{aligned} \tag{18}$$

with

$$\beta_{nm} = f_1(z_m) \cdot g_n \odot \sigma_s(1.702 v_m). \tag{19}$$

Although Equation 18 assumes α to be normalized, not normalizing α does not affect β and only adds a context-dependent scale in front of b. All in all, the Equations show that with or without layer normalization, gating introduces the token-mixing weights β.

C Theoretical complexity comparison

We compare theoretical complexities across position-based token-mixing approaches, the Transformer, and Shaw et al. (2018) concerning the number of operations and parameters in Table 7.

Table 7: We compare the theoretical complexity and number of parameters per attention layer. $\hat{K}$ refers to the bidirectional context size. With the formulation of position-based attention, the attention energies can be pre-computed after training, resulting in different complexities between training and search.

Model	Parameters		Operations	
	Train	Search	Train	Search
Transformer	$4D^2$		$2N^2D + 4ND^2$	
Shaw et al. (2018)	$\hat{K}D + 4D^2$		$\hat{K}ND + 2N^2D + 4ND^2$	
FNet	$2D^2$		$N\log(N)D + D\log(D)N$	
GaussianNet	$2D^2$		$\hat{K}ND + 2ND^2$	
LinearNet	$HN^2 + 2D^2$		$N^2D + 2ND^2$	
LightConv	$H\hat{K} + 3D^2$		$\hat{K}ND + 3ND^2$	
gLinearNet	$HN^2 + 3D^2$		$N^2D + 3ND^2$	
aPosNet	$5D^2$	$HN^2 + 3D^2$	$2N^2D + 5ND^2$	$N^2D + 3ND^2$
rPosNet	$\hat{K}D + 4D^2$	$H\hat{K}N + 3D^2$	$\hat{K}ND + N^2D + 4ND^2$	$N^2D + 3ND^2$

D Table: The impact of gating and query-key information

By depicting COMET scores in Figure 2, we visualized how the effectiveness of gating decreases with increased token-mixing weight expressiveness. In Table 6, we provide the full results with the number of parameters, BLEU, BLEURT, and COMET.

E Example failure cases of BLEU

Throughout our analysis, we observed that BLEU often disagrees with the semantic metrics BLEURT and COMET. For example, the translation quality in the Base configuration on EN→DE of GaussianNet, LinearNet, (see Table 2), aPosNet without gating, and rPosNet without gating (see Table 6) is similarly measured by BLEU but varies significantly in BLEURT and COMET. We analyzed translation samples of GaussianNet and LinearNet (see Table 8) and observed that BLEU often falsely depicts translation quality when hypotheses have little overlap with the reference or changing a single word alters the meaning of the sentence. While the inaccuracies of BLEU are already known (Kocmi et al., 2021), we want to show exemplarily how BLEU would have misled our analysis. Without using BLEURT and COMET, we would have concluded that aPosNet and rPosNet would be equally good without gating and that the hard-coded weights of GaussianNet are as good as the learnable weights of LinearNet.

Table 8: Example failure cases on EN→DE in which BLEU depicts a misleading score. These inaccurate BLEU scores are best visualized when comparing GaussianNet and LinearNet. Both models achieve the same corpus-level BLEU score but differ significantly in BLEURT and COMET (see Table 2). The translations show that measuring the syntactical overlap between the hypothesis and reference translation is not an accurate measure of translation quality.

Abstract

Multimodal machine translation (MMT) systems have been successfully developed in recent years for a few language pairs. However, training such models usually requires tuples of a source language text, target language text, and images. Obtaining these data involves expensive human annotations, making it difficult to develop models for unseen text-only language pairs. In this work, we propose the task of **zero-shot cross-modal machine translation** aiming to transfer multimodal knowledge from an existing multimodal parallel corpus into a new translation direction. We also introduce a novel MMT model with a visual prediction network to learn visual features grounded on multimodal parallel data and provide pseudo-features for text-only language pairs. With this training paradigm, our MMT model outperforms its text-only counterpart. In our extensive analyses, we show that (i) the selection of visual features is important, and (ii) training on image-aware translations and being grounded on a similar language pair are mandatory. Our code are available at https://github.com/toshohirasawa/zeroshot-crossmodal-mt

1 Introduction

Multimodal machine translation (MMT) aims to improve translation quality with the help of other modalities, such as images (Specia et al., 2016) or videos (Wang et al., 2019). MMT models have shown promising improvement over their text-only neural machine translation (MT) counterparts, especially when it matters (Li et al., 2021; Lala and Specia, 2018; Gella et al., 2019). While prior work has successfully developed MMT models for language pairs with available multimodal parallel corpora, incorporating visual information into language pairs with no multimodal dataset has received limited attention. As shown in Table 1, multimodal parallel corpora are only available for a few language pairs (Elliott et al., 2016, 2017; Barrault et al., 2018; Nakayama et al., 2020; Sanayai Meetei et al., 2019; Wang et al., 2019), which is quite less than the language pairs with text-only parallel corpora. Since building a multimodal parallel corpus by professional translators is costly and time-consuming (Wang et al., 2019), creating high-quality multimodal parallel corpora for many language pairs is not feasible.

Modality	Lang.	Examples
Text	> 700	BG, CS, DA, DE, EL, ES, ET, FR, JA, ...
Text+Image	~ 10	DE, FR, CS, JA, ...

Table 1: Number of target languages with text-only (Text) or multimodal (Text+Image) parallel corpora for the translation from English.

One approach to addressing this problem is zero-shot cross-lingual transfer, which has proven successful in text-only machine translation (Firat et al., 2016; Johnson et al., 2017, *inter-alia*). In this paper, we investigate whether this success also extends to a multimodal setting. To this end, we propose the task of **zero-shot cross-modal machine translation**, where models need to perform multimodal machine translation in language pairs that lack multimodal parallel training data. In this task, there are still language pairs with multimodal training data, but the target language pairs consist of text-only training data.

To tackle this novel task, we propose a simple **M2KT-VPN** method that aims at performing Multimodal Knowledge Transfer via Visual Prediction Network in the *zero-shot cross-modal* translation setup. Inspired by El-

Proceedings of the Eighth Conference on Machine Translation (WMT), pages 522–535
December 6–7, 2023.

liott and Kádár (2017), a visual prediction network is employed to mimic visual features from the textual modality. We hypothesize that the predicted feature can help bridge the gap between text-only and multimodal translation pairs, so the model is not surprised when it receives true images at inference time.

The contributions of this work are as follows:

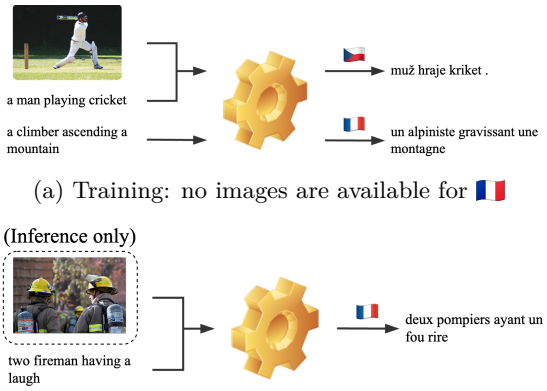
- We introduce a novel task, namely **zero-shot cross-modal machine translation** task, aiming to build MMT systems that can transfer multimodal knowledge from multimodal language pairs into text-only language pairs.
- We propose the **M2KT-VPN** model, a Transformer-based MMT model along with a visual prediction network, and show its zero-shot cross-modal translation capability.
- Our findings suggest the importance of image-aware translations and language similarity between translation directions.

2 Zero-shot Cross-Modal Machine Translation

We propose a new challenge for multimodal machine translation systems that we denote **zero-shot cross-modal machine translation** (Figure 1). This task is motivated by the real-world lack and cost of multimodal parallel corpora, which inhibits the development of multimodal translation systems beyond a few, mostly Indo-European, language pairs.

Task definition. The *zero-shot cross-modal* machine translation task aims to transfer multimodal knowledge learned from a (visually) grounded language pair into a language pair with no multimodal information at training. We define the two types of machine translation resources used for this task as follows:

- **Grounded language pairs**: language pairs where a multimodal parallel corpus is available, both at training and test time.
- **Zero-shot language pairs**: language pairs that only have a text parallel corpus for training, but have multimodal parallel data for test.



(a) Training: no images are available for 🇫🇷

(b) Inference: images are provided for 🇫🇷

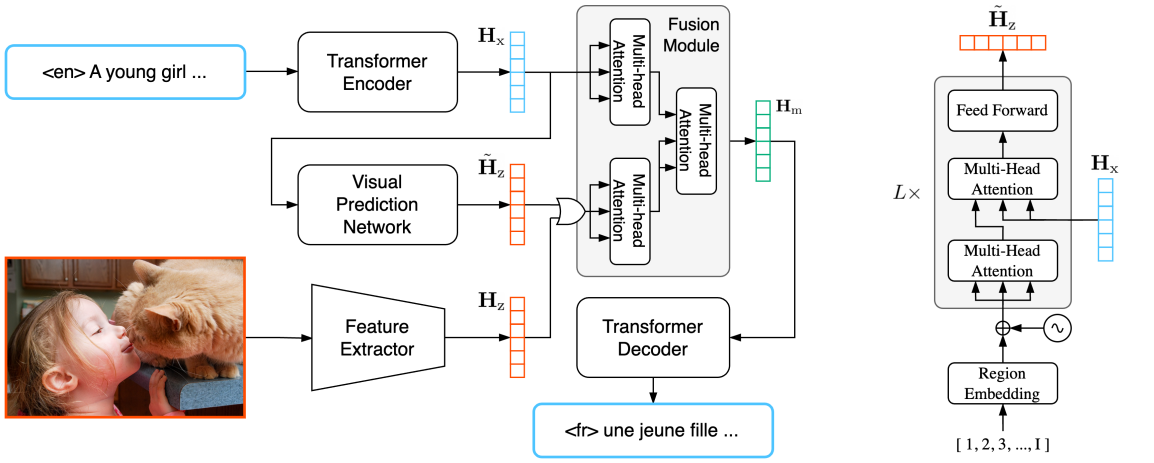
Figure 1: Overview of the **zero-shot cross-modal machine translation** task. For the zero-shot language pair (e.g., 🇫🇷), images are unavailable during training (a), but given at the inference (b).

Thus, a model is encouraged to transfer multimodal knowledge learned from grounded language pairs to zero-shot ones in order to best leverage multimodal data that may be available at test time.

Notation. We consider the following setup in our paper. Given a sequence of N tokens in a given source language, $\mathbf{x} = \langle x_1, x_2, \cdots, x_N \rangle$, and its associated image z, a multimodal machine translation model learns to translate $\mathbf{x}$ into a sentence of M tokens in a target language, $\mathbf{y} = \langle y_1, y_2, \cdots, y_M \rangle$. In the following, we directly consider a dense representation of the image z given by a visual feature extractor, which outputs I features that are then projected into a given model dimension d, $\mathbf{H}_z \in \mathbb{R}^{I \times d}$.

3 Proposed Approach: M2KT-VPN

In this section, we introduce a new MMT model, called **M2KT-VPN**, which aims to transfer multimodal knowledge learned from the multimodal corpus into the zero-shot language pair. M2KT-VPN comprises four modules (Figure 2): a Transformer (Vaswani et al., 2017) encoder to encode a source sentence, a visual prediction network (VPN) to predict a visual feature, a fusion module to incorporate multimodal information, and a Transformer decoder to generate a system output. All modules are trained simultaneously on grounded and zero-shot language pairs.



(a) M2KT-VPN (b) Visual prediction network

Figure 2: The overview of the M2KT-VPN model (a) and the visual prediction network (b).

3.1 Multilingual Machine Translation Module

We design M2KT-VPN as a multilingual MMT model. Following Fan et al. (2021), we prepend a special token (*e.g.*, `<en>`) to the source sentence $\mathbf{x}$ indicating the source language, and another special token (*e.g.*, `<fr>`) to the target sentence $\mathbf{y}$ indicating the target language. Similarly, for inference, we condition the decoder to generate a translation in a given target language by prepending its language indicator token as the first token of the sequence to be generated. We employ a cross-entropy loss to train M2KT-VPN models.

3.2 Attention-based Fusion Module

The Transformer encoder embeds a source text $\mathbf{x}$ into a high-dimensional representation $\mathbf{H}_x \in \mathbb{R}^{N\times d}$ without any presence of images. We then introduce a fusion module to ground the text-only representation $\mathbf{H}_x$ into the image z through its corresponding visual feature $\mathbf{H}_z$. This grounded representation of the source sequence $\mathbf{H}_m \in \mathbb{R}^{N\times d}$ constitutes the input to the Transformer decoder.

We use an attention-based module to fuse the visual input into multimodal representations of language. Our module first applies two dedicated self-attention operations on the text and visual features:

$$\mathbf{H}'_x = \mathrm{MHA}(\mathbf{H}_x, \mathbf{H}_x, \mathbf{H}_x) \quad (1)$$

$$\mathbf{H}'_z = \mathrm{MHA}(\mathbf{H}_z, \mathbf{H}_z, \mathbf{H}_z) \quad (2)$$

where MHA denotes the multi-head attention function (Vaswani et al., 2017). Then, a cross-attention module fuses these representations to get the multimodal representation $\mathbf{H}_m$:

$$\mathbf{H}_m = \mathrm{MHA}(\mathbf{H}'_x, \mathbf{H}'_z, \mathbf{H}'_z) \quad (3)$$

3.3 Visual Prediction Network

As described so far, our MMT model assumes the input is complete, having both text and image available for translation, both during training and inference. However, in the zero-shot cross-modal machine translation task, the visual modality is absent during training for the zero-shot language pairs.

To mitigate this gap, we propose a **Visual Prediction Network** (**VPN**) to mimic visual features for zero-shot language pairs during training. The VPN generates visual predictions from the text encoder representation $\mathbf{H}_x$. The generated visual predictions $\tilde{\mathbf{H}}_z$ in a zero-shot pair are then fed into the fusion module instead of the visual feature $\mathbf{H}_z$.

To predict the visual features corresponding to I image regions, VPN first embeds learnable visual queries (*e.g.*, Lee et al., 2018; Alayrac et al., 2022; Mañas et al., 2023; Li et al., 2023), adds positional information, and then applies layer normalization to obtain the position-aware region representations $\tilde{\mathbf{H}}^0_z$.

$$\tilde{\mathbf{H}}^0_{z,i} = \mathrm{LayerNorm}(\mathbf{E}_z(i) + \mathrm{PE}(i)) \quad (4)$$

where $\mathbf{E}_z(i)$ is the embedding representation for the i-th region, and $\mathrm{PE}(i)$ is the positional embedding for the i-th region.

The following L layers are the same as in a standard Transformer decoder, each comprising a self-attention, cross-attention, and a pairwise feed-forward module.[1] The l-th layer takes the output of the previous layer $\tilde{\mathbf{H}}_{\mathrm{z}}^{l-1}$ as input. The cross-attention module in the l-th layer takes the output of the self-attention module as the query and the text encoder output $\mathbf{H}_{\mathrm{x}}$ as the key and value. The M2KT-VPN model uses the output representation of the final layer as the visual prediction:

$$\tilde{\mathbf{H}}_{\mathrm{z}} = \tilde{\mathbf{H}}_{\mathrm{z}}^{L} \tag{5}$$

The VPN module is trained on grounded language pairs, using a max-margin loss (Elliott and Kádár, 2017) in a contrastive learning manner (Radford et al., 2021a). Given a batch of K examples, we first generate K ($\tilde{\mathbf{H}}_{\mathrm{z}}$, $\mathbf{H}_{\mathrm{z}}$) pairs. We then compute a max-margin loss for the batch:

$$\sum_{p \neq k}^{K} \sum_{i=1}^{I} \max\{0, \alpha - d({}_{k}\tilde{\mathbf{H}}_{\mathrm{z},i}, {}_{k}\mathbf{H}_{\mathrm{z},i}) + d({}_{k}\tilde{\mathbf{H}}_{\mathrm{z},i}, {}_{p}\mathbf{H}_{\mathrm{z},i})\} \tag{6}$$

where ${}_{j}\tilde{\mathbf{H}}_{\mathrm{z},i}$, ${}_{j}\mathbf{H}_{\mathrm{z},i}$ is the predicted i-th vector and the true i-th vector of j-th example in the batch; d is a cosine similarity function; and α is the margin[2]. The max-margin loss is merged with the cross-entropy loss with a coefficient of 1.0 to obtain the final loss.

4 Experiments

4.1 Experimental Setting

Dataset. We train and evaluate models on `Multi30K` dataset. We select English–Czech as a grounded language pair and English–French as a zero-shot language pair. For the training, we divide the training split of `Multi30K` into two folds of the same size; one for the grounded language pair and the other for the zero-shot language pair. The validation splits for grounded and zero-shot language pairs have the same source language texts and the target language texts, but images are absent for the zero-shot language pair. The test splits are also the same, and images are available for both grounded and zero-shot language pairs. Table 2 shows the statistics of each split. We follow a standard evaluation to report performance on four test sets: test_2016_flickr (**2016**), test_2017_flickr (**2017**), test_2017_mscoco (**mscoco**), and test_2018_flickr (**2018**).

Split	Images	Sents.
Grounded (English–Czech)		
Training	14,500	14,500
Validation	1,014	1,014
Test	2,071	2,071
Zero-shot (English–French)		
Training	–	14,500
Validation	–	1,014
Test	3,532	3,532

Table 2: The number of examples in each split for the grounded and zero-shot language pairs.

Preprocessing. For textual modality, we use Moses (Koehn et al., 2007) to lowercase, normalize punctuation, and tokenize the source and target sentences. We then learn byte pair encoding (Sennrich et al., 2016) with 10,000 merge operations on the concatenation of the training text over all language pairs to obtain a shared vocabulary for all languages. For visual modality, we extract a visual feature using **DETR-ResNet-50-DC5**[3] (Carion et al., 2020), which is an object detection model backed by a **ResNet-50** model (He et al., 2016). **DC5** stands for dilated C5 stage, which increases the feature resolution and consequently provides more information for the small objects. The extracted feature has 100 bounding boxes, each with a visual representation of 256 dimensions.

Model. We use a tiny version of the Transformer model (Transformer-tiny) as our text-only baseline and the relying model of M2KT-VPN, as this smaller model works better on `Multi30K` (Wu et al., 2021; Li et al., 2022b). This model comprises four encoder layers and four decoder layers, and the model hidden size of both decoder and decoder is 128. It also has a smaller number of attention heads and a hidden size of pair-wise feedforward network, 4 and 256, respectively. The vocabulary and

[1] We use $L = 1$ in our experiments.

[2] We use $\alpha = 0.1$ in our experiments.

[3] facebook/detr-resnet-50-dc5

embedding weights are shared across all languages. We compare our model against some baseline models:

- Transformer: a text-only Transformer-tiny model trained only on English–French data.
- mTransformer: a text-only multilingual Transformer-tiny model trained on both English–Czech and English–French data.
- IMAGINATION: a text-only multilingual Transformer with a VPN module. This model also trained on both English–Czech and English–French data.

Implementation details. We implement our models on the Fairseq (Ott et al., 2019) toolkit. The optimizer is Adam (Kingma and Ba, 2015) with $\beta_1 = 0.9$ and $\beta_2 = 0.98$. The learning rate warms up from $1e-7$ to 0.005 over $2,000$ steps, then decays with the `inverse_sqrt` scheduler. We apply label smoothing of 0.1 for computing the cross-entropy loss and the dropout of 0.3. Early stopping with a patience of 10 is used to stop training models. We average the last ten checkpoints and use beam search with width=5 for inference.

Metrics. We train all models three times with different seeds and report averaged 4-gram BLEU (Papineni et al., 2002) and METEOR (Banerjee and Lavie, 2005) scores for all test sets. Additional to the classic n-gram matching evaluation, we also compute the COMET score (Rei et al., 2020)[4]. We also report statistical significance ($p < 0.05$) on the difference in BLEU scores[5].

4.2 Results

The results of our experiments are shown in Table 3. We found that our M2KT-VPN model provides an improvement over the text-only baselines and IMAGINATION model for all four test sets. The M2KT-VPN model achieves an averaged improvement of 2.65% over the mTransformer model (varies from 1.90% to 3.70% across the test sets). This performance gain would be owed to the multitask learning of the visual prediction network; the module learns to predict visual features and tailor the features for the machine translation task simultaneously.

[4]We use **Unbabel/wmt22-comet-da** (Rei et al., 2022).

[5]We used Moses' **bootstrap-hypothesis-differencesignificance.pl.**

5 Discussion

This section first provides two basic analyses of the M2KT-VPN model: model analysis and probing. We then examine various kinds of features to investigate the importance of feature selection. Finally, we ran an analysis to identify the requirement for the grounded language pair.

5.1 Model Analysis

Model ablation. Table 4 shows the results of a comprehensive ablation analysis to identify the contribution of each module in the M2KT-VPN model on entire test splits. To evaluate the contribution of the attention-based fusion module, we compare two well-known fusion strategies: concatenation-based (Li et al., 2021) and gate-based (Li et al., 2021). Firstly, the model without a VPN module drops -1.0 METEOR score, indicating a VPN module is key to resolving the missing visual modality problem in the zero-shot cross-modal machine translation task. Second, concatenation-based and gate-based models do not outperform the M2KT-VPN model and even the mTransformer baseline. The concatenation-based model fails to translate most of the examples. This evidences that attention-based fusion strategies indeed transfer multimodal knowledge.
