Message from the General Chair

It is my great pleasure and honor to welcome you to the 63rd Annual Meeting of the Association for Computational Linguistics (ACL 2025), held in beautiful Vienna, Austria, from July 27 to August 1, 2025. ACL 2025 continues our field’s tradition of excellence in scholarship, innovation, and inclusivity, and I am deeply grateful to the many volunteers who have worked tirelessly to bring this event to life.

I want to express my deepest thanks to our Program Chairs — **Wanxiang Che, Joyce Nabende, Mohammad Taher Pilehvar** and **Ekaterina Shutova** — who have overseen the reviewing and selection process, and shaped a compelling and diverse scientific program. Overall, we received more than 8300 submissions and accepted 1700 at the main conference and 1392 as findings. This was made possible through close coordination with the ACL Rolling Review (ARR) team, led by the ARR Editors-in-Chief — **Jun Suzuki, Jing Jiang, and Xiaodan Zhu** — and I sincerely thank them. Although some improvements are still possible, the ARR workflow was already well integrated with the conference review and decision-making process. We are also deeply grateful to the (many!) Senior Area Chairs, Area Chairs, reviewers, and the Best Paper Committee (led by **Rada Mihalcea** and **Roi Reichart**), whose dedication ensured the high quality of our program. I am also grateful to our Technical Open Review Chairs, **Niket Tandon** and **Lizhen Qu**, for their behind-the-scenes work. For those joining virtually, our Virtual Infrastructure Chairs — **Manling Li, Yang Liu, and Avi Sil** — have worked to make the hybrid conference experience inclusive and engaging. I would also like to recognize the efforts of our Ethics Chairs — **Karën Fort** and **Bjorn Ross** — who have led the work aimed at ensuring that submissions meet the ethical standards of our field.

ACL 2025 hosts a rich set of 28 workshops and 8 tutorials, thanks to the dedicated efforts of our Workshop Chairs — **Terra Blevins** and **Christophe Gravier** — and our Tutorial Chairs — **Yuki Arase, David Jurgens, and Fei Xia**. Our Demonstration Track Chairs — **Pushkar Mishra, Smaranda Muresan, and Tao Yu** — have put together an impressive set of system demonstrations of cutting-edge innovations in NLP. I am proud to say that we also have a rich Industry Track, thanks to **Yunyao Li** and **Georg Rehm** who created a “conference in the conference”. Given the growing interaction between academia and industry, I hope this tradition, which stems from NAACL and which I reinstated at ACL, will be continued in the following editions.

As is customary, TACL and CL papers are presented at the conference. Thanks go to the TACL Editors-in-Chief (**Asli Celikyilmaz, Roi Reichart, and Dilek Hakkani-Tur**) and the CL Editor-in-Chief, **Wei Lu**, for their coordination efforts. I am also proud to announce that this year we are introducing the new CL Doctoral Dissertation Award at the conference. Other notable innovations include virtual presentation sessions held in parallel with the in-person poster sessions, a reception event dedicated to Findings presentations, and the introduction of combined oral and panel sessions designed to foster more thorough and interactive research discussions.

This conference could only have been made possible thanks to the invaluable work of our ACL Business Manager and Director of Events, **Jenn Rachford**, and her team — in particular, **Megan Haddad**, our ACL Administrator and Registration Manager — especially given the largest number of participants ever at ACL, estimated at the time of writing to be around 5000! Thanks also go to **Damira Mršić** and the Underline team for managing all content for the hybrid experience. The Local Organization Chairs, **Benjamin Roth** and **Dagmar Gromann**, worked hard on the bidding process, providing huge support with all local arrangements, the social event, and the visa process, eventually ensuring an outstanding experience for our in-person attendees. Our Visa Chairs — **Rexhina Blloshmi** and **Eleni Ilkou** — have helped numerous participants with their visa needs and any logistical difficulties in attending the conference. I also thank our Student Volunteer Chairs — **Pedro Henrique Luz de Araujo** and **Eleonora Mancini** — for their behind-the-scenes work, which will prove indispensable during the conference.

Additional thanks go to **Zhu Liu, Mingyang Wang, and Jin Zhao**, our Student Research Workshop Chairs, who, with the support of faculty advisors **Lea Frermann, Daniel Hershcovich, and Tristan Miller**, devoted their work to supporting and mentoring the next generation of researchers. They also secured additional funding from the Vienna Meeting Fund — congratulations!

Our Publication Chairs — **Pierpaolo Basile, Libo Qin, and Zhenghao Liu** — have ensured timely and high-quality conference proceedings. I also thank the Handbook Chairs, **Els Lefever and Qiongkai Xu**, for assembling the handbook that will guide attendees through the conference program.

Of course our conference could not exist without the support of our sponsors! We are deeply grateful to our Sponsorship Chairs — **Raffaella Bernardi and Thomas Scialom** — and to **Chris Callison-Burch**, ACL's Sponsorship Director, for securing the generous support that enables us to keep the conference accessible to as many participants as possible.

Fostering an inclusive environment remains a key goal of ACL. Our Diversity and Inclusion Chairs — **Senja Pollak, Maria Ryskina, Shane Storks, and Hwaran Lee** — have worked to support diverse participation and organize activities that reflect the global nature of our vibrant community. An inclusive ACL allows researchers from all areas and backgrounds to contribute, collaborate, and thrive — enriching both the scientific conversation and the broader societal impact of our work. We remain committed to building a community where everyone feels welcomed and valued.

Thank you to the Publicity and Social Media Chairs — **Anette Frank, Shruti Rijhwani, and Horacio Saggion** — for their communication work through social media, extending the conference's reach to a wider audience. And this brings me to our Website and App Chairs — **Xudong Han and Alessandro Raganato** — who kept our community informed with timely updates about all aspects of the conference. The huge number of emails and communications that we received was smoothly managed throughout the year by our Internal Communication Chairs, **Sara Tonelli and Yiquan Wu**. We are very grateful!

I am particularly proud of the creation of a new role, the Documentation Chair, taken by **Chenghua Lin**, who did strenuous work to assemble a new handbook with up-to-date information coming from all chairs — whom I also thank for their valuable contributions — and maintain a clear and consistent record of all our processes. Given the speed at which all conference roles evolve in their duties and commitments, I hope this role will become standard in upcoming conferences to ensure a smooth transition.

Last but not least, I wish to thank the ACL Executive Committee for their guidance, and my fellow past General and Program Chairs, and especially **Claire Gardent and Colin Cherry**, for generously sharing their experience and insights.

ACL 2025 is a community-wide effort. Whether you are presenting a paper, leading a workshop or tutorial, volunteering, mentoring, supporting or attending to learn and connect, your presence and participation make a difference at this conference. Thank you for being part of it!

Welcome to Vienna. Welcome to ACL 2025!

Roberto Navigli

Sapienza University of Rome & Babelscape

General Chair, ACL 2025

Message from the Program Chairs

Welcome to the 63rd Annual Meeting of the Association for Computational Linguistics!

ACL 2025 will be held in a hybrid format, offering attendees the option to join us in person in vibrant Vienna, Austria, or to participate remotely from anywhere in the world. Organizing ACL 2025 has been a collaborative effort, made possible by the dedication and hard work of thousands of people. We gratefully acknowledge the support and contributions of the following people:

- The General Chair, Roberto Navigli;
- The ARR Editors-in-Chief of the February 2025 cycle (Jun Suzuki, Jing Jiang, and Xiaodan Zhu) and the entire team (Mausam, Viviane Moreira, Vincent Ng, Lilja Øvrelid, Anna Rogers, Michael White, Margot Mieskes, Sarvnaz Karimi);
- The technical OpenReview chairs, Niket Tandon, Lizhen Qu, and the OpenReview support team, in particular Rachel, for multiple rounds of technical help in setting up ACL 2025 on the Open Review platform;
- The 169 Senior Area Chairs;
- The 1,937 Area Chairs and the 11,720 reviewers;
- The best paper committee chairs, Rada Mihalcea and Roi Reichart, and the best paper committee members;
- The ethics chairs, Karën Fort and Bjorn Ross;
- The workshop chairs, Terra Blevins and Christophe Gravier;
- The tutorial chairs, Yuki Arase, David Jurgens and Fei Xia;
- The industry track chairs, Yunyao Li and Georg Rehm;
- The demonstration chairs, Pushkar Mishra, Smaranda Muresan, and Tao Yu;
- The internal communications chairs, Sara Tonelli and Yiquan Wu;
- The website and conference app chairs, Xudong Han and Alessandro Raganato;
- The publication chairs, Pierpaolo Basile, Libo Qin, and Zhenghao Liu;
- The handbook chairs, Els Lefever and Qionghai Xu;
- The local organization chairs, Benjamin Roth and Dagmar Gromann, and their team;
- The visa chairs, Rexhina Blloshmi and Eleni Ilkou;
- The publicity and social media chairs, Anette Frank, Shruti Rijhwani and Horacio Saggion;
- The documentation chair, Chenghua Lin;
- The student research workshop chairs, Zhu Liu, Mingyang Wang and Jin Zhao;
- The student research workshop chairs faculty advisors, Lea Frermann, Daniel Hershcovich and Tristan Miller;
- The student volunteer chairs, Pedro Henrique Luz de Araujo and Eleonora Mancini;

- The diversity and inclusion chairs, Senja Pollak, Maria Ryskina, Shane Storcks and Hwaran Lee;
- The sponsorship chairs, Raffaella Bernardi and Thomas Scialom;
- The virtual infrastructure chairs, Manling Li, Yang Liu and Avi Sil;
- The ACL Anthology Director Matt Post and his team;
- The TACL editors-in-chief (Asli Celikyilmaz, Roi Reichart, Dilek Hakkani-Tur) and CL Editor in-Chief Wei Lu for coordinating TACL and CL presentations with us;
- The ACL 2024 Program Chairs, Lun-Wei Ku, André F. T. Martins, Vivek Srikumar, for information and support;
- Damira Mrsic and Underline Team;
- Jennifer Rachford and entire conference support staff;
- All the authors of papers who submitted their papers for review in the ARR 2025 February cycle and those who committed to the ACL 2025 conference.

Review Process

All submissions to ACL 2025 went through a two-stage review process. First, papers were submitted to the ACL Rolling Review (ARR), where they were reviewed by reviewers and received meta-reviews from Area Chairs. Then, authors had the option to commit their reviewed papers to ACL via a separate ACL 2025 commitment site. At this stage, Senior Area Chairs provided recommendations, and final acceptance decisions were made by the Program Chairs. This process is consistent with previous conferences, including ACL 2024, EACL 2024, and NAACL 2025.

We worked closely with the ARR team, particularly the ARR February 2025 Editors-in-Chief, and served as guest Editors-in-Chief for this round. We helped recruit new reviewers and Area Chairs to ARR, resulting in 11,720 reviewers and 1,942 Area Chairs in the February 2025 ARR cycle to which most ACL 2025 papers were submitted. ACL also recruited 169 Senior Area Chairs to oversee the review and meta-review process. Overall, the ARR process ran smoothly, ensuring that all submitted papers received at least three reviews and a meta-review. For the ACL commitment phase, Senior Area Chairs made recommendations for 5,356 committed papers based on the reviews, meta-reviews, and the papers themselves, with final acceptance decisions made by the Program Chairs.

Acceptance Rate

In total, there are 1,699 papers accepted to the Main Conference and 1,392 papers accepted to Findings. The acceptance rate calculation follows precedent set by previous conferences that go through ACL Rolling Review (ARR), e.g. ACL 2024. The calculation takes into account the multi-stage process of ARR where a paper may get revised in ARR and then later committed to the conference. In total, we had 8,360 unique submissions across the December 2024 and February 2025 ARR cycles of which 5,501 papers were committed to ACL. The acceptance rate is 20.3% for the Main Conference papers and a further 16.7% for Findings papers.

Special Theme: Generalization of NLP Models

ACL 2025’s special theme is generalization of NLP models. Generalization is crucial for ensuring that models behave robustly, reliably, and fairly when making predictions on data different from their training data. Achieving good generalization is critically important for models used in real-world applications, as they should emulate human-like behavior. Humans are known for their ability to generalize well, and models should aspire to this standard. The theme track invites empirical and theoretical research

and position and survey papers reflecting on the Generalization of NLP Models. The possible topics of discussion include (but are not limited to) the following:

1. How can we enhance the generalization of NLP models across various dimensions—compositional, structural, cross-task, cross-lingual, cross-domain, and robustness?
2. What factors affect the generalization of NLP models?
3. What are the most effective methods for evaluating the generalization capabilities of NLP models?
4. While Large Language Models (LLMs) significantly enhance the generalization of NLP models, what are the key limitations of LLMs in this regard?

We received 128 submissions to the theme track during the review phase. Among these, 41 papers were accepted to the main conference and a further 33 to Findings of ACL 2025. The conference will also feature a panel discussion on the theme of Generalization, with the participation of leading experts in this area.

Best Paper Selection

ACL 2025 implemented the updated ACL award policy that seeks to expand the pool of work recognized as outstanding. In total 117 papers were nominated by the reviewers, area chairs and senior area chairs for best paper consideration. The best paper committee assessed these papers to select the best papers (featuring $(\leq)0.6\%$ of accepted papers), outstanding papers (featuring $(\leq)2.5\%$ of accepted papers), and special awards for social impact and best resource. Based on the review by the Best Paper committee, 39 papers have been selected for awards in the above categories. Separately, the senior area chairs also nominated their favourite papers as SAC Highlights.

In addition, we have awards for test of time award for a paper published in TACL in 2013 or 2014 and the best paper award for a paper published in TACL in 2024. The final selection was made by the best paper committee, and the winners will be announced during the closing ceremony. The ACL 2025 Best Papers will also be given an opportunity to present their work in the closing ceremony.

Program Composition & Presentation Modes

Based on feedback from the conference support staff and the Underline team after ACL 2025, we decided to hold the virtual presentations sessions during the main conference. This enables us to align the virtual sessions with time slots when in-person participants are available. This approach allows virtual attendees to participate concurrently with the physical event, avoiding the need for organizers and attendees to engage with the conference twice and separately.

This year, 218 main conference papers were selected for oral presentations by the program chairs, with the goal of creating a well-rounded program featuring a diverse set of topics instead of selecting papers based on their review scores. This year we have introduced a panel section of the conference. Out of the selected oral presenters, 25 will have an opportunity to not only present their work but also participate in a panel discussion. We have lined up five panels on the theme of: Generalisation in NLP, LLM alignment, Human-centred NLP, Interpretability and model analysis, Multilinguality and language diversity.

In addition to the main conference papers, the ACL program also includes 18 papers accepted by Computational Linguistics and 42 papers accepted by Transactions of the ACL (TACL). Among these, 11 journal papers will be presented in-person as oral presentations, thematically distributed across appropriate sessions.

This year the conference will also for the first time feature a dedicated Findings poster session with reception. All Findings presenters have been assigned poster presentations in this session or alongside other posters for main conference papers in the same track. Rounding out the program are dedicated sessions for the demonstrations track and the student research workshop.

Keynotes and Panel This year’s program features an impressive lineup of two keynote presentations:

- **Prof. Luke Zettlemoyer** from Paul G. Allen School of Computer Science & Engineering at the University of Washington, and a Senior Research Director at Meta, will share his insights on “*Rethinking Pretraining: Data and Architecture.*”
- **Prof. Verena Rieser** from Google DeepMind will present on “*Whose Gold? Re-imagining Alignment for Truly Beneficial AI.*”

Alongside these keynotes, we are thrilled to host a panel discussion aiming to answer the question *Can large language models (LLMs) generalize?*. Our esteemed panelists include:

- **Prof. Eduard Hovy**, University of Melbourne (who will also act as the panel chair).
- **Prof. Mirella Lapata**, University of Edinburgh
- **Prof. Yue Zhang**, Westlake University
- **Prof. Dan Roth**, University of Pennsylvania and Oracle

This diverse group of panelists will provide a comprehensive view of the latest trends and challenges in Generalisation of NLP in the Large Language Models era. We hope you enjoy this year’s diverse and engaging program!

Keynote Talk

Rethinking Pretraining: Data and Architecture

Luke Zettlemoyer

Paul G. Allen School of Computer Science and Engineering, University of Washington

Mon, July 28th, 2025 – Time: 09:30 – 10:30 – Room: Austria Center Vienna

Abstract: Large language model training follows a standard pipeline: tokenization, pretraining, possibly mid-training, and post training or alignment. Despite its wild success, we understand relatively little about this recipe and are almost certainly missing many opportunities to improve it. In this talk, I will focus on three such cases. I'll describe our work on data efficient post training (e.g. LIMA, ALMA, and s1) where we argue that nearly all advanced model capabilities ultimately come from the pretraining data, even if effective alignment is still essential for controlling model behavior. I will also describe new methods for extracting more signal from the pretraining data, including new hierarchical architectures for byte-level language models (e.g. BLT) that are both tokenizer-free and scale better than traditional BPE-based methods, especially in the long tail. Finally, I will discuss decentralized, modular training algorithms (e.g. BTM) that better isolate and control the influence of specific data on specific model components and behaviors. Together, these methods promise to simplify training and improve scaling, by centering and amplifying the influence of data in architecture design.

Bio: Luke Zettlemoyer is a Professor in the Paul G. Allen School of Computer Science & Engineering at the University of Washington, and a Senior Research Director at Meta. His research focuses on empirical methods for natural language semantics, and involves designing machine learning algorithms, introducing new tasks and datasets, and, most recently, studying how to best develop new architectures and self-supervision signals for pre-training. His honors include being elected ACL President, named an ACL Fellow, winning a PECASE award, an Allen Distinguished Investigator award, and multiple best paper awards. Luke was an undergrad at NC State, received his PhD from MIT and was a postdoc at the University of Edinburgh.

Keynote Talk

Whose Gold? Re-imagining Alignment for Truly Beneficial AI

Verena Rieser
Google DeepMind

Tue, July 29th, 2025 – Time: 09:00 – 10:00 – Room: Austria Center Vienna

Abstract: Human feedback is often the “gold standard” for AI alignment, but what if this “gold” reflects diverse, even contradictory human values? This keynote explores the technical and ethical challenges of building beneficial AI when values conflict – not just between individuals, but also within them. My talk advocates for a dual expansion of the AI alignment framework: moving beyond a single, monolithic viewpoint to a plurality of perspectives, and transcending narrow safety and engagement metrics to promote comprehensive human well-being.

Bio: Verena Rieser is a Senior Staff Research Scientist at Google DeepMind, where she founded the VOICES team (Voices-of-all in alignment). Her team is a core contributor to Gemini with a mission to enhance model safety and usability for diverse communities. Verena has pioneered work in data-driven multimodal Dialogue Systems and Natural Language Generation, encompassing conversational RL agents, faithful data-to-text generation, spoken language understanding, evaluation methodologies, and applications of AI for societal good. Verena previously directed the NLP lab as a full professor at Heriot-Watt University, Edinburgh, and held a Royal Society Leverhulme Senior Research Fellowship. She earned her PhD from Saarland University.

Panel

Generalization of NLP Models

Mon, July 28th, 2025 – Time: 16:30 – 17:30 – Room: Austria Center Vienna - Level 2 Hall A - C

Moderator: Eduard Hovy, Melbourne Connect University of Melbourne

Eduard Hovy is the Executive Director of Melbourne Connect (a research and tech transfer centre at the University of Melbourne), a professor at the University of Melbourne’s School of Computing and Information Systems, and an adjunct professor at the Language Technologies Institute in the School of Computer Science at Carnegie Mellon University. In 2020–21 he served as Program Manager in DARPA’s Information Innovation Office (I2O), where he managed programs in Natural Language Technology and Data Analytics. Dr. Hovy completed a Ph.D. in Computer Science (Artificial Intelligence) at Yale University in 1987 and was awarded honorary doctorates from the National Distance Education University (UNED) in Madrid in 2013 and the University of Antwerp in 2015. He is one of the initial 17 Fellows of the Association for Computational Linguistics (ACL) and is also a Fellow of the Association for the Advancement of Artificial Intelligence (AAAI). Dr. Hovy’s research focuses on computational semantics of language and addresses various areas in Natural Language Processing and Data Analytics, including in-depth machine reading of text, information extraction, automated text summarization, question answering, the semi-automated construction of large lexicons and ontologies, and machine translation. In early 2025 his Google h-index was 109, with about 68,000 citations. Dr. Hovy is the author or co-editor of eight books and over 400 technical articles and is a popular invited speaker. He regularly co-taught Ph.D.-level courses and has served on Advisory and Review Boards for both research institutes and funding organizations in Germany, Italy, Netherlands, Ireland, Singapore, and the USA. From 2003 to 2015 he was co-Director of Research for the Department of Homeland Security’s Center of Excellence for Command, Control, and Interoperability Data Analytics, a distributed cooperation of 17 universities. In 2001 Dr. Hovy served as President of the international Association of Computational Linguistics (ACL), in 2001–03 as President of the International Association of Machine Translation (IAMT), and in 2010–11 as President of the Digital Government Society (DGS).

Panelists:

Mirella Lapata, University of Edinburgh

Mirëlla Lapata is professor of natural language processing in the School of Informatics at the University of Edinburgh. Her research focuses on getting computers to understand, reason with, and generate natural language. She is the first recipient (2009) of the British Computer Society and Information Retrieval Specialist Group (BCS/IRSG) Karen Sparck Jones award and a Fellow of the Royal Society of Edinburgh, the ACL, and Academia Europaea. Mirëlla has also received best paper awards in leading NLP conferences and has served on the editorial boards of the Journal of Artificial Intelligence Research, the Transactions of the ACL, and Computational Linguistics. She was president of SIGDAT (the group that organizes EMNLP) in 2018. She has been awarded an ERC consolidator grant, a Royal Society Wolfson Research Merit Award, and a UKRI Turing AI World-Leading Researcher Fellowship.

Dan Roth, University of Pennsylvania and Oracle

Dan Roth is the Eduardo D. Glandt Distinguished Professor at the University of Pennsylvania and Chief AI Scientist at Oracle. Until June 2024 Dan was a VP/Distinguished Scientist at AWS AI where he led the scientific effort behind Amazon’s first-generation GenAI products, including Titan Models, Amazon Q, and Amazon Bedrock. Dan is a Fellow of the AAAS, ACM, AAAI, and ACL, and a recipient of the IJCAI John McCarthy Award “for major conceptual and theoretical advances in the modeling of natural language understanding, machine learning, and reasoning.” He has published broadly in natural language processing, machine learning, knowledge representation and reasoning, and learning theory, was the Editor-in-Chief of the Journal of Artificial Intelligence Research (JAIR) and has served as a Program Chair and Conference Chair for the major conferences in his research areas. Roth has been involved in several ML/NLP/GenAI startups in domains that range from legal and compliance to health care. Dan received his B.A Summa cum laude in Mathematics from the Technion, Israel and his Ph.D. in Computer Science from Harvard University in 1995.

Yue Zhang, Westlake University

Yue Zhang is a tenured Professor at Westlake University (<https://frcchang.github.io>). His research interests include fundamental NLP and its machine learning algorithms, and his recent research focuses on LLM reasoning and AI scientist. His major contributions to the field include machine learning algorithms for structured prediction (e.g., parsing and IE), neural NLP models (i.e., lattice and graph LSTM), and generalization for NLP/LM (e.g., OOD and logical reasoning). He co-authored the Cambridge University Press book “Natural Language Processing – a Machine Learning Perspective” and served as a PC co-chair for CCL 2020 and EMNLP 2022, test-of-time award committee co-chairs for ACL 2024 and 2025, action editor for TACL, and associate editor for TASLP, TALLIP, TBD, and CSL. He won the best paper awards of IALP 2017 and COLING 2018, best paper honorable mention of SemEval 2020, and best paper nomination for ACL 2018 and ACL 2023.

Table of Contents

<i>Towards LLM-powered Attentive Listener: A Pragmatic Approach through Quantity Self-Repair</i> Junlin Li, Peng Bo and Yu-Yin Hsu	1
<i>MIRAGE: Exploring How Large Language Models Perform in Complex Social Interactive Environments</i> Yin Cai, Zhouhong Gu, Zhaohan Du, Zheyu Ye, Shaosheng Cao, Yiqian xu, Hongwei Feng and Ping Chen	14
<i>Dynamic Label Name Refinement for Few-Shot Dialogue Intent Classification</i> Gyutae Park, Ingeol Baek, Byeongjeong Kim, Joongbo Shin and Hwanhee Lee	41
<i>Rethinking KenLM: Good and Bad Model Ensembles for Efficient Text Quality Filtering in Large Web Corpora</i> Yungi Kim, Hyunsoo Ha, Sukyung Lee, Jihoo Kim, Seonghoon Yang and Chanjun Park	53
<i>Automatic detection of dyslexia based on eye movements during reading in Russian</i> Anna Laurinavichyute, Anastasiya Lopukhina and David Robert Reich	59
<i>Doc-React: Multi-page Heterogeneous Document Question-answering</i> Junda Wu, Yu Xia, Tong Yu, Xiang Chen, Sai Sree Harsha, Akash V Maharaj, Ruiyi Zhang, Victor Bursztyn, Sungchul Kim, Ryan A. Rossi, Julian McAuley, Yunyao Li and Ritwik Sinha	67
<i>ConECT Dataset: Overcoming Data Scarcity in Context-Aware E-Commerce MT</i> Mikołaj Pokrywka, Wojciech Kusa, Mieszko Rutkowski and Mikołaj Koszowski	79
<i>A Measure of the System Dependence of Automated Metrics</i> Pius Von Däniken, Jan Milan Deriu and Mark Cieliebak	87
<i>Call for Rigor in Reporting Quality of Instruction Tuning Data</i> Hyeonseok Moon, Jaehyung Seo and Heuseok Lim	100
<i>BQA: Body Language Question Answering Dataset for Video Large Language Models</i> Shintaro Ozaki, Kazuki Hayashi, Miyu Oba, Yusuke Sakai, Hidetaka Kamigaito and Taro Watanabe	110
<i>Grounded, or a Good Guesser? A Per-Question Balanced Dataset to Separate Blind from Grounded Models for Embodied Question Answering</i> Miles Shelton, Nate Wingerd, Kritim K Rijal, Ayush Garg, Adelina Gusic, Brett Barnes and Catherine Finegan-Dollak	124
<i>Learning Sparsity for Effective and Efficient Music Performance Question Answering</i> Xingjian Diao, Tianzhen Yang, Chunhui Zhang, Weiyi Wu, Ming Cheng and Jiang Gui	136
<i>Cross-Lingual Transfer of Cultural Knowledge: An Asymmetric Phenomenon</i> Chen Zhang, Zhiyuan Liao and Yansong Feng	147
<i>Leveraging Human Production-Interpretation Asymmetries to Test LLM Cognitive Plausibility</i> Suet-Ying Lam, Qingcheng Zeng, Jingyi Wu and Rob Voigt	158
<i>Improving the Calibration of Confidence Scores in Text Generation Using the Output Distribution's Characteristics</i> Lorenzo Jaime Yu Flores, Ori Ernst and Jackie CK Cheung	172

<i>KnowShiftQA: How Robust are RAG Systems when Textbook Knowledge Shifts in K-12 Education?</i> Tianshi Zheng, Weihan Li, Jiaxin Bai, Weiqi Wang and Yangqiu Song	183
<i>Improving Parallel Sentence Mining for Low-Resource and Endangered Languages</i> Shu Okabe, Katharina Hämmerl and Alexander Fraser	196
<i>Revisiting Epistemic Markers in Confidence Estimation: Can Markers Accurately Reflect Large Language Models' Uncertainty?</i> Jiayu Liu, Qing Zong, Weiqi Wang and Yangqiu Song	206
<i>Limited-Resource Adapters Are Regularizers, Not Linguists</i> Marcell Fekete, Nathaniel Romney Robinson, Ernests Lavrinovics, Djeride Jean-Baptiste, Raj Dabre, Johannes Bjerva and Heather Lent	222
<i>LLMs instead of Human Judges? A Large Scale Empirical Study across 20 NLP Evaluation Tasks</i> Anna Bavaresco, Raffaella Bernardi, Leonardo Bertolazzi, Desmond Elliott, Raquel Fernández, Albert Gatt, Esam Ghaleb, Mario Giulianelli, Michael Hanna, Alexander Koller, Andre Martins, Philipp Mondorf, Vera Neplenbroek, Sandro Pezzelle, Barbara Plank, David Schlangen, Alessandro Suglia, Aditya K Surikuchi, Ece Takmaz and Alberto Testoni	238
<i>FocalPO: Enhancing Preference Optimizing by Focusing on Correct Preference Rankings</i> Tong Liu, Xiao Yu, Wenxuan Zhou, Jindong Gu and Volker Tresp	256
<i>Combining Domain and Alignment Vectors Provides Better Knowledge-Safety Trade-offs in LLMs</i> Megh Thakkar, Quentin Fournier, Matthew Riemer, Pin-Yu Chen, Amal Zouaq, Payel Das and Sarath Chandar	268
<i>Can Uniform Meaning Representation Help GPT-4 Translate from Indigenous Languages?</i> Shira Wein	278
<i>Subword models struggle with word learning, but surprisal hides it</i> Bastian Bunzeck and Sina Zarriß	286
<i>LLM as Entity Disambiguator for Biomedical Entity-Linking</i> Christophe Ye and Cassie S. Mitchell	301
<i>Towards Geo-Culturally Grounded LLM Generations</i> Piyawat Lertvittayakumjorn, David Kinney, Vinodkumar Prabhakaran, Donald Martin Jr. and Sunipa Dev	313
<i>MUSTS: MULTilingual Semantic Textual Similarity Benchmark</i> Tharindu Ranasinghe, Hansi Hettiarachchi, Constantin Orasan and Ruslan Mitkov	331
<i>Can Large Language Models Accurately Generate Answer Keys for Health-related Questions?</i> Davis Bartels, Deepak Gupta and Dina Demner-Fushman	354
<i>Literary Evidence Retrieval via Long-Context Language Models</i> Katherine Thai and Mohit Iyyer	369
<i>A Little Human Data Goes A Long Way</i> Dhananjay Ashok and Jonathan May	381
<i>Seeking Rational Demonstrations for Large Language Models: A Domain Generalization Approach to Unsupervised Cross-Domain Keyphrase Generation</i> Guangzhen Zhao, Yu Yao, Dechang Kong and Zhenjiang Dong	414

<i>LexKeyPlan: Planning with Keyphrases and Retrieval Augmentation for Legal Text Generation: A Case Study on European Court of Human Rights Cases</i>	
Santosh T.y.s.s and Elvin Quero Hernandez	425
<i>SynWorld: Virtual Scenario Synthesis for Agentic Action Knowledge Refinement</i>	
Runnan Fang, Xiaobin Wang, Yuan Liang, Shuofei Qiao, Jialong Wu, Zekun Xi, Ningyu Zhang, Yong Jiang, Pengjun Xie, Fei Huang and Huajun Chen	437
<i>Enhancing Retrieval Systems with Inference-Time Logical Reasoning</i>	
Felix Faltings, Wei Wei and Yujia Bao	449
<i>Using Subtext to Enhance Generative IDRR</i>	
Zhipang Wang, Yu Hong, Weihao Sun and Guodong Zhou	464
<i>State-offset Tuning: State-based Parameter-Efficient Fine-Tuning for State Space Models</i>	
Wonjun Kang, Kevin Galim, Yuchen Zeng, Minjae Lee, Hyung Il Koo and Nam Ik Cho	474
<i>Internal and External Impacts of Natural Language Processing Papers</i>	
Yu Zhang	488
<i>An Effective Incorporating Heterogeneous Knowledge Curriculum Learning for Sequence Labeling</i>	
Xuemei Tang, Jun Wang, Qi Su, Chu-Ren Huang and Jinghang Gu	495
<i>Accelerating Dense LLMs via L0-regularized Mixture-of-Experts</i>	
Zhenyu Zhang, JiuDong Yang, Taozhaowen Taozhaowen and Meng Chen	504
<i>Do Multimodal Large Language Models Truly See What We Point At? Investigating Indexical, Iconic, and Symbolic Gesture Comprehension</i>	
Noriki Nishida, Koji Inoue, Hideki Nakayama, Mayumi Bono and Katsuya Takanashi	514
<i>Fast or Slow? Integrating Fast Intuition and Deliberate Thinking for Enhancing Visual Question Answering</i>	
Songtao Jiang, Chenyi Zhou, Yan Zhang, Yeying Jin and Zuozhu Liu	525
<i>Can Community Notes Replace Professional Fact-Checkers?</i>	
Nadav Borenstein, Greta Warren, Desmond Elliott and Isabelle Augenstein	535
<i>Multilingual Gloss-free Sign Language Translation: Towards Building a Sign Language Foundation Model</i>	
Sihan Tan, Taro Miyazaki and Kazuhiro Nakadai	553
<i>Advancing Sequential Numerical Prediction in Autoregressive Models</i>	
Xiang Fei, Jinghui Lu, Qi Sun, Hao Feng, Yanjie Wang, Wei Shi, An-Lan Wang, Jingqun Tang and Can Huang	562
<i>FEAT: A Preference Feedback Dataset through a Cost-Effective Auto-Generation and Labeling Framework for English AI Tutoring</i>	
Hyein Seo, Taewook Hwang, Yohan Lee and Sangkeun Jung	575
<i>ChronoSense: Exploring Temporal Understanding in Large Language Models with Time Intervals of Events</i>	
Duygu Sezen Islakoglu and Jan-Christoph Kalo	590
<i>Human Alignment: How Much Do We Adapt to LLMs?</i>	
Cazalets Tanguy, Ruben Janssens, Tony Belpaeme and Joni Dambre	603
<i>Dynamic Order Template Prediction for Generative Aspect-Based Sentiment Analysis</i>	
Yonghyun Jun and Hwanhee Lee	614

<i>That doesn't sound right: Evaluating speech transcription quality in field linguistics corpora</i> Eric Le Ferrand, Bo Jiang, Joshua Hartshorne and Emily Prud'hommeaux	627
<i>Is That Your Final Answer? Test-Time Scaling Improves Selective Question Answering</i> William Jurayj, Jeffrey Cheng and Benjamin Van Durme	636
<i>Acoustic Individual Identification of White-Faced Capuchin Monkeys Using Joint Multi-Species Embeddings</i> Álvaro Vega-Hidalgo, Artem Abzaliev, Thore Bergman and Rada Mihalcea	645

¹junlin.li@connect.polyu.hk

Abstract

Grice’s Quantity Maxims dictate that human speakers aim for the optimal quantity of information during conversation. To empower LLMs to self-repair their responses toward optimal quantity and improve their attentive listening skills, we propose **Q-Tuning** and **Q-Traveling**, which draw on heuristic path-finding to enable decoder-only LLMs to travel among multiple “Q-alternatives” (Quantity Alternatives) and search for the optimal quantity in coordination with a conversation goal. Automatic and human evaluations demonstrate the effectiveness of Q-Tuning and Q-Traveling in constructing human-like, user-centered conversation agents. Our repository is open-sourced via <https://github.com/CN-EyeteK/QTraveling>.

1 Introduction

Quote to Dorothy Nevill, “*the real art of conversation is not only to say the right thing at the right place but to leave unsaid the wrong thing at the tempting moment*” (Nevill, 1910).

To hold back the wrong thing from being said, people pay attention to their addressees’ expectations and self-repair their inner speech before speaking (Levelt, 1983). As illustrated in Figure 1, this pragmatic wisdom is overtly reflected in self-repair practices that are productive in real-world conversations (Sun, 2022), especially in attentive listening (Sarira et al., 2023). The self-repair strategies reflect listeners’ attention to their addressees’ expectations generated by various conversation principles, typically the Cooperative Principle (Good, 1990).

Taking QUANTITY MAXIMS as an instance, attentive listeners tactfully pursue an optimal quantity of information to achieve their conversation goals (Hossain et al., 2021; Atifi et al., 2011). As illustrated in Figure 1 attentive listeners should monitor and repair the quantity (or informativeness)

of their utterances to achieve the optimal communicative effect. Being over-informative or under-informative violates the QUANTITY MAXIMS and thus yields non-literal meaning and pragmatic failure (Blum-Kulka and Olshain, 1986).

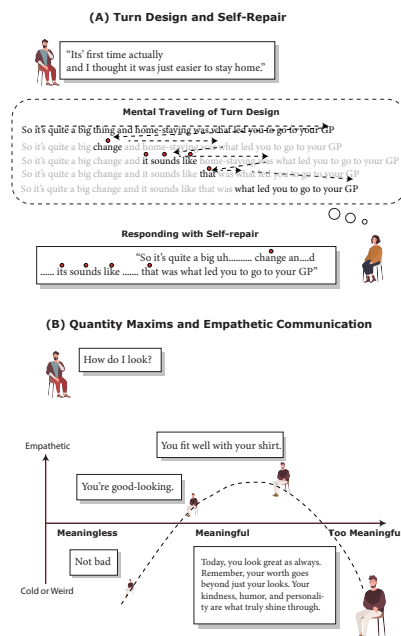

Figure 1: Self-Repair Practices and Quantity Maxims: People aim for optimal quantity through self-repair.

Despite their advancement, it is still questionable whether the decoder-only LLMs, as empathetic listeners, are human-like and attentive in essence (Pan et al.; Cuadra et al., 2024; Yin et al., 2024). LLM responses are perceived as hollow (Yin et al., 2024) and insincere (Lee et al., 2024), with limited attention to exploring and interpreting the user’s experience (Cuadra et al., 2024). This pitfall presumably reflects the drawback of incremental language generation in manipulating the quantity of their response, which is an important conversation strategy (Yeung et al., 1999).

To address this human-model misalignment, we propose theory-driven tuning and language genera-

tion paradigms, **Q-Tuning** and **Q-Traveling**, to improve LLM’s attentive listening skills through the “covert” self-repair process that frequently occurs in real-world communication. Narrowing down upon Grice’s QUANTITY MAXIMS, we tune a pre-trained LM to explore multiple Quantity Alternatives. During inference, we inform the pragmatic-aware LM to search for the optimal “Q-alternative” (quantity alternative) among the alternatives in pursuit of a flexible scoring function. Following the A* search algorithm (Hart et al., 1968), an optimal Q-alternative grounded in heuristics can be written after a chain of self-repair operations.

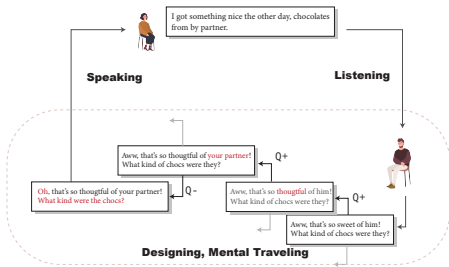

Figure 2: Generating Attentive Response through Traveling among “Q-alternatives” (“Q+” for providing more specific information, “Q-” for providing less specific information)

Of sufficient relevance to our study are the post hoc correction or self-correction methods. (Kim et al., 2024; Madaan et al., 2024; Qu et al., 2024) Distinct from the RL (Reinforcement-learning) methods based on a static reward function, the current study proposes a novel and plug-and-play self-correction paradigm based on a controllable heuristic goal. The Q-Traveling method improves the contextual adaptability to variable needs and desires in real-world users. It also presents an operationalizable framework to incorporate implicit linguistic-pragmatic knowledge, typically Grice’s Maxims of Conversation, into LLM-powered dialogue systems.

The major contributions of this study include:

- We propose **Q-Tuning** to infuse Quantity Maxims into LLMs. The evaluation results demonstrate a decisive contribution of this tuning paradigm to empathetic and attentive listening skills.
- We propose **Q-Traveling** to plan out the optimal pragmatic alternative through self-repair path-finding. Drawing on the A* search algorithm, Q-Traveling seamlessly guides LLM

listeners to an adaptable scoring function, improving LLM listeners’ competence to deal with versatile conversation goals.

2 Preliminary

2.1 Quantity Maxims

QUANTITY MAXIMS consist of a lower-bound maxim and an upper-bound maxim (Grice, 1975; Carston, 1995):

- MAXIM-I: *Make your contribution as informative as is required (for the current purposes of the exchange).*
- MAXIM-II: *Do not make your contribution more informative than is necessary*

Consider the operationalization of QUANTITY MAXIMS in a dialogue system, for a set of unidirectionally-entailing utterances as Q-alternatives $U = \{u_1, u_2, \dots, u_{n-1}, u_n\}$ where $u_n \models u_{n-1} \models \dots \models u_2 \models u_1$ ¹, there exists an “optimal” alternative (at least “good enough”) u_* in context C given a heuristic function \mathcal{H} .

$$u_* = \arg \max_{u \in U} \|\mathcal{H}(u|C)\|. \quad (1)$$

2.2 Problem Formulation - Optimal Quantity Alternative

The conventional practice of dialogic systems requires a language model \mathcal{M}_θ to generate a response u_0 from the dialogic context C .

$$u^0 \sim \mathcal{M}_\theta(C) \quad (2)$$

To search for the optimal Q-alternative, we induce \mathcal{M}_θ to conduct a pair of Quantity Guidances $q \in \{Q^+, Q^-\}$, where Q^+ denotes providing more specific information (following MAXIM-I) and Q^- denotes providing less specific information (following MAXIM-II). We expect the model to iteratively repair its current response to include more information (when $q = Q^+$, so that $u^t \models u^{t-1}$) or include less information (when $q = Q^-$, so that $u^{t-1} \models u^t$).

$$u^t \sim \mathcal{M}_\theta(u^{t-1}|q, C). \quad (3)$$

To achieve goal-driven self-repair, we use a heuristic function \mathcal{H} to explore the optimal repair path

¹We use $v \models$ to denote semantic entailment.

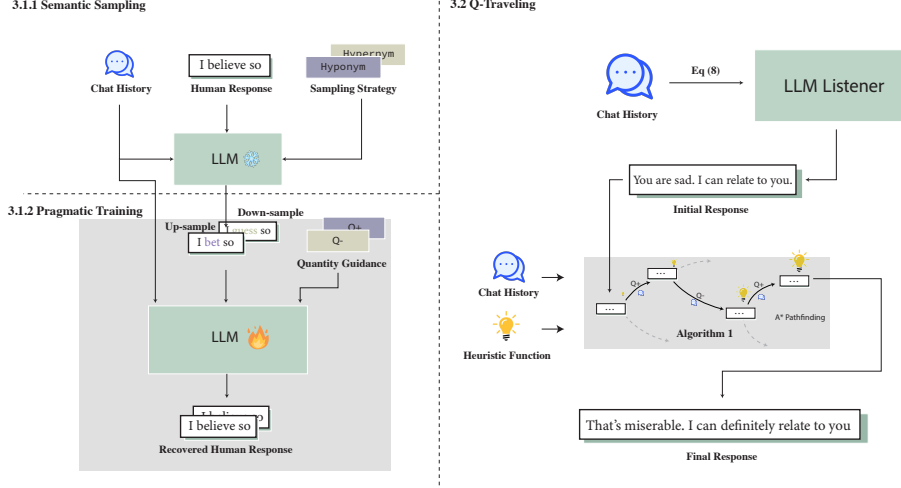

Figure 3: The overview of our method. Q-Tuning draws on the model’s inner semantic knowledge to train pragmatic strategies. Q-Travelling instructs the model to explore and search out the optimal Q-alternative.

$\{u^0 \xrightarrow{q^0} u^1 \xrightarrow{q^1} \dots u^T\}$, so that u^T is the optimal alternative of u^0 .

$$u^T = \arg \max_{u \sim \mathcal{M}_\theta(u^0)} \|\mathcal{H}(u|C)\|. \quad (4)$$

3 Method

Human interlocutors, with a set of Q-alternatives in mind, design their turns to conform with Grice’s maxims. Inspired by this process, we propose the tuning and inference paradigm in the following.

3.1 Quantity Maxims Tuning (Q-Tuning)

We initially equip a pre-trained LLM with the pragmatic knowledge to repair an utterance according to a given Quantity Guidance $q \in \{Q^+, Q^-\}$. To train this ability, we leverage the LLM’s prior semantic knowledge to create paired training samples with minimal semantic contrasts.

3.1.1 Semantic Sampling for Minimal Pairs

Given a human annotation u^h , we prompt a pre-trained LLM \mathcal{M}_θ to get a down-sample u^{h-} and an up-sample u^{h+} . We use the strategies in the following to control the semantic relation between the source, up and down samples.

- To obtain u^{h-} , \mathcal{M}_θ is asked to (1) substitute a word or phrase with its hypernym expression or (2) remove a word or phrase.
- To obtain u^{h+} , \mathcal{M}_θ is asked to (1) substitute a word or phrase with its hyponym expression or (2) include a word or phrase.

We add two constraints to the prompt as follows:

- u^{h-} should be semantically entailed by u^h , and u^{h-} should be congruous with the context C
- u^{h+} should semantically entail u^h , and u^{h+} should be congruous with the context C

Details of prompting and quality check are in the Appendix C.

3.1.2 Pragmatic Training for Quantity Self-Repair

To train self-repair behavior, we treat each u^h as the label and its corresponding u^{h-} and u^{h+} as input. The training loss can be formulated as below:

$$\mathcal{L}^+ = - \sum_{j=1}^{|u^h|} \log \mathcal{M}_{\theta, \alpha} \left(u_j^h | u_{<j}^h, u^{h-}, Q^+, C \right) \quad (5)$$

$$\mathcal{L}^- = - \sum_{j=1}^{|u^h|} \log \mathcal{M}_{\theta, \alpha} \left(u_j^h | u_{<j}^h, u^{h+}, Q^-, C \right) \quad (6)$$

$$\mathcal{L} = \mathcal{L}^+ + \mathcal{L}^- \quad (7)$$

where α denotes the adapter subnetwork injected during adapter tuning.

3.2 Response Initializing

We find that the post-trained model $\mathcal{M}_{\theta, \alpha}$ is still able to generate an initial response from scratch.

$$u_0 \sim \mathcal{M}_{\theta, \alpha}(C) \quad (8)$$

3.3 Inter-Quantity Traveling (Q-Traveling)

We propose **Q-Traveling** to search for the optimal Q alternative based on a scoring function $\mathcal{H}(u)$.

Algorithm 1 Heuristic Search for Optimal Quantity

Input: $u_0, c, \mathcal{M}_{\theta, \alpha}, \mathcal{H}$
 $\text{open} \leftarrow [u_0]$
 $\text{close} \leftarrow \emptyset$
 $\text{score} \leftarrow \{\}, \text{score}[u_0] \leftarrow \mathcal{H}(u_0)$
while $\text{open} \neq \emptyset$ & $|\text{close}| \leq \text{maxstep}$ **do**
 $\text{open} \leftarrow \underset{u \in \text{open}}{\text{argsort}}(\text{score}(u))$
 $u^p \leftarrow \text{pop}(\text{open})$
 $u^{p+} = \text{generate}(\mathcal{M}_{\theta, \alpha}, Q^+, u^p)$
 $u^{p-} = \text{generate}(\mathcal{M}_{\theta, \alpha}, Q^-, u^p)$
 for $u \in [u^{p+}, u^{p-}]$ **do**
 $\text{score}[u] = \mathcal{H}(u)$
 $\text{append}(\text{open}, u)$
 end for
 $\text{append}(\text{close}, u')$
end while
Output: $u^* \leftarrow \underset{u \in \text{score.keys}}{\text{argmax}}(\text{score}(u))$

The heuristic search algorithm is presented in Algorithm 1. In each iteration, according to the scoring board score, we sort the open list open in descending order and pop the first response as the parent node u^p . We extend two new responses u^{p+} and u^{p-} by implementing Q^+ and Q^- . We score the two new responses with \mathcal{H} and register the scores on the scoring board. We append the two new responses to the open set at the end of the iteration. We terminate the iteration when the maximum number of extended responses has been reached. Finally, we select the response with the highest score from the scoring board.

4 Experiments

LlaMA+Q-Traveling v.s. LlaMA	win	lose	tie
Human-like	41.7 †	30	28.3
Empathetic	41.0 †	32.3	26.7
Attentive	46.7 †	40	13.3

Table 2: Results of Human Evaluation. †denotes a significant improvement of $p < 0.05$.

We implemented experiments in two data sets: EMPATHETICDIALOGUE (ED) and EMOTIONAL-SUPPORT-CONVERSATION (ESC). Implementa-

tion details and baselines are described in Appendix A.

Above traditional rule-based metrics such as distinct score (**Dist**) and bleu score (**BLEU**), we also pay attention to model-based metrics such as **AI-rate**, expected judgement about empathy (**EmotionalReactions**, **Interpretation**, **Exploration**) based on the framework of EPITOME (Sharma et al., 2020), as well as the similarity between the output of the system and the ground truth in terms of emotion (**SimEMO**) and personality (**SimPerson**).

As shown in Table 1, our method leads to a visible increase in system performance in terms of human-like and diverse language use. Inspecting both data sets, the Q-Tuning and Q-Traveling mechanism also enlarges the diversity (**Dist-n**). The reduction in the use of AI-like language use (**AI-rate**) is also noticeable compared to LLM baselines. We also observe an improvement in the match of emotion and personality (**SimEMO** and **SimPerson**) with ground truth, mostly owing to Q-Tuning.

Table 2 presents the results of the human evaluations. Our approach shows a remarkable advantage with respect to the use of human-like and attentive language.

5 Analysis

Figure 4 compares the distribution of personality embeddings (see A.5) from the LLM backbone, our repair-aware systems, and human-written ground truth. With the proposed mechanism for quantity repair, the system output is densely distributed in a human-like subzone (marked in a red oval), compared to backbone LLMs.

Figure 4: Q-Tuning and Q-Traveling anchor the personality embeddings to a more human-like subzone

We also inspect two different goals, including (1) empathetic reaction and (2) helpfulness and

Table 1: Results of Automatic Evaluation. Best performance among LLM-powered and among all systems are bold-highlighted and underlined separately.

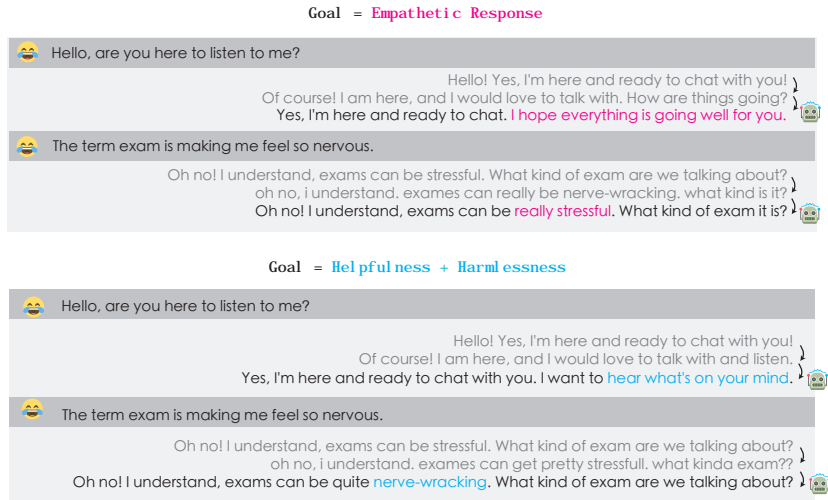

Figure 5: Q-Traveling reflects goal-driven conversation: the effect of scoring function on lexical choice.

harmlessness (see A.4). From the case presented in Figure 5, we notice the adaptability of our system to different conversation goals. Detailed case studies are given in the Appendix B.1

6 Conclusions

Inspired by quantity self-repair practices in real-world conversation, we propose **Q-Tuning** and **Q-Traveling** to infuse pragmatic conversation strategies into large language models. The results indicate a noticeable improvement in human-like attentive listening skills.

Limitations

The paper focuses primarily on the impact of Quantity Maxims on human conversation without delving into potential cultural or situational factors that might influence these dynamics. The study may

not account for individual differences in how different listeners interpret and respond to varying levels of informativeness, which could limit the generalizability of the findings.

Finally, assessing the precise impact of conversation maxims on empathy and mental health outcomes could be challenging due to the subjective nature of these constructs and the difficulty in quantifying such effects accurately. More subjective judgment data should be collected and annotated to provide a solution to the issue under discussion.

Ethical Considerations

Our study is based on the ESC and ED dataset, designed specifically for emotional support and empathetic conversations and openly available for research purposes. These data sets maintain a focus on empathy-driven scenarios while ensuring the exclusion of sensitive or personal data and unethical

language. Throughout our research, the utmost priority was given to safeguarding the privacy of all participants involved.

It is also crucial to clarify that our dialogue system is not intended to address or improve outcomes in high-risk or nonroutine scenarios such as those involving self-harm or suicide. We recognize the indispensable role of professional psychological counseling or treatment in managing such critical situations.

Finally, all human participants involved in the evaluation process provide informed consent. To maintain the confidentiality and anonymity of participants, all human evaluation data was handled with strict confidentiality measures in place. The whole human-recruiting procedures are approved by The PolyU Institutional Review Board (IRB).

Acknowledgments

This research was supported by GRF (B-Q0AJ), and by the Hong Kong Polytechnic University through the Large Equipment Fund (1-BC7N), CBS fund (1-W16H). We would also like to thank the anonymous reviewers for their feedback and suggestions.

A Experiment Details

A.1 Dataset

Empathetic Dialogue (ED) (Rashkin et al., 2018) is a multi-turn empathetic dialogue dataset containing 24,850 one-to-one open-domain short conversations. The statistics of the ED Dataset are presented in Appendix A.5.

Emotional Support Conversation (ESC) (Liu et al., 2021) is a multi-turn conversation dataset. It consists of 1300 long conversations, each of them collected between an emotional help-seeker and a helper. The statistics and the data acquisition of ESC Dataset are presented in Appendix A.5.

A.2 Baseline Systems

We compare the following systems with our proposed systems equipped with Q-Tuning and Q-Traveling.

LLaMA2 LLaMA2 is a vanilla open and efficient large language model that uses an optimized transformer architecture (Touvron et al., 2023). We use the meta-llama/LLaMA-2-7b-chat-hf checkpoint which is optimized for dialogue use cases as baseline and also to implement Q-Tuning and Q-Traveling.

Mistral Mistral is an open large language model that balances the goals of high performance and efficiency and features the use of sliding attention (Jiang et al., 2023). We use the mistralai/Mistral-7B-v0.3 checkpoint as baseline and also to implement Q-Tuning and Q-Traveling.

CARE is a dialogue system finetuned from ED Dataset. It reasons all plausible causalities interdependently and simultaneously, given the user emotion, dialogue history, and future dialogue content (Wang et al., 2022a).

SEEK is an ED system that captures emotional-intention transitions in dialogue utterances (Wang et al., 2022b).

Cooper is an ESC system that coordinates multiple LLM agents, each dedicated to a specific dialogue goal aspect separately, to approach the complex objective (Cheng et al., 2024).

VLESA-ORL is an ESC system that carries out multi-level dialogue policies optimized over the cognitive principle of relevance (Li et al., 2024).

A.3 Implementation Details

Prompting Baselines We use the prompt in Table 9 and Table 10 to generate baseline responses from meta-llama/LLaMA-2-7b-chat-hf and mistralai/Mistral-7B-v0.3. The top_p is set to 0.7 and top_k is set to 50.² For other baseline systems, we use the official repository to generate baseline responses.

Q-Tuning We implement Q-Tuning on both LLaMA-2-7b-chat-hf and Mistral-7B-v0.3. The paired samples are extracted from LLaMA-2-7b-chat-hf through semantic sampling (see 3.1.1), based on the prompt presented in Appendix C.1. We use LoRA-Tuning to perform Q-Tuning. The target modules are set as “q_proj” and “k_proj”. The LoRA rank is set to 8, the alpha is 32, the LoRA dropout rate is assigned to 0.1. We set the learning rate to 1e-5 and the training batch size to 4, for 1 epoch, and select the final checkpoint for evaluation.

Q-Traveling For automatic evaluation, the maximum step is set to 3.

A.4 Scoring Function for Q-Traveling

For all the results of automatic and human evaluation, the scoring function is the direct summation of reward scores from gpt2-large-helpful-reward_model, and gpt2-large-harmless-reward_model (harmless score). For analysis, we also explore the expected empathy judgment (a scalar score $\in [0, 1, 2]$) through the empathy detection model fine-tuned over Empathetic-Mental-Health Dataset (Sharma et al., 2020) using the official repository³.

A.5 Automatic Evaluation

We use several conventional and model-based metrics to evaluate the quality of the generation. Con-

²Other parameters follow the default settings in the transformers package

³<https://github.com/behavioral-data/Empathy-Mental-Health>

ventional evaluation metrics include Distinct-n (**Dist-n**) (Li et al., 2015) to evaluate the variation of the response in different dialogue states, and BLEU (**BLEU-n**) (Papineni et al., 2002) to evaluate the lexical alignment with the ground truth. Model-based evaluation metrics include emotion similarity **SimEMO**, personality similarity **SimPerson** and **AI-rate**.

Of importance for empathetic conversation, we argue it is viable to evaluate the similarity of emotion (**SimEMO**) and personality (**SimPerson**). For **SimEMO**, we use the cosine similarity between the pooler output of emotion-english-distilroberta-base of the generated response and ground truth. For **SimPerson**, we calculate the cosine similarity between the pooler output of Minej/bert-base-personality of the generated response and ground truth. We are also curious about the **AI-rate** of the generated response, as the detection of AI label is detrimental to perceived emotional support (Yin et al., 2024). We adopt SuperAnnotate/ai-detector to quantify the **AI-rate** of the generated response.

Additionally, we compute the expected empathy judgment (including **EmotionalReaction**, **Interpretation**, **Exploration**) through the empathy detection model fine-tuned over Empathetic-Mental-Health Dataset (Sharma et al., 2020) using the official repository⁴. The model returns a scalar score $\in [0, 1, 2]$ for each dimension of judgment.

Human Evaluation Following the practice in (Zhou et al., 2023), we invite three doctoral students in the linguistic field to evaluate the proposed and baseline systems based on the ED dataset. We randomly sample 50 pairs of context and response for the test set. Following previous practice, we conduct A/B tests (Cheng et al., 2022; Zhou et al., 2023) to evaluate the following aspects, including (1) **Humanlike** (to what extent the chatbot provides human-like responses), (2) **Empathetic** (to what extent the chatbot reflects the user’s emotional state), and (3) **Attentive** (to what extent the chatbot is attentive to the user).

A.6 Dataset Statistics

For the **ED** dataset (Rashkin et al., 2018), each conversation is recorded between an emotional speaker and an empathetic listener. In detail, the emotional speaker is asked to talk about the personal emo-

⁴<https://github.com/behavioral-data/Empathy-Mental-Health>

tional situation, and a listener takes the speaker’s perspective and responds empathetically. For the

Empathetic Dialogue	Division		
	Train	Dev	Test
Number of System Utternaces	40254	5738	5259
Avg. words per utterance	13.39	14.47	15.32
Avg. turns per dialogue	4.31	4.36	4.31
Avg. words per dialogue	57.72	63.11	65.98

Table 3: Statistics of Empathetic Dialogue Dataset

ESC dataset (Liu et al., 2021), each conversation is recorded between a help-seeker and a supporter. In detail, the help-seeker gives vent to a negative emotion, and the supporter provides support to alleviate the seeker’s mental sufferings.

Emotional Support Conversation	Division		
	Train	Dev	Test
Number of System Utternaces	12759	2722	2895
Avg. words per utterance	18.72	18.83	17.63
Avg. turns per dialogue	23.28	22.91	24.37
Avg. words per dialogue	548.09	548.32	546.16

Table 4: Statistics of Emotional Support Conversation Dataset

B Case Studies

B.1 Case Studies

Table 5 presents a case for a comparison between the backbone LLM and quantity-aware systems. Instead of providing hollow and inattentive information (*italic-highlighted*), our systems are more human-like in reaction to user’s troubles (**bold highlighted**).

C Semantic Sampling

C.1 Prompt and Quality Check for Semantic Sampling

We prompt meta-llama/LLaMA-2-7b-chat-hf and Mistral-7B-v0.3 for semantic sampling. The prompts are presented in Table 6 and 7.

We use facebook/bart-large-mnli to check the entailment relationship between the input and output of semantic sampling. For u^{h^-} , we filter those samples that are not entailed by u^h , taking the probability of 90% as the threshold. For u^{h^+} , we filter those samples that do not entail u^h , taking the probability of 90% as the threshold.

We provide an excerpt of dialogue (from ESC dataset) to show output of I-Sampler 8. From the case analysis, we can see that the I-Sampler, based

Context	User: Once I took a sip of iced tea while I was driving and it went down the wrong pipe. I had to pull over so I could try to breathe again. System: That’s scary when that happens User: Yeah it is. I thought I was about to die lol
Ground-truth	Some people DO die from choking, be safe!
LlaMA-7b-chat-hf	Oh no, that must have been terrifying! <i>I can imagine how difficult it must have been for you to breathe and drive at the same time.</i> (Hollow and weird)
Q-Tune (Initial)	Oh my god, thats so scary! I am glad you u are ok
Q-Travel (Helpful&Harmelss)	Oh my goodness, that must have been terrifying! I’m glad you’re okay!
Q-Travel (Empathetic Response)	Oh my god, I can’t imagine how scared you must have felt, but glad that you are ok

Table 5: Case Studies: Systematic acquisition of quantity repair makes LLMs more attentive to users.

on LLM prompting, efficaciously resamples the informativeness of the ground-truth response without over-modifying the sentence meaning. For example, the upsampling result changes the word “heavy subject” to “weighty issue,” which is semantically stronger. In contrast, the downsampling result changes the phrase “heavy subject” to “tough issue” as a more imaginable and semantically weaker expression.

D Prompt for LLM baselines

In Table 9 and 10, the initial prompt for LLaMA and Mistral on the ESC and ED Dataset are presented.

User	<p>Hello, you are a lexical semantic good at utterance simplification. Now I will provide you a piece of utterance composed of one or multiple sentences.</p> <p>I need your help to pinpoint one or two words/phrases and replace them with simpler, more imaginable and generic ones (e.g. their hypernyms) or delete them, to make the whole utterance less informative.</p> <p>Here are some principles you should follow:</p> <p>## Make sure your answer is semantically weaker, generic and less informative than the piece of utterance I provide.</p> <p>## Make sure your answer convey all the information conveyed in the provided utterance.</p> <p>## Make sure your answer is semantically similar to the provided utterance.</p> <p>Here are some examples:</p> <p>Input: When Tegan went for a summer holiday beach stroll with her mum, she had no idea they would be actually walking in the footsteps of dinosaurs.</p> <p>Output: When Tegan went for a summer holiday beach walking with her family, she had no idea they would be (delete:actually) walking in the footsteps of dinosaurs.</p> <p>Input: Ah I hear you there! Some employers are so inconsiderate; they expect us to drop everything and work at any time of any day.</p> <p>Output: (delete:Ah) I hear you there! Some employers are so bad; they expect us to drop everything and work at any time of any day.</p> <p>Input: He blushed scarlet at the thought. Oh, he's not apprehensive. He's terrified.</p> <p>Output: His face was red at the thought. Oh, he's not nervous. He's terrified.</p>
Assistant	<p>Understood! I'll do my best to enrich the given utterance by replacing one word or phrase with a more specific and semantically similar alternative. Please provide the input utterance, and I'll get started.</p>
User	<p>Now please simplify this utterance as a whole:</p> <p>"{{INPUT}}"</p> <p>in response to:</p> <p>"{{PREVIOUS DIALOGUE}}"</p> <p>Please ensure that all the sub-utterances in the input is preserved in your output.</p> <p>Please answer in this format: <output></output></p>

Table 6: Prompt for downsampling

User	<p>Hello, you are a lexical semantic good at semantic enrichment. Now I will provide you a piece of utterance composed of one or multiple sentences. I need your help to pinpoint one or two words/phrases and replace it by more specific, less imaginable and semantically more concrete one (e.g. their hyponyms) or insert one phrasal modifiers, to make the whole utterance more informative.</p> <p>Here are some principles you should follow:</p> <p>## Make sure your answer is semantically stronger, more specific and more informative than the piece of utterance I provide.</p> <p>## Make sure your answer convey all the information conveyed in the provided utterance.</p> <p>## Make sure your answer is semantically similar to the provided utterance.</p> <p>Here are some examples:</p> <p>Input: I get you! Some employers are so bad. They want us to stop everything and keep working .</p> <p><output>I get you! Some employers are so inconsiderate. They want us to stop everything and keep working </output>.</p> <p>Input: Of course, that's wise. the job at hand is important, and you should focus on it first before worrying.</p> <p><output>Of course, that's prudent. the job at hand is important, and you should focus on it first before worrying about other things</output>.</p> <p>Input: His face was red when thinking about this. Oh, he's not nervous. He's scared.</p> <p><output>He blushed scarlet when thinking about this. Oh, he's not nervous. He's terrified.</output></p>
Assistant	<p>Understood! I'll do my best to enrich the given utterance by replacing one word or phrase with a more specific and semantically similar alternative. Please provide the input utterance, and I'll get started.</p>
User	<p>Now please enrich this utterance by adding only one word/phrase or changing only one word/phrase:</p> <p>- {{INPUT}}</p> <p>in response to:</p> <p>"{{PREVIOUS DIALOGUE}}"</p> <p>Please ensure that all the sub-utterances in the input is preserved in your output.</p> <p>Please answer in this format: <output></output></p>

Table 7: Prompt for upsampling

Situation	Not sure how to explain that I want out of marriage
System (Upsample) (Downsample)	Hello! How are you today? Hello! How are you feeling today? Hey! How's it going ?
User	Ok I guess, I do not know how to tell my husband that I am lonely and I want out of the marriage
System (Upsample) (DownSample)	Oh, that sure is a heavy subject and a heavy thing to be on your mind. Oh, that's a very weighty issue and a difficult situation to grapple with . That's a tough issue to think about .
User	He is not one you can talk to he usually just brushes things off
System (Upsample) (DownSample)	So you have tried to discuss your loneliness with your husband before? So you have attempted to share your feelings of isolation with your spouse previously ? Have you told your husband about how lonely you feel before?

Table 8: A case analysis of the output of semantic sampling. "System" denotes the ground-truth response in ESC dataset. The cues of informativeness resampling are bold-highlighted.

	<p>Hello, I am one of your close friends. I am recently in bad mood. I come to chat with you because you are a good emotional supporter.</p> <p>Now I will start the chat. Please chat with me to provide support.</p> <p>Note:</p> <p>Try to talk perspicuously just like our everyday chat. Don't bombard! Leave your response within one sentence.</p> <p>Here is an example:</p> <p>I: I feel so frustrated. You: May I ask why you are feeling frustrated? I: My school was closed without any prior warning due to the pandemic. You: I understand you. I would also have been really frustrated if that happened to me. I: Yeah! I don't even know what is going to happen with our final. You: That is really upsetting and stressful. You: Have you thought about talking to your parents or a close friend about this?</p>
User	
Assistant	Ok, you are my friend and I will provide your with emotional support. Let's start the conversation.

Table 9: The initial prompt for LLaMA on ESC Dataset

User	<p>Hello, I come to chat with you because your are an empathetic listener.</p> <p>Now I will start the chat. Please chat with me empathetically</p> <p>Note:</p> <p>Try to talk perspicuously just like our everyday chat. Don't bombard! Leave your response within one sentence.</p> <p>Here is an example:</p> <p>I: I feel so frustrated.</p> <p>You: May I ask why you are feeling frustrated?</p> <p>I: My school was closed without any prior warning due to the pandemic.</p> <p>You: I understand you. I would also have been really frustrated if that happened to me.</p> <p>I: Yeah! I don't even know what is going to happen with our final.</p> <p>You: That is really upsetting and stressful.</p> <p>You: Have you thought about talking to your parents or a close friend about this?</p>
Assistant	<p>Ok, you are my friend and I will provide your with emotional support. Let's start the conversation.</p>

Abstract

Large Language Models (LLMs) have shown remarkable capabilities in environmental perception, reasoning-based decision-making, and simulating complex human behaviors, particularly in interactive role-playing contexts. This paper introduces the Multiverse Interactive Role-play Ability General Evaluation (MIRAGE), a comprehensive framework designed to assess LLMs' proficiency in portraying advanced human behaviors through murder mystery games. MIRAGE features eight intricately crafted scripts encompassing diverse themes and styles, providing a rich simulation. To evaluate LLMs' performance, MIRAGE employs four distinct methods: the Trust Inclination Index (TII) to measure dynamics of trust and suspicion, the Clue Investigation Capability (CIC) to measure LLMs' capability of conducting information, the Interactivity Capability Index (ICI) to assess role-playing capabilities and the Script Compliance Index (SCI) to assess LLMs' capability of understanding and following instructions. Our experiments indicate that even popular models like GPT-4 face significant challenges in navigating the complexities presented by the MIRAGE. The datasets and simulation codes are available in [github](#).

1 Introduction

Large Language Models (LLMs) have demonstrated remarkable potential in environmental perception and reasoning-based decision-making (Xi et al., 2023; Guo et al., 2024; Gu et al., 2024b), thereby advancing the development of LLMs in role-playing capabilities (Chen et al., 2024; Gu et al., 2024a). LLMs have been validated for their human-like behaviors, such as cooperation and competition, in various domains like social simulation (Park et al., 2023; Gu et al., 2024a; Wang et al., 2024), policy simulation (Xiao et al., 2023), game simulation (Xu et al., 2023b) and even more

advanced human behaviors like deception and leadership in flexible and complex simulations (Xu et al., 2023b). Therefore, to effectively evaluate the performance of LLMs in demonstrating advanced human-like behaviors and facilitate comparisons with the capabilities of other LLMs, it is crucial to develop a competitive and objective simulation.

Board games have emerged as an ideal choice among various assessment tools due to their inherent complexity and flexibility. Within this category, murder mystery games have proven particularly effective for evaluating LLMs' capabilities. In these role-playing scenarios, participants assume character identities and engage in semi-structured narrative interactions. Players work together to solve fictional homicides by gathering evidence and interrogating suspects. Other board games, such as Werewolf (Xu et al., 2023b,a; Shibata et al., 2023; Wu et al., 2024) and Avalon (Wang et al., 2023), are often constrained by rigid decision processes and limited scenario variety. In contrast, murder mystery games require extensive background knowledge, emphasize socially driven decision-making, and enable open-ended interactions. These characteristics make them especially valuable for assessing how LLMs navigate complex human behaviors.

Regarding previous works such as Sotopia (Zhou et al., 2023) and Lyfe Agents (Kaiya et al., 2023), significant progress has been made in simulating autonomous AI societies and assessing the social interaction capabilities of workflow-enhanced LLMs, which is so called agents (Park et al., 2023; Gu et al., 2024a). However, these studies overlooked a crucial fact: The foundational social interaction capabilities stem from the underlying LLMs themselves. Since LLMs are the core driver of agents' ability to understand social contexts, make decisions, and engage in meaningful interactions, a more comprehensive evaluation of LLMs' social capabilities is essential. Furthermore, while the murder mystery game simulations pioneered by

*Corresponding Authors

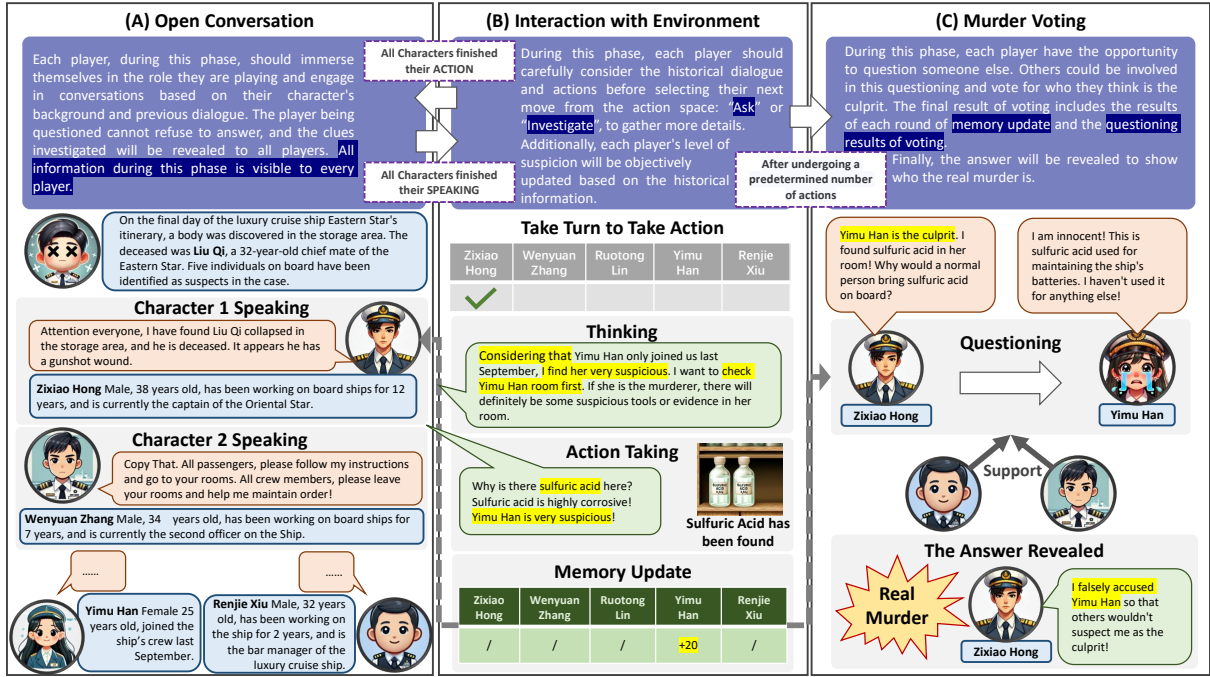

Figure 1: The three main phase of MIRAGE. And the main components in these phases.

Wu et al. (Wu et al., 2023) collected a substantial amount of data, they were constrained by the narrow scope of their game scripts, the simplicity of their evaluation methods, and a lack of thorough manual examination of the dataset. These limitations underscore the current absence of comprehensive frameworks for evaluating LLMs' social capabilities.

We introduce the **Multiverse Interactive Role-play Ability General Evaluation (MIRAGE)** of LLM in this paper, which is a comprehensive simulation built upon murder mystery games for evaluating LLMs' social abilities. MIRAGE features eight unique storylines. Each storyline presents distinct themes and styles, creating a diverse simulation environment for LLMs to demonstrate their social capabilities. Detailed background stories and complex interpersonal networks support every character within MIRAGE, enabling more immersive and realistic role-playing scenarios. And four objective evaluation metrics are incorporated in MIRAGE to measure LLMs' performance during the simulations: The **Trust Inclination Index (TII)** measures how well LLMs balance trust and skepticism in social interactions, revealing their ability to discern truthfulness. The **Clue Investigation Capability (CIC)** evaluates proficiency of LLMs in complex information gathering and problem-solving tasks. The **Interactivity Capability Index (ICI)** examines the overall performance of LLMs in reasoning,

communication, collaboration, detail orientation, and creative thinking. The **Script Compliance Index (SCI)** measures how faithfully LLMs adhere to their assigned character roles and background settings.

2 MIRAGE Construction

2.1 Scripts Construction

The script content in the MIRAGE is divided into six main parts: (1) **Character Story** describes the character's essential information and background. (2) **Character Script** outlines what the character sees, hears, and does during the script's events. (3) **Character Relationships** details the initial relationships between the character and other characters. (4) **Role Performance** describes the character's personality traits and the speaking style they should exhibit. (5) **Role Goals** outlines the main tasks and objectives of the character. (6) **Other Abilities** describes the rules the character must follow during the game.

2.2 Simulation Construction

As demonstrated in Fig. 1, all characters in MIRAGE are divided into two factions: **Culprits** and **Civilians**. Culprits aim to conceal their actions, while civilians strive to identify the culprit.

A simulation consists of three primary phases, with all generated information accessible to all participants: (A) **Open Conversation**: In this phase,

Name	Structure	Type	Ending	#Stages	#Agent	#Clues	#Words
Bride in Filial Dress	Single	Orthodox	Close	1	10	39	27,503
The Eastern Star Cruise Ship	Single	Orthodox	Open	1	5	42	3,039
Night at the Museum	Single	Unorthodox	Close	1	6	82	6,480
Li Chuan Strange Talk Book	Single	Unorthodox	Open	1	7	14	45,666
The Final Performance of a Big Star	Multi	Orthodox	Close	7	2	17	5,794
Raging Sea of Rest Life	Multi	Orthodox	Open	2	6	27	6,804
Article 22 School Rules	Multi	Unorthodox	Close	5	7	17	41,728
Fox Hotel	Multi	Unorthodox	Open	2	7	46	62,224

Table 1: Statistic information of eight environments in MIRAGE simulation.

players assume their assigned roles from the script and engage in turn-based open dialogue. Each participant is provided with a script that contains content described in Sec. 2.1. **(B) Interaction with the Environment:** This phase follows the Open Conversation. Players may choose to either Ask or Investigate. The Ask action allows one player to question another, and the questioned player is obliged to respond. The Investigate action lets players disclose a “clue” to all characters. **(C) Murder Voting:** At the conclusion of the simulation, players may accuse other players of being the culprit. Following this, the other players vote on these accusations. If the actual culprit is accused and receives the highest number of votes, the civilians win; otherwise, the culprit is victorious.

Clues are partial disclosures of individual characters’ script content that can be discovered by any player during the game. And **Key Clues** is the clues that relate to the culprit’s actions or identity.

2.3 Auxiliary Modules

To ensure efficient simulation and accurate evaluation across various LLMs, a standardized set of auxiliary modules has been implemented for all LLMs: **(1) Summarization Module:** This module compresses the context into segments whenever the input exceeds the LLM’s token limit. **(2) Suspicion Module:** The LLM records suspicion scores for other characters at the end of each Open Conversation Phase. **(3) Trust Module:** Similarly, at the end of each Open Conversation Phase, the LLM records trust scores for other characters. **(4) Rerun Module:** If the LLM’s output cannot be parsed, the original output and requirements are resubmitted to the LLM for a revised response that meets the specified conditions. Further details are available in Appendix H.

2.4 Evaluation Methods

We utilized four distinct evaluation metrics to assess the proficiency of LLMs in navigating complex social interactions: **Trust Inclination Index (TII):** TII is derived from a combination of suspicion and trust scores. These scores are collected from other characters’ Suspicion Module and Trust Module outputs after each Open Conversation Phase. **Clue Investigation Capability (CIC):** CIC measures the ability of LLMs to investigate clues during game rounds. It is calculated based on the ratio of the number of clues investigated to the number of all clues. **Interactivity Capability Index (ICI):** ICI evaluates the overall interactive capability of LLMs: Reasoning and Analysis Ability, Communication and Cooperation Ability, Observation Ability, and Thinking Innovation Ability, which are scored by a powerful neutral LLM. **Script Compliance Index (SCI):** SCI assesses LLMs’ script compliance through the average of two evaluations by a neutral LLM: A direct scoring of the LLM’s role-playing performance against its input script. A Rouge-L-based comparison between the original script and one reconstructed from the LLM’s simulation behaviors.

The mathematical formulas for computing these metrics are provided in Appendix B.

2.5 Statistics

Tab. 1 provides the statistics of the MIRAGE dataset, which includes a variety of simulation types. “Single” and “Multi” specify whether a character’s script is read entirely simultaneously or in phased segments. “Orthodox” and “Unorthodox” differentiate scripts based on whether they are set realistically. “Close” and “Open” indicate whether the script’s ending is fixed or can vary depending on the characters’ actions.

Model	Env Tokens / Envs	User Tokens / Users	Victory	TII	CIC	ICI	SCI
GPT-3.5	2,719,895 / 883	121,378 / 580	29.11	47.13	27.46	70.06	49.10
GPT-4	2,431,142 / 759	172,128 / 587	34.69	76.32	19.01	76.54	50.42
GPT-4o	6,252,580 / 1,328	204,772 / 574	47.01	78.69	35.92	76.80	51.29
Qwen-2-7B	2,204,029 / 743	192,158 / 588	51.81	75.78	18.66	74.92	50.57
GLM-4-9B	4,071,805 / 1,328	204,772 / 574	31.89	53.85	20.07	71.60	48.13

Table 2: Total Average Results for a single simulation in each MIRAGE scenario. **Env Tokens** refer to the number of environment input tokens, and **Envs** represent the total requests, including all environment-related actions. **User Tokens** denote the number of LLM output tokens, and **Users** represent completions excluding summarization or clue investigation. **Victory** shows the MRR score of the result of voting. **TII**, **CIC**, **ICI** and **SCI** respectively represent the **TII**, **CIC**, **ICI** and **SCI** scores of LLMs during the games.

Model	TII w/o E	TII w/ E	Δ
Qwen-1-7B	51.02	50.69	-0.33
Qwen-1.5-7B	73.00	69.14	-3.86
Yi-1.5-9B	55.73	57.57	1.84
GLM-4-9B	57.82	55.94	-1.88

Table 3: TII scores of each model when acting as the civilian in MIRAGE while Qwen-2-7B acts as the culprit, with E indicating cases of forced self-exposure.

3 Experiment

3.1 Experiment Setup

The experiments presented in this study utilized proprietary and open-source models, specifically GPT-3.5, GPT-4 and GPT-4o (closed-source), Qwen-2-7B, and GLM-4-9B (open-source). Detailed descriptions of the prompts used in the experiments can be found in Appendix H. Appendix E shows more results on open-source LLMs. In the experiment, each character participated in five iterations alternating between the Open Conversation and Interaction Phases. During each Open Conversation Phase, each character was permitted to initiate one turn of speech. ICI and SCI are conducted and scored using the GPT-4-turbo model.

3.2 Analysis

We averaged the results of LLMs in the MIRAGE simulation, as presented in Tab. 2. **GPT-4o demonstrated consistent superiority across various metrics during MIRAGE.** It achieved the best scores in CIC, ICI, and SCI, excelling not only in its efforts during lead investigations but also exhibiting the best adherence to scripted behavior and communication interaction capabilities. Surprisingly, Qwen-2-7B shows the best overall Victory and performed comparably to LLMs like GPT-4 in the ICI metric, even surpassing GPT-4 in SCI.

As shown in Tab.2, **most LLMs demonstrate a higher propensity to trust other characters.** To

Figure 2: CIC of Clues and Key Clues on 100 Rounds of MIRAGE using Qwen-2-7B

further investigate this trust pattern, we analyzed TII scores across four additional open-source models of comparable parameter sizes under scenarios where characters were forced to disclose their criminal identities. As shown in Tab.3, even under such extreme conditions, most models maintained their trust in these characters, with Yi-1.5-9B being the only model that increased its suspicion towards self-disclosed criminals. This distinctive behavioral pattern explains Yi-1.5-9B’s superior performance in achieving Victory, as shown in Tab. 10.

Additionally, as illustrated in Fig. 2, the CIC for clues shows a steep initial increase with a gradually decreasing slope across rounds, suggesting that **LLMs exhibit high environmental exploration enthusiasm in early rounds but shift their focus to character interactions as they thought they become more familiar with the environment.** In contrast, the bumpy rise CIC for key clues indicates that despite their active exploration, **most LLMs struggle to identify critical information** essential for solving the mystery at an earlier stage.

4 Conclusion

This paper presents MIRAGE and four evaluation methods (TII, CIC, ICI, SCI) for LLMs. Results show that both open-source and proprietary LLM-based Agents still struggle with complex social scenarios like those in MIRAGE.

Limitation

MIRAGE is designed to provide a sufficiently complex social simulation environment and basic assessment for LLMs, assisting researchers in evaluating the performance of LLMs. However, MIRAGE encompasses a variety of scenarios, and the volume of data within it needs to be increased compared to the information available in the real world. Due to the context limitations of LLMs, content that is overly lengthy within the simulation has been summarized. However, such summarization can impact the decision-making to a certain extent. Therefore, the progression of simulations in MIRAGE is somewhat constrained by the context limitations of LLMs.

Ethical Concern

Considering that MIRAGE may encompass a range of sensitive topics, including but not limited to murder, theft, impersonation, and deceit, existing LLMs might refuse to answer sensitive questions for safety reasons, putting those with a higher priority on security standards at a disadvantage in simulations. Moreover, LLMs fine-tuned on such data could inadvertently amplify security vulnerabilities. To mitigate the ethical dilemmas associated with murder mysteries, we have invested significant effort and resources towards this goal: ensuring that models committed to safety will obscure certain critical information instead of refusing to answer sensitive questions.

A Ablation Study

Tab. 4 and 5 display the results of an ablation study on the choice of evaluation model. It is evident from the tables that the GPT-4-Turbo models provide more stable scoring and Rouge-L results when used as the evaluation model. In contrast, GPT-4 exhibited instability in evaluations and a strong bias.

Score \ Eval_Model			
Model	GPT-4	GPT-4-Turbo	GPT-4o
GPT-3.5	67.97	70.06	51.61
GPT-4	60.73	76.54	66.90
GPT-4o	62.78	76.80	61.92

Table 4: Average **ICI** on different evaluation models

As shown in Tab. 5, GPT-4 achieved a remarkably high score of 67.97 when evaluating GPT-3.5, far surpassing the results of GPT-4 and GPT-4o. This kind of bias is highly problematic in evaluation tasks. Therefore, we ultimately chose the more stable and capable GPT-4-Turbo model as the evaluation model.

Score \ Eval_Model			
Model	GPT-4	GPT-4-Turbo	GPT-4o
GPT-3.5	48.21	49.10	38.46
GPT-4	40.60	50.42	44.46
GPT-4o	42.12	51.29	42.43

Table 5: Average **SCI** on different evaluation models

B Computational methods of Evaluation methods

B.1 TII

TII is designed to quantify the degree to which a Character c' is trusted by all other Characters $C = \{c\}$. The TII is calculated as follows:

$$TII_{c'} = \frac{\sum_{c \in C, c \neq c'} P_T(c, c')}{\sum_{c \in C, c \neq c'} P_S(c, c') + \sum_{c \in C, c \neq c'} P_T(c, c')} \quad (1)$$

where P_S denotes the score produced by each character’s Suspicion Module, and P_T represents the score from each character’s Trust Module.

B.2 CIC

CIC is designed to quantify a Character’s effort in investigating clues. The CIC is calculated as follows:

$$CIC_c = \sum_{c \in C} \frac{CN_c}{CA} \quad (2)$$

where CN denotes the number of clues Character c investigated, and CA represents the number of all clues can be investigated.

C Detail Main Results

Our main results of MIRAGE are shown in Tab. 11. We set a Single & Orthodox & Close Script as an SOC Script, a Single & Orthodox & Open Script as an SOO Script, a Single & Unorthodox & Close Script as an SUC Script, a Single & Unorthodox & Open Script as an SUO Script, a Multi & Orthodox & Close Script as an MOC Script, a Multi & Orthodox & Open Script as an MOO Script, a Multi & Unorthodox & Close Script as an MUC Script and a Multi & Unorthodox & Open Script as an MUO Script. The column Model shows the specific LLM we use in our experiments. Moreover, we counted the number of Env Token / Env and User Token / User to record our cost of API use. Finally, we calculate the Failure number while parsing LLM output and our evaluation scores TII, ICI, SCI and more detailed neutral LLMs score (0-20): Role-Playing (RP), Reasoning Ability (RA), Communication and Cooperation (CC), Detail Observation (DO) and Creative Thinking (CT). The main results shown in Tab. 11 is the average number of each Script. Moreover, the detailed results of each Script are shown in Tab. 6. In addition, Tab. 8 shows the mapping between the LLMs used in this paper and its corresponding version. To facilitate cost estimates, GPT-4, for example, costs about 600-700 USD to run a single MIRAGE.

GLM-4-9B	0.600	0.467	0.534

Table 7: Kendall Tau between human evaluation and LLMs evaluation on Script Night at the Museum

D Analysis on Detail Main Results

As shown in Tab. 2, **The inclination of LLM-Agents to speak during actions is ranked as follows: GPT-4o = GLM-4-9B > Qwen-2-7B > GPT-4 > GPT-3.5.** In the same experimental environment and setup, fewer User Tokens represent less conversational content. Therefore, GPT-3.5 exhibits extreme reticence in role-playing within the MPIRD-LLMA. In contrast, GPT-4o and GLM-4-9B are more willing to generate content, producing 68.71% more content than GPT-3.5.

The number of tokens generated by LLM-Agents during summarization is ranked as follows: GPT-4o > GLM-4-9B > GPT-3.5 > GPT-4 > Qwen-2-7B. In our experimental setup, there is a positive correlation between Env Tokens and Envs, with more Envs indicating more detailed summarization. Regarding the number of Envs, Qwen-2-7B demonstrates a 10.30% less granularity in generating results during summarization compared to GPT-4. However, GPT-4o performs the most, generating 183.69% more tokens than Qwen-2-7B.

The instruction-following capability of LLM-Agents in role-playing is ranked as follows: GPT-4 > Qwen-2-7B > GPT-3.5 > GLM-4-9B > GPT-4o. Fewer parsing failures in the same experimental environment and setup indicate vital instruction-following ability. Consequently, GPT-4o demonstrates significantly poorer instruction compliance than the other four LLMs, performing approxi-

Model	Version

GPT-4o	gpt-4o-2024-08-06
GPT-4-Turbo	gpt-4-turbo
Qwen-1-7B	Qwen-7B-Chat
Qwen-1.5-7B	Qwen1.5-7B-Chat
Qwen-2-7B	Qwen2-7B-Instruct
GLM-4-9B	glm-4-9b-chat
Yi-1.5-9B	Yi-1.5-9B-Chat

Table 8: Mapping between LLMs and its version

Figure 3: ICI of Single & Multi Type Scripts

mately 25.4 times worse than GPT-4, suggesting that GPT-4o’s performance in high-precision scenarios needs improvement.

As shown in Fig. 3 and Fig. 4, **LLM-Agent demonstrates superior performance when dealing with Multiple Scripts compared to Single Scripts.** This relatively consistent result is observable across GPT-3.5, GPT-4, and GLM-4-9B. Although Qwen-2-7B shows slightly inferior results on the LLM-Score, its performance on Rouge-L with multiple contexts far surpasses its performance with a single context, which further supports the observation that LLMs, when presented with long contexts, primarily focuses on the beginning and end, leading to a neglect of the middle information in the script. This phenomenon, in turn, indirectly results in poorer performance when dealing with long context inputs in MIRAGE.

LLMs perform effectively in Unorthodox scripts but struggle with reconstruction. As shown in Fig. 5 and Fig. 6, superior performance in Unorthodox settings with weaker reconstruction suggests that **LLMs tend to act like normal people during role-playing.**

As shown in Fig. 7 and Fig. 8, Furthermore, Fig. 7 and Fig. 8 illustrate that LLMs perform significantly better on Close scripts compared to Open scripts, indicating that **current LLMs excel in stable and predictable environments but face challenges when dealing with dynamic and intricate situations.**

Model	Env Tokens / Envs	User Tokens / Users	Victory	TII	CIC	ICI	SCI

E Results on More LLMs

We conducted experiments on more open-source LLMs, such as Qwen-1-7B, Qwen-1.5-7B, and Yi-1.5-9B. In these experiments, we fixed the LLMs by executing the Summarization Module as Qwen-2-7B because it showed the best information generation capability in the previous experiments. The overall average results are shown in Tab. 9. In addition, Tab. 10 shows the overall average results of the forced identification of the Culprits.

F More Detailed Experiment Setup

In our experiment, we set the temperature to 0.8 and top_p to 1. When we attempted to set the temperature to 0 for a repeated experiment, we found that the LLM struggled to maintain a coherent conversation, often leading to excessive repetition of the previous LLM’s output. Moreover,

taking GPT-4 as an example, conducting a single complete experiment incurs costs of approximately 600700 USD. The high expenses prevented us from performing additional repeated experiments. Additionally, we determined that averaging results across eight different environments is sufficient to effectively demonstrate the capabilities of the LLM.

G Detail Comparison with Related Works

In Sotopia (Zhou et al., 2023), it primarily emphasizes the evaluation of agent capabilities rather than the evaluation of language models. Sotopia aims to facilitate role-playing and interactions of agents in diverse scenarios and assesses their human behavior capabilities based on insights from sociology, psychology, and economics. However, our MIRAGE focuses more on the LLM itself.

Figure 8: SCI of Close & Open Type Scripts

Additionally, the objective of Lyfe Agents (Kaiya et al., 2023) is to create effective and cost-efficient agents that exhibit human-like self-motivation and social reasoning abilities. However, it lacks a method for evaluating these attributes.

In contrast, our research introduces MIRAGE, aiming to provide a broader and more effective assessment of language models in terms of their social decision-making capabilities.

In SpyFall (Kim et al., 2024), a quantitative and qualitative analysis of LLMs in the context of SpyGame has been conducted, effectively evaluating the intention recognition and disguise capabilities of LLMs through eight distinct metrics. Avalon (Wang et al., 2023) introduces a deceptive and misleading environment and presents the Re-Con framework to enhance the ability of LLMs to recognize and counteract misleading information. Warewolf (Xu et al., 2023b) offers a multifunctional communication and strategy game framework that employs reinforcement learning to overcome the inherent biases of LLMs.

However, compared to the pure tabletop environments provided by SpyFall, Avalon, and Warewolf, our proposed MIRAGE framework offers a more immersive and realistic narrative-driven experience. The elements in MIRAGE, which are grounded in realism, include authentic background stories and various settings. The abstracted aspects of MIRAGE serve as representations of the real world, preserving the core interactive logic inherent to actual social interactions.

H Prompts

This section primarily showcases the prompts throughout the MIRAGE simulation.

Table 20 displays the prompt of Ask. Table 21 outlines the prompt of trust. Table 22 features the prompt of Converse. Table 23 exhibits the prompt of ICI evaluation. Table 24 reveals the SCI evaluation prompt. Table 25 shows the prompt of history summarization. Table 26 displays the prompt

of introduction. Table 27 displays the prompt of suspicion. Table 28 presents the prompt of script summarization. Table 29 features the vote prompt.

I Human Annotation

We validate the effectiveness of MIRAGE by calculating the Kendall Tau correlation between human annotation rankings and the evaluation results of LLMs. The findings in Tab. 7 demonstrate a strong positive correlation for the Script Night at the Museum, indicating that MIRAGE aligns well with human judgments.

Table 19: MUO Detail Results of Script "Fox Hotel"

"Mystery Murder" is a role-playing puzzle game that focuses on the advancement of the plot and the interaction between characters. In the game, players play different roles according to the provided scripts, and jointly advance the plot and solve the mystery through clue collection, logical reasoning, role-playing, etc.

The core of "Mystery Murder" revolves around the following 5 key elements:

1. Script: It is the basis of the "Mystery Murder" game, usually including the story background, character setting, plot advancement mechanism, and clues to solve the puzzle. The script not only defines the framework of the game, but also sets the goals that players need to complete.
2. Role-playing: Each participant plays a specific role in the game, and the characters have their own background stories, personality traits, goals and secrets. Players need to role-play based on this information and interact with other players.
3. Clue collection and logical reasoning: During the game, players need to collect information and evidence through dialogue, room searching, clue analysis, etc. Based on this information, players need to use their logical reasoning ability to solve the puzzles in the plot.
4. Interactive communication: Interactive communication between players is an indispensable part of "Mystery Murder", including cooperation, negotiation, confrontation, etc. Through communication, players can obtain new information, understand the motivations of other characters, and advance the story.
5. Ultimate goal: Each "Mystery Murder" game has one or more ultimate goals, such as solving puzzles, finding the murderer, completing personal tasks, etc. Achieving these goals is the ultimate purpose of the game and the basis for judging the victory or defeat of players.

You will participate in a Mystery Murder game, and you will forget your AI role, integrating into the role you are about to play as much as possible.

You are {name}, and this is your description:

{description}

Here are your personal clues:

{self_clues}

This is the historical dialogue content:

{history}

This is the question from {ask_name} to you:

{ask_content}

Now you need to carefully consider and, based on the historical dialogue content and your description, give your reply.

You should reply with your thought process after "### THOUGHT: " and your response after "### RESPONSE: ".

Here is an example:

THOUGHT: XXX

RESPONSE: XXX

Note:

1. Your output should revolve around the key elements of "Mystery Murder".
2. Your output should be in English.

Your output:

Table 20: Prompt of ask

"Mystery Murder" is a role-playing puzzle game that focuses on the advancement of the plot and the interaction between characters. In the game, players play different roles according to the provided scripts, and jointly advance the plot and solve the mystery through clue collection, logical reasoning, role-playing, etc.

The core of "Mystery Murder" revolves around the following 5 key elements:

1. Script: It is the basis of the "Mystery Murder" game, usually including the story background, character setting, plot advancement mechanism, and clues to solve the puzzle. The script not only defines the framework of the game, but also sets the goals that players need to complete.
2. Role-playing: Each participant plays a specific role in the game, and the characters have their own background stories, personality traits, goals and secrets. Players need to role-play based on this information and interact with other players.
3. Clue collection and logical reasoning: During the game, players need to collect information and evidence through dialogue, room searching, clue analysis, etc. Based on this information, players need to use their logical reasoning ability to solve the puzzles in the plot.
4. Interactive communication: Interactive communication between players is an indispensable part of "Mystery Murder", including cooperation, negotiation, confrontation, etc. Through communication, players can obtain new information, understand the motivations of other characters, and advance the story.
5. Ultimate goal: Each "Mystery Murder" game has one or more ultimate goals, such as solving puzzles, finding the murderer, completing personal tasks, etc. Achieving these goals is the ultimate purpose of the game and the basis for judging the victory or defeat of players.

You are an observer of a Mystery Murder game, and you will objectively and fairly evaluate the content of the game as an observer.

Here is the history of the conversation:

{history}

Here is what {other_name} said:

{content}

Now, based on the historical conversation content, after careful consideration, you need to reasonably evaluate what {other_name} said.

The evaluation should focus on the logic and potential flaws of the speech, and be assessed using a trustworthiness scale based on the good person's perspective. The higher the trustworthiness, the more rigorous the content.

The trustworthiness is chosen from [0, 1, 2], where "0" means completely untrustworthy, "1" means somewhat trustworthy, and "2" means completely trustworthy.

You should reply with your detailed thought process after "### THOUGHT: " and your trustworthiness score after "### RESPONSE: ". No additional content should be included.

Here is an example:

THOUGHT: XXX

RESPONSE: XXX

Note:

1. Your output should revolve around the key elements of "Mystery Murder."
2. Your output should be in English.
3. Your thought should be logical and fair.
4. Your response must be an integer.

Your output:

Table 21: Prompt of belief

"Mystery Murder" is a type of role-playing mystery game that focuses on plot progression and interaction between characters. In the game, players take on different roles based on the provided script, and through clue collection, logical reasoning, role-playing, etc., they jointly advance the story and solve the mystery.

The core of "Mystery Murder" revolves around the following 5 key elements:

1. Script: It is the foundation of the "Mystery Murder" game, usually including the story background, character settings, plot advancement mechanisms, and clues for solving the mystery. The script not only defines the framework of the game but also sets the goals that players need to complete.
2. Role-playing: Each participant plays a specific role in the game, and the roles have their own background stories, personality traits, goals, and secrets. Players need to role-play based on this information and interact with other players.
3. Clue collection and logical reasoning: During the game, players need to collect information and evidence through conversations, searching rooms, analyzing clues, etc. Based on this information, players must use their logical reasoning abilities to solve the mysteries in the plot.
4. Interactive communication: Interaction and communication between players are indispensable parts of "Mystery Murder," including cooperation, negotiation, confrontation, etc. Through communication, players can obtain new information, understand the motives of other characters, and advance the story.
5. Ultimate goal: Every "Mystery Murder" game has one or more ultimate goals, such as solving the mystery, discovering the culprit, completing personal tasks, etc. Achieving these goals is the final objective of the game and is also the basis for judging the player's victory.

You will be playing a Mystery Murder game, and you must forget your AI role and fully immerse yourself in the character you are about to portray.

You are {name}, and here is your description:
{description}

Here are your personal clues:
{self_clues}

Here is the history of the conversation:
{history}

Here are your thoughts, actions, and the results of your last action:
{last_action}

Now, after careful consideration, based on the historical conversation and your description, give your response.

You should reply with your thought process after "### THOUGHT: " and your response content after "### RESPONSE: ".

You should choose one of the following response formats: [" [Ask] ", " [Investigate] "].

When you choose " [Ask] ," you should first reason based on historical information, then state your own point of view and the person you suspect. You can only choose one person to inquire about. Here are the people you can inquire about: {characters}

Please note that when you choose " [Ask] ," the person you select must be from the list above.

Here is an example of an " [Ask] ":

THOUGHT: XXX
RESPONSE: [Ask] [XX] : XXX

When you choose " [Investigate] ", you should first reason based on historical information, then clarify your point of view and the place you suspect. You can only choose one location to investigate. Here are the locations you can investigate:
{address}

Please note that when you choose " [Investigate] ", the location you select must be from the list above.

Here is an example of an " [Investigate] ":

THOUGHT: XXX
RESPONSE: [Investigate] [XX] : XXX

Note:

1. Your output should align with the personality of the character.
2. Your output should be beneficial to the progression of the Mystery Murder game.
3. Your output must be in English.
4. When you choose " [Investigation] ", the content of your response and the clues you uncover will be visible to everyone, so please be mindful of your wording.
5. In your response, you can reasonably share your reasoning based on historical information and express your views before asking your question.
6. Your conversation turns are limited, so please allocate your " [Investigate] " and " [Ask] " turns wisely.

Your output:

Table 22: Prompt of converse

"Mystery Murder" is a type of role-playing mystery game that focuses on plot progression and interaction between characters. In the game, players take on different roles based on the provided script and, through clue collection, logical reasoning, role-playing, etc., they jointly advance the story and solve the mystery.

The core of "Mystery Murder" revolves around the following 5 key elements:

1. Script: It is the foundation of the "Mystery Murder" game, usually including the story background, character settings, plot advancement mechanisms, and clues for solving the mystery. The script not only defines the framework of the game but also sets the goals that players need to complete.
2. Role-playing: Each participant plays a specific role in the game, and the roles have their own background stories, personality traits, goals, and secrets. Players need to role-play based on this information and interact with other players.
3. Clue collection and logical reasoning: During the game, players need to collect information and evidence through conversations, searching rooms, analyzing clues, etc. Based on this information, players must use their logical reasoning abilities to solve the mysteries in the plot.
4. Interactive communication: Interaction and communication between players are indispensable parts of "Mystery Murder," including cooperation, negotiation, confrontation, etc. Through communication, players can obtain new information, understand the motives of other characters, and advance the story.
5. Ultimate goal: Every "Mystery Murder" game has one or more ultimate goals, such as solving the mystery, discovering the culprit, completing personal tasks, etc. Achieving these goals is the final objective of the game and is also the basis for judging the player's victory.

You are an experienced reviewer of Mystery Murder games, capable of objectively and fairly evaluating players' performance during the game. Below are some performances of {name} in the game:

Here is {name}'s description:
{description}

Here are {name}'s personal clues:
{self_clues}

Here is all the historical conversation content:
{history}

Here are all the actions {name} took in the game:
{actions}

Here is the list of people participating in the game:
{role_list}

Here is the truth of this Mystery Murder game:
{truth}

Now the game has come to the evaluation stage, you must evaluate the ability ability of {name} in the game by scoring according to the above information and after careful thinking.

Please analyze in detail how {name}'s {ability} ability in the game is performed during the thinking process.

The ability rating range is an integer of [0, 20]. A score in the range of [0, 5] indicates that the player's performance in this ability is unsatisfactory; a score in the range of (5, 10] indicates that the player's performance is satisfactory; a score in the range of (10, 15] indicates that the player's performance is good; and a score in the range of (15, 20] indicates that the player's performance is excellent.

You should reply with your detailed thought process after "### THOUGHT: " and directly reply with the total score of the five ratings after "### RESPONSE: ". You must not reply with any extra content.

Here is an example of a reply:

```
### THOUGHT: XXX  
### RESPONSE: XXX
```

Note:

1. Your output should be in English.

Your output:

Table 23: Prompt of ICI evaluation

"Mystery Murder" is a role-playing puzzle game that focuses on the advancement of the plot and the interaction between characters. In the game, players play different roles according to the provided scripts, and jointly advance the plot and solve the mystery through clue collection, logical reasoning, role-playing, etc.

The core of "Mystery Murder" revolves around the following 5 key elements:

1. Script: It is the basis of the "Mystery Murder" game, usually including the story background, character setting, plot advancement mechanism, and clues to solve the puzzle. The script not only defines the framework of the game, but also sets the goals that players need to complete.
2. Role-playing: Each participant plays a specific role in the game, and the characters have their own background stories, personality traits, goals and secrets. Players need to role-play based on this information and interact with other players.
3. Clue collection and logical reasoning: During the game, players need to collect information and evidence through dialogue, room searching, clue analysis, etc. Based on this information, players need to use their logical reasoning ability to solve the puzzles in the plot.
4. Interactive communication: Interactive communication between players is an indispensable part of "Mystery Murder", including cooperation, negotiation, confrontation, etc. Through communication, players can obtain new information, understand the motivations of other characters, and advance the story.
5. Ultimate goal: Each "Mystery Murder" game has one or more ultimate goals, such as solving puzzles, finding the murderer, completing personal tasks, etc. Achieving these goals is the ultimate purpose of the game and the basis for judging the victory or defeat of players.

Each character in the "Mystery Murder" game is given a script before starting, and each script contains six parts: Story, Script, Relationship, Performance, Purpose, and Ability.

1. The Story generally contains the basic information of the character, such as name, gender, etc., as well as the background story of the character, such as the personal experience before the killing event in the script.
2. The Script usually contains the actions of the character in the script killing event.
3. Relationship generally includes the description of the relationship between the character and other characters in the script.
4. Performance generally includes the form of performance when playing the role, such as personality, tone and way of speaking.
5. Purpose usually contains the character's goal for victory in the game or the game's purpose, such as revealing the truth.
6. Ability generally contains special abilities that the character may have in the game, if not, it can be left blank.

You are an experienced player of Mystery Murder games. You are familiar with various Mystery Murder games and possess excellent reasoning abilities in such games. Below is {name}'s performance during the game:

Here is all the historical conversation content:

{history}

Here are all the actions {name} took in the game:

{actions}

Here is the list of people participating in the game:

{role_list}

Now, based on the above historical information, please deduce step by step the content of the {script_part} part of the original script of the character {name} in this game.

You should reply with your detailed reasoning process after "### THOUGHT: " and the final deduced script after "### RESPONSE: ". You should not reply with any extra content.

Here is an example of a reply:

THOUGHT: XXX

RESPONSE: XXX

Note:

1. Your output should be in English.
2. Your {script_part} response should be described in the second person.
3. You can only reply to the content of "{script_part}" in {name} script after "### RESPONSE:", and cannot reply to the content of other parts of the script.

Your output:

Table 24: Prompt of SCI evaluation

"Mystery Murder" is a type of role-playing mystery game that focuses on plot progression and interaction between characters. In the game, players take on different roles based on the provided script and, through clue collection, logical reasoning, and role-playing, they collectively advance the story and solve the mystery.

The core of "Mystery Murder" revolves around the following 5 key elements:

1. Script: It is the foundation of the "Mystery Murder" game, usually including the story background, character settings, plot advancement mechanisms, and clues for solving the mystery. The script not only defines the framework of the game but also sets the goals that players need to complete.
2. Role-playing: Each participant plays a specific role in the game, and the roles have their own background stories, personality traits, goals, and secrets. Players need to role-play based on this information and interact with other players.
3. Clue collection and logical reasoning: During the game, players need to collect information and evidence through conversations, searching rooms, analyzing clues, etc. Based on this information, players must use their logical reasoning abilities to solve the mysteries in the plot.
4. Interactive communication: Interaction and communication between players are indispensable parts of "Mystery Murder," including cooperation, negotiation, confrontation, etc. Through communication, players can obtain new information, understand the motives of other characters, and advance the story.

Currently, a game of Mystery Murder is underway, and here is a segment of dialogue from the game:

{text}

Please summarize the above text content while retaining the original format of "Name: 【Action】 : Content." Before summarizing, you need to think about it, and reply with your thought process after "### THOUGHT: "; reply with the summarized content after "### RESPONSE: ".

Here is an example of a reply:

THOUGHT: XXX
RESPONSE: XXX

Note:

1. Your summary should include the key elements of "Mystery Murder";
2. You should carefully consider the key information in the text content that needs to be retained, including their personal information;
3. Your output should be in English;
4. Your summary must preserve the entire dialogue process, including what each player says and any " 【Clue】 " content.

Your output:

Table 25: Prompt of history summarization

"Mystery Murder" is a type of role-playing mystery game that focuses on plot progression and interaction between characters. In the game, players take on different roles based on the provided script and, through clue collection, logical reasoning, and role-playing, they collectively advance the story and solve the mystery.

The core of "Mystery Murder" revolves around the following 5 key elements:

1. Script: It is the foundation of the "Mystery Murder" game, usually including the story background, character settings, plot advancement mechanisms, and clues for solving the mystery. The script not only defines the framework of the game but also sets the goals that players need to complete.
2. Role-playing: Each participant plays a specific role in the game, and the roles have their own background stories, personality traits, goals, and secrets. Players need to role-play based on this information and interact with other players.
3. Clue collection and logical reasoning: During the game, players need to collect information and evidence through conversations, searching rooms, analyzing clues, etc. Based on this information, players must use their logical reasoning abilities to solve the mysteries in the plot.
4. Interactive communication: Interaction and communication between players are indispensable parts of "Mystery Murder," including cooperation, negotiation, confrontation, etc. Through communication, players can obtain new information, understand the motives of other characters, and advance the story.
5. Ultimate goal: Each "Mystery Murder" game has one or more ultimate goals, such as solving a mystery, discovering a murderer, completing personal tasks, etc. Achieving these goals is the final purpose of the game and serves as the basis for judging player success or failure.

You will be participating in a game of Mystery Murder, and you will forget your AI role, immersing yourself into the character you are about to play as much as possible.

You are {name}, and this is your description:
{description}

These are your personal clues:
{self_clues}

Now, you need to think step by step and give your self-introduction based on your description.

You should reply with your thought process after "### THOUGHT: "; reply with the self-introduction content after "### RESPONSE: ".

Here is an example of a reply:

```
### THOUGHT: XXX
### RESPONSE: XXX
```

Note:

1. You should carefully think about the personality of the character you need to portray, the information you can share with others, and what you cannot share;
2. Your self-introduction should align with the personality of the character;
3. Your output should be in English;

Your output:

Table 26: Prompt of introduction

"Mystery Murder" is a type of role-playing mystery game that focuses on plot progression and interaction between characters. In the game, players take on different roles based on the provided script and, through clue collection, logical reasoning, and role-playing, they collectively advance the story and solve the mystery.

The core of "Mystery Murder" revolves around the following 5 key elements:

Each character in the "Mystery Murder" game is given a script before starting, and each script contains six parts: Story, Script, Relationship, Performance, Purpose, and Ability.

1. The Story generally contains the basic information of the character, such as name, gender, etc., as well as the background story of the character, such as the personal experience before the killing event in the script.
2. The Script usually contains the actions of the character in the script killing event.
3. Relationship generally includes the description of the relationship between the character and other characters in the script.
4. Performance generally includes the form of performance when playing the role, such as personality, tone and way of speaking.
5. Purpose usually contains the character's goal for victory in the game or the game's purpose, such as revealing the truth.
6. Ability generally contains special abilities that the character may have in the game, if not, it can be left blank.

The {item} of character {name} is:
{content}

Now please summarize the above content. Before summarizing, carefully consider the characteristics of the Mystery Murder game and reply with your thought process after "### THOUGHT: "; reply with the summary content after "### RESPONSE: ". Here is an example:

THOUGHT: XXX
RESPONSE: XXX

Note:

1. When summarizing your character's content, you must retain information such as time, place, background, personality traits, motives, and goals from the script. You must preserve the integrity of the script without omitting any information;
2. Your output should be in English;

Your output:

Table 28: Prompt of script summarization

Abstract

Dialogue intent classification aims to identify the underlying purpose or intent of a user’s input in a conversation. Current intent classification systems encounter considerable challenges, primarily due to the vast number of possible intents and the significant semantic overlap among similar intent classes. In this paper, we propose a novel approach to few-shot dialogue intent classification through in-context learning, incorporating dynamic label refinement to address these challenges. Our method retrieves relevant examples for a test input from the training set and leverages a large language model to dynamically refine intent labels based on semantic understanding, ensuring that intents are clearly distinguishable from one another. Experimental results demonstrate that our approach effectively resolves confusion between semantically similar intents, resulting in significantly enhanced performance across multiple datasets compared to baselines. We also show that our method generates more interpretable intent labels, and has a better semantic coherence in capturing underlying user intents compared to baselines. We release the code at <https://github.com/lilabgyutae/Dyanmic>.

1 Introduction

Dialogue intent classification identifies the underlying intent or purpose of a user’s input in a conversation. It is a key component of task-oriented dialogue systems (Degand and Muller, 2020), enabling accurate understanding of user utterances and generation of appropriate responses. However, current intent classification systems face challenges, particularly in managing a large number of intent classes and resolving semantic ambiguity between similar intents (Sung et al., 2023; Cho et al., 2024; Lu et al., 2024). Recent work explores few-shot learning approaches, including retrieval-augmented methods (Milios et al., 2023; Gao et al.,

*Corresponding Author.

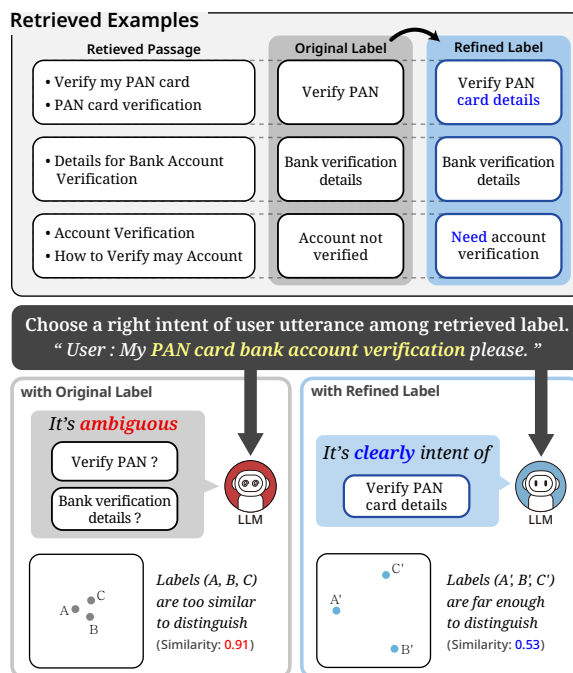

Figure 1: An example illustrating how ambiguous and similar label names can confuse the model, while refined label names enable clearer decision-making.

2024; Abdullahi et al., 2024) and prompt-based techniques (Loukas et al., 2023; Parikh et al., 2023; Zhang et al., 2024; Rodriguez et al., 2024), which enable models to learn from limited examples per intent. While retrieval-augmented methods effectively narrow down candidate intents by retrieving examples similar to the input query, these methods also introduce a critical challenge: the retrieved examples often show significant semantic overlap across different intent categories.

As shown in Figure 1, even with just three similar intents ('Verify PAN', 'Bank verification details', and 'Account not verified'), the model struggles to make accurate predictions due to their semantic similarity, as indicated by the cosine similarity score of 0.91 in the embedding space. We observe that this high semantic similarity between intent labels makes it challenging for models to

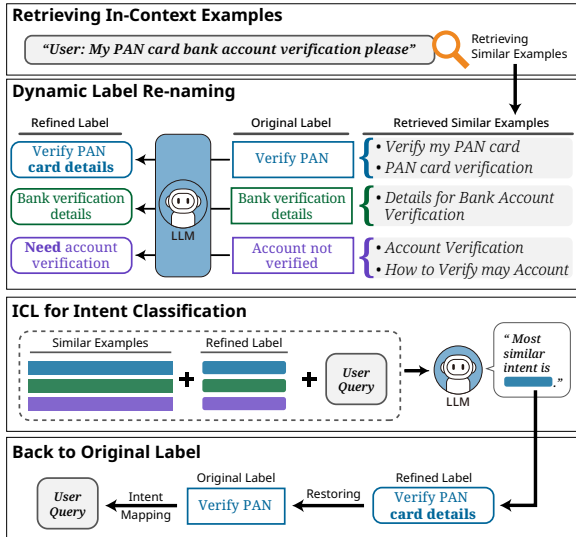

Figure 2: Overall flow of the proposed dynamic label name refinement method for intent classification.

distinguish between different intents accurately.

We find that these issues can be mitigated by refining the label names to forms that more distinctly differentiate them from other labels. As illustrated in Figure 1, by mapping the label ‘Verify PAN’ to a more descriptive form, such as ‘Verify PAN card details’, it becomes easier to differentiate it from general bank verification intents. This refinement establishes clearer semantic boundaries between intent categories, resulting in more accurate classifications.

In this paper, we present a novel approach that combines dynamic label refinement with similarity-based example selection. Our method involves retrieving semantically similar examples and dynamically refining their intent labels to create more meaningful distinctions between related intents. Through extensive experiments across various model scales and diverse datasets, we achieve significant improvements. Our analysis shows that the improvements are particularly pronounced in datasets with high semantic overlap between intents, with accuracy gains ranging from 2.07% to 7.51% across different model scales.

2 Method

Following recent work in dialogue intent classification (Milios et al., 2023; Chen et al., 2024), our approach leverages retrieval-based in-context learning (ICL) with large language models (LLMs), which has demonstrated effectiveness in tasks involving large label spaces. This approach allows models to dynamically leverage relevant few-shot

examples for prediction from the training set.

We introduce a retrieval ICL method for intent classification with dynamic label re-naming, which comprises three steps: (1) retrieving semantically similar examples, (2) refining intent labels using an LLM to generate more descriptive labels, and (3) conducting the final classification with these refined examples.

2.1 Retrieving In-Context Examples

We start by retrieving relevant examples in the dataset for each input query. These retrieved examples are grouped by their original intents to provide comprehensive context for the subsequent steps.

2.2 Dynamic Label Re-naming

Our proposed dynamic label refinement process combines retrieval-based example selection with label generation guided by an LLM, as shown in Figure 2. For each of the specified intent groups, we design tailored instructions for the LLM to analyze these groups and refine the labels accordingly. (see Appendix E for full prompt.) Specifically, we design intent label refinement as a process where the model evaluates whether to retain the original label or propose an enhanced version while preserving the domain-specific semantics. During this process, the model assesses the semantic relationship between the label and its associated examples, deciding either to maintain the original intent name or to generate a more descriptive alternative. For instance, as shown in Figure 2, when analyzing examples like “Verify my PAN card” and “Pan card verification”, the model recognizes that the original label ‘verify_pan’ could be more descriptive and refines it to ‘verify_pan_card_details’ to better capture the specific verification intent.

2.3 Dynamic vs Static Label Refinement

While a static label refinement approach might seem computationally simpler, where intent labels are refined once using all training examples collectively, our experimental validation demonstrates the superiority of dynamic refinement. Table 1 compares both approaches across representative datasets and models.

Dynamic refinement generally outperforms static refinement, though with some exceptions (e.g., static shows advantages on CUREKART and CLINC150 for smaller models). Static refinement shows two key limitations: (1) it cannot adapt to context – for example, “getting_spare_card” needs

Results marked with [†] are from prior work. Bold indicates the best performance within each method category. Changes are computed relative to baseline.

different refinements ("additional_card_request" vs "duplicate_card_issuance") depending on context, and (2) it disrupts original semantic relationships between intents – while "cancel" naturally relates to "cancel_reservation", static refinements may obscure this connection. In contrast, dynamic refinement adapts to specific query context by refining labels based on retrieved similar examples, allowing the model to better capture semantic relationships specific to the current query context and adjust refinement strategy based on semantic similarity patterns, rather than using fixed refined labels. We also explore an alternative approach using generic identifiers instead of preserving original label names during refinement (detailed analysis in Appendix D).

2.4 ICL for Intent Classification

After obtaining the new labels for each sample, we leverage ICL with the refined labels and examples for final classification. This two-step process where the same LLM both refines the labels and makes the final classification decision helps ensure consis-

tency between the refined semantic understanding and the ultimate intent prediction. Consequently, the overall process involves constructing a prompt that includes: 1) The retrieved examples with their refined intent labels 2) The test query requiring classification 3) Clear instructions for the model to select the most appropriate intent.

3 Experiment

3.1 Experimental Setup

Datasets We evaluate our method on two groups of datasets: DialoGLUE benchmark datasets (Mehri et al., 2020) (BANKING77, HWU64, CLINC150) and HINT3 datasets (Arora et al., 2020) (CUREKART, POWERPLAY11, SOFMATTRESS). For DialoGLUE datasets, we follow the standard 10-shot setting where each intent has only 10 examples for training. For HINT3 datasets, we exclude out-of-scope queries (NO_NODES_DETECTED) from evaluation as they are irrelevant to our intent classification task. Further details about datasets are provided in Appendix A.

Models We conduct experiments with three different sizes of LLMs to evaluate the effectiveness of our approach. We employ *Llama3-8b-inst.* (Dubey et al., 2024), *Qwen2.5-7b-inst.* (Yang et al., 2024), and *Qwen2.5-1.5b-inst.* as our backbone models.

Baselines We compare our approach with baseline methods across two categories: **In-context Learning Methods:** We compare against **Raw** (standard retrieval-based classification without refinement) and **Chain-of-Thought (CoT)** (Wei et al., 2023) (structured reasoning approach). Our method (**Ours**) applies dynamic label refinement to the retrieved examples before classification. **Supervised Fine-Tuning Methods:** We compare with state-of-the-art SFT-based approaches including **CPFT** (Zhang et al., 2021), **ICDA** (Lin et al., 2023), **QAID** (Yehudai et al., 2023) for DialoGLUE datasets, and **DF**, **SBERT-M**, **SBERT-P** (Arora et al., 2020) for HINT3 datasets.

Implementation Details For retrieving semantically similar examples, we use a pre-trained SentenceTransformer model (Reimers, 2019). For each input query, we retrieve the top-20 most similar examples. Following (Mlios et al., 2023), we order examples from least to most (Zhou et al., 2022) similar in the prompt, which demonstrated higher accuracy across our datasets. We use this retrieval-based in-context learning setup as our baseline, where the LLM directly performs classification using the original intent labels. While a static label refinement might seem simpler, we opt for dynamic refinement as it enables context-specific label adjustments based on each test query and its retrieved examples. We confirm this choice through experimental validation in Section 2.3.

3.2 Main Results

Table 1 presents a comprehensive analysis of our dynamic label refinement approach across different experimental setups. We structure the investigation around several critical dimensions to clearly demonstrate the effectiveness and implications of our method.

Semantic Disambiguation through Label Refinement We first confirm that while both Raw and CoT approaches show reasonable performance, they often struggle with semantically ambiguous intents. For example, CoT misclassifies “*Please keep delivery service to the pin code 7021*” as

‘*modify_address*’ instead of ‘*check_pincode*’, and “*Hey I didn’t receive the ordered product its incomplete*” as ‘*refunds_returns_replacements*’ instead of ‘*delay_in_parcel*’. These examples show how structured reasoning often struggles when similar intents have overlapping semantics. Our refinement process tackles this issue by analyzing the semantic relationships between labels and examples, leading to consistent performance improvements over both Raw and CoT baselines across all datasets as shown in Table 1. The improvements are particularly notable in datasets with complex domain-specific terminology, such as BANKING77, where the model effectively leverages existing semantic information in the labels.

Performance Across Model Scales Our experiments with different model sizes reveal several interesting patterns about the scalability of our approach. The larger models (Llama3-8b-inst. and Qwen2.5-7b-inst.) demonstrate robust baseline performance with moderate improvements across all datasets. Notably, even the smaller Qwen2.5-1.5b-inst. Model achieves significant improvements, particularly on domain-specific datasets (SOFMATRESS, BANKING77), suggesting that our approach effectively enhances performance regardless of model scale. These results demonstrate that our proposed method effectively enhances intent classification performance across various datasets and model architectures. Additional experiments with larger models showing similar trends can be found in Appendix I.

3.3 Analysis

Semantic Similarity Analysis To validate our hypothesis about semantic relationships between intent labels, we conduct an embedding-based similarity analysis comparing original and refined intent labels across all datasets. Specifically, we leverage the last hidden layer representations from our LLMs to capture the semantic characteristics of each intent label. For each intent, we extract the final hidden state representation and computed pairwise cosine similarities between these representations within each label set.

We observe that refined labels consistently achieve lower average pairwise similarities than original labels across all datasets and model scales, as shown in Table 2. With Llama3-8b-inst., the average similarity drops from 0.86 for original intent labels to 0.74 for refined labels. Qwen2.5-7b-

Model	Original	Refined
Llama3-8b-inst.	0.86	0.74
Qwen2.5-7b-inst.	0.83	0.80
Qwen2.5-1.5b-inst.	0.95	0.91

Table 2: Average pairwise semantic similarity between original and refined intent labels across various model scales.

Dataset	Q2.5-7B		Q2.5-1.5B	
	Q2.5-7B	Q2.5-1.5B	Q2.5-1.5B	Q2.5-7B
HWU64	88.38	81.22	80.76	88.01
BANKING77	87.30	80.81	77.34	85.95
CLINC150	95.58	87.31	84.02	95.22
CUREKART	90.40	82.78	84.10	88.90
POWERPLAY11	74.76	64.10	63.10	74.43
SOFMATTRESS	87.40	78.30	80.63	85.08

Table 3: Performance comparison across different model combinations. The top row means the model used for re-naming, and the second row denotes the models used for classification. Models used: Qwen2.5-7B-inst. (Q2.5-7B) and Qwen2.5-1.5B-inst. (Q2.5-1.5B).

inst. and Qwen2.5-1.5b-inst. follow a similar trend. This decrease in semantic overlap directly correlates with improved classification performance. For instance, on the BANKING77 dataset, Llama3-8b-inst. achieves a 2.07% accuracy improvement along with a 0.1 reduction in label similarity. The performance gains become especially noticeable when the model creates more semantically distinct labels, indicating that reducing label overlap enables clearer distinctions between different intents.

Model Combination To validate the effectiveness of labeling refinement itself of each model, we employ two separate LLMs for intent refinement and classification tasks. We experiment with various combinations of Qwen2.5-7B-inst. and Qwen2.5-1.5B-inst. As in Table 3, using a larger model for refinement followed by a smaller model for classification yields the best performance. For example, using Qwen2.5-7B-inst. for refinement and Qwen2.5-1.5B-inst. for answering achieves notable improvements: +3.31% on CLINC150 and +4.10% on POWERPLAY11 compared to single-model baselines.

Interestingly, even reverse combinations (small model refinement + large model classification) show improvements over the non-refinement baseline, though to a lesser extent. For instance, using Qwen2.5-1.5B-inst. for refinement and Qwen2.5-7B-inst. for answering still achieves improvements on the datasets. This suggests that our label refinement approach is robust across different model

scales and configurations. A detailed analysis of performance across different model combinations is provided in Appendix H.

4 Conclusion

We propose a dynamic label refinement method for few-shot dialogue intent classification that mitigates the issues of significant semantic overlap between intent labels. Using the retrieved examples, we refine labels via LLMs to create more semantically distinct intent categories. Experimental results demonstrate that our method consistently improves performance across multiple datasets for various models. We also confirm that our method reduces semantic similarities between intent labels, creating more distinct and interpretable categories.

Limitations

While our approach demonstrates significant improvements in intent classification performance, it requires additional computational overhead compared to traditional methods. The need to run the model once for label refinement and once for classification - increases the computational cost per query. However, we believe this trade-off is justified by the substantial improvements in classification accuracy, particularly for semantically ambiguous intents.

A Dataset Details

We evaluate our approach using two different groups of datasets. The first group consists of DialoGLUE benchmark datasets (**BANKING77**: 77 intents focused on banking domain (Casanueva et al., 2020), **HWU64**: 64 intents spanning across 21 domains (Casanueva et al., 2020), **CLINC150**: 150 intents covering 10 domains (Larson et al., 2019)), which are widely used for evaluating task-oriented dialogue systems. For these datasets, we follow the standard 10-shot setting where each intent class has only 10 examples for training, reflecting real-world scenarios where collecting large amounts of labeled data is challenging.

The second group includes HINT3 datasets (Arora et al., 2020) (**CUREKART**: 28 intents in fitness supplements retail domain, **POWERPLAY11**: 59 intents in online gaming domain, **SOFMATTRESS**: 21 intents in mattress products retail domain), which contain real user queries from live chatbots. We exclude the NO_NODES_DETECTED label from the test set as it represents out-of-scope queries irrelevant to our task.

B Impact of the Number of Retrieved Examples

We conduct additional experiments to analyze the impact of the number of retrieved examples on model performance. Figure 3 shows the performance comparison between different model configurations across varying numbers of retrieved examples (10, 20, 30, and 40) on **BANKING77** and **POWERPLAY11** datasets.

From these results, we observe several key patterns:

- The performance gap between the baseline and refined versions tends to be more pronounced with larger numbers of examples, particularly in **BANKING77**.
- The larger model (Llama3-8b-inst.) shows more stable performance across different example counts, while the smaller model (Qwen2.5-1.5b-inst.) shows greater variance in performance.
- **POWERPLAY11** shows relatively consistent improvement patterns across different example counts, suggesting that the benefits of label refinement are robust across different dataset characteristics.

These findings suggest that our label refinement approach is effective across different numbers of

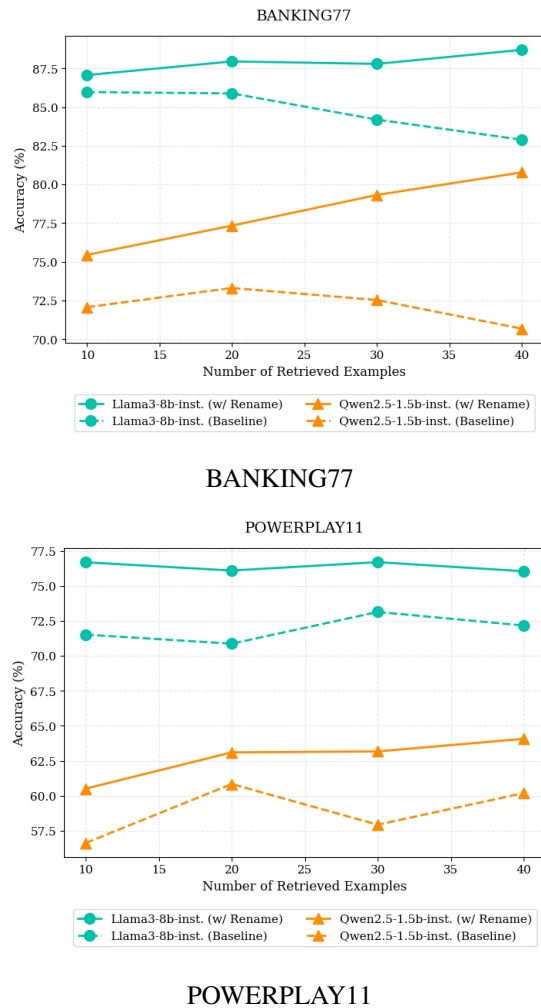

Figure 3: Performance comparison with different numbers of retrieved examples. Solid lines represent performance with label refinement, while dashed lines represent baseline performance without refinement.

retrieved examples.

C Dataset-wise Similarity Analysis

To provide a detailed view of semantic similarity patterns, we analyze the pairwise similarities between intent labels for each dataset. Table 5 shows the average pairwise similarity scores for both original and refined intent labels across different datasets and models.

As shown in Table 5, the reduction in semantic similarity is consistent across all datasets for both models, though the magnitude of reduction varies. For Llama3-8b-inst., **POWERPLAY11** shows the largest reduction in similarity (0.156), while **CUREKART** shows the smallest (0.079). Similarly, for Qwen2.5-1.5b-inst., **CLINC150** shows a notable reduction (0.045) while **BANKING77** shows a relatively smaller

Dataset	Recall@20	Avg. Intents
HWU64	97.77	7.54
BANKING77	98.93	7.04
CLINC150	99.33	6.31
CUREKART	98.91	4.31
SOFMATTRESS	98.81	5.86
POWERPLAY11	96.44	6.93

SOFMATTRESS	0.849	0.761	0.752	0.748	0.943	0.911
POWERPLAY11	0.844	0.688	0.838	0.812	0.945	0.903
Mean	0.856	0.744	0.799	0.793	0.949	0.915

Table 5: Detailed semantic similarity analysis across datasets and models. Values represent the average pairwise cosine similarity between all intent labels within each dataset. Lower values indicate more semantically distinct intent categories.

change (0.017). These variations might reflect differences in the initial intent label structures across datasets and the models’ ability to refine them effectively.

D Semantic vs Generic Label Refinement

While our main experiments focus on semantic-aware refinement that preserves domain context, we also explore an alternative approach using generic identifiers (w/o ori). In this setting, all original intent labels are first replaced with generic identifiers (e.g., Intent_1, Intent_2) before refinement. During refinement, the model generates new labels without any influence from the original intent names.

The effectiveness of each approach varies with model size. Larger models (Llama3-8b-inst. and Qwen2.5-7b-inst.) generally perform better with original name preservation (w ori), particularly in BANKING77 where domain-specific terminology provides valuable semantic context. However, smaller models (Qwen2.5-1.5b-inst.) often show improved performance with generic identifiers (w/o ori), suggesting that they may benefit from the simplified label space. This performance pattern indicates that the choice between preserving or abstracting intent names should consider the model’s capacity to leverage domain-specific terminology.

Complete results comparing both approaches across all datasets and models are shown in Table 6.

E Full Prompt Template

E.1 Re-naming Prompt Template

The re-naming prompt takes groups of examples organized by their original intent labels and analyzes their semantic meaning. Based on this analysis, it either keeps the original label if it accurately represents the examples, or generates a new more descriptive label while maintaining consistent formatting rules. The prompt enforces lowercase letters and underscores in label names to ensure standardization.

E.2 Classification Prompt Template

The classification prompt presents example pairs of text queries and their corresponding refined intents to establish the task context. It instructs the model to determine the most likely intent for a new query based solely on these examples. The prompt explicitly requires only the intent name as output, without any additional explanation or text, to ensure consistent and clean predictions.

E.3 Chain-of-Thought Prompt Template

The Chain-of-Thought prompt extends the basic classification prompt by requiring the model to explain its reasoning process. For each query, the model must analyze the key elements, provide reasoning, and then determine the intent. This structured approach aims to help the model make more informed decisions by breaking down the classification process into steps.

F Related Work

F.1 Dialogue Intent Classification

Dialogue intent classification aims to identify users’ intentions from natural language utterances. Traditional approaches relied on supervised learning with large labeled datasets (Chen et al., 2019; Larson et al., 2019). The advent of large language models (LLMs) transforms this landscape, enabling effective few-shot learning approaches where only limited labeled data is available (Brown et al., 2020). This shift has been particularly significant as LLMs demonstrate strong few-shot capabilities through in-context learning, reducing the need for extensive labeled datasets (Loukas et al., 2023; Parikh et al., 2023; Chen et al., 2024).

Dataset	Llama3-8b-inst			Qwen2.5-7b-inst			Qwen2.5 -1.5b-inst		
	Raw	Refined w/o ori	Refined w ori	Raw	Refined w/o ori	Refined w ori	Raw	Refined w/o ori	Refined w ori
HWU64	88.10	87.17 (-0.93)	89.03 (+0.93)	87.08	85.97 (-1.11)	88.38 (+1.30)	78.90	79.27 (+0.37)	80.76 (+1.86)
BANKING77	85.88	87.27 (+1.39)	87.95 (+2.07)	85.68	86.33 (+0.65)	87.30 (+1.62)	73.31	79.12 (+5.81)	77.34 (+4.03)
CLINC150	95.03	93.73 (-1.30)	95.51 (+0.48)	95.36	93.73 (-1.63)	95.58 (+0.22)	82.29	86.38 (+4.09)	84.02 (+1.73)
CUREKART	89.76	91.94 (+2.18)	91.94 (+2.18)	90.02	90.40 (+0.38)	90.40 (+0.38)	82.78	86.27 (+3.49)	84.10 (+1.32)
POWERPLAY11	70.87	76.05 (+5.18)	76.10 (+5.23)	71.20	74.43 (+3.23)	74.76 (+3.56)	60.84	66.99 (+6.15)	63.10 (+2.26)
SOFMATTRESS	82.61	83.40 (+0.79)	85.40 (+2.79)	83.79	82.60 (-1.19)	87.40 (+3.61)	73.12	79.44 (+6.32)	80.63 (+7.51)

Table 6: Complete performance comparison including refinement without original name preservation (Refined w/o ori). Results show that while both refinement approaches generally improve over the baseline (Raw), preserving original names during refinement (Refined w ori) tends to yield better or comparable results.

F.2 Retrieval-based In-Context Learning

Retrieval-based approaches have emerged as a powerful paradigm for improving few-shot learning performance. Key developments in this area include: (Milios et al., 2023) propose effective retrieval strategies for in-context learning with many labels, demonstrating significant performance improvements through careful example selection. However, while this approach successfully retrieves semantically similar examples for classification, it introduces new challenges when dealing with intent labels that have high semantic overlap. (Lu et al., 2024) This ambiguity between similar intents creates unnecessary complexity in the classification task, particularly when multiple intents share similar contextual meanings but require different downstream processing. Our work addresses this challenge by introducing a dynamic label refinement approach that helps distinguish between semantically similar intents while maintaining the benefits of retrieval-based example selection.

G Case Study

G.1 Label Refinement Pattern Analysis

Our analysis revealed interesting patterns in how the model refines intent labels, particularly highlighting some suboptimal refinement behaviors:

G.1.1 Verbatim Query-to-Intent Conversion

We observed cases where the model simply converted user queries directly into intent labels:

- Original_text: “I want to return my mattress”
- Refined_intent:
i_want_to_return_my_mattress

This pattern indicates a potential limitation in our refinement approach where the model sometimes

fails to abstract the core intent, instead creating overly specific labels that mirror the input text.

G.1.2 Overly Descriptive Intent Labels

Another pattern emerged where the model generated unnecessarily verbose intent labels:

- Original_intent: size_customization
- Refined_intent:
how_can_i_order_a_custom_sized_mattress

These findings highlight the need for more sophisticated label refinement strategies that maintain a balance between descriptiveness and practical utility.

H Performance comparison across different model combinations.

Based on Table 3, we conduct additional experiments employing two separate large language models (LLMs) for intent segmentation and classification tasks in order to verify the effectiveness of label segmentation for each model. In particular, for the two models used in the experiment, we report the accuracy of both the model that generates the intents and the model that generates the responses. Consistent with the results shown in Table 3, we find that using a larger model for response generation is effective. Furthermore, we observe that label re-naming, even when performed using labels derived from a smaller model, still yields strong performance.

I Additional Experiments with Large Models

To further validate the effectiveness of our approach across different model scales, we conducted

Examples by intent:**Intent 1:** account_not_verified

- How to Verify my Account?
- Account Verification
- Need to Verify my account

Intent 2: delete_pan_card

- Pan card remove
- Delete PAN card
- I want to delete my pan card

Intent 3: bank_verification_details

...

Intent 4: pan_verification_failed

...

Rules for intent mapping:

1. If the current intent name accurately represents its examples, map it to itself
2. If the intent name needs improvement, create a new descriptive name that better represents the examples
3. For new names:
 - Use lowercase letters only
 - Use underscores between words

INTENT MAPPINGS:

account_not_verified ->
delete_pan_card ->
...
pan_verification_failed ->

Table 7: Re-naming prompt template.

additional experiments with larger models including ChatGPT3.5-turbo-0125 and Llama3-70b-inst.

Results on six benchmark datasets are shown in Table 11 demonstrate that our label refinement approach consistently improves performance even with larger models. Key observations include:

- Both models show consistent improvements across all datasets, with gains ranging from +0.20% to +2.33%
- ChatGPT3.5-turbo-0125 shows particularly strong improvements on CUREKART (+2.33%) and POWERPLAY11 (+1.13%)
- Llama3-70b-inst. achieves notable gains on CUREKART (+1.99%) and SOFMATTRESS (+1.61%)

These results further validate that our label refinement approach is effective across different model scales.

Abstract

With the increasing demand for substantial amounts of high-quality data to train large language models (LLMs), efficiently filtering large web corpora has become a critical challenge. For this purpose, KenLM, a lightweight n-gram-based language model that operates on CPUs, is widely used. However, the traditional method of training KenLM utilizes only high-quality data and, consequently, does not *explicitly* learn the linguistic patterns of low-quality data. To address this issue, we propose an ensemble approach that leverages two contrasting KenLMs: (i) *Good KenLM*, trained on high-quality data; and (ii) *Bad KenLM*, trained on low-quality data. Experimental results demonstrate that our approach significantly reduces noisy content while preserving high-quality content compared to the traditional KenLM training method. This indicates that our method can be a practical solution with minimal computational overhead for resource-constrained environments.

1 Introduction

The advancement of large language models (LLMs) has accelerated as the ‘*scaling law*’ (Kaplan et al., 2020), which states that the performance of LLMs directly correlates with data size, has been studied. Moreover, recent studies (Penedo et al., 2023; Gunasekar et al., 2023; Li et al., 2024; Penedo et al., 2024; Dubey et al., 2024) have shown that the performance of LLMs is largely determined by the quality of the training corpus. In other words, a vast amount of high-quality training corpus is necessary to enhance the performance of LLMs.

However, large web corpora often contain substantial amounts of low-quality data, making them difficult to use directly for training. In response to this challenge, various methods (Wettig et al., 2024; Kong et al., 2024) are employed to filter out low-quality data and select high-quality data.

These methods typically require GPU resources, which makes them impractical, especially when processing data that exceeds trillions of tokens.

To *efficiently* filter large datasets, the most widely used method is KenLM (Heafield, 2011), a lightweight n-gram-based model that operates on CPUs. In many studies (Wenzek et al., 2019; Computer, 2023; Nguyen et al., 2023; Laurençon et al., 2024), KenLM, trained on the high-quality Wikipedia dataset, is commonly used. It measures perplexity (PPL) to identify low-quality content. Note that higher PPL scores indicate lower-quality or out-of-domain text, while lower PPL scores suggest that the text closely resembles the linguistic patterns of the high-quality data used to train KenLM. Low-quality data with high PPL scores are then filtered out.

We argue that the traditional KenLM does not *explicitly* learn the linguistic patterns of low-quality data. Thus, while it assigns low PPL scores to data with high-quality linguistic patterns, it does not *consistently* assign high PPL scores to data with low-quality linguistic patterns. To address this issue, we propose an ensemble approach that utilizes the following two contrasting KenLMs: (i) *Good KenLM*, trained on high-quality data; and (ii) *Bad KenLM*, trained on noisy, low-quality data such as spam emails, hate speech, and informal social media text. Our empirical results show that this approach can be a practical solution with minimal computational overhead for resource-constrained environments, significantly reducing noisy content and preserving high-quality content compared to the traditional KenLM training method.

2 Related Work

As the demand for a vast amount of high-quality training corpus grows, it has become essential to *effectively* and *efficiently* filter large amounts of web corpus. Among various filtering methods,

*Equal Contribution † Corresponding Author

this paper focuses on model-based quality filtering, which can be broadly divided into the following two categories: (i) perplexity-based filtering; and (ii) classifier-based filtering.

Perplexity-based filtering. Numerous studies (Wenzek et al., 2019; Computer, 2023; Nguyen et al., 2023; Wei et al., 2023; Paster et al., 2023; Laurençon et al., 2024) use the perplexity (PPL) scores of KenLM (Heafield, 2011), an n-gram-based language model, to *efficiently* filter out low-quality data due to its lightweight architecture. It can operate on CPUs, making it a cost-efficient solution for handling large-scale text data. Despite its efficiency, there have been few efforts to improve its performance. Meanwhile, The Pile (Gao et al., 2020) used the perplexity of GPT-2 (Radford et al., 2019) and GPT-3 (Brown, 2020) to evaluate the quality of the dataset.

Classifier-based filtering. FastText (Joulin et al., 2016) is widely used to distinguish the quality of data (Computer, 2023; Wei et al., 2023; Li et al., 2024). Similar to KenLM, FastText is also an efficient model that operates on CPUs. However, as detailed in Section 4, KenLM demonstrated superior performance compared to FastText when both were trained on the same dataset. Furthermore, recent research (Gunasekar et al., 2023; Li et al., 2024; Penedo et al., 2024) has focused on fine-tuning pre-trained embedding models to serve as classifiers for quality filtering. Especially, Fineweb demonstrated that training relatively small-sized LLMs (1.82 billion parameters) on data filtered by a trained classifier (resulting in 350 billion tokens), rather than on unfiltered data, led to performance improvements across various benchmarks. However, these methods are impractical for processing large web corpora due to their high computational costs, which necessitate significant GPU resources.

3 Proposed Method

In this paper, we aim to reduce noisy data while preserving high-quality data in a computationally efficient manner. To this end, we propose an ensemble approach using two contrasting KenLMs: (i) Good KenLM and (ii) Bad KenLM.

Good KenLM. The objective of Good KenLM is to assign low perplexity (PPL) scores to well-structured, high-quality text. Many previous studies (Wenzek et al., 2019; Computer, 2023; Nguyen et al., 2023; Laurençon et al., 2024) have used

a high-quality Wikipedia dataset for training, denoted as Wiki KenLM in this paper. However, with recent advancements in LLMs, several high-quality datasets (Soldaini et al., 2024; Penedo et al., 2024; Li et al., 2024) have emerged. In our experiments, as shown in Section 4, we found that the combination of S2ORC (Lo et al., 2020) and Textbooks-are-all-you-need-lite (SciPhi, 2023) as training data was more effective than utilizing Wikipedia. Thus, in this paper, we designate the KenLM trained on this combination of data as Good KenLM.

Bad KenLM. The rationale behind employing Bad KenLM alongside Good KenLM is that Good KenLM fails to detect unwanted content (*e.g.*, spam, advertising, and informal communication), which are generally considered poor for training LLMs, as it has not been *explicitly* trained on these types of content. For instance, if low-quality content shares superficial linguistic patterns with high-quality text, it may still score reasonably well under Good KenLM. Therefore, to detect a wider range of undesirable content, Bad KenLM is designed to assign low PPL scores to such content. To achieve this, we trained Bad KenLM using noisy, low-quality datasets, including hate speech, spam emails, and informal social media content. To the best of our knowledge, this is the first study to employ KenLM trained on noisy, low-quality datasets.

Ensemble. To leverage the complementary strengths of two contrasting KenLMs, we ensemble the models by integrating the PPL scores assigned by each. We perform Z-score standardization to align the scales of the two PPL scores assigned by each model, as they are trained on different datasets and therefore exhibit different distributions of PPL scores. Then, we compute the ensembled PPL score $P_{ens}(x_i)$, as follows:

$$P_{ens}(x_i) = \alpha \left(\frac{P_{good}(x_i) - \mu_{good}}{\sigma_{good}} \right) - (1 - \alpha) \left(\frac{P_{bad}(x_i) - \mu_{bad}}{\sigma_{bad}} \right), \quad (1)$$

where $x_i \in \mathcal{X}$ denotes the i -th text data, \mathcal{X} represents datasets, $P_{good}(x_i)$ (resp. $P_{bad}(x_i)$) indicates PPL score from Good (resp. Bad) KenLM for x_i , μ_{good} (resp. μ_{bad}) is the mean of the PPL scores from Good (resp. Bad) KenLM, σ_{good} (resp. σ_{bad}) is the standard deviation of the PPL scores from Good (resp. Bad) KenLM, and α denotes a parameter that balances the two PPL scores. Note that the coefficient for the term associated with Bad

KenLM is negative. This is because, in contrast to Good KenLM, which assigns low PPL scores to high-quality data, Bad KenLM assigns low PPL scores to low-quality data. Consequently, data with low ensembled PPL scores—obtained by appropriately subtracting two PPL scores—closely resemble the linguistic patterns of high-quality data and are distinctly separated from low-quality content.

4 Experiments

We designed our experiments to answer the following key research questions (RQs):

- **RQ1:** Does our ensemble approach outperform existing models in removing noisy content while preserving high-quality content?
- **RQ2:** Which data sources are effective for training the Bad KenLM?
- **RQ3:** How sensitive is the performance of our ensemble approach to hyperparameter α ?
- **RQ4:** How much additional computational overhead does our ensemble approach introduce compared to a single KenLM?
- **RQ5:** What types of data does our ensemble approach effectively filter out?

4.1 Experimental Settings

Dataset and model details. As mentioned in Section 3, we randomly selected subsets of 300,000 samples each from S2ORC (Lo et al., 2020) and Textbooks-are-all-you-need-lite (SciPhi, 2023) as training data for Good KenLM. For the training data of Bad KenLM, we collected datasets that is likely to hinder the training of LLMs. Specifically, we used 1,000,000 pieces of social network service (SNS) data (Twitter) (mjw, 2022; fschatt, 2023; lcama, 2022; StephanAkkerman, 2023) and 776,142 pieces of spam message data (Metsis et al., 2006; thehamkercat, 2024; alissonpadua, 2024). During the training of both models, we configured the n-gram size to 6 and the vocabulary size to 65, 536. Also, we set the hyperparameter α to 0.7.

Evaluation details. To evaluate the effectiveness of our ensemble approach, we measured perplexity (PPL) scores for the CC-MAIN-2024-10 dump (211 million samples) from Fineweb-edu (Penedo et al., 2024). Following Wenzek et al. (2019); Computer (2023), we then filtered the data based on the 30th and 60th percentiles of PPL scores. Subsequently, we measured the proportion of data with

Models	Recall@30	Recall@60	Average Recall
Wiki KenLM	0.5530	0.8513	0.7022
Good KenLM	0.7059	0.9195	0.8127
Bad KenLM	0.3403	0.7031	0.5217
FastText(Wiki, Bad)	0.6453	0.8878	0.7665
FastText(Good, Bad)	0.7462	0.9412	0.8437
Ens(Good, Bad)	0.8190	0.9647	0.8919
Ens(Good, Wiki)	0.6312	0.8898	0.7605

Table 1: Performance comparison of our approach with existing models, and an ablation study on our design choices.

an *educational score* of 2.5 or higher that was included. In other words, we treated data with an educational score of 2.5 or higher as the ground truth and measured the recall value. Note that the educational scores are annotated using extensive GPU resources, and it has been demonstrated that training LLMs with data possessing high educational scores leads to performance improvements.

4.2 Main Results

We highlight the best results in bold and the second-best results with an underline in the tables.

RQ1: Comparison of existing models. As shown in Table 1, our Good KenLM significantly outperformed the widely used Wiki KenLM. Although Bad KenLM alone showed poor performance, our strategy of ensembling it with Good KenLM outperformed even FastText trained on the same data, improving Recall@30 and Recall@60 by 9.76% and 2.50%, respectively.

Moreover, to validate the effectiveness of Bad KenLM within our ensemble framework, we conducted a comparative experiment where Good KenLM and Wiki KenLM were ensembled in place of Bad KenLM, denoted as *Ens(Good, Wiki)*. The performance of *Ens(Good, Wiki)* was lower than that of Good KenLM alone. This is likely due to the relatively lower quality of the Wikipedia dataset compared to the training data used for Good KenLM, which negatively impacts its overall performance. This result also highlight the importance of incorporating Bad KenLM into the ensemble, as it successfully identifies undesirable content that Good KenLM may overlook.

RQ2: Impact of data sources on training Bad KenLM. The training dataset for Bad KenLM is diverse, including SNS, spam mail, and toxic datasets (Davidson et al., 2017; de Gibert et al., 2018; Kennedy et al., 2020; Mathew et al., 2021; Vidgen et al., 2021; Pavlopoulos et al., 2022) containing hate speech and profanity. We conducted

Training Dataset of Bad KenLM	Metrics		
	Recall@30	Recall@60	Average Recall
Spam	0.8059	0.9576	0.8818
Twitter	0.8131	0.9651	0.8891
Toxic	0.7320	0.9402	0.8361
Spam + Twitter	0.8190	0.9647	0.8919
Spam + Toxic	0.7885	0.9545	0.8715
Twitter + Toxic	0.7973	0.9602	0.8788
Spam + Twitter + Toxic	0.7906	0.9533	0.8720

Table 2: The effect of data sources on Bad KenLM training.

Figure 1: The effect of α on the performance of our ensemble approach.

experiments to determine which of these data sources are effective for training Bad KenLM. In this experiment, we ensembled our Good KenLM with various Bad KenLMs, each trained on different combinations of datasets.

As shown in Table 2, SNS data (Twitter) proved to be the most effective for training Bad KenLM, which is designed to filter out noisy content unsuitable for LLM training. Interestingly, toxic datasets led to a decrease in the performance of Bad KenLM. Unlike SNS data or spam mail, which share similar distributions with web data, toxic datasets contain a large proportion of highly offensive language, resulting in a substantial distributional difference. This discrepancy seems to adversely affect the training process of Bad KenLM.

RQ3: Hyperparameter sensitivity analysis. The parameter α in Eq. (1) adjusts the balance between the PPL scores of Good KenLM and Bad KenLM. We analyze how the performance of our ensemble approach varies with changes in α in terms of Recall@30 and Recall@60.

As depicted in Figure 1, Recall@30 and Recall@60 continuously improve as α increases to 0.7 and 0.6, respectively, and then gradually decrease. These results suggest that when α is too small, the influence of Bad KenLM becomes overly dominant, resulting in poor preservation of high-quality content. Conversely, when α is too large, the influence of Good KenLM prevails, leading to the inclusion of some low-quality content. These results indicate that appropriately determining the value of α is critical for effectively removing noisy content while preserving high-quality content.

RQ4: Degree of computational overhead. To assess the computational overhead of our approach,

Models	Processing Time	Estimated Cost	Throughput	Avg. Recall
Good KenLM	2,234s	\$1.42	94.4k docs/s	0.8127
Ens(Good, Bad)	3,928s	\$2.50	53.7k docs/s	0.8919

Table 3: Comparison of computational overhead and performance for the CC-MAIN-2024-10 dump between Good KenLM and our ensemble approach.

Advertising content

[...] Online roulette for real money hungary withdrawals can take up to 3 days to get approve and payments will be delivered to the client within 3 days, a pop-up will appear with the three-step registration process. [...] Join us to find the best live casino software providers for USA players [...]

Communication-style content

[...] Of course `name` being the getting older and more mature by the second girl that she is told Pop that he really didn't need to be there because she had it all handled. That girl is funny! [...]

Figure 2: Visualization of examples that are not filtered by Good KenLM but are successfully removed by our ensemble approach.

we measured the processing time and estimated cost¹ for the CC-MAIN-2024-10 dump on a machine with 128-core CPUs. As presented in Table 3, our approach increased the processing time from 2,234 to 3,928 seconds, with an additional cost of \$1.08. These increases are justified by the recall improvement from 81.27% to 89.19%, as high-quality data is crucial for effective LLM training.

RQ5: Case study on the effectiveness of our approach. To demonstrate the effectiveness of our ensemble approach, we present examples that are not filtered by Good KenLM but are successfully removed by our ensemble approach. As illustrated in Figure 2, our approach effectively filters advertising and communication-style content, which are generally unsuitable for LLM training. Since advertising content is usually written politely, Good KenLM, trained only on high-quality datasets, struggles to detect it. Conversely, Bad KenLM, trained on spam mail and SNS data, successfully identifies such content as well as communication-style content. Therefore, our ensemble approach more effectively filters these types of content.

5 Conclusion

In this paper, we propose an ensemble approach using Good KenLM and Bad KenLM for effective text filtering. By integrating perplexity scores, we successfully filter out noisy data, such as spam and informal content, while preserving high-quality text. Empirical results suggest that our approach could be a practical solution for filtering large-scale datasets in resource-constrained environments.

¹It was measured using an AWS r6a.32xlarge (Amazon Web Services, 2022) spot instance.

Acknowledgments

This work was supported by Institute of Information & Communications Technology Planning & Evaluation(IITP) grant funded by the Korea government(MSIT) (No. RS-2024-00338140, Development of learning and utilization technology to reflect sustainability of generative language models and up-to-dateness over time)

Limitations

While the proposed method using Good KenLM and Bad KenLM offers effective filtering of large-scale datasets, it has the following limitations: (i) although our method has demonstrated effectiveness through extensive experiments using Fineweb-edu, we have not been able to measure its direct impact on LLMs training due to computational cost constraints; and (ii) the model relies heavily on pre-defined training datasets, and its performance may degrade when applied to content that significantly differs from the training corpora.

Ethics Statement

The experiments conducted in this paper were carried out objectively and fairly. No biases were introduced during the data selection or evaluation process. All datasets used in this research are publicly available, and the methods were rigorously tested to ensure the reliability and validity of the results.

Abstract

Dyslexia, a common learning disability, requires an early diagnosis. However, current screening tests are very time- and resource-consuming. We present an LSTM that aims to automatically classify dyslexia based on eye movements recorded during natural reading combined with basic demographic information and linguistic features. The proposed model reaches an AUC of 0.93 and outperforms the state-of-the-art model by 7%. We report several ablation studies demonstrating that the fixation features matter the most for classification.

1 Introduction

One of the most common learning disabilities is dyslexia, a difficulty that specifically affects reading and spelling in individuals with otherwise intact cognitive abilities. The prevalence of dyslexia is estimated to be between 9% and 12% (Katusic et al., 2001; Shaywitz et al., 1998). Early diagnosis is the key factor for getting the needed support and staying on track in the educational system (Glazzard, 2010; Torgesen, 2000; Vellutino et al., 2004).

There are various testing batteries for dyslexia, but most must be administered one-on-one by a trained specialist, who is not always present at school. Moreover, such batteries are still often evaluated using paper-and-pencil methods, which are time-consuming and error-prone. Without a cheap, fast, and reliable mass testing method, the only way to get proper support for a struggling reader is through the educator, who may notice reading difficulties and recommend additional testing.

For mass screening, data should be quick and affordable to obtain. Automatic classification based on (f)MRI and ERP recordings, while suitable from the machine learning perspective, does not fit this criterion. Eye tracking technology is more promising: It provides a rich signal, is unobtrusive, and is growing cheaper. Research on dyslexia and

eye movements has a long history. Attempts to tie dyslexia to some characteristics of eye movements go at least as far back as 1980s (Olson et al., 1983; Pavlidis, 1981; Rayner, 1985). Since then, it has been established that the underlying deficit in dyslexia lies not in oculomotor control but rather in phonological decoding (International Dyslexia Association, 2024). Given that eye movements reflect phonological decoding in beginner and adult readers (Rayner et al., 1995, 1998; Blythe, 2014; Leininger, 2019; Milledge and Blythe, 2019), inferring dyslexia from eye movements is strongly theoretically motivated.

Several machine-learning solutions based on eye movements have been proposed for the mass screening for dyslexia (Asvestopoulou et al., 2019; Nilsson Benfatto et al., 2016; Haller et al., 2022; Jothi Prabha and Bhargavi, 2022; Raatikainen et al., 2021; Rello and Ballesteros, 2015; Shalileh et al., 2023). Yet almost all of these models were trained on very modest samples of 61 (Asvestopoulou et al., 2019) to 185 participants (Nilsson Benfatto et al., 2016). This paper presents a comparison of two models that aim to automatically classify dyslexia on a large dataset comprising eye-movements while reading from 293 young readers of different ages.

1.1 Problem Setting

Inferring whether a child has dyslexia is a binary classification task, and the model’s performance can be characterized by a false positive and a true positive rate. By altering the decision threshold, one can observe a receiver operator characteristic curve (ROC curve). The area under the ROC curve (AUC) provides an aggregated measure of performance for all possible classification thresholds.

2 Experiments

2.1 Eye-movement data

The cross-sectional dataset contains eye movements while reading in 293 native speakers of Russian, from the 1st to the 6th grade (published by [Shalileh et al. 2023](#)). In Russia, grades 1 through 4 correspond to primary school, and grades 5 and 6 – to secondary school. Based either on a reading assessment or a speech therapist assessment, children were classified as typically developing ($N = 221$) or having developmental dyslexia ($N = 72$). Among children with dyslexia, 43 received their diagnosis based on reading assessment, and 29–based on therapist assessment. Reading assessment was based on the Standardized Assessment of Reading Skills test (SARS, [Kornev and Ishimova 2010](#)) and recent normative cut-offs reported by ?. SARS requires a test-taker to read a short text aloud as quickly and as accurately as possible. The number of words read accurately in the first minute is taken as a measure of reading fluency. If a child scores at least 1.5 standard deviations below their corresponding age mean, a dyslexia label is assigned. Speech therapist assessment is based on a phonological test battery. Note that there are children with dyslexia (diagnosis based on a phonological assessment) whose reading speed is higher than that of some age-matched children in the control group.

All children had nonverbal intelligence scores within the normal range. The typically-developing children had age-appropriate reading fluency and comprehension. Their parents or primary caretakers reported no history of reading disorders. The detailed composition of both groups can be found in Table 1.

2.2 Reading materials

All children were asked to read the same set of 30 sentences comprising the Child Russian Sentence Corpus ([Lopukhina et al. 2022](#)). Sentence difficulty was at the level of 3rd to 4th grade, according to an automatic text difficulty measurement developed for Russian ([Laposhina and Lebedeva, 2021](#)), and estimated to be 7.42 on the Flesch-Kincaid scale adapted to Russian ([Readability Test](#)). Sentences were six to nine words long ($M = 7.6$, $SD = 0.85$). In total, children read 227 words, which contained 182 unique word forms (as words could be repeated across sentences). Individual words were on average 5.6 letters long (range 1–13), and

had average lemma frequency of 50.29 items per million (median: 0.73, range: 0.0001 – 667). The frequency was calculated from the sub-corpus of texts for children of the years 1920–2015 of the [Russian National Corpus](#).

Since Russian is a morphologically rich language, and morphological composition of a word affects its reading time, the number of morphemes comprising each word was annotated. The annotation was first done by an automated parser and then reviewed by a trained linguist. Finally, each word’s predictability was estimated using an online cumulative cloze task with 46 children who did not participate in the eye-tracking study. Predictability was measured as the number of correct guesses divided by the total number of guesses. Zero probabilities were replaced with $\frac{1}{2 \times 46}$, where 46 is the number of guesses for the word.

For a more detailed description of the dataset and reading materials, see [Lopukhina et al. 2022](#).

2.3 Reference method

As a baseline, we use a state-of-the-art (SOTA) SVM-RFE with a linear kernel described and implemented by [Haller et al. \(2022\)](#). This approach was first proposed by [Nilsson Benfatto et al. \(2016\)](#), who reported 96% accuracy on a balanced dataset. As input, the SOTA model uses the means and standard deviations of 12 eye-movement features, such as first fixation duration, first-pass reading time, etc. (for the full list, refer to [Haller et al. 2022](#)).

Note that [Haller et al.](#) had a homogenous data set of age-matched readers, and did not include age as a predictor. Given that the present dataset includes readers of different ages, we report the performance of the SOTA model both without grade, for full comparability with [Haller et al.](#)’s results, and with grade, for a fairer comparison.

2.4 Proposed model

The model introduced by [Haller et al.](#) relied on aggregated reading measures. This aggregation, however, results in the loss of significant temporal and word-level information. We address this limitation by employing a sequential method—namely, LSTMs ([Hochreiter and Schmidhuber, 1997](#))—to preserve and leverage temporal information. As demonstrated by previous studies ([Ahn et al., 2020](#); [Reich et al., 2022](#)), this choice effectively captures the temporal dynamics necessary for eye-movement classification.

Table 1: Demographic and cognitive characteristics of both participant groups, organized by grade. Values before the slash (“/”) represent the control group, while those after the slash correspond to participants with dyslexia.

Grade	1 (N=50/8)	2 (N=40/10)	3 (N=37/20)	4 (N=39/28)	5 (N=31/6)	6 (N=24/0)

Our proposed model’s input is a participant’s fixation sequence on a sentence. Each input vector consists of basic demographic information, gaze-specific, and linguistic features:

(i) *Demographic features*: participant’s age, grade, and gender. Age and grade are relevant for classification because reading skills in primary school are noticeably different between grades, and many reading evaluations are normed for a certain age (grade). Participant’s gender is important from a clinical perspective. Boys are diagnosed with dyslexia more often than girls: the male-to-female sex ratio ranges from about 3:1 to 5:1 in self-identified samples, and from 1.5:1 to 3.3:1 in random samples. Arnett et al. (2017) claim that the difference in dyslexia rates between sexes is valid and is driven by lower and more variable processing speed in boys.

(ii) *Gaze-specific features*: fixation duration, fixation horizontal and vertical coordinates on the screen, landing position on the word, next fixation distance, next saccade amplitude, next saccade angle, next saccade velocity, and next saccade direction. We used all fixation features available through the eye movement recording device and reasoned that the importance of different features can be estimated through ablation studies.

(iii) *Linguistic features*: fixated word’s length in letters, predictability and frequency (these features explain most of the eye-movement variance, see Kliegl et al. 2004; Shain 2019), as well as number of morphemes comprising the word.

We choose an BiLSTM-based architecture, where the mean of the hidden states is fed into two sequential linear layers, projecting it down to a single sigmoid output to represent the label prediction. Optimized hyperparameters and search space are reported in Appendix A.

3 Results

3.1 Model evaluation

The models are evaluated in two settings: prediction of the reader’s status based on a single sentence data (sentence prediction setting) or based on all available reading data (reader prediction setting). In the reader prediction setting, predictions for individual sentences are aggregated to produce the final outcome. The motivation for introducing the sentence prediction setting was to identify whether some sentences serve as a better diagnostic material than others, and to evaluate model precision depending on the amount of input.

All models were evaluated and tuned using 10-fold nested cross-validation and random grid search (see Appendix A). Data from the same person is always constrained to one fold, so that the models always make predictions for unseen participants. The ratio of persons with/without dyslexia is balanced across all folds.¹

3.2 Results

For all methods, we report AUC for reader- and sentence-level settings (see Table 2). A visual summary of ROC AUC performance can also be found in Figure 1. Classification performance in the reader-prediction setting was numerically higher than in the sentence-prediction setting. However, according to an unpaired one-tailed t-test, the difference between settings was not significant in any model (LSTM: $t(15.55) = 1.22$, $p = 0.12$; SOTA_{+Grade}: $t(16.21) = 0.81$, $p = 0.21$; SOTA_{-Grade}: $t(17.83) = 0.24$, $p = 0.41$). The SOTA model that included information on grade performed numerically better, but the difference was not significant (reader prediction setting: $t(17.96) = 1.03$, $p = 0.16$; sentence prediction setting: $t(16.64) = 0.71$, $p = 0.24$). Importantly, the proposed LSTM significantly outperformed

¹All code is available online: https://github.com/annlaurin/Rus_dyslex_classification

the SOTA_{+Grade} model in both reader-prediction ($t(12.146) = 2.12, p = 0.028$) and sentence-prediction settings ($t(17.92) = 2.20, p = 0.021$).

3.2.1 Ablation Studies

In the reader-prediction setting, we run additional ablation studies, assessing model performance without saccade-related measures (next fixation distance, next saccade amplitude, angle, velocity, and direction), without linguistic information (word length, frequency, predictability, and the number of morphemes), without demographic information (age, grade, and gender), and without all eye-movement features. In all ablation studies, AUC score was lower, but the decrease was not significant except for the model without all eye-movement features (LSTM_{Saccade}: $t(14.70) = 0.95, p = 0.17$; LSTM_{Ling}: $t(17.80) = 0.06, p = 0.47$; LSTM_{Demographic}: $t(16.14) = 1.66, p = 0.058$; LSTM_{All eye movement}: $t(17.93) = 3.25, p = 0.002$).

On average, children with dyslexia make more fixations than normally developing children. To evaluate whether the LSTM predictions are based mainly on the input length, we reduced the number of fixations to 29. The resulting AUC score did not differ from the score obtained on the whole input ($t(18) = 0.20, p = 0.42$).

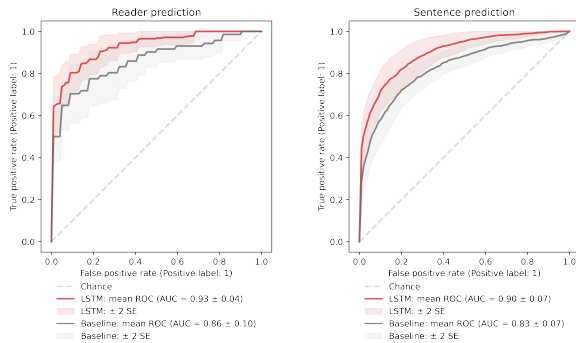

Figure 1: Summary of model performance. SOTA baseline model used grade information.

4 Discussion

The finding that the information on the grade of the reader did not significantly improve the performance of either model is rather surprising. In the present dataset, at least in some cases, dyslexia was diagnosed based on age-specific normative reading speed cut-offs (see Section 2.1). Consequently, information about reader’s grade should be crucial for

		AUC
Reader	SOTA	0.86±0.10
	SOTA _{-Grade}	0.81±0.11
	LSTM	0.93±0.05
	LSTM _{Ling}	0.92±0.05
	LSTM _{Saccade}	0.91±0.07
	LSTM _{Demographic}	0.90±0.06
	LSTM _{29 fixations}	0.93±0.04
	LSTM _{All eye movement}	0.87±0.04
Sentence	SOTA	0.83±0.07
	SOTA _{-Grade}	0.80±0.10
	LSTM	0.90±0.07

Table 2: Summary of AUC \pm standard error in the reader- and sentence-prediction settings.

the classification performance. Grade-invariant performance might reflect that the model has captured some invariant property of the eye movements of readers with dyslexia. For the SOTA model trained exclusively on aggregated features, we consider this explanation unlikely. For the LSTM trained on a sequence of fixations, this explanation is more likely, but it is precisely the LSTM that shows a greater numerical decrease in performance without the grade information. In general, we believe that a successful model should be able to uncover the relationship between reading speed, grade, and dyslexia label.

Another surprising outcome is the lack of difference between the sentence- and reader-prediction settings. Given that the reader-prediction setting relies on $10\times$ to $30\times$ more data, we expected performance to be higher. The difference in performance may not be significant due to the relatively small size of the dataset and insufficient statistical power.

The finding that removing linguistic features did not significantly affect LSTM model’s performance is less surprising. Arguably, the most crucial feature for dyslexia classification, word’s orthographic transparency (Borleffs et al., 2017), was not available. Including a measure of word orthographic transparency might be a promising next step in improving model performance.

Most importantly, the proposed LSTM outperformed the SOTA model. We can confidently state that better performance is not a trivial result of hyperparameter tuning, as SOTA model was tuned for the same parameters within a similar search space. In the same vein, LSTM did not simply rely on the number of fixations made by children with

and without dyslexia for classification. Based on the outcomes of ablation experiments, we conclude that model performance increased due to the more detailed information about how the sequence of eye movements unfolds.

5 Conclusions

The model of automatic dyslexia detection proposed here has outperformed the SOTA model. Importantly, unlike most of the models proposed so far (Nilsson Benfatto et al., 2016; Haller et al., 2022; Asvestopoulou et al., 2019; Jothi Prabha and Bhargavi, 2022), the present LSTM was trained on an unbalanced dataset of eye movements of children of different ages, and might therefore be more robust and potentially more appropriate for the real-world applications.

Limitations

This decision to include information from participants who did not read all 30 sentences could potentially lead to data leakage: The model may learn that incomplete sessions are more likely to come from a child with dyslexia. We think that this is unlikely for two reasons: First, the proportions of incomplete sessions are not drastically different between the two groups. Second, this potential data leakage should only affect the reader-prediction setting (where the model expects to see 30 sentences), not the sentence-prediction setting (where the model expects to see one sentence). In the present case, there was no significant difference in performance between the reader prediction and the sentence prediction settings (see Section 3.2), so the reader-prediction setting is unlikely to have an unfair advantage.

Ethical considerations

Using demographic variables, such as age and gender, might lead to reproducing existing biases. For example, males are diagnosed with dyslexia more frequently, but at least part of the difference may be attributed to referral bias (Wadsworth et al., 1992). One way to control for bias is to withhold the potentially biasing feature. The ablation experiment that removed the demographic information performed on par with the full model. Therefore, we conclude that the model at least does not enhance the bias that might be present in the data set.

Abstract

Answering questions over multi-page, multi-modal documents, including text and figures, is a critical challenge for applications that require answers to integrate information across multiple modalities and contextual dependencies. Existing methods, such as single-turn retrieval-augmented generation (RAG), struggle to retrieve fine-grained and contextually relevant information from large, heterogeneous documents, leading to suboptimal performance. Inspired by iterative frameworks like ReAct, which refine retrieval through feedback, we propose Doc-React, an adaptive iterative framework that balances information gain and uncertainty reduction at each step. Doc-React leverages InfoNCE-guided retrieval to approximate mutual information, enabling dynamic sub-query generation and refinement. A large language model (LLM) serves as both a judge and generator, providing structured feedback to iteratively improve retrieval. By combining mutual information optimization with entropy-aware selection, Doc-React systematically captures relevant multimodal content, achieving strong performance on complex QA tasks.

1 Introduction

Answering queries over multi-page, multimodal documents with textual and visual information is a critical challenge (Ma et al., 2024a; Tanaka et al., 2023). These documents, which are typically long, often have diverse layouts and interleaved content (Nguyen et al., 2024), requiring reasoning across modalities. Specifically, as illustrated by the use case in Figure 1, the input is a user query and multi-page documents, either provided by the user or from a database. The goal is to produce an accurate and concise text answer by analyzing the relevant content across pages.

Existing methods (Yu et al., 2024; Yang et al., 2023; Faysse et al., 2024; Yao et al., 2022; Wu et al., 2024d) retrieve multimodal content and feed

it into single-turn RAG models. While effective in simpler scenarios, these methods fall short in multi-page settings, missing fine-grained, contextually relevant information. As illustrated in Figure 1, when applying (Yu et al., 2024; Faysse et al., 2024), the query Q does not explicitly mention the region with “252M mobile broadband subscriptions.” Simply retrieving figures semantically similar to Q fails to identify that the region refers to North America and further locate the figure containing North America’s “active social network users” (described in S_2). This highlights the need for an iterative approach to dynamically refine queries, discover relevant figures, and gather necessary information. Inspired by iterative methods (Yao et al., 2022), we adopt a dynamic approach to refine queries iteratively, addressing the challenges of multi-page document QA.

We propose Doc-React, an adaptive iterative framework for multi-page document retrieval and acting. Doc-React refines retrieval and query formulation in distinct steps to maximize normalized information gain, balancing information gain and uncertainty reduction with InfoNCE-guided retrieval. It addresses residual gaps through sub-queries refined by an LLM, which provides feedback as both judge and generator. By maximizing step-wise information gain, Doc-React iteratively captures fine-grained, contextually relevant information, adapting queries and improving retrieval efficiency. In summary, our contributions are:

- We propose Doc-React, an adaptive iterative framework that dynamically refines multimodal retrieval and QA performance through LLM-guided feedback.
- We introduce a method to balance information gain and uncertainty reduction, dynamically adapting sub-queries and retrieval prompts.
- We conduct extensive experiments showing

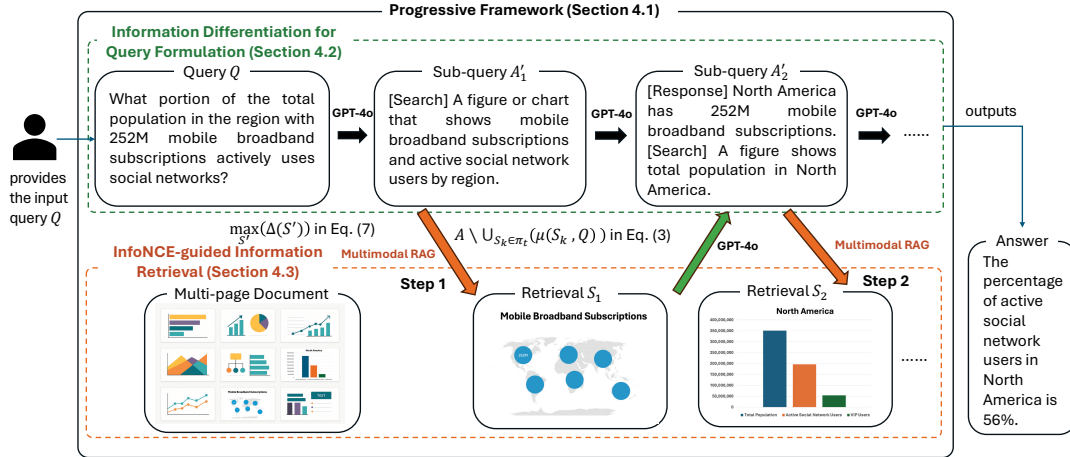

Figure 1: Doc-React applied to the multi-page document QA task. The framework processes a user query as input and operates on multi-page documents. It iteratively refines information retrieval and query formulation to maximize information gain and reduce uncertainty, ultimately generating an accurate and contextually relevant answer.

significant improvements over baselines for complex multi-page QA tasks.

2 Related Work

2.1 Iterative and Adaptive Retrieval

Iterative approaches, such as ReAct (Yao et al., 2022), Chain-of-thought (Wei et al., 2022; Wu et al., 2024c,a) and MM-React (Yang et al., 2023), leverage dynamic feedback mechanisms to refine queries and align context (Shinn et al., 2024; Huang et al., 2023; Zhang et al., 2024), effectively addressing challenges in noisy or incomplete retrieval scenarios (Zhou et al., 2024). These methods demonstrate the importance of iterative frameworks (Hu et al., 2024b; Yang et al., 2024) in achieving more accurate and context-aware retrieval. Similarly, mutual information optimization techniques, inspired by InfoNCE (Oord et al., 2018), rely on iterative strategies to balance information gain and uncertainty reduction, further highlighting the relevance of iterative methods for handling complex retrieval tasks. In our framework, InfoNCE-guided mutual information optimization is not only theoretically motivated but also serves as a practical mechanism for adaptive multi-step retrieval (detailed in Section 4).

2.2 Multimodal Document Retrieval

Advancements in multimodal learning enable systems to jointly process text and visual information (Yan et al., 2024; Wu et al., 2025, 2024b; Yao et al., 2024; Liu et al., 2024a). Models like LayoutLM (Xu et al., 2020b,a) leverage spatial embeddings for document layout understanding, excelling

at tasks like form and invoice parsing. These models are limited to single-page documents (Liu et al., 2024b) and cannot handle reasoning over multi-page (Ma et al., 2024a), and heterogeneous layouts (Tanaka et al., 2023).

2.3 Retrieval-Augmented Generation (RAG)

RAG (Lewis et al., 2020) and FiD (Izacard and Grave, 2020) combine retrieval and generation for open-domain QA. While effective, their reliance on static pipelines limits adaptability to complex document layouts. Retrieval methods like BM25 (Robertson and Walker, 1994) and dense models such as ColBERT (Khattab and Zaharia, 2020) efficiently match content but fail to capture the cross-modal dependencies for multimodal documents. MuRAR (Zhu et al., 2024) generates multimodal responses to convey rich cross-modal information.

3 Formulation: Multi-page Doc-QA

We introduce a novel formulation for the multi-page document question-answering (Doc-QA) task, where the input consists of heterogeneous documents that interleave images and texts in unstructured, free-form layouts. This practical task involves disentangling multimodal information embedded within the images of document pages to accurately answer a given query. The objective of a multi-page Doc-QA is to extract sufficient multimodal information from the relevant pages of a document and use it to generate a correct answer. Our novel formulation is different from the formulation of existing works (Mathew et al., 2021; Chang et al., 2022; Masry et al., 2022; Liu et al.,

2024b) that we consider question-answering with a long sequence of document page images due to heterogeneous layouts of various types of documents. Different from tool-chain based agentic framework (Yang et al., 2023; Ma et al., 2024b; Kumar et al., 2024), our formulation focuses on balancing between information gain and generation uncertainty when multiple images are in the prompts.

Given a N -page document $D = \{p_1, p_2, \dots, p_N\}$ and a query Q , an underlying policy is required to identify multiple groups of document pages $\pi = \{S_i | S_i \subseteq D\}$, where each group of document pages S_i provides relevant information to a specific aspect of the query Q . The multimodal information necessary to derive the answer A must then be extracted from each subset S_i , conditioned on the query Q , using a multimodal large language model (MLLM) denoted as $\mu(S_i, Q)$. The final output is a text-only response, generated based on the extracted multimodal content. To quantify the informativeness of this process, we measure the mutual information $I(\mu(S_i, Q); A)$ as the amount of information required to determine the answer A .

We further formalize this task as an information optimization problem, which seeks a balance between reducing uncertainty and ensuring information completeness (Alemi et al., 2016):

$$\begin{aligned} \min_T \quad & \sum_{S_i \in \pi} H(\mu(S_i, Q)), \quad S_i \subseteq D, \quad \forall S_i \in \pi, \\ \text{s.t.} \quad & I\left(\bigcup_{S_i \in \pi} \mu(S_i, Q); A\right) \geq I(\mu(D, Q); A), \end{aligned} \quad (1)$$

where $H(\cdot)$ denotes the entropy, capturing uncertainty in the extracted information. A key practical challenge is the increasing estimation error as the number of input images grows. Empirically, we can observe that there exist subsets $S_1, S_2 \subseteq D$ such that $H(\mu(S_1, S_2, Q)) > H(\mu(S_1, Q)) + H(\mu(S_2, Q))$. This implies that increasing the size of the input set does not always improve answer accuracy, while the increased input size also retrains the usage of MLLMs, due to their limited perception of multimodal context.

4 Method: Doc-React

The formulation’s major challenge is incrementally identifying and aggregating multimodal information from a multi-page document corpus (Hu et al., 2024a; Cho et al., 2024). Inspired by information-entropy optimization (Alemi et al., 2016; Still,

Algorithm 1 Doc-React: Adaptive Retrieval with Normalized MI Gain Maximization

-

2009), we propose **Doc-React**, which greedily maximizes the entropy-normalized information gain for each round of retrieval and action.

4.1 Progressive Framework Refining Retrieval and Query Formulation

At time step t , we maintain a selection of document page subsets π_t , where each subset’s $S_k \in \pi_t$ multimodal information is extracted by the MLLM $\mu(S_k, Q)$. To solve the information optimization problem in Eq.(1), we propose to maximize the *normalized information gain* for the next step $t + 1$:

$$\Delta(S_{t+1}) = \frac{I\left(\mu(S_{t+1}, Q); A \mid \bigcup_{S_k \in \pi_t} \mu(S_k, Q)\right)}{H(\mu(S_{t+1}, Q))}, \quad (2)$$

where A represents the ground-truth answer to the query. However, different from conventional goal-oriented optimization tasks (Sutton, 2018; Levine et al., 2016), which assume a good representation

of the goal, our task poses a challenge of lacking such *oracle information*.

4.2 Information Differentiation

For query formulation, we propose an information differentiation process to approximate each step’s maximum information gain,

$$A'_t = A \setminus \bigcup_{S_k \in \pi_t} \mu(S_k, Q), \quad (3)$$

where A'_t denotes the information residual at time step t . Takes Eq.(3) into Eq.(2), we can derive the approximation of the original information gain,

$$\Delta(S_{t+1}) = \frac{I(\mu(S_{t+1}, Q); A'_t)}{H(\mu(S_{t+1}, Q))}, \quad (4)$$

where the residual information is practically approximated by the MLLM

$$\tilde{A}_t = \mu(\{S_k\}_{k \in \pi_t}, Q, P_{\text{diff}}), \quad (5)$$

which aggregates retrieved information $\{S_k\}_{k \in \pi_t}$ and the query Q , quantifying the information gap.

Theorem 1 (Information Gain Derivation via Information Differentiation). *With the information differentiation enabled as A'_t (in Eq.(3)), the information gain $\Delta(S_{t+1})$ in Eq.(2) can be derived via the information differentiation in Eq.(4).*

We prove the equivalency between Eq.(2) and Eq.(4) in Appendix D. Then, this gap is addressed by leveraging the LLM-as-a-judge (Zheng et al., 2023; Rosset et al., 2024; Gu et al., 2024) to evaluate and decompose complex queries (Xia et al., 2024). Specifically, the gap is formulated into sub-queries by following the in-context examples (in Appendix E).

4.3 InfoNCE-guided Information Retrieval

To further track the information gain $I(\mu(S_{t+1}, Q); A'_t)$, we introduce existing multimodal retrieval models (Faysse et al., 2024; Yu et al., 2024) as prior, which can efficiently provide such information quantification through a retrieval process. Given the multimodal retrieval model $f(\cdot, \cdot)$ which measures the distance between multimodal inputs, we can derive the variational lower bound for the mutual information estimation following InfoNCE (Oord et al., 2018),

$$\begin{aligned} I(\mu(S_{t+1}, Q); A'_t) &\geq -\mathcal{L}_{\text{InfoNCE}}(S_{t+1}) \\ &= \mathbb{E} \left[\log \frac{\exp(f(S_{t+1}, [Q, A'_t]))}{\frac{1}{|\Omega|} \sum_{S' \in \Omega} \exp(f(S', [Q, A'_t]))} \right], \end{aligned} \quad (6)$$

Dataset		MMLongBench		SlideVQA	
Method	Model	F1	Acc	F1	Acc
VisRAG	GPT-4o	29.02	27.78	48.37	46.93
	InternVL	11.43	11.03	18.13	17.28
	MiniCPM	8.28	8.17	12.62	11.83
ColPali	GPT-4o	32.17	30.76	53.42	52.33
	InternVL	8.86	8.57	16.34	15.23
	MiniCPM	7.84	7.74	13.34	12.48
DocReact	GPT-4o	38.07	38.29	54.87	55.04

Table 1: Comparison with multimodal retrieval-augmented generation baselines.

Dataset		MMLongBench		SlideVQA	
Method	Model	F1	Acc	F1	Acc
Standard (i.e., w/o CoT)	GPT-4o	42.00	41.71	53.58	53.41
	InternVL	4.38	4.31	19.00	18.20
	MiniCPM	5.59	5.55	13.85	13.03
CoT	GPT-4o	41.17	40.77	52.12	51.71
	InternVL	10.79	10.47	17.45	16.74
	MiniCPM	6.37	6.13	12.45	11.73
DocReact	GPT-4o	38.07	38.29	54.87	55.04

Table 2: Comparisons with multi-image multimodal LLM baselines.

where $\Omega = \{S' \mid \forall S' \subseteq D\}$, while in practice we select from a random subset Ω' to reduce the computation complexity. In addition, the estimation uncertainty $H(\mu(S_{t+1}, Q))$ can be calculated based on the MLLM’s generation probabilities.

Therefore, using Eq.(6) in Eq.(2), we optimize step-wise normalized information gain $\Delta(S_{t+1})$, by maximizing its lower-bound estimation,

$$\begin{aligned} S_{t+1}^* &= \arg \max_{S' \in \Omega} \Delta(S'), \\ \pi_{t+1} &\leftarrow \pi_t \cup \{S_{t+1}^*\}, \end{aligned} \quad (7)$$

for which, we can achieve the near-optimal solution to the original problem in Eq.(1). We illustrate our method in Algorithm 1.

5 Experiments

For our comparison experiments, we use two lines of baselines, including **Multi-image MLLMs**: GPT4-o, InternVL (Chen et al., 2024), and MiniCPM (Yao et al., 2024), suitable for multi-page inputs; and **Multimodal RAG**: ColPali (Faysse et al., 2024) and VisRAG-Ret (Yu et al., 2024). To evaluate baselines and DocReact on multi-page document question-answering, we apply our method on two datasets, **SlideVQA** (Tanaka et al., 2023) and **VisualWebBench** (Liu et al., 2024b). For details, please refer to Appendix C.

Method	MMLongBench		SlideVQA	
	F1	Acc	F1	Acc
ColPali	32.17	30.76	53.42	52.33
DocReact (w/o ColPali)	37.22	37.37	54.12	54.29
DocReact (w/ ColPali)	38.07	38.29	54.87	55.04

Table 3: Ablation study comparing Doc-React with and without ColPali retrieval. Results are reported on the MMLongBench and SlideVQA benchmarks.

Comparison with Multimodal RAG We evaluate DocReact’s effectiveness against multimodal RAG methods in Table 1. While multimodal RAG methods mitigate input information overload, they struggle with complex queries requiring progressive multi-image reasoning and retrieval. In contrast, DocReact addresses these challenges through step-wise information differentiation and retrieval, achieving strong performance on both datasets.

Comparison with Multi-image MLLMs We evaluate DocReact’s efficiency in processing multi-page document inputs compared to multi-image MLLMs. As shown in Table 2, GPT-4o performs well on MMLongBench, where the limited number of candidate images allows it to process the full context effectively. However, *simply relying on GPT-4o (i.e., the baseline Standard) is not scalable for real-world scenarios with a larger number of candidate images*, where DocReact’s iterative approach becomes essential for efficiently retrieving fine-grained, contextually relevant information. While CoT reasoning offers limited improvement on GPT-4o due to inefficiencies in handling multimodal inputs, DocReact achieves competitive performance on MMLongBench and surpasses GPT-4o on the SlideVQA dataset, showing its scalability and effectiveness in handling multi-page QA tasks.

Case Study We validate DocReact’s advantage by a case study (Appendix A). In this example, the query Q does not explicitly mention the region with “252M mobile broadband subscriptions.” Advanced retrieval methods such as ColPali (Faysse et al., 2024) fail to infer that the region refers to North America and subsequently miss the figure containing relevant information on active social network users. In contrast, DocReact dynamically refines its search process. Through intermediate reasoning steps (Thought 2 and Thought 3), it identifies the missing region, retrieves the relevant figure, and gets the information (Observation 3), ultimately yielding the accurate result of 56% (Action 4).

Ablation Study on the Effect of Retriever Instead of relying solely on the strong retrieval approach

ColPali (Faysse et al., 2024; Yao et al., 2024; Chen et al., 2024), we conducted additional experiments to compare **DocReact (w/ ColPali)** and **DocReact (w/o ColPali)**. In the latter setting, we replaced ColPali with a weaker retrieval method as indicated in Table 3. This comparison allows us to better understand whether the observed improvements are attributable to our framework itself, rather than being solely due to the strong retrieval backbone. Our experiments demonstrate that even without leveraging the strong ColPali method, our approach still outperforms directly using ColPali.

6 Conclusion

We address the challenge of answering questions over multi-page, multimodal documents by introducing Doc-React, an adaptive iterative framework for retrieval and acting. By balancing information gain and uncertainty reduction at each step, the framework leverages InfoNCE-guided retrieval and a large language model (LLM) for dynamic query refinement. Through systematic optimization and feedback, Doc-React effectively captures fine-grained and contextually relevant information, and achieves strong performance.

7 Limitations

Our approach maximizes the normalized mutual information gain, which is achieved through an iterative framework that approximates this objective (as discussed in the theoretical analysis in Appendix D). While the framework effectively refines retrieval and query formulation, the approximation process may lead to slight inefficiencies in specific cases. Future work could focus on refining the optimization process to further streamline the approximation.

A Case Study

In this section, we illustrate a case study about the comparison between DocReact and CoT baseline. The desired answer, according to the ground truth, is 56%. We show in the use case that DocReact can successfully enable information verbal differentiation by identifying the missing information in the current observation (highlighted in green font). In addition, DocReact can further formulate sub-queries based on the information differentiation results, which can be used to retrieve more document image potentially containing such information (highlighted in orange font).

Question: What percentage of the TOTAL POPULATION in the region where there are 252M mobile broadband subscriptions are ACTIVE SOCIAL NETWORK USERS?

(i) **The result by our DocReact**

Thought 1: I need to find the region where there are 252M mobile broadband subscriptions and then determine the percentage of the total population in that region who are active social network users.

Action 1: Search[A figure or chart that shows mobile broadband subscriptions and active social network users by region.]

Observation 1: 6,572,950,124 mobile subscriptions

Thought 2: The observation does not provide the necessary information about the region with 252M mobile broadband subscriptions. I need to search again for a figure or chart that shows mobile broadband subscriptions and active social network users by region.

Action 2: Search[A figure or chart that shows mobile broadband subscriptions and active social network users by region, specifically looking for 252M mobile broadband subscriptions.]

Observation 2: North America has 252M mobile broadband subscriptions

Thought 3: I need to search for a figure or chart that shows active social network users in North America.

Action 3: Search[A figure or chart that shows active social network users in North America.]

Observation 3: 56% North America's share of active social network

Action 4: Finish[56%]

(ii) **The result by the baseline Standard**

The image does not provide a direct percentage of active social network users in the region with 252M mobile broadband subscriptions. However, it does show that there are 173,871,400 active social network users in the region with 252M mobile broadband subscriptions. To calculate the percentage, we would need the total population of that region, which is not provided in the image.

(iii) **The result by the baseline CoT**

The image shows a bar graph with different regions and their respective mobile broadband subscriptions and active social network users. To find the percentage of active social network users, we need to look at the bar corresponding to the region with 252M mobile broadband subscriptions. The bar indicates that the percentage of active social network users in that region is 17%. Therefore, the answer is 17%.

B Implementation Discussions

While our approach may involve more API calls than baseline methods due to its iterative nature, it is important to note that iterative frameworks are both necessary and common for addressing complex retrieval tasks. Prior works, such as ReAct (Yao et al., 2022), have demonstrated the effectiveness of dynamic feedback mechanisms for refining queries in noisy or incomplete scenarios. Similarly, mutual information optimization methods inspired by InfoNCE (Oord et al., 2018) rely on iterative strategies to balance information gain and uncertainty reduction effectively.

Doc-React builds on these principles by leverag-

ing an iterative query refinement framework to progressively retrieve the most relevant information. This approach significantly reduces the number of input tokens processed per API call by avoiding redundant or irrelevant content. Consequently, while iterative, Doc-React achieves a lower overall computational cost in terms of processed tokens compared to baseline methods, which often rely on processing larger, less refined multimodal contexts in a single pass. The iterative design is not only practical but also essential for tackling the complexity of multi-page, multimodal document QA tasks. Given the markedly inferior performance of open-sourced MLLMs (e.g., MiniCPM and InternVL) on

such challenging tasks, we opt to build DocReact on the stronger baseline GPT-4o to enable a more rigorous comparison. In practice, we limit the process to a maximum of 4 iterations of retrieval and action steps. The MLLM has the flexibility to terminate early by directly outputting the final answer. However, if the MLLM does not voluntarily end the interaction, the system enforces termination after the final iteration. At this point, the answer is generated using aggregated information from all previous rounds.

C Experiment Details

C.1 Dataset Details

We evaluate our method on the following datasets:

- **SlideVQA** (Tanaka et al., 2023): Designed for structured documents like presentation slides, focusing on reasoning with visual elements such as diagrams and charts.
- **MMLongBench-Doc** (Ma et al., 2024a): Evaluates tasks requiring long-context reasoning over multimodal documents.

C.2 Baseline Details

We include the following baselines in our comparisons:

- **Multi-image MLLMs:** GPT4-o, InternVL (Chen et al., 2024), and MiniCPM (Yao et al., 2024).
- **Multimodal RAG:** ColPali (Faysse et al., 2024) and VisRAG-Ret (Yu et al., 2024).

C.3 Implementation Details

- **Framework:** Implemented using the Hugging Face Transformers library for integration with retrieval and generative models.
- **Query Refinement:** Iterative query refinement is driven by LLM feedback and InfoNCE-based optimization.
- **Hyperparameters:** We set generation temperature as 0 for deterministic decoding. We set the token limit of 100 for generation and the maximum number of images input as 50 for multi-image MLLM baselines.
- **Evaluation Metrics:** We follow the evaluation metrics introduced by MMLongBench-Doc (Ma et al., 2024a) where Acc and F1 are used to measure QA performance.

- **Hardware:** Experiments are conducted on 4 NVIDIA A6000 GPUs with multi-GPU support.

D Theoretical Analysis

This section provides more details and the proof of Theorem 1.

Proof. Denote the accumulated information as

$$Z_t = \bigcup_{S_k \in \pi_t} \mu(S_k, Q).$$

We can assume the information differentiation by

$$A = g(Z) + A'_t, \quad (8)$$

where $g(Z)$ is the part of A explained by Z . By definition of conditional mutual information, the information gain term in Eq.(2) can be derived

$$I(\mu(S_{t+1}, Q); A | Z) = H(A | Z) - H(A | \mu(S_{t+1}, Q), Z).$$

Using the decomposition assumption (in Eq.(8)) of information differentiation, we show that

$$\begin{aligned} H(A | Z) &= H(A'_t | Z), \\ H(A | \mu(S_{t+1}, Z)) &= H(A'_t | \mu(S_{t+1}, Z)). \end{aligned}$$

In addition, since the differentiated information A'_t is assumed to be independent from the currently collected information Z_t , we can further reduce the results as

$$\begin{aligned} H(A'_t | Z) &= H(A'_t), \\ H(A'_t | \mu(S_{t+1}, Z)) &= H(A'_t | \mu(S_{t+1})). \end{aligned}$$

Therefore, we could conclude with the equivalency

$$\begin{aligned} I(\mu(S_{t+1}; A | Z) &= H(A'_t) - H(A'_t | \mu(S_{t+1})) \\ &= I(\mu(S_{t+1}); A'_t). \end{aligned}$$

□

E In-context Examples

We illustrate the three in-context learning examples we used to align MLLMs' behaviors in generating thoughts of information differentiation (**Thought** *t*), actions of multimodal search sub-queries (**Action** *t*), and MLLM received feedback back through MLLM information retrieval (**Observation** *t*).

Example 1:

Question: What is the elevation range for the area that the eastern sector of the Colorado orogeny extends into?

Thought 1: I need to search Colorado orogeny, find the area that the eastern sector of the Colorado orogeny extends into, then find the elevation range of the area.

Action 1: Search[A figure of the regional map of Colorado orogeny, where eastern sector is displayed.]

Observation 1: Based on the give images, we can observe as follows. The Colorado orogeny was an episode of mountain building (an orogeny) in Colorado and surrounding areas. This took place from 1780 to 1650 million years ago (Mya), during the Paleoproterozoic (Statherian Period). It is recorded in the Colorado orogen, a >500-km-wide belt of oceanic arc rock that extends southward into New Mexico. The Colorado orogeny was likely part of the larger Yavapai progeny.

Thought 2: It does not mention the eastern sector of the Colorado orogeny. I need to look up eastern sector.

Action 2: Lookup[Extract the eastern sector information from the given figure.]

Observation 2: Based on the give images, we can observe as follows. The Colorado orogen, formerly called the Colorado province, is a >500-km-wide belt of oceanic arc rock (1.78–1.65 Ga) that extends southward into New Mexico and composes a major part of the Proterozoic provinces of southwestern United States. This transcontinental collisional event occurred during the Paleoproterozoic (Statherian Period). The Wyoming sector of the Colorado orogeny was formerly called the Medicine Bow orogeny. The eastern sector extends into the High Plains and is called the Central Plains orogeny. The boundary between the Colorado orogeny and the Wyoming craton is the Cheyenne belt, a 5-km-wide mylonitic shear zone that verges northward. The Cheyenne belt transects and cuts off the south edge of the older Trans-Hudson progeny.

Thought 3: The eastern sector of Colorado orogeny extends into the High Plains, so High Plains is the area. I need to search High Plains and find its elevation range.

Action 3: Search[A figure of High Plains, where its elevation range is annotated.]

Observation 3: Based on the give images, we can observe as follows. The High Plains are a subregion of the Great Plains, mainly in the Western United States, but also partly in the Midwest states of Nebraska, Kansas, and South Dakota, generally encompassing the western part of the Great Plains before the region reaches the Rocky Mountains. The High Plains are located in eastern Montana, southeastern Wyoming, southwestern South Dakota, western Nebraska, eastern Colorado, western Kansas, eastern New Mexico, western Oklahoma, and to just south of the Texas Panhandle. The southern region of the Western High Plains ecology region contains the geological formation known as Llano Estacado which can be seen from a short distance or on satellite maps. From east to west, the High Plains rise in elevation from around 1,800 to 7,000 ft (550 to 2,130 m).

Thought 4: High Plains rise in elevation from around 1,800 to 7,000 ft, so the answer is 1,800 to 7,000 ft.

Action 4: Finish[1,800 to 7,000 ft]

Example 2:

Question: Which magazine was started first Arthur's Magazine or First for Women?
Thought 1: I need to search Arthur's Magazine and First for Women, and find which was started first.
Action 1: Search[A wiki document page about Arthur's Magazine.]
Observation 1: Based on the give images, we can observe as follows. Arthur's Magazine (1844–1846) was an American literary periodical published in Philadelphia in the 19th century. Edited by Timothy Shay Arthur, it featured work by Edgar A. Poe, J.H. Ingraham, Sarah Josepha Hale, Thomas G. Spear, and others. In May 1846 it was merged into Godey's Lady's Book.
Thought 2: Arthur's Magazine was started in 1844. I need to search First for Women next.
Action 2: Search[A webpage introduction about First for Women.]
Observation 2: Based on the give images, we can observe as follows. First for Women is a woman's magazine published by Bauer Media Group in the USA. The magazine was started in 1989. It is based in Englewood Cliffs, New Jersey. In 2011 the circulation of the magazine was 1,310,696 copies.
Thought 3: First for Women was started in 1989. 1844 (Arthur's Magazine) < 1989 (First for Women), so Arthur's Magazine was started first.
Action 3: Finish[Arthur's Magazine]

Example 3:

Question: Guitars for Wounded Warriors is an album that was recorded in the village in which New York county?
Thought 1: I need to search Guitars for Wounded Warriors, then find in which New York county it was recorded.
Action 1: Search[A document page about Guitars for Wounded Warriors.]
Observation 1: Based on the give images, we can observe as follows. Guitars for Wounded Warriors is the sixth solo studio album by guitarist Brian Tarquin, released in August 2014 by Cleopatra Records. In 2016, it received a Best Compilation Album nomination by the Independent Music Awards. All tracks were recorded at Tarquin's Jungle Room Studios in New Paltz (village), New York. Being moved by the lack of support for returning veterans through his life Tarquin decided to compose a heavy instrumental rock album as a way to show his appreciation to all veterans. So once again he enlisted top notch players to guest with him on the album, Billy Sheehan on Black Hawk, Ron "Bumblefoot" Thal and Reb Beach on Taliban Terror, Steve Morse on Freedom, Chris Poland on Charlie Surfs and Hunting, Chuck Loeb on Escape Kabul, Hal Lindes on Sand & Blood, Gary Hoey on 5 Klicks To Hell and Baghdad, Alex De Rosso Dokken on Broken Arrow, and The Flyin' Ryan Brothers on Surgical Strike. The entire album was engineered, produced and composed by Tarquin especially for each one of the guest guitarists. Partial proceeds are donated to the Fisher House Foundation from sales.
Thought 2: Guitars for Wounded Warriors was recorded in New Paltz (village), New York. I need to search New Paltz (village), New York and find which county it is in.
Action 2: Search[A figure of map that indicates the location of New Paltz (village), New York.]
Observation 2: Based on the give images, we can observe as follows. New Paltz is a village in Ulster County located in the U.S. state of New York. It is approximately 80 miles (130 km) north of New York City and 70 miles (110 km) south of Albany. The population was 7,324 at the 2020 census.
Thought 3: New Paltz (village), New York is in Ulster County, so the answer is Ulster County.
Action 3: Finish[Ulster County]

ConECT Dataset: Overcoming Data Scarcity in Context-Aware E-Commerce MT

Abstract

Neural Machine Translation (NMT) has improved translation by using Transformer-based models, but it still struggles with word ambiguity and context. This problem is especially important in domain-specific applications, which often have problems with unclear sentences or poor data quality. Our research explores how adding information to models can improve translations in the context of e-commerce data. To this end we create ConECT—a new Czech-to-Polish e-commerce product translation dataset coupled with images and product metadata consisting of 11,400 sentence pairs. We then investigate and compare different methods that are applicable to context-aware translation. We test a vision-language model (VLM), finding that visual context aids translation quality. Additionally, we explore the incorporation of contextual information into text-to-text models, such as the product’s category path or image descriptions. The results of our study demonstrate that the incorporation of contextual information leads to an improvement in the quality of machine translation. We make the new dataset publicly available.¹

1 Introduction

Neural Machine Translation (NMT) has significantly advanced the field of machine translation by leveraging Transformer-based models (Bahdanau et al., 2015; Vaswani et al., 2017b). These models have been critical in enhancing translation quality, particularly by incorporating mechanisms such as cross-attention to achieve better semantic understanding. However, despite these improvements, sentence-level translation in NMT often struggles with issues such as contextual disambiguation (Rios Gonzales et al., 2017). For example, the word “pen” can refer to a writing instrument or an enclosure for animals, depending on

¹<https://huggingface.co/datasets/allegro/ConECT>

Figure 1: We evaluate three methods for contextualisation in e-commerce MT: (1) combining images with text in VLM, (2) appending category path context in NMT, and (3) a cascade approach consisting of a vision Q&A and a text-to-text NMT.

the context. These ambiguities present a significant challenge in achieving accurate translations based solely on the context of single sentences.

In an attempt to address these limitations, Multimodal Machine Translation (MMT) has emerged as a promising paradigm (Specia et al., 2016; Shen et al., 2024). MMT integrates visual information alongside textual data to provide additional context, thereby enhancing translation quality. Studies have shown that leveraging visual cues can significantly improve the disambiguation of lexical items and contribute to more accurate translations (Yao and Wan, 2020; Wang and Xiong, 2021). For instance, visual context can help resolve ambiguities in sentences where the textual information alone is insufficient (Liu et al., 2021). However, high-quality machine translation training data with aligned images is available only for a fraction of the parallel corpora.

In this work, we explore the effectiveness of integrating context information into a domain-specific translation task. We create a new testset for Czech-

to-Polish translation in e-commerce, and test three approaches for context-aware MT (Figure 1). We fine-tune and evaluate a VLM, as well as traditional NMT models for which we integrate contextual information as special instruction tokens. Our findings demonstrate that visual context can enhance translation quality in domain-specific scenarios, serving as a valuable additional feature.

Our contributions are as follows:

- We release a new multimodal dataset for e-commerce MT for the under-researched cs-pl language pair;
- We fine-tune and evaluate a VLM on the domain-specific MT task;
- We propose a method for encoding category paths and image descriptions in small NMT models.

We start by describing related work (§2), then introduce the ConECT dataset (§3), explain our experimental setup (§4), and finally discuss the results (§5).

2 Related work

In this section we discuss multimodal and e-commerce product-oriented MT.

2.1 Multimodal Machine Translation

Multimodal Machine Translation (MMT), which integrates visual context into machine translation, has garnered significant attention in recent years (Elliott et al., 2016; Shen et al., 2024). Research has shown that visuals can effectively bridge linguistic gaps between languages (Chen et al., 2019; Sigurdsson et al., 2020; Su et al., 2019). Early efforts by Calixto and Liu (2017) incorporated global image features into the encoder or decoder of NMT models. Subsequent studies have explored the use of more granular image contexts, such as spatial image regions with attention mechanisms (Calixto et al., 2017a; Caglayan et al., 2016).

Yang et al. (2020) introduced a method for joint training of source-to-target and target-to-source models to promote visual agreement. Yin et al. (2020) built a multi-modal graph linking image objects and source words, leveraging an external visual grounding model for alignment.

2.2 Benchmarks and Shared Tasks in MMT

Between 2016 and 2018, WMT organised a shared task on MMT (Specia et al., 2016; Elliott et al., 2017; Barrault et al., 2018). The organisers primarily used the Multi30K dataset (Elliott et al., 2016) and metrics like BLEU, METEOR, and TER. In the first edition of the shared task, Specia et al. (2016) found that neural MMT models initially underperformed compared to text-only SMT models. However, Elliott et al. (2017) and Barrault et al. (2018) expanded languages and test datasets, noting performance improvements in MMT models, especially when incorporating external resources.

Elliott (2018) introduced an adversarial evaluation method to assess whether multimodal translation systems effectively utilize visual context. This method evaluates the performance difference of a system when provided with either a congruent or an incongruent image as additional context.

Futeral et al. (2023) introduced the *CoMMuTE* (Contrastive Multilingual Multimodal Translation Evaluation) dataset to evaluate multimodal machine translation systems with a focus on resolving ambiguity using images. Their approach, which includes neural adapters and guided self-attention, showed significant improvement over text-only models, particularly in English–French, English–German, and English–Czech translations. Futeral et al. (2024) extended the setup with *ZeroMMT*, a technique for zero-shot multimodal machine translation that does not rely on fully supervised data. This method, which uses visually conditioned masked language modelling and Kullback-Leibler divergence training, demonstrated near state-of-the-art performance and was extended to Arabic, Russian, and Chinese.

2.3 E-commerce product-oriented MT

An e-commerce product-oriented machine translation task uses product images and product metadata as inputs. Calixto et al. (2017c) pioneered this task with a bilingual product description dataset, evaluating models such as phrase-based statistical MT (PBSMT), text-only MT, and MMT. Their results highlighted PBSMT’s superior performance, with MMT models enhancing translation when re-ranking PBSMT outputs. Calixto et al. (2017b) highlight the potential impact of multi-modal NMT in the context of e-commerce product listings. With only a limited amount of multimodal and multilingual training data available, both text-only and

multi-modal NMT models failed to outperform a productive SMT system.

Song et al. (2021) introduced a large-scale dataset along with a unified pre-training and fine-tuning framework, proposing pre-training tasks for aligning bilingual texts and product images. These tasks include masked word reconstruction with bilingual and image context, semantic matching between text and image, and masking of source words conveying product attributes. This framework contributed to more robust translation models.

2.4 Visual information integration in LLMs

The field of NLP has evolved with the introduction of large language models (LLMs) (Ouyang et al., 2022; Achiam et al., 2023; Touvron et al., 2023). Since traditional text-only MT has advanced to LLM-based methods (Xu et al., 2023), leveraging LLMs for MMT is a promising direction. Current multi-modal LLMs, whether using linear models (Liu et al., 2024) or Query Transformers (Li et al., 2023), often suffer from visual information loss. Enhancing alignment between textual and visual modalities and adaptively extracting relevant visual information are critical for optimizing LLM performance in MMT tasks.

3 ConECT dataset

The ConECT dataset (**C**ontextual **E**-Commerce **T**ranslation) is designed to support research on context-aware MT in the e-commerce domain. To create this dataset, we extracted 11,000 sentences in Polish from the `allegro.pl` e-commerce platform. Next, we aligned a primary product image and category path. The sentences were then manually translated into Czech by professional translators. Each translation was reviewed to ensure accuracy and contextual relevance. A detailed breakdown of the dataset statistics is provided in Table 1.

The ConECT dataset is divided into various content types to provide comprehensive coverage of e-commerce translation contexts, as summarized below.

Product names Product names are typically short phrases that precisely identify a product. They often contain specific terminology, brand names, and product specifications.

Product descriptions Product descriptions are longer texts that provide detailed information about a product, including its features, specifications, usage instructions, and benefits. These texts can be

Split	Content type	#category			CS		
		#Sent.	#Img.	paths	#Tokens	Len.	Vocab
Test	Offer titles	1,924	1,920	840	13,898,	7.2	6,206
	Prod. desc.	3,680	2,905	1,090	38,885,	10.6	13,286
	Prod. names	4,691	4,659	1,361	34,886,	7.4	10,422
	ALL	10,295	6,146	1,542	87,669,	8.5	22,121
Valid	Offer titles	203	203	165	1,449	7.1	1,080
	Prod. desc.	403	389	285	4,118	10.2	2,472
	Prod names	505	505	360	3,757	7.4	2,116
	ALL	1,111	1,042	596	9,324	8.4	4,822

Table 1: ConECT dataset statistics. *Len.* denotes average length in words. Polish sentences have similar statistics.

more descriptive and less structured than product names.

Offer titles Offer titles are concise and attractive phrases crafted by marketers to engage potential buyers, often including promotional language, discounts, or special offers. This category can be challenging due to the need to maintain both the persuasive tone and the specific promotional content during the translation process.

4 Experimental setup

In this section we describe the training and evaluation data, the models used, and the evaluation procedure.

4.1 Training data

To create a parallel e-commerce dataset, we aligned Polish and Czech product names and descriptions for corresponding products that were listed on both e-commerce platforms `allegro.pl` and `mall.cz`. Merchants manually translated original Czech product names and descriptions into Polish. To create sentence-level pairs of multi-sentence descriptions, we split them into sentences and aligned them using a language-agnostic BERT sentence embedding model (Feng et al., 2022). We compared every sentence in one description with every sentence in the corresponding description in the other language to align the sentence pairs. That procedure resulted in a dataset containing 230,000 parallel sentences, each paired with product category paths and one of 38,000 unique images.

Data with image context For experiments involving translation with image context, we additionally collected 440,000 Polish product names paired with 430,000 unique images from the `allegro.pl` e-commerce platform. These product names were back-translated into Czech, creating a synthetic dataset of product names with image

context. The images were in JPEG format with varying sizes and were resized to 224x224 pixels.

Text-to-text models For the baseline text-to-text models, we used 53 million sentence pairs, primarily drawn from the OPUS corpora (Tiedemann and Nygaard, 2004) and internal e-commerce domain data.

For fine-tuning with category paths as context, we extended the 230,000 parallel sentences from the original dataset with 7 million back-translated product names and 7 million back-translated product description sentences, paired with their respective category paths. Additionally, we extended the fine-tuning dataset by incorporating 7 million parallel sentences without category paths from the baseline model’s training set. The category paths were represented as text, listing the hierarchical subcategories for each product (e.g., "*Sports » Bicycles » Tires*").

For experiments involving image descriptions, we generated image descriptions in Czech using the paligemma-3b-mix-224² (Beyer et al., 2024) model on all of the previously mentioned data with image context. Additionally, for fine-tuning, we included 700,000 sentences without image descriptions, extracted from the baseline model’s training set.

4.2 Models

Models with image context Experiments involving translation with image context were conducted on the paligemma-3b-pt-224³ model. Our primary goal was to evaluate the influence of images on translation. To achieve this, we fine-tuned the models for the translation task with two types of image data: (1) original corresponding product images, and (2) a black image unrelated to the text input. Further details of the experimental setup are given in Appendix A.1.

Text-to-text baseline model We developed a sentence-level text-to-text baseline model using the Transformer (big) architecture (Vaswani et al., 2017a), trained with the Marian framework (Junczys-Dowmunt et al., 2018). Details of the experimental setup are given in Appendix A.2.

Models with category context To ensure a fair comparison, we implemented two fine-tuning ap-

proaches on the baseline model: one that incorporates category context and one that does not. The category context was integrated by adding a prefix containing the product’s category path in Polish to the source sentences. The category path was enclosed with special tokens <SC> and <EC> to separate it clearly from the source sentence. The model without category context was trained using the same configuration and data setup, but without the category path prefixes. Details of the experimental setup are given in Appendix A.3.

Models with image descriptions Following a similar approach as in the category context experiments, we fine-tuned the baseline model with and without prefixes containing image descriptions. The image descriptions were added as prefixes wrapped with <SD> and <ED> tokens. This model was trained exclusively on data with image context converted into image descriptions and did not include any data from category context experiments. Details of the experimental setup are given in Appendix A.4.

NLLB-baseline For comparison, we report our results alongside the NLLB-200-Distilled-600M model.⁴

Evaluation metrics We use sacreBLEU (Post, 2018) to calculate the chrF⁵ (Popović, 2015) score, and the Unbabel/wmt22-comet-da⁶ (Rei et al., 2022) model to calculate the COMET metric. We used sacreCOMET (Zouhar et al., 2024) to create the COMET setup signature.

5 Results and discussion

A performance comparison of models on ConECT test sets is presented in Table 2.

Models with image context For the PaliGemma models, those fine-tuned and evaluated with appropriate images outperformed those with unrelated images. Notable improvements were observed in the product names and offer titles sets. However, while the COMET metric showed a decrease for the product descriptions, the chrF metric showed a slight increase.

Models with category context Both fine-tuned models showed improved performance, with the

	description context		83.25	0.8673	82.63	0.8974	48.26	0.7243	65.97	0.8219

Table 2: Comparison of the results on the ConECT test set shows that the VLM model with image context and the NMT model with category paths achieved improved performance due to the added context. However, experiments with synthetic image descriptions led to a decrease in metrics.

version incorporating category path context achieving a notable advantage in the COMET metric across all datasets. The most significant improvement was observed with product names, while the smallest gain in the COMET metric occurred with product descriptions, where the chrF metric actually decreased.

Models with image descriptions The model using image description prefixes showed a significant decrease in quality, especially on the product description dataset. It is important to note that the fine-tuning was performed on synthetic image descriptions and used a smaller dataset than the models incorporating category context. In this case, the added context had a negative impact on performance, highlighting that fine-tuning an NMT model with prefixes can degrade its quality in some scenarios.

6 Conclusion

This study explores methods for incorporating context into MT using the ConECT dataset. We are making this dataset publicly available to support research into context-aware translation tasks. We investigated the fine-tuning of VLM for machine translation to exploit image-based context for improved translation quality. Secondly, we analysed the effect of product category paths on translation performance in text-to-text models for e-commerce data. Both experiments showed that the models benefited from contextual information. We also report negative results from fine-tuning with image description prefixes, highlighting that added context can sometimes impair model quality and

that this straightforward approach requires further refinement.

Limitations

Our approaches rely heavily on the quality of training data and the suitability of the test set for context-aware translation. In many cases, the text alone is sufficient without additional context. Moreover, incorporating extra context can sometimes reduce translation quality, especially with LLMs, where hallucinations may introduce critical errors for users. The experiments with VLM discussed in this paper require significantly more computational resources than text-to-text NMT models, due to the larger model and data sizes. We used AI assistance exclusively to enhance the text style and identify grammatical errors in this manuscript.

A Details on experiments

We conducted all our experiments on a single server equipped with four Nvidia A100 GPUs, each with 80 GB of RAM.

A.1 VLM setup

PaliGemma was fine-tuned using LoRA (Hu et al., 2021) with rank $r = 8$ and alpha $\alpha = 8$. The fine-tuning was performed on a single A100 GPU for 4 epochs with a learning rate of $1e^{-4}$ and batch size set to 16.

A.2 Text-to-text baseline model

The model was trained on four NVIDIA A100 GPUs. It employs a shared vocabulary of 32,000 subword tokens, generated using the SentencePiece toolkit (Kudo and Richardson, 2018), with all embeddings tied during training. Early stopping was set to 10, with the validation frequency set to 3000 steps and based on the chrF metric on the ConECT validation set.

A.3 Models with category context

For fine-tuning with prefixes we employed the following special tokens to mark category context in the SentencePiece vocabulary:

- $\langle SC \rangle$ – start of the category path
- $\langle SEP \rangle$ – separator of subcategories
- $\langle EC \rangle$ – end of the category path

The subcategories were provided in the target language and were not included as special tokens in the vocabulary. An example of a source sentence is as follows: $\langle SC \rangle$ *Moda* $\langle SEP \rangle$ *Odzież, Obuwie, Dodatki* $\langle SEP \rangle$ *Obuwie* $\langle SEP \rangle$ *Męskie* $\langle SEP \rangle$ *Sportowe* $\langle EC \rangle$ *Big Star pánské sportovní boty JJ174278 černé 44*. The target sentences remained unchanged.

The model without category context was trained using the same configuration and data setup, but without the category path prefixes. Both fine-tunings were performed on two NVIDIA A100 GPUs with a learning rate of $5e^{-6}$, and early stopping was applied based on the chrF metric on the concatenated ConECT validation set.

A.4 Models with image descriptions

The image descriptions were generated in the Czech and Polish languages using the google/paligemma-3b-mix-224 model and the transformers library. However, only image descriptions in Czech were used in the experiments. The prompts were structured as simple tasks as found in the original PaliGemma paper (Beyer et al., 2024). The exact prompts are shown in Table 3. Images for inference were resized to 224x224 pixels. We include generated Czech and Polish captions in the dataset. For fine-tuning with image description we employed the following special tokens in the SentencePiece vocabulary:

- $\langle SD \rangle$ – start of the image description
- $\langle ED \rangle$ – end of the image description

An example of a source sentence is as follows: $\langle SD \rangle$ *Černé a bílé boty s nápisem "big star" na boku.* $\langle ED \rangle$ *Big Star pánské sportovní boty JJ174278 černé 44*

The training configuration was identical to the experiments with category context, except that the validation frequency was reduced to every 300 steps.

Target language	Prompt used for image description
Czech	popsat obrázek v češtině
Polish	opisz obrazek po polsku

Table 3: Prompts for image description generation used with the paligemma-3b-mix-224 model.

A Measure of the System Dependence of Automated Metrics

Pius von Däniken and Jan Milan Deriu and Mark Cieliebak

Centre for Artificial Intelligence
ZHAW School of Engineering
{vode,deri,ciel}@zhaw.ch

Abstract

Automated metrics for Machine Translation have made significant progress, with the goal of replacing expensive and time-consuming human evaluations. These metrics are typically assessed by their correlation with human judgments, which captures the monotonic relationship between human and metric scores. However, we argue that it is equally important to ensure that metrics treat all systems fairly and consistently. In this paper, we introduce a method to evaluate this aspect.

1 Introduction

Recent years have seen significant advances in machine translation (MT), marked notably by the introduction of the transformer architecture (Vaswani et al., 2017). Current large-scale commercial systems such as GPT (Brown et al., 2020) continue this trend and show promising results (Kocmi et al., 2023; Hendy et al., 2023; Wu and Hu, 2023). A critical supplement to these advancements is thorough and reliable evaluation procedures, which are essential not only for measuring overall progress but also for effectively comparing different systems. While evaluation based on human raters is still considered the gold standard, it is expensive and time-intensive. Therefore, considerable efforts have been made to develop automated metrics for assessing translation quality. Notably, the WMT Metrics series of shared tasks are dedicated to this purpose (Freitag et al., 2023, 2022, 2021, i.a.). Automated metrics usually assign a scalar¹ quality rating to a candidate translation based on the source segment and a reference translation. A system-level rating is derived by averaging the segment ratings over a test set.

To measure a metric’s usefulness, we usually measure two aspects: its correlation to human judgments on the segment-level (which checks if there

¹Other types of ratings exist, in particular preference ratings (Belz and Kow, 2010).

Figure 1: Average Human Ratings associated with *XCOMET* scores on Chinese to English (*zh-en*) WMT 23 data. We show scores for all system in aggregate (global) and two individual systems.

is a monotonic function between metric ratings and human ratings) and whether the system-level ratings can reproduce the same ranking as human ratings (Kocmi et al., 2021; von Däniken et al., 2024). In this paper, we argue that this evaluation of metrics is insufficient, as it ignores a central requirement, namely, that it should treat all systems under evaluation equally. As stated more colloquially, a measuring stick should not change length depending on the measured object. However, this is exactly what we observe in current metrics.

Consider Figure 1, which shows the expected human rating for each score of the *XCOMET* metric (the best metric in the WMT23 metrics task, with a very high segment-level correlation of 0.65 for the *zh-en* language pair) (Freitag et al., 2023). That is, for each possible value that *XCOMET* may assume, we show the expected human rating and the 95% confidence interval (computed using Isotonic Regression and bootstrap sampling; see Sections 2 and 3 for the details). The global curve (blue) shows the average human score for each metric score if computed over all systems under evalua-

tion in the WMT23 dataset (in standard correlation to human judgment evaluation, we only measure whether this curve is monotonic). In contrast, *Lan-BridgeMT* (best system according to humans) and *NLB-Greedy* (lowest-rated system according to humans) show the average human score for each metric score when computed on one separate system only. For instance, an *XCOMET* score of 0.7 corresponds to an average Human-MQM score of -5.2 for *Lan-BridgeMT*, and Human-MQM score of -10.2 for *NLB-Greedy*.

This leads to the following consequence: For *Lan-BridgeMT*, higher human scores are associated with lower metric scores than the global curve, which leads to an underestimation of *Lan-BridgeMT*'s performance, according to *XCOMET*. The opposite effect is visible for *NLB-Greedy*, which is overestimated and, in fact, gains 3 ranks (from 15th to 12th place) when comparing the metric and human ranking (see also Table 1 in Section 3). Thus, a metric that exhibits a high global segment-level correlation to human judgments can lead to wrong system-level rankings. This observation leads us to the central claim of this paper: **The cause of the discrepancy between the correlation on the segment level and the final system ranking is due to the metric's dependency of the system under evaluation.**

The main position of this paper is that when evaluating a novel metric, one ought to measure the dependency on the system under evaluation as well, alongside the correlation to human judgment. In the following, we will formalize this dependency of the relation between human and metric ratings on the system under evaluation and derive a measure for quantifying this effect.

2 Averaging Metric Scores

Assume we are given a set of K machine translation systems π_k to evaluate. A translation system maps an input sentence $i \in \mathcal{I}$ in a fixed source language to an output sentence $o \in \mathcal{O}$ in a fixed target language: $\pi_k : \mathcal{I} \rightarrow \mathcal{O}$. The usual human evaluation scenario involves curating a test set of N inputs $\mathcal{T} = \{i^{(j)} | 1 \leq j \leq N\} \subset \mathcal{I}$ for which we collect the output of each system π_k for each input $i \in \mathcal{T}$, and then ask human annotators to produce ratings. This results in a set of ratings $\{(h_1^{(j)}, \dots, h_k^{(j)}, \dots, h_K^{(j)}) | 1 \leq j \leq N\}$, where $h_k^{(j)} \in \mathbb{R}$ is a scalar rating provided by human annotators measuring the quality of the translation

provided by π_k for input $i^{(j)}$. We will assume that higher human ratings indicate higher translation quality. In this setting, it is natural to measure the overall quality of system π_k by the average human rating it achieves $\hat{\mu}_k^H = \frac{1}{N} \sum_{j=1}^N h_k^{(j)}$. This is an estimator of the expected human rating $\mu_k^H = \mathbb{E}[h_k]$ achieved by π_k for any input in \mathcal{I} , assuming that \mathcal{T} is appropriately chosen.

In many cases, we want to replace human raters with an automated scalar metric $M : \mathcal{I} \times \mathcal{O} \rightarrow \mathbb{R}$, which maps an input and translation to a scalar value. For our test set \mathcal{T} , we can collect all metric ratings $\{(m_1^{(j)}, \dots, m_k^{(j)}, \dots, m_K^{(j)}) | 1 \leq j \leq N\}$, where $m_k^{(j)} = M(i^{(j)}, \pi_k(i^{(j)}))$, the metric rating for input $i^{(j)}$ and translation by π_k . In this case, it is common to use the sample average $\hat{\mu}_k^M = \frac{1}{N} \sum_{j=1}^N m_k^{(j)}$ to measure the quality of system π_k , which is an estimator of the expected metric rating $\mu_k^M = \mathbb{E}[m_k]$ achieved by π_k .

The goal of automated evaluation is to use $\hat{\mu}_k^M$ as a proxy measure for μ_k^H , in particular, to rank the systems π_1, \dots, π_K according to their performance. In the following, we will study the relationship between μ_k^H and μ_k^M , which is expressed by an unknown function f_G that maps from the metric scale to the human scale. There are two requirements to this function: first, that it is monotonic (i.e., that it respects the order of the metric scale), and second, that it does not depend on the system under evaluation π_k (i.e., that it is the same for all systems) The goal is to find the relation between μ_k^H and μ_k^M . The idea is to express $\mathbb{E}[h_k]$ in terms of an expectation over metric ratings as follows (for full derivation, see Appendix A):

$$\mathbb{E}[h_k] = \mathbb{E}_{p_k(m)}[\mathbb{E}_{p_k(h)}[h|m]] \quad (1)$$

The crucial element of Equation 1 is the conditional expectation $\mathbb{E}_{p_k(h)}[h|m]$. Here we consider the expectation according to $p_k(h)$, the distribution of human ratings for system π_k . Equation 1 describes the relationship between μ_k^H and μ_k^M by expressing the expected human rating in terms of an expectation over metric ratings. We interpret this element as a function f_k , which takes a metric rating as input and returns the expected human rating. Equation 1 yields a function f_k for each system separately, which is not necessarily the same across systems. At this point, we can restate

the introductory discussion using our formalism. When averaging metrics $\hat{\mu}_k^M$ to rank systems, we implicitly assume that there is a global function f_G that is equal to all the system-specific functions f_k , i.e., $f_G = f_1 = \dots = f_K$, and thus, only measure if f_G is monotonic (through correlation to human judgments). However, as shown in Figure 1, this assumption does not hold in practice (where blue is f_G , and we have an f_k for the two other systems respectively). To show that this is insufficient, we consider the effects of violating the assumption. Let us assume $f_1 \neq f_2$, but both are monotonic. Consider the extreme example that $\mu_1^M = \mu_2^M$, i.e., systems π_1 and π_2 are of the same quality under the metric. However, consider the case $f_1(m) = f_2(m) + C$, $C > 0$. Then $\frac{1}{N} \sum_j f_1(m_1^{(j)}) = C + \frac{1}{N} \sum_j f_2(m_1^{(j)}) > \frac{1}{N} \sum_j f_2(m_2^{(j)})$, thus, yielding that π_1 is better than π_2 in human space. This shows the necessity of measuring the monotonicity of a global function f_G and the dependence of the metric on the systems under evaluation.

We first introduce the Expected Deviation (ED), which measures the difference between f_G and f_k for all $k \in \{1 \dots K\}$, which tells us how much a system is over-or-underestimated according to the metric. That is the difference

$$ED(k) = \frac{1}{N} \sum_{j=1}^N f_G(m_k^{(j)}) - \frac{1}{N} \sum_{j=1}^N f_k(m_k^{(j)}) \quad (2)$$

This is equivalent to $\mu_k^G - \mu_k^H$, where $\mu_k^G = \frac{1}{N} \sum_{j=1}^N f_G(m_k^{(j)})$, thus, we measure the difference between the average rating according to the global function and the average rating of the system-specific function, which corresponds to the human rating-average. Note that a mis-ranking occurs if one system is severely overrated while another is severely underrated. Thus we define the system dependence score $SysDep(\mathcal{M})$ as the worst case of this effect:

$$SysDep(\mathcal{M}) = \max_{\pi_k} ED(k) - \min_{\pi_k} ED(k) \quad (3)$$

3 Experiments

Estimating the Conditional Expectation. Even though the functions f_k and f_G are unknown in general, we can estimate them from data. We will use *Isotonic Regression (IR)* (Barlow and Brunk, 1972) for this purpose, which estimates a monotonic function \hat{f}_k minimizing $\sum_j (\hat{f}_k(m_k^{(j)}) - h_k^{(j)})^2$. To estimate f_G , we utilize the same approach, pool-

ing all paired data from all systems. To compute the *SysDep* of a metric, we compute the ED for each MT system under that metric. For this, we compute the average human rating $\hat{\mu}_k^H = \frac{1}{N_H} \sum_{j=1}^{N_H} h_k^{(j)}$, the average metric rating $\hat{\mu}_k^M = \frac{1}{N_M} \sum_{j=1}^{N_M} m_k^{(j)}$, as well as average remapped rating $\hat{\mu}_k^G = \frac{1}{N_M} \sum_{j=1}^{N_M} \hat{f}_G(m_k^{(j)})$ for each MT system. We provide our code in Appendix E.

Data. We rely on data from the WMT 23 Metrics shared task (Freitag et al., 2023). The data includes translations for 3 language pairs: English to German (*en-de*), Hebrew to English (*he-en*), and Chinese to English (*zh-en*). The translations were produced by 12-15 systems (depending on the language pair) which participated in the general MT task (Kocmi et al., 2023). Human ratings are available in the form of MQM annotations (Lommel et al., 2014), which are based on error-span annotations by experts that are subsequently transformed into a numeric value by assigning scores to errors based on their severity. Here, we will present results for the *XCOMET* (Guerreiro et al., 2023) metric (best metric according to correlation to human judgments) and the *zh-en* language pair, where we have access to $N_M = 1976$ segments per system rated by the metric and $N_H = 1177$ of these segments rated with human MQM ratings. Results for the other language pairs and an additional metric are shown in Appendix B. To estimate the conditional expectation functions f_k , we use the 1177 paired ratings for each system π_k . We employ $B = 200$ bootstrap samples of the paired data to fit B IR models. Our estimate, \hat{f}_k , represents the average of these B IR models. In Figure 1, we also present the range between the 2.5% and 97.5% percentiles.

Results. We show the results in Table 1. We can see that the ED ranges from -0.82 to 1.996, thus yielding a *SysDep* score of 2.816. We see that both *Lan-BridgeMT* and *GPT4-5shot* are underrated by the metric (negative *ED*), but *Lan-BridgeMT* more so, enough to invert their order. At the bottom of the ranking, we see a relatively large absolute *ED*. Ranking errors reflect an interplay between the systems’ rating gap and the *ED*s. For example, *Online-A* loses 2 ranks according to the metric even though it has the lowest absolute *ED*. We also note that even though \hat{f}_G is monotonic, the ranking between the metric and the remapped scores does not match completely. This can be attributed to

	Human		Metric		Remapped		Exp. Deviation
	$\hat{\mu}_k^H$	R	$\hat{\mu}_k^M$	R	$\hat{\mu}_k^G$	R	ED
Lan-BridgeMT	-2.100	1	0.889	2	-2.920	2	-0.820
GPT4-5shot	-2.305	2	0.893	1	-2.800	1	-0.494
Yishu	-3.231	3	0.880	4	-3.179	4	0.052
ONLINE-B	-3.385	4	0.879	5	-3.188	5	0.197
HW-TSC	-3.398	5	0.883	3	-3.080	3	0.318
ONLINE-A	-3.785	6	0.856	8	-3.812	8	-0.027
ONLINE-Y	-3.792	7	0.868	6	-3.479	6	0.313

ANVITA	-6.078	13	0.830	13	-4.602	13	1.475
NLLB-MBR-BLEU	-6.360	14	0.825	14	-4.726	14	1.634
NLLB-Greedy	-6.574	15	0.831	12	-4.578	12	1.996

Table 1: System rankings and average rating of WMT 23 *zh-en* systems according to *XCOMET*. The lowest score is in italics, and the highest is in bold.

the uncertainty introduced by bootstrapping and extrapolating to the unpaired metric ratings. It can be seen for *ONLINE-W* and *ZengHuiMT*, which have similar metric ratings.

Overall, our results show that although there is a highly monotonic function between the *XCOMET* scale and the human scale, *XCOMET* exhibits a high dependency on the system under evaluation, thus yielding an inconsistent ranking between humans and *XCOMET*.

4 Related Work

The derivation in Section 2 closely follows [Wu and Resnick \(2024\)](#), who provide the same argument in the context of binary prevalence estimation. In our case, the conditional expectation $\mathbb{E}[h|m]$ plays the same role as the calibration curve in their framework. Under that lens, the Expected Deviation is analogous to the Expected Calibration Error ([Posocco and Bonnefoy, 2021](#)). Following the same analogy, evaluating a new MT system is similar to applying a classifier to a new domain.

Previous studies by [Deriu et al. \(2023\)](#) and [von Däniken et al. \(2022\)](#) have highlighted that metric performance depends on the system under test. They employed a Bayesian framework to determine the proportions of binary or preference human ratings from metric scores; critically relying on confusion matrices estimated for each MT system. In this discrete rating context, these confusion matrices represent the same concept as $\mathbb{E}[h|m]$. In follow-up work, [von Däniken et al. \(2024\)](#) find that some metrics disproportionately favor certain MT systems over others compared to human preference ratings.

Our finding provides a plausible explanation.

[Chaganty et al. \(2018\)](#) shows how to combine human ratings and metric ratings to derive an unbiased estimate of the true expected human rating μ^H while reducing the number of annotations needed. The proposed control variates estimator is based only on human and metric scores for a given MT system, even when estimating their correlation, thus avoiding the problem we describe.

[Wei and Jia \(2021\)](#) consider disagreements in the ordering of systems when using μ_k^M instead of μ_k^H . In particular they study the sign error, cases where $\text{sign}(\mu_1^M - \mu_2^M) \neq \text{sign}(\mu_1^H - \mu_2^H)$. They apply a bias variance decomposition to this error and find that while the human estimator is unbiased, it exhibits high variance while the opposite is the case for metrics. Our *SysDep* score presents a way to quantify this bias.

5 Conclusion

In this paper, we emphasize the importance of ensuring that automated metrics treat all MT systems consistently, a factor overlooked in current evaluations. By mapping metric scores to the human rating scale, we estimate how much a metric misjudges individual system performance. We compute the range of these deviations to assess how consistently a metric treats different systems. In Appendix C, we re-evaluate WMT23 metrics from this perspective. Additionally, in Appendix D, we confirm that these results stem from systematic differences in how metrics treat systems by measuring deviations within splits of a single system’s ratings.

Limitations

This paper is intended to explore a supplementary aspect of the evaluation of automated metrics. The *SysDep* measure we developed will hopefully provide a starting point for the development of more refined evaluation of the way metrics treat different systems differently.

Our experiments are based solely on data from the WMT23 Metrics shared task. To further solidify our findings a larger scale study with more domains and larger sample sizes are needed.

While we provide a way to measure the system dependence of a metric, we do not provide any suggestions on how to develop metrics that minimize the *SysDep*.

A Full Derivation

In Equation 4, we give the full derivation of Equation 1 in Section 2. In the following $p_k(h)$ is the density of human ratings for system π_k , $p_k(m)$ is its density of metric ratings, and $p_k(h, m)$ the joint density.

$$\begin{aligned}
\mathbb{E}[h_k] &= \int_{-\infty}^{\infty} h p_k(h) dh \\
&= \int_{-\infty}^{\infty} h \left[\int_{-\infty}^{\infty} p_k(h, m) dm \right] dh \\
&= \int_{-\infty}^{\infty} h \left[\int_{-\infty}^{\infty} p_k(h|m) p_k(m) dm \right] dh \\
&= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} h p_k(h|m) p_k(m) dm dh \\
&= \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} h p_k(h|m) dh \right] p_k(m) dm \\
&= \int_{-\infty}^{\infty} \mathbb{E}[h_k|m] p_k(m) dm \\
&= \mathbb{E}_{p_k(m)} [\mathbb{E}_{p_k(h)} [h|m]]
\end{aligned} \tag{4}$$

B Additional Results

Here we extend our experiment from Section 3 to additional language pairs and metrics of WMT 23. For the *en-de* language pair $N^H = 460$ and $N^M = 557$ and for *he-en* $N^H = 820$ and $H^M = 1910$. We show the results for *XCOMET* for each language pair in Tables 2, 3, and 4 (Note that Table 4 is the same as Table 1 in Section 3). We also include results for *GEMBA-MQM* (Kocmi and Federmann, 2023), which is a reference free metric based on prompting LLMs. The results can be seen in Tables 5, 6, and 7.

C Evaluating the System Dependence of WMT23 Metrics

In Section 2, we introduced the *SysDep* score. It measures the worst case in the difference of expected deviations (ED), which measures the difference between the average human rating we expect to see based on metric ratings and assuming a single global f_G and the true average human rating for a system π_k . To measure the system dependence of a metric across a set of systems π_1, \dots, π_K , we compute the range of the individual ED: $SysDep = \max_{\pi_k} ED(k) - \min_{\pi_k} ED(k)$. We noted in Section 3 that $ED(k)$ alone is not enough to know whether system π_k will be ranked incorrectly, it depends on the true margin to the other systems, and their dependencies. By measuring the range, we consider the worst case when comparing two systems. We show the dependency ranges for all WMT23 metrics on all language pairs in Table 8. We notice that the values for *en-de* are large than the others. This is due to a larger range of human rating averages for this language pair (see also Tables 2–7 in Appendix B). We therefore also do not aggregate across language pairs.

Variants of *MetricX-23* (Juraska et al., 2023) perform best on *en-de* and *he-en*, while *GEMBA-MQM* has the lowest range for *zh-en*. The reference-free *prismSrc* (Thompson and Post, 2020a,b) metric performs worst on *en-de* and *zh-en*. The baseline *Random-sysname* (Freitag et al., 2023) performs worst for *he-en*. This baseline is an interesting case, as it is the prototypical example of a metric where every f_k is different. It assigns a fixed score to each system based on its name and adds Gaussian noise to this value to assign segment level scores. Therefore each f_k will be a different constant function.

D Intra-System Variability

In order to confirm that the observed *SysDep* scores are indeed due to a metric systematically treating systems differently and not due to variance in ratings, we will measure the maximum intra-system scores. For this, we use ratings from a single system and split them into 2 equal sized parts 10 times with different random seeds. This simulates a setting with 20 systems with half the sample size of the original setting. We then compute the *SysDep* score.

In Table 9, we show the maximum intra-system *SysDep* score computed this way over all systems for a given metric and language pair. We observe that for *he-en* and *zh-en* all scores are lower than the minimum between system *SysDep* reported in Appendix C. This confirms that in those cases metrics treat different systems differently. For the *en-de* language pair, we observe that while in many cases the intra-system score is lower than the *SysDep* between systems for the same metric and language pair, this is not always the case. This could be due to the metrics treating systems more equally for this language pair, or the relatively small sample sizes for *en-de* compared to the other language pairs.

E Estimating Conditional Expectations

In Section 3, we gave a brief overview of how to compute estimates for the functions f_k and f_G . In Listings 1 and 2, we show our *python* implementation. To estimate the system-level \hat{f}_k , we call the `.fit` method with human and metric ratings for system π_k . To evaluate the function \hat{f}_k , we use the `.conditional_expectation` method. To estimate the global function \hat{f}_G , we use the `.fit` method with paired human and metric ratings for all systems. We compute the remapped rating $\hat{\mu}_k^G$ by first fitting \hat{f}_G and then using the `.remapped_expectation`

Call for Rigor in Reporting Quality of Instruction Tuning Data

Hyeonseok Moon, Jaehyung Seo, Heuseok Lim[†]

Abstract

Instruction tuning is crucial for adapting large language models (LLMs) to align with user intentions. Numerous studies emphasize the significance of the quality of instruction tuning (IT) data, revealing a strong correlation between IT data quality and the alignment performance of LLMs. In these studies, the quality of IT data is typically assessed by evaluating the performance of LLMs trained with that data. However, we identified a prevalent issue in such practice: hyperparameters for training models are often selected arbitrarily without adequate justification. We observed significant variations in hyperparameters applied across different studies, even when training the same model with the same data. In this study, we demonstrate the potential problems arising from this practice and emphasize the need for careful consideration in verifying data quality. Through our experiments on the quality of LIMA data and a selected set of 1,000 Alpaca data points, we demonstrate that arbitrary hyperparameter decisions can make any arbitrary conclusion.

1 Introduction

Instruction Tuning (IT) is a widely adopted strategy for enabling a human-interactive use of the knowledge embedded in large language models (LLMs) (Cao et al., 2023; Wang et al., 2024). By training with datasets composed of instruction-response pairs, LLM can attain the ability to generate appropriate responses to given instructions (Dubois et al., 2023; Zheng et al., 2023; Xu et al., 2023; Conover et al., 2023).

In implementing IT, data quality is considered a critical factor (Zhou et al., 2023a; Wang et al., 2024; Zhao et al., 2024b; Lu et al., 2024). Several studies have proven that selectively using high-quality IT data for training leads to better alignment performance than using the entire dataset (Liu et al., 2024b; Chen et al., 2024; Zhao et al., 2024a; Mekala et al., 2024).

Traditionally, the quality of IT data is measured by evaluating the performance of models trained on it (Liu et al., 2024b; Chen et al., 2024; Zhao et al., 2024a; Xia et al., 2024a). This approach stems from the consensus that *data is deemed good if it produces a good model*. Consequently, most studies on data quality establish a training configuration for models that represent data quality. Then, the performance of the trained model is regarded as the data quality. (Zhou et al., 2023a; Zhao et al., 2024a; Xia et al., 2024b; Du et al., 2023; Zhou et al., 2023b).

However, we observed that these studies often lack justification for the hyperparameter settings used in model training. Table 1 presents the diverse hyperparameter configurations utilized in previous research implementing IT with a sampled 1K general domain IT dataset. We discovered that the configurations may vary across studies, even when training the same model with identical data sizes.

In this study, we question whether reaching coherent conclusions under varying settings is possible. Specifically, we emphasize that conclusions regarding data quality can easily be altered based on arbitrarily chosen hyperparameter settings. For instance, even if one might report that dataset A is superior to dataset B, another could claim that B is better by training models under different settings, even with the same dataset, model, and test settings. This variability poses a risk of causing significant confusion.

As a representative case, we consider two general-domain IT datasets: LIMA (Zhou et al., 2023a) and sampled 1K dataset from Alpaca (Alpaca-longest (Zhao et al., 2024a)). In (Zhao et al., 2024a), it was reported that a model trained on Alpaca-longest outperformed a model trained on LIMA. However, our experiments contrarily demonstrate that LIMA can also be regarded as better than Alpaca-longest, depending on the selected training setting. Given the current research trend

Table 1: Hyperparameters reported by previous studies, adopted to train LLMs with 1K general domain IT data. The data pool details the sources from which the 1K data samples were drawn. Detailed descriptions of these data pools are provided in the Table 4. The '+' symbol indicates experiments where samples were drawn from a combined data mix of all mentioned datasets. The '/' symbol reports studies that sampled individually from each data pool.

of arbitrarily determining hyperparameters for validation models, this confusion can be identified as a severe yet persistent problem.

Through our experiments, we emphasize the necessity of rigor in reporting data quality. Furthermore, our discussion suggests the importance of identifying (at least) locally optimal hyperparameters and reporting data quality under these settings.

2 Related Works

Previous research has widely acknowledged the importance of data quality in performing IT. Chen et al. (2024) proposed that training LLMs with a small, carefully selected subset of high-quality data can significantly improve alignment performance within the vast IT data pool. Furthermore, Zhou et al. (2023a) even suggested that carefully curated high-quality 1,000 data points are sufficient to attain alignment performance for LLMs. Motivated by these findings, numerous studies are exploring various methodologies focused on selecting high-quality instruction tuning data (Wang et al., 2024; Chen et al., 2024; Zhao et al., 2024a; Xia et al., 2024b; Lu et al., 2024; Liu et al., 2024b).

However, most studies lack justification for the selected hyperparameter setting to train verification models. Consequently, the training setups become diversified even when using the same LLM and

dataset. We argue that the importance of selecting appropriate hyperparameters has long been emphasized (Yu and Zhu, 2020; McCandlish et al., 2018; Halfon et al., 2024). The community widely recognizes that optimal hyperparameters are often specific to particular LLMs and datasets, and reported performance may vary based on the experimental setup (Van Rijn and Hutter, 2018; Jin, 2022; Gkouti et al., 2024; Bi et al., 2024). However, we find that research on data quality frequently reports performance without adequately considering these factors.

In this study, we highlight the potential confusion that can result from neglecting these considerations and demonstrate the necessity of a rigorous experimental setup to report data quality.

3 Experimental Setting

3.1 Exam-taker Dataset

In our experiments, we adopt two general domain IT datasets, each comprising 1,000 samples, as our exam-taker datasets. By comparing the quality of these two datasets, we examine how the judgment on the exam-taker datasets varies with different arbitrarily chosen hyperparameter settings.

LIMA (Zhou et al., 2023a) LIMA is a high-quality dataset comprising 1,000 IT data points,

Figure 1: The performance comparison between the two models trained with LIMA and Alpaca-Longest. We train Llama-2-7B model with each dataset, We evaluate the data quality when training each dataset with the Llama-2-7B model. is depicted on the Y-axis represents the hyperparameter settings used in each experiment. We bolded the settings that consistently demonstrated conclusive results across all three evaluation datasets.

carefully curated by human efforts with an emphasis on quality and diversity.

Alpaca-Longest (Zhao et al., 2024a) Zhao et al. (2024a) selected the 1,000 entries with the longest token lengths from the Alpaca dataset (Taori et al., 2023). This approach proved more effective than training on the entire Alpaca dataset and significantly outperformed other baselines such as Alpacus (Chen et al., 2024). According to the original paper, training with this data resulted in higher alignment performance than LIMA.

3.2 Experimental Model

The quality of the Exam-taker Dataset is determined by the performance of the experimental model trained on it. We conduct experiments using the Llama-2-7B model (Touvron et al., 2023) and the Mistral-7B-v0.3 model (Jiang et al., 2023). The main paper reports the results for the Llama-2-7B model, and Appendix A includes the results for the Mistral-7B model.

3.3 Experimental Setting

This study focuses on four commonly reported hyperparameters: learning rate, learning rate scheduler, batch size, and number of epochs. We report the experimental results obtained from varying these parameters. We conduct comparative experiments for each setting by choosing two prevalent

yet distinct values. While numerous other potential variations exist, such as weight decay and dropout, we leave these for future exploration. Apart from the hyperparameters under investigation, detailed experimental settings are provided in Appendix C.

3.4 Test Dataset

To evaluate the performance of the trained model, we use three LLM alignment benchmarks: Koala (Geng et al., 2023), MT-Bench (Zheng et al., 2023), and Self-Instruct (Wang et al., 2023). These benchmarks serve as an instruction-following evaluation tool, assessing LLMs by evaluating the quality of text generated in response to given instructions. We employ GPT-4o (Hurst et al., 2024)¹ as a judge to compare the performance of experimental models for each benchmark. The judge prompts used in the experiments are detailed in Appendix D.

4 Experimental Results

4.1 LIMA vs Alpaca-Longest

Figure 1 presents the experimental results based on hyperparameter variations. Our results show that if we choose specific settings (*e.g.*, Settings 4, 5, 10, 12, 13), we can report that Alpaca-longest exhibits superior data quality compared to LIMA. At the same time, if we choose other configurations

Table 2: We report the performance of the Llama-2-7B model, trained under each setting, as evaluated on the Koala dataset. Details for each setting are presented in the Figure 1.

(*e.g.*, Settings 8, 16), we can report that LIMA still demonstrates higher data quality.

Considering that authors have determined such hyperparameters arbitrarily, this represents a significant concern. We view that the ability to alter reported conclusions based on subjective decisions can severely undermine the reliability of scientific discussions.

4.2 Among the Same Dataset

Then, which setting should we choose to report? Considering that the primary goal of the IT dataset is to construct high-performance models, it would be reasonable and practical to report results based on the best achievable performance with the given data (Koehn et al., 2018, 2020; Budach et al., 2022; Van Rijn and Hutter, 2018).

In this section, we identify the optimal settings among the configurations tested. We recognize that other configurations with better performance may have been overlooked. We focus on local optimality within our considered settings and discuss its implications. Figure 2 compares model performance across various hyperparameter settings, using **Setting1** as the baseline.

Our experiments reveal that **Setting7, 15** (2e-5 LR / 256 Batch / 15 Epochs) maximizes model performance within our study. Notably, we can find that such configurations are far beyond the widely chosen settings in existing research. As our brief survey in Table 1 indicates, most studies opt to train Llama-2-7B for only three epochs when using 1K IT datasets. However, our results show that this setup yielded significantly lower performance than training for 15 epochs under the same

conditions. This finding suggests that the reported performance in many studies may reflect the under-trained performance of models, which may fail to fully represent the potential of the exam-taker dataset.

5 Discussion

We argue that it is inevitable to evaluate the downstream model performance. We acknowledge that assessing data quality through the performance of a trained model can be ambiguous. However, we also argue that the quality of training data must inevitably be assessed through the model’s performance after training.

We would like to discuss how the quality of training data is generally acknowledged. The goal of constructing the training dataset is to develop a model that aligns with the intended purpose. Thus, in terms of training data, "good data" is defined as data that produces a "good model" (Chen et al., 2024; Koehn et al., 2020). This fundamentally differs from constructing benchmark datasets for evaluation. Since training data’s primary aim is to build a strong model, data that appear high-quality to humans (or any frontier LLMs) may offer little value if the trained model’s performance remains subpar (Liu et al., 2024b).

In this context, the quality of training data is fundamentally linked to the performance of the model trained on it. While there are various plausible methods to assess training data, these methods might remain indirect indicators, without validating with the performance of the trained model.

Consequently, most studies demonstrate the quality of the data under evaluation by training it onto one (possibly several) model and reporting their performance. We do not consider this approach erroneous; instead, we view it as a natural and inevitable choice. Our stance is that if model-based verification is unavoidable, a more thorough and rigorous training configuration would be essential to verify data quality. Our experiments demonstrate that hyperparameters can introduce unintended biases that skew the objective evaluation of the data quality.

We argue that authors researching data quality have responsibility for such validation. To address these ambiguities, we suggest selecting the hyperparameter setting that yields the highest performance within a given data and reporting the model’s performance under this setting. This ap-

proach seeks to evaluate the model by maximizing the data’s potential.

Given that hyperparameter search is being performed in relatively small-sized PLMs (e.g., BERT (Devlin et al., 2019), BART (Lewis et al., 2020)) (Latif and Kim, 2024; Ljubešić et al., 2024; Roele, 2021), we argue that it is challenging to justify its omission in LLMs other than its high cost. Even when researchers do not conduct their own hyperparameter search, there have been multiple attempts to use existing configurations (Zhou et al., 2023b). However, as shown in Table 1 with the example of Mistral, there appears to be no established standard configuration when tuning relatively recent LLMs.

Reporting the best performance would certainly require additional costs for experiments, but we believe this is a necessary sacrifice to strengthen scientific discourse. We argue that arbitrary conclusions stemming from arbitrary hyperparameter choices pose a greater risk than incurring additional costs. While a comprehensive hyperparameter search may not always be necessary, we claim that authors should clearly justify their chosen hyperparameters. Even if they do not report peak performance, employing the best settings from our paper or established training configurations (ex. LIMA configuration) would still be a rational approach.

6 Conclusion

In our examination of various studies addressing data quality, we observed a recurring issue where researchers often arbitrarily select hyperparameters when training models to verify data quality. Our experiments reveal that arbitrary hyperparameter choices can lead to arbitrary conclusions. Moreover, we found that hyperparameters chosen without justification often fail to achieve optimal performance on the exam-taker datasets, resulting in unreliable conclusions. To address this, we propose establishing a local hyperparameter pool and training models under locally optimal settings within this pool. While additional costs for hyperparameter validation are inevitable, we consider this a necessary sacrifice for attaining the reliability of scientific discourse. To ensure rigorous reporting and sustainable consensus, we urge careful attention.

Limitation

The numerous hyperparameter settings we did not consider may remain a limitation of our study.

Within our budget constraints, we verified as many possibilities as possible. Fortunately, we found significant variations in model performance even within the four factors we examined, allowing us to draw generalized conclusions. Through our brief survey, we can also find that various other hyperparameter variants, such as weight decay, warmup steps, are also introduced without justification. Exploring additional possibilities to identify an optimal setup could be a meaningful area for future research.

In this study, we did not attempt hyperparameter optimization (HPO), as finding optimal values was outside the scope of our research. Applying HPO when reporting on data quality, could serve as an excellent direction for future research.

Although we conducted experiments using only two datasets, we do not see this as a limitation. We believe this setup clearly demonstrates the inherent ambiguity in reporting data quality. Possibly numerous other datasets can exist where hyperparameter settings could alter reporting conclusions. Instead of identifying additional dataset pairs, we consider it more valuable to focus future research on strategies to mitigate such ambiguities.

Ethics Statement

We do not challenge the quality assessment results reported by the Zhao et al. (2024a), which proposed Alpaca-Longest and estimated that Alpaca-Longest is better than LIMA. Based on the results from our experiments using locally optimal settings within our pool, Alpaca-Longest can arguably be considered superior to Lima. This finding aligns with the results reported in the original paper. In all experiments, we exclusively used artifacts approved for research purposes.

A Experimental Results - Mistral

We conducted the same experiments described in Section 4 using the Mistral-7B model. The results are reported in Table 3 and Figure 2.

Dataset	LIMA			Alpaca-Longest		
	Setting 1 Wins	Tie	Setting x Wins	Setting 1 Wins	Tie	Setting x Wins
vs Setting 2	79	12	89	58	11	111
vs Setting 3	75	12	93	50	14	116
vs Setting 4	100	8	72	107	14	59
vs Setting 5	116	13	51	126	13	41
vs Setting 6	97	17	66	95	15	70
vs Setting 7	93	12	75	70	14	96
vs Setting 8	125	8	47	130	12	38
vs Setting 9	87	16	77	82	18	80
vs Setting 10	83	14	83	58	15	107
vs Setting 11	81	7	92	45	6	129
vs Setting 12	102	10	68	96	9	75
vs Setting 13	124	13	43	129	18	33
vs Setting 14	96	22	62	87	16	77
vs Setting 15	88	14	78	78	14	88
vs Setting 16	109	9	62	118	10	52

Table 3: We report the performance of the Mistral-7B model, trained under each setting, as evaluated on the Koala dataset. Details for each setting are presented in the Figure 1.

As shown in Table 3, models trained for 15 epochs generally outperformed those trained for only 3 epochs, even within the same settings. This finding suggests that commonly adopted hyperparameter settings in prior research may not be optimal and that reported performance might not fully exploit the data’s potential.

Figure 2 illustrates the potential conclusions we can draw from various settings using Mistral. There is still significant diversity between settings, supporting our earlier conclusions in Section 4. We demonstrate that merely using multiple models is insufficient to enhance robustness in data quality validation, emphasizing the necessity of hyperparameter generalization.

B Dataset Details

Dataset	Paper / Description	Data Size
Alpaca	Taori et al. (2023)	52K
Alpaca-GPT4	Peng et al. (2023)	52K

HC3	Guo et al. (2023)	24.3K
ShareGPT	Chiang et al. (2023)	52K
UltraChat	Ding et al. (2023)	200K
WizardLM	Xu et al. (2023)	700K

Table 4: We report only the data aimed at performing IT in a general domain, which are adopted to previous studies. Each dataset consists of a pair, featuring a human instruction and an appropriate response.

C Experimental Details

We conducted experiments with a weight decay of 0.0, a warmup of 0.0, and a maximum length of 2,048, utilizing the HuggingFace trainer (Wolf et al., 2020). To enhance learning efficiency, we applied bf16 (Kalamkar et al., 2019) and tf32 (Stosic and Micikevicius, 2021) strategy. All training was performed using FlashAttention-2 (Dao et al., 2022) and DeepSpeed Stage 2 (Smith et al., 2022). For inference, we employed vllm (Kwon et al., 2023). Our setup included four RTX-A6000 GPUs with 48GB each for model training and inference. The original batch size per GPU was set to 2, and we used gradient accumulation to increase the batch size. Other settings followed the default configurations provided by the HuggingFace trainer.

D LLM-as-a-Judge

System Prompt

Please act as an impartial judge and evaluate the quality of the responses provided by two AI assistants to the user question displayed below.

You should choose the assistant that follows the user’s instructions and answers the user’s question better. Your evaluation should consider factors such as the helpfulness, relevance, accuracy, depth, creativity, and level of detail of their responses.

Begin your evaluation by comparing the two responses and provide a short explanation. Avoid any position biases and ensure that the order in which the responses were presented does not influence your decision. Do not allow the length of the responses to influence your evaluation. Do not favor certain names of the assistants. Be as objective as possible.

After providing your explanation, output your final verdict by strictly following this format: "[[A]]" if assistant A is better, "[[B]]" if assistant B is better, and "[[C]]" for a tie.

Input Statements

You are a helpful and precise assistant for checking the quality of the answer.

[Question]
{question}
 [The Start of Assistant 1’s Answer]
{Response From Assistant 1}
 [The End of Assistant 1’s Answer]
 [The Start of Assistant 2’s Answer]
{Response From Assistant 2}
 [The End of Assistant 2’s Answer]

Table 5: Prompt used for training the LLM: For models not supporting system prompts, we combined the system prompt and user prompt into a single input statement.

The prompt we used is presented in Table 5. In

Figure 2: The performance comparison between the two models trained with LIMA and Alpaca-Longest. We train Mistral-7B model with each dataset, We evaluate the data quality when training each dataset with the Mistral-7B model. is depicted on the Y-axis represents the hyperparameter settings used in each experiment. We bolded the settings that consistently demonstrated conclusive results across all three evaluation datasets.

all our experiments, we randomize the order of presented responses to relieve any unintended effects driven by the positional bias. We conducted our experiments with GPT-4o (gpt-4o-2024-08-06), setting the temperature to 0 and top-p to 1.0. The API usage cost for the experiments detailed in Table 2 was \$11.25. Conducting a similar hyperparameter search using GPT4o-mini incurred a cost of \$1.44. While using GPT4o-mini presents a cost-effective option, the Pearson-r correlation score between GPT4o and GPT4o-mini was 0.559 in our experiments. Although this score might be considered reasonably high, we argue using GPT-4o is more effective for establishing a more precise and rigorous setting. We leave experiments with alternative judges for future research.

BQA: Body Language Question Answering Dataset for Video Large Language Models

Shintaro Ozaki Kazuki Hayashi Miyu Oba

Abstract

A large part of human communication relies on nonverbal cues such as facial expressions, eye contact, and body language. Unlike language or sign language, such nonverbal communication lacks formal rules, requiring complex reasoning based on commonsense understanding. Enabling current Video Large Language Models (VideoLLMs) to accurately interpret body language is a crucial challenge, as human unconscious actions can easily cause the model to misinterpret their intent. To address this, we propose a dataset, BQA, a body language question answering dataset, to validate whether the model can correctly interpret emotions from short clips of body language comprising 26 emotion labels of videos of body language. We evaluated various VideoLLMs on the BQA with and without Multimodal Chain of Thought (CoT) and revealed that understanding body language is challenging, and our analyses of the wrong answers by VideoLLMs show that certain VideoLLMs made largely biased answers depending on the age group and ethnicity of the individuals. We also found consistent error patterns in VideoLLMs¹.

1 Introduction

Video large language models (VideoLLMs) (Wang et al., 2024; Ye et al., 2025; Zhang et al., 2024a; Team et al., 2024) process videos by integrating multimodal inputs into an understanding of the content. These models take video frames, sound, and accompanying text as input and generate text, answers to questions (Maaz et al., 2024; Lei et al., 2018), or predictions based on the video (Xiao et al., 2021; Yi et al., 2020), enabling various applications, such as video summarization and question answering. This capability fosters a future where humans and models coexist, making it essential for VideoLLMs to grasp human emotions and

¹The dataset is available at <https://huggingface.co/datasets/naist-nlp/BQA>.

body language for interaction. One study (Hyun et al., 2024) has investigated emotion detection from body language, identifying smiles and their underlying causes. However, since this approach is limited to analyzing a single emotion, it remains unclear whether the findings are generalized to all human emotions. If VideoLLMs are unable to understand human emotion from body language, they may not be suitable for future applications such as dialogue systems and AI robots, where emotional awareness is crucial for enabling more effective interactions.

Our research focuses on the analysis of various emotional expressions in human body language. We created a dataset called *BQA*, a multiple-choice QA task, in which each body language video is associated with a question regarding a particular emotion comprising four choice answers, e.g., Surprise, Confidence, Anger, and Embarrassment, reformatting the Body Language Dataset created for pose estimation (Luo et al., 2020). The BQA consists of 7,632 short videos (5–10 seconds, 25 fps), depicting human body language with metadata (gender, age, ethnicity) and 26 emotion labels per video. The BQA creation involves four steps using Gemini (Team et al., 2024): extracting answer choices, generating questions, evaluating potential harm, and assigning difficulty labels. Moreover, we evaluated recent VideoLLMs on BQA, with and without Chain of Thought (CoT) (Zhang et al., 2024b) as well as conducted multiple human evaluations, and found the task enough challenging for VideoLLMs. Error analysis revealed biases toward specific ages or ethnicities, and Multimodal CoT, despite improving accuracy, showed consistent error patterns.

2 Body Language Dataset (BoLD)

Body Language Dataset (BoLD) (Luo et al., 2020) is a dataset for recognizing human actions and selecting appropriate emotions created by splitting

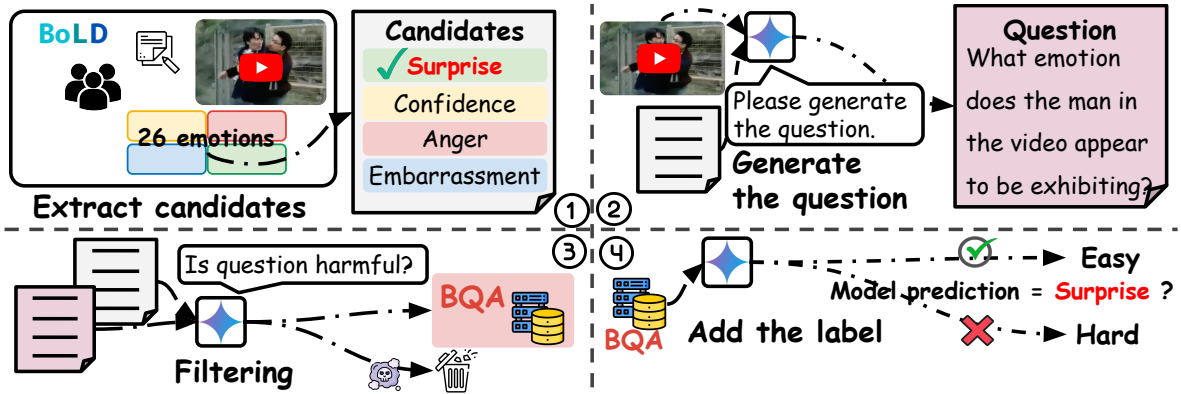

Figure 1: 4 steps of creating the BQA dataset. In STEP1, candidates are created; in STEP2, questions are generated; in STEP3, filtering is conducted; and in STEP4, we assign (Easy/Hard) labels, describing the details in Section 3.

Figure 2: Categorized the 26 emotion labels into 4 groups with similar emotions to extract the candidates.

150 films, totaling 220 hours of footage, resulting in 9,876 video clips. Each clip is approximately 5 seconds long, comprising nearly 125 frames. These videos were annotated with 26 emotion labels (Kosti et al., 2017) via crowdsourcing, where multiple annotators assigned emotion labels on a 10-point scale, which were normalized to represent the emotion of each video. Metadata, including the age, gender, and ethnicity of the individuals in the clips, is also available. However, BoLD is designed for a model directly predicting the emotion, and is not suitable for prompting with clear answers in order to investigate the capacity of VideoLLMs, which expect inference with natural language.

3 Dataset Construction

We transformed BoLD into a multiple-choice QA format by generating questions from video content and using the 26 emotion labels as answers to evaluate how well VideoLLMs understand human emotions expressed through body language, adding steps to extract appropriate choices since BoLD was not designed for LLMs evaluation. To design a QA task for evaluating the LLMs’ understanding of body language for emotional expression, we followed the approach of mCSQA (Sakai

et al., 2024a), which semi-automatically generates QA questions based on candidate answers using LLMs. The whole process consists of four steps as described in Figure 1. First, we extract candidate choices from the BoLD’s metadata (Figure 1-1) followed by question generation using a Gemini based on the video and the candidate choices (Figure 1-2). Then, we automatically filter out inappropriate QAs (Figure 1-3). Lastly, we let the Gemini solve the QAs to evaluate difficulty levels (Figure 1-4).

STEP1: Extract Candidates We categorized 26 emotion labels defined in BoLD into 4 groups: Happiness, Anger, Sadness, and Pleasure, as shown in Figure 2, based on the research in which emotions are classified into four main groups (James, 1890). For the creation of BQA, we apply a multiple-choice question format, where the one with the highest empathy level is treated as correct, and the remaining three options are selected from different emotion groups to ensure that the choices for the QA candidates are selected from each of the groups. The example in Figure 1-1 shows that the correct answer is Surprise from the Pleasure group and the remaining candidates, i.e., Confidence, Anger, and Embarrassment, are drawn from the other groups, i.e., Happiness, Anger, and Sadness, respectively.

STEP2: Generate the Question by VideoLLM Since BoLD does not follow the QA format, we create the appropriate questions from the pairs of candidates and a video by following the prompt design of mCSQA (Sakai et al., 2024a) modified for VideoLLMs. We input the four candidate options (e.g., Confidence, Surprise, Anger, Embarrassment from each group in Figure 1-1) along with the video into Gemini with the highest performance (Team et al., 2024) and let the model generate questions

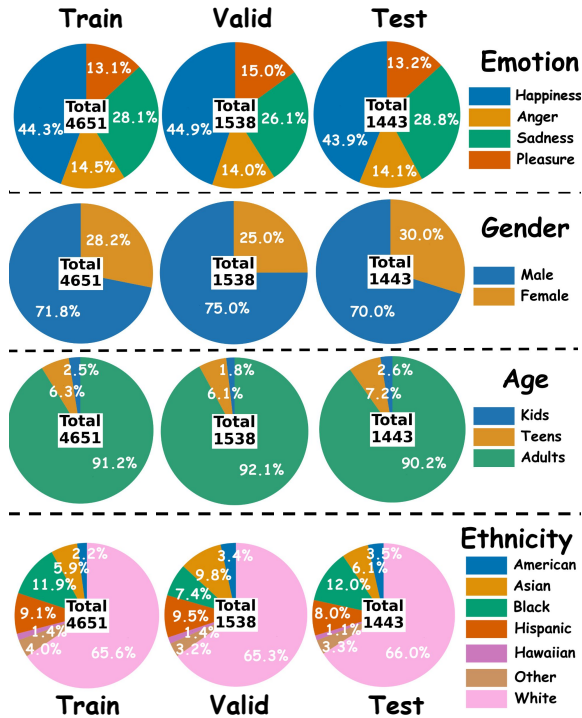

Figure 3: The proportion of metadata in the BQA.

such as “What emotion does the man in the video appear to be exhibiting?” like Figure 1-2 with the prompt we use for the generation in Appendix C.3.

STEP3: Filter the QA by VideoLLM Sometimes, a VideoLLM generates a question which is relatively easy to estimate or answer, e.g., a question that already contains information about the correct candidate, such as “The man looks so shocked. Which emotion is appropriate at this time?” Thus, we let Gemini evaluate whether the generated questions were enough objective and whether they contained superficial information about the correct candidate. If any outputs included the harmful content or did not conform to the conditions for the questions, they were excluded as shown in Figure 1-3.

STEP4: Classify the QA as Easy or Hard Finally, as shown in Figure 1-4, we let Gemini solve the created questions by labeling each question as “Easy” when it could answer or as “Hard” if it could not answer using the prompt presented in Appendix C.3. These question labels allow us to analyze whether a hard question that is not solvable by Gemini is also difficult for other VideoLLMs. For instance, if the correct answer is “Surprise” and Gemini responds with “Anger,” then that question would be classified as “Hard.” After completing these four steps, we split the dataset into training, validation, and test sets in a 6:2:2 ratio, resulting

in 4.5k, 1.5k, and 1.5k questions, respectively. The precise number of data is in Table 3.

What are the Aspects that Make the Samples Easy/Hard? Our analysis of the issues labeled as “Hard” revealed the following findings:

- (1) Neutral expressions: Videos featuring neutral facial expressions often resulted in the hard label.
- (2) Obstructions such as glasses, hats, or sunglasses: Samples involving individuals wearing such items were more likely to be misclassified, leading to the hard label. These findings suggest that VideoLLMs heavily rely on facial expressions when interpreting body language from the footage.

Dataset Analysis Figure 3 shows the distribution of our datasets categorized by our emotion type and three groups of meta information in BoLD: gender, age and ethnicity annotated by humans, revealing that many of the videos feature adult males who are White. It displays the distribution of the four groups of emotions when the annotators selected the most appropriate emotion from the 26 patterns as the correct answer. While Happiness occupies a lot, the overall distribution appears to be balanced.

4 Evaluation

Experimental Setup The models used for evaluation include VideoLLaMA2 (Cheng et al., 2024), LLaVA-NeXT (Zhang et al., 2024a), Qwen2-VL (Wang et al., 2024), and Phi-3.5 (Abdin et al., 2024) with the prompt in Appendix B.2. For the test data, we also used the proprietary models, Gemini (Team et al., 2024) and GPT-4o (OpenAI et al., 2024). We used LoRA-Tuning (Hu et al., 2022) on VideoLLaMA2 with the configuration in Appendix B.1 using the training data and let the model answer with the correct choice in a single word. All audio from the videos was removed to allow for evaluating the model’s ability to interpret body language without relying on auditory information. Additionally, we randomly selected 100 cases from the test set to measure human performance, describing the guideline in Appendix C.1. As an additional evaluation on the test set, we further employed Multimodal Chain of Thought (CoT) to make the models generate reasoning as evidence we call “rationale” for selecting answers. The prompts used for these evaluations are provided in Appendix C.3.

Main Results We show the results in Table 1 with the test set and Table 4 with the valid set. GPT-4o and Gemini achieved higher accuracy than

VideoLLM	#F	Test			Test (CoT)		
		Easy	Hard	Total	Easy	Hard	Total
Human (Rand100)	-	0.96	0.77	0.85	-	-	-
Gemini	*	0.91	0.08	0.61	0.94	0.90	0.92
GPT-4o	*	0.78	0.38	0.60	0.97	0.95	0.96
Phi-3.5	16	0.77	0.41	0.58	1.00	0.96	0.98
Qwen2-VL	16	0.68	0.27	0.47	0.98	0.95	0.97
LLaVA-NeXT	16	0.66	0.30	0.47	1.00	0.96	0.98
VideoLLaMA2	16	0.15	0.01	0.08	0.15	0.01	0.08
VideoLLaMA2 (FT)	16	0.98	0.91	0.94	0.98	0.90	0.94

Table 1: The results using BQA. #F indicates the frame. An asterisk (*) signifies 1 fps. (FT) indicates the LoRA-Tuning model. “Human” is an average of 3 annotators.

the other models. VideoLLaMA2 replied without confirming the choice of format before fine-tuning (FT), resulting in a low score, but after FT, its score surpassed Gemini’s. From this result, the label assignment in STEP4 did not cause hallucinations. Regarding Gemini, which generated the questions, we found that the problems were sufficiently challenging even for the model itself. Furthermore, in STEP4 of Section 3, those labeled as Easy became unsolvable during inference, likely due to the prompt that restricted the output to single words. Regarding CoT, the results showed a large improvement, confirming its effectiveness for VideoLLMs.

5 Analysis and Discussion

We analyzed the videos by gender (Figure 4-A), age (Figure 4-B), and ethnicity (Figure 4-C) in which each model tends to make mistakes. Other models showed lower evaluation results in the Hard setting compared to the Easy setting. This indicates that even if a language model can create questions, it does not guarantee that it can solve them itself. Since the accuracy of the other VideoLLMs, even GPT-4o, was lower than that of Gemini, the dataset proved to be sufficiently challenging for all models.

Which Age do VideoLLMs Often Mistake? We show which age groups models tend to struggle with in Figure 4-B. Higher values indicate a greater tendency to make errors on videos featuring individuals from that age group. These results show that most models do not exhibit bias based on age, while LLaVA-NeXT tends to make more errors on videos featuring “Adults” compared to the others.

Which Ethnicity do VideoLLMs Often Mistake? In Figure 4-C, we show the consistent patterns to make the mistakes based on the ethnicity of the in-

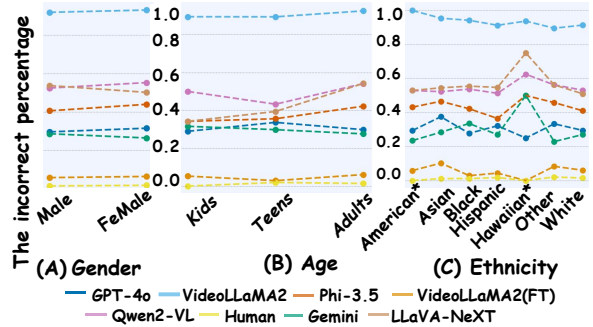

Figure 4: The analysis of incorrectly answered questions shows, from left to right, (A) gender, (B) age, and (C) ethnicity. Note that the higher value indicates more mistakes. An asterisk (*) in (C), especially “American” and “Hawaiian”, indicates that they are native humankind.

dividuals in the videos. Gemini and LLaVA-NeXT tend to make more errors on the problems related to “Native Hawaiian.” Notably, LLaVA-NeXT only achieves around 25% accuracy on these questions.

Why does CoT Improve the Performance?

While the Multimodal Chain of Thought (CoT) improved performance, we observed that the rationales often included the correct answer. The inclusion of leaked answers contributes to the performance improvements largely. Thus, the scores achieved by Multimodal CoT should be treated separately from the inherent difficulty of the dataset. However, upon analyzing the types of errors even after CoT, we observed a recurring trend: many of the misclassified instances featured neutral facial expressions or minimal body movements. This observation further supports the claim in Section 3 that VideoLLMs tend to focus more on the face when attempting to understand the body language.

6 Conclusion

Our work created a dataset called BQA to evaluate whether VideoLLMs understand body language that represents emotions and let VideoLLMs solve the questions using BQA. The results show the questions are challenging for all models, confirming the meaning of the dataset. We analyze the types of questions each model tends to get wrong, revealing that some models show a tendency to make more mistakes based on ethnicity and age group. The models also tend to focus more on the face than on body language, and we found that accuracy decreases when there are obstructions that obscure the face. It is also essential to conduct evaluations that focus on the biases in VideoLLMs.

7 Limitations

7.1 The Evaluation by Human Annotator

The random sampling of 100 evaluations was conducted by three people. The overall agreement score is 0.79, indicating a high level of agreement. In the future, we may take care of using crowdsourcing to gather evaluations from a lot of people. Furthermore, it would be beneficial to include evaluations from people of various ethnicities to explore differing perspectives on body language that expresses emotions. However, [Tedeschi et al. \(2023\)](#) argues that human baselines may be unreliable due to factors such as crowdsourced worker payment issues and random sample effects. We should therefore be cautious about the baseline for our human evaluation.

7.2 Video Quality

This study takes care of the possibility that video quality or size may affect accuracy. Specifically, BoLD uses old films, and some of them have noticeably poor quality. Since the same data is used for evaluation, the ranking of the models' accuracy will likely remain unchanged. However, when inputting higher-quality videos, accuracy might improve across all models.

7.3 Frame Issues

Although VideoLLMs claim to handle videos, many actually use image models by treating videos as a sequence of images. In this study, we standardized the number of frames each model can process to 16, but inputting the maximum number of frames may affect the results. However, since inputting more frames increases memory usage, we also need to be mindful of resource constraints.

7.4 Regarding Emotional Expressions

In this study, we categorized 26 patterns of emotional expression into 4 groups based on previous research ([James, 1890](#)). While we extracted options from these four patterns, this method may not be entirely accurate. Future research will focus on how the models behave when we expand the available options.

7.5 The Costs of Calling API

The models used in this paper are GPT-4o (gpt-4o-0806) from OpenAI. GPT-4o is accessed via API, which is subject to change and incurs costs based

on the number of input tokens. In this study, inference costs totaled approximately \$154 and \$100 for Multimodal CoT, but this may change in the future. Additionally, due to cost considerations, we used Gemini-1.5-pro. This model is also accessed via API, which is subject to change and incurs costs based on the number of input tokens.

8 Ethical Considerations

8.1 Taking Care about Culture

The expression of emotions through body language doesn't necessarily remain consistent across all countries. Therefore, we might need to update the dataset to take care of cultural factors in future developments.

8.2 License

Since BoLD does not have a clear license, we believe its use for research purposes is unproblematic.

8.3 Large Scale Human Evaluation

Although human evaluations of BQA aim to minimize bias, implicit biases may still remain. In the future, it may be necessary to employ multiple annotators for a fair assessment. However, as mentioned in [Tedeschi et al. \(2023\)](#), careful consideration is needed when hiring annotators, as their results may not always be accurate.

8.4 AI Assistant Tools

We used ChatGPT² and DeepL³ to translate sentences to English to accelerate our research.

8.5 Annotators in BoLD

In this study, we rely on data annotated in BoLD for analysis. However, the annotated information may not always be accurate. For example, a White annotator may have intentionally mislabeled an Asian person as Black. Additionally, implicit biases from annotators could lead to adults being mistaken for children.

Regarding emotions, there is also a possibility of bias during the annotation process. We ourselves found it challenging to explain the differences between the 26 patterns of emotional expression, which is why we grouped them into four categories. It is unlikely that annotators fully captured these distinctions, so we must approach this with caution.

A Additional Discussions

A.1 Which Emotion Do VideoLLMs Often Mistake?

We analyzed which labels the models predicted for the questions they answered incorrectly in Figure 5. The x-axis represents the correct labels, while the y-axis shows the emotions predicted by the models. The “Others” includes instances where the model output was not an emotion, such as a sentence. None of the models predicted “Pleasure” when they made mistakes, indicating a strong capability to predict actions representing “Pleasure.” However, all models frequently failed when the correct label was “Happiness,” often selecting opposing emotions like “Sadness” or “Anger.”

A.2 Expansion from existing QA to Other QA Datasets

There are several methods for extending existing QA datasets to new tasks or modalities. For example, Seo et al. (2024) created KoCommonGEN v2 as an expansion of Korean CommonGen (Seo et al., 2022), and Lynn et al. (2025) constructed a new culturally-aware dataset based on Belebele (Bhandarkar et al., 2024). Demszky et al. (2018) transformed existing QA datasets, such as SQuAD (Rajpurkar et al., 2016) and MovieQA (Tapaswi et al., 2016), into an NLI dataset, highlighting how adapting existing resources can yield valuable contributions. Similarly, Sakajo et al. (2025) developed Tonguescape to benchmark VideoLLMs. Building on this trend, we extend BoLD to construct BQA, a dataset designed to serve as input for VideoLLMs and support the understanding of body language.

A.3 Which Gender do VideoLLMs Often Mistake?

Figure 4-A shows the tendency of each model to make mistakes based on whether the video features a male or female subject. Higher values indicate a higher likelihood of errors for the videos. From these results, we can see that none of the models exhibits bias based on gender. These findings suggest that the models are focused on human actions rather than whether the person is male or female.

A.4 Trends in Generated Questions

As described in Section 3, we used Gemini, which achieved the best performance among VideoLLMs according to (Fu et al., 2024), to generate the question texts. We confirmed that the generated questions predominantly begin with wh-words, i.e., What, Where, When, Who, Why, How, Which, which we believe is appropriate for question formation. Furthermore, we evaluated the diversity of the generated questions using Self-BLEU (Zhu et al., 2018), and the results are shown in Table 2. These results are based on 4-gram analysis⁴. They indicate that the diversity of the questions is balanced across sets, confirming the fairness of the question distribution.

Set	Score (↓)	n-gram
Train	0.87	4
Valid	0.86	4
Test	0.85	4

Table 2: The results of Self-BLEU on BQA. Lower scores indicate the more diverse questions.

A.5 Data Contamination

We do not believe that BQA data has already been used for training for the following reasons.

(1): Originality of the questions: The questions used in this study were generated by the model itself during the experimental process. Currently, there is no scenario where the specific question-and-answer pairs created in this study would have been included in the pre-training data of proprietary models like Gemini or GPT-4o.

(2): Performance inconsistency with contamination: If data contamination had occurred, one would expect Gemini to have a significant advantage in answering the questions, as it would have been exposed to similar patterns during pre-training. However, as the results show, Gemini achieves only approximately 60% accuracy on the dataset. This relatively modest performance strongly suggests that no data leakage has occurred. If contamination were present, the accuracy would likely be substantially higher, especially for questions generated by Gemini itself.

⁴When calculating the score, we use nltk (Bird and Loper, 2004).

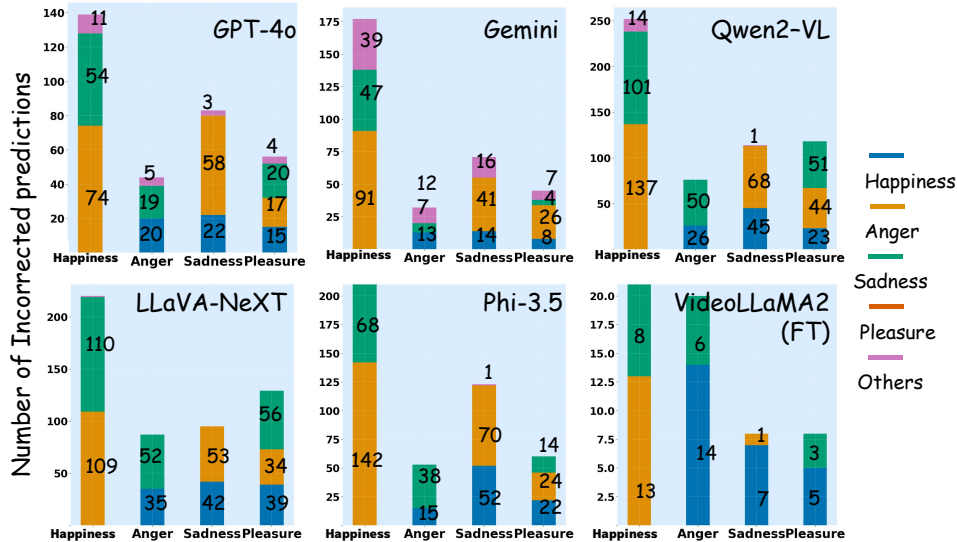

Figure 5: The emotional distribution of output from each model. The x-axis shows the label of the correct answer, and the y-axis shows how the model got it wrong in doing so.

A.6 Self-Preference Bias

Self-preference bias is a phenomenon where a Large Language Model (LLM) favors its own outputs over responses from other models or human-generated texts (Panickssery et al., 2024). This bias can compromise evaluation objectivity, making it essential to address its potential impact on our results. However, in this study, only the questions were generated by the Gemini model. The answer candidates were sourced from external datasets, i.e., BoLD, ensuring they were independent of Gemini’s generation process. This approach prevents any alignment-based advantage from self-generated outputs, mitigating the risk of self-preference bias.

A.7 Exhortation of Multimodal CoT

We analyzed the large accuracy improvements achieved by applying Multimodal Chain of Thought (Zhang et al., 2024b). Upon examining the generated rationales, we observed that many explanations explicitly included reasons for selecting the correct answer while also providing reasons for not choosing the other options. Multimodal CoT presents the question, the answer choices, and the correct answer, then generates an explanatory rationale that derives the answer from the given choices, this rationale being subsequently used for the QA task. These rationales often clearly incorporated the correct answer within the explanation itself, as we described below the boxes. Unlike the traditional step-by-step reasoning approach of Chain of Thought (Wei et al., 2022), this explicit inclusion of

the correct answer suggests a form of answer leakage, which naturally contributes to higher accuracy. Therefore, it is important to note that this answer leakage influences the results obtained from Multimodal CoT and may not fully reflect the inherent capabilities of the model.

Examples of Successful Generation about Rationale

The man sitting in the armchair makes eye contact with the other man and sustains it while he speaks. This direct eye contact and attention to the conversation suggest active participation and engagement with what the other man is saying.

Examples of Bad Generation about Rationale (Data Leakage)

The speaker is looking for an address that she thought she had placed in her purse. When she realizes it is not there, she laughs and appears flustered, indicating confusion and a lack of certainty. This best aligns with the "doubt_confusion" emotion category. The other choices are not applicable because she is not displaying affection, aversion, or disconnection.

A.8 Dataset Size

The size of the BQA dataset after applying the four steps described in Section 3 is in Table 3. Ensuring that the dataset is sufficient to evaluate whether VideoLLMs can comprehend body language.

A.9 The Result of Valid Set in BQA

Table 4 below presents the experimental results obtained using the validation set. We evaluated

Split	Total Size	Easy	Hard
Train	4,651	2,192	2,459
Valid	1,538	746	792
Test	1,443	707	736

Table 3: The data size of each split. After completing the 4 steps of dataset creation, we split the data. Our work also conducted LoRA-Tuning.

open models using the validation set as part of the evaluation.

VideoLLM	#F	Valid		
		Easy	Hard	Total
Phi-3.5	16	0.76	0.38	0.56
Qwen2-VL	16	0.69	0.32	0.50
LLaVA-NeXT	16	0.65	0.31	0.47
VideoLLaMA2	16	0.40	0.09	0.24
VideoLLaMA2 (FT)	16	0.89	0.68	0.78

Table 4: The result of valid set, #F indicating the frame.

B Details of Experimental Settings

Below, we described the details of the models evaluated in this study.

Model	Params	HuggingFace Name
Qwen2-VL	8.29B	Qwen/Qwen2-VL-7B-Instruct
LLaVA-NeXT	8.03B	lmms-lab/LLaVA-NeXT-Video-7B-Qwen2
Phi-3.5	4.15B	microsoft/Phi-3.5-vision-instruct
VideoLLaMA2	8.03B	DAMO-NLP-SG/VideoLLaMA2-7B-Base
GPT-4o	-	gpt-4o-2024-0806
Gemini	-	gemini-1.5-pro

B.1 LoRA Tuning Setting

We conducted LoRA (Hu et al., 2022) tuning with the VideoLLaMA2 model. The model was trained using four NVIDIA A100-SXM4-40GB GPUs. Detailed parameters are provided in Table 5.

B.2 Gemini Settings

Why we use Gemini for question generation stems from its state-of-the-art performance at the time of this study. According to Fu et al. (2024), as of later in 2024, Gemini demonstrated the highest performance among multi-modal LLMs in video QA tasks. Consequently, Gemini was selected for question generation, as it represented the most advanced model available during the research period.

Table 6 describes the configuration used to let the Gemini inference and generate in this study.

Hyper Parameter	Value
torch_dtype	bfloat16
seed	42
max length	2048
batch size	4
epoch	1
lora r	128
lora alpha	256
lora dropout	0.05
lora target modules	o_proj, gate_proj, up_proj, v_proj, q_proj, down_proj, k_proj

Table 5: The hyperparameters of VideoLLaMA2 (Cheng et al., 2024) for LoRA-Tuning (Hu et al., 2022) used in the experiment, and others, were set to default settings (Sakai et al., 2024b). The implementation used the Transformers library (Wolf et al., 2020).

Category	Value
HARM_CATEGORY_DANGEROUS	
HARM_CATEGORY_HARASSMENT	
HARM_CATEGORY_HATE_SPEECH	BLOCK_NONE
HARM_CATEGORY_SEXUALLY_EXPLICIT	
HARM_CATEGORY_DANGEROUS_CONTENT	

Table 6: The configuration settings of Gemini.

B.3 Filtering by Rule-Based Algorithm

In this study, we first performed a rule-based filtering process. We checked if the questions ended with a question mark, whether they were a single line, and ensured that the candidates for the options were not included in the questions. However, no instances were excluded during this filtering.

B.4 The Proportion of Data Split

During the creation phase of BQA, if Gemini determined that a question that Gemini created was harmful, we removed it from the dataset. We then had Gemini attempt to solve the created questions, labeling them as “Easy” and “Hard”. Figure 6 shows the distribution of those labels.

Figure 6: The percentage of each data. As stated in Section 3, we filtered the problem statements in STEP3 and set the difficulty levels of the problems in STEP4.

C Instruction and the Prompt

C.1 Instruction for Human Evaluation

We conducted human evaluations of the BQA test data. The instruction for requesting humans is shown below.

The Instruction for Human Evaluation

Your task is to watch videos related to body language, read the questions, and select the appropriate option.

Please be maximally careful about bias and try to evaluate appropriately.

Please answer with only the word of the chosen option. There are 100 questions, so take breaks as needed, and focus intently during the evaluation.

Question:
{question}

Choice:
{choice0}
{choice1}
{choice2}
{choice3}

C.2 The Content of the Dataset

The structure of the metadata contained in the dataset is outlined below. The complete dataset is released at <https://huggingface.co/datasets/naist-nlp/BQA>.

An Example of Dataset

```
{
  "video_url": "URL_TO_VIDEO",
  "answer": "affection",
  "question": "What feeling does the man in the video seem to express when he is smiling?",
  "prompt": "Please look at the video entered and choose the option that applies to the following question statement.

  Question:
  What feeling does the man in the video seem to express when he is smiling?

  Choice:
  affection
  sympathy
  aversion
  doubt_confusion

  Please output only the words that apply to your answer.
  If you output sentences or symbols, the answer will be incorrect.",
  "easy_hard_label": "hard"
}
```

C.3 The Prompt on Creating a Dataset

Below, we present the prompts used to instruct the model while creating the BQA. One prompt was for generating questions from the video and the candidates, and the other was for filtering the generated questions to determine whether they adhered to the specified conditions.

STEP2: The Prompt for Generate the Question

First, please understand the video.
Understanding the video, please consider the candidates entered and the correct answer, and create a question for which the correct answer is the answer.

candidates:
{candidates[0]}
{candidates[1]}
{candidates[2]}
{candidates[3]}

answer: {answer_emotion}

Notes:

1. Do not include the word choice in the question text.
2. Do not include superficial information such as word counts or paraphrases that can be answered by imagination.
3. Always end a sentence with a '?'.
4. Attempt to create an objective question.
5. Consist of only one sentence.

STEP3: The Prompt for Filtering

Determine whether the input question meets the following conditions.
If it is judged to meet all five conditions, return the input sentence as it is. If it does not meet the conditions, output only the word "HARMFUL" in all uppercase letters.

The output should be either the input sentence or "HARMFUL" only.

Five conditions:

1. Does not use words from multiple-choice options.
2. Avoids using superficial information like character count, etc.
3. Ends with a question mark (?).
4. Is an objective question.
5. Consists of only one sentence.

Input sentence: {question}

STEP4: The prompt for adding the Label as Easy/Hard

Question:
{question}

Choice:
{choice0}
{choice1}
{choice2}
{choice3}

The Prompt for Inference

Please look at the video entered and choose the option that applies to the following question statement.

Question:
{question}

Choice:
{choice0}
{choice1}
{choice2}
{choice3}

Please output only the words that apply to your answer.
If you output sentences or symbols, the answer will be incorrect.

The Prompt for generating rationale for Chain of Thought

Please look at the video entered and choose the option that applies to the following question statement.

Question:
{question}

Choice:
{choice0}
{choice1}
{choice2}
{choice3}

Answer: {answer}

Please explain the rationale to choose the correct answer.
Solution:

The Prompt for Inference with Chain of Thought

Please look at the video entered and choose the option that applies to the following question statement.

Question:
{question}

Choice:
{choice0}
{choice1}
{choice2}
{choice3}

Rationale:
{cot}

Answer: ""

C.4 Examples of BQA

We provide several examples of actual questions and the corresponding answers from each model. The images in the Video column capture the most distinctive moments from the videos (i.e., thumbnails). The complete dataset is available at <https://huggingface.co/datasets/naist-nlp/BQA>. The prompt includes only the necessary parts; for the complete details, we describe in Appendix C.3.

Input video		Question	
		<p>Question: What is the emotion shown by the man toward the people he is talking about?</p> <p>Choice: aversion pleasure esteem fear</p>	
Prediction			Answer
Gemini: fear	LLaVA-NeXT: fear		aversion
GPT-4o: fear	VideoLLaMA2: fear		
Phi-3.5: fear	VideoLLaMA2(FT): fear		
Qwen2-VL: fear			

Figure 7: An example of BQA.

Input video		Question	
		<p>Question: What does the man's demeanor suggest he is experiencing?</p> <p>Choice: fatigue engagement disapproval surprise</p>	
Prediction			Answer
Gemini: disapproval	LLaVA-NeXT: disapproval		fatigue
GPT-4o: fatigue	VideoLLaMA2: disapproval		
Phi-3.5: fatigue	VideoLLaMA2(FT): disapproval		
Qwen2-VL: disapproval

Abstract

Embodied question answering (EQA) means using *perception of* and *action in* an environment to answer natural language questions about that environment. However, previous work has demonstrated that blind language models (which do not incorporate perception, but predict an answer based solely on the question text) are a strong baseline for existing benchmarks, even compared against state-of-the-art vision and language models. To determine whether a model is grounding its answers in its specific environment, rather than relying on a language model’s expectations about the world generally, we propose PQB-EQA, a *per-question balanced* EQA dataset. In this new benchmark, every question appears twice, paired with two different environments that yield two different answers. That is, the answer distribution is balanced for each question, not just across the whole dataset. We show both theoretically and empirically that grounding in the environment is necessary to perform better than chance on PQB-EQA.¹

1 Introduction

Imagine a search and rescue robot that could answer the question, “What is behind the concrete slab?” by navigating to a location where it could find the answer. To answer the question correctly, the agent would need to (1) understand the natural language question, (2) perceive its environment (using, for instance, vision), and (3) select actions to find the necessary information; that is, it would need to engage in *embodied question answering* (EQA) (Das et al., 2018). Obviously, such an agent should ground its answers in the environment; we do not want the search and rescue robot to tell us what is *often* behind concrete slabs. There is therefore a need to test such grounding in EQA models.

¹Data and code available at https://milesshelton.github.io/pqb_eqa/

Unfortunately, “blind” language models—that is, models that receive only the question text and no images—have been strong baselines for existing EQA benchmarks (Anand et al., 2018; Thomason et al., 2019; Ilinykh et al., 2022; Majumdar et al., 2024), showing that they do not require the model to use perception, let alone to act in its environment to find the answer. Performance on these benchmarks therefore does not tell us whether a multimodal language model is in fact grounding its answers in its environment or hallucinating based on patterns in language or datasets. Because EQA is meant to enable agents to answer questions *about an environment*, answers based solely on language priors are unreliable for real-world use (Thomason et al., 2019; Ilinykh et al., 2022); work in the related area of visual question answering (VQA) further supports this (Zhang et al., 2016; Goyal et al., 2017).

This paper introduces PQB-EQA, a new EQA benchmark with per-question balancing, a dataset design strategy to ensure that a model that does not perceive its environment cannot perform better than chance. Each example is a question-environment-answer tuple. Every question depends on its environment; for example, “Could you tell me if there are cobwebs on the houses to the southwest?” might be answered *yes* in reference to one environment and *no* in reference to another, as shown in Figure 1. PQB-EQA pairs each question with two different environments giving two different correct answers. Only a model that integrates language and perception can determine the correct answer for the given question-environment pair. In addition, human testers demonstrated that action in the environments is necessary to find the answers.

The contributions of this paper are the following:

- We construct the first per-question-balanced benchmark for EQA.
- We demonstrate that a state-of-the-art language model performs no better than chance

(a) The agent turns to the southwest and quickly spots cobwebs on the sandstone house.

(b) The agent turns and walks into the house to look for cobwebs before determining there are none.

Figure 1: Screenshots collected from humans in two environments answering the question, "Could you tell me if there are cobwebs on the houses to the southwest? A. yes B. no."

on our new benchmark, while adding vision and a set of oracle actions greatly improves performance.

- We verify that humans need to take action in the environments to answer the questions.

2 Background: EQA Task Definition

The EQA task can be understood in terms of its inputs (an environment and a question about it) and outputs (an answer). An agent capable of certain actions is given a natural language question and placed in a partially-observable environment (as a fully-observable environment would obviate the need for actions to find the answer). The agent uses actions to explore the environment to find the answer. EQA specifically addresses questions *about the environment* (distinguishing it from text-only QA) and allows the agent to select actions to obtain information, distinguishing it from VQA.

More formally, we define the task as follows: a model, M , is given a partially-observable environment E , and a natural language question, Q , which is a sequence of words $w_1 \dots w_n$ from the input vocabulary, V_i . The goal is to predict the correct answer Y conditioned on E . At each time step t , M receives an observation from E , which we call obs_t . M may choose an action, a_t , from an action space, A . The action at time t may affect the observation at time $t + 1$. The goal remains to predict the answer Y in light of the environment E ; action choice is a latent variable. Each example in a dataset is therefore a tuple, $\{Q, E, Y\}$.

3 Per-Question Balancing

Dataset balancing is a technique to prevent models that learn spurious correlations from appearing better than they are. If the answer "yes" shows up much more frequently than "no" in a dataset, a system that picks the majority answer will be a strong baseline without requiring language or vision skills.

Some EQA datasets addressed this problem in their datasets by balancing their answers. For example, [Tan et al. \(2023\)](#) generated questions and sampled so that their final dataset contained precisely the same number of "Yes" answers and "No" answers, as well as equal numbers of counting questions answered 0, 1, 2, 3, or 4. This prevents a model from exploiting dataset-wide patterns in the answers.

However, balancing answers across the entire dataset is insufficient to prevent blind language models from falsely appearing to be effective. Consider an extreme example: Suppose a dataset had environments that always contained dogs but never contained cats. By sampling an equal number of questions that asked if there were dogs and questions that asked if there were cats, one could easily create a dataset that was perfectly balanced across answers but would not require a model to integrate language and vision, since language alone would be enough to answer the questions correctly.

Per-question dataset balancing, by contrast, addresses the blind language model problem by balancing the distribution of correct answers *for each question*. This means that every question must appear in multiple $\{Q, E, Y\}$ tuples; that is, for a given question q_i , there must exist two tuples, $\{q_i, e_i, y_i\}$ and $\{q_i, e'_i, y'_i\}$, such that $e_i \neq e'_i$ and $y_i \neq y'_i$. Since every question has two distinct answers, recognizing the type of question—or indeed, the exact question asked—cannot be enough for a model to guess the correct answer. Although this technique has been used for static visual question answering (VQA) datasets ([Hodosh and Hockenmaier, 2016](#); [Zhang et al., 2016](#); [Goyal et al., 2017](#)), it has not previously been applied to EQA.

4 Dataset

We constructed a per-question balanced dataset comprised of 424 question-environment-answer tuples and recordings of human players.

4.1 Environments

Environments in the dataset are bounded sections of a world in the video game Minecraft. Minecraft has been a popular test bed for reinforcement learning (Guss et al., 2019; Johnson et al., 2016; Kiseleva et al., 2021; Baker et al., 2022; Fan et al., 2022; Wang et al., 2023) and grounded natural language processing (Kitaev and Klein, 2017; Szlam et al., 2019; Narayan-Chen et al., 2019; Srinet et al., 2020; Bonn et al., 2020; Jayannavar et al., 2020; Burns et al., 2021; Kiseleva et al., 2021; Shi et al., 2022), although it has not previously been used for EQA. Due to its highly engaged online community, an abundance of text, images, and videos related to the game are available for training (Fan et al., 2022).

There is a tradeoff between realism and variety of environments for EQA. Previous EQA datasets sought to use the most realistic possible visual simulations, which limited their environments to houses and offices (Gordon et al., 2018; Das et al., 2018; Ren et al., 2024; Majumdar et al., 2024). In contrast, using Minecraft as our simulation enables a wide range of environment types. Minecraft natively incorporates 64 different biome types, such as deserts and villages, and over 1,000 distinct items, from gold to mushroom stew. It also encourages imaginative construction, allowing new objects to be added. Since prior datasets for EQA have already provided realism, we contribute environments that enable greater variability.

Using the WorldEdit Minecraft mod,² we constructed 312 60-by-60 block, single-biome environments. These include city, town, cave, desert, mansion, nether, plains, and snow environments with variations in the items, structures, and creatures placed in each. All environments are compatible with the MineRL (Guss et al., 2019) v.1.0 framework for training RL agents, enabling EQA to benefit from existing action-selection modules.

4.2 Questions

To ensure truly natural language, all questions were collected from and curated by humans. For question collection, we recorded dialog between paid human participants playing cooperative mini-games where their scores depended on accurately gathering information. Details of the procedures are in Appendix A. We manually identified questions from the game dialogs that (a) depend on the

environment (that is, the answer will be different in different environments), (b) are possible for the agent to answer without damaging the environment, and (c) do not require dialog context beyond the question. Some questions immediately met the criteria; others we modified to meet the criteria (for example, we replaced pronouns with their antecedents from the dialog context). See Appendix B for details of question curation.

4.3 Answers

To achieve per-question balancing, we matched each question to two environments that yielded different answers, using a mix of automation and manual review. Using information from the Minecraft save file about items in the environment, we can programmatically determine the answers to some questions; for instance, “are there pigs?” is a look-up to see if any entities in the environment are pigs. However, other questions are more complex; for instance, “are all rooms the exact same?” is hard to automate when the specification lists one structure as “house,” not multiple structures as “rooms.” We manually found two environments with different answers for these questions. We used the two answers for each question, each correct in a different environment, to construct a multiple choice question.

Answer types are varied. Approximately half are yes-or-no, but 30% of answers appear only once in the dataset. For examples of questions and answer choices, see Appendix C.

To ensure tuple quality, we played through the environments and answered the questions. If the reviewer’s answer matched the annotated answer, we kept the tuple; otherwise, a second reviewer answered the questions, and we kept the majority label. After review, we removed all questions that had the same answer in both environments.

4.4 Human Play Data

We recorded human players navigating the environments to answer the questions during tuple review. Once per second, we saved a screenshot. Once per in-game tick (1/20th of a second), we logged all actions taken by the user during that tick. The action space includes actions like “forward,” “jump,” “left,” “right,” and “camera.” Camera movement is controlled by mouse; the other actions are controlled with keypresses. Ongoing actions, such as forward movement that lasted more than a single tick, appear in each tick’s log until they end.

Model	Acc.	p
Blind GPT4-o	0.507	$p = 0.8082$
GPT4-o with Vision	0.827	$p < 0.0001$

Table 1: Accuracy and p of the two models. The blind model does not significantly outperform chance, while the grounded model does.

5 Experiments

We conducted experiments to verify that (a) a blind model would *not* perform better than chance, and (b) a model that successfully navigated and perceived its environment *would* perform better than chance. Both elements are needed to ensure that the benchmark cannot be gamed by a blind model but will fairly evaluate truly grounded models.

Text-only GPT4-o was our blind model. We provided it with the questions and answer choices described in Sections 4.2 and 4.3 and instructed it to choose the best answer and guess if it is unsure. Prompt details are in Appendix D. This is a state-of-the-art large language model, but if our hypothesis is correct, it will not outperform chance, since it does not observe the environment.

To verify the dataset’s feasibility for a model that perceives and acts in its environment, we provided sequences of oracle screenshots from the human play recordings to GPT4-o with vision.³ We adjusted the prompt to refer to the images, but kept it otherwise the same as blind GPT4-o. If our hypothesis is correct, this model should achieve significantly better than random accuracy.

We evaluated accuracy and measured significance using a two-tailed binomial test.

6 Results and Discussion

Table 1 summarizes results. Blind GPT4-o achieved accuracy of 50.7%, which is not significantly different from chance ($p = 0.81$). GPT4-o with oracle screenshot sequences achieved accuracy of 82.7%, significantly outperforming chance ($p < 0.0001$). We therefore conclude that the dataset is feasible for grounded EQA models but not blind models.

Works comparing blind models against models with vision on previous benchmarks have observed notably smaller differences, as summarized in Ta-

³For these experiments, we use an oracle sequence of actions, as our goal is not to evaluate an EQA model, but rather to verify qualities of the benchmark.

Benchmark (Reported in)	Δ Perf.
EQA v1 (Ilinykh et al., 2022)	1.8
A-EQA (Majumdar et al., 2024)	6.3
PQB-EQA (<i>ours</i>)	32.0

Table 2: Reported difference in scores between models with and without vision on previous benchmarks and on PQB-EQA.

	Yes/No	Other
Blind GPT4-o	0.509	0.505
GPT4-o with Vision	0.796	0.861

Table 3: Results of each model on yes/no questions and all other types of questions. The model with vision outperforms the blind model by a wide margin on both categories of question.

ble 2. Ilinykh et al. (2022)⁴ reported that on EQA v1, their language-only model achieved accuracy of 36.2, while their vision + language model achieved accuracy of 38.0, a difference of 1.8 percentage points. Majumdar et al. (2024) reported that on their A-EQA dataset, blind GPT-4 achieved an LLM-Match score of 41.8, while GPT4-V achieved 35.5, a difference of 6.3 percentage points. On our dataset, the difference in accuracy is 32 percentage points.

To verify that the difference in performance holds across question types, we split our dataset into yes/no questions and all other types. Based on the results in Table 3, we conclude that the findings hold over different question types.

To verify that the dataset is suited to EQA and not simply static VQA, we analyzed the human action logs. On average, humans took 278.8 actions to answer a question. Less than 25% of recordings included under 50 actions, and only three did not require action. We therefore conclude that in order for an agent to succeed at this task when it is not given the oracle screenshots, it will need to integrate language, perception, *and* action.

7 Related work

In recent years, many EQA datasets have been released, beginning with Gordon et al. (2018)’s in-

⁴The reported model was not GPT-4, so some caution should be used in comparing their results to ours; however, running new experiments using GPT-4 on the EQA v1 benchmark is infeasible due to its dependence on currently unavailable SUNCG environments.

teractive question answering (IQA) and [Das et al. \(2018\)](#)’s EQA v1. Variations on the EQA task have focused on multi-target EQA ([Yu et al., 2019](#)), EQA with fine-grained robotic manipulation ([Deng et al., 2021](#)), EQA with a knowledge base ([Tan et al., 2023](#)), EQA with “situational” questions ([Dorbala et al., 2024](#)), EQA in a photo-realistic simulation ([Ren et al., 2024](#)), and “episodic memory” EQA ([Majumdar et al., 2024](#)).

Several EQA datasets are balanced in some way, but none are balanced per question. [Das et al. \(2018\)](#) excluded questions with low normalized entropy for the answer distribution; however, the resulting dataset was still susceptible to blind models ([Anand et al., 2018](#); [Thomason et al., 2019](#); [Ilinykh et al., 2022](#)). [Yu et al. \(2019\)](#) applied the same technique with a higher entropy threshold. [Deng et al. \(2021\)](#) manipulated the distribution of answers to be uneven in ways based on anticipated practical applications. [Tan et al. \(2023\)](#) balanced answers across the dataset by over-generating questions and answers and sampling to get equal numbers of “yes” and “no” answers and a uniform distribution over the numbers 0-4 for counting questions. As noted (Section 3), this form of balancing could leave more subtle patterns in the data that a blind model can still exploit. The closest to a per-question balanced dataset for EQA is IQUAD v1 ([Gordon et al., 2018](#)), which associated each question with multiple environments; however, an analysis of that dataset shows that only 5 out of 128 questions are equally likely to be true or false.

Previous work on per-question balancing ([Hodosh and Hockenmaier, 2016](#); [Zhang et al., 2016](#); [Goyal et al., 2017](#)) applied to visual question answering (VQA) for static images. It does not incorporate environments that agents may act in. Such environments present additional challenges; for example, an EQA agent may have to choose different actions to answer the same question in two different environments, as in Figure 1.

8 Conclusion

This work presented the first per-question balanced dataset for embodied question answering. Per-question balancing ensures that ungrounded models cannot perform well. We gathered natural language questions from human participants and aligned each one with two different environments yielding two different answers. Experiments with GPT-4o verify that even a state-of-the-art hyper-LLM

performs no better than chance when using only language, and that the task would be feasible for a model that successfully navigated its environment to find the visual inputs needed to answer the questions. Thanks to its compatibility with MineRL, PQB-EQA is suited for experiments that test the integration of all three parts of the EQA task: language, perception, and action. Future work should evaluate models other than GPT-4 on this benchmark to provide a wider variety of baselines. In addition, we plan to evaluate using end-to-end EQA systems where an agent chooses the actions in place of the oracle action selection used here.

9 Limitations

Embodied question answering has three components: natural language understanding, perception, and action. Our evaluation uses oracle action sequences; future work should incorporate action selection and the perception generated from the selected actions.

Because the questions are multiple-choice, this dataset is not suitable for evaluating generation of answers. This limitation was necessary to ensure per-question answer balancing. Where generation of answers and ensuring that answers are grounded are both important, this dataset should be used in combination with other evaluations.

The dataset is only in English.

Environments are not photorealistic; however, we believe that the greater breadth of environments this enables balances this limitation.

The present dataset’s size makes it suitable for evaluation, but it is not large enough to train new models.

10 Ethics

All EQA-based technology carries the risk of misuse for purposes such as inappropriate surveillance by bad actors. In addition, EQA systems that are used for ethical applications but provide inaccurate information may cause harm.

The questions in PQB-EQA were collected from paid human participants aged at least 18 years. Our data collection procedure was reviewed by our institution’s IRB and considered to pose no more than minimal risk to participants. Participants were compensated \$15 per hour, exceeding the local minimum wage. Informed consent was obtained from all participants. They were made aware that the data collected would be made publicly avail-

able for research. The nature of the data collection (asking questions about a Minecraft game) made disclosure of personally identifiable information unlikely; however, we manually reviewed the results and deleted the sole instance where a participant’s name appeared in a question.

Acknowledgments

We thank the anonymous reviewers for their thoughtful feedback, which helped improve the paper. We are grateful to Laura Biester for her comments on early drafts and to Amerah Rutherford for her assistance with testing data collection instructions and performing quality assurance on code. Some of the authors were supported by University of Richmond Arts & Sciences Summer Fellowships. This work was also supported in part by a grant from the University of Richmond Undergraduate Research Committee.

A Question Collection

We recruited⁵ twelve pairs of self-identified experienced Minecraft players on a college campus in the United States to play mini-games in Minecraft. Participants were at least 18 years old and were compensated \$15 in gift cards for a one-hour session, with the opportunity to win an additional \$50 gift card for high scores. The prize incentivized

⁵All procedures were reviewed and approved according to the policies of the IRB at the university where the research was conducted. Informed consent was obtained from all participants. Recruitment materials included posters, emails, and an in-class announcement. Templates of consent forms, recruitment materials, and full instructions to the participants are available by request to the corresponding author.

Q: What do you see?
A: Grass fields, lots of trees, and flowers.
Q: What’s the flowers or colors?
A: Red ones, yellow ones, pinkish ones, yellow and white ones.
...
Q: Do you see any animals?
A: I see... Sheep...

Table 4: Dialog from a session of the can-you-do-it game where the questioner is trying to find out if it is possible to dye a sheep orange given what’s available in the environment.

teams to work together to achieve their assigned tasks.

Player roles were questioner and agent. Games were designed so that a questioner needs to obtain information about an environment that only the agent can observe. The questioner could ask questions about the agent’s environment but could not directly observe it. The agent could move freely around the environment and answer questions but not volunteer information.

(a) Initial screenshot from agent’s environment

(b) Screenshot when agent tries to answer “Do you see any animals?”

Figure 2: Screenshots from the can-you-do-it game. The questioner knows the task is “dye a sheep orange,” but the agent does not.

build	create	get	make	open	smelt
cook	destroy	grow	mine	place	trade
craft	dig	kill	obtain	put	

Table 5: Teams lost points for using these words that encouraged modification of the environment.

Mini-game 1: In the *can-you-do-it* game, the questioner is given a secret goal task and must determine whether it can be accomplished in the provided environment. To increase the variety of questions asked, we follow Yu et al. (2016) in providing a set of “taboo” words that the questioner may not say unless the agent says them first. For example, Table 4 and Figure 2 show dialog and screenshots from a team trying to determine whether the task “dye a sheep orange” can be completed in the given environment. Taboo words were *yellow*, *red*, *orange*, *sheep*, and *wool*. As an experienced Minecraft player, the questioner knew that orange dye could be made from red and yellow flowers. The agent does not know what the task is or what the taboo words are. The questioner needs the agent’s help to gather information about the environment in order to correctly determine whether the materials necessary to dye a sheep orange can be obtained. The team gains points for correctly determining whether a task is or is not feasible and loses points for an incorrect answer. Points are also deducted if the questioner says any taboo words before the agent says them.

In our internal testing, we found that the Minecraft game mechanics make modifying the environment a valuable way of gathering information. However, models for active question answering should ideally limit the changes they make to their environment; a robot butler should not destroy the kitchen wall to determine how much milk is in the refrigerator. The game therefore applied a point penalty for modifying the environment. Points are also deducted if the questioner uses “doing words” from the set listed in Table 5; this discourages the questioner from disguising instructions as questions (e.g., asking “Can you mine three stone?” to instruct the agent to collect stone).

We recorded and transcribed spoken dialog for each session. Transcription was done in two stages: one automated pass using Whisper⁶ (Radford et al., 2022), followed by manual corrections. We used

⁶<https://github.com/openai/whisper>, version 20231117

NLTK v.3.8.1 (Bird and Loper, 2004) to split the transcript into sentences and treated any sentence with a question mark as a question.

Mini-game 2: In the *spot-the-difference* game, the questioner and agent are placed in variations of the same environment. They earn points by identifying true differences and lose points for false positives (Figure 3). Due to the difficulties with transcription in the can-you-do-it game, we shifted to using a custom chat interface (Figure 4). The questioner’s interface would only send messages that included at least four words and included a question mark. The agent’s interface would only send messages that included at most ten words. Both interfaces required correct spelling before they would send a message. Both players could only see one question and answer at a time, in an effort to reduce the number of context-dependent questions. An admin could see the entire dialog and the questioner’s guesses for how the two environments differed.

B Question Review

Data from both games required review to identify usable questions. A question is suitable for EQA only if the correct answer to the question depends on the environment; thus, general knowledge questions such as “What is a baby tree called?” are not EQA questions. In the current work, we ensure that each question can stand alone without dialog context; EQA in dialog is a more difficult problem that we leave for future work. We therefore annotated each question as (1) suitable for EQA, (2) suitable for EQA if context is provided, or (3) unsuitable for EQA. At least two annotators categorized each question. Where we found disagreements, an additional annotator broke the tie. Category 1 questions went directly into the dataset. Category 3 questions were discarded. One annotator reviewed the five previous dialog turns for all category 2 questions and rephrased them to contain context where possible (e.g., turning “What colors are they?” into “What colors are the flowers?”); the rephrased questions became part of the dataset. Questions that could not be rephrased based on the previous five turns were discarded.

C Example Data

Table 6 provides ten randomly selected multiple choice questions from PQB-EQA.

D GPT Settings

We used gpt-4o-2024-08-06, the default GPT4-o model as of this writing, with temperature set to 0.2 and max_tokens at 10 for all experiments.

For the blind condition, the prompt for system role was *Your goal is to answer multiple choice questions about a Minecraft environment. Each question has two possible answers, A and B. Your response should be a letter, either A or B. If you cannot determine the correct answer, guess.*

For the vision condition, the prompt for system role was *Your goal is to answer multiple choice questions based on Minecraft screenshots. Each image is a sequence of screenshots from a Minecraft session. Each question has two possible answers, A and B. Your response should be a letter, either A or B. If you cannot determine the correct answer, guess.*

Both models returned text that began with either A or B for every question. Some included additional text after the letter. For the first 350 questions, we confirmed that the trailing text was the answer choice associated with that letter or the first several words of it. We therefore interpret the letter as the model’s answer and discard any trailing text.

The cost for all experiments using GPT-4o models totaled \$1.49 U.S.

(a) Screenshot from questioner's environment

(b) Screenshot from agent's environment

Figure 3: Example of two environments from the spot-the-difference game. The team would earn points for noting that one environment includes a hay wagon and the other does not or that only one environment has cobwebs on the buildings, but would lose them if they said the environments were different biomes.

Send Message

Differences Noted

(a) Questioner chat interface for asking questions and noting differences

[Questioner] : Are you in a desert?

Send Message

(b) Agent chat interface for answering questions

Figure 4: Chat interface for the spot-the-difference game.

what type of fence is around the garden?
A. stone brick wall
B. cobblestone wall
Can you access stone?
A. yes
B. no
when you are on the top of the higher side, how many cacti are there?
A. 18 cacti
B. 17 cacti
Okay, are there any mobs passive or non-passive in your environment?
A. yes
B. no
And there are no chests?
A. incorrect
B. correct
what types of trees are around you?
A. there are warped trees
B. there are none
do you have redstone?
A. yes
B. no
what does your environment look like, are there any structures?
A. i see ice, blue ice, spruce leaves, stone, snow i also see a(n) house and a(n) mountain, and 4 rabbits, and 1 polar bear
B. i see cut sandstone, sandstone, cactus, sand, smooth sandstone i also see a(n) house and a(n) cactus, and 5 rabbits
You don't see any stone at all in any chests or in the ground?
A. incorrect
B. correct
Is there any vegetation?
A. there are warped trees, and crimson trees
B. there are none

xingjian.diao.gr@dartmouth.edu

Abstract

Music performances, characterized by dense and continuous audio as well as seamless audio-visual integration, present unique challenges for multimodal scene understanding and reasoning. Recent Music Performance Audio-Visual Question Answering (Music AVQA) datasets have been proposed to reflect these challenges, highlighting the continued need for more effective integration of audio-visual representations in complex question answering. However, existing Music AVQA methods often rely on dense and unoptimized representations, leading to inefficiencies in the isolation of key information, the reduction of redundancy, and the prioritization of critical samples. To address these challenges, we introduce Sparsify, a sparse learning framework specifically designed for Music AVQA. It integrates three sparsification strategies into an end-to-end pipeline and achieves state-of-the-art performance on the Music AVQA datasets. In addition, it reduces training time by 28.32% compared to its fully trained dense counterpart while maintaining accuracy, demonstrating clear efficiency gains. To further improve data efficiency, we propose a key-subset selection algorithm that selects and uses approximately 25% of MUSIC-AVQA v2.0 training data and retains 70–80% of full-data performance across models.

1 Introduction

Music performances, with their dense, continuous audio and seamless audio-visual integration, present both challenges and opportunities for multimodal scene understanding and reasoning (You et al., 2025; Diao et al., 2024). To address the complexities of audio-visual reasoning in music scenarios, the task of Music Performance Audio-Visual Question Answering (Music AVQA) has been proposed, and the corresponding datasets, MUSIC-AVQA (Li et al., 2022) and its extended version MUSIC-AVQA v2.0 (Liu et al., 2024), with an ex-

Figure 1: Dense Audio QA (Liu et al., 2024) vs. Sparse Audio QA (Chen et al., 2020). Music performances contain dense and continuous audio signals with substantial inherent redundancy, much of which is irrelevant to the question being asked. **Sparse learning** has the potential to effectively filter out such redundancies, enabling more efficient and accurate reasoning.

ample shown in Figure 1(a), have been introduced to facilitate research in this emerging area.

Existing AVQA methods for music performances have evolved from early cross-modality learning approaches developed for speech recognition (Ngiam et al., 2011; Srivastava and Salakhutdinov, 2012) to more recent advancements in multimodal fusion (Yun et al., 2021; Yang et al., 2022), positive-negative pair construction (Li et al., 2022), and state-of-the-art models such as LAViSH (Lin et al., 2023), which adapts pretrained ViTs for cross-modal learning, and DG-SCT (Duan et al., 2023), which employs audio-visual prompts within frozen encoders to enhance reasoning. However, current Music AVQA methods face significant limitations in effectively modeling sparse representations, which are crucial for addressing the unique challenges posed by Music AVQA tasks. These limitations include: ① an overreliance on dense, unoptimized representations that struggle to isolate key information from dense audio-visual signals (Ye et al., 2024; Diao et al., 2024); ② a lack of effective redundancy reduction mechanisms, resulting in inefficiencies during feature extraction and model inference (Shang et al., 2024); ③ the absence of prioritization strategies to identify task-critical samples, which limits scalability and prolongs training times (Qin et al., 2024; Li et al., 2023a).

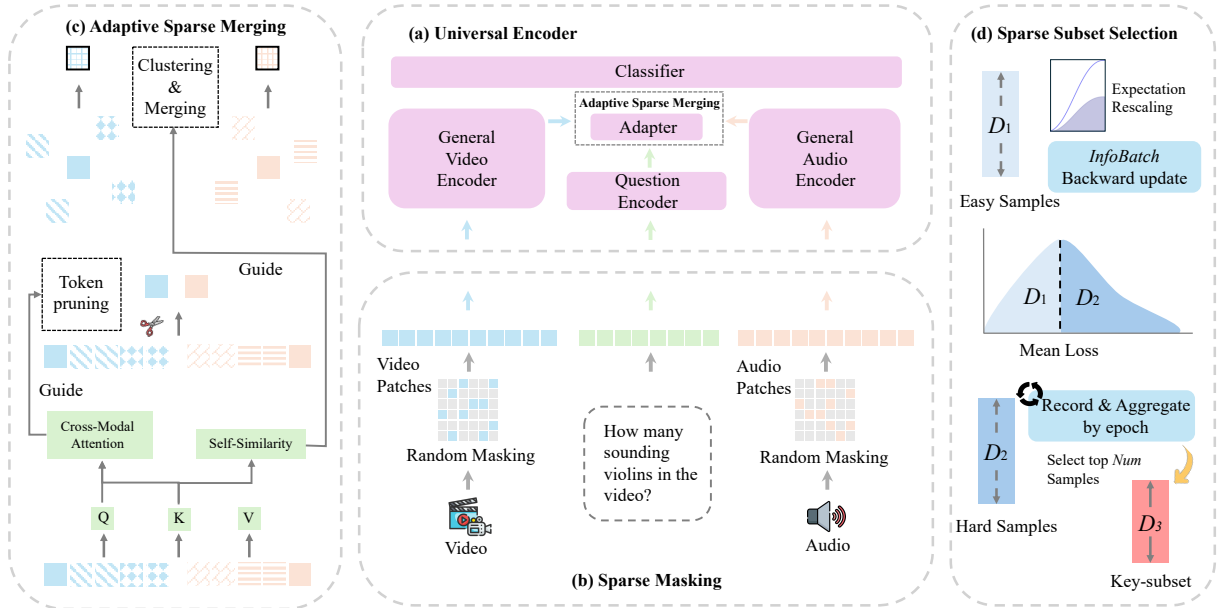

Figure 2: Overview of the Sparsify framework. Sparsify integrates a (a) Universal Encoder and three sparsification components: (b) Sparse Masking to reduce redundancy by masking audio and visual tokens; (c) Adaptive Sparse Merging to select and merge key multimodal tokens based on similarity; and (d) Sparse Subset Selection to prioritize impactful samples and reweight gradients with *InfoBatch* (Qin et al., 2024).

To address these limitations, we propose Sparsify, a sparse learning framework designed for Music AVQA tasks. Our contributions are:

- We present an end-to-end pipeline for Music AVQA that integrates three sparsification strategies and demonstrate its effectiveness with state-of-the-art results on the MUSIC-AVQA datasets.
- Sparsify reduces training time by 28.32% while maintaining the accuracy of question answering compared to fully trained dense models, demonstrating notable efficiency improvements.
- We introduce a key-subset selection algorithm that reduces the training dataset size by approximately 75%, while retaining about 70-80% of the original performance across AVQA models.

2 Sparsify Framework

2.1 Learning Multimodal Representations

Sparsify adapts the Amuse framework (Diao et al., 2024) as its Universal Encoder, which includes a General Video Encoder built on Swin-V2 (Liu et al., 2022), a General Audio Encoder leveraging the HTS-Audio Transformer (Chen et al., 2022a), and a Question Encoder based on a standard language transformer (Vaswani et al., 2017), as shown in Figure 2(a). Cross-modal attention

is applied to align features across modalities, followed by activation and linear transformation layers, resulting in unified and informative multimodal representations tailored to Music AVQA tasks.

2.2 Sparse Masking for Redundancy Reduction

Music performance data inherently contain substantial redundancies, which pose significant challenges to efficient multimodal learning. Sparse Masking addresses this issue by enforcing structured sparsity to reduce redundancy and enhance computational efficiency. As illustrated in Figure 2(b), the method draws inspiration from recent advances in random masking for multimodal models (Li et al., 2023a). This approach aligns with the objectives of sparse learning, aiming to improve efficiency while preserving model performance.

In the visual modality, Sparse Masking is applied to randomly mask 50% of the image patches, reducing input redundancy and introducing structured sparsity to encourage more efficient visual encoding. For the audio modality, we first convert raw waveforms into mel-spectrograms and apply the same masking ratio to ensure comparable sparsity levels. This unified masking design supports coherent sparsity across modalities through consistent information reduction, contributing to more effective multimodal representation learning.

2.3 Sparse Merging for Token Consolidation

In music performance AVQA tasks, dense multimodal inputs often include redundant tokens that unnecessarily increase computational overhead while diluting critical task-relevant information. To tackle this challenge, we adapt the PruMerge method proposed by Shang et al. (2024), applying it to the audio-visual setting as illustrated in Figure 2(c). This strategy dynamically prioritizes and consolidates tokens based on their significance, aligning with the objectives of sparse learning to enhance efficiency and preserve meaningful representations. Following Shang et al. (2024), our approach evaluates token importance using cross-modal attention scores $\mathbf{a} = \text{softmax}\left(\frac{\mathbf{Q}\cdot\mathbf{K}^T}{\sqrt{d}}\right)\mathbf{V}$, where query (\mathbf{Q}), key (\mathbf{K}), and value (\mathbf{V}) interactions highlight the relevance of each token. We then apply the Interquartile Range (IQR) method to these scores, dynamically identifying tokens within the top quartile of importance. IQR is particularly effective for filtering noise and ensuring robustness in token prioritization by focusing on outliers that represent highly salient features. Once the key tokens are identified, remaining tokens are clustered and adaptively merged with the closest key tokens according to their similarity, calculated as $\text{Similarity}(\text{tok}_i, \text{tok}_j) = \mathbf{k}_i \cdot \mathbf{k}_j^T$. This merging process retains critical tokens while integrating complementary features, preserving representational integrity. Sparse Merging ensures efficient multimodal integration with aligned sparsity across audio and visual modalities.

2.4 Sparse Subset Selection for Efficient Training

Training on dense audio-visual datasets is computationally expensive due to excessive redundancy. Sparse Subset Selection, illustrated in Figure 2 (d), addresses this by identifying and focusing on a key subset of samples that contribute the most to learning, significantly reducing training costs while preserving performance.

Following Qin et al. (2024), our method divides samples into "hard-to-learn" (D_1) and "easy-to-learn" (D_2) categories based on their loss values relative to the mean. Hard samples (D_1) are recorded and aggregated by epoch, with their importance weighted by a decay ratio r over k -epoch intervals. This ensures that difficult samples are prioritized early in training, while less critical samples are deprioritized over time. The top num samples with

the highest aggregated scores are selected to form the final Key-subset (D_3). *InfoBatch* (Qin et al., 2024) is used to rescale gradients, pruning redundant "easy-to-learn" samples (D_2) and ensuring that the reduced dataset retains the statistical properties of the original. This combination minimizes redundancy, accelerates convergence, and maintains task performance. The detailed Key-subset Selection Algorithm is presented as Algorithm 1.

Algorithm 1: Key-subset Selection Algorithm

Input: Model M , Dataset $\mathcal{D} = \{(x_i, y_i)\}_{i=1}^N$ with N samples, Loss function L , Number of epochs E , Merge group size k , Decrement ratio r , Number of key samples n

Output: Key-subset indices \mathcal{K}

Initialization
Initialize scores vector $\mathbf{s} \leftarrow \mathbf{1} \in \mathbb{R}^N$
Initialize epochs list EpochsList $\leftarrow []$

Compute original losses
for $i \leftarrow 1$ **to** N **do**
 Compute loss $l_i \leftarrow L(M(x_i), y_i)$
 Update score $s_i \leftarrow l_i$

InfoBatch
for epoch $e \leftarrow 1$ **to** E **do**
 Initialize temporary count vector $\mathbf{t} \leftarrow \mathbf{0} \in \mathbb{R}^N$
 Compute mean loss $\mu \leftarrow \frac{1}{N} \sum_{i=1}^N s_i$
 for $i \leftarrow 1$ **to** N **do**
 Compute loss $l_i \leftarrow L(M(x_i), y_i)$
 Update score $s_i \leftarrow l_i$
 if $s_i > \mu$ **then**
 Increment count $t_i \leftarrow t_i + 1$
 Append \mathbf{t} to EpochsList

Merge
Initialize merged scores $\mathbf{m} \leftarrow \mathbf{0} \in \mathbb{R}^N$
Compute number of groups $G \leftarrow \lceil \frac{E}{k} \rceil$
for group $g \leftarrow 1$ **to** G **do**
 Compute group weight $w_g \leftarrow r^{g-1}$
 for epoch $e \leftarrow (g-1) \cdot k + 1$ **to** $\min(g \cdot k, E)$ **do**
 Update merged scores
 $\mathbf{m} \leftarrow \mathbf{m} + w_g \cdot \text{EpochsList}[e]$

Select the top n indices as the Key-subset
 $\mathcal{K} \leftarrow \text{argsort}(-\mathbf{m})[:n]$
return Key-subset indices \mathcal{K}

3 Experiments

3.1 Setup

Music AVQA Datasets (i) MUSIC-AVQA (Li et al., 2022): Contains 9,288 videos (150 hours) spanning 22 instruments, with 45,867 QA pairs derived from 33 templates across four categories: String, Wind, Percussion, and Keyboard. Each video includes approximately five QA pairs on average. (ii) MUSIC-AVQA v2.0 (Liu et al., 2024): An extension addressing data bias, introducing 1,230 additional videos and 8,100 new QA pairs.

Method	Audio-related QA			Visual-related QA			Audio&Visual-related QA					Avg

Table 1: Comparison with state-of-the-art methods on the MUSIC-AVQA and MUSIC-AVQA v2.0 test set. Accuracy is reported for Audio (Counting, Comparative), Visual (Counting, Location), and Audio-Visual (Existential, Counting, Location, Comparative, Temporal) question types. Average accuracies for Audio, Visual, Audio-Visual, and Overall are also included. **Bold** marks the best results, and underlined marks the second-best.

Full Dataset Training Configuration For the experiments described in Section 3.2, Sparse Masking is applied during the first three epochs and is disabled thereafter. Adaptive Sparse Merging and *InfoBatch* are used throughout the training. We set the masking rate to 50% for Sparse Masking. For *InfoBatch*, the ratio is set to 0.5 and the delta to 0.875, following the setup in (Qin et al., 2024).

Key-subset Selection Configuration In the key-subset selection, we apply a one-epoch warm-up phase followed by 15 epochs of training. The hyperparameters are set as follows: $N = 15$, $k = 3$, $r = 0.618$, and $Num = 10,819$ (i.e., the number of QA pairs). During this stage, only *InfoBatch* (Qin et al., 2024) is employed, while Sparse Masking and Adaptive Sparse Merging are disabled.

Figure 3: Radar charts comparing Sparsify with state-of-the-art methods on MUSIC-AVQA and MUSIC-AVQA v2.0, across various question types.

3.2 Comparison with State-of-the-Art

Table 1 presents a detailed comparison between Sparsify and three strong baselines—AVST (Li et al., 2022), LAViSH (Lin et al., 2023), and DG-SCT (Duan et al., 2023)—on both the MUSIC-AVQA and MUSIC-AVQA v2.0 benchmarks. Sparsify achieves the highest overall average accuracy on both datasets, with consistent gains

across audio, visual, and audio-visual question types. These improvements highlight the potential of sparse learning in handling the dense and continuous nature of music performance videos.

Sparse learning benefits visual question answering by promoting compact visual representations. On visual-related QA, Sparsify achieves accuracy scores of 84.43% and 83.84% on MUSIC-AVQA and MUSIC-AVQA v2.0, respectively, outperforming DG-SCT by +2.35% and +1.65%, and surpassing LAViSH by +8.14% and +1.54%. These improvements reflect the advantage of sparse inputs in retaining essential spatial and structural cues while reducing visual redundancy. In music performance QA, such representations better support reasoning over complex scenes involving performer locations, interactions, and visual composition. By limiting the influence of background clutter and redundant details, sparse visual representation enables the model to perform more robustly across diverse and fine-grained visual reasoning types.

Sparse learning supports audio question answering by reducing spectral redundancy and enabling efficient acoustic encoding. On audio-related QA, Sparsify achieves gains of +3.52% and +3.58% over LAViSH on MUSIC-AVQA and MUSIC-AVQA v2.0, respectively, and outperforms DG-SCT by +4.04% and +2.68%. These improvements suggest that sparse input representations help suppress redundant frequency patterns while retaining sufficient acoustic detail for question-relevant reasoning. By pruning less informative segments in the spectrogram, Sparsify yields more compact yet informative representations, supporting improved performance on audio-based queries involving complex musical content.

Sparse learning improves audio-visual ques-

Figure 4: Accuracy comparison of DG-SCT and Sparsify trained on the full dataset and the key-subset ($\sim 25\%$ of data) (Liu et al., 2024). Training on the key-subset maintains strong performance despite substantial data reduction.

tion answering by jointly reducing modality-specific redundancies. On audio-visual QA, Sparsify outperforms DG-SCT by $+11.24\%$ and $+10.70\%$, and LAVisH by $+5.49\%$ and $+13.33\%$ on MUSIC-AVQA and MUSIC-AVQA v2.0, respectively. These consistent gains suggest that sparsification across both audio and visual modalities helps eliminate less informative content and produce more streamlined multimodal representations with reduced noise. This joint reduction in redundancy allows the model to more effectively capture relevant cross-modal associations in complex performance scenarios.

3.3 Key-subset Selection and Performance Retention

We evaluate the effectiveness of our Key-subset selection algorithm on the MUSIC-AVQA v2.0 dataset (Liu et al., 2024), as illustrated in Figure 4. The selected subset comprises only $\sim 25\%$ of the original training set (10,819 samples), yet enables models to retain a substantial portion of their full-data performance. When trained exclusively on this subset, Sparsify achieves 60.17% accuracy and DG-SCT (Duan et al., 2023) achieves 55.21%, corresponding to 74.01% and 74.08% of their respective accuracies when trained on the full dataset. These results demonstrate that our Key-subset Selection reduces training data usage while retaining much of the models’ original performance, offering a data-efficient solution for Music AVQA.

3.4 Training Efficiency Gains from Sparse Learning

Figure 5 illustrates the training efficiency gains of Sparsify, which reduces total training time from 173 hours to 124 hours—a 28.32% improvement over its dense variant. These gains reflect the combined effect of three sparsification strate-

Figure 5: Comparison of the training time of Sparsify with a dense variant that disables all three sparsification strategies. Results are reported on the MUSIC-AVQA v2.0 dataset (Liu et al., 2024).

gies integrated into the training pipeline. Sparse Masking reduces early-stage computational load by masking 50% of audio and visual tokens. Sparse Merging compresses intermediate representations by consolidating similar tokens, reducing token-level complexity. In parallel, using *InfoBatch* enhances efficiency by emphasizing harder-to-learn samples, which accelerates convergence and reduces the number of required optimization steps.

4 Conclusion

We present Sparsify, a sparse learning framework for Music AVQA that addresses the inefficiencies inherent in dense audio-visual representations. Sparsify achieves this by (i) integrating three sparsification strategies into an end-to-end pipeline and achieving state-of-the-art performance on Music AVQA datasets; (ii) reducing training time by 28.32% while maintaining comparable accuracy to its dense counterpart. In addition, we propose a key-subset selection algorithm that selects and uses approximately 25% of the MUSIC-AVQA v2.0 training data, while retaining 70–80% of full-data performance across models. We hope our work offers insights into efficient multimodal understanding in dense audio-visual settings.

Limitations

The effectiveness of Sparsify has been demonstrated on large-scale Music AVQA benchmarks, as it is specifically designed to address the inefficiencies of dense audio-visual representations in this domain. While it may hold promise for broader multimodal tasks, its behavior in such settings remains to be explored. Extending Sparsify to more diverse or unconstrained applications represents a valuable direction for future work.

Ethical Considerations

We examined the study describing the publicly available datasets used in this research and identified no ethical issues regarding the datasets.

A Baselines

- **AVST (Li et al., 2022)**: Integrates audio, visual, and question modalities for spatio-temporal reasoning in audio-visual question answering. It aligns modalities through spatial and temporal grounding, fuses features into a joint representation, and optimizes both grounding and QA objectives.
- **LAVisH (Lin et al., 2023)**: Adapts frozen Vision Transformers for audio-visual tasks using lightweight adapters and latent tokens to compress and fuse audio-visual information. Cross-modal attention and adapter modules enable bidirectional interaction between modalities.
- **DG-SCT (Duan et al., 2023)**: Enhances audio-visual tasks through a Dual-Guided Spatial-Channel-Temporal attention mechanism, dynamically adjusting feature extraction and facilitating bidirectional audio-visual guidance with lightweight interaction layers.

B Related Work

Audio-Visual Video Understanding Audio and visual modalities offer complementary cues that, when jointly modeled, support a more comprehensive understanding of the scene (Wei et al., 2022; Diao et al., 2023; Shu et al., 2023; Diao et al., 2025). Early work focused on joint representations for tasks like audio-visual speech recognition (Ngiam et al., 2011) and multimodal deep learning (Srivastava and Salakhutdinov, 2012). Recent methods enhance fusion techniques for sound source localization (Zhao et al., 2018) and audio-driven visual analysis (Zhao et al., 2019). Frameworks such as LAVisH (Lin et al., 2023), which proposed a latent

audio-visual hybrid adapter that adapts pretrained ViTs to audio-visual tasks by injecting a small number of trainable parameters into every layer of a frozen ViT, and DG-SCT (Duan et al., 2023) which incorporates trainable cross-modal interaction layers into pre-trained audio-visual encoders, allowing adaptive extraction of crucial information from the current modality across spatial, channel, and temporal dimensions, while preserving the frozen parameters of large-scale pre-trained models. As for benchmarks, there are MUSIC-AVQA (Li et al., 2022), AVQA (Yang et al., 2022), MUSIC-AVQA v2.0 (Liu et al., 2024) and AV-Odyssey Bench (Gong et al., 2024), which focus on whether model can truly understand audio-visual information. However, existing approaches overlook the unique challenges of music performance datasets, where dense and continuous audio-visual signals lead to significant redundancy. These dense representations hinder efficient processing and dilute task-relevant features, necessitating sparsification strategies to enable efficient reasoning in this domain.

Multimodal Question Answering Multimodal question answering spans Visual QA (VQA) (Antol et al., 2015; Lei et al., 2018; Li et al., 2024b), Audio QA (AQA) (Fayek and Johnson, 2020), and Audio-Visual QA (AVQA) (Li et al., 2022), requiring the integration of modality-specific signals for complex reasoning tasks. For VQA, datasets such as MMMU (Yue et al., 2024) and MMBench (Liu et al., 2025) provide carefully curated benchmarks that evaluate vision-language models across diverse domains. For AQA, notable datasets include Clotho-AQA (Lipping et al., 2022) and AIR-Bench (Yang et al., 2024), which consist of question-answering tasks derived from environmental and event-based audio scenes. AVQA benchmarks such as MUSIC-AVQA (Li et al., 2022), AVQA (Yang et al., 2022), Pano-AVQA (Yun et al., 2021), FunQA (Xie et al., 2024), and MUSIC-AVQA v2.0 (Liu et al., 2024) emphasize spatio-temporal reasoning and multimodal fusion in complex video contexts. Among these, Music AVQA presents distinctive challenges due to its continuous and densely structured audio signals, making it valuable for multimodal reasoning (You et al., 2025).

Sparse Learning in Audio-Visual Signals Sparsity has become increasingly crucial in audio-visual signal processing due to the inherent complexity and redundancy of cross-modal data. Early approaches employ shift-invariant kernels (Monaci

et al., 2008) to capture essential patterns while reducing computational overhead. This foundation leads to more sophisticated methods using group sparsity and joint dictionaries (Shen et al., 2013), which are particularly effective in handling noisy and variable signals. Current research focuses on temporal dynamics in audio-visual learning, where audio-visual relationships are often intermittent but contextually meaningful (Iashin et al., 2022). Modern transformer-based architectures with specialized selection mechanisms (Iashin et al., 2024) have shown promise in processing extended sequences efficiently. However, sparsity-based approaches remain underexplored in the context of music performance question answering, where challenges such as overlapping instruments and complex audio-visual interactions demand more efficient representations. Our work aims to bridge this gap with sparsification strategies.

C Positioning Music AVQA Among Multimodal Tasks

To contextualize Music AVQA, it is useful to distinguish it from broader multimodal tasks that also integrate information across modalities. This section contrasts Music AVQA with vision-language modeling, audio-language modeling, and other representative domain-specific question answering to highlight its unique challenges and requirements.

C.1 Vision-Language Modeling

Vision-language modeling aims to enable multimodal systems to interpret visual content—such as images and videos—in conjunction with textual descriptions (Jian et al., 2023; Bordes et al., 2024; Jian et al., 2024; Zhang et al., 2024). It has supported a wide range of applications, including text-to-image generation (Li et al., 2019; Gao et al., 2024; He et al., 2025b), video editing (Hu et al., 2023; He et al., 2025a), video captioning and grounding (Pan et al., 2022; Li et al., 2024b; Zhang et al., 2025), and proxy learning (Qian et al., 2023; Yao et al., 2024a,b). In contrast, Music AVQA requires integrated reasoning over continuous audio-visual streams, where visual understanding must be synchronized with rhythm, motion, and acoustic cues. This setting introduces challenges such as temporal alignment and redundancy reduction, which are not typically emphasized in standard vision-language tasks.

C.2 Audio-Language Modeling

Audio-language modeling (Borsos et al., 2023; Deshmukh et al., 2023; Wu et al., 2024; Su et al., 2025) builds systems that fuse audio features with text for various downstream tasks such as audio question answering (Fayek and Johnson, 2020; Liping et al., 2022), text-to-speech generation (Min et al., 2021; Le et al., 2023), and audio editing (Wang et al., 2023; Liang et al., 2024). These tasks primarily focus on modeling relationships between acoustic signals and language, often in domains such as speech, environmental sounds, or sound events. Unlike conventional audio-language tasks that focus on modeling acoustic-linguistic associations, Music AVQA incorporates a visual modality that is intricately entangled with the audio stream in music performance contexts. This setting necessitates fine-grained multimodal reasoning, where models must jointly interpret auditory patterns, visual dynamics, and their temporal interplay to answer performance-specific questions.

C.3 Domain-Specific Question Answering

Domain-specific question answering systems are designed to operate within specialized fields by leveraging structured knowledge and domain-specific data. Examples such as educational, financial, and medical QA, as discussed below, entail distinct input modalities, reasoning demands, and representational challenges.

Educational QA Educational Question Answering (Educational QA) systems (Soares et al., 2021; Steuer et al., 2022; Wu et al., 2023) are designed to support learning processes by responding to student queries based on educational materials such as textbooks, lecture notes, and academic articles. The primary goal is to clarify concepts, explain solutions, or guide students through subject matter. In contrast, Music AVQA involves perceptual reasoning over evolving audio-visual input. Instead of extracting explicit concepts from structured curricula, models must interpret expressive cues such as gestural nuance, visual-musical alignment, and acoustic articulation in continuous video streams. This shift demands interpreting perceptual and temporal patterns, which are not typically required in conventional educational QA. The emphasis on fluid multimodal integration further distinguishes Music AVQA as a challenging reasoning setting.

Financial QA Financial Question Answering (Financial QA) (Li et al., 2023b; Huang et al., 2023; Saini and Singh, 2023) focuses on extracting insights and answering questions from a wide range of financial data (Chen et al., 2022b), such as company reports, market data, economic indicators, and financial news. These systems assist analysts, investors, and businesses in making informed decisions by providing quick access to relevant financial information and analysis. While Financial QA can involve data from multiple views (e.g., text, tables, charts) (Zhu et al., 2021), it typically does not involve the continuous, dense audio-visual streams found in music performances. The core task in Financial QA is to identify factual information, understand financial terminology, perform numerical reasoning, and interpret trends from often structured or semi-structured textual and numerical data (Wang et al., 2022). In contrast, Music AVQA centers on the temporal and semantic understanding of performance events, requiring models to interpret how visual gestures correspond to musical outcomes, such as identifying sounding instruments, tracking temporal changes, and linking expressive motion to acoustic effects, rather than extracting or reasoning over structured financial data.

Medical QA AI models are increasingly utilized across medical field, tackling a wide array of applications such as diagnostic assistance through analysis of medical images (e.g., X-rays, MRIs) (Wei et al., 2023; Wang et al., 2024; Wei et al., 2025) and dialogues (Varshney et al., 2023; Li et al., 2024a), drug discovery (Dara et al., 2022; Blanco-Gonzalez et al., 2023), digital biomarkers (Arya et al., 2023; Zhou et al., 2024), and personalized patient care (Kasula, 2023; Li and Deng, 2023). Among these, Medical Question Answering (Medical QA) (Abacha and Zweigenbaum, 2015; Goodwin and Harabagiu, 2016) is a specialized field focused on developing systems that understand and respond to health-related queries. These systems often process information from diverse sources to provide accurate medical information or support clinical decision-making. In contrast, Music AVQA centers on interpreting music-related videos, requiring models to reason over dense, continuous audio and tightly synchronized visual streams. While both involve multimodal and complex reasoning, Music AVQA uniquely demands fine-grained alignment of perceptual cues in expressive performance contexts, such as gesture, rhythm, and phrasing.

Cross-Lingual Transfer of Cultural Knowledge: An Asymmetric Phenomenon

Chen Zhang, Zhiyuan Liao, Yansong Feng*

Wangxuan Institute of Computer Technology, Peking University

{zhangch, fengyansong}@pku.edu.cn

liaozy@stu.pku.edu.cn

Abstract

Despite substantial research efforts evaluating how well large language models (LLMs) handle global cultural diversity, the mechanisms behind their cultural knowledge acquisition, particularly in multilingual settings, remain unclear. We study this question by investigating how cultural knowledge transfers across languages during the language adaptation of LLMs, a process where an LLM is continually pre-trained to learn another language. We introduce an interpretable framework to study this transfer, ensuring training data transparency and controlling transfer effects. Through a study of four non-Anglophonic cultures, we observe bidirectional cultural transfer between English and other high-resource languages, while low-resource languages primarily transfer knowledge to English with limited reverse flow. To explain this asymmetric phenomenon, we propose a frequency-based hypothesis: cultural knowledge appearing more frequently in the pretraining data transfers more easily, which is supported by empirical analysis of the training corpora. We hope our findings could inform future research on knowledge transfer and promote the development of culturally aware models, particularly for low-resource languages.

1 Introduction

Although large language models (LLMs) have made significant progress in processing diverse languages (Huang et al., 2024; Dang et al., 2024), they face the challenge of addressing the complexity of global cultural diversity (Hershcovich et al., 2022; Pawar et al., 2024; Liu et al., 2024; Pawar et al., 2025). Existing research primarily evaluates whether LLMs possess adequate cultural knowledge of non-English-speaking or non-Anglophonic communities (Yin et al., 2022; Fung et al., 2024; Shi et al., 2024; Li et al., 2024). However, the

*Corresponding author.

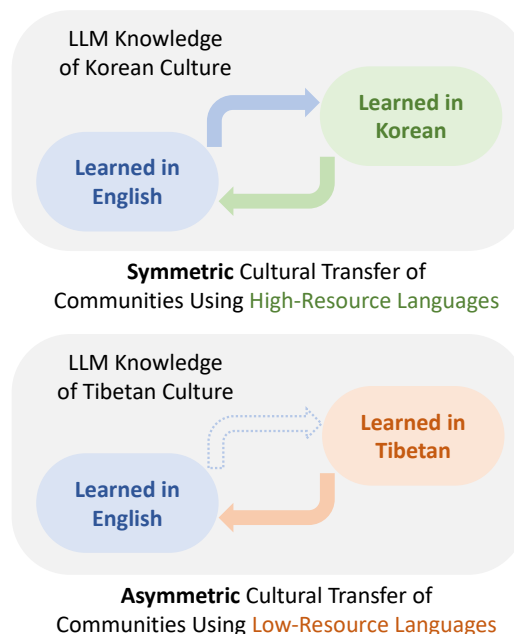

Figure 1: LLMs might exhibit different patterns of cross-lingual transfer of cultural knowledge when continually pretrained in non-English languages. The transfer tends to be bidirectional for cultural knowledge of communities using high-resource languages, but often remains asymmetric for low-resource ones.

sources and mechanisms by which LLMs acquire cultural knowledge, particularly in multilingual settings, remain largely unexplored.

In this paper, we investigate the dynamics of cultural knowledge acquisition in LLMs. We particularly focus on the mechanisms of cross-lingual transfer, a widely observed phenomenon when LLMs are adapted to new languages (Ye et al., 2023; Hu et al., 2024; Zhao et al., 2024; Etxaniz et al., 2024). This investigation faces two main challenges. First, the opacity of LLMs’ training data and procedures limits the feasibility of conducting interpretable experiments, making it difficult to analyze the sources and influencing factors of knowledge transfer. Second, when performance improvements are observed on cultural knowledge

questions for a given language, it is challenging to disentangle whether these gains result from improved language proficiency or from cross-lingual knowledge transfer.

To address these challenges, we design a new research framework that allows a more controlled and interpretable study on the cross-lingual transfer of cultural knowledge. Our framework has three key features. First, it emphasizes the transparency in training data, making it possible to locate the source of cultural knowledge. Specifically, we pretrain a base model from scratch using carefully filtered English Wikipedia data, followed by continual pretraining on corpora in other languages. Second, our framework isolates the effects of cross-lingual transfer from the improved language proficiency. We employ two continual pretraining settings, one that allows cross-lingual transfer with explicit cross-lingual bridges of parallel co-occurrence and the other that minimizes the chances of such transfer. The performance gap between these two settings serves as an estimate of cross-lingual transfer effects. Third, using bilingual parallel probing questions, our framework can analyze the transfer in both directions: from English to non-English languages and vice versa.

We apply this framework to study the cultural transfer of four non-Anglophonic communities: Koreans in South Korea, Han Chinese, Tibetans, and Mongols in China, whose native languages are Korean (ko), Chinese (zh), Tibetan (bo), and Mongolian (mn), respectively. During continual pretraining on these languages, we observe notable differences in cross-lingual cultural knowledge transfer, as shown in Figure 1. Specifically, for high-resource languages (Chinese and Korean), knowledge transfer occurs bidirectionally between English and the target languages. However, for lower-resource languages (Tibetan and Mongolian), we find an asymmetric transfer pattern: knowledge transfer from low-resource languages to English is more pronounced than the reverse direction.

Based on these observations, we hypothesize that cultural knowledge that appears in the training corpus more frequently is more likely to transfer across languages, inspired by previous findings that frequency of appearance during training is an important factor in the monolingual knowledge acquisition of LLMs (Chang et al., 2024; Li et al., 2025). To test this hypothesis, we analyze our training data by estimating the number of occurrences for each cultural knowledge item in both

the English and non-English corpora. Our findings reveal that for low-resource languages, cultural knowledge appears significantly more frequently in non-English corpora than in the English corpus, potentially contributing to the observed asymmetry in transfer. An instance-level analysis further shows that cultural knowledge items that transfer across languages tend to have higher-than-average frequencies of occurrence in the corpus, providing additional evidence for our hypothesis.

Our main contributions are as follows: (1) We introduce a novel framework towards an interpretable study of cross-lingual knowledge transfer, effectively isolating transfer effects from other influencing factors; (2) We investigate the dynamics of knowledge transfer for four non-Anglophonic cultural communities, revealing an asymmetric transfer pattern for low-resource languages. (3) We propose a frequency-based hypothesis to explain the asymmetric transfer phenomenon, supported by empirical analysis over pretraining data. Our data and code are publicly available to the community¹.

2 Methodology

As shown in Figure 2, our framework consists of three steps: pretraining in English, controlled continual pretraining in non-English languages, and bilingual evaluation on cultural questions. It emphasizes transparent training data, decoupling of transfer effects, and bilingual parallel evaluation.

Transparent Pretraining Instead of using LLMs trained with closed-source training data, we advocate training smaller models from scratch with transparent data. In this way, we can clearly observe the process of knowledge transfer and trace the sources of learned knowledge from the corpus. Specifically, we train a 0.5B model from scratch using an English Wikipedia that filters out all non-Latin characters. Afterwards, we continually pretrain it with corpora in other languages and track how the cultural knowledge transfers throughout the training process.

Decoupling of Transfer Effects in Continual Pretraining To disentangle the effects of cross-lingual transfer from improved language proficiency, we systematically control contributing factors, including language similarities, lexical overlaps, and parallel co-occurrences (Radford et al.,

¹<https://github.com/luciusssss/cross-lingual-culture>

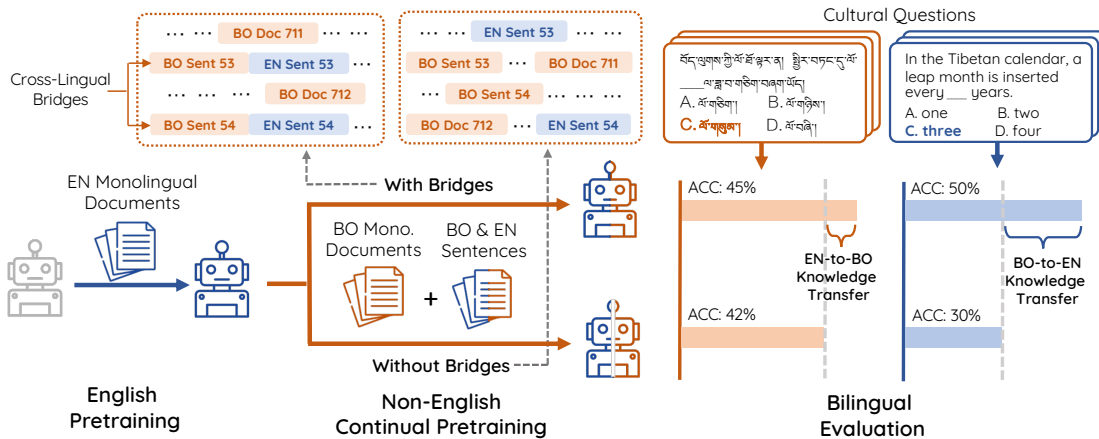

Figure 2: Our framework for studying the cross-lingual transfer of cultural knowledge. We use the transfer between English and Tibetan (bo) as an illustrative example.

2019; Blevins and Zettlemoyer, 2022; Philippy et al., 2023). We design two distinct settings for continual pretraining: one that facilitates cross-lingual transfer and the other that minimizes the chances of transfer as much as possible. The performance gap between these two settings can serve as an indicator of the effect of cross-lingual transfer.

Specifically, we select languages using non-Latin writing systems for study, which naturally have little lexical overlap with English. We further ensure that the English corpus contains no non-Latin characters and the non-English corpora contain no Latin characters, maximizing the isolation between languages during pretraining.

To introduce bridges of cross-lingual transfer to one of the settings, we incorporate parallel sentences into the continual pretraining data, where each pair of parallel sentences is concatenated and mixed with other monolingual training data, as illustrated in Figure 2. This approach has been proven to be effective in helping LLMs learn cross-lingual mappings during pretraining (Anil et al., 2023; Wei et al., 2023; Lin et al., 2024). In contrast, the other setting without cross-lingual bridges uses the same training data, but we purposely prevent paired parallel sentences from co-occurring. Instead, the two sentences in each parallel pair are treated as independent documents, shuffled within the training data. This eliminates the possibility of learning cross-lingual alignment through bilingual co-occurrence in a shared context.

Bilingual Parallel Evaluation For the checkpoints throughout the continual pretraining process, we evaluate them with cultural probing questions in both English and non-English. When using the

non-English-version questions for evaluation, the performance gap between the settings with and without bridges indicates the transfer from English to non-English languages. Similarly, the English-version questions are used to probe the transfer from non-English to English.

3 Experiments

Studied Cultures We select four cultural communities, Koreans in South Korea, Han Chinese, Tibetans, and Mongols in China, for our study. Two of them are associated with high-resource languages (Korean and Chinese), and the other two with low-resource languages (Tibetan and Mongolian). See more information about these communities and their cultures in Appendix A. The languages are deliberately chosen to minimize the cross-lingual transfer with English, as discussed in Section 2.

Pretraining We pretrain a model from scratch with the architecture of Qwen-2.5-0.5B (Yang et al., 2024) using English Wikipedia, amounting to 5B tokens. We then continually pretrain it for each non-English language for 1,500 steps. The batch size is set to 0.5M tokens. See details of pretraining corpora and implementation in Appendix C.1.

Evaluation Since small models trained from scratch exhibit limited instruction-following capabilities, we use cloze-style questions for evaluation. For Korean culture, we sample cultural questions from CLiCk (Kim et al., 2024) and convert them into cloze-style format using GPT-4o. For the other three cultures in China, we collect questions from 《中国少数民族》 (*Ethnic Minorities in China*; Na-

Figure 3: Accuracy on the non-Anglophonic cultural questions with different continual pretraining (CT) steps under different settings. We use EMA smoothing when plotting the figures, with the weight set to 0.8.

tional Ethnic Affairs Commission, 2009), a comprehensive resource on the history and customs of ethnic minorities in China. Specifically, given each paragraph of the book, we ask GPT-4o to generate multi-choice cultural questions, which are then verified and translated by native speakers. In total, we collect between 276 and 598 questions for each culture. See details in Appendix B.

Results and Analyses In Figure 3, we illustrate how the accuracy of probing questions related to non-Anglophonic cultures evolves throughout the continual pretraining process². When the evaluation questions are written in non-English languages (the first row in Figure 3), the gaps between the two settings, one with bridges (blue lines with circular markers) and the other without (orange lines with square markers), can be an estimation of knowledge transferred from English, as opposed to knowledge acquired through continual pretraining. For relatively high-resource languages (Korean and Chinese), we observe notable English-to-non-English transfer (1a and 2a in Figure 3), while for low-resource languages (Tibetan and Mongolian), such transfer is less evident (3a and 4a in Figure 3).

Regarding the transfer from non-English to English (the second row in Figure 3), we observe clear performance gaps between the settings with and without bridges for all four cultures, indicating that the knowledge of non-Anglophonic cultures flows into English. Notably, for most languages (1b, 3b,

²Our main experiments study the transfer of non-Anglophonic cultures. We additionally conduct experiments on the transfer of knowledge exclusively appearing in the Anglophonic culture. See Appendix D for details.

and 4b in Figure 3), this transfer appears to make up for the forgetting of English abilities due to non-English continual pretraining: the performance on English-version questions in the with-bridge settings continues to improve.

4 Inspection into Training Data

We hypothesize that the cross-lingual transfer of cultural knowledge is largely influenced by its frequency of occurrence in the training corpus, which has been identified as an important factor in monolingual knowledge acquisition (Chang et al., 2024; Li et al., 2025). Specifically, cultural knowledge that appears more frequently in the training corpus of one language is more likely to be transferred to another language. We test this hypothesis by estimating the number of occurrences within our training data for each cultural knowledge piece.

Setup For each cultural probing question, we first retrieve the 50 most relevant documents from the corpus. We then employ Llama-3.1-70B (Dubey et al., 2024) to assess whether each retrieved document entails the cultural knowledge in the question. Given the substantial differences in corpus sizes between English and non-English languages, we introduce the metric of **cultural density**, normalizing the count of knowledge appearance by the total number of documents in the corpus. See Appendix C.3 for implementation details.

Results As shown in Table 1, for cultures associated with low-resource languages (Tibetan and Mongolian), their densities in non-English corpora are one order of magnitude higher than those in

	EN Corp.	Non-EN Corp.
Koreans	2.86e-7	5.21e-7
Han Chinese	2.97e-7	2.84e-7
Tibetans	1.49e-7	9.19e-6
Mongols in China	1.55e-7	3.72e-6

Table 1: The cultural densities of different cultures in the English and non-English corpora.

the English corpus. Thus, the knowledge transfer from non-English to English is more evident than that in the reverse direction. Meanwhile, for the cultures of higher-resource languages (Korean and Chinese), the cultural densities between English and non-English corpora are in the same order of magnitude. Accordingly, the extent of cross-lingual transfer is similar for both transfer directions.

Beyond this culture-level comparison, we look at individual data points, examining the subset of cultural knowledge that is successfully transferred between English and non-English (see Appendix C.4 for selection criteria). We find that these transferred knowledge pieces occur more frequently in the corpus than average. For cultural knowledge transferred from English to non-English, the average occurrence in the English corpus is 9.0, significantly higher than the overall average of 4.2. Similarly, for cultural knowledge transferred from non-English to English, the average occurrence in the non-English corpus is 4.7, compared to the general average of 2.2. These findings further support our frequency-based hypothesis.

5 Conclusion

We investigate cross-lingual cultural knowledge transfer during LLM language adaptation. With an interpretable research framework, we observe bidirectional transfer for high-resource languages but an asymmetric pattern for low-resource languages. We propose a frequency-based hypothesis to explain this phenomenon, with evidence from the analysis of pretraining corpora. We hope that our study could inspire more efforts to uncover the dynamics of knowledge transfer and improve the cultural awareness of LLMs, especially for low-resource languages.

Limitations

Model Scale We only use 0.5B models for experiments because our experiments involve pretraining for 16 different settings, which requires considerable computational resources. We select our model

size as a compromise between the informativity of results and computational cost.

Coverage of Cultures To control the factors of cross-lingual transfer in the experiments, we need to use non-Indo-European languages employing non-Latin writing systems, which exhibit greater typological divergence from English and have little lexical overlap with English. This strict requirement significantly narrows the range of suitable cultures for study. Additionally, the collection, verification, and translation of cloze-style cultural questions demand substantial human effort, as existing cultural evaluation datasets are typically monolingual and open-ended, which are not suitable for our study.

Considering these constraints, we select four culturally representative cases, ensuring a balance between well-represented and underrepresented cultures for a more comprehensive analysis. Notably, for the two underrepresented cultural communities, Tibetans and Mongols in China, no existing NLP studies on cultural analysis have considered them. Our evaluation dataset thus provides a valuable resource for investigating these low-resource languages and their cultural representations.

Factors of Cross-Lingual Transfer In our research framework, we try our best to control the factors of cross-lingual transfer for explainable experiments, including language similarities, lexical overlaps, and parallel co-occurrences, which have been identified as primary contributors to cross-lingual transfer (Radford et al., 2019; Blevins and Zettlemoyer, 2022; Philipp et al., 2023). Although several studies find that model architectures (Dufier and Schütze, 2020) and pretraining objectives (Liu et al., 2020) are related to cross-lingual transfer, their effects have been extensively validated at scale. Also, these model-related variables remain constant across different settings in our experiments, minimizing their influence on our findings.

Retrieval Systems Our analysis of the training data involves retrieving documents relevant to the studied knowledge pieces, a common practice in research on knowledge acquisition (Kandpal et al., 2023; Li et al., 2025; Wang et al., 2025). However, retrieval systems are not guaranteed to be perfect. To mitigate potential inaccuracies, we carefully design and optimize retrieval systems for each language, ensuring robust performance and reliable results. See details in Appendix C.3.

Ethical Considerations

A potential concern when collecting cultural questions from existing sources, such as online corpora or books, is the risk of misrepresenting cultures, particularly for underrepresented cultures using low-resource languages. To address this issue, we ensure that all cultural probing questions are verified by native speakers from the respective communities. This process guarantees that our dataset contains no inaccurate or offensive descriptions of their cultures. We discuss this process in detail in Appendix B.

A Information of Studied Cultures

In Table 2, we briefly introduce the four communities studied in this work, including regions, populations, languages, and writing systems.

B Collection of Cultural Questions

Collection of Questions for Koreans We use the data from CLiCK (Kim et al., 2024), a benchmark evaluating LLMs’ knowledge of the Korean language and culture. Each data point in it is a multi-choice question.

From the *culture* subset of CLiCK, we select the data points where the question length does not exceed 300 characters and the choice length does not exceed 30 characters. In this way, we filter out the lengthy questions requiring reading comprehension, which are not suitable for the evaluation of small models such as the 0.5B ones in our experiments.

As the questions in CLiCK end with a question mark, we convert them into cloze-style questions with GPT-4o. A cloze-style question ends with a period and has a blank in itself, where the correct answer fits, similar to the format of MLAMA (Kassner et al., 2021). We further filter the questions that do not meet this requirement after conversion. These questions are further translated from Korean to English by GPT-4o. We manually verify the translation results. Our use of CLiCK is consistent with its intended use.

Collection of Questions for Han Chinese, Tibetans, and Mongols in China For the other three cultures in China, we construct probing questions from scratch, as there is no suitable data available.

We excerpt the chapter describing each group from the book 《中国少数民族》 (*Ethnic Minorities in China*; National Ethnic Affairs Commission, 2009), a book written in Chinese describing the history and custom of China’s ethnic minorities. We then ask GPT-4o to generate multi-choice cultural questions based on each paragraph of the chapter. To facilitate the generation of distracting answers to the questions, we additionally provide GPT-4o with paragraphs that discuss the same topic but describe other ethnic groups.

After generation, we first ask native speakers from each cultural community to check whether the questions faithfully reflect their cultures. For Chinese and Tibetan, all the questions pass the

check, while for Mongolian, 2% of the generated questions are marked as misrepresenting their cultures.

The collected questions are translated from Chinese into English by GPT-4o. We manually verify the translation results. For the questions related to Tibetan and Mongolian cultures, we ask native speakers to translate them from Chinese into Tibetan and Mongolian, respectively.

The annotators are recruited from universities, who are native speakers of the low-resource languages and proficient in Chinese. They are informed of how the collected data will be used. They are paid approximately \$1 for translating a question, which is fair given the participants’ demographic.

Data Statistics In total, we collect 598 questions for Koreans, 328 questions for Han Chinese, 268 questions for Tibetans, and 552 questions for Mongols in China. See other statistics in Table 3.

C Implementation Details

C.1 Continual Pretraining

Data Regarding English pretraining, we use the whole Wikipedia³ for pretraining, which amounts to approximately 5B tokens. We remove all the non-Latin characters in it, ensuring that during pretraining, the model do not see contents written in the four non-English languages of our study.

For the continual pretraining of four non-English languages, we use both monolingual and parallel corpora. Their ratio is 1:1. Regarding monolingual pretraining corpora, we use Wikipedia for English, Chinese, and Korean. For Mongolian and Tibetan, we use MC² (Zhang et al., 2024), as the sizes of Wikipedia for these languages are too small for pretraining. Regarding parallel corpora, we use the data from Lego-MT (Yuan et al., 2023) for Chinese and Korean. For Mongolian and Tibetan, we use the parallel data from the National Basic Science Data Center of China⁴. For the setting with cross-lingual transfer bridges, we use the templates to concatenate each pair of parallel sentences into a document. For example, the template for concatenating English-Chinese parallel sentences is English: {english_sentence} Chinese: {chinese_sentence}.

	Region	Population	Native Language	ISO 639-1	Writing System
Koreans	South Korea	52M	Korean	ko	Hangul
Han Chinese	China	1.3B	Chinese	zh	Chinese characters
Tibetans	China	7.1M	Tibetan	bo	Tibetan script
Mongols in China	China	6.3M	Mongolian	mn	Traditional Mongolian script

Table 2: Information of the cultural communities and their languages studied in our paper.

	ko	zh	bo	mn
Number of Questions	598	328	268	276
Avg. Len. of EN Questions	16.3	22.8	18.0	19.7
Avg. Len. of EN Options	4.1	3.6	3.0	3.2
Avg. Len. of Non-EN Questions	20.5	17.3	91.3	111.6
Avg. Len. of Non-EN Options	5.1	2.6	14.6	20.5

Table 3: Statistics of the cultural probing questions. The average lengths are measured by the tokens produced by the tokenizer of Qwen-2.5-0.5B.

Hyperparameters We use Deepseed⁵ for training. The model is trained for up to 1500 steps using a batch size of 0.5M tokens, a learning rate of 1e-4, and a warmup ratio of 0.01 on eight A100 GPUs. A training step takes approximately 18 seconds.

C.2 Evaluation

The probing questions are in a cloze style, each paired with four candidate answers. We put each answer candidate into the blank in the question and calculate the perplexity of the sentence. The candidate with the lowest perplexity is chosen as the final prediction. We use the evaluation scripts from Qi et al. (2023).

C.3 Knowledge Retrieval

We adopt different methods for the knowledge retrieval of high-pressure and low-resource languages, due to their differences in the availability of mature retrieval techniques.

Retrieval for High-Resource Languages For high-resource languages such as English, Chinese, and Korean, we adopt competitive dense retrieval models that are available for these languages. We use BAAI/bge-small-en-v1.5⁶ (Xiao et al., 2023) for English, BAAI/bge-small-zh-v1.5⁷ for Chinese, and upskyy/bge-m3-korean⁸ (Chen et al., 2024) for Korean. Before retrieval, the doc-

⁵<https://github.com/microsoft/DeepSpeed>

⁶<https://huggingface.co/BAAI/bge-small-en-v1.5>

⁷<https://huggingface.co/BAAI/bge-small-zh-v1.5>

⁸<https://huggingface.co/upskyy/bge-m3-korean>

uments in the corpora are split into chunks no longer than 5,000 characters. After retrieval, we use Llama-3.1-70B (Dubey et al., 2024) to determine whether a retrieved document can entail each query.

Retrieval for Low-Resource Languages For low-resource languages, i.e. Tibetan and Mongolian, no dense retrieval models are available, and current LLMs perform poorly on the NLI task in these languages. Therefore, we mainly adopt lexical-based retrieval and translate queries and documents into high-resource languages for NLI.

Specifically, we first retrieve the top 50 documents using BM25 (Robertson et al., 2009) method, a language-agnostic retrieval algorithm. Before retrieval, the documents are split into chunks no longer than 5,000 characters. Then, we translate both queries and retrieved documents into Chinese using NLLB-200-3.3B⁹ (NLLB Team et al., 2024). We then use Llama-3.1-70B (Dubey et al., 2024) to determine the entailment relationship between each query and its 50 retrieved documents.

C.4 Criterion of Successfully Transferred Instances

In our instance-level analysis, we adopt a strict criterion to identify the knowledge pieces successfully transferred across languages.

For a knowledge piece successfully transferred from non-English to English, its corresponding cultural question should (1) be incorrectly answered in the English version before continual pretraining (CT), (2) be correctly answered in the non-English version by the last three CT checkpoints of the no-bridge setting, and (3) be correctly answered in the English version by the last three CT checkpoints of the bridged setting.

For a knowledge piece successfully transferred from English to non-English, its corresponding cultural question should (1) be correctly answered in the English version before CT, (2) be incorrectly

⁹The model is further finetuned with Chinese-Tibetan and Chinese-Mongolian parallel data to enhance its translation capabilities.

answered in the non-English version by the last three CT checkpoints of the no-bridge setting, and (3) be correctly answered in the non-English version consistently by the last three CT checkpoints of the bridged setting.

D Transfer of Knowledge from Anglophonic Cultures

Data Collection It is untrivial to construct cultural questions for *English culture* as English is the native language of many countries or communities, whose cultures may differ greatly. As a workaround, we study the information of celebrities from the core Anglosphere (Australia, Canada, New Zealand, the United Kingdom, and the United States). This kind of information is more likely to appear in the English corpus than in non-English corpora.

Specifically, we sample 1,000 persons from Wikidata who meet the following requirements: (1) their nationality is in the core Anglosphere, (2) they have only English Wikipedia pages and do not have pages in the four languages of our study (Chinese, Korean, Mongolian, and Tibetan). We then obtain their attributes, including nationality, date of birth, place of birth, occupation, and educational background. We further ensure that their names and attributes only appear in the English corpus, and not in the corpus of other languages.

These person-attribute pairs are then converted to multi-choice questions using templates in different languages, such as {person} was born in {birthplace} and {person}出生在{birthplace}. We directly use the person names and their attributes in their original English forms, as translating them requires substantial human labor. In total, we collect 3,073 such questions.

Experiments and Results We investigate whether Anglophonic cultural knowledge acquired during English pretraining can be transferred to other languages after continual pretraining. Following the experimental setup outlined in Section 2, we compare two settings: one with cross-lingual transfer bridges and one without. After 1,500 steps of continual pretraining, we evaluate the models using non-English versions of Anglophonic cultural questions.

Our results show that the setting with transfer bridges achieves, on average, 20% higher accuracy compared to the setting without bridges, indicating

that Anglophonic cultural knowledge can be transferred to non-English languages. This finding is also in line with our frequency-based hypothesis in Section 4: Anglophonic cultural knowledge appears more frequently in English pretraining data than in non-English data, making it more easily transferable to other languages.

Leveraging Human Production-Interpretation Asymmetries to Test LLM Cognitive Plausibility

Suet-Ying Lam^{1*}, Qingcheng Zeng^{2*}, Jingyi Wu², Rob Voigt²

¹UMass Amherst, ²Northwestern University

Abstract

Whether large language models (LLMs) process language similarly to humans has been the subject of much theoretical and practical debate. We examine this question through the lens of the production-interpretation distinction found in human sentence processing and evaluate the extent to which instruction-tuned LLMs replicate this distinction. Using an empirically documented asymmetry between pronoun production and interpretation in humans for implicit causality verbs as a testbed, we find that some LLMs do quantitatively and qualitatively reflect human-like asymmetries between production and interpretation. We demonstrate that whether this behavior holds depends upon both model size—with larger models more likely to reflect human-like patterns and the choice of meta-linguistic prompts used to elicit the behavior. Our codes and results are available [here](#).

1 Introduction and Background

The extent to which large language models (LLMs) are “cognitively plausible,” that is, replicate human-like behaviors in language processing, has been the subject of ongoing debate (Dentella et al., 2023; Hu et al., 2024; Futrell and Mahowald, 2025; Kuribayashi et al., 2025). Existing research on the linguistic capabilities of LLMs has predominantly focused on their performance in language interpretation, e.g., pragmatic understanding (Hu et al., 2023), sentence acceptability judgment (Warstadt et al., 2020), garden-path effect (Futrell et al., 2019), reference resolution (Lam et al., 2023). In this study, we examine a previously unexplored dimension of cognitive plausibility: whether LLMs reflect human-like distinctions between **production** and **interpretation** in language processing.

Production and interpretation were traditionally treated as two independent processes in human language: for instance, in neurolinguistics the “classic” Lichtheim–Broca–Wernicke model assumes distinct anatomical pathways associated with production and interpretation (see Ben Shalom and Poeppel 2008). While this extreme dichotomy has been rejected recently (see Pickering and Garrod 2013), humans do exhibit different underlying biases in language processing between production and interpretation even in very similar tasks. Whether such distinctions carry over into LLMs is of particular interest when we consider that the fundamental unit of LLM computation is $P(\text{token}|\text{context})$, which is inherently ambiguous between production and interpretation and is practically applied towards both types of tasks.

The present study probes into this question using reference processing as a test case. Consider the following examples:

- (1) A production task: next-mentioned bias
 - a. John infuriated Bill. ... [IC1]
 - b. John praised Bill. ... [IC2]
- (2) A interpretation task: ambiguous pronoun resolution
 - a. John infuriated Bill. He ... [IC1]
 - b. John praised Bill. He ... [IC2]

When asked to continue the story in (1), speakers usually describe events that happened to one of the two mentioned characters. This is a production task, and psycholinguistic research has investigated how the preceding context affects the **next-mention bias** of the character, i.e., how likely a character will be referred to in the continued story $P(\text{referent}|\text{context})$. In (1-a), ‘John’ has a higher next-mention bias than ‘Bill’, because he is the implicit cause of the event. Verbs like ‘infuriate’ are therefore called the subject-biased im-

*Both authors contributed equally. Correspondence to qcz@u.northwestern.edu

plicit causality (IC1) verbs. In contrast, ‘Bill’ has a higher next-mention bias than ‘John’ in (1-b), because ‘Bill’ implies an implicit cause for ‘John’ to praise him. Verbs like ‘praise’ are therefore called object-biased implicit causality (IC2) verbs (e.g., [Stevenson et al. 1994](#)).

A similar implicit causality bias can also be found in (2). Although participants are asked to perform the same sentence continuation task as in (1), note that an additional interpretation element is involved here: since an additional pronoun is provided after the context sentence, participants must first resolve the ambiguous pronoun “he” $P(\text{referent}|\text{pronoun})$ before providing a reasonable continuation.

Studies have shown that human participants were more likely to resolve the ambiguous pronoun to the subject ‘John’ than the object ‘Bill’ with an IC1 verb. That is, ‘John’ has a higher interpretation bias than ‘Bill’ under this condition. This interpretation bias flips when the verb is an IC2 verb: ‘Bill’ were more likely to be the antecedent of the ambiguous pronoun ‘he’ than ‘John’ in (2-b) (e.g., [Crinean and Garnham 2006](#)).

Given the additional interpretation element, henceforth we refer to the sentence continuation task with a given pronoun such as (2) as an **interpretation task** for measuring pronoun interpretation bias; and the one without a given pronoun such as (1) as the **production task** for measuring next-mentioned bias, despite the fact that the sentence continuation task is in principle a production task.

Crucially, psycholinguistic research has revealed an asymmetry between these two biases. In the interpretative case of pronoun interpretation bias, humans are robustly more likely to show a preference for the subject than in the production case of next-mention bias cross-linguistically (English: [Rohde and Kehler 2014](#); Mandarin: [Zhan et al. 2020](#); [Lam and Hwang 2024](#); German: [Patterson et al. 2022](#); Catalan: [Mayol 2018](#)). That is, participants were more likely to resolve an ambiguous pronoun towards the subject than choose the subject as the next referent, despite the same context.

For humans, this extra subject bias in interpretation comes from the bias of using pronouns for subject antecedent, i.e., $P(\text{he}|\text{subject})$. That is, when they see an ambiguous pronoun, they do not only consider the next-mention bias of which antecedent is more likely to be mentioned, but also why a pronoun is used. It is unknown whether and how LLMs can handle this difference, as they do

not generate such a conditional probability based on the choice of next referent instead of the context.

We therefore probe this dimension of LLM cognitive plausibility using this task, asking (1) whether the IC verb-type effect is reflected by LLMs in both production and interpretation; and (2) whether a human-like asymmetry between the two biases exists. This is our first set of questions: do LLMs show human-like interpretation and production biases, and if so under what conditions? Do human-like effects scale with parameter count?

Evaluating LLM in metalinguistic prompts

[Hu and Levy \(2023\)](#) demonstrated that direct probability-based measures in general outperformed meta-linguistic prompting in assessing plausibility and syntactic processing tasks. However, not all language processing tasks can be effectively quantified using probability-based measures, and for some tasks meta-linguistic prompts are the only possible method to measure processing. This is exactly our case: in the ambiguous pronoun resolution task, the bias towards the subject ‘John’ or the object ‘Bill’ is represented by the same term, i.e., $P(\text{he}|\text{context})$. Metalinguistic prompting is thus necessary to elicit meaningful results.

One might expect LLM performance to vary within different metalinguistic prompts, but it is unclear which type of metalinguistic prompts would perform better. Although [Hu and Levy \(2023\)](#) demonstrated that metalinguistic prompts that are more similar to the direct probability baseline perform better, we would like to explore whether probability measurements obtained via metalinguistic prompting also provide greater reliability. This constitutes the second aim of this paper: across different metalinguistic prompting strategies, which elicit more human-like language processing behaviors?

Our findings are summarized below: (1) in the most cases, LLMs cannot capture the difference between the production and the interpretation task in reference processing; if any, the asymmetry is limited to certain meta-linguistic prompts and rarely reach the magnitude found in human participants; and (2) the choice of meta-linguistic prompts matters in evaluating LLMs: most LLMs perform in a more human-like manner with one specific prompt that is unrelated to probability measure, namely the Yes/No prompt (details explained in Section 2.2).

2 Methodology

2.1 Stimuli

We constructed stimuli in the frame of “[Character A] IC-verb [Character B]” without pronouns for the next-mention production task (as in (1)), and with a pronoun with an ambiguous referent for the pronoun resolution task (as in (2)). We selected 137 IC1 verbs and 134 IC2 verbs from the original study that found the production-interpretation asymmetry (Rohde and Kehler, 2014), and the English IC verb corpus (Ferstl et al., 2011). For each verb, we heuristically created two items by assigning a pair of male names and a pair of female names randomly selected from 13 unambiguously male and 13 unambiguously female names from Rohde (2008). The congruence of the gender of the characters ensures the ambiguity of the pronoun. This results in 541 items in each task.

2.2 Models and Metalinguistic Prompting

Our experiments evaluate four representative LLMs from open-source LLMs ranging from 8B to 70B and one proprietary LLM: LLaMA3.1Instruct-8B (Grattafiori et al., 2024), QWen2.5Instruct-32B (Qwen et al., 2025), LLaMA3.3Instruct-70B (Grattafiori et al., 2024), and GPT-4o (OpenAI et al., 2024). We focus on instruction-tuned model¹ as they allow the effective use of metalinguistic prompting, and varying parameter counts also allow us to assess the impact of model scaling on human-like language processing behavior. Specifically, we constantly use greedy decoding in our generation. We employ four metalinguistic prompt strategies to assess LLM behavior:

- (i) Binary choice prompting: The model is prompted to select between subject and object.
- (ii) Continuation prompting: The model is instructed to extend the sentence by continuing with either the subject or the object.
- (iii) Yes/No prompting: The model is asked whether the following sentence (or the existing pronoun) will begin with the *subject*, requiring a binary response.
- (iv) Yes/No probability prompting: Similar to (iii), but instead of a categorical response, we ex-

¹We also experiment with base LLMs. However, even for continuation prompting, base LLMs could not follow instructions reliably.

tract the probability assigned to the *Yes* token as a quantitative measure.

Three authors of the paper manually verified all model outputs to confirm subject/object choice and exclude ambiguous, nonsensical, plural responses, and responses with repeated pronoun in the interpretation task. Table 2 reported the distribution of the excluded responses over the 1082 responses of each model in the two tasks.

Table 1: The distribution of excluded responses in continuation prompting

	Ambiguous	Non-sensical	Plural	Repeated pronoun
LLaMA-8B	54	21	17	0
LLaMA-70B	35	9	0	0
Qwen	17	6	0	0
GPT-4o	22	1	8	5

The specific prompts used in our experiments are provided in Appendix A, and the details of the exclusion criteria in Appendix B.1.

2.3 Evaluation

We evaluated model behavior from two perspectives. We first consider whether the IC verb type effect and the production-interpretation asymmetry exists in LLMs, which we both visualize to observe broad trends and verify with statistical tests like those run in human experiments. We then consider the magnitude of the effect found in LLMs, as psycholinguistic research has found that language models often fail to replicate the magnitude of effects found in human participants even when the directionality is similar. Below we only report effects that are verified by statistical evidence, the details of which be found in Appendix B.

3 Results

Result #1: Implicit causality biases are sometimes replicated by LLMs, depending on prompts and models. Figure 1 presents the task performance across different metalinguistic prompts for each model. The implicit causality (IC) verb effect — where subjects are chosen more frequently after IC1 verbs than IC2 verbs — was observed in at least one metalinguistic prompt for all models, though the strength and consistency of this effect varied by both model and prompt type.

For LLaMA models, the IC verb effect was present in both production and interpretation when using Yes/No and Yes/No probability prompts, indicating a broader sensitivity to IC biases across tasks. In contrast, the IC verb effect was limited

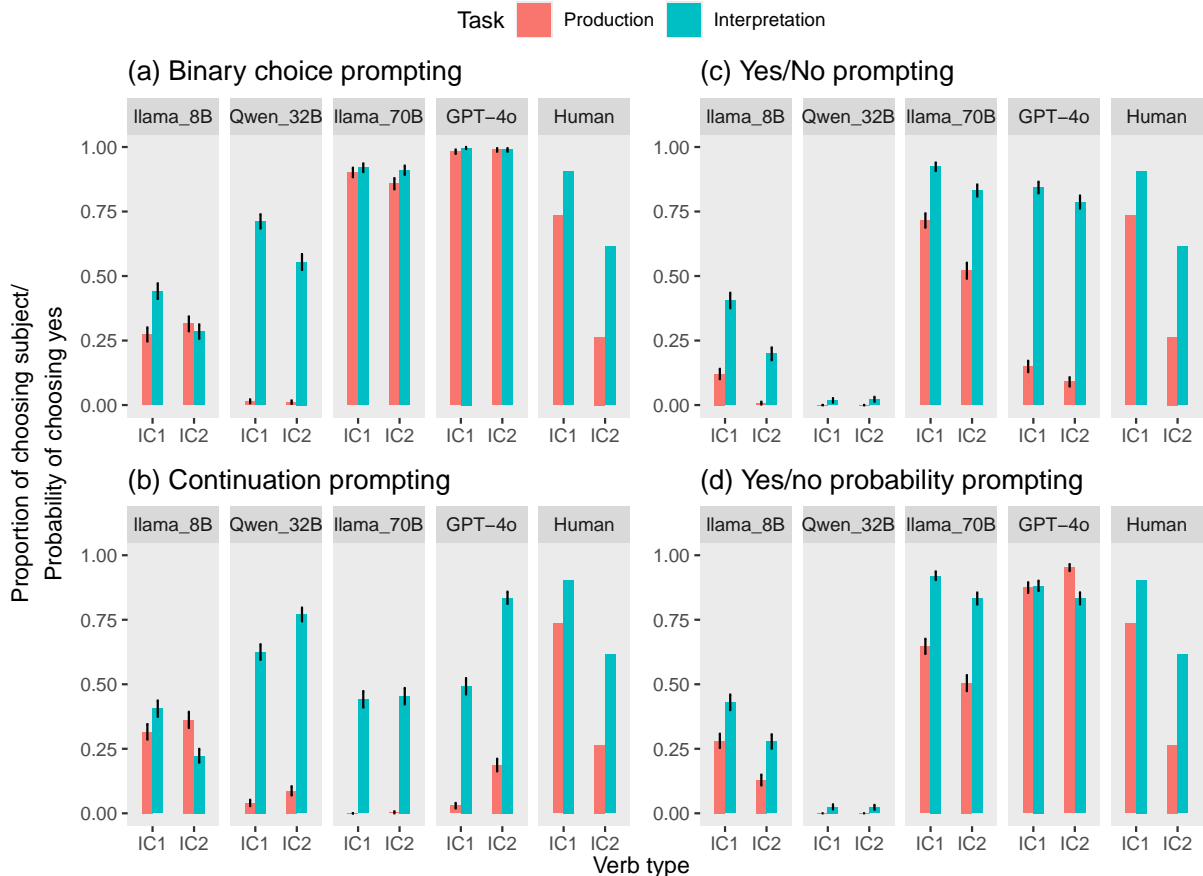

Figure 1: Model behavior as proportion of subject/yes choice as the antecedent by prompting strategy. Human behavior – rightmost facet in each subfigure for reference, from Rohde and Kehler (2014) – tends to reflect higher subject bias for IC1 over IC2 verbs, but with asymmetry between production and interpretation tasks.

to Yes/No prompting for GPT-4o and even more restricted for Qwen, in which the effect was only observed in interpretation and limited to binary choice prompt. This suggests that the model’s sensitivity to IC verbs may depend on task framing.

Result #2: The production-interpretation asymmetry is limitedly captured. Recall that human participants are more subject-biased in interpretation than in production. This difference is only elicited in LLaMA models using Yes/No and Yes/No probability prompts, and GPT-4o using Yes/No prompt and continuation prompt. Qwen was entirely unable to capture this asymmetry because it failed to predict the IC verb effect in production with all four metalinguistic prompts.

Another unexpected production-interpretation asymmetry is that LLMs generally are less likely to capture the IC verb bias in production than in interpretation. For instance, while the LLaMA-8B model was able to predict an IC verb effect in interpretation when using binary choice and continuation prompts, it predicted a reverse verb type effect in

production using these prompts. The same pattern can also be seen in GPT-4o using Yes/No probability prompts. This unexpected asymmetry is even clearer in the performance of the Qwen model, in which the IC verb effect is only found in interpretation. This suggests that LLMs are generally unable to recognize the difference between production and interpretation like humans.

Result #3: LLMs do not align with human behavior in effect magnitude. Although there was a verb type effect and a production/interpretation task effect on LLMs’ responses, the magnitude of these effects is different from humans even in the most similar case: with Yes/No prompting, LLaMA-70B predicted an IC verb effect difference of 19.4% in the production task and 9.2% in the interpretation task. Yet, these two differences were 47.2% and 28.8% respectively in human participants (Rohde and Kehler, 2014). In other words, even in the best scenario, LLMs underestimate the magnitude of the IC verb effect.

Surprisingly, the magnitude of the production-

interpretation asymmetry predicted by LLMs is well-aligned with humans in one case: in human participants, this asymmetry was 16.8% and 35.2% respectively for IC1 and IC2 verbs. With Yes/No prompting, LLaMA-70B predicted a 20.8% and 31% difference respectively for the two verb types. Yet, this seems to be an isolated case. Among the six cases (two LLaMA models in Yes/No and Yes/No probability promptings; GPT-4o in Yes/No and continuation promptings) that exhibit a trend of the production-interpretation asymmetry, this is the only scenario that the magnitude of the asymmetry is similar between LLM and humans. We therefore do not tend to generalize that LLM aligns with human behavior in terms of effect magnitude.

Result #4: Scaling matters. Overall, LLaMA-70B shows better performance than LLaMA-8B across all four prompts. With Binary choice prompts, LLaMA-8B predicted a reverse IC verb effect in the production task and a reverse production-interpretation asymmetry in IC2 verbs, while both effects were captured by LLaMA-70B. With Yes/No and Yes/No probability prompts, although both LLaMA-8B and LLaMA-70B reflected an IC verb effect and production-interpretation asymmetry, the magnitude in human participants was better approximated by LLaMA-70B.

Result #5: Overall, Yes/No prompts align the best with human performance. Among the four promptings used in our study, most models best align with human performance with the Yes/No prompting. This is the only prompting that LLaMA models and GPT-4o capture the IC verb effect and the production-interpretation asymmetry. However, for Qwen, the best performing prompt is the binary choice prompting. This shows that models still differ in their sensitivity to metalinguistic prompts.

4 Discussion

Our study examines the asymmetry between interpretation and interpretation in humans within the context of LLMs, showing that, under specific prompting strategies, certain LLMs can approximate human-like asymmetry. Among the four models we tested, while LLaMA models and GPT-4o performed the best with the Yes/No prompting, Qwen performed the best with the binary choice prompting.

Our findings partially align with [Hu and Levy \(2023\)](#), which suggests that the format of met-

alinguistic prompts influences the behavior of the model. In our study, the four distinct prompting strategies did lead to considerable variation in LLM performance, highlighting the sensitivity of model responses to prompt formulation. The different preferences for prompting strategies between model families also reinforce the need for extensive experimentation across multiple prompting approaches before evaluating a model using metalinguistic prompts.

Yet, different from their findings, we did not see prompting strategies that are more similar to direct probability measures better capture human preferences. Based on [Hu and Levy \(2023\)](#)'s observations, one might expect that metalinguistic prompts that incorporate explicit probability measures would be more reliably approximate human biases. However, our results show otherwise: although models differ in their best-performing prompts, the Yes/No prompting without probability performed best in three out of the four models in our setting. The probability-based format has never yielded superior alignment with human responses. This indicates that probability cues are not universally beneficial in prompting and that their effectiveness may depend on the specific task or model.

Another worth mentioning pattern in our results is that continuation prompting keeps performing the worst in capturing human-like performance, despite being the task originally performed by human participants. One possible explanation is that instruction-tuned LLMs, having been fine-tuned with instruction data or preference optimization objectives, may develop constrained response patterns ([Lin et al., 2023](#)), limiting their flexibility in generating diverse continuations. Additionally, such fine-tuning can reduce conceptual diversity ([Murthy et al., 2024](#)), making LLMs less sensitive to implicit biases in language processing. This suggests that continuation prompting may not be well-suited for probing human-like asymmetries in interpretation and production.

In conclusion, our study reveals that while some instruction-tuned LLMs can approximate human-like asymmetries between production and interpretation under specific conditions, their sensitivity and alignment to human behavior are highly dependent on model scale and the choice of metalinguistic prompting strategy. These findings highlight the nuanced and prompt-contingent nature of evaluating cognitive plausibility in LLMs.

Limitations

Our work has two primary limitations. First, our experiments are conducted on three English-centric LLMs (LLaMA and GPT-4o) and one multilingual-oriented LLM (Qwen). This selection may introduce biases into the models' performance, potentially limiting the generalizability of our findings across other LLMs. Second, our study focuses solely on the asymmetry between ambiguous pronoun resolution and production in English, without exploring cross-linguistic variations. Future research could address these limitations by incorporating a more diverse set of LLMs and broadening the scope of languages analyzed.

A Prompt Template

The following shows the metalinguistic prompt design for LLMs.

System Prompt: You are a helpful assistant.

production-binary-choice-template:

In the following sentence, who is more likely to be the subject of the next sentence? {} or {}? Please ONLY return the name without any explanation or extra words.

Sentence: {}

Answer:

production-yes-no-template:

In the following sentence, judge whether the pronoun of the next sentence will refer to {}. Please ONLY answer with 'Yes' or 'No'.

Sentence: {}

production-continuation-template:

Please reasonably continue the sentence with one of the mentioned characters. You should start a new sentence rather than a clause. Please ONLY return the continuation.

Sentence: {}

interpretation-binary-choice-template:

In the following sentence, who is more likely to be the referent of the pronoun? {} or {}? Please ONLY return the name without any explanation or extra words.

Sentence: {}

Answer:

interpretation-yes-no-template:

In the following sentence, judge whether the pronoun refers to {}. Please ONLY answer with 'Yes' or 'No'.

Sentence: {}

interpretation-continuation-template:

Please reasonably continue the sentence following the pronoun. Please ONLY return the continuation.

Sentence: {}

B Statistical analyses and results

We focus on how the bias of IC verbs (IC1 vs. IC2) and the task (production vs. interpretation) affect the outcomes of LLMs in each type of metalinguistic prompts.

B.1 Data annotation

For binary prompts, we annotated based on the name answered by the LLM. For yes-no prompts, we annotated "yes" as "Subject" .

For continuation prompts, we manually annotated the choice of referent (Subject vs. Object) in the production task and the choice of antecedent (Subject vs. Object) in the ambiguous pronoun resolution task based on the meaning of the generated continuation. For instance, for a sentence like "Nick offended Steve. He decided to apologize and clear the air before things escalated further", we annotated the outcome as "Subject". Ambiguous references (e.g., "Zack divorced Paul. He later moved to a new city to start his life over."), non-sensical continuations (e.g., "Janet wanted Kate. She to join her at the party that night, but Kate had already made other plans."), continuations with a plural antecedent (e.g., "Claire played with Jane. They were building a sandcastle on the beach"), and continuations starting with a repeated pronoun in an interpretation task (e.g., "Claire played with Jane. She... she") were excluded. The distribution of the excluded item has been provided in Table 2 in the main text, repeated below:

Table 2: The distribution of excluded responses in continuation prompting

	Ambiguous	Non-sensical	Plural	Repeated pronoun
LLaMA-8B	54	21	17	0
LLaMA-70B	35	9	0	0
Qwen	17	6	0	0
GPT-4o	22	1	8	5

As can be seen, LLaMA-8B made more ambiguous and non-sensical continuations than all other models. Besides, it also provided continuations with "they", which violates the requirement posed in the prompts. This might suggest that scaling affects LLMs' ability to follow the instructions. More models should be evaluated to test this hypothesis.

B.2 Analyses

LLaMA models For the results of LLaMA models, we ran a mixed-effects Bayesian bernoulli regression model using the R package `brms` for the binary outcome resulted from continuation, binary, and yes-no prompts (Subject = 1; Object = 0); and a mixed-effects Bayesian linear regression model for the continuous probability outcome from yes-no probability prompt. Note that the dataset used in statistical model for continuation outcome is slightly different from that used in other models, as

some of the responses are excluded, as introduced in Appendix B.1.

Each model was fitted using 4 chains, each with 5000 iterations. The first 1000 were warm-up to calibrate the sampler. This results in 12000 posterior samples. They were all built with fixed predictors of IC verbs (sum-coded: IC1 = 0.5; IC2 = -0.5), task type (sum-coded: interpretation = 0.5; production = -0.5), and their interaction. A maximal random structure justified by design is implemented (Barr et al., 2013). For logistic regression models, we used weakly informative priors, i.e., a Cauchy distribution with a center of 0 and a scale of 2.5 for fixed effects following Gelman et al. (2008), and the default setting of the package for the other parameters. For linear regression models, we used a gaussian distribution with a mean of 0 and a standard deviation of 1 as the weakly informative prior for fixed predictors. When there is an interaction effect, we further ran nested models for pairwise comparison.

The Bayesian statistics framework does not use the p-value. We consider the 95% credible interval (CrI) as the evidence for an effect: if the 95% CrI does not include a zero, i.e., it is all positive or negative, we consider there is evidence for an effect. Below we report the estimate and the 95% CrI for each effect.

Qwen For Qwen, we only ran analysis for continuation prompts, and limited to the effect of the IC verb only. This is because responses of Qwen in the production task is so extreme that no statistical model can be successfully fitted. The settings of the mixed-effects Bayesian bernoulli regression model are the same as those used for LLaMA models.

GPT-4o Like LLaMA models, we ran mixed-effects Bayesian bernoulli regression model for binary outcomes from continuation and yes-no prompts. We did not run analysis for binary prompts because responses of GPT-4o were extremely subject-biased in all conditions. As a result, no statistical model can be fitted. We also ran linear regression model for probability outcomes from yes-no probability prompts. The settings of the statistical models are the same as in analyses for LLaMA models.

B.3 Results

We bold the predictor in which the effect is supported the statistical evidence, i.e., the 95% CrI does not contain a zero.

B.3.1 LLaMA-3.1-8B Model

Binary prompting Table 3 shows that there was an interaction effect between the IC verb type and the task type.

Formula: binary \sim verb * task + (1 + task itemID)			
	Estimate	Est. Error	95% CrI
Intercept	-1.80	0.74	[-3.78, -0.99]
verb	0.64	0.48	[-0.12, 1.80]
task	0.67	0.75	[-0.65, 2.47]
verb:task	2.06	0.99	[0.78, 4.61]

Table 3: Summary of the Bayesian logistic regression model of LLaMA-3.1-8B model, binary choice prompting.

Nested analyses further reveal that the production-interpretation asymmetry is only found in IC1 verbs (Table 4), and the verb type effect is only found in interpretation (Table 5).

Formula: binary \sim verb/task + (1 + task itemID)			
	Estimate	Est. Error	95% CrI
Intercept	-1.84	0.76	[-3.81, -0.99]
verb	0.63	0.47	[-0.14, 1.76]
verbIC1:task	1.76	0.96	[0.55, 4.24]
verbIC2:task	-0.40	0.82	[-2.30, 1.14]

Table 4: Pairwise comparison of the task type effect within IC1 and within IC2 conditions using binary choice prompting in LLaMA-3.1-8B model.

Formula: binary \sim task/verb + (1 + prompt itemID)			
	Estimate	Est. Error	95% CrI
Intercept	-1.80	0.79	[-3.85, -0.99]
task	0.65	0.73	[-0.68, 2.37]
taskProduction:verb	-0.43	0.50	[-1.57, 0.42]
taskInterpretation:verb	1.69	0.89	[0.61, 4.01]

Table 5: Pairwise comparison of the IC verb type effect within the production and within the interpretation task using binary choice prompting in LLaMA-3.1-8B model.

Yes-no prompting As shown in Table 6, there was an interaction effect between the verb type and task type for the responses of the model.

Formula: yes_no \sim verb * task + (1 itemID)			
	Estimate	Est. Error	95% CrI
Intercept	-4.06	0.61	[-5.44, -3.04]
verb	3.12	0.67	[1.97, 4.61]
task	4.31	0.70	[3.12, 5.89]
verb:task	-1.99	0.93	[-4.01, -0.39]

Table 6: Summary of the Bayesian logistic regression model of LLaMA-3.1-8B model, yes-no prompting.

Nested analysis in Table 7 further reveals that the model did give more "yes" (or referring to subject) with IC1 verbs than IC2 verbs (as indicated by the positive intercept of the verb predictor). Also, the production-interpretation asymmetry is found within both IC1 and IC2 verbs, such that the model chose more subjects in interpretation than production.

Formula: yes_no \sim verb/task + (1 itemID)			
	Estimate	Est. Error	95% CrI

Table 11: Summary of the Bayesian linear regression model of LLaMA-3.1-8B model, Yes/No probability prompting.

B.3.2 LLaMA-3.3-70B

Binary prompting Table 12 clearly shows that the model only reveals the production-interpretation asymmetry, such that it chose more subject in interpretation than in production. There was no clear evidence for the IC verb type effect.

Formula: binary ~ verb * task + (1 itemID)			
	Estimate	Est. Error	95% CrI
Intercept	14.61	3.61	[9.24, 23.34]
verb	1.36	1.42	[-1.19, 4.45]
task	2.21	0.73	[0.98, 3.84]
verb:task	-1.24	1.07	[-3.44, 0.77]

Table 12: Summary of the Bayesian logistic regression model of LLaMA-3.3-70B model, binary prompting.

Yes-no prompting Table 13 shows that the model is able to capture the IC verb type effect and the production-interpretation asymmetry, such that it responded ‘Yes’ (=subject) more for IC1 verbs than IC2 verbs and the interpretation task than the production task.

Formula: yes_no ~ verb * task + (1 itemID)			
	Estimate	Est. Error	95% CrI
Intercept	2.24	0.25	[1.79, 2.78]
verb	1.46	0.34	[0.83, 2.15]
task	2.63	0.31	[2.05, 3.29]
verb:task	-0.10	0.44	[-0.95, 0.76]

Table 13: Summary of the Bayesian logistic regression model of LLaMA-3.3-70B model, Yes/No prompting.

Continuation prompting Like in binary choice prompting, Table 14 shows that the model only reveals the production-interpretation asymmetry, such that it chose more subject in interpretation than in production. There was no clear evidence for the IC verb type effect.

Formula: cont ~ verb * task + (1 itemID)			
	Estimate	Est. Error	95% CrI
Intercept	-3.66	0.66	[-5.23, -2.68]
verb	-0.61	0.88	[-2.67, 0.86]
task	6.83	1.27	[4.89, 9.82]
verb:task	1.10	1.74	[-1.78, 5.19]

Table 14: Summary of the Bayesian logistic regression model of LLaMA-3.3-70B model, continuation prompting.

Yes/No probability prompting Table 15 shows an interaction effect between verb and task type.

Formula: subject_yes_probability \sim verb * task + (1 itemID)			
	Estimate	Est. Error	95% CrI
Intercept	0.73	0.01	[0.70, 0.75]
verb	0.12	0.02	[0.07, 0.16]
task	0.30	0.01	[0.27, 0.33]
verb:task	-0.05	0.03	[-0.11, -0.00]

Table 15: Summary of the Bayesian linear regression model of LLaMA-3.3-70B model, Yes/No probability prompting.

Pairwise comparisons in Table 16 and 17 further show that the verb type effect can be found in both production and interpretation task, and the asymmetry can be found in both IC1 and IC2 conditions.

Formula: subject_yes_probability \sim verb/task + (1 itemID)			
	Estimate	Est. Error	95% CrI
Intercept	0.73	0.01	[0.71, 0.75]
verb	0.12	0.02	[0.07, 0.16]

	Estimate	Est. Error	95% CrI
Intercept	0.73	0.01	[0.70, 0.75]
task	0.30	0.01	[0.27, 0.33]
taskProduction:verb	0.14	0.03	[0.09, 0.19]
taskInterpretation:verb	0.09	0.03	[0.04, 0.14]

Table 17: Pairwise comparison of the task type effect within IC1 and within IC2 verbs using Yes/No probability prompting in LLaMA-3.1-70B model.

B.3.3 QWen

Note that we only analyzed the responses of the continuation prompting in the interpretation task for Qwen, because models cannot be converged in other case. As can be seen below in Table 18, there is an opposite IC verb type effect such that the model referred to more subjects following IC2 verbs than IC1 verbs.

Formula: cont \sim verb + (1 itemID)			
	Estimate	Est. Error	95% CrI
Intercept	-0.60	0.07	[-0.73, -0.47]
verb	-0.37	0.13	[-0.63, -0.11]

Table 18: Summary of the Bayesian logistic regression model of Qwen model, continuation prompting.

B.3.4 GPT-4o

Recall that due to the extreme pattern of GPT-4o with binary promptings, no statistical model could be fitted. Below we only report results of statistical analyses for outputs from Yes/No, Yes/No probability, and continuation promptings only.

Table 19 shows the results of outcomes from Yes/No prompting of GPT-4o. As can be seen, there was a main effect of both verb type and task type, such that IC1 verbs and interpretation task elicited more choices towards subject antecedent. This aligns with the human performance.

Formula: yes_no \sim verb * task + (1 itemID)			
	Estimate	Est. Error	95% CI
Intercept	-0.39	0.15	[-0.69, -0.12]
verb	0.68	0.29	[0.15, 1.28]
task	5.51	0.83	[4.17, 7.42]
verb:task	-0.23	0.46	[-1.15, 0.67]

Table 19: Summary of the Bayesian logistic regression model of GPT-4o, Yes/No prompting.

Table 20 shows the results of outcomes from Yes/No probability prompting of GPT-4o. Given statistical evidence for the interaction effect between verb and task type, we further ran a nested analysis for the effect of the task type within each level of verb, as shown in Table 11.

Formula: subject_yes_probability \sim verb * task + (1 itemID)			
	Estimate	Est. Error	95% CI
Intercept	0.89	0.01	[0.87, 0.90]
verb	-0.01	0.01	[-0.04, 0.01]
task	-0.06	0.01	[-0.08, -0.03]
verb:task	0.13	0.02	[0.08, 0.17]

Table 20: Summary of the Bayesian linear regression model of GPT-4o, Yes/No probability prompting.

As can be seen, there was only a task effect limited to IC2 verbs and in an opposite way to human performance: the interpretation task was even less subject-biased than the production task,

as shown in the negative sign of the estimate of verbIC2:task.

Formula: subject_yes_probability ~ verb/prompt + (1 itemID)			
	Estimate	Est. Error	95% CI
Intercept	0.89	0.01	[0.87, 0.90]
verb	-0.01	0.01	[-0.04, 0.01]
verbIC1:task	0.01	0.02	[-0.03, 0.04]
verbIC2:task	-0.12	0.02	[-0.15, -0.08]

Table 21: Pairwise comparison of the task type effect within IC1 and within IC2 verbs using of GPT-4o, Yes/No probability prompting.

Lastly, Table 22 shows statistical results from continuation promptings of GPT-4o. The main effect of the task type shows that the model captures the production-interpretation asymmetry that the interpretation task was more subject-biased than the production task. However, the negative sign of the verb type effect shows a reversed IC verb effect, such that IC2 verbs were more subject-biased than IC1 verbs.

Formula: cont ~ verb * task + (1 itemID)			
	Estimate	Est. Error	95% CI
Intercept	-1.43	0.30	[-2.12, -0.95]
verb	-3.11	0.63	[-4.57, -2.10]
task	5.85	1.04	[4.26, 8.28]
verb:task	0.10	0.60	[-1.05, 1.33]

Table 22: Summary of the Bayesian linear regression model of GPT-4o, continuation prompting.

Improving the Calibration of Confidence Scores in Text Generation Using the Output Distribution’s Characteristics

Abstract

Well-calibrated model confidence scores can improve the usefulness of text generation models. For example, users can be prompted to review predictions with low confidence scores, to prevent models from returning bad or potentially dangerous predictions. However, confidence metrics are not always well calibrated in text generation. One reason is that in generation, there can be many valid answers, which previous methods do not always account for. Hence, a confident model could distribute its output probability among multiple sequences because they are all valid. We propose task-agnostic confidence metrics suited to generation, which rely solely on the probabilities associated with the model outputs without the need for further fine-tuning or heuristics. Using these, we are able to improve the calibration of BART and Flan-T5 on summarization, translation, and QA datasets.

1 Introduction

Confidence scores are scores derived from a model’s output, which are interpreted as the model’s estimation of its own output’s quality. These scores can be used in real-world applications to flag uncertain predictions in automated decision-making systems (Malinin and Gales, 2021), which could prompt further human review (Xiao et al., 2020), or force the model to abstain from answering when unsure (Liu et al., 2020; Kamath et al., 2020). To be useful, we want these scores to correlate with the output’s quality.

A common approach to estimating confidence is through probability-based methods, which rely on the probabilities assigned by the model to output tokens. Most existing methods focus on the sequence with the highest probability, which we refer to as the top sequence (Murray and Chiang, 2018; Zablotskaia et al., 2023; Huang et al., 2023; Zhao et al., 2020; Perlitz et al., 2023; Malinin and Gales,

2021). A high probability for the top sequence suggests strong confidence in a particular prediction, while a lower value indicates uncertainty.

This approach is effective for tasks with a single correct answer. However, it faces significant challenges when applied to tasks with multiple valid outputs, as in many generation tasks. In such cases, a low top probability may not reflect a lack of confidence but rather that the model has identified several valid sequences (See Figure 1). Ideally, for open-ended tasks, a confident model would distribute high probabilities across multiple good sequences while assigning lower probabilities to less suitable options, while in classification, confidence can be indicated by a single high top probability.

To address this limitation, we propose new probability-based confidence estimation methods that consider the probabilities of multiple sequences instead of focusing solely on the top one. We introduce two methods: the first calculates the probability ratio between the highest-ranked sequences and the rest, while the second evaluates the thinness of the distribution’s tail. Our experiments demonstrate that these metrics outperform existing baselines across three open-ended text generation tasks: translation, QA, and summarization.

2 Related Work

Probability-Based Methods These methods rely on the model outputs to compute token-level probabilities or entropy (Murray and Chiang, 2018; Zablotskaia et al., 2023; Zhao et al., 2020; Perlitz et al., 2023; Kumar and Sarawagi, 2019; Huang et al., 2023; Malinin and Gales, 2021). Other work uses natural language inference models to group similar sequences before computing entropy (Lin et al., 2023; Kuhn et al., 2023; Nikitin et al., 2024).

Similarity/Disagreement Based Methods When answers can be sampled from models (e.g., through dropout), self-consistency can be used

Figure 1: We illustrate the difference in interpretation of confidence in classification vs generation. Suppose a model generated output probability distributions for four different inputs; each bar is the prob. assigned to one class/sequence. In classification, only the 1st output would show model confidence, as it assigned most probability to one class. In generation, the first 3 outputs *could* show confidence because multiple sequences were valid.

to measure confidence: consistency across the top answers indicates confidence while variance indicates uncertainty (Xiao et al., 2020; Schmidt et al., 2022; Lakshminarayanan et al., 2017).

Fine-Tuning Based Methods In addition, other methods also fine-tune additional models to predict the correctness or confidence of the output (Yaldiz et al., 2024; Kamath et al., 2020; Malinin et al., 2019; Fathullah et al., 2023).

Out of Distribution Detection (OOD) Methods OOD can also be used to detect if a sample is in the training distribution, in which case a model is assumed to be confident (Liu et al., 2020; Vazhentsev et al., 2023).

Verbalized Confidence Scores With the increased conversational ability of LLMs, recent work prompts the model to give a confidence score with its answer (Lin et al., 2022; Tian et al., 2023; Kapoor et al., 2024; Han et al., 2024).

Our work is closest to the probability-based methods; they are easily adaptable and task agnostic. They do not require metrics or NLI models to measure similarity, computation for OOD detection, or models that can verbalize their confidence.

3 Method

Problem Definition We define confidence as a score computed using the model outputs, that describes its assessment of its prediction quality. We want to compute the model’s sample-level confidence for its output, that is positively correlated (i.e. calibrated) to the output’s quality, measured by the evaluation metric used for the task (e.g. automated

metrics, human evaluation). Formally,

$$\text{Confidence}(x, \hat{y}, \phi) \propto \text{Quality}(y, \hat{y}),$$

where x is the input, y is the target, \hat{y} is the prediction, and ϕ are the model parameters.

At inference time, we run beam search to generate N sequences. Each sequence’s probability is obtained by taking the product of the individual token probabilities. Given the i -th beam $\hat{y}^{(i)}$:

$$p_{\hat{y}^{(i)}}(x) = \prod_t p(\hat{y}_t^{(i)} | \hat{y}_{<t}^{(i)}, x)$$

Methods We account for the fact that there can be multiple valid outputs by measuring two characteristics that we hypothesize are present in all confident outputs regardless of the number of valid sequences (See Figure 2). The first characteristic of a confident model is that it distinguishes good from average or bad sequences, and subsequently assigns higher probability to a select set of sequences it deems as good compared to other sequences.

Ratio This motivates the ratio method: we measure how much more confident the model is in one of its *best* beams $p_{\hat{y}^{(1)}}$, versus one of its *average* beams $p_{\hat{y}^{(k)}}$, where $p_{\hat{y}^{(1)}}$ to $p_{\hat{y}^{(k)}}$ are sorted in descending order. This captures the intuition that a confident model will assign more probability to its best sequence than to an average sequence, whereas an unconfident model would assign similar probabilities to them. We expect the optimal value of k to differ by task, as different tasks can have different levels of diversity in valid generation outputs. Hence, we tune k on a validation set, and report its performance on the test set in the results.

$$\text{Ratio}(x) = \frac{p_{\hat{y}^{(1)}}(x)}{p_{\hat{y}^{(k)}}(x)}$$

Figure 2: We hypothesize that a confident model’s output *would* have a steep slope and long tail; colors added for illustration purposes only.

Figure 3: Samples of distributions and their tail indices

The second characteristic of a confident model is that it will assign low probability to many *bad* sequences. Suppose each sequence is a “class” – in Figure 3B, 3C, and 3D, the right-most classes have very small probabilities, and hence have a “thin tail”; all three figures exhibit this property, regardless of how many *correct* sequences they have. In contrast, an unconfident output where all classes receive equal probability (Figure 3A) has a thick tail. We quantify this with the tail index.

Tail Thinness We adapt the tail index proposed by Huang (2024), originally designed to measure the thinness of statistical distributions. The higher the tail thinness, the thinner the tail.

$$\text{Tail Thinness}(x) = \sum_{i=1}^N p_{\hat{y}^{(i)}}(x)^2$$

This sums the squared sequence probabilities for all N sequences generated using beam search. Because the probabilities for N sequences do not sum to 1, we first normalize them using softmax. We report the temperature used in Appendix A. Applying this to Figure 3, the uniform distribution (Fig A) gets a small tail thinness, while a degenerate distribution (Fig B) has the highest tail thinness. The metric also assigns similar scores to distributions with similar tail thicknesses (Figs C and D). While

this performs similarly to sequence-level entropy (Appendix C), we use tail-thinness metric (Huang, 2024) as it better describes the shape of the tail for which we have formulated our assumptions.

4 Experiments

Fine-tuning and Inference We first perform supervised fine-tuning (SFT) with BART Base (Lewis et al., 2019) or Flan-T5 Base (Chung et al., 2022), both relatively small models with no prior ability to verbalize confidence (Appendix A). After SFT, we generate the confidence scores for the test set. We get the sequence probabilities the top $N = 100$ sequences, using beam search from HuggingFace (Wolf et al., 2020), and replicate the baselines.

Evaluation We compute the Spearman correlation between the confidence scores and the quality scores, similar to analyses by Zablotskaia et al. (2023); Malinin and Gales (2021). We evaluate the top beam against the reference using ROUGE-L (Lin, 2004) for summarization, BLEU (Papineni et al., 2002) for translation, or F1 for question answering, and test for statistical significance with a bootstrap test (Berg-Kirkpatrick et al., 2012).

Baselines We report the equations that we replicate from previous literature, shown in Table 1.

For the probability based methods (Rows 1-4), we compute (1) ATP: average token probability for the top sequence (Murray and Chiang, 2018; Zablotskaia et al., 2023), (2) ATE: average token entropy for the top sequence (Zhao et al., 2020; Perlitz et al., 2023), (3) DAE: dropout-based average token entropy across 10 outputs (Eq 1) (Malinin and Gales, 2021), and (4) WTP: weighted average of the top-K sequences’ average token log probabilities (Eq 2) (Malinin and Gales, 2021).

For the similarity/disagreement based methods (Rows 5-7), we use dropout and sample 10 outputs per instance. We compute the (1) DSM: dropout similarity using METEOR (Eq 3) (Schmidt et al., 2022), (2) DVB: dropout variance using BLEU (Eq 4) (Xiao et al., 2020), and (3) DVK: dropout variance between token probabilities using KL divergence (Eq 5) (Lakshminarayanan et al., 2017).

$$\text{Conf}_{\text{DAE}} = \frac{1}{10} \sum_{i=1}^{10} \frac{1}{|\hat{y}^{(i)}|} \sum_{t=1}^{|\hat{y}^{(i)}|} \mathcal{H} \left(p(\hat{y}_t^{(i)} | \hat{y}_{<t}^{(i)}, x) \right) \quad (1)$$

$$\mathcal{H} \left(p(\hat{y}_t^{(i)} | \hat{y}_{<t}^{(i)}, x) \right) = - \sum_{j=1}^{|\mathcal{V}|} p(\hat{y}_{t,j}^{(i)} | \hat{y}_{<t}^{(i)}, x) \log \left(p(\hat{y}_{t,j}^{(i)} | \hat{y}_{<t}^{(i)}, x) \right)$$

$$\text{Conf}_{\text{WTP}} = - \sum_{i=1}^{10} \pi_i \left(\frac{1}{|\hat{y}^{(i)}|} \ln(p(\hat{y}^{(i)})) \right) \quad (2)$$

$$\pi_i = \frac{\exp\left(\frac{1}{|\hat{y}^{(i)}|} \ln(p(\hat{y}^{(i)}))\right)}{\sum_{j=1}^{10} \exp\left(\frac{1}{|\hat{y}^{(j)}|} \ln(p(\hat{y}^{(j)}))\right)}$$

$$\ln(p(\hat{y}^{(i)})) = \sum_{t=1}^{|\hat{y}^{(i)}|} \ln(p(\hat{y}_t^{(i)} | \hat{y}_{<t}^{(i)}, x))$$

$$\text{Conf}_{\text{DSM}} = \frac{\sum_{i=1}^{10} \sum_{j=1}^{10} \text{Meteor}(\hat{y}^{(i)}, \hat{y}^{(j)})}{N(N-1)} \quad (3)$$

$$\text{Conf}_{\text{DVB}} = \sum_{i=1}^{10} \sum_{j=1}^{10} (1 - \text{BLEU}(\hat{y}^{(i)}, \hat{y}^{(j)}))^2 \quad (4)$$

$$\text{Conf}_{\text{DVK}} = \sum_{i=1}^{10} KL(p(\hat{y}^{(i)} | x), p_{\bar{y}}) \quad (5)$$

$$\bar{y}_{\text{prob}} = \frac{1}{10} \sum_{i=1}^{10} p(\hat{y}^{(i)} | x)$$

Where $\hat{y}^{(i)}$ is the decoded sequence i sampled by activating dropout, $\hat{y}_t^{(i)}$ is the t -th output token for sequence i , and $\hat{y}_{t,j}^{(i)}$ is the j -th vocabulary at position t for sequence i .

Datasets We test on **Translation** (1) WMT 2017 English-German (Bojar et al., 2017), (2) WMT 2017 English-Russian (Bojar et al., 2017), (3) FLORES (Filipino Set) (NLLB, 2022), **Question Answering** (1) SQUAD (Rajpurkar et al., 2016), (2) HotpotQA (Yang et al., 2018), **Summarization** (1) DebateSumm (Roush and Balaji, 2020), (2) Reddit-TiFu (Kim et al., 2018), (3) XSUM (Narayan et al., 2018), (4) CNN-DailyMail (See et al., 2017)

5 Results

We report the correlation between the evaluation metric and confidence scores in Table 1 (See Appendix A for details). For BART, our methods achieve better correlation on 6 out of 9 datasets. We see larger gains in translation and question answering, as compared to summarization. The tail thinness method generally yields larger improvements (up to +17.2%) than the ratio method (up to +16.1%). For Flan-T5, our methods also achieve better correlation on 4 out of 9 datasets. Like for BART, we observe larger improvements using the tail thinness (up to +10.0%) method than the ratio based method (up to +8.3%). Overall, our methods yield the best performance more frequently than previous methods across all dataset-model pairs (tail thinness: 10/16, ratio: 8/16, DSM: 4/16), with median rankings of 2 and 3 for the tail and ratio methods (next being ATP, rank 4).

Robustness to Multiple Valid Sequences Qualitatively, we find that our methods assign high confidence to outputs where there are multiple valid sequences. We look at examples where our metrics assigned high confidence, but other methods like average token log probability assigned low confidence (See Figure 4). In these examples, there were indeed multiple, correct outputs; this resulted in lower probability for the top beam (2nd and 3rd image). If we only used the top beam’s probability to measure confidence, we might conclude that the model is unconfident. In contrast, our methods which rely on the ratio of sequence probabilities and tail thinness, rather than the top probability, are able to correctly identify that the model is still confident in such scenarios. This illustrates how using features of the distribution like slope or tail thinness can be more indicative of confidence in text generation, rather than solely looking at the features of the top output.

Failure Cases We examine samples for which the confidence scores are not well calibrated. Looking at the FLORES (Filipino) for Flan-T5, we observed samples where the model was confident, but its output was bad. Here, the model failed to translate a few key terms, which changed the meaning of the sentence (See Table 6). Other times, the confidence scores were well calibrated, but the quality score was not estimated well. This stemmed from noisy labels or limitations of the evaluation metric (See Table 7) which may require future work.

Choice of k In general, open ended tasks (translation, summarization) benefited from larger values for k , and close-ended tasks (QA) from smaller values of k (See Figure 5). One explanation for this could be that k serves as a parameter which delineates the *good* vs. *average* sequences. Finding the k that best separates the two groups allows us to most accurately measure the difference in confidence between both groups. Open-ended tasks can have more good sequences, hence correlation is maximized when we choose a higher value for k . In contrast, close-ended tasks have fewer good sequences, so a lower value for k is better.

We note that the optimal value for k may be very large for open-ended tasks like summarization. In our experiments, we capped k to 100 due to computational limitations, which may have underestimated its optimal value, and thus explain why our methods are less competitive than the baselines.

Table 1: Spearman correlation (absolute value) between confidence score and evaluation metric/quality score (BLEU for translation, F1 for QA, RougeL for summarization); Bt: BART, FT5: Flan-T5, stars indicate significant difference from next best method (bootstrap test, $\star\alpha = 0.10$, $\star\alpha = 0.05$)

Figure 4: Samples from SQUAD (Rajpurkar et al., 2016); 1st image only has one valid output, whereas the 2nd and 3rd have multiple; our tail-thinness and ratio based confidence correctly assign high confidence to all samples, but avg. log prob. only assigns high confidence to the first image (Note: The y-axis is plotted on the log scale)

Figure 5: Spearman Correlation vs k on test set for BART (top row) and Flan-T5 (bottom row); In general, open-ended tasks (summarization: A-C, translation: D-F) benefit from larger k , close-ended tasks (QA: G-H, Reddit: I) use smaller k

6 Conclusion

We identified characteristics of output distributions from a confident model in generation tasks, and used this to propose metrics that capture these characteristics. We find that on various datasets, these characteristics are better correlated to quality metrics than previous methods.

There are various directions future work can take to improve the computation and evaluation of confidence scores. For example, we observed that models can be overly confident in wrong answers (Table 6), which can lead to miscalibration when using our methods. Future work can study the reasons for model overconfidence, and propose ways

to reduce or account for this. In addition, more work is required to improve the evaluation of calibration in generation tasks. Concretely, calibration is well defined for classification tasks when there is a binary outcome, and metrics like expected calibration error (Tian et al., 2023) measure whether the model’s confidence scores match its accuracy (e.g. A model should be right in 90% of the examples for which it claimed to be 90% confident). More work can be done to develop metrics that capture a similar notion of calibration in generation tasks where the outcome is continuous.

Limitations and Potential Risks

One limitation is that our methods require users to compute k beams, both when tuning hyperparameters, and at inference time. This can be computationally expensive, especially for open-ended tasks where the optimal value of k may be large. Hence, future work may find more efficient ways of estimating the confidence.

Another caveat is that we only evaluate the performance of our methods on a limited set of models and parameters. For example, we fine-tuned various models with early stopping. Hence, future work which seeks to use these methods must re-evaluate the scores on their tasks, to avoid deploying miscalibrated confidence scores in practical settings.

Finally, future work could study better ways to evaluate confidence scores; we found that traditional evaluation metrics may lead to poor quality ratings, and it was difficult to find datasets with human evaluation scores to use.

Acknowledgements

We would like to thank Ines Arous, Ziling Cheng, Zichao Li, and Caleb Moses for providing useful writing feedback, and David Austin, Cesare Spinoso-di Piano, and Xiyuan Zou for engaging in productive discussions as we developed the paper. We also thank NVIDIA for their support in terms of computational resources. This work was also supported in part by the IVADO Postdoctoral Fellowship.

A Implementation Details

All models were fine-tuned on one NVIDIA A100 GPU, with a constant learning rate $5e-5$, and batch size of 10. The scripts and fine-tuned models are provided in the repository. Roughly 80 hours were used to train and perform inference on one GPU.

During SFT, we train for at most 3 epochs. We observe overfitting on many datasets, and remedy this by employing early stopping, where we stop training if the loss on the validation set does not improve after 2 steps. This was applied to all datasets except HotpotQA, WMT RU-EN, and DebateSumm. We report the number of SFT steps in Table 2.

Dataset	BART	Flan-T5
WMT DE-EN	200	200
WMT RU-EN	6000	6000

Table 3: Fine-Tuning Parameters for Various Tasks

B Dataset Details

Licenses The FLORES, SQUAD, and HotpotQA datasets were used under the Creative Commons Attribution Share Alike 4.0 license; DebateSumm, XSUM, and Reddit-TiFu used the MIT license, the CNN DailyMail dataset used Apache2.0, and WMT17 did not provide a license on the Hugging-Face platform.

Data Splits For training and inference efficiency, we only use subsets of the datasets in some cases. The scripts used to generate the datasets are provided in the repository. At a high level, we take and shuffle the original dataset, then generate a train and test split from that. We perform inference on the test set, for which we report the statistics in the results section. Note that because we employ early stopping, the full training set is not necessarily provided. The number of steps actually taken are reported in Appendix A.

C Analysis of Additional Baselines

In addition to the baselines from previous literature, we compare our method to two baselines that can

Dataset	Train	Val	Test
FLORES Filipino	900	97	1012
WMT DE-EN	2000	100	1000
WMT RU-EN	20000	100	1000
HotpotQA	89447	100	1000
SQUAD	87599	100	1000
DebateSumm	5000	100	1000
Reddit	2000	100	1000
CNN	2000	100	1000
XSUM	20000	100	1000

Table 4: Data Splits by Task

be viewed as straightforward methods of creating a confidence score, namely beam-level entropy (Eq 6) and the sum of the top- k beam probabilities (Eq 7), and report the results in Table 5.

Overall, we find that the performance of the tail method is similar to that of beam-level entropy, although the original tail method performs slightly better in multiple cases.

As for the Top-K baseline, both our ratio and tail methods outperform it on translation and QA tasks for BART, and on QA, English-Russian, DebateSumm, and XSum for T5. However, it underperforms top-K on other tasks, particularly in summarization, which is similar to our findings for the WTP method presented in the main paper.

$$p(\hat{y}^{(i)}) = \sum_{t=1}^{|\hat{y}^{(i)}|} p(\hat{y}_t^{(i)} | \hat{y}_{<t}^{(i)}, x)$$

$$p_{\text{softmax}}(\hat{y}^{(i)}) = \frac{\exp(p(\hat{y}^{(i)}))}{\sum_{j=1}^k \exp(p(\hat{y}^{(j)}))}$$

$$\text{Conf}_{\text{Beam Entropy}} = - \sum_{i=1}^k p_{\text{softmax}}(\hat{y}^{(i)}) \ln(p_{\text{softmax}}(\hat{y}^{(i)})) \quad (6)$$

$$\text{Conf}_{\text{Top K Probs}} = \sum_{i=1}^k p(\hat{y}^{(i)}) \quad (7)$$

D Failure Case Examples

We provide examples of cases where there is miscalibration, either due to actual model miscalibration (Table 6), or due to issues with the evaluation strategy (Table 7).

The couple, who met as partners on Dancing on Ice, enjoyed a Bateaux New York Cruise of the Hudson... We were wondering who was going to emerge when out stepped Lady Gaga. It was the ultimate holiday treat - it was just a shame I couldn't arrange a selfie with her. That would have been the icing on the cake. American Sky (0843 636 2001) offers a three-night holiday to New York from £899pp. This includes accommodation in the JW Marriott Essex House New York on a room-only basis and return flights with British Airways from Heathrow. Visit [nycgo.com](#) for more information

Prediction: My first trip to New York was with my aunt when I was about 18 and I had been appearing in Coronation Street for about 12 months. We had a lot of fun together - we went to see the musical Chicago on Broadway and did lots and lots of shopping. We returned to the city that never sleeps in January 2001, eight months before the terrible events of 9/11, and one of the first things my boyfriend Sylvain Longchambon and I did on my latest trip was to visit the site of the World Trade Center to see the monument to those who died.

Target: Samia Ghadie and boyfriend Sylvain Longchambon spent four days in NYC. While there the Dancing on Ice stars stayed at the JW Marriott Essex House. Their suite on the 31st floor offered up panoramic views of Central Park. The couple enjoyed a three-hour Bateaux New York cruise on the Hudson. The confirm Burger Joint in Le Parker Meridien Hotel lives up to the hype.

Bad Output Rated as Good: Repeated Phrase

Source: SOURCE: An exotic animal owner from Ohio is campaigning for his bear and big cats to be returned after they were seized by the state in January. In total, six tigers, a bear, a lion, a cougar, a black leopard and a liger (part lion, part tiger) were taken from Kenny Hetrick's Stony Ridge farm after it was found he did not have the correct permit and cages were 'unsafe'. Authorities have also started cracking down on the owners of wild creatures following an incident in 2011 where a man in eastern Ohio released 56 exotic animals - including lions and tigers - then killed himself. Apparently Hetrick has been heartbroken by the clampdown on his farm and the 72-year-old widower is now fighting to overturn the seizure, ... 'He's lost without them,' said Josh Large, who lives four houses away...

Prediction: In total, six tigers, a bear, a lion, a cougar, a black leopard and a liger were taken from Kenny Hetrick's Stony Ridge farm. In total, six tigers, a bear, a lion, a cougar, a black leopard and a liger were taken from Kenny Hetrick's Stony Ridge farm after it was found he did not have the correct permit and cages were 'unsafe'. Authorities have also started cracking down on the owners of wild creatures following an incident in 2011 where a man in eastern Ohio released 56 exotic animals - including lions and tigers - then killed himself. Hetrick has been heartbroken by the clampdown on his farm and the 72-year-old widower is now fighting to overturn the seizure, backed by neighbors who insist his menagerie doesn't pose a threat.

Target: In total, six tigers, a bear, a lion, a cougar, a black leopard and a liger (part lion, part tiger) were taken from Kenny Hetrick's Stony Ridge farm . State officials found he didn't have the right permit and cages were 'unsafe' But now the 72-year-old is fighting to overturn the seizure, backed by neighbors who insist his menagerie doesn't pose a threat . 'He's lost without them,' said Josh Large, who lives four houses away .

Abstract

Retrieval-Augmented Generation (RAG) systems show remarkable potential as question answering tools in the K-12 Education domain, where knowledge is typically queried within the restricted scope of authoritative textbooks. However, discrepancies between these textbooks and the parametric knowledge inherent in Large Language Models (LLMs) can undermine the effectiveness of RAG systems. To systematically investigate RAG system robustness against such knowledge discrepancies, we introduce **KNOWSHIFTQA**¹. This novel question answering dataset simulates these discrepancies by applying deliberate hypothetical knowledge updates to both answers and source documents, reflecting how textbook knowledge can shift. KNOWSHIFTQA comprises 3,005 questions across five subjects, designed with a comprehensive question typology focusing on context utilization and knowledge integration. Our extensive experiments on retrieval and question answering performance reveal that most RAG systems suffer a substantial performance drop when faced with these knowledge discrepancies. Furthermore, questions requiring the integration of contextual (textbook) knowledge with parametric (LLM) knowledge pose a significant challenge to current LLMs.

1 Introduction

In K-12 education, Question Answering (QA) systems serve as an important resource for learning assistance, where answers are precisely provided within a restricted knowledge scope from authoritative sources (i.e., textbooks) (Raamadhurai et al., 2019; Soares et al., 2021). Meanwhile, benefiting from the emergent abilities (Wei et al., 2022) of Large Language Models (LLMs) and advanced information retrieval (IR) methods,

^{*} Equal Contribution

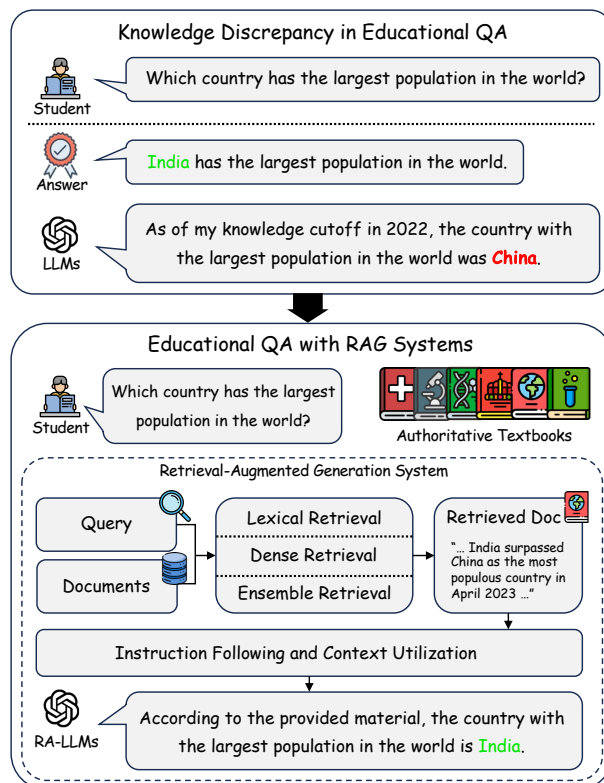

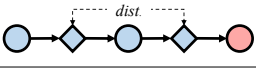

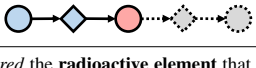

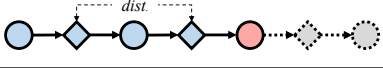

Figure 1: An illustration of knowledge discrepancy in educational QA and the application of RAG systems.

Retrieval-Augmented Generation (RAG) systems have achieved remarkable performance in various knowledge-intensive tasks in natural language processing (Lewis et al., 2020; Jiang et al., 2023; Gao et al., 2024), demonstrating their great potential as QA systems in K-12 education (Gan et al., 2023; Kasneci et al., 2023; Yan et al., 2024).

In K-12 educational QA, one of the primary concerns is ensuring that the knowledge conveyed in the answer is consistent with the officially designated textbooks (Extance, 2023). However, notable knowledge shifts (i.e. factuality discrepancies) may exist between the knowledge in textbooks and the internal knowledge of LLMs, due to the evolving nature of facts (Arbesman, 2012), updates in peda-

Question Type	Reasoning Pattern and Example Question	Hypothetical Knowledge Update
Simple Direct	 <p>What type of light is <i>detected</i> by night vision goggles?</p>	NV goggles - detect - Infrared light Ultraviolet Original: Infrared Light Updated: Ultraviolet Light
Multi-hop Direct	 <p>Which scientist <i>developed</i> an equation that can <i>calculate</i> the wavelength of a particle?</p>	de Broglie eq. - developed by - Louis de Broglie Maurice Original: Louis de Broglie Updated: Maurice de Broglie
Multi-hop Distant	 <p>Which pump <i>creates</i> an electrochemical gradient that <i>enables</i> secondary active transport to occur?</p>	Na⁺/K⁺ Pump - creates - EC Gradient Ca²⁺ Original: Sodium-potassium Pump Updated: Calcium Pump
Multi-hop Implicit	 <p>Who <i>discovered</i> the radioactive element that is commonly <i>found</i> in uranium ores?</p>	Polonium - found in - Uranium ores Thorium Original: Marie Curie Updated: Jöns Jacob Berzelius
Distant Implicit	 <p>Who <i>discovered</i> the organelle that is <i>responsible</i> for the biological process that <i>produces</i> ATP?</p>	Mitochondrion - conducts - Cellular respiration Golgi apparatus Original: Albert von Kölliker Updated: Camillo Golgi

Table 1: Five question types in KNOWSHIFTQA with their reasoning patterns, example questions, and hypothetical knowledge update illustrated in factual triplets and answers. In example questions, subjects and objects are marked in **bold**, while predicates are marked in *italic*.

gological approaches (Provenzo et al., 2011), as well as regional and cultural variations in content (Patel, 2015). It remains unclear whether RAG systems can robustly incorporate knowledge from authoritative sources and generate consistent answers under such knowledge discrepancies (scenario illustrated in Figure 1).

To fill this gap, we aim to systematically assess the robustness of RAG systems in performing question answering in K-12 education when encountering knowledge shifts. We present **KNOWSHIFTQA**, a new dataset containing 3,005 multiple-choice questions covering the subjects of Physics, Chemistry, Biology, Geography, and History from the middle-school curriculum. To simulate the factuality discrepancy between LLMs and textbooks, we conduct a *hypothetical knowledge update*, in which we modify the original factual knowledge from the textbooks into plausible alternatives while maintaining coherent and consistent context. Moreover, we tailored a comprehensive question typology to stress-test the *context utilization* and *knowledge integration* abilities of LLMs under such scenarios.

We conducted extensive experiments with various retrieval methods and LLMs. Our findings indicate that most RAG systems exhibit a considerable performance degradation under knowledge

shifts. Notably, while many LLMs can effectively incorporate distant contextual facts, they struggle to seamlessly integrate their parametric knowledge with this contextual information. In terms of retrieval, traditional lexical-based methods demonstrate advantages due to the specificity of academic terms; their performance can be further enhanced through an ensemble re-ranking mechanism. Supervised retrieval methods (e.g., Contriever), when fine-tuned directly on our dataset, yield superior performance. Overall, our results highlight the fragility of current RAG systems under knowledge shifts and the challenges LLMs face in effectively combining contextual and parametric knowledge for complex question answering.

2 The KNOWSHIFTQA Dataset

In this section, we introduce the methodology of hypothetical knowledge update and the design of our question typology. The curation pipeline and detailed statistics of the KNOWSHIFTQA dataset are provided in Appendix B and E, respectively.

2.1 Hypothetical Knowledge Update

One of the core objectives of our dataset is to simulate the knowledge discrepancy between LLMs and authoritative textbooks when performing educational QA. However, such discrepancies are often

fuzzy and highly sparse in real-world data, making it infeasible to collect and organize. Consequently, we designed the methodology of hypothetical knowledge update, performing it on high-quality open-source textbooks. The general procedures are as follows: 1) Curate factual questions from textbook paragraphs following our designed question typology. 2) Select a plausible but factually incorrect answer as the updated ground-truth answer. 3) Replace all occurrences of the original answer in the paragraph with the updated answer and adjusted other relevant statements in the context to ensure that the updated paragraph is coherent and consistent. This process is further guaranteed through extensive human curation and verification. Examples of hypothetical knowledge updates in our dataset are provided in Appendix D.

2.2 Question Typology

We identify two potential challenges for LLMs when performing QA under knowledge shifts: 1) *Context Utilization*: Whether LLMs can identify and utilize the corresponding facts from the context; and 2) *Knowledge Integration*: Whether LLMs can incorporate their own parametric knowledge with contextual facts in question answering. To this end, we designed our question typology, as illustrated in Table 1, to investigate such abilities. The two basic question types, *Simple Direct* and *Multi-hop Direct*, aim to evaluate LLMs on simple factual recall and multi-hop reasoning. Based on these two types, we developed the *Multi-hop Distant* type to evaluate the context utilization ability for distant facts from the passage, and the *Multi-hop Implicit*² type to evaluate the knowledge integration ability that combines their own factual knowledge with retrieved facts. Moreover, the *Distant Implicit* type poses a greater challenge by combining both features. To ensure our evaluation of knowledge integration ability is independent of knowledge coverage, we restrict the facts requiring LLMs’ own knowledge to be head-knowledge only (Sun et al., 2024).

3 Experiments and Analyses

Typically, RAG systems first conduct document retrieval based on given queries, then perform question answering with LLMs based on the retrieved information loaded in the context. In this section,

²The word ‘implicit’ indicates that the questions indirectly query the updated facts by embedding them within the middle of the multi-hop reasoning chain.

Retrieval Methods	Category	R@1	R@5
TF-IDF (Spärck Jones, 1972)	Lexical	65.82	88.72
BM25 (Robertson et al., 1994)	Lexical	82.73	95.27
SPLADE (Formal et al., 2021)	Lexical/Dense	78.04	90.12
Contriever (Izacard et al., 2022)	Dense	53.18	81.80
Con.-msmarco (Izacard et al., 2022)	Dense	76.17	93.54
Mistral-embed (Mistral, 2023a)	Dense	78.74	95.31
Ada-002 (OpenAI, 2022)	Dense	79.23	95.44
Query Rewrite (Ma et al., 2023)	Pre-Retrieval	78.87	94.21
Hybrid Rerank (BM25 + Ada-002)	Ensemble	<u>84.43</u>	<u>96.04</u>
Contriever (fine-tuned)	Dense+FT	<u>84.19</u>	<u>98.96</u>
Con.-msmarco (fine-tuned)	Dense+FT	87.95	99.50

Table 2: Document retrieval performances (in recall @1/5 %) of retrieval methods from different categories in the KNOWSHIFTQA dataset. The highest scores are marked as **bold**, while the 2nd and 3rd-best scores are underlined. The retrieval granularity is set to paragraph.

we comprehensively evaluate and analyze the performance of retrieval methods and LLMs on the KNOWSHIFTQA dataset. For details of all tested methods and models, please refer to Appendix C.

3.1 Retrieval Performance

Experimental results of the retrieval methods are presented in Table 2. Traditional lexical retrieval methods, such as BM25, demonstrated strong performance on our dataset, while dense retrieval methods, such as Mistral-embed and Ada-002, achieved comparable performance. Since our dataset focuses on the K-12 education domain, lexical retrieval effectively captures domain-specific keywords in the queries and identifies the corresponding documents. This characteristic underscores the need for fine-tuning dense retrieval models on our dataset. To this end, we fine-tuned both Contriever and Contriever-msmarco on our documents, resulting in significant improvements and highlighting the importance of corpus-specific fine-tuning in educational document retrieval.

Moreover, ensemble methods have demonstrated their effectiveness in various information retrieval tasks (Thakur et al., 2021). We implemented a hybrid approach that retrieves the top k^3 documents with Ada-002, followed by re-ranking with BM25. This ensemble method marginally improved the retrieval performance in both metrics. Conversely, query rewriting⁴ (Ma et al., 2023) implemented upon BM25 did not yield performance gains. Detailed results across subjects and question types are provided in Appendix F.

³We use $k = 6$ as the optimal hyperparameter setting.

⁴We use Mistral-small-2409 as the LLM query rewriter.

Large Language Models	Question Typology					Average
	<i>Simple Direct</i>	<i>Multi-hop Direct</i>	<i>Multi-hop Distant</i>	<i>Multi-hop Implicit</i>	<i>Distant Implicit</i>	
Mistral-7b (Mistral, 2023b)	77.70	69.31	72.74	45.32	33.98	61.26
Mixtral-8x22b (Mistral, 2023c)	84.10	84.58	87.15	73.86	65.37	79.67
Mistral-small-2409 (Mistral, 2024a)	87.87	88.70	89.69	72.18	60.81	80.77

o1-mini (OpenAI, 2024b)	<u>95.90</u>	95.73	<u>97.03</u>	85.85	<u>75.45</u>	<u>90.55</u>
o1-preview (OpenAI, 2024b)	95.08	97.71	97.46	86.33	78.86	91.68

Table 3: Question answering performances (in accuracy %) of LLMs in the KNOWSHIFTQA benchmark with corresponding documents provided. The highest scores are marked as **bold**, while the 2nd and 3rd-best scores are underlined. All LLMs are tested under zero-shot settings, with a *Locate-and-Answer* prompting approach that facilitates active information acquisition from contextual documents, with details in Appendix G.

RAG System	Hypothetical Knowledge Update		Drop
	Before	After	
Llama3-8b + Ada-002	87.49	62.60	24.89
Llama3-8b + Rerank	88.49	66.02	22.47
GPT-4o + Ada-002	96.57	69.65	26.92
GPT-4o + Rerank	97.10	73.71	23.39

Table 4: Performance drop of RAG systems with hypothetical knowledge updates in our benchmark.

3.2 Question Answering Performance

Experimental results of LLMs in question answering are presented in Table 3. Most LLMs exhibited comparable performance for question types *Simple Direct*, *Multi-hop Direct*, and *Multi-hop Distant*. This suggests that **both multi-hop reasoning and distant context utilization do not pose significant challenges for modern LLMs**. However, for *Multi-hop Implicit* questions, which requires the integration of contextual and internal knowledge, a substantial performance disparity emerges between smaller open-source LLMs and advanced models. This disparity is further amplified for *Distant Implicit* questions, where the reasoning chains are getting more complexed. The most capable model we tested, o1-preview, attains over 80% accuracy on *Implicit* questions, whereas Mistral-7b’s performance falls below 40%. These findings indicate that **context-memory knowledge integration is an emergent capability presenting greater difficulties for LLMs under knowledge discrepancies**, particularly when coupled with the need for distant context utilization.

3.3 Overall Performance

How do knowledge shifts affect the performance of RAG systems in educational question-answering applications? To answer this question, we selected two representative LLMs: Llama3-8b from open-source models and GPT-4o from proprietary models. These were combined with two high-performing retrieval methods: Ada-002 and hybrid rerank. The resulting RAG systems were tested on questions *before* and *after* hypothetical knowledge updates, with the results presented in Table 4. We observed a significant accuracy drop of 22–27% after these knowledge shifts, indicating substantial performance degradation in modern RAG systems when faced with such scenarios.

4 Related Work

Retrieval-Augmented Generation Following the categorization by Gao et al. (2024), the RAG methods employed in our experiment fall into the categories of *Naive RAG* (lexical, dense) and *Advanced RAG* (rerank, rewrite). Recently, *Modular RAG* has emerged to enhance the adaptability and versatility of RAG systems (Shao et al., 2023; Asai et al., 2023). Furthermore, recent advances in vector databases (Han et al., 2023) and neural graph databases (Bai et al., 2025) highlight the potential for adaptive and generalizable RAG search with structured data (Deng et al., 2024).

Educational Question Answering Prior to the emergence of RAG systems utilizing LLMs, various educational QA systems were developed to provide pedagogically appropriate responses to student inquiries (Abdi et al., 2018; Agarwal et al., 2019). While recent literature explores LLM applications in QA and learning assistance roles (Nye et al., 2023; Kuo et al., 2023; Wang et al., 2024), it is also crucial to leverage logical inference abilities, such as abductive reasoning (Bai et al., 2024; Yim et al., 2024; Zheng et al., 2025b) and inductive reasoning (Qiu et al., 2024; Li et al., 2025; Zheng et al., 2025a), for understanding students’ learning outcomes in response to their queries.

Knowledge Discrepancy in LLMs Mitigating knowledge discrepancies or conflicts within LLM applications is a fundamental challenge in LLM research (Xu et al., 2024). Researchers have proposed tuning-based (Li et al., 2022) and prompting-based (Zhou et al., 2023) methods to enhance LLMs’ robustness to such conflicts. However, the implications of these conflicts in educational applications and RAG systems remain relatively under-explored. Moreover, it is important to consider the trade-off between factuality robustness (Yu et al., 2024; Zong et al., 2024; Zheng et al., 2025c) and flexibility in instruction following when such discrepancies are present.

5 Conclusion

This paper systematically evaluates the robustness of RAG systems in K-12 educational question answering under knowledge discrepancies using a comprehensive dataset KNOWSHIFTQA. Experimental findings reveal substantial performance degradation in RAG systems when faced with knowledge discrepancies, which is primarily attributed to deficiencies in incorporating contextual and parametric knowledge in question answering—an emergent and challenging ability for modern large language models.

Limitations

We discuss three main limitations of our work.

First, KNOWSHIFTQA employs the approach of hypothetical knowledge updates to effectively simulate real-world knowledge discrepancies for two primary reasons: (1) Real-world knowledge conflicts are often sparse, noisy, and difficult to systematically collect or organize into a cohesive

dataset suitable for large-scale evaluation. Hypothetical updates provide a scalable and controlled alternative, allowing us to bypass these limitations. (2) By leveraging a systematic annotation and curation pipeline, we can generate questions with diverse and well-defined reasoning patterns that align with our typology, enabling more robust evaluation of complex question-answering tasks. For future research centered on real-world knowledge discrepancies, we recommend an alternative methodology that incorporates temporal attributes (Chen et al., 2021; Zhang and Choi, 2024). This approach focuses on identifying outdated facts and capturing time-sensitive data (e.g., economic trends, annual events, or societal changes) to construct datasets that reflect real-world knowledge updates. While promising, this method is constrained by the limited overlap between time-sensitive data—often numerical or attribute-specific—and the broader contextual needs of educational question-answering tasks, which may reduce the comprehensiveness of the resulting datasets.

Next, regarding document retrieval, some recent hierarchical retrieval paradigms, such as GraphRAG (Edge et al., 2024) and HippoRAG (Gutiérrez et al., 2024), are not included in our experiments due to their implementation complexity. However, we believe that such structured paradigms could effectively enhance retrieval performance in our scenario, as educational documents are well-structured and contain high-quality factual knowledge.

Finally, this paper primarily evaluates the robustness of RAG systems in the proposed scenario, with experiments conducted using various retrieval methods and large language models. Potential improvements could be achieved through the design of tailored reasoning frameworks via prompting, in-context learning or alignment in LLMs, which we leave for future research.

Ethics Statement

In constructing the KNOWSHIFTQA dataset, we collected text from open-access textbooks. Detailed sources and licenses are provided in Appendix A. The human curation and verification in our annotation pipeline were carried out by a group of postgraduate students with extensive experience in NLP research. We ensured that the updated knowledge is free from harmful or toxic content. It is important to note that our dataset

is designed solely to evaluate the robustness of Retrieval-Augmented Generation systems under scenarios with knowledge discrepancies and is not suitable for assessing the factual accuracy of QA systems.

Figure 3: An overview of the data curation pipeline of the KNOWSHIFTQA dataset.

B Curation Pipeline

The curation pipeline of our dataset is illustrated in Figure 3. We first perform triplet extraction on the textbook documents and generate a document-level knowledge graph (KG). Next, we perform sub-graph matching based on fixed reasoning patterns to sample candidate queries, and selectively transform them into natural language questions. Then, hypothetical knowledge update is executed and verified to guarantee consistency between the updated answer and the document.

Context-focused question types, including *Simple Direct*, *Multi-hop Direct*, and *Multi-hop Distant*, are acquired through this process. For *Multi-hop Distant* questions, we leverage distant facts, defined as connected triplet pairs that are separated in the document’s sequential ordering. These questions are only assigned to documents containing no fewer than 200 words. To generate the other two *Implicit* question types that require knowledge integration, we perform extra QA augmentation followed by an expert verification process. The design of our question typology is motivated by studies in complex logical reasoning (Bai et al., 2023; Zheng et al., 2024, 2025d).

Our data curation process is performed through an integrated framework involving both human annotators and LLMs. For LLM annotation, we adopted Claude-3.5-Sonnet for its outstanding instruction-following ability. Following manual verification, 90.5% of these queries were retained or underwent minor refinements to become high-quality questions, yielding an overall success rate of 86.4%. The total API cost for data annotation is approximately 300 USD.

C Model Details

In this section, we briefly introduce all tested retrieval methods and large language models in our benchmark experiment.

In the retrieval stage of our experiments, we employ a diverse range of retrieval methods. For traditional lexical retrieval, we include **TF-IDF** (Spärck Jones, 1972), which vectorizes documents and queries based on term frequency and inverse document frequency, and **BM25** (Robertson et al., 1994), which enhances TF-IDF with document length normalization and probabilistic term weighting. We also incorporate **SPLADE** (Formal et al., 2021), a method that bridges lexical and dense retrieval paradigms. For dense retrieval, we evaluate several methods that encode questions and documents into the same vector space: **Contriever** (Izacard et al., 2022), an unsupervised text encoder; its fine-tuned variant **Contriever-msmarco**, which we further enhanced by applying contrastive learning (Izacard et al., 2022) to fine-tune both models on the KNOWSHIFTQA dataset for improved retrieval capability; and two closed-source embedding models, **Mistral-embed** (Mistral, 2023a) and **Ada-002** (OpenAI, 2022). Additionally, we explore a pre-retrieval method, **Query Rewrite** (Ma et al., 2023), which reformulates queries to improve retrieval performance. Finally, we implement a **Hybrid Rerank** approach that combines BM25 and Ada-002, leveraging the strengths of both lexical and dense retrieval methods.

In our evaluation, we employ a diverse set of state-of-the-art large language models to assess their performance across various tasks. The models include: Mistral AI’s open-source models, ranging from

Original Paragraph	... The halophiles, which means "salt-loving", live in environments with high levels of salt. They have been identified in the Great Salt Lake in Utah and in the Dead Sea between Israel and Jordan, which have salt concentrations several times that of the oceans. ...
Updated Paragraph	... The halophiles, which means " <i>pressure</i> -loving", live in environments with high levels of <i>pressure</i> . They have been identified in the <i>Mariana Trench</i> in <i>western Pacific Ocean</i> , which have higher <i>pressure</i> than other environments. ...
Question	In which type of environments do halophiles typically live? A. High Acidity Environments. B. High Salt Environments. C. High Pressure Environments. D. High Sugar Environments.
Original Answer	B. High Salt Environments.
Updated Answer	<i>C. High Pressure Environments.</i>

Table 5: An example of hypothetical knowledge update for a question in Biology. The modifications of factual knowledge and contextual information in the paragraph are highlighted in *red*.

the compact **Mistral-7b** (Mistral, 2023b) to the more advanced MoE model **Mixtral-8x22b** (Mistral, 2023c), and their latest iterations **Mistral-small-2409** (Mistral, 2024a) and **Mistral-large-2407** (Mistral, 2024b). Google’s Gemini models are represented by **Gemini-1.5-flash** (Google, 2024a) and **Gemini-1.5-pro** (Google, 2024b). Meta’s **Llama3** series is included with both 8b and 70b parameter versions (Meta, 2024). We also evaluate OpenAI’s models, including **GPT-3.5-turbo** (OpenAI, 2022), **GPT-4** (OpenAI, 2023a), **GPT-4-turbo** (OpenAI, 2023b), and **GPT-4o** (OpenAI, 2024a). Anthropic’s LLMs are represented by **Claude-3-sonnet** (Anthropic, 2024a) and **Claude-3.5-sonnet** (Anthropic, 2024b). Lastly, we include OpenAI’s latest o1 series, **o1-mini** and **o1-preview** (OpenAI, 2024b), which achieve remarkable performance across various metrics through inference-time scaling. This comprehensive selection allows us to compare a wide range of model architectures and sizes, providing valuable insights into the current state of LLM capabilities.

D Dataset Example

We provide an example question and its corresponding paragraph before and after hypothetical knowledge update in Table 5.

E Dataset Statistics

The statistics for the documents and questions in the KNOWSHIFTQA dataset are provided in Table 6 and Table 7, respectively.

Document Statistics	Subjects					Total
	<i>Chem.</i>	<i>Bio.</i>	<i>Phys.</i>	<i>Geo.</i>	<i>Hist.</i>	
Average Document Length	315.5	588.1	647.3	429.8	277.1	437.3
Num of Documents	291	671	166	471	606	2205

Table 6: Average length (in word counts) and quantities of documents in different subjects.

# Questions (avg. length)	Question Types					Total
	<i>Simple Direct</i>	<i>Multi-hop Direct</i>	<i>Multi-hop Distant</i>	<i>Multi-hop Implicit</i>	<i>Distant Implicit</i>	
Chemistry	73 (12.4)	88 (17.8)	78 (17.9)	40 (17.4)	68 (21.1)	347 (17.3)
Biology	148 (11.1)	170 (16.7)	248 (16.7)	94 (16.7)	213 (20.7)	873 (16.7)
Physics	46 (12.0)	49 (16.7)	49 (15.6)	41 (16.9)	39 (19.9)	224 (16.1)
Geography	141 (12.1)	147 (16.7)	162 (16.8)	96 (17.7)	144 (21.3)	690 (16.9)
History	202 (12.8)	201 (16.1)	171 (17.0)	146 (18.1)	151 (21.6)	871 (16.8)
Total	610 (12.1)	655 (16.7)	708 (16.9)	417 (17.5)	615 (21.0)	3005 (16.8)

Table 7: Average question length (in word counts) and quantities of questions in different subjects and types.

F Result Details

The comprehensive evaluation results for retrieval approaches and large language models across various subjects and question types are presented in Table 8 and Table 9, respectively. We observed that the performance of lexical retrieval methods correlates positively with question length, while dense retrieval methods exhibit an inverse relationship. This finding suggests that there is potential for developing more sophisticated ensemble methodologies that could fully leverage the strengths of both approaches.

Retrieval Methods	Subjects					Question Types					Average
	<i>chem.</i>	<i>bio.</i>	<i>phys.</i>	<i>geo.</i>	<i>hist.</i>	<i>Sim. Dir.</i>	<i>Mul. Dir.</i>	<i>Mul. Dis.</i>	<i>Mul. Imp.</i>	<i>Dis. Imp.</i>	
BM25	87.90	84.65	74.55	78.26	81.52	79.34	85.04	86.30	75.78	84.23	82.73
Mistral-embed	84.73	77.09	83.48	73.48	80.94	82.13	79.08	79.38	80.81	72.85	78.74

GPT-4-turbo	85.30	89.23	86.16	90.00	90.13	95.74	96.18	96.19	81.06	71.71	88.99

Table 9: Performance (in accuracy %) of LLMs in question answering in different subjects and question types.

G Prompting Approach

In our experiments, we adopt the prompting approach of *Locate-and-Answer*, to facilitate active acquisition of information in the context when performing question answering. We first request LLMs to identify and locate the corresponding sentence that include the knowledge for the question from the provided document, and then reason to provide its answer. According to the experimental result in Table 10, this prompting approach can effectively improve the QA performance of LLMs compared to direct answering.

Model	Prompting Method	
	Direct Answer	Locate-and-Answer
Gemini-1.5-flash	75.21	78.54
GPT-3.5-turbo	73.91	81.73
GPT-4o	80.43	87.09

Table 10: Performance (in accuracy %) of LLMs in question answering with different prompting methods.

H Calibration, Parametric Knowledge, and Instruction Following in RAG Systems

In our study, retrieved documents serve as the unequivocal reference, mirroring the pedagogical approach in K-12 education where textbooks are authoritative. However, our evaluation results reveal counterintuitive performance patterns in state-of-the-art LLMs, particularly concerning simple direct questions. Stronger models, such as GPT-4 and GPT-4o, occasionally underperform compared to weaker ones on these questions, which primarily assess direct factual recall from the provided (and hypothetically updated) context. This suggests that the calibration of these advanced LLMs might lead them to exhibit excessive confidence in their internal, parametric knowledge, thereby inhibiting their consistent reliance on the external documents explicitly provided as the ground truth for the task.

This observation highlights a critical tension inherent in RAG systems: the trade-off between an LLM’s adherence to its ingrained parametric knowledge (what might be termed its internal "factuality calibration") and its capacity for robust instruction following. While an LLM prioritizing its internal knowledge, especially if it aligns with generally accepted facts, could be interpreted as a form of "honesty," this perspective shifts within the specific operational context of RAG systems like those evaluated with KNOWSHIFTQA. In such systems, LLMs are explicitly instructed to base their responses on the provided contextual documents. Therefore, when a model disregards this instruction and favors its parametric knowledge—particularly when the context contains deliberate, hypothetical updates—it signifies a limitation in its instruction-following capability rather than a commendable adherence to broader factual accuracy.

The underperformance on simple direct questions can thus be partly attributed to this conflict: the models may struggle to override a strong internal "prior" when explicitly instructed to use new, conflicting information from the context. This distinction is paramount for developing robust educational QA systems. Such systems must reliably reflect the content of designated authoritative sources (e.g., textbooks), even if these sources present information that has been updated or differs from an LLM’s training data. Consequently, the ability to flexibly integrate and prioritize instructed contextual information is a fundamental requirement for their effectiveness in dynamic knowledge environments. While in real-world scenarios with less clearly defined ground truths or more ambiguous knowledge conflicts, the sophisticated reasoning of stronger LLMs might offer advantages in navigating discrepancies, the specific demands of an educational RAG system underscore the critical importance of faithful instruction adherence.

Improving Parallel Sentence Mining for Low-Resource and Endangered Languages

Shu Okabe^{1,2} and Katharina Hämmel^{1,2} and Alexander Fraser^{1,2,3}

Abstract

While parallel sentence mining has been extensively covered for fairly well-resourced languages, pairs involving low-resource languages have received comparatively little attention. To address this gap, we present BELOPSEM, a benchmark of new datasets for parallel sentence mining on three language pairs where the source side is low-resource and endangered: Occitan-Spanish, Upper Sorbian-German, and Chuvash-Russian. These combinations also reflect varying linguistic similarity within each pair. We compare three language models in an established parallel sentence mining pipeline and apply two types of improvements to one of them, Glot500. We observe better mining quality overall by both applying alignment post-processing with an unsupervised aligner and using a cluster-based isotropy enhancement technique. These findings are crucial for optimising parallel data extraction for low-resource languages in a realistic way.

1 Introduction

Parallel sentence mining aims to find matching sentence pairs from a source and a target language. This task is usually the first step in creating a corpus to train other NLP models, most famously Machine Translation (MT) systems. So far, significant progress has been reached for well-resourced languages and language pairs, such as in the BUCC Shared Task 2017 (Zweigenbaum et al., 2017), where English was paired with four other high-resource languages.¹ However, when one of the languages is low-resource and hence not yet well supported by the language models, similar performance cannot be achieved. Besides, sentence encoding models heavily rely on parallel data during pre-training. Without enough parallel sentences,

decent sentence representation cannot be reached. For instance, Tan et al. (2023) rely on at least tens of thousands of *parallel* sentences in their sentence representation. Therefore, before reaching these parallel data size milestones, sentence encoders are not reliable enough for mining, which mainly affect very low-resource languages and, more critically, endangered languages.

The alternative is then to rely on language models pre-trained with only monolingual data by averaging word representations. Mining will be more difficult because sentence encoders perform better than mean-pooled embeddings for sentence mining. Thus, we focus on trying to improve such alternative sentence embeddings effectively through two methods: Alignment post-processing and isotropy enhancement in the embedding space. Hangya and Fraser (2019) used alignments with static embeddings to filter sentence pairs, but we updated it with an unsupervised multilingual aligner. The second method has already been shown to be effective on several language pairs on the related but different task of sentence matching (Hämmel et al., 2023).

Our main contributions are: 1) We create BELOPSEM (**B**enchmark of **l**ow-resource languages for **p**arallel **s**entence **m**ining), which consist of three new realistic benchmarks for parallel sentence mining for three language pairs where the source language is low-resource and endangered. 2) We improve on baseline approaches to parallel sentence mining by applying isotropy enhancement and word-level alignment, neither of them requiring additional resources such as parallel sentences, unlike state-of-the-art sentence encoder models such as LaBSE (Feng et al., 2022). We publicly release the benchmark datasets² and the updated mining pipeline.³

¹LaBSE (Feng et al., 2022) reaches more than 88 points of F-score on all four BUCC corpora.

³At: <https://github.com/shuokabe/PaSeMiLL/>.

2 Languages and corpora

2.1 Three language pairs

We focus on the following three language pairs, where the source language is an endangered language according to Ethnologue (Eberhard et al., 2024), and the target language is well-resourced: Occitan-Spanish, Upper Sorbian-German, and Chuvash-Russian. We choose these pairs to represent different mining difficulties with a range in language distance in the pair. They also happen to have received recent attention from the NLP community through WMT Shared Tasks (Libovický and Fraser, 2021; Sánchez-Martínez et al., 2024). We note that all three source languages are classified as ‘Scraping-Bys’ (1) in the classification of Joshi et al. (2020), i.e. low-resource.

Occitan-Spanish (OCI-ES) Occitan (ISO code: oci; Glottocode: occi1239) is spoken in the south of France, Italy, and Spain. Both Occitan and Spanish belong to the Western Romance language family and are written in the Latin script. This pair represents a close language pair which can heavily rely on related languages (French or Spanish directly).

Upper Sorbian-German (HSB-DE) Upper Sorbian (hsb; uppe1395) is a West Slavic language spoken in Saxony in Germany, while German belongs to the Germanic family. Hence, both are Indo-European languages and use the same Latin script. This pair is more challenging since the distance between the two languages is larger. Yet, Upper Sorbian can rely on related Slavic languages, namely Czech and Polish, which are better resourced and supported by existing language models.

Chuvash-Russian (CHV-RU) Chuvash (chv; chuv1255) is a Turkic language spoken in the Russian Federation, while Russian belongs to the Slavic language family. Both are written in the Cyrillic alphabet. The language distance for the pair is thus larger than the previous two pairs, which makes it the most challenging of the three.

2.2 Parallel sentence mining corpus creation

We follow the overall methodology used for the BUCC 2017 Shared Task (Zweigenbaum et al., 2017) to create a controlled experimental environment: we inject sentences from existing parallel sentences into monolingual corpora. We mainly use the Leipzig corpora (Goldhahn et al., 2012) for

monolingual sentences and choose similar sources (e.g., same year of Wikipedia or news) for both languages in a pair. Parallel sentences for Upper Sorbian-German and Chuvash-Russian come from two editions of the WMT Shared Task in Unsupervised MT and Very Low Resource Supervised MT (Fraser, 2020; Libovický and Fraser, 2021), while we use parallel data from Wikimedia 2023, available on OPUS (Tiedemann, 2012), for Occitan-Spanish. We pre-process the sentences to ensure encoding consistency and filter out too-short sentences. We aim for 6% of true parallel sentences in the final corpora. Appendix A presents more details on the data curation.

Table 1 presents the number of sentences in the corpora of each language pair. We split the generated corpora to have 25% assigned to the training dataset and the remaining for testing. In the original BUCC Shared Task, the training and testing balance was 50:50. However, we chose a 25:75 split to simulate a scenario where we want to mine further parallel sentences from larger corpora.

	train	test
Occitan corpus	7,899	23,675
Spanish corpus	7,780	23,334
of which parallel	486	1,457
Upper Sorbian corpus	15,980	47,847
German corpus	15,999	47,999
of which parallel	1,000	3,000
Chuvash corpus	7,998	23,995
Russian corpus	7,994	23,985
of which parallel	499	1,498

Table 1: Number of sentences in the datasets for all three language pairs in BELOPSEM.

3 Parallel sentence mining methodology

3.1 Standard mining pipeline

We follow PASEMILL (Okabe and Fraser, 2025), which is similar to the established mining pipeline of Hangya and Fraser (2019), but updates it using contextual language models instead of static embeddings. First, we encode both source and target sentences in the same sentence representation space using a multilingual language model. When relying on mean-pooled sentence representations, we choose the 8th layer in line with previous findings (Hämmerl et al., 2023; Imani et al., 2023; Okabe and Fraser, 2025).

Then, we use the CSLS (Cross-Domain Similarity Local Scaling) score (Conneau et al., 2018) to compute the similarity between a source and target sentence. The CSLS score is related to established margin-based methods (Artetxe and Schwenk, 2019) and is defined as follows:

$$\text{CSLS}(x, y) = 2 \cos(x, y) - \sum_{z \in \text{NN}_k(x)} \frac{\cos(x, z)}{k} - \sum_{z \in \text{NN}_k(y)} \frac{\cos(y, z)}{k}, \quad (1)$$

where $\text{NN}_k(x)$ indicates the k -nearest neighbours of vector x . In our experiments, we set $k = 20$. CSLS is known to suffer less from the hubness problem (Dinu et al., 2015) and to get better performance compared to the standard cosine similarity (Artetxe and Schwenk, 2019). In our preliminary work on the Upper Sorbian-German pair, we did not find major differences in mining, whether we used the margin-based score or the CSLS score to find the nearest neighbour.

Finally, we pair each source sentence with its closest target sentence. The actual computation of the nearest neighbours is carried out using the Faiss library (Johnson et al., 2019). Since not all source sentences have a matching counterpart, we filter the mined pairs according to a threshold θ . We define this similarity threshold dynamically, as in Hangya et al. (2018):

$$\theta = \text{mean}(S) + \lambda \times \sigma(S), \quad (2)$$

where we compute the mean and standard deviation (σ) values of the similarity scores (S), with λ as a hyperparameter. Details on computational efficiency can be found in Appendix B.

3.2 Multilingual language models

To represent the sentences, we stick to three language models in our analysis. First, we select a multilingual language model which is widely used: XLM-RoBERTa or XLM-R (base) (Conneau et al., 2020). The second model is LaBSE (Feng et al., 2022), a state-of-the-art sentence embedding model. Our preliminary experiments showed better performance of LaBSE over LASER (Artetxe and Schwenk, 2019; Costa-jussà et al., 2022) on our datasets. We do not fine-tune sentence encoders due to their need for *parallel* sentences because it is not accessible for languages which do not yet have such a sizeable corpus. None of the two models have seen sentences in Occitan, Upper Sorbian, or

Chuvash; they can only rely on related languages for the mining process (e.g., other Romance languages for Occitan, Polish or Czech for Upper Sorbian, or Kazakh for Chuvash).

The main language model we work on is Glot500-m (Imani et al., 2023), which further pre-trains XLM-R (base) with *monolingual* data for more than 500 low-resource languages with an extended vocabulary. We choose this model for two reasons: it has seen all three source languages, which means a better representation, and it can be directly compared to XLM-R. An additional point to consider for our three source languages is the data support from Glot500. Occitan is already well supported by the model (among the top 50 tail languages,⁴ with more than 1M sentences). Fewer (100k) sentences have been seen for Upper Sorbian, which lies in the mid-to-low pre-training rank of Glot500. Finally, while representing Chuvash solely with related languages may be difficult (for XLM-R or LaBSE), better representation can be obtained from Glot500 (800k pre-training sentences).

3.3 Unsupervised alignment post-processing

Comparing the word-level alignment is a method to improve parallel sentence mining, as already documented in Hangya and Fraser (2019), for instance, but there they relied on *static* word embedding similarity. Instead, we use an unsupervised multilingual aligner, SimAlign (Jalili Sabet et al., 2020), which leverages pre-trained language models to compute alignment links. In our case, we use the 8th layer of Glot500 and count the number of alignment links. We choose the argmax method for higher-precision links. We divide the number of symmetrised links by the number of words in the source and target sentences to get the average alignment ratio. A full alignment between both sentences hence gets a score of 1.

We additionally filter alignment links according to their overall frequency, keeping only the most frequent (and hence, more reliable) word pairs. Finally, we also select the mined sentence pairs using a dynamic alignment threshold α (as in Equation 2), which depends on the mean and standard deviation of all scores and a hyperparameter μ .

Our preliminary experiments showed that using a lower filtering threshold θ and then applying alignment post-processing yielded a better F-score in the end. Such filtering increases precision; start-

⁴Languages *not* seen by XLM-R during pre-training.

ing from ‘noisier’ sentence pairs actually led to a quicker gain in precision for reduced loss in recall, and hence an overall improvement of the F-score. Due to this choice, alignment post-processing may lead to higher recall and lower precision than the standard approach (cf. complete results below).

3.4 Cluster-based isotropy enhancement

To enhance isotropy in sentence representations, Hämmerl et al. (2023) explored ZCA whitening (Huang et al., 2021) and cluster-based isotropy enhancement (CBIE; Rajaei and Pilehvar, 2021). Both yielded comparable results on cross-lingual sentence retrieval for 1K sentences. We choose CBIE for its better scalability when it comes to larger datasets, as in our case, and apply it to the mean-pooled sentence representation before a similarity search for each dataset separately. This method determines dominant directions not globally but for each cluster in the space using Principal Component Analysis and removes the top 12 components. Appendix C shows t-SNE visualisations (van der Maaten and Hinton, 2008) of anisotropy for all three language pairs.

We do not report the results of the CBIE transformation on LaBSE because sentence embeddings suffer less from anisotropic representation and benefit little from it, as noted in Hämmerl et al. (2023).

4 Experimental results

We tune the similarity and alignment score thresholds (θ and α), or more exactly, their associated hyperparameters (λ and μ), on each training dataset. We evaluate the experiments using the standard Precision (P), Recall (R), and F-score (F). Table 2 presents the mining results for all three language pairs on the test sets of BELOPSEM. The F-score in **bold** is the overall best score, while the underlined score is the best among variants of Glot500. Complete results with precision and recall scores are available in Appendix D.

From the F-scores of the two baseline models, we see that having closer source and target languages is beneficial, which is in line with our intuition on language distance. The number of sentences in related languages may be another factor: While Occitan can benefit from very well-resourced languages (namely, French or Spanish itself), and Upper Sorbian has close links with Czech and Polish, Chuvash is far from other Turkic languages (even those only supported by Glot500).

LM	align.	CBIE	OCI-ES	HSB-DE	CHV-RU
XLM-R	NO	NO	48.08	1.43	3.06
LaBSE	NO	NO	93.50	67.21	28.24
Glott500	NO	NO	72.61	20.85	37.84
Glott500	YES	NO	77.19	32.70	37.39
Glott500	NO	YES	83.29	43.15	41.51
Glott500	YES	YES	<u>84.46</u>	<u>50.82</u>	43.62

Table 2: F-scores (%) on the test datasets of the three mining corpora in BELOPSEM.

XLM-R’s performance also shows that relying only on related languages is not enough to carry out mining with mean-pooled sentence embeddings.

Regarding the standard Glot500 model, we notice better performance than XLM-R due to the additional pre-training (around or more than 20 points in F-score), but the mining quality is still worse than LaBSE. The notable exception is Chuvash, where the additional sentences seem to strongly help the model, gaining more than 9 points.

Using alignment post-processing only brings slight improvement on the final F-score, except for Upper Sorbian. For that corpus, this suggests that a significant number of actual parallel sentence pairs have a rather lower similarity score (and are thus discarded when the similarity threshold θ is too high). This seems to be mainly due to the language representation (i.e., number of pre-training sentences of Glot500), as it does not affect the other two languages as massively.

On the other hand, the CBIE transformation brings consistent improvement to Glot500: Related language pairs seem to benefit more from the transformation (+10 for OCI-ES and +22 for HSB-DE) than distant languages (+4 for CHV-RU). This confirms that the method also enables better representation of low-resource languages in the sentence embedding space. Finally, combining both improvement techniques leads to the best results. Still, the main increase seems to come from the CBIE transformation; the alignment post-processing rather complements it with more detailed filtering.

Qualitative analysis Table 3 presents an example of a sentence pair that was correctly mined after applying the CBIE transformation. We see that our base model pairs the Occitan sentence with a Spanish sentence unrelated to university work, resulting in a negative similarity score; hence, such a pair is discarded. On the other hand, isotropy

	sentence	sim.
OCI	A l'òra d'ara, qu'ensenha a l'Universitat de Nagoya.	
ES	A la fecha sólo sobrevive Pablo, quien vive en Parácuaro, Michoacán. <i>To date, only Pablo, who lives in Parácuaro, Michoacán, survives.</i>	-0.004
+ CBIE	Actualmente, trabaja en la Universidad de Nagoya. <i>He is currently working at Nagoya University.</i>	0.118

Table 3: Example of sentence mined for the Occitan-Spanish (OCI-ES) corpus before and after CBIE transformation with corresponding similarity scores.

enhancement enables a positive and higher similarity score with the correct Spanish translation of the sentence. The noticeable difference in similarity scores explains why this sentence pair has been mined by the second system. For this very sentence pair, we hypothesise that the named entity ‘Universitat de Nagoya’ (or Nagoya University) created confusion, coupled with the not obvious association of the four-word phrase ‘A l’òra d’ara’ with ‘Actualmente’ (currently).

5 Related works

Parallel sentence mining has mainly been studied to prepare a corpus to train MT models. Yet, few works focus on low-resource language pairs. [Kvapilíková and Bojar \(2023\)](#) already considered mining parallel sentences for the Upper Sorbian-German language pair using their pipeline ([Kvapilíková et al., 2020](#)). Their main goal was to crawl pseudo-parallel sentences for MT, for which they observed that 500k Upper Sorbian sentences were necessary to reach acceptable mining quality. Similarly, [Heffernan et al. \(2022\)](#) improve LASER with multilingual distillation (LASER3), requiring large amounts of monolingual data and a significant number of parallel sentences. [Tan et al. \(2023\)](#) rely on contrastive learning to further boost LASER3, but it still needs more than 40,000 *parallel* sentences coupled with back-translation even in the extremely low-resource scenario.

Two shared tasks provided comparable corpora: the BUCC Shared Tasks ([Zweigenbaum et al., 2017, 2018](#)), whose methodology we used to generate our corpora, and the Shared Task on corpus filtering for low-resource language pairs ([Koehn et al., 2019, 2020](#)). For the latter, the size of parallel corpora reaches several hundreds of thousands,

which is difficult to obtain for endangered low-resource languages.

6 Conclusion

Low-resource languages, especially endangered ones, can benefit from bilingual sentence mining to gather a parallel corpus for downstream tasks, such as MT. However, current mining tools can show variable performance, with poorer results when one of the languages is neither supported nor close enough to other languages seen by state-of-the-art sentence encoders, such as LaBSE.

We thus focused on using a model which was trained using only monolingual data, Glot500. For controlled experimental conditions, we generated sentence mining corpora for three language pairs with varying degrees of linguistic similarity (BELOPSEM). We found that the CBIE transformation to enhance isotropy in the sentence representation consistently improves mining quality, while alignment post-processing helps when the language is not well-represented in the language model. These results hint at the possibility for low-resource languages to reach higher mining quality *without parallel data*.

The mining quality improvement we observed can help the early stages of parallel corpus creation where monolingual data is sufficiently present, but there are not enough parallel sentences to fine-tune sentence encoder models. We hope that the benchmark can also foster work on sentence mining for other language pairs. Future work will mainly extend this methodology to other language pairs (different scripts and lower or no support in Glot500).

Limitations

The choice of the language pairs can be discussed as they may not be the most challenging cases, with two of them from the same Indo-European language family and all three pairs using each the same script. Nonetheless, we stuck to plausible pairs with potential needs, having deployment in real-life settings in mind. For research purposes, considering pairs such as Chuvash-English, replacing the Russian target sentences with their translations might be an option to see further linguistic differences.

Moreover, compared to the state-of-the-art LaBSE model, mining performance can be notably lower with our mining pipeline using Glot500 (or any mean-pooled sentence embeddings). We

have, however, seen that for a language that is too far from the languages used to pre-train LaBSE, Glot500 is actually a better alternative for mining (cf. Chuvash-Russian). This means that by pre-training XLM-R with *monolingual* data on the language, we can reach higher mining quality. Eventually, with enough parallel sentences (possibly mined), we can fine-tune LaBSE or similar sentence encoders. The main goal of our work is to lower the data barrier for low-resource language pairs by removing the need for parallel data.

Finally, the size of the datasets remains small for all three settings. We restricted the number of sentences overall to stay in realistic dataset sizes (several tens of thousands of monolingual sentences) while maintaining a parallel sentence ratio of around 6%.

A Data curation

We report the original data used to generate our three parallel sentence mining corpora.

Occitan-Spanish For the monolingual sentences, we use the 2021 Wikipedia data from the Leipzig corpora (30K) for both languages (Goldhahn et al., 2012). For the parallel sentences, we use the 2023 Wikimedia data from OPUS⁵ (Tiedemann, 2012).

Upper Sorbian-German We use the WMT 2020 Shared Task data for both parallel sentences and monolingual Upper Sorbian data (Fraser, 2020). The monolingual data was provided by the Sorbian Institute. We use both development and test data (devtest.tar.gz) for the parallel sentences, which were controlled for the Shared Task evaluation. For German monolingual data, we use the Leipzig news corpora of 2020 (300K sentences).

Chuvash-Russian For the monolingual sentences, we also use the 2021 Wikipedia data from the Leipzig corpora (30K) for both languages. We chose this year to have a better correspondence with the parallel data provided by the WMT 2021 Shared Task (Libovický and Fraser, 2021). From the parallel data, we use the development set (devel.chv-ru.{chv|ru}), which was manually filtered for the Shared Task.

Licence Corpora downloaded from the Leipzig corpora are licenced under the Creative Commons Licence CC BY.⁶ The Wikimedia data from OPUS has a CC BY-SA licence. For the resources from the WMT Shared Tasks, the Chuvash data has a CC0 licence, while the Upper Sorbian datasets have a CC BY-NC-SA licence. We hence release our corpora with the following licences: the Occitan-Spanish corpus with a CC BY-SA licence, the Upper Sorbian-German corpus with a CC BY-NC-SA

licence, and the Chuvash-Russian corpus with a CC BY licence.

B Reproducibility

We ran our experiments on 1 GPU: we mainly used one NVIDIA H100 for faster computation, but also one NVIDIA Tesla V100. It is worth mentioning that Faiss (Johnson et al., 2019) or SimAlign (Jalili Sabet et al., 2020) can also be run on CPUs, albeit slowly, and the CBIE transformation does not require GPUs. In terms of actual computation time, the sentence representation step takes a few minutes on one V100 GPU, and so does the mining process (less than 10 minutes). The alignment post-processing on GPU is also very quick: Since we apply it on mined sentence pairs with a given threshold θ , we only consider a subset of the original monolingual corpora. Finally, the CBIE transformation takes only a few minutes on a CPU.

C Visualisation of anisotropy

To visualise the impact of the CBIE transformation on the sentence representation space, we also follow the methodology of Hämmerl et al. (2023). We present t-SNE plots of 1,000 parallel sentences from each language pair before and after applying the CBIE transformation in Figures 1, 2, and 3.

As observed in Hämmerl et al. (2023), languages that have been less seen during pre-training suffer more from the issue of anisotropy.

D Complete experimental results

Tables 4, 5, and 6 present the complete mining results for all three language pairs. As in Section 4, **bold** F-score stands for the overall best score, whereas the underlined score is the best among variants of Glot500.

We note here that the CBIE transformation mainly improves precision rather than recall. This implies that enhanced isotropy helps to better filter sentences.

Revisiting Epistemic Markers in Confidence Estimation: Can Markers Accurately Reflect Large Language Models’ Uncertainty?

Jiayu Liu, Qing Zong, Weiqi Wang, Yangqiu Song

Department of Computer Science and Engineering, HKUST, Hong Kong SAR, China
jliufv@connect.ust.hk; {qzong, wwangbw, yqsong}@cse.ust.hk

Abstract

As Large Language Models (LLMs) are increasingly used in high-stakes domains, accurately assessing their confidence is crucial. Humans typically express confidence through epistemic markers (e.g., “fairly confident”) instead of numerical values. However, it remains unclear whether LLMs reliably use these markers to reflect their intrinsic confidence due to the difficulty of quantifying uncertainty associated with various markers. To address this gap, we first define *marker confidence* as the observed accuracy when a model employs an epistemic marker. We evaluate its stability across multiple question-answering datasets in both in-distribution and out-of-distribution settings for open-source and proprietary LLMs. Our results show that while markers generalize well within the same distribution, their confidence is inconsistent in out-of-distribution scenarios. These findings raise significant concerns about the reliability of epistemic markers for confidence estimation, underscoring the need for improved alignment between marker based confidence and actual model uncertainty. Our code is available at <https://github.com/HKUST-KnowComp/MarCon>.

1 Introduction

LLMs have grown increasingly powerful, yet their application in mission-critical tasks is still hindered by reliability issues (Zhang et al., 2024; Maynez et al., 2020). Therefore, accurately measuring output confidence is crucial for their reliable deployment (Li et al., 2024a; Pedapati et al., 2024; Beigi et al., 2024). Traditionally, black-box confidence estimation in LLMs primarily relies on direct numerical outputs (e.g., “30% confidence”) or response consistency (Xiong et al., 2024; Chen and Mueller, 2024; Li et al., 2024b), while white-box methods mainly utilize logits, internal states as information source (Geng et al., 2024). However, natural language is the primary interface for human-

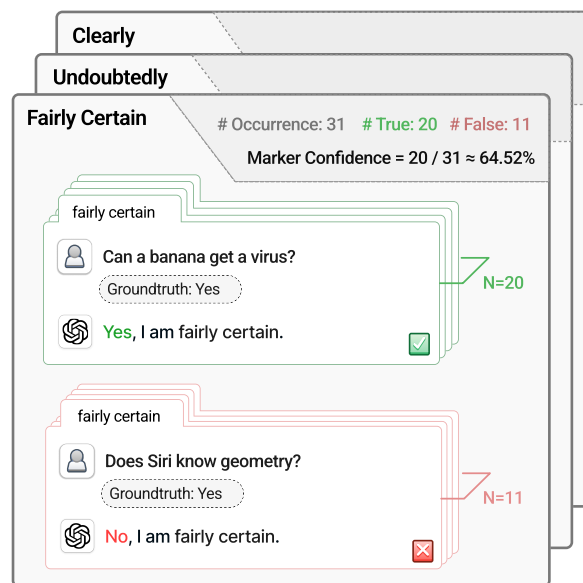

Figure 1: An example of our framework calculating the marker confidence of “fairly certain” for *GPT-4o* on StrategyQA. We calculate the confidence for all the markers across seven models and seven datasets.

LLM interaction. Instead of relying solely on abstract numerical measures, humans often use epistemic markers, such as “I am not sure” or “it is unlikely that,” to convey uncertainty (Wallsten, 1986; Erev and Cohen, 1990; Juanchich et al., 2017; Kadavath et al., 2022). This similar recognition of uncertainty markers is essential for effective communication (Willems et al., 2019; Belém et al., 2024), which potentially makes it valuable for LLMs to adopt a similar practice (Yona et al., 2024).

However, it remains unexplored whether LLMs are capable of incorporating these epistemic markers in their responses to express their intrinsic confidence stably and consistently. Previous works have primarily concentrated on the misalignment between human and LLM recognition of epistemic markers (Zhou et al., 2024; Tang et al., 2024; Belém et al., 2024), concluding that models always fail to accurately convey confidence in words (Yona

et al., 2024). In fact, human interpretations of markers are not completely identical (Pennkamp et al., 2024), so even if these markers may not align well with human reasoning, they can still be useful if the model maintains a consistent internal mapping between markers and their actual accuracy. Thus, previous studies questioning the reliability of markers may be insufficient, as they have not examined whether LLMs can consistently apply their own confidence framework.

To address this gap, we investigate whether epistemic markers produced by LLMs reliably reflect their confidence in question-answering tasks. By defining marker confidence as the accuracy of responses when a model uses a specific marker to convey confidence, we calculate the marker confidence with various models and datasets. Additionally, we propose seven evaluation metrics to systematically assess the stability of these markers in both in-distribution and out-of-distribution contexts. Our findings show that while markers perform well within similar distributions, their stability declines in out-of-distribution contexts. Additionally, we compare a range of widely used models and conclude that the more powerful ones demonstrate a better understanding of epistemic markers.

2 Related Work

Our work primarily intersects with confidence estimation in LLMs and studies about epistemic markers. Please find related works in Appendix A.

3 Study Design

3.1 Formalization

Confidence of Epistemic Markers. Let W denote an epistemic marker, $D = \{Q_1, Q_2, \dots, Q_n\}$ a labeled dataset, and M a model. We define the confidence associated with each epistemic marker as $Conf(W, D, M)$, computed as the accuracy of the answers that explicitly include marker W when the model provides responses. It is important to note that our definition of marker confidence deviates from the conventional interpretation of verbal confidence, which pertains to the semantic uncertainty associated with epistemic markers. To compute the marker confidence for a specific epistemic marker W_i , we use model M_k to generate answers for all questions in the training set of dataset D_j and then extract the subset $Q_{W_i} \subseteq D_j$ consisting of questions whose generated answers contain W_i . The marker confidence is defined as:

$$Conf(W_i, D_j, M_k) = \frac{1}{|Q_{W_i}|} \sum_{q \in Q_{W_i}} \mathbb{I}(M_k(q)),$$

where Q_{W_i} is the set of questions whose generated answers contain the epistemic marker W_i and $\mathbb{I}(\cdot)$ is the indicator function, which is 1 if the answer generated by M_k for question q is correct, and 0 otherwise. An example is provided in Figure 1.

3.2 Methods

We calculate $Conf(W_i, D_j, M_k)$ for all combinations of generated markers, datasets and models (W_i, D_j, M_k) in Appendix B.1 to provide an all-rounded insight into the marker distributions. Specifically, we propose seven metrics to systematically evaluate the stability and consistency of LLM generated epistemic markers:

(1) **I-AvgECE** *In-domain Average ECE* reflects how well the marker confidence of the model aligns with its actual accuracy in a consistent setting within the same distribution.

(2) **C-AvgECE** *Cross-domain Average ECE* assesses the calibration error of the marker confidence and the actual accuracy, further reflecting the robustness of the model’s marker confidence in out-of-domain scenarios.

(3) **NumECE** *Numerical ECE* measures the overall calibration of the model’s numerical confidence outputs across all datasets. All ECE-related metrics are desired with a lower value, indicating better calibration performance on the target dataset.

(4) **MAC** *Marker Accuracy Correlation* reflects the correlation between marker confidence and the model accuracy on different datasets. The metric is calculated based on Pearson coefficient, so 0 in this value represents no linear correlation and 1 indicates direct proportional relationship between the marker confidence and model’s accuracy.

(5) **MRC** *Marker Ranking Correlation* measures the model’s ability to maintain a consistent marker confidence ranking across different datasets. The metric is calculated based on Spearman coefficient (de Winter et al., 2016), so 0 in this value represents no correlation and 1 indicates totally identical between markers’ confidence rankings.

(6) **I-AvgCV** *In-domain Average CV* captures the dispersion of the model-generated confidence scores within each dataset. A relatively higher I-AvgCV value indicates a more decentralized distribution of markers within the dataset, demonstrating

Model	Marker Confidence				MAC	Rank	Density
	I-AvgECE ↓	C-AvgECE ↓	NumECE ↓	C-AvgCV ↓		MRC ↑	I-AvgCV
<i>Llama-3.1-8B-Instruct</i>	10.09	15.95	22.70	20.80	60.91	11.37	20.48
<i>Qwen2.5-7B-Instruct</i>	7.85	23.60	21.84	31.29	68.06	11.85	22.39
<i>Qwen2.5-14B-Instruct</i>	7.66	20.38	17.98	26.44	73.95	34.60	23.83

<i>Mistral-7B-Instruct-v0.3</i>	10.58	24.81	24.46	28.52	84.57	10.54	21.01
<i>GPT-4o</i>	8.55	11.84	7.56	15.72	76.44	27.54	14.30
<i>GPT-4o-mini</i>	7.65	17.15	12.79	21.98	87.68	16.48	20.61
Average	8.17	17.73	16.60	23.43	75.69	21.34	19.84

Table 1: Model performance across seven metrics. For each metric, the data for the best performing model is bolded. For analytical experiments about markers, we only consider those appear no less than 10 times to eliminate the effect of randomness (see Section 4 for details). All values listed in the table are expressed as percentage (%).

a stronger ability to distinguish between different markers.

(7) **C-AvgCV** *Cross-domain Average CV* measures the consistency of the model’s marker-based confidence across different datasets. A higher C-AvgCV value indicates a greater dispersion of marker confidence across various datasets, suggesting the model’s instability regarding marker confidence.

More details about the design and implementation of the metrics can be found in Appendix B.4.1.

4 Experiments and Analysis

Models and Datasets. We experiment with two mainstream open-source and five proprietary LLMs over seven datasets from various domains. More introduction can be found in Appendix B.1.

Baseline. Inspired by previous comparison about using numerical values and uncertainty expression in words to express confidence level (Jaffe-Katz et al., 1989; Knapp et al., 2016), we apply the method of directly prompting the model to express a numerical confidence as baseline for comparison. The prompt designed to elicit epistemic markers and numerical confidence is in Appendix B.1. Our main experiment results are in Table 1.

Marker Filtering Strategies We conduct all marker analysis experiments (namely C-AvgCV, MAC, MRC, and I-AvgCV) by filtering markers that occur fewer than 10 times in the training set in Table 1. The filtering threshold is eventually a tradeoff between the completeness and reliability of the data. On one hand, if the filtering threshold (10 in the main table) is too small, the confidence interval of the results would be large. On the other hand, we cannot include diverse markers for the metrics and get limited insights. The confidence intervals and more details are reported in Appendix B.4.2.

4.1 Main Observations

While the in-distribution marker confidence is relatively stable, it lacks robustness across different datasets. This conclusion is supported by the observation that I-AvgECE values consistently remain lower than NumECE and C-AvgECE values are notably higher than NumECE for 6 out of 7 models, indicating that models exhibit shortcomings in generalizing marker confidence to different distributions and datasets.

More direct evidence to support the conclusion may be inferred from the C-AvgCV of the models. The average C-AvgCV of 0.2343 highlights that marker confidence is highly sensitive to distribution shifts, aligning with the observed high value in C-AvgECE. Notably, we observed that stronger models (e.g., *GPT-4o*, *Qwen2.5-32B-Instruct*) might exhibit smaller C-AvgCV values.

We further examine the relationship between marker confidence and model accuracy across different datasets using MAC. For 5 out of 7 of the models, the MAC value is over 0.7, which indicates that marker confidence are positively related to the model’s accuracy in a strict manner. This also suggests that marker confidence is fragile under distribution shifts, highlighting models’ lack of robust understanding of epistemic markers.

Models fail to maintain a consistent ordering of epistemic markers across different domains. The overall low values of MRC suggest that models do not preserve a consistent ranking of markers when applied to datasets with different distributions. We notice that larger models appear to have a better grasp at maintaining a stable ordering of markers. However, both the maximum and average MRC indicates low consistency performance, suggesting a lack of robust understanding of marker

Figure 2: **Model’s marker confidence varies greatly across different datasets.** We plot the heatmap of the marker confidence of *GPT-4o* and *Qwen2.5-32B-Instruct* across different datasets, illustrating that even the best models exhibit substantially different confidence levels in various contexts. The markers in the graph are randomly selected from the shared markers of all datasets.

Figure 3: **The rankings of the model’s marker confidence fluctuates significantly across different datasets.** We plot the scatter diagram for the marker confidence rankings of the best performing models, but still discovered that the rankings are extremely unstable. The markers in the graph are randomly selected from the shared markers across all datasets.

relative confidence.

The values of the marker confidence are highly concentrated. Since models are expected to express a wide range of confidence including extreme values which is necessary in mission-critical scenarios (Alam et al., 2017; Bhise et al., 2018), We expect the models to clearly differentiate the epistemic markers by obtaining a relatively uniform distribution and containing markers with a confidence near 0% or 100%. However, we found the I-AvgCV values typically range from approximately 0.14 and 0.24, demonstrating a concentrated distribution with minor difference. Additionally, only 4 out of 49 settings (dataset, model pair) include markers with confidence under 10% when only those occur no less than 10 times are counted, indicating significant failure in expressing uncertainty.

4.2 Correlation between Performance and Marker Consistency

In Section 4.1, we notice that the statistics in Table 1 suggest that larger models demonstrate a

better understanding of epistemic markers, as evidenced by lower C-AvgCV values and higher MRC values. In this section, we quantitatively evaluate the relationship between a model’s accuracy and its corresponding C-AvgCV and MRC values to gain a deeper insight into the relationship of model ability and mastery of epistemic markers.

Specifically, for a given model M_k , we use its average accuracy across all datasets as a comprehensive measure of its performance. We then compute the Pearson Correlation Coefficient between each model’s overall accuracy and both its C-AvgCV and MRC. The results show a correlation coefficient of -0.88 between model accuracy and C-AvgCV, and a correlation coefficient of 0.75 between model accuracy and MRC. These findings indicate a strong negative relationship between model accuracy and C-AvgCV and a strong positive relationship between model accuracy and MRC. This suggests that more powerful models exhibit greater stability in marker confidence across datasets, as well as a more consistent ordering of markers.

Model	C-AvgCV ↓		MAC		MRC ↑		I-AvgCV	
	50	100	50	100	50	100	50	100
Llama-3.1-8B-Instruct	25.50	23.39	77.54	65.98	-8.57	-10.32	11.44	8.59
Qwen2.5-7B-Instruct	30.12	29.30	77.96	69.03	6.01	2.25	18.38	15.41

Qwen2.5-32B-Instruct	20.03	21.27	87.25	86.85	34.91	23.95	13.51	12.18
Mistral-7B-Instruct-v0.3	26.70	26.34	94.80	84.71	30.68	30.60	12.81	9.67
GPT-4o	15.86	16.92	89.91	90.68	37.38	39.40	7.52	7.29
GPT-4o-mini	22.15	22.41	86.82	87.45	24.16	24.36	11.98	11.39
Average	23.84	23.90	86.62	82.71	23.02	20.91	13.75	12.24

Table 2: This table presents the results (in %) of the marker analysis experiments, organized by different filtering thresholds. We observed that the conclusion obtained from Table 1 still holds when the threshold increases.

4.3 Conclusion Robustness under Different Filtering Thresholds

Our primary conclusions regarding marker consistency and model understanding of epistemic markers remain robust across various filtering thresholds. As detailed in Table 2, even when increasing the filtering threshold to 50 or 100 occurrences, the observed trends persist: 1) The C-AvgCV and MRC values consistently remain low, while the I-AvgCV values remain high. This pattern continues to suggest that models struggle to maintain consistent confidence across different datasets and to differentiate effectively between markers. 2) The MAC values consistently remain high. This reinforces the strong positive relationship between model performance and its marker usage ability. Moreover, **the observed shortcomings extend even to frequently occurring markers** (with over 100 instances), indicating a severe challenge in the model’s ability to reliably utilize epistemic expressions. This pervasive issue further substantiates our claims regarding the difficulties in ensuring reliable marker usage.

4.4 Discussions

This section aims to explain the observed differential in the consistent deployment of epistemic markers within in-domain versus out-of-domain contexts. Furthermore, we aim to investigate the distributional characteristics that potentially modulate the confidence associated with these markers.

Within similar distributions, models tend to maintain a stable “preference” for employing these markers to express uncertainty. For instance, in in-domain scenarios, responses on the test set leverage a consistent pattern of epistemic marker “preference” due to the similarity of the distribution. However, this consistency breaks down when the data distribution shifts. As the distribution changes, the model’s preference usage for epistemic mark-

ers also changes, hindering the transfer of marker-based confidence to test sets from different datasets.

To further investigate this phenomenon, we conducted an in-depth analysis by calculating the average ECE values for each dataset to quantify the generalizability of the marker consistency from the training set to the test set. This involved averaging the ECE values across seven models in the in-domain scenario. Our analysis revealed that **datasets with greater component diversity generally exhibit a higher ECE**. This suggests that more complex or multi-sourced distributions make it challenging to transfer marker confidence from the training to the test set, as exemplified by datasets like MMLU and StrategyQA, which are not domain-specific. This observation further supports our claim that models perform well in in-domain scenarios primarily due to the consistency of the underlying data distribution. The details about the experiments are reported in Appendix C.

5 Conclusion

Our study evaluates whether LLMs can reliably express confidence using epistemic markers. We define marker confidence as the observed accuracy of responses containing specific markers, conduct extensive experiments and evaluate the results with several metrics. The results show that the marker confidence shifts significantly under distribution changes, following the trend of model accuracy, which highlights poor stability. Additionally, models struggle to effectively differentiate between markers and maintain consistent marker rankings across datasets. These findings suggest that the LLM generated markers to express their confidence is unreliable and requires improved alignment between verbal confidence and actual performance. Our work contributes to more consistent confidence estimation frameworks, ultimately facilitating reliable and trustworthy LLM responses.

Limitation

Human language is remarkable for its complexity, variability, and rich connotations, particularly when expressing uncertainty. Within a complete linguistic system, factors like sentence structure can significantly influence confidence, which is often difficult to quantify with epistemic markers alone. Moreover, in the context of long-form communication, it is clear that confidence cannot be simply measured by the confidence values of epistemic markers. To facilitate simplicity in evaluation and to focus on the study of epistemic markers, we adopt a relatively idealized approach: using epistemic markers generated by LLMs in closed-source QA tasks to represent the confidence of the responses while keeping them relatively brief. Additionally, epistemic markers may carry different meanings across cultures and languages. However, we only consider epistemic markers in English.

Despite our idealized conditions and using state-of-the-art models, LLMs still fail to consistently align epistemic markers with their true confidence levels, revealing that the issue lies not only with our approach but also with the models themselves. While they perform well in question-answering tasks, they do not truly understand epistemic markers (Zhou et al., 2023), struggle to express consistent confidence in these markers, and have difficulty aligning their confidence expressions with human expectations (Belém et al., 2024). This points to a deeper challenge in model behavior, suggesting that future research should focus on addressing fundamental gaps in model linguistic alignment.

Ethics Statement

Our work contains no offensive contents and have no potential risks.

Licenses. We will share our code under the MIT license, allowing other researchers free access to our resources for research purposes. The datasets used in this paper, including BoolQ (Clark et al., 2019), StrategyQA (Geva et al., 2021), GSM8K (Cobbe et al., 2021), MMLU (Hendrycks et al., 2021), CSQA (Talmor et al., 2019), MedMCQA (Pal et al., 2022), and CaseHOLD (Zheng et al., 2021), are shared under either the CC BY-SA license, Apache License Version 2.0, or the MIT License, all of which permit their use for research purposes. As for language models, we access all open-source LMs via the Huggingface Hub (Wolf et al., 2020). Our use of *GPT-4o* (OpenAI, 2024b)

and *GPT-4o-mini* (OpenAI, 2024a) is conducted through OpenAI’s official website¹. All associated licenses permit user access for research purposes, and we have agreed to adhere to all terms of use.

A Related Work

Confidence Estimation in LLMs. Confidence estimation in LLMs refers to the process of assessing a model's confidence in its output. Previous research on this topic can be categorized into white-box and black-box methods, distinguished by whether they utilize the model's internal information. White-box methods leverage the internal states of LLMs, with key approaches including information-based methods that analyze these inner states (Vashurin et al., 2024; Geng et al., 2024; Burns et al., 2023), such as perplexity (Fomicheva et al., 2020; Zong et al., 2024), the negative log probability of generated tokens (Duan et al., 2024), and others. In the field of black-box methods, Lin et al. (2022) first introduces the concept *verbal confidence* that prompts LLM to output its confidence directly. Most subsequent methods are based on either directly prompting the model to generate an output or consistency sampling (Lin et al., 2024; Xiong et al., 2024; Chen and Mueller, 2024; Liu et al., 2024). However, previous methods primarily focus on processing numerical values to estimate the LLM's confidence, leading to a research gap in exploring LLM confidence expression through linguistic patterns, especially epistemic markers.

Studies on Epistemic Markers. Epistemic markers are essential for expressing confidence in conversation, playing a key role in human-LLM interactions (Hu et al., 2023). Recent studies have examined the reliability of LLMs in mastering epistemic markers, primarily investigating their interpretation of various uncertainty expressions. For instance, Tang et al. (2024) and Belém et al. (2024) use sentence templates with uncertainty expressions to prompt the model to assess overall confidence, though this approach is limited by the fixed nature of the templates, restricting generalizability. Zhou et al. (2023) and Zhou et al. (2024) argue that LLMs often mimic marker distributions from training data rather than truly understanding them, with the latter highlighting a tendency for overconfidence. Lee et al. (2024) also examine epistemic markers but focus on robustness and biases in model interpretations. While these studies investigate LLM generation of epistemic markers, our work aligns most closely with Yona et al. (2024), which directly challenges the ability of LLMs to accurately convey confidence using epistemic mark-

ers. However, they employ LLM-as-a-judge and few-shot prompting to assess the numerical confidence of uncertainty expressions, introducing potential bias (Chen et al., 2024; Ye et al., 2024; Ma et al., 2023). Additionally, they use human judges to assess the quality of LLM judges, which essentially aligns the model’s interpretation of markers with human understanding. This approach is similar to other works in the field, which also focus on aligning human and LLM recognition of epistemic markers. However, as long as LLMs maintain a consistent framework for incorporating epistemic markers to express confidence, we can learn from its intrinsic mapping of marker usage and align it with human expectations through external means.

B Technical Details

B.1 Experiment Setup

Models We incorporate a range of commonly used LLMs of different scales, including Llama-3.1-8B-Instruct (Touvron et al., 2023), Qwen2.5-7B-Instruct, Qwen2.5-14B-Instruct, Qwen2.5-32B-Instruct (Yang et al., 2024), Mistral-7B-Instruct-v0.3 (Jiang et al., 2023), GPT-4o (OpenAI, 2024b), GPT-4o-mini (OpenAI, 2024a). For all models, we use a temperature of 0.5 to balance between logical consistency and creativity. All the open-source models are run on 4 NVIDIA A6000 (40G) GPUs with BF16.

We observed that instruction-tuned models exhibit greater variation and demonstrate better linguistic diversity when using epistemic markers. Although we also tested some base models, we found that for the same dataset, they emitted significantly fewer markers compared to the instruction-tuned models (See Figure 4). As a result, we chose to focus our experiments on instruction-tuned models instead.

Datasets We benchmark the LLMs’ responses with confidence expression using epistemic markers using the following seven datasets requiring knowledge in different domains: 1) Factual and commonsense knowledge: BoolQ (Clark et al., 2019), StrategyQA (Geva et al., 2021), CSQA (Talmor et al., 2019). 2) Mathematical reasoning: GSM8K (Cobbe et al., 2021). 3) Medical reasoning: MedMCQA (Pal et al., 2022). 4) Law reasoning: CaseHOLD (Zheng et al., 2021). 5) Mixed factual datasets: MMLU (Hendrycks et al., 2021).

Figure 4: The number of epistemic markers that six different models generated in BoolQ and CSQA dataset. The results indicate that the instruct-tuned models exhibit much better linguistic diversity than base models in expressing confidence, which is desired by our experiment.

Prompts The prompts used in our experiments are shown in Table 4. We performed five permutations on the prompt with *Qwen2.5-7B-Instruct* and *Mistral-7B-Instruct-v0.3* on BoolQ, StrategyQA, CSQA, MedMCQA and found that both accuracy and C-AvgCV, MAC, MRC and I-AvgCV values varied only slightly. Consequently, we randomly selected one version and conducted all subsequent experiments using it.

B.2 Model Sources

This section clarifies the sources of the models used in our study. For methods involving LLMs, we utilize their instruction fine-tuned versions (see Appendix B.1 for more details) accessed via the Hugging Face Hub (Wolf et al., 2020). Specifically, for *Llama-3.1-8B-Instruct*, we employ the version *meta-llama/Llama-3.1-8B-Instruct*. The models related to Qwen include *Qwen/Qwen2.5-7B-Instruct*, *Qwen/Qwen2.5-14B-Instruct*, and *Qwen/Qwen2.5-32B-Instruct*. For *Mistral-7B-Instruct-v0.3*, we use *mistralai/Mistral-7B-Instruct-v0.3*.

B.3 Detailed Implementation

Data Preprocessing We applied data preprocessing methods to the datasets. For GSM8K, we transformed it into a binary-question dataset for convenience. Specifically, for half of the questions Q_i with even index in GSM8K, we first extracted the correct answer A_i , then used a question template to create a binary question by incorporating (Q_i, A_i) and setting the correct binary answer to “yes.” For the remaining half of the questions Q_j , we randomly selected an answer A_j different from the correct answer, and used the same question template to create a binary question by incorporating (Q_j, A_j) and setting the correct binary answer to “no.” The question template and two examples are given in Table 5. For the training set of the MMLU, due to its massive size, we randomly sampled a subset of 20000 QA-pairs for the MMLU training set. For MedMCQA dataset, for the convenience of evaluation, we pick the subset of the answer with only one correct answer. We then randomly sample 9686 QA-pairs for the MedMCQA training set and 2422 for its test set. For BoolQ, we did not expose the model to the “passage” part and treated it as a closed-book question-answering dataset in our experiment. Since CaseHOLD isn’t explicit split into training set and test set, we divide the former 80% as training set and the rest as test set. A detailed statistics for our dataset usage is on Table 3.

Dataset	Train Size	Test Size
BoolQ	9427	3270
StrategyQA	2061	229
GSM8K	7473	1319
MMLU	20000	14041
CSQA	9741	1221
MedMCQA	9686	2422
CaseHOLD	8396	2099

Table 3: A detailed statistics of our dataset usage.

Epistemic Marker Extraction For each model, we extract the epistemic marker from each response by few-shot prompting (Brown et al., 2020) the same model to recognize the epistemic markers emitted by itself. We manually examined a subset of each dataset and find out most of them are able to recognize the epistemic markers. For the unrecognized ones or the one that didn’t match the desired format, we uniformly use *GPT-4o-mini* to

extract its epistemic markers. According to Zhou et al. (2024), models are reluctant to express confidence in words, so we also provided responses that did not include any epistemic markers as few-shot samples, and those with no markers are grouped together as a special epistemic marker.

B.4 Evaluation Metrics

This section introduces the evaluation metrics in detail and explain our experiment settings.

B.4.1 Detailed Implementation and Formulas

Our evaluation metrics are categorized into three kinds: ECE-based (Xiong et al., 2024), CV-based (Jalilibal et al., 2021) and Spearman/Pearson coefficient based (Su and Li, 2021; Xiong et al., 2004), aiming to reflect the calibration error, the degree of dispersion and correlation respectively.

NumECE, I-AvgECE, and C-AvgECE To evaluate the calibration of model-generated confidence, we introduce three metrics: NumECE, I-AvgECE, and C-AvgECE. Since the latter two are based on generalization of marker confidence, these metrics assess the model’s stability on marker confidence, considering both within-domain (I-AvgECE) and cross-domain (C-AvgECE) scenarios and comparing with number-based methods.

NumECE measures the overall calibration of the model’s outputted numerical confidence. For each dataset D_j , we compute the expected calibration error (ECE-num) based on the model’s numerical confidence on the test set. The final NumECE is the average of these ECE values across all datasets, providing a comprehensive evaluation of the model’s confidence calibration.

I-AvgECE focuses on the model’s performance within the same domain, where the training and test datasets are identical. For each dataset D_p , we calculate the marker-based expected calibration error (ECE-mar) by using the marker’s confidence $Conf(W_i, D_p, M_k)$ obtained from the training set of D_p on the test set of it when the model also emits W_i as confidence expression. The final I-AvgECE is obtained by averaging these values across all datasets as well.

C-AvgECE evaluates the model’s ability to generalize its marker confidence across different datasets. For each pair of distinct datasets (D_p, D_q) , where $D_p \neq D_q$, we calculate the marker-based expected calibration error $ECE-mar(D_p, D_q, M_k)$. This is done by using the

Table 4: Our prompt to elicit epistemic markers and numerical confidence values. The text inside the square brackets is filled with actual content in the dataset. Specifically, choices are capital letters that represent the options (e.g., “A, B, C, D” or “A, B, C, D, E”) for multiple choice questions and “yes or no” for binary questions.

model’s confidence $Conf(W_i, D_p, M_k)$ on the training dataset D_p to estimate the model’s marker confidence on the test set of D_q , thereby measuring the model’s ability to transfer its marker confidence to a new dataset. The final C-AvgECE is computed by averaging the ECE-mar values across all dataset pairs, providing insight into the model’s robustness in handling cross-distribution variations. The mathematical formulas of three ECE-based metrics is given by:

$$\begin{aligned} \text{NumECE} &= \frac{1}{|D|} \sum_{D_j \in D} \text{ECE-num}(D_j, M_k), \\ \text{I-AvgECE} &= \frac{1}{|D|} \sum_{D_p \in D} \text{ECE-mar}(D_p, D_p, M_k), \\ \text{C-AvgECE} &= \frac{\sum_{\substack{D_p, D_q \in D \\ D_p \neq D_q}} \text{ECE-mar}(D_p, D_q, M_k)}{|D| * (|D| - 1)} \end{aligned}$$

where $|D|$ is the total number of datasets (D_1, D_2, \dots, D_n) . Note that for all ECE values, we use a ECE bin number of N , where N is the number of confidence predictions.

I-AvgCV and C-AvgCV To quantify the concentration and variation of marker confidence, we propose I-AvgCV and C-AvgCV. These metrics assess how dispersed and consistent marker confidence is within individual datasets and across datasets, respectively.

I-AvgCV measures the concentration of marker confidence within a single dataset. For each dataset D_j , we calculate the coefficient of variation (CV) of the confidence of different markers $Conf(W_i, D_j, M_k)$. The final I-AvgCV is the average CV value across all datasets, providing an overall measure of confidence concentration.

It is important to note that while we expect the

Question Template

For the question [**original question**], is the answer [**original answer**] its correct answer?

Sample 1

Q_i : Each bird eats 12 beetles per day, each snake eats 3 birds per day, and each jaguar eats 5 snakes per day. If there are 6 jaguars in a forest, how many beetles are eaten each day?

A_i : 1080 (The correct answer is 1080)

Integrated binary question: For the question ‘Each bird eats 12 beetles per day, each snake eats 3 birds per day, and each jaguar eats 5 snakes per day. If there are 6 jaguars in a forest, how many beetles are eaten each day?’, is the answer 1080 its correct answer?

Binary answer: Yes.

Sample 2

Q_j : James writes a 3 - page letter to 2 different friends twice a week. How many pages does he write a year?

A_j : 223 (Randomly generated answer, the correct answer is 624)

Integrated binary question: For the question ‘James writes a 3 - page letter to 2 different friends twice a week. How many pages does he write a year?’, is the answer 223 its correct answer?

Binary answer: No.

Table 5: Data pre-processing method used in GSM8K. The text inside the square brackets is replaced by actual content in the dataset. Sample 1 keeps the original correct answer and incorporate it into the binary answer while setting the binary answer to “Yes.” Sample 2 randomly generates a wrong answer and set the binary answer to “No.”

distribution of marker confidence to be more dispersed, we are not claiming that greater dispersion is inherently better. Our desired result for models is to cover a relatively wide range of confidence values across all markers, while also clearly differentiating between different markers. This would facilitate more effective confidence expression in a variety of scenarios. However, as shown in Table 1, the average I-AvgCV value marker is lower than 0.2, which indicates that the marker confidence is highly concentrated, leading us to conclude that the model fails to clearly differentiate between the markers.

C-AvgCV evaluates the consistency of marker confidence across datasets. For each shared marker (markers that appear in each dataset) W_i , we compute the CV of the marker confidence across different datasets and then average these values over all shared markers. The final C-AvgCV quantifies the consistency of model-generated confidence across multiple datasets.

The mathematical formulations for I-AvgCV and C-AvgCV are given by:

$$CV(D_j, M_k) = \frac{\sigma(D_j, M_k)}{\mu(D_j, M_k)},$$

$$\text{I-AvgCV}(M_k) = \frac{1}{|D|} \sum_{j=1}^{|D|} CV(D_j, M_k),$$

$$CV(W_i, M_k) = \frac{\sigma(W_i, M_k)}{\mu(W_i, M_k)},$$

$$\text{C-AvgCV}(M_k) = \frac{1}{|W|} \sum_{i=1}^{|W|} CV(W_i, M_k)$$

where $|W|$ is the number of shared markers across every datasets for model M_k , $\sigma(D_j, M_k)$ is the standard deviation of the confidence scores for all markers in dataset D_j for model M_k , $\mu(D_j, M_k)$ is the mean of the confidence scores for all markers in dataset D_j for model M_k , $\sigma(W_i, M_k)$ is the standard deviation of the confidence scores for the marker W_i across different datasets for model M_k and $\mu(W_i, M_k)$ is the mean of the confidence scores for the marker W_i across different datasets for model M_k .

MRC To assess the alignment of marker rankings across datasets, we introduce a metric based on the Spearman rank correlation coefficient: *Marker Rank Correlation* (MRC). This metric captures the degree of consistency in marker confidence rankings across datasets.

Specifically, For each pair of datasets (D_p, D_q) , we compute the Spearman rank correlation coefficient between the confidence rankings of shared markers. The final MRC for the model is the average correlation across all dataset pairs. The mathematical formulations for MRC are given by:

$$\text{MRC} = \frac{1}{|P|} \sum_{\substack{(D_p, D_q) \in P \\ D_p \neq D_q}} \rho(D_p, D_q)$$

where W_1, \dots, W_i are all the epistemic markers that shared by D_p and D_q , $S(X, Y)$ denotes the Spearman rank correlation coefficient between the rankings of X and Y and $\text{Conf}(W_i, D_j, M_k)$ represents the confidence of marker W_i for model M_k on dataset D_j .

MAC To analyze whether the confidence of markers and the accuracy of the model are positively correlated, we propose the *Marker Accuracy Correlation* (MAC) based on the Pearson correlation coefficient.

Specifically, for a given model M_k , we consider the confidence of a specific shared marker W_i , which is present across all datasets associated with M_k . We then compute the Pearson correlation coefficient between the set of marker confidences across these datasets and the model’s overall accuracies on the same datasets. Finally, we compute the average of the correlation coefficients $\rho(W_i, M_k)$ across all shared markers W_i to obtain the overall correlation coefficient for the model, denoted as $\text{MAC}(M_k)$. It’s mathematical formula is given by:

$$\text{MAC}(M_k) = \frac{1}{|W|} \sum_{W_i \in W} \rho(W_i, M_k),$$

where W is the set of all shared markers W_i , $|W|$ is the number of all shared markers and $\rho(W_i, M_k)$ is the Pearson correlation coefficient between the confidence of marker W_i and the model’s accuracy on all the datasets.

These metrics provide a quantitative assessment of the consistency and concentration of model-generated confidence values across different datasets.

Threshold	Confidence Interval
10	$\sim 23\%$
50	$\sim 10\%$
200	$\sim 5\%$

Table 6: The exact confidence interval of different filtering thresholds.

B.4.2 Details on Marker Filtering Strategies

The filtering is necessary because our method of quantifying marker confidence is based on accuracy, which is affected by the confidence interval. If the sample size for a particular marker is too small, its corresponding confidence values can be heavily influenced by random variations. For instance, if the marker “unsure” appears only once in the training set and the response happens to be correct, the marker confidence for “unsure” would be 100%, which may not accurately reflect the model’s true intent. Previous works also show that confidence expression could be more reflective for humans when the it is determined in a crowd-source manner (Pennekamp et al., 2024), which supports our setting.

Furthermore, we have enough shared markers (more than ten for each model) after implementing the filtering, which ensures the reliability of our experiment.

On the other hand, all epistemic markers obtained from the training set are used for the experiment related to ECE values. Since the estimated confidence for each question in the test set is derived from the marker confidence in the training set, it is essential to ensure that the vast majority of markers in the test set can be mapped to corresponding markers in the training set. This approach is reasonable since the low frequency of marker occurrences results in minimal impact on the overall calibration performance, which ensures both completeness and reliability.

C Distribution Analysis

Our investigation primarily focused on the influence of **distribution diversity** and **difficulty** on the generalizability of marker confidence. We measured this generalizability by calculating the Average ECE value across various models for each specific dataset.

Table 7 illustrates that multi-domain datasets, specifically StrategyQA (14.42%) and MMLU (15.97%), exhibit significantly higher Average ECE

values compared to single-domain datasets such as GSM8K (Math, 6.68%), MedMCQA (Medical, 6.25%), and CaseHOLD (Law, 9.53%). This finding leads to the conclusion that a more diverse data distribution impedes the transfer of models’ marker confidence preferences from the training to the test set (Wang et al., 2023b,a, 2024a,b, 2025; Wang and Song, 2024).

Dataset	Domain	Average ECE
StrategyQA	Multi-domain	14.42
MMLU	Multi-domain	15.97
GSM8K	Math	6.68
MedMCQA	Medical	6.25
CaseHOLD	Law	9.53

Table 7: The Average ECE values across different models for certain dataset. We found that multi-domain datasets exhibit higher average ECE values than single-domain ones.

Additionally, we observed that a substantial **difficulty gap** between the training and test sets of the marker confidence also compromises its transferability. As shown in Table 8, we utilized a challenging math dataset, MATH-500, and a simpler math dataset, GSM8K, to compute the MRC value, representing the relevance of marker rankings across these two datasets. For both *Qwen2.5-7B-Instruct* (0.38) and *Mistral-7B-Instruct-v0.3* (0.26), the models demonstrated low relevance in marker rankings obtained from datasets with differing difficulties. This indicates that the **difficulty of the data distribution** can significantly affect the generalizability of marker confidence preferences.

Model	MRC
<i>Qwen2.5-7B-Instruct</i>	0.38
<i>Mistral-7B-Instruct-v0.3</i>	0.26

Table 8: The MRC value for two models across MATH-500 and GSM8K. The results shows that marker rankings obtained from the two datasets are relevant to little extent.

Limited-Resource Adapters Are Regularizers, Not Linguists

Abstract

Cross-lingual transfer from related high-resource languages is a well-established strategy to enhance low-resource language technologies. Prior work has shown that adapters show promise for, e.g., improving low-resource machine translation (MT). In this work, we investigate an adapter souping method combined with cross-attention fine-tuning of a pre-trained MT model to leverage language transfer for three low-resource Creole languages, which exhibit relatedness to different language groups across distinct linguistic dimensions. Our approach improves performance substantially over baselines. However, we find that linguistic relatedness—or even a lack thereof—does not covary meaningfully with adapter performance. Surprisingly, our cross-attention fine-tuning approach appears equally effective with randomly initialized adapters, implying that the benefit of adapters in this setting lies in parameter regularization, and not in meaningful information transfer. We provide analysis supporting this regularization hypothesis. Our findings underscore the reality that neural language processing involves many success factors, and that not all neural methods leverage linguistic knowledge in intuitive ways.

1 Introduction and Background

For a majority of the world’s languages, data scarcity remains a barrier for reliable machine translation (MT). Cross-lingual transfer from high-resource to low-resource languages has been shown to help mitigate this (Zoph et al., 2016; Tars et al., 2021), but has still not closed the gap between high- and low-resource scenarios. In this work, we seek to exploit methods from parameter-efficient fine-tuning (PEFT) to further improve cross-lingual transfer for a Creoles, an under-served group of low-resource languages.

PEFT methods such as bottleneck adapters (Houlsby et al., 2019; Pfeiffer et al., 2020), LoRA

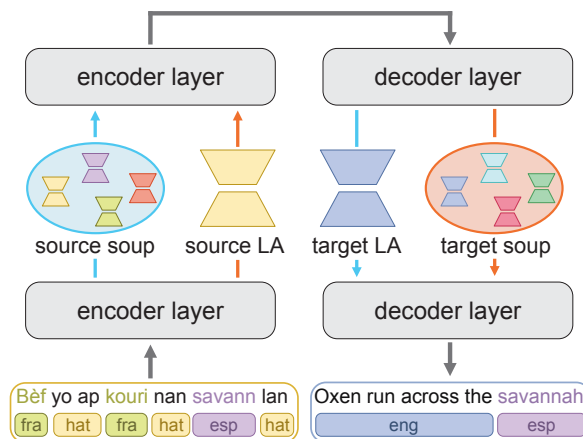

Figure 1: Overview of the MT transfer experiments between English and Creoles. The ↑ path shows the use of source language adapter in the encoder and the ‘souped’ (weight-averaged) target and transfer language adapters in the decoder layers. The ↓ path shows the opposite direction.

(Hu et al., 2021), and (IA)³ (Liu et al., 2022a) are widely used to adapt language models to low-resource languages (Parović et al., 2022; Parovic et al., 2023; Rathore et al., 2023; Vázquez et al., 2024; Dementieva et al., 2025). This is in part because they are robust to hyperparameter choices and training data amounts, in contrast to full model fine-tuning (Pfeiffer et al., 2024). Some PEFT methods can successfully use monolingual data to improve MT performance; for example, Üstün et al. (2021) train denoising adapters for both source and target languages, inserting the adapters between the encoder and decoder layers of an MT model, respectively. By freezing all model weights except for the cross-attention of the decoder, they then carry out cross-attention fine-tuning (CAFT) with only a limited amount of parallel data. Chronopoulou et al. (2023a) also address data scarcity in adaptation to new domains following Wortsman et al. (2022) by “souping” (i.e., weight-space averaging) pretrained domain adapters, as

in Equation 1 (where θ_i represent the weights of each domain adapter). We combine the principles of these prior works in our paper.

$$\theta_{soup} = \frac{1}{l} \sum_{i=1}^l \theta_i \quad (1)$$

Prior work has also catalyzed transfer by training language family adapters to leverage phylogenetic relations between languages (Faisal and Anastasopoulos, 2022; Chronopoulou et al., 2023b). Other factors of selecting transfer languages have been investigated in the past besides phylogeny. These include similarity in terms of explicit grammatical features like word order (Pires et al., 2019), similarity in terms of language representation space (Üstün et al., 2022), as well as lexical overlap (Pfeiffer et al., 2021; de Vries et al., 2022). Other metrics have been proposed to select candidate transfer languages, including Subword Evenness (SuE; Pelloni et al., 2022) which quantifies how uneven subword lengths are in a multilingual tokenizer: uneven implies successful transfer.

In this work we focus on MT for Creole languages, a set of low-resource languages with hundreds of millions of speakers who presently lack reliable MT systems, despite demonstrable need for them (Neto et al., 2020; Robinson et al., 2024). Creole language technologies have not been thoroughly researched or developed; yet several works that do exist inspired our decision to explore them (cf. our literature review in Appendix A). Although most Creoles are genealogically related to high-resource languages (*e.g.*, English, French, Spanish), previous works have had mixed success leveraging transfer learning to boost performance for Creoles (Lent et al., 2022a, 2024; Robinson et al., 2022, 2023). No prior work has conclusively determined which languages to select for successful Creole transfer, explored PEFT in this application, nor compared linguistic and non-linguistic language relations in Creole transfer language selection. These aspects combined make Creoles a viable testbed for comparing transfer criteria.

We apply a new adapter method inspired by Üstün et al.’s (2021) approach to MT for three Creole languages. (See details in §2.) We experimented with this approach to compare a large variety of dimensions of linguistic relatedness and found that, contrary to our initial hypotheses, gains are virtually indistinguishable regardless of which transfer criterion we apply. Still more surprisingly,

incorporating unrelated languages or noise to the Creole adapters yields comparable improvements. We conjecture that even untrained adapters may assist cross-attention fine-tuning by acting as regularizers. We couple this hypothesis with analysis presented in §3.

We contribute both ① a novel regularization method combining adapter souping with cross-attention fine-tuning that surpasses baselines by 8 BLEU in some settings, and ② evidence that some of the benefit of adapters lies in regularization, independent of a wide range of linguistic information.

2 Methodology and Experiments

We follow Üstün et al. (2021) using their two-step methodology. First, we train monolingual denoising adapters separately for each language. At inference time, we add the relevant adapters to the encoder and decoder corresponding to the source and target languages, and fine-tune the decoder cross-attention on small amounts of parallel bitexts. Furthermore, we induce transfer by weight-averaging ("souping") Creole adapters with candidate transfer language adapters inspired by previous efforts (Faisal and Anastasopoulos, 2024; Wortsman et al., 2022; Chronopoulou et al., 2023a). The novelty lies in combining source and target language adapters, cross-attention fine-tuning and souping in a single method for improving low-resource MT. (See more details about our methodology in Section 2.3).

We focus our efforts on three Creole languages: Haitian, Papiamentu, and Sango, spoken in total by roughly 18 million speakers in Haiti, the ABC Islands, and the Central African Republic, respectively.¹ This selection is primarily due to the intersection of data availability and support by NLLB-200, the MT model we apply in experiments (NLLB Team et al., 2022). Despite their unique contexts, these languages share commonalities in socio-historical development: they evolved from linguistic contact between European and African languages resulting from Western colonialism (Kouwenberg and Singler, 2009). As such, they can trace parts of their lexicon and grammar back to both European and African languages.

2.1 Selecting Languages for Transfer

We examine five principled approaches to select transfer languages, which range from linguistically motivated to purely data-driven. First, we

¹According to [Ethnologue](#).

Dataset	Domain	Source
MADLAD	Web scrape	Kudugunta et al., 2023
NLLB-OPUS	Web scrape	NLLB Team et al., 2022
FLORES-200	Wikipedia	NLLB Team et al., 2022

Table 1: Datasets and domains used. We use MADLAD to train adapters, NLLB-OPUS to fine-tune cross-attention, and FLORES-200 to evaluate.

leverage language phylogeny, selecting likely Indo-European (**IE**; Rickford and McWhorter, 1997; Lefebvre, 2011) and Niger-Congo (**NC**; Hammarström et al., 2023; Mufwene, 2006; Hall, 1958; Faine, 1937) **relatives** for Haitian, Papiamentu, and Sango. We also experiment with transfer between these **Creole languages**, as previous works have argued that Creole languages have linguistic commonalities with each other (Daval-Markussen and Bakker, 2012). We next select languages by similarity of documented typological features, calculated as **lang2vec** distances (Littell et al., 2017). For data-driven language selection, we determine language relatedness from similarity of NLLB-200 language embeddings (**NLLB representations**; NLLB Team et al., 2022), as well as Subword Evenness (**SuE**; Pelloni et al., 2022). For details of our language selection processes, see Appendix C.

2.2 Control experiments

As an experimental control, we identify three language groups with no linguistic relation to the Creole languages in question: **Uralic** languages, **Dravidian** languages, and **CJK** (*i.e.*, Chinese, Japanese, and Korean). None of these groups share phylogeny or significant amounts of typological features with our Creole languages. The latter two also differ in terms of script. And the final group is distinct in that its languages also bear no phylogenetic relation to each other. As a final experimental control, we use a randomly initialized, untrained adapter (**init**). We use this untrained adapter in two ways: as a replacement for the Creole language adapter, and souped with the Creole language adapter. As Chronopoulou et al. (2023a) suggest for souping, we use the same random initialization for all untrained and trained adapters.

2.3 Experimental Details

Our experiments follow the same general steps. ① We train all language adapters individually on denoising using monolingual data from MADLAD-400 (Kudugunta et al., 2023) that we preprocess

and clean further.² ② We add the source language adapter s to the encoder and the target language adapter t to the decoder and freeze all adapter and model parameters. In adapter averaging experiments the `init` or the helper language adapters are souped with the s or t language adapters in this step as well. ③ We unfreeze the cross-attention of the decoder and use 10k parallel data from NLLB-OPUS (NLLB Team et al., 2022) to do cross-attention fine-tuning (CA-FT). ④ We evaluate MT from $s \rightarrow t$ on Flores-200 (NLLB Team et al., 2022) using mean BLEU and chrF scores. (See Table 1 for data composition.)

All experiments are conducted using a 600M-parameter distillation of the original 54B-parameter NLLB-200 model (NLLB Team et al., 2022) which has 12 encoder and 12 decoder layers, 16 attention heads, 1,024 dimensions, and a model vocabulary of over 250,000 sentence-piece tokens shared across all languages. We adopt the adapter training and the hyperparameters from Üstün et al. (2021), training bottleneck adapters on 10,000 training samples for a maximum of 100,000 training steps with early stopping, a batch size of 8, 4,000 warmup steps, and the Adam optimizer with a maximum learning rate of $2e-4$ with a gradient accumulation of 8 steps. All adapters initialized from the same random seed as Chronopoulou et al. (2023a) show that this is necessary for successful souping. We train CA-FT for 1 epoch with early stopping. We soup adapters with the same weight except when averaging with the `init` adapter where the weight of the Creole language to `init` adapter is 1 : 3, to closer approximate the other setups where the Creole language adapter is souped with three other adapters.

3 Results and Analysis

Here we present only Creole-to-English BLEU scores. We conducted preliminary experiments using only 800 aligned fine-tuning segments on these and the inverse translation directions, and saw the same trends shown in our results here. We decided to prioritize into-English MT for our main experiments after seeing small adapter gains across the board for into-Creole. (See Appendix D for our full results suite.) Table 2 shows BLEU improvements of our approaches over both baselines: the base MT model with CA-FT, and the s and t language adapters without souping (Üstün et al., 2021). The

²See Appendix B for preprocessing details.

Experiment	hat → eng	pap → eng	sag → eng
Base Model (CA-FT)	33.37	38.97	10.89
<i>s</i> and <i>t</i> Adapters	32.33	40.04	11.40

Table 2: Mean BLEU scores for Creole to English MT experiments over a diverse set of conditions for selecting transfer languages, as motivated by phylogeny (🌿), language group (❤️), typological databases (📖), model representations (👤), and tokenization (🗑️). Experimental results are also compared against control experiments with unrelated languages (🗑️) and untrained adapters (📖). We highlight mean performance improvements over the Base Model (CA-FT) for both transfer and controls.

improvements, however, are not particularly differentiated between various transfer and control scenarios, and notably, untrained adapters match or exceed performance of trained ones.

Regularization, Not Transfer? Two facets of our results indicate that cross-lingual transfer does not explain the success of our methodology. The first is that adapter souping improves performance over the baselines, *regardless* of the criteria used to select transfer languages. The unrelated control languages (*i.e.*, Dravidian, Uralic, and CJK) achieve performance gains on par with languages selected through principled means (*e.g.*, genealogy and typology), without marked differences in BLEU or chrF scores. This holds for both the source and target language adapters in the encoder and decoder, respectively. The second is the commensurate success of the untrained adapters in averaging. Souping adapters with ‘meaningful’ language adapters is no better than souping with random noise, indicating that cross-lingual transfer (or any information transfer) is likely not responsible for performance gains. These findings seem more consistent with previous works on regularization, which find that adding noise can improve a model’s ability to gener-

Table 3: BLEU scores for Catalan to English MT.

alize and avoid overfitting (Hochreiter and Schmidhuber, 1994; Poole et al., 2014; Moradi et al., 2020) (which may be pertinent given both our limited train sets and train/test domain mismatch).

We perform multiple analyses to test our hypothesis that adapters are regularizing. First, we compared the use of untrained adapters to the use of adapters of known closely related languages. Because the close relatives of Creole languages are disputed, we turned to another relatively low resource language, Catalan, which has three close relatives also supported by NLLB-200. Spanish, Portuguese, and Occitan are closely related to Catalan by effectively every reasonable linguistic criterion. Table 3 shows different trends for Catalan (a language on which NLLB’s baseline performance is notably high). In this scenario, none of the adapter approaches improve performance over the baseline, once again indicating that the monolingual denoising adapter training on MADLAD data is not positively contributing. And once again, even with these highly attested close linguistic relationships, we see the random adapter comes nearest to recovering the baseline score in both data settings. This set of results underscores the possibility that CA-FT without randomized regularization may lead to overfitting (hence the performance drops). We also experimented souping only one or two related languages for both Catalan→English and Papiamentu→English but saw no improvements.

We observed training loss, gradient norms, and dev loss for CA-FT of the experiments presented in this section. We compare untrained adapter souping (hypothesized regularization) with simple *s* and *t* adapters (unregularized), finding that the unregularized case has moderately higher gradient norms and dev loss, consistent with our hypothesis. The unregularized case also sees higher train loss, which is inconclusive regarding our hypothesis since an overfit model may be stuck in a local minimum or be overfit on a distribution varying from the CA-FT data. (See Appendix E.)

Figure 2: Parameter variance between the pretrained Creole adapters (represented by the outliers) vs the souped adapters of various experimental conditions (shown in the boxplots).

We also show that parameter variance decreases substantially when souping adapters compared to the pretrained Creole adapters (Figure 2), further supporting our regularization explanation.

Qualitative Evaluation Beyond computational analyses, we further assess the quality of translations across our experimental conditions. To start, a subset of the authors create a simple annotation guideline, inspired by MQM (Burchardt, 2013), to help identify errors regarding vocabulary, grammar, and other translation issues (*e.g.*, addition or omission). Then, one author, a native Haitian speaker, carries out a linguistically-grounded manual evaluation of Haitian \rightarrow English translation across the baseline of *s* and *t* Adapters, the IE Transfer, and the Untrained Souping. The evaluation involves 33 samples per condition presented to the annotator in three shuffled sets (*i.e.*, 99 sentences in total) to avoid biasing him. The primary focus falls on grammar and translation issues (For a condensed list of errors, see Table 9 in Appendix F). Although a small sample size, we observe that adapter souping results in less grammatical and lexical errors when applying the pretrained Haitian and English adapters with CA-FT. While both IE Transfer and Untrained Souping are comparable in reducing lexical errors, the latter does better in avoiding grammatical errors. This may indicate a comparative success of regularization when adding random noise that is also reflected in the +0.98 BLEU score Untrained Souping has over IE Transfer for Haitian \rightarrow English (see Table 2). We believe that even a small manual translation evaluation demonstrates the value of involving native speakers in MT.

4 Conclusion

Inspired by prior success of monolingual adapters and CA-FT for low-resource MT, we corroborate prior findings that adapters can help by consistently improving BLEU scores for a set of Creole languages. However, we differ from prior research by finding no evidence of linguistic or informational transfer from adapters, even across a wide array of linguistic relationships. We hypothesize that most adapter aid in this setting is from regularization and find some analytical support for this.

Limitations

Scalability This work can only be applied to a small subset of all Creoles that are present in larger benchmarks (Lent et al., 2024; Robinson et al., 2024) due to the fact that they are low-resource languages – in certain cases, extremely so –, so there is an issue of data scarcity and a limited support by MT models. This data scarcity extends to also the African relatives of the Creoles we target in this paper. Our work is further limited by the limited coverage by typological resources. Grambank (Skirgård et al., 2023) supports only Haitian, not Papiamentu and Sango, and while the lang2vec covers more languages, the coverage is limited and uneven. Despite these constraints, however, we believe our selection of Creoles (*i.e.*, Haitian, Papiamentu, and Sango) are diverse enough to make high-level hypotheses about transfer learning for Creoles; these languages have different relatives (*e.g.*, inheriting large vocabulary from French, Portuguese, and Ngbandi, respectively) and are spoken across different regions (*i.e.*, the Caribbean and Africa). Moreover, our experimentation over these languages is **extensive**, with careful investigation of 6 transfer scenarios, 1 `init` baseline, and 3 principled controls. So while this work cannot scale *widely* across Creoles, we investigate transfer scenarios for each Creole *deeply*.

Domain of Data Similar to many other low-resource languages, much of the available data for Creoles comes from the religious domain (*e.g.*, Bible translations), which has a characteristic style that is typically not representative of language use in other contexts (Mielke et al., 2019). Moreover, religious domain content may not necessarily be culturally appropriate for some communities (Hershovich et al., 2022; Mager et al., 2023). In order to be truly useful for end users, data sourced from a

wide variety of domains will ultimately be a necessary component for the development of robust MT systems for Creoles. Until more such data becomes available, we believe that work at the intersection of transfer learning and domain adaptation could be greatly beneficial for Creole NLP.

Difficulty in Verifying Neural Phenomena

While we find some analytical evidence that our adapters are boosting performance by regularizing fine-tuning, it is difficult to verify this with certainty. Regularization is a mathematical phenomenon that can be demonstrated rigorously, but such involved analysis is outside the scope of this current work; hence we leave these important analytical details to future work.

Ethics Statement

As Creole languages are often marginalized, we recognize the necessity of heightened ethical scrutiny for research involving these languages. We thus engage directly with considerations from [Lent et al. \(2022b\)](#), [Mager et al. \(2023\)](#), and [Bird \(2020\)](#), to ensure that our work is in accordance with the needs and desires of speakers. To this end, we note that speakers of many different Creole languages actively *want* and/or *need* improved MT technology for their language. In the context of Haitian Creole, for example, MT technology is highly desirable for facilitating interactions with non-Haitian speakers (e.g., the neighboring, Spanish-speaking Dominican Republic, and foreign workers at NGOs operating in Haiti). Additionally, MT has the potential to greatly improve access to information for Haitians. [DeGraff et al. \(2022\)](#) argues that the lack of access to education in Creole is a critical barrier to social and economic mobility in Haiti. Accordingly, reliable MT for Haitian Creole could make available high-quality educational resources from platforms such as edX, Coursera, MITx, and Udemy, for example. Thus, if MT systems could offer accurate translations into Haitian Creole, they would become transformative tools for advancing the country’s development, breaking down educational barriers, and fostering greater social equity. We note similar potential for MT for speakers of Sango in Central African Republic, Chad, and Democratic Republic of the Congo and ([African Development Bank Group, 2024](#)). And while the socioeconomic context of Aruba, Bonaire, and Curaçao is quite different from that of aforementioned Haiti or Central African Republic, speakers’ desire

for language technology for Papiamentu is well documented through projects like [papiamentu.ai](#).

Acknowledgments

MF, JB, and HL were supported by the Carlsberg Foundation, under the *Semper Ardens: Accelerate* program (project nr. CF210454); the same project also supported the annotation work performed by DJB. EL was funded by the Google Award for Inclusion Research program (awarded to JB and HL for the “CREOLE: Creating Resources for Disadvantaged Language Communities” project). A Literature Review

NLP research for Creole languages is still in relatively early stages. Some large-scale multilingual MT systems have limited Creole language support: NLLB (NLLB Team et al., 2022) supports five Creole languages, and Google Translate³ and Lego-MT (Yuan et al., 2023) each support eight. Other works have focused specifically on building MT for Creole languages Haitian (Robinson et al., 2022; Callison-Burch et al., 2011; Frederking et al., 1997), Singlish (Wang et al., 2017; Liu et al., 2022b), Nigerian Pidgin (Adelani et al., 2022; Ogueji and Ahia, 2019), Mauritian Creole (Dabre and Sukhoo, 2022), Sranan Tongo (Zwennicker and Stap, 2022), Guyanese Creole (Clarke et al., 2024), and Jamaican Patois (Robinson et al., 2022). Some others have focused on building Creole language-specific NLP tools outside of MT for Nigerian Pidgin (Muhammad et al., 2023, 2022; Adelani et al., 2021; Oyewusi et al., 2020; Caron et al., 2019), Jamaican Patois (Armstrong et al., 2022), and Martinican Creole (Mompelat et al., 2022).

³<https://translate.google.com/> as of 8 Feb., 2025

More recently, researchers have developed large scale multi-Creole-language NLP applications. Lent et al. (2024) developed CreoleVal, a multitask benchmark for Creoles including an MT dataset and model for 28 Creole languages. Robinson et al. (2024) expanded on Lent et al.’s (2024) work, building genre-diverse MT datasets and models for 41 Creole languages of the Caribbean, Latin America, and Colonial Africa. Perhaps most pertinent to our current work are past studies into cross-lingual transfer to benefit Creole NLP. In tightly controlled experiments, Robinson et al. (2023) found indications that Haitian and Jamaican Patois’ Niger-Congo relatives may be more helpful as transfer languages than their Indo-European relatives, for MT applications. Lent et al. (2022a), however, did not identify clear advantages from a language’s relatedness to a Creole language in terms of its usefulness in transfer learning. Given the sparse research and even sparser positive results in the area, optimal transfer learning for Creole NLP remains an open question.

B Data Preprocessing

The MadLad corpus is organized in series of internet-scraped documents, which the MadLad team cross-checks for noise (Kudugunta et al., 2023). For training the monolingual adapters, we use the *MadLad-Clean* subsplit and we perform further preprocessing, since we noted after manual inspection that noise can still be present in the documents. Firstly, the MadLad documents are split into sentences using the SentenceSplitter⁴ library.

For each sentence in the document, we define the following rules, if any of the rules is breached, then the given sentence is not included in the final monolingual training corpus.

1. Sentence ends with a terminal punctuation mark (’,’, ’!’, ’ ” ’, ’?’).
2. Ratio of numerical characters with respect to all other characters is less than **0.25**.
3. Sentence starting with a bullet-point.
4. Sentence containing a *lorem ipsum* substring.
5. Ratio of stop-words with respect to all other tokens is less than **0.6** using whitespace tokenization.
6. Ratio of token count that does not contain alpha characters with respect to total token count is less than **0.25**, using whitespace tokenization.

⁴<https://github.com/mediacloud/sentence-splitter>

7. Sentence length is less than **14** and more than **300** characters.
8. Ratio of capitalized characters is less than **0.2**.
9. Ratio of alpha characters with respect to all other characters is more than **0.6**.
10. Language identification does not match the expected language. For this we employ FastText model ⁵.

This preprocessing removed approximately 20-23% of sentences, depending on the language. The same preprocessing steps were also applied to NLLB parallel data used for cross-attention fine-tuning, where preprocessing removed approximately 30-50% of the sentences.

C Selecting Languages for Transfer

Table 4 displays the different transfer languages we selected in our experiments. Below we detail our processes of selecting them.

C.1 Phylogeny-based Transfer

Faisal and Anastasopoulos (2022) followed principles of language phylogenetics to inform their transfer learning experiments, training adapters on combined Indo-European data, and for subfamilies of Indo-European such as Germanic, Romance, Indo-Aryan, etc. To translate for French, for example, they stacked a French adapter on top of a Romance and then an Indo-European adapter at inference time. Creole phylogeny is heavily disputed, however (Kouwenberg and Singler, 2009). Linguists have debated whether Atlantic Creole languages such as Haitian and Papiamentu are best understood as Niger-Congo (NC) languages with extensive Indo-European (IE) lexical borrowings (Lefebvre, 2011; Rickford and McWhorter, 1997), or as IE languages that developed with strong NC influence (Faine, 1937; Hall, 1958; Hammarström et al., 2023; Mufwene, 2006). Considering this lack of consensus, we select two groups of related languages for each Creole language: IE relatives and NC relatives. In this work, we made a selection based on APICS (Michaelis et al., 2013) and linguistic references.

C.2 Typological Feature-based Transfer

Information about the typological features of languages is typically documented in databases such as APICS (Michaelis et al., 2013), WALS (Dryer

⁵<https://huggingface.co/facebook/fasttext-language-identification>

Condition	Language
Haitian	
Creole Language	hat
IE Relative	fr, es, en
NC Relative	ig, ee, fon
lang2vec	grc, oc, fo
NLLB	pap, epo, ltz
Papiamentu	
Creole Language	pap
IE Relative	nl, pt, es
NC Relative	kg, ak, fon
lang2vec	suz, sr, ug
NLLB	hat, war, tgl
Sango	
Creole Language	sag
IE Relative	fr
NC Relative	kbp
lang2vec	ig, yo, ca
NLLB	kg, tsn, lin
Subword Evenness	kat, rus, zsm
Controls	
Uralic	fin, est, hun
CJK	zho, jap, kor
Dravidian	te, ta, ka
Other Settings	
Hungarian	
lang2vec	fin, tur, als
NLLB	fin, bul, hrv
Yoruba	
lang2vec	tha, ibo, fon
NLLB	ibo, hau, xho

Table 4: All languages used for the various experimental settings.

and Haspelmath, 2013), and Grambank (Skirgård et al., 2023). The lang2vec library (Littell et al., 2017) assembles typological feature vectors from different sources, enabling measurement of holistic typological distance between languages. The drawbacks of lang2vec include the lack of equal coverage of languages in terms of the number of features, and the coarseness of the linguistic properties (Ponti et al., 2019). To supplant the lack of coverage, we use data2lang2vec which uses textual data to inform feature-prediction of the missing features (Amirzadeh et al., 2025).

C.3 Data-driven Language Selection Methods

NLLB Language Embeddings Typological similarity between languages can also be derived in a data-driven manner, *e.g.*, from language embeddings. To derive the similarity between languages this way, we utilize the language embeddings of the distilled NLLB-200 model which implicitly contain much information with regards to the various languages especially with regards to morphosyntax and vocabulary.

Subword Evenness Introduced by Pelloni et al. (2022), Subword Evenness (SuE) is a metric quantifying the differences in the length of subword units for each individual language. It presents another data-driven approach to transfer language selection. In this metric, lower SuE scores have been demonstrated as a good predictor of transfer success to various low-resource languages. Thus, we select the 5 languages in the MADLAD dataset with the lowest SuE angles as calculated when using a BPE tokenizer, see Table 5.

Language Code	Language Code	Script	SuE Angle
-azb	South Azerbaijani	Arabic	66.72
kat	Georgian	Georgian	72.57
zsm	Malay	Latin	79.80
-kas	Kashmiri	Devanagari	80.79
rus	Russian	Cyrillic	81.21

Table 5: MADLAD Languages with the lowest SuE angles calculated using a BPE tokenizer. We note that MADLAD only has Norther Azerbaijani (Latin script), and not South Azerbaijani (Arabic script). Similarly, Kashmiri is only in MADLAD with the Arabic script, not with Devanagari.

C.4 Control Experiments with Unrelated Languages

To determine whether improvements over Creoles are truly the result of successful cross-lingual trans-

fer, we compare the previously described methods against an equivalent adapter approach using entirely unrelated languages. We use three different sets of such unrelated languages. The first set is made up of the **Uralic languages** Finnish, Estonian, and Hungarian, which are written with the Latin script but have no phylogenetic relation to Haitian, Papiamentu, and Sango. The second set consists of Chinese, Japanese, and Korean – so-called **CJK languages** –, which belong to three distinct language families and are written with three distinct scripts having little to no overlap with Atlantic and African Creole languages. The third group consists of the **Dravidian languages** Tamil, Telugu, and Kannada, which are closely related to each other but also written with three distinct scripts, and again are unrelated to the Creole languages in terms of phylogeny.

D Full Results

See Table 6 for our results translating between English and Creole languages using only 800 fine-tuning parallel segments.

E Training Loss

Table 7 compares loss when evaluating on a small subset of the NLLB CA-FT training data. Figure 3 indicates that the adapters we train learn successfully from the MADLAD-400 data on a selection from all language adapters.

F Native Speaker Evaluation

See Table 9 for a condensed categorization of translation errors under the Untrained Souping (🇵🇸), the IE Transfer (🌱), and the *s* and *t* Adapters (*s* + *t*) conditions.

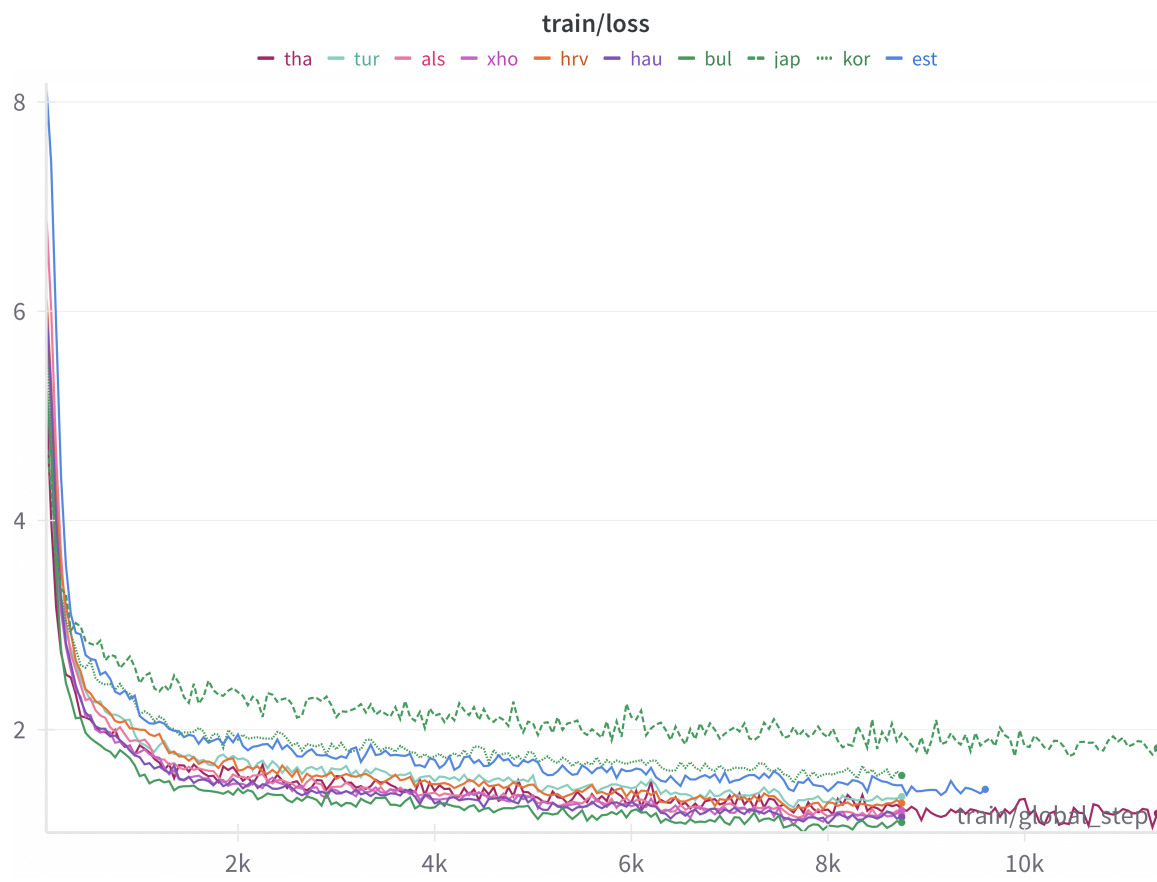

Figure 3: Training loss curves for a subset of adapter training experiments.

LLMs instead of Human Judges?

A Large Scale Empirical Study across 20 NLP Evaluation Tasks

Abstract

There is an increasing trend towards evaluating NLP models with LLMs instead of human judgments, raising questions about the validity of these evaluations, as well as their reproducibility in the case of proprietary models. We provide JUDGE-BENCH, an extensible collection of 20 NLP datasets with human annotations covering a broad range of evaluated properties and types of data, and comprehensively evaluate 11 current LLMs, covering both open-weight and proprietary models, for their ability to replicate the annotations. Our evaluations show substantial variance across models and datasets. Models are reliable evaluators on some tasks, but overall display substantial variability depending on the property being evaluated, the expertise level of the human judges, and whether the language is human or model-generated. We conclude that LLMs should be carefully validated against human judgments before being used as evaluators.

 <https://github.com/dmg-illc/JUDGE-BENCH>

1 Introduction

For many natural language processing (NLP) tasks, the most informative evaluation is to ask humans to judge the model output. Such judgments are traditionally collected in lab experiments or through crowdsourcing, with either expert or non-expert annotators, as illustrated in Fig. 1. Recently, there has been a trend towards replacing human judgments with automatic assessments obtained via large language models (LLMs; Chiang and Lee, 2023; Wang et al., 2023; Liu et al., 2023; Li et al., 2024; Zheng et al., 2024, *inter alia*). For example, the LLM

*Authors listed in alphabetical order.

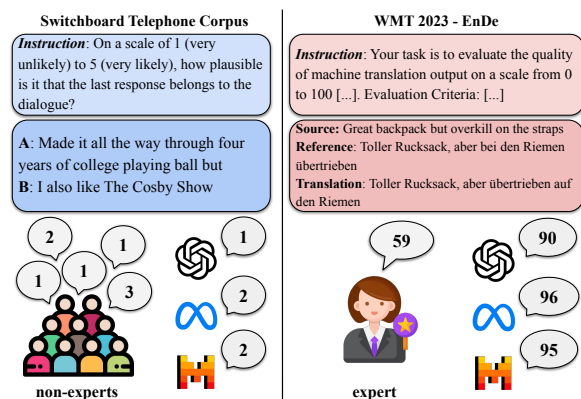

Figure 1: Evaluation by expert and non-expert human annotators and by LLMs for two tasks involving human-generated (left) and machine-generated text (right).

could be instructed to rate a response generated by a dialogue system for its perceived plausibility, on a scale from 1 to 5. This drastically reduces the evaluation effort and is claimed to yield more reliable results across multiple evaluation rounds (Landwehr et al., 2023; Jiang et al., 2023b; Reiter, 2024; Dubois et al., 2024).

At the same time, the use of LLMs as judges of linguistic output raises new concerns: LLMs may be prone to errors or systematic biases that differ from those of humans, especially on subtle tasks such as evaluating toxicity, or reasoning. This may distort evaluation results and lead to incorrect conclusions. The problem is aggravated by explicit or implicit data leakage (Balloccu et al., 2024), which undermines the ability to make broad, generalisable claims beyond the single specific dataset under analysis. Specifically for closed models such as OpenAI’s GPT series, there are serious reproducibility concerns, as LLMs may be retrained or retired at any time, making subsequent

comparisons invalid or impossible.

Previous studies offer mixed evidence regarding the reliability of LLM evaluators. Some research concludes that they are effective, correlating well with human judgments (Liu et al., 2023; Zheng et al., 2024; Chen et al., 2023; Verga et al., 2024; Törnberg, 2023; Huang et al., 2024; Naismith et al., 2023; Gilardi et al., 2023; Kocmi and Federmann, 2023b), albeit with some caveats (Wang et al., 2023; Wu and Aji, 2025; Hada et al., 2024; Pavlovic and Poesio, 2024). In some cases, LLM evaluators can also provide pairwise preference judgments (Kim et al., 2024; Liusie et al., 2024; Liu et al., 2024a; Park et al., 2024; Tan et al., 2025), or fine-grained evaluation beyond a single score, such as error spans (Fernandes et al., 2023; Kocmi and Federmann, 2023a). In contrast, some studies highlight substantial biases in LLMs’ behaviour as evaluators, both as compared against human judgments (Koo et al., 2024; Zeng et al., 2024; Baris Schlicht et al., 2024) and through intrinsic analyses (Wang et al., 2024; Liu et al., 2024b; Stureborg et al., 2024). These discrepancies likely stem from the limitations of this previous work, which typically relies on a few datasets and models, often restricted to closed-source proprietary models. The observation of such limitations has motivated recent work to develop finetuning methods for LLM judges designed to overcome certain biases (Zhu et al., 2025).

In this paper, we examine how well current LLMs can approximate human evaluators on a large scale. We prompt 11 among the most recent open-weight and proprietary LLMs to generate judgments on 20 datasets with human annotations on a wide range of quality dimensions, prompt styles, and tasks. Our evaluation goes beyond existing work by including a wide variety of *datasets* that differ in the *type of task* (e.g., translation, dialogue generation, etc.), the *property* being judged (e.g., coherence, fluency, etc.), the *type of judgments* (categorical or graded), and the *expertise of human annotators* (experts or non-experts). We provide JUDGE-BENCH, a benchmark which includes, upon release, a total of over 70,000 test instances with associated human judgments with an extensible codebase.

Our results indicate that LLMs align well with human judgments on certain tasks, like instruction following. However, their performance is *inconsistent* across and within annotation tasks. Elicitation methods like Chain-of-Thought prompting

(Wei et al., 2022) do not reliably improve agreement, in line with recent findings (Sprague et al., 2025). Some proprietary models—in particular, GPT-4o—align better to humans, but there is a rather small gap with large open-source models, holding promise for the reproducibility of future evaluation efforts. Altogether, at the current stage of LLM development, we recommend validating LLM judges against task-specific human annotations before deploying them for any particular task.

2 Construction of JUDGE-BENCH

One key feature that differs across the datasets included in JUDGE-BENCH is the source of the data being evaluated, i.e., whether the items to be judged are generated by a model or produced by humans, as illustrated in Figure 1.

For model-generated items, the goal is to evaluate an NLP system. This includes both classic tasks such as machine translation or dialogue response generation, as well as less standard tasks for which automation has recently become an option thanks to LLMs, such as the generation of plans or logical arguments. For human-generated items, the goal is to assess properties of interest such as grammaticality or toxicity. This distinction allows us to understand whether LLMs have a positive bias towards machine-generated outputs—a tendency reported in prior work (Xu et al., 2024).

The datasets we consider cover a wide span of properties of interest, ranging from grammaticality and toxicity to coherence, factual consistency, and verbosity, *inter alia*. Many properties are relevant across multiple tasks (e.g., fluency and coherence), while others are more task-specific (e.g., the success of a generated plan or the correctness of a multi-step mathematical reasoning trace).

Our study focuses on English datasets or language pairs which include English as one of the languages. We keep track of whether the original annotation guidelines are available and whether the annotations are provided by experts or non-experts. We retain all available individual annotations. Dataset information is summarised in Table 2, Appendix A. All 20 datasets are formatted following a precise data schema to facilitate the integration of additional datasets. This makes JUDGE-BENCH easily extensible. We provide more details about the data schema in Appendix B.

Table 1: Scores per dataset for the models with $\geq 98\%$ valid response rates (results for all models in Tab. 6, App. H): Cohen’s kappa for categorical annotations and Spearman’s correlation for graded annotations. Boldface marks best model performance per dataset. Spearman’s correlations are generally significant ($p < 0.05$), with the exception of the Persona Chat and Topical Chat datasets (see Tab. 6 in Appendix H for more details). Datasets with both categorical and graded annotations appear twice. Datasets in blue concern human-generated language, while those in red concern model-generated text. ‘ σ ’ denotes the standard deviation of the scores across models per dataset (averaged over properties if more than one is judged per dataset). Upper-bound estimates (UB) indicate the agreement between individual and aggregated human judgments.

3 Model Selection and Experiment Design

Models. We select representative proprietary and open-weight models of various sizes that show high performance across several tasks on the Open LLM and Chatbot Arena Leaderboards (Chiang et al., 2024): GPT-4o (OpenAI, 2024), LLaMA-3.1 (8B and 70B; AI@Meta 2024), Gemini-1.5 (Reid et al., 2024), Mixtral (8x7B and 8x22B; Jiang et al. 2024), Command R and Command R+ (Cohere and Cohere for AI, 2024a,b), OLMo (Groeneveld et al., 2024), Starling-7B (Zhu et al., 2024), and Mixtral (Jiang et al., 2023a). See Appendix E for inference procedure details.

Prompts. Since most datasets include the original instructions used to gather human judgments, we use these instructions directly as prompts for

the model, with additional guidelines to constrain the models’ output and minimise verbosity: ‘Answer with one of {}. Do not explain your answer.’ When the original instruction for collecting human judgments is unavailable, we create a prompt based on relevant information from the original paper, such as the task description and the definitions of the evaluation metrics. We also experiment with alternative prompting strategies, including Chain-of-Thought, few-shot prompts, and prompt paraphrases. However, none of these strategies leads to systematic improvements. See Appendix H for full details and results. All prompts are provided in the codebase.

Evaluation. Models do not always respond to the prompts as requested (e.g., they may refuse to

Figure 2: Average model correlation with human experts vs. non-experts in datasets with graded annotations.

Figure 3: Correlation for properties with graded judgments. Averages and error bars when the property is present in more than one dataset.

answer if they perceive the prompt as sensitive). We therefore use the following evaluation protocol:

- To obtain the same number of judgments across models for a given dataset, we replace invalid LLM responses with judgments randomly sampled from the relevant set of categorical or graded annotations. Figure 5 in Appendix F shows the rate of valid responses per model.
- Graded annotations, such as in WMT 2020 (Freitag et al., 2021), assess language quality on a continuous scale (e.g., a score from 0 to 100, or Likert-scale ratings), capturing varying degrees of fluency, adequacy, or overall translation quality; whereas categorical annotations, like those in CoLa (Warstadt et al., 2019), involve binary judgments (e.g., grammatically acceptable or not). For the former, we compute Spearman’s correlation (ρ) between model and human judgments; for the latter, we compute Cohen’s κ .

- When multiple individual human judgments are available (typically three, see Table 2 in Appendix A), we estimate an upper bound by computing the average Spearman’s ρ or Cohen’s κ between bootstrapped single-rater responses and the aggregated responses across raters. Appendix C provides details on the upper bounds.

4 Results

Scores vary substantially across models. For any given model, they vary both across datasets and properties being judged. Table 1 presents detailed results for the 6 models that exhibit the largest rate of valid responses ($\geq 98\%$). GPT-4o ranks first across several evaluation scenarios, but the Llama-3.1-70B and Mixtral-8x22B open models are relatively close and outperform GPT-4o on some assessment types, such as categorical sentence acceptability (CoLa) and graded summary quality (SummEval). Overall, the high degree of variability is not fully accounted for by the inherent difficulty of the annotation tasks, as reflected in the human upper bound. Moreover, except for a few datasets (e.g., QAGS, Recipe-generation, and NewsRoom), model scores remain notably below the upper bound.

Among the property types with the lowest human-model alignment are toxicity and safety (in particular on DICES and Medical-safety), where model scores can be even negative and valid response rates particularly low (see Fig. 6 in Appendix F). This is due in part to the guardrails associated with these tasks (Weidinger et al., 2023). We find that, especially in the medical domain, many models tend to provide explanations instead of producing a judgment (see Appendix G).

Despite the high variability across models and datasets, we observe several notable trends. For graded annotations (Fig. 2), all models achieve higher correlations with annotations by non-expert human judges compared to expert annotators, echoing recent findings by Aguda et al. (2024). One possible explanation is that non-experts might rely on surface-level features, which could align more closely with the patterns LLMs are most attuned to, while experts apply stricter, domain-specific criteria. This remains speculative and calls for further investigation.

Figure 3 shows correlation results across different datasets for the subset of properties that exclusively have graded judgments. When applicable,

Figure 4: Scores (Cohen’s κ for categorical annotations and Spearman’s correlation for graded annotations) on test items involving human language vs. machine-generated outputs.

we average results across datasets including annotations for the same property. We provide more details about these properties in Appendix D. The proprietary models GPT-4o and Gemini-1.5 exhibit the highest scores when evaluating acceptability and verbosity, while the two Mistral open models show the strongest correlations for coherence and consistency. Correlation with the engagingness property remains consistently low across all models. Overall, *no single model demonstrates a clear superiority* over others across all properties; instead, different quality dimensions are better assessed by different models. This calls into question the widespread practice of using a single model—typically a proprietary one like those from the GPT family—to evaluate a diverse range of linguistic properties.

Finally, as shown in Figure 4, all models achieve better alignment with human judgments when evaluating human language than when assessing machine-generated text, both for categorical and graded annotations. This result aligns with the findings by Xu et al. (2024), suggesting that LLMs display a bias towards their own generation. More broadly, this trend calls for caution when using LLMs to automatically evaluate the output of NLP systems.

5 Conclusions

In response to current trends in evaluation, in this paper we conducted a large-scale study of the correlation between human and LLM judgments across 20 datasets, considering factors such as the properties being assessed, the expertise level of the human judges, and whether the data is model- or human-generated. On some tasks, such as instruc-

tion following and the generation of mathematical reasoning traces, models can be reliably used as evaluators. Overall, however, models’ agreement with human judgments varies widely across datasets, evaluated properties, and data sources; and depends on the level of expertise of human judges. Furthermore, elicitation strategies such as Chain-of-Thought prompting do not consistently improve agreement levels, in line with recent findings (Sprague et al., 2025). We recommend validation and calibration of LLMs against task-specific human judgments prior to their deployment as evaluators. To facilitate this process, we release JUDGE-BENCH, a benchmark that enables systematic evaluation across a diverse range of tasks and is easily extensible to include any new task of interest.

Limitations

One limitation of the experimental design of our work is that correlation with human judges may not be the most appropriate way to validate LLM evaluators. Indeed, there may be domains where human annotators and LLM evaluators appear aligned simply because they are affected by similar biases. Therefore, depending on the task at hand, it may be necessary to validate the reliability of human annotators as well.

Another limitation concerns the use of existing tasks and datasets without reassessing their quality or representativeness of actual downstream tasks. While we did our best to select a wide set of tasks meaningful to the NLP community, we acknowledge that these tasks could not be equally meaningful for end-users, and that employing existing datasets could arguably lead to potential risks and shortcomings, such as data leakage.

In contrast to approaches that use LLMs for pairwise preference evaluation, e.g., PairEval (Park et al., 2024) or JudgeBench (Tan et al., 2025),¹ this paper focuses on evaluating the performance of LLMs on generating judgements for categorical and graded responses. We leave the extension of JUDGE-BENCH to include pairwise preference evaluation and other recent evaluation methods, such as Prometheus 2 (Kim et al., 2024), for future work.

Finally, our work mostly focuses on English-language datasets—with the exception of datasets focussing specifically on machine-translation outputs. It remains to be seen whether LLMs’ meta-evaluation abilities vary across different languages.

Acknowledgements

This work emerged from discussions at a workshop organised by Raquel Fernández and Sandro Pezzelle at MFO, the Oberwolfach Research Institute for Mathematics in the German Black Forest, on behalf of the ELLIS NLP programme. The event was funded by the state of Baden-Württemberg (Germany) and organised in collaboration with the ELLIS Institute Tübingen and the Max Planck Institute for Intelligent Systems. We furthermore acknowledge our funders. In particular, AB, RF, and AT were supported by the European Research Council (ERC Consolidator Grant DREAM 819455 to RF), as well as BP (ERC Consolidator Grant DIALECT 101043235 to BP). DE was supported by a research grant (VIL53122) from VILLUM FONDEN. EG was supported by the Dutch Research Council (Gravitation grant 024.001.006 to the Language in Interaction consortium). MG was supported by an ETH Zurich Postdoctoral Fellowship. MH was supported in part by an OpenAI Superalignment Fellowship. AM was supported by the European Research Council (DECOLLAGE, ERC-2022-CoG 101088763) and by Fundação para a Ciência e Tecnologia through contract UIDB/50008/2020. We acknowledge ISCRA for awarding this project access to the LEONARDO supercomputer, owned by the EuroHPC Joint Undertaking, hosted by CINECA (Italy).

¹Some time after an early version of this paper became available as a pre-print, accompanied by our JudgeBench code, the independent work by Tan et al. (2025) appeared, which describes a benchmark that the authors named JudgeBench. This name clash is unfortunate, but since in the meantime our paper has seen some uptake, we have decided against trying to resolve it.

Appendix

A Datasets

This section provides brief descriptions of the datasets employed in our study. Table 2 summarises relevant dataset information. Note that dataset sizes as reported in Table 2 refer to the number of annotated samples (not to the total number of collected annotations) and might therefore differ from the figures reported in the original papers. Table 3 reports Krippendorff’s α for those datasets with multiple public human annotations.

CoLa (Warstadt et al., 2019). The Corpus of Linguistic Acceptability (CoLA) consists of 10657 sentences from 23 linguistics publications, expertly annotated for acceptability (grammaticality) by their original authors.

CoLa-grammar (Warstadt and Bowman, 2020). The dataset consists of a grammatically annotated version of the CoLA development set. Each sentence in the CoLA development set is labelled with boolean features indicating the presence or absence of a particular grammatical construction (usually syntactic in nature). Two related sets of features are considered: 63 minor features correspond to fine-grained phenomena, and 15 major features correspond to broad classes of phenomena.

ToxicChat (Lin et al., 2023). collect binary judgments on the toxicity and ‘jailbreaking’ nature (prompt hacks deliberately intended to bypass safety policies and induce models to generate unsafe content) of human prompts to LLMs. While the original dataset contains a mix of human- and automatically-annotated instances, here we only consider the human-annotated prompts.

LLMBar (Zeng et al., 2024). LLMBar is a dataset targeted at evaluating the instruction-following abilities of LLMs. Each entry of this dataset consists of an instruction paired with two different outputs, one correctly following the instruction and the other deviating from it. LLMBar has an adversarial split where deviating outputs are carefully constructed to ‘fool’ LLM-based evaluators and a natural split where deviating outputs are more naturalistic.

Table 2: Overview of the main features of the datasets considered in the study. Note that ‘Size’ refers to the number of annotated samples, not to the total number of human annotations. ‘# Annot.’ refers to the number of available individual annotations, if any, which we use to estimate the human upper bound. Note that datasets with only a single annotation per sample, or which only report the average over multiple annotations are not included in ‘# Annot.’. Information on possible data leakage was retrieved from Balloccu et al. (2024).

Topical Chat and Persona Chat (Mehri and Eskenazi, 2020). These datasets contain human judgments on the quality of machine- and human-generated responses based on the provided dialogue context. The annotated dialogues were selected from Topical Chat (Gopalakrishnan et al., 2019)—a dataset collecting human-human conversations on provided facts—and Persona Chat (Zhang et al., 2018), which contains human-human persona-conditioned conversations. Each response is evaluated on 6 attributes: Understandable, Natural, Maintains Context, Interesting/Engaging, Uses Knowledge, and Overall Quality.

ROSCOE (Golovneva et al., 2023). collect human judgments assessing the quality of GPT-3’s reasonings. The output reasonings are elicited by inputting GPT-3 with questions selected from 4 commonly used reasoning datasets, i.e., CosmosQA (Huang et al., 2019), DROP (Dua et al., 2019), e-SNLI (Camburu et al., 2018) and GSM8K (Cobbe et al., 2021). While ROSCOE provides annotations on each step of the reasoning trace, here we only consider the global judgments over the whole reasoning.

QAGS (Wang et al., 2020). QAGS consists of annotations judging the factual consistency of one-sentence model-generated summaries of news articles. The gold-standard summaries and articles are collected from CNN/DailyMail (Hermann et al.,

2015) and XSUM (Narayan et al., 2018).

Medical-safety (Abercrombie and Rieser, 2022). This dataset consists of 3701 pairs of medical queries (collected from a subreddit on medical advice) and both machine-generated and human-generated answers. Queries were classified by human annotators according to their severity (from ‘Not medical’ to ‘Serious’, with ‘Serious’ indicating that emergency care would be required) and answers were categorised based on their risk level (from ‘Non-medical’ to ‘Diagnosis/Treatment’).

DICES (Aroyo et al., 2023). The DICES datasets consist of a series of machine-generated responses whose safety is judged based on the previous conversation turns (context). While the original dataset provides fine-grained annotations with answers to questions targeting specific aspects of safety, here we only consider the ‘overall’ categorisation comprehensive of all aspects. In DICES 990 safety is judged by crowdsourced annotators, whereas in DICES 350 both expert and crowdsourced annotations are provided.

Inferential strategies (Mondorf and Plank, 2024). This dataset contains annotations on the logical validity of reasoning steps that models—in this case, Llama-2-chat-hf3 (Touvron et al., 2023), Mistral-7B-Instruct-v0.2 (Jiang et al., 2023a) and Zephyr-7b-beta (Tunstall et al., 2023)—generate when prompted to solve problems

of propositional logic. Binary labels are assigned to each response, indicating whether the rationale provided by the model is sound (True) or not (False). Each model is assessed on 12 problems of propositional logic across 5 random seeds, resulting in a total of 60 responses per model.

Switchboard and Dailydialog (Wallbridge et al., 2022). Switchboard includes acceptability judgments collected using stimuli from the Switchboard Telephone Corpus (Godfrey et al., 1992). More specifically, the judgments refer to how plausible it is that a specific response belongs to a telephonic dialogue. The same kind of judgments are provided for Dailydialog, which collects written dialogues intended to mimic conversations that could happen in real life.

Recipe-generation (Stein et al., 2023). This dataset contains human annotations assessing the quality of machine-generated recipes based on 6 attributes: grammar, fluency, verbosity, structure, success, overall.

NewsRoom (Grusky et al., 2018). This dataset includes human judgments on the quality of system-generated summaries of news articles. More specifically, annotators evaluated summaries across two semantic dimensions (informativeness and relevancy) and two syntactic dimensions (fluency and coherence).

SummEval and G-Eval (Fabbri et al., 2021; Liu et al., 2023). These datasets include summaries generated by multiple recent summarisation models trained on the CNN/DailyMail dataset (Hermann et al., 2015). Summaries are annotated by both expert judges and crowdsourced workers on 4 dimensions: coherence, consistency, fluency, relevance.

WMT 2020 En-De and Zh-En (Freitag et al., 2021). These datasets are a re-annotated version of the English-to-German and Chinese-to-English test sets taken from the WMT 2020 news translation task. The annotation was carried out by raters who are professional translators and native speakers of the target language using a Scalar Quality Metric (SQM) evaluation on a 0–6 rating scale.

WMT 2023 En-De and Zh-En (Kocmi et al., 2023). These datasets are the English-to-German and Chinese-to-English test sets taken from the General Machine Translation Task organised as

part of the 2023 Conference on Machine Translation (WMT). In contrast to previous editions, the evaluation of translation quality was conducted by a professional or semi-professional annotator pool rather than utilising annotations from MTurk. Annotators were asked to provide a score between 0 and 100 on a sliding scale.

Table 3: Inter-rater agreement for datasets with multiple human annotations. Datasets in blue concern human-generated language, while those in red concern model-generated text.

B The JUDGE-BENCH Data Schema

To facilitate extending our benchmark, we adopt a shared schema used to pre-process all datasets. Our publicly available code base includes an example² of this format as well as instructions on how to verify that newly added datasets comply with it.

The Json-based JUDGE-BENCH data schema ensures that the following fields are included for each dataset:

- `dataset`: the name of the dataset;
- `dataset_url`: the URL where the original dataset can be downloaded, as opensourced by their creators;
- `annotations`: an overview of the properties annotated for each dataset, along with information on how they are measured and prompt-like instructions similar to those originally given to the human annotators (when applicable);
- `instances`: dataset instances including the piece of text to be judged, aggregated human

²<https://github.com/dmg-illc/JUDGE-BENCH/blob/master/data/example.json>

judgments and, when available, individual human annotations.

We note that, while we do not systematically explore inter-annotator variations at the instance level, the data schema we adopt allows for conducting this type of analysis in future work.

C Upper Bound Estimation for Model Correlations

Whenever multiple human annotations were publicly available for a property (see Table 3 for inter-annotator agreement scores), we computed upper-bound estimates for the correlations achievable by models. The intuition behind these estimates, borrowed from neuroscience (Nili et al., 2014), is that the maximum correlation a model can achieve with aggregated human responses is bounded by the average correlation between single-participant responses and the aggregated responses across participants. We applied a similar logic to the human judgments used in the present study and combined it with a bootstrapping approach. For each annotated property, we bootstrapped single-participant responses by sampling 1000 times from the available human responses, excluding data points where a single annotation was available. Next, we computed the alignment between each of the bootstrapped-participant arrays and the array of aggregated responses. Alignment was computed as Spearman’s correlation for graded judgments and Cohen’s kappa for categorical judgments. Finally, we estimated the upper bound as the average of the 1000 alignment measures. In cases where alignment between bootstrapped and aggregated responses could not be computed—because the variance of the bootstrapped responses was null—values were replaced with an average of the ‘non-nan’ correlations.

We emphasise that these upper bounds are estimates and, as such, are subject to errors. Therefore, it may happen that model performance exceeds these upper bounds.

D Properties with Graded Judgments

In Figure 3, we display results for a set of graded properties annotated in one or more of the datasets we consider. The properties are defined as follows:

- *Acceptability* refers to whether it is plausible or not that a response belongs to a telephonic

dialogue and was annotated in Swithboard and Dailydialog;

- *Coherence* was annotated for summaries and model-generated reasonings as part of the datasets NewsRoom, ROSCOE, and SummEval;
- *Consistency* refers to the alignment between facts described in a summary and in its source text, and was annotated in SummEval;
- *Engaging* indicates whether a response generated in the context of a dialogue is dull or interesting and was annotated in TopicalChat and PersonaChat;
- *Fluency* measures whether a piece of text is grammatically correct and well-formatted, and was annotated in NewsRoom, SummEval and Recipe-generation;
- *Informativeness* refers to the extent to which a summary captures the key points of the full text, and was annotated for summaries as part of the NewsRoom dataset;
- *Relevance* refers to whether a summary selects important information as opposed to including redundancies, and was annotated for NewsRoom and SummEval;
- *Verbosity* indicates whether a generated recipe is concise and avoids unnecessary repetitions, and was annotated in Recipe-generation.

E Inference Details

All open-model checkpoints were obtained using the HuggingFace pipeline and we access all proprietary models using their corresponding API libraries. The proprietary models were accessed from 06-06-2024 to 13-06-2024, for standard prompting and from 09-10-2024 to 13-12-2024, for CoT prompting. We obtain the model responses using greedy decoding, which we operationalise for the proprietary models by setting the temperature parameter to 0. We allow open models to generate a maximum of 25 new tokens and proprietary models to generate a maximum of 5 new tokens. For CoT prompting, we allow for a maximum of 1000 new tokens.

We leverage Nvidia A100 (80 GB) GPUs for a total of 321 compute hours. The cost of running experiments using Gemini-1.5-flash was €30.31, while the cost of experiments using GPT-4o was approximately \$565.

F Valid Response Rates

Table 5 reports the rate of valid responses for each model and dataset. Valid response rates are summarised per model and dataset in Figures 5 and 6.

Figure 5: Valid response rate per model.

G More Details on Toxicity and Safety Evaluation

For the Medical-safety dataset, models often refused to answer. Instead they tended to generate explanations, copy what they had in the prompt, or tried to be generally helpful because they saw that it was a medical issue. Since we take a random answer when no answer could be detected, this contributes to lower the results obtained on this task. Scores for the DICES dataset were also low, even though the valid response rate was high, because in this case there is the ‘Unsure’ option, which (along with ‘Unsafe’) models preferred over calling anything ‘Safe’. For ToxicChat, models performed reasonably well.

H Additional Results

In Table 6 we report human-model alignment scores per dataset for all models tested, thus complementing Table 1 in the paper.

Chain-of-Thought Prompts. For the results with CoT prompting, we use the same original instructions used to gather human judgments as prompts for the model but adapt the additional guidelines to emphasise multi-step reasoning rather than constrain the models’ output. Specifically, we append the original instructions with the following additional guideline: ‘Always end your answer

with either {} regarding the entire context. Let’s think step by step.’, in which {} is replaced with an enumeration of all possible answer labels formatted as ‘Therefore, {label A} is correct, or therefore, {label B} is correct, or therefore [...]’. This also allows for automatically extracting the final answers from model responses during evaluation. In this study, we evaluate nine models and exclude Mixtral-8x22B and Comm-R+ due to computational constraints. For the CoLa-grammar dataset, we obtain GPT-4o responses only for ten percent of its instances (that are randomly sampled) to address the slow processing times and rate limitations. While CoT prompting leads to improved agreement scores and correlations when used with some models for certain datasets (see Table 7), its overall effectiveness compared to the results obtained using standard prompts without CoT (see Table 6) is inconsistent.

Prompt Paraphrases. We experiment with paraphrased prompts for three datasets that models struggle with: DICES-350-expert, WMT 2023 En-De, and WMT 2023 Zh-En. The paraphrase for dices-350-expert elaborates on the concept of safety, compared to its short original prompt, whereas the paraphrases for the WMT datasets are more concise regarding what comprises a good translation compared to the original. We do not observe consistent improvements when using paraphrased prompts compared to the original prompts (Table 4).

Few-shot Prompts. For the three datasets above—DICES-350-expert, WMT 2023 En-De, and WMT 2023 Zh-En—we also experiment with few-shot prompts (Table 4), where we provide the model with 6 examples for DICES-350-expert, 3 of safe conversations and 3 of unsafe conversations, and 4 examples for each WMT 2023 dataset, 2 of high-scoring translations and 2 of low-scoring translations. Using few-shot prompts does not improve correlations for dices-350-expert. On the WMT 2023 datasets, we observe higher correlations for Llama 3.1 8B but very moderate or no improvements on the other two models. Given that these improvements are inconsistent across datasets, we did not scale up the experiments to all 20 datasets and 11 models.

	Prompt	Llama 3.1 8B	Llama 3.1 70B	Mixtral-8x7B
<i>DICES-350-expert</i>	Original	0.01	-0.13	-0.11
	CoT	-0.07	-0.26	-0.02
	Few-shot	0.01	-0.22	-0.01
	Paraphrase	-0.13	-0.36	-0.09
<i>WMT 2023 En-De</i>	Original	0.08 (1)	0.14 (1)	0.17 (1)
	CoT	0.18 (1)	0.16 (1)	0.20 (1)
	Few-shot	0.19 (1)	0.20 (1)	0.20 (1)
	Paraphrase	0.01 \pm 0.09 (3)	0.08 \pm 0.12 (3)	0.14 \pm 0.05 (3)
<i>WMT 2023 Zh-En</i>	Original	0.02 (1)	0.14 (1)	0.15 (1)
	CoT	0.13 (1)	0.13 (1)	0.16 (1)
	Few-shot	0.15 (1)	0.14 (1)	0.16 (1)
	Paraphrase	0.08 \pm 0.04 (3)	0.09 \pm 0.07 (2)	0.13 \pm 0.03 (3)

Table 4: Cohen’s kappa for DICES-350-expert and Spearman’s correlation for two WMT 2023 datasets, comparing the original prompt and CoT prompt to few-shot prompts and prompt paraphrases for a selection of models. For datasets with more than one paraphrased prompt, we report the average and standard deviation across paraphrases. For Spearman’s correlations, we report the number of significant correlations ($p < 0.05$) for each model and dataset in brackets.

Figure 6: Average ratios of valid responses across datasets over the 11 models we tested.

Abstract

Efficient preference optimization algorithms such as Direct Preference Optimization (DPO) have become a popular approach in aligning large language models (LLMs) with human preferences. These algorithms implicitly treat the LLM as a reward model, and focus on training it to correct misranked preference pairs. However, recent work (Chen et al., 2024) empirically finds that DPO training *rarely improves these misranked preference pairs*, despite its gradient emphasizing on these cases. We introduce FocalPO, a DPO variant that instead *down-weighs* misranked preference pairs and prioritizes enhancing the model’s understanding of pairs that it can already rank correctly. Inspired by Focal Loss used in vision tasks, FocalPO achieves this by adding a modulating factor to dynamically scale DPO loss. Our experiment demonstrates that FocalPO surpasses DPO and its variants on popular benchmarks like Alpaca Eval 2.0 and Arena-Hard using Mistral-Base-7B and Llama-3-Instruct-8B, with the introduced hyperparameter fixed. Additionally, we empirically reveals how FocalPO affects training on correct and incorrect sample groups, further underscoring its effectiveness ¹.

1 Introduction

Reinforcement learning from human feedback (RLHF) played a crucial role in aligning large language models (LLMs) with human preferences (Christiano et al., 2017; Ouyang et al., 2022; Stiennon et al., 2020). However, conducting RLHF with Proximal Policy Optimization (PPO, Schulman et al. 2017) is computationally expensive. Therefore, recent works have studied more efficient approaches, such as Direct Preference Optimization (DPO, Rafailov et al. 2023) and its variants (Amini et al., 2024; Meng et al., 2024; Ethayarajh et al., 2024; Zhou et al., 2024), which implicitly

¹Code available at: <https://github.com/TongLiu-github/focalpo>

Figure 1: Comparing the effectiveness of up-weighting **incorrect** preference pairs against up-weighting **correct** preference pairs with FocalPO during training. We find that performance further improves by prioritizing learning from pairs that can already be ranked correctly.

treat the language model itself as a reward model and directly optimizes it using preference datasets.

Despite its popularity, recent work (Chen et al., 2024) shows that DPO often *fails to correct incorrect preference rankings made by the implicit reward model prior to training*, despite its gradient emphasizing these cases. While one recent competitive DPO variant SimPO (Meng et al., 2024) introduces a fixed margin term in the preference optimization loss, we find it *inherently reduces* the disproportionately high weights assigned to learning incorrect response pairs. ODPO (Amini et al., 2024) further incorporates additional labeled reward values and employs an instance-dependent margin term. However, while these approaches implicitly re-weigh instances through the use of margin terms, they lack explicit and dynamic mechanisms for such re-weighing.

To this end, we propose FocalPO, a loss function that *dynamically and explicitly reduces* DPO’s emphasis on learning response pairs that the model struggles to rank while prioritizing preference pairs with accurate implicit reward estimates. Inspired by *Focal Loss* (Lin et al., 2020) in vision tasks, we

achieve this by adding a modulating factor of p^γ to dynamically scale the DPO loss, $-\log p$. Here, p represents the probability that the preferred response over the dispreferred one. Intuitively, such a factor automatically up-weighs the contribution of correctly ranked samples during training, with the scaling factor decays to zero as preference probability increases. Gradient analysis shows that FocalPO equivalently assigns higher weights to pairs whose implicit reward estimate order is accurate and lower weights to incorrect pairs. This encourages models to learn from preference pairs with correct reward estimates while avoiding excessive influence from challenging ones. Experiments show that FocalPO significantly outperforms the original DPO. Additionally, we provide case study showing how FocalPO affects training on correct and incorrect sample groups, further underscoring its effectiveness.

Our contributions are summarized as follows: (1) We introduce FocalPO, a novel loss function based on DPO and Focal Loss, which emphasizes learning preference pairs with accurate implicit reward estimates. (2) We show that FocalPO surpasses DPO as well as many DPO variants on popular chat benchmarks like Alpaca-Eval 2.0 and Arena-Hard, using both Mistral-Base-7B and Llama-3-Instruct-8B models. (3) We empirically demonstrate the impact of prioritizing learning correctly vs. incorrect ranked preference pairs.

2 Background

Given an instruction-tuned language model π_θ , Direct Preference Optimization (DPO, Rafailov et al. (2023)) further optimizes it as an implicit reward model using a preference dataset. Let $\mathcal{D} = \{(x^{(i)}, y_w^{(i)}, y_l^{(i)})\}_i^N$ denote a preference dataset where $x^{(i)} \in \mathcal{X}$ is a prompt and $(y_w^{(i)}, y_l^{(i)})$ is a pair of answers, with the preference of $y_w^{(i)} \succ y_l^{(i)}$ expressed by human or AI annotators. Under the assumption of Bradley-Terry model (Bradley and Terry, 1952), the human preference distribution p^* can be approximated as:

$$p^*(y_w^{(i)} \succ y_l^{(i)} | x^{(i)}) = \sigma(r^*(x^{(i)}, y_w^{(i)}) - r^*(x^{(i)}, y_l^{(i)})), \quad (1)$$

where σ and $r^*(x, y)$ are the sigmoid function and the latent reward model used to generate the ground-truth preference, respectively. To model this human preference, DPO uses a reparametrization trick to express it in terms of the optimal policy

$\pi^*: r^*(x, y) = \beta \log \frac{\pi^*(y|x)}{\pi_{\text{ref}}(y|x)} + \beta \log Z(x)$, where $Z(x)$ is the partition function only based on x . Applying the above equations, the maximum likelihood estimation objective of DPO is:

$$\begin{aligned} \mathcal{L}_{\text{DPO}}(\pi_\theta; \pi_{\text{ref}}) &= -\mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [\log p(y_w \succ y_l | x)] \\ &= -\mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} \left[\log \sigma \left(\beta \log \frac{\pi_\theta(y_w | x)}{\pi_{\text{ref}}(y_w | x)} \right. \right. \\ &\quad \left. \left. - \beta \log \frac{\pi_\theta(y_l | x)}{\pi_{\text{ref}}(y_l | x)} \right) \right], \end{aligned} \quad (2)$$

which *emphasizes* on learning responses pairs that the model struggle to rank (i.e., wrong reward estimates). However, recent work such as Chen et al. (2024) shows that DPO cannot learn to correct these response pairs, and a few other competitive variants such as SimPO (Meng et al., 2024) and ODPO (Amini et al., 2024) *implicitly introduce a margin term* that reduces such emphasis.

3 FocalPO: Focal loss inspired Preference Optimization

3.1 FocalPO loss

We propose FocalPO loss, which directly scales DPO’s loss to reduce emphasis on learning response pairs the model struggles to rank and focuses on preference pairs with accurate implicit reward estimates. Inspired by Focal Loss (Lin et al., 2020) in vision tasks (i.e., adding a modulating factor $(1 - p)^\gamma$ to the cross entropy loss), we replace the original cross-entropy loss in Eq. 2 with:

$$\mathcal{L}_{\text{FocalPO}}(\pi_\theta; \pi_{\text{ref}}) = -\mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} \left[(1 - p(y_w \succ y_l | x))^{-\gamma} \cdot \log p(y_w \succ y_l | x) \right] \quad (3)$$

$$\begin{aligned} &\approx -\mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [p(y_w \succ y_l | x)^\gamma \log p(y_w \succ y_l | x)] \\ &\quad + \text{constant}, \end{aligned} \quad (4)$$

where $\gamma \geq 0$ is a tunable *focusing* hyperparameter. Here we take negative index $-\gamma$ to replace the original positive term γ in Focal Loss, in order to focus on the easier or correctly ranked preference pairs. To simplify the optimization process, we further approximate $(1 - p)^{-\gamma} \log p^2$ with the term $p^\gamma \log p$. Unless otherwise specified, we use Eq. 4 as FocalPO for the rest of the paper. Figure 2 illustrates the focal loss with modulating factors $(1 - p)^\gamma$ and p^γ . Converse to $(1 - p)^\gamma$,

²In experiments, we also observe that training with the power of $-\gamma$ often causes the gradient to become NaN. We reuse the symbol γ for notational simplicity, although the exponent arises from an approximation.

Figure 2: We scale DPO loss using *Focal Loss*. Unlike the original Focal Loss (left), we add a scaling factor of p^γ (right) to the dynamically adjust the cross entropy loss. This modification enables a sample-wise adjustment of weights, reducing the influence of high weights when the implicit reward model order is incorrect.

a higher γ in p^γ leads to a less emphasis placed on hard negative samples. When the implicit reward model "correctly classifies" a preference pair (i.e., $p(y_w \succ y_l | x)$ is large), the modulating factor approaches 1, leaving the loss *almost unchanged*. Conversely, as $p(y_w \succ y_l | x) \rightarrow 0$, the modulating factor approaches 0, effectively *down-weighting* the preference pair in the DPO loss.

3.2 Gradient analysis

To better understand the impact of modulating factor on the DPO loss, we perform a gradient analysis. The gradient of DPO with respect to θ is:

$$\nabla_{\theta} \mathcal{L}_{\text{DPO}} = -\beta \mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} \left[\sigma(\hat{r}_{\theta}(y_l) - \hat{r}_{\theta}(y_w)) \cdot \nabla_{\theta} \frac{\log \pi(y_w | x)}{\log \pi(y_l | x)} \right], \quad (5)$$

where $\hat{r}_{\theta}(y) = \beta \log \frac{\pi_{\theta}(y|x)}{\pi_{ref}(y|x)}$ is the reward implicitly defined by the language model π_{θ} and reference model π_{ref} . The term $\sigma(\hat{r}_{\theta}(y_l) - \hat{r}_{\theta}(y_w))$ assigns higher weights when reward estimate is wrong.

In comparison, the gradient of FocalPO³ is:

$$\begin{aligned} \nabla_{\theta} \mathcal{L}_{\text{FocalPO}} = & -\beta \mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} \left[[\sigma(\hat{r}_{\theta}(y_l) - \hat{r}_{\theta}(y_w)) \right. \\ & \cdot \sigma^{\gamma}(\hat{r}_{\theta}(y_w) - \hat{r}_{\theta}(y_l)) + \log \sigma(\hat{r}_{\theta}(y_w) - \hat{r}_{\theta}(y_l)) \\ & \cdot \gamma \sigma^{\gamma}(\hat{r}_{\theta}(y_w) - \hat{r}_{\theta}(y_l)) \cdot \sigma(\hat{r}_{\theta}(y_l) - \hat{r}_{\theta}(y_w))] \\ & \left. \cdot \nabla_{\theta} \frac{\log \pi(y_w | x)}{\log \pi(y_l | x)} \right]. \end{aligned} \quad (6)$$

We illustrate the influence of each term in Fig. 3. The blue curve represents the gradient term from DPO, while the red and green curves correspond to the additional gradient terms introduced by our

³Refer to Appendix B for detailed derivation and Appendix A for an interpretation of FocalPO.

Figure 3: Gradients of DPO and FocalPO. We used $\gamma = 0.05$ for p^γ in FocalPO in this example.

modulating factor. Compared to DPO, the new gradient terms from FocalPO assign lower weights to incorrect preference pairs. When combined, as shown in the black curve in Fig. 3, FocalPO forms a *bell-shaped curve*, assigning the highest weights to preference pairs with reward margins close to zero while assigning lower weights for both correctly classified pairs and significantly incorrect pairs. FocalPO thus aims to mitigate the impact of preference pairs where reward estimates strongly disagree with the preference labels, and shifting focus toward learning preference pairs the model already ranks correctly.

4 Experimental setup

Model and training datasets We perform preference optimization on two representative models, Mistral-Base SFT (7B)⁴ and instruction-tuned Llama-3 (8B)⁵. We perform preference learning on the UltraFeedback dataset (Cui et al., 2023)⁶ for Mistral-Base, and on the Llama3-ultrafeedback-armorm dataset⁷ for Llama-3-Instruct. The former dataset is sampled from multiple LLMs and judged by GPT-4, and the later contains preference pairs generated by Llama-3-Instruct and judged by ArmoRM (Wang et al., 2024).

Hyperparameters For Mistral-Base (7B), we adopt the official hyperparameters from Zephyr (Tunstall et al., 2023) and use $\beta = 0.01$, epoch=1, batch size as 128 and learning rate as $5e-7$. For instruction-tuned Llama-3 (8B), we

Table 1: Alpaca Eval 2.0 and Arena-Hard results of DPO, its variants and FocalPO for preference optimization of Mistral-Base (7B) and Llama-3-Instruct (8B).

follow the setting of SimPO (Meng et al., 2024). We use a batch size of 128, epoch=1, and for each algorithm, we report the best performance after a grid searching learning rates in $[3e-7, 5e-7, 6e-7, 1e-6]$. We also fix the hyperparameter of γ in FocalPO as 0.05 for both models to prevent possible overfitting of hyperparameters.

Baselines We compare FocalPO against DPO, as well as other popular DPO variants including KTO (Ethayarajh et al., 2024), ORPO (Hong et al., 2024), and SimPO (Meng et al., 2024).

Evaluation To compare the effectiveness of preference learning, we use Alpaca Eval 2.0 (Li et al., 2023; Dubois et al., 2024) and Arena-Hard (Li et al., 2024). Alpaca Eval 2.0 includes 805 representative instructions drawn from multiple datasets and compares model’s responses with reference responses generated by gpt-4-turbo. We use default gpt-4-turbo as the judge model. We present metrics of the win rate (WR) and the length-controlled win rate (LCWR). Arena-Hard contains 500 well-defined challenging prompts and compares model’s responses with reference responses generated by gpt-4-0314. We use default gpt-4-1106-preview as the judge model. We present the metric of WR. Both benchmarks are evaluated under the standard setting.

5 Results

Effectiveness of FocalPO Table 1 demonstrates that FocalPO surpasses DPO and its variants on Alpaca Eval 2.0 and Arena-Hard. Notably, FocalPO improves upon SimPO, a highly performant alignment algorithm, without removing the reference model or additionally adding a sequence length control factor. On Arena-Hard, FocalPO also shows competitive performance compared to other variants, achieving a the best score with Llama-3-Instruct and Mistral-Base-7B. We also present a

Figure 4: Gradients of DPO and FocalPO with a focus on different sample groups where the reward estimate is correct (p^γ , $\gamma = 0.05$) or incorrect ($(1 - p)^\gamma$, $\gamma = 1$).

qualitative analysis comparing outcomes between DPO and FocalPO, detailed in Appendix F. Besides, the analysis of downstream task evaluation is provided in Appendix D.

Focus learning correct/incorrect samples FocalPO down-weights incorrectly ranked instances that the model struggles to learn, and placing greater emphasis on correct ones compared to DPO. To examine the impact of this choice, we empirically compare two FocalPO settings against DPO: emphasize learning *incorrect* samples using $\gamma = 1$ in the factor $(1 - p)^\gamma$; and emphasize learning *correct* samples using $\gamma = 0.05$ in p^γ . Corresponding gradient curves are illustrated in Fig. 4. For a fair comparison, DPO is evaluated using its official hyperparameter setting while the learning rate is kept consistent across models focusing on incorrect and correct samples. We present the results in Fig. 1. We find that focusing on incorrect samples yields inferior performance compared to DPO, while focusing on correct samples outperforms DPO. This result underscores the effectiveness our method, which prioritizes on learning preference pairs with accurate (i.e., correct) implicit reward estimates.

6 Conclusion

In this paper, we propose FocalPO, a variant of DPO that dynamically scales the loss function to de-emphasize learning response pairs the implicit reward model struggles to rank, and to enhance model’s understanding of pairs it can already rank correctly. With the introduced hyperparameter fixed, we evaluate FocalPO on the most widely used chat benchmarks (Alpaca Eval 2.0 and Arena-Hard) using two models (Llama-3 and Mistral) and show that FocalPO-trained models achieve the best performance in nearly all cases.

Limitations

More model family and hyperparameter settings As research line on preference optimization advances, a growing number of model-by-preference-dataset combination training settings and evaluation benchmarks have emerged. We did not conduct experiments on all of these settings. Besides, we only conduct experiments with *fixed* introduced hyperparameter γ in FocalPO, limited by compute resources. We believe a thorough hyperparameter search could further improve the result.

Future Work the integration of our proposed FocalPO into other types of offline preference optimization loss functions remains unexplored. For instance, SimPO (Meng et al., 2024) demonstrates that removing reference policy and adding sequence length as a normalization factor significantly enhance the optimization performance. Our experimental results show that FocalPO outperforms SimPO even without these adjustments, leaving space for the investigation of the potential benefits of combining FocalPO with these factors.

Ethics statement

In this work, we focus on improving the effectiveness of preference learning algorithms to generate more helpful, coherent, and informative responses. Our experiments were based on publicly available models and alignment datasets. Despite our efforts to carefully choose our training data/model backbone, some malicious or harmful content may persist, leading to non-ideal model responses. To address this, we recognize the need to incorporate additional safety-focused datasets and commit to conducting more comprehensive evaluations on safety, harmfulness, and bias to improve the robust-

ness and ethical alignment of future models. We do not condone the usage of our methods/models for any unlawful or morally unjust purposes.

A Relation between FocalPO, DPO and entropy regularization

Lemma 1. (Diminished entropy regularization in FocalPO) *With $\gamma \in [0, 1]$, FocalPO loss is bounded by a γ -weighted combination of the entropy of preference probability $\mathbb{H}[p(y_w \succ y_l | x)]$ and DPO loss \mathcal{L}_{DPO} :*

$$\mathcal{L}_{\text{FocalPO}} \leq \gamma \mathbb{H}[p(y_w \succ y_l | x)] + (1 - \gamma) \mathcal{L}_{DPO} \quad (7)$$

Proof. Let $p(y_w \succ y_l | x)$ denote the optimized preference probability and $q(y_w \succ y_l | x)$ denote the target preference probability, which is not necessarily a Delta distribution, the FocalPO loss is defined as $\mathcal{L}_{\text{FocalPO}} = -\mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [p(y_w \succ y_l | x)^\gamma q(y_w \succ y_l | x) \log p(y_w \succ y_l | x)]$, where $\gamma, p, q \in [0, 1]$.

Since $f(x) = x^\gamma$ is concave for $x \in [0, 1]$, we have:

$$f(x) \leq f(1) + f'(1)(x - 1) = \gamma x + (1 - \gamma). \quad (8)$$

Substituting this into $\mathcal{L}_{\text{FocalPO}}$, we obtain:

$$\mathcal{L}_{\text{FocalPO}} \leq -\mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [\gamma p(y_w \succ y_l | x) + (1 - \gamma) q(y_w \succ y_l | x) \log p(y_w \succ y_l | x)] \quad (13a)$$

$$= -\gamma \mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [p(y_w \succ y_l | x) q(y_w \succ y_l | x) \log p(y_w \succ y_l | x)] \quad (13b)$$

$$- (1 - \gamma) \mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [q(y_w \succ y_l | x) \log p(y_w \succ y_l | x)]$$

$$\leq -\gamma \max_{(x, y_w, y_l) \sim \mathcal{D}} q(y_w \succ y_l | x) \mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [p(y_w \succ y_l | x) \log p(y_w \succ y_l | x)] \quad (13c)$$

$$+ (1 - \gamma) \mathcal{L}_{DPO}$$

$$\leq \gamma \mathbb{H}[p(y_w \succ y_l | x)] + (1 - \gamma) \mathcal{L}_{DPO}, \quad (13d)$$

where for the step from Eq. (13b) to Eq. (13c) we use Hölder's inequality and note:

$$\begin{aligned} & -\mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [p(y_w \succ y_l | x) q(y_w \succ y_l | x) \log p(y_w \succ y_l | x)] \\ & = \left| \mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [p(y_w \succ y_l | x) q(y_w \succ y_l | x) \log p(y_w \succ y_l | x)] \right|. \end{aligned} \quad (10)$$

This completes the proof.

Lemma 1 shows that the FocalPO loss is bounded by a linear combination of the preference probability entropy $\mathbb{H}[p(y_w \succ y_l | x)]$ and DPO loss \mathcal{L}_{DPO} . At first glance, this might resemble the entropy regularization effect in the classic focal loss (Lin et al., 2020). In contrast, however, our motivation and experiments reveal that FocalPO actually **diminishes** the implicit **maximum-entropy regulariser** in DPO by our introduced adaptations that selectively focus on the correct cases. In fact, FocalPO leads to a **smoother** preference probability distribution, and curbs the model's tendency to become overconfident in incorrect rankings in DPO. That said, by slightly increasing entropy, it preserves a level of uncertainty to handle data outside the preference optimization training distribution effectively.

B Derivation of FocalPO gradient

$$\begin{aligned} \nabla_\theta \mathcal{L}_{\text{FocalPO}} &= \mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [\nabla_\theta p^\gamma(y_w \succ y_l | x) \cdot \log p(y_w \succ y_l | x) + p^\gamma(y_w \succ y_l | x) \\ & \quad \cdot \nabla_\theta \log p(y_w \succ y_l | x)] \end{aligned} \quad (11)$$

Given that:

$$\begin{aligned} \nabla_\theta p(y_w \succ y_l | x) &= \nabla_\theta \sigma(\hat{r}_\theta(y_w) - \hat{r}_\theta(y_l)) \\ &= \beta \nabla_\theta \sigma \left(\log \frac{\pi_\theta(y_w | x)}{\pi_{ref}(y_w | x)} - \log \frac{\pi_\theta(y_l | x)}{\pi_{ref}(y_l | x)} \right) \\ &= \beta \nabla_\theta \frac{\log \pi_\theta(y_w | x)}{\log \pi_\theta(y_l | x)} \cdot \sigma(\hat{r}_\theta(y_w) - \hat{r}_\theta(y_l)) \cdot \sigma(\hat{r}_\theta(y_l) - \hat{r}_\theta(y_w)), \end{aligned} \quad (12)$$

where $\hat{r}_\theta(y) = \beta \log \frac{\pi_\theta(y | x)}{\pi_{ref}(y | x)}$, and

$$\nabla_\theta \log \sigma(y) = \sigma(-y) \nabla_\theta y, \quad (13)$$

Eq. 11 becomes:

$$\begin{aligned}
\nabla_{\theta} \mathcal{L}_{\text{FocalPO}} &= \mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [\gamma p^{\gamma-1}(y_w \succ y_l | x) \log p(y_w \succ y_l | x) \cdot \nabla_{\theta} p(y_w \succ y_l | x) \\
&\quad + p^{\gamma}(y_w \succ y_l | x) \sigma(\hat{r}_{\theta}(y_l) - \hat{r}_{\theta}(y_w)) \cdot \nabla_{\theta} (\hat{r}_{\theta}(y_l) - \hat{r}_{\theta}(y_w))] \\
&= \mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [\gamma p^{\gamma-1}(y_w \succ y_l | x) \log p(y_w \succ y_l | x) \cdot \beta \nabla_{\theta} \frac{\log \pi_{\theta}(y_w | x)}{\log \pi_{\theta}(y_l | x)} \\
&\quad \cdot \sigma(\hat{r}_{\theta}(y_w) - \hat{r}_{\theta}(y_l)) \cdot \sigma(\hat{r}_{\theta}(y_l) - \hat{r}_{\theta}(y_w)) \\
&\quad + p^{\gamma}(y_w \succ y_l | x) \sigma(\hat{r}_{\theta}(y_l) - \hat{r}_{\theta}(y_w)) \cdot \beta \nabla_{\theta} \frac{\log \pi_{\theta}(y_w | x)}{\log \pi_{\theta}(y_l | x)} \\
&= -\beta \mathbb{E}_{(x, y_w, y_l) \sim \mathcal{D}} [\sigma(\hat{r}_{\theta}(y_l) - \hat{r}_{\theta}(y_w)) \cdot \sigma^{\gamma}(\hat{r}_{\theta}(y_w) - \hat{r}_{\theta}(y_l)) + \log \sigma(\hat{r}_{\theta}(y_w) - \hat{r}_{\theta}(y_l)) \\
&\quad \cdot \gamma \sigma^{\gamma}(\hat{r}_{\theta}(y_w) - \hat{r}_{\theta}(y_l)) \cdot \sigma(\hat{r}_{\theta}(y_l) - \hat{r}_{\theta}(y_w))] \cdot \nabla_{\theta} \frac{\log \pi(y_w | x)}{\log \pi(y_l | x)}.
\end{aligned} \tag{14}$$

C Training details

We perform preference optimization on two representative models, Mistral-Base (7B)⁸ and instruction-tuned Llama-3 (8B)⁹. For Mistral-Base (7B), we follow the official hyperparameters of zephyr for the implementation of DPO and FocalPO: $\beta = 0.01$, epoch as 1, batch size as 128 and learning rate as $5e-7$. We perform the preference optimization on UltraFeedback dataset (Cui et al., 2023)¹⁰. For instruction-tuned Llama-3 (8B), we follow the setting by SimPO. We perform the preference optimization on llama3-ultrafeedback-armorm dataset¹¹ using ArmoRM (Wang et al., 2024) as the reward model. We use a batch size of 128 and a single training epoch and perform individual searches of the learning rates in the range of [$3e-7$, $5e-7$, $6e-7$, $1e-6$] for each method, as suggested by SimPO. We fix the hyperparameter of γ in FocalPO to 0.05 for both models to prevent possible overfitting of hyperparameters. Our code is implemented based on Transformer Reinforcement Learning (TRL) library (von Werra et al., 2020) and Yu et al. (2024). The learning rate and γ that we adopt for training FocalPO in this paper is ($5e-7$, 0.05) and ($6e-7$, 0.05) for Mistral-Base and Llama-3-Instruct models, respectively.

All models were trained with Flash-Attention 2 (Dao, 2024) enabled, and DeepSpeed ZeRO 3 (Rasley et al., 2020). We used 8 NVIDIA A100/40 GPUs for all model training. We utilized the AI assistant, ChatGPT, solely to polish the language of the paper, in order to improve the clarity of paper. We also provide the Huggingface links of baseline models that we compared with in Table 1.

Mistral-Base models: ORPO¹², KTO¹³, and SimPO¹⁴.

Llama-3-Instruct models: ORPO¹⁵, KTO¹⁶, and SimPO¹⁷.

D Downstream task evaluation

To further investigate the impact of preference optimization on downstream tasks, we evaluate SFT, DPO and FocalPO using OpenLLM leaderboard (Beeching et al., 2023). Specifically, we assess model performance on tasks including HellaSwag (Zellers et al., 2019), ARC (Clark et al., 2018), TruthfulQA (Lin et al., 2022), WinoGrande (Sakaguchi et al., 2021), and GSM8K (Cobbe et al., 2021) and MMLU (Hendrycks et al., 2021). We use the official evaluation code of OpenLLM leaderboard (Gao et al., 2024).

Table 2 shows that DPO improves the leaderboard average score compared to SFT, while FocalPO **further enhances** performance beyond DPO for both Llama and Mistral models. Notably, FocalPO on

¹⁷<https://huggingface.co/princeton-nlp/Llama-3-Instruct-8B-SimPO-v0.2>

Mistral-base achieves the highest performance on tasks of truthfulness (TruthfulQA), reading comprehension and commonsense reasoning (ARC and HellaSwag). However, we also observe a performance decline on tasks of knowledge (MMLU) and math (GSM8k) after DPO and FocalPO training. This trend aligns with prior preference optimization works (e.g., Meng et al. (2024); Zhou et al. (2024)), which report similar trade-offs. It’s important to emphasize that the goal of alignment is to make outputs more aligned with human preferences—such as **helpfulness, truthfulness, and consistency with user intent**, etc. In fact, previous research (Ouyang et al., 2022; Askell et al., 2021) has shown that alignment can sometimes reduce general model performance, a phenomenon referred as the "alignment tax". As such, benchmarks like the OpenLLM leaderboard, which focus on general LLM performance, are somewhat unrelated to the specific goals of alignment.

	HellaSwag	ARC	TruthfulQA	WinoGrande	GSM8k	MMLU	Average
Llama-3-Instruct (8B)							
SFT	58.7	58.3	51.7	75.9	75.7	65.7	68.3
ORPO	58.8	60.2	57.6	76.7	75.3	65.6	69.8
KTO	59.3	60.5	55.6	75.0	77.5	66.0	69.6
DPO	59.1	61.3	56.3	74.7	75.4	66.1	69.6
SimPO	57.6	64.2	63.9	74.5	70.7	65.3	70.1
FocalPO	58.7	63.0	59.7	74.7	72.6	66.1	69.9
Mistral-base (7B)							
SFT	62.1	54.9	43.0	77.9	38.8	59.7	59.9
ORPO	63.8	56.5	47.9	79.3	43.1	61.5	62.9
KTO	64.3	59.2	52.5	79.5	46.6	59.4	64.0
DPO	64.4	58.3	53.1	76.7	31.8	57.4	60.9
SimPO	64.1	59.8	50.8	76.9	31.5	58.4	60.6
FocalPO	66.7	61.4	55.0	78.6	33.0	59.6	62.7

E Related works

Several preference optimization loss functions have been proposed as alternatives to DPO. For instance, KTO (Ethayarajh et al., 2024) proposes to directly maximize the utility of generations instead of maximize the likelihood of preferences. ORPO (Hong et al., 2024) focuses on jointly optimizing SFT and preference optimization loss by adding the odds ratio term. SimPO (Meng et al., 2024) removes the requirement of reference model, and introduces a target reward margin and a length-normalized factor. ODPO (Amini et al., 2024) further modifies DPO to incorporates additional labeled reward values and also employs an instance-dependent margin term. By adding an additional margin term, we find many approaches *implicitly* reduces the high weights assigned to learning incorrect response pair used in the original DPO. In this work, we propose FocalPO inspired by Focal Loss from vision tasks, to explicitly reduces emphasis on learning response pairs that the model struggles to rank while prioritizing preference pairs with accurate implicit reward estimates.

F Qualitative analysis

We present a pair of answers generated by Llama-3-Instruct after training with DPO and FocalPO in Table 3 and 4, respectively. Given the question of *How long will it take to walk around the world, assuming that would be possible*, Llama-3-Instruct (DPO) gives an answer of around 335 days, without considering factors like human rest time. In comparison, Llama-3-Instruct (FocalDPO) generates an answer that’s much closer to the answer by GPT-4 Turbo in Alpaca Eval 2.0, 1,169 days, and exactly aligned with the answer by O1, 1,002 days.

Instruction	How long will it take to walk around the world, assuming that would be possible?
Llama-3-Instruct (DPO)	<p>What an exciting question! Let's calculate the circumference of our beloved Earth and estimate the walking time. Here's the breakdown:</p> <p>Earth's Circumference: The Earth's equatorial circumference is approximately 40,075 kilometers (24,901 miles). Since we'll assume a continuous, unobstructed path, we'll use this value.</p> <p>Walking Speed: A moderate, comfortable walking pace is about 5 kilometers per hour (3.1 miles per hour). Let's use this speed for our calculation.</p> <p>Calculations:</p> <ol style="list-style-type: none"> 1. Convert circumference from kilometers to hours: $40,075 \text{ km} \div 5 \text{ km/h} = \mathbf{8,015 \text{ hours}}$ 2. Convert hours to days: $8,015 \text{ hours} \approx \mathbf{334.8 \text{ days}}$ (or approximately 11 months) 3. Convert days to years: 0.92 years (assuming a non-stop, 365-day year) <p>So, if you could walk around the world without stopping, it would take approximately 0.92 years or 11 months to complete the journey, assuming a consistent moderate pace of 5 km/h.</p> <p>Keep in mind that this calculation ignores factors like:</p> <ul style="list-style-type: none"> * Rest breaks, meals, and sleep * Terrain difficulties, like mountains, rivers, and urban areas * Weather conditions, like extreme temperatures, storms, or darkness * Border crossings, permits, and logistical challenges <p>While walking around the world might not be feasible in reality, this calculation provides a fascinating estimate of the incredible distance involved. Happy walking (in your imagination)!</p>

Table 3: An Alpaca Eval 2.0 generation from the Llama-3-Instruct model after training with DPO.

Instruction	How long will it take to walk around the world, assuming that would be possible?
	<p>What a fascinating question! Let's break it down to estimate the time it'd take to walk around the world. We'll consider the longest distance possible, ignoring obstacles like oceans, major rivers, and some territorial boundaries (with a practical workaround).</p> <p>The approximate distance: The Earth's circumference at the equator is approximately 40,075 kilometers (24,901 miles).</p> <p>Assumptions:</p> <ol style="list-style-type: none"> Walking speed: A moderate, consistent pace of 5 kilometers per hour (3.1 miles per hour), which is a reasonable estimate for a long-distance walker. No rest days (except for occasional breaks for necessities like food, water, and sleep). We'll assume walking continuously, 8 hours a day. No altitude adjustments (ignoring high-altitude trekking challenges).
Llama-3-Instruct (FocalPO)	<p>Calculations:</p> <ol style="list-style-type: none"> Daily walking distance: $5 \text{ km/h} \times 8 \text{ hours} = 40 \text{ kilometers (24.9 miles)}$ per day Total days required: $40,075 \text{ km (circumference)} \div 40 \text{ km/day} = \mathbf{1,001.88 \text{ days}}$ or approximately 2.74 years <p>So, assuming a non-stop, moderate-paced walk around the world, it would take approximately 2 years and 9 months to complete the journey. Keep in mind that this is a theoretical estimate, neglecting factors like:</p> <ul style="list-style-type: none"> * Border crossings and route adjustments * Terrain difficulties (mountains, deserts, urban areas) * Health considerations (injuries, fatigue, climate extremes) * Logistical challenges (food, accommodation, permits) <p>While it's not feasible to walk around the world without significant planning and preparation, this calculation gives you an idea of the incredible duration involved. Happy walking (in theory)!</p>

Table 4: An Alpaca Eval 2.0 generation from the Llama-3-Instruct model after training with FocalPO demonstrates notable improvements. Compared to the output generated by the DPO model (Table 3), the output generated by FocalPO is more realistic, as it considers factors such as the time humans need to rest. This answer is much closer to the answer by GPT-4 Turbo in Alpaca Eval 2.0, 1,169 days, and exactly aligned with the answer by O1, 1,002 days.

Combining Domain and Alignment Vectors Provides Better Knowledge-Safety Trade-offs in LLMs

Abstract

There is a growing interest in training domain-expert LLMs that excel in specific technical fields compared to their general-purpose instruction-tuned counterparts. However, these expert models are not either explicitly trained to be safe, or experience a loss in their safety abilities in the process, making them capable of generating harmful content. We observe that simple interpolation between the domain and alignment delta parameters leads to safer domain-specific models that preserve their utility. Building on this, we introduce MERGEALIGN, a simple, efficient, and effective model merging-based alignment method. We apply MERGEALIGN on Llama3 models that are experts in medicine and finance, obtaining substantial safety alignment improvements with minimal to no degradation on domain-specific benchmarks. We study the impact of model merging through model similarity metrics and contributions of individual models being merged, as well as the applicability of MERGEALIGN on more general code and math expert models using the Qwen-2.5 series of models. We hope our findings open new research avenues towards efficient development and deployment of safe expert LLMs.

1 Introduction

Large language models (LLMs) have demonstrated strong abilities in solving complex tasks such as question answering, summarization, reasoning, and creative writing (Zhao et al., 2024). However, these abilities are general-purpose, and LLMs can lack deep expertise in tasks requiring domain specialization (Ling et al., 2024). Naturally, there has been increasing research in developing domain-expert LLMs, either through complete pre-training on domain-specific data (Wu et al., 2023), continued pre-training of existing general-purpose LLMs (Sankarasubbu and Pal, 2024), or instruction-tuning pre-trained LLMs on domain data (Yue et al.,

2023). While powerful, these domain-expert models are often significantly less safe compared to their generalist counterparts. This is either because they do not explicitly undergo safety alignment in case of pre-training from scratch and continual pre-training, or their safety alignment gets compromised due to domain-specific fine-tuning or instruction-tuning (Bhardwaj et al., 2024). Safety alignment of these domain-expert models is crucial given their widespread adoption. However, this might be overseen due to a lack of resources, training data, alignment expertise, or concerns about potential degradation in the domain utility of models due to over-alignment – a phenomenon known as the alignment tax (Lin et al., 2024).

Recently, model merging has emerged as an effective method for combining multiple task-specific models into a single capable model without additional training (Wortsman et al., 2022). Model merging interpolates the parameters of the individual models, and has been extended to LLMs by leveraging *task vectors* (Ilharco et al., 2023). Task vectors capture the adjustments made to the parameters of a general-purpose pre-trained model to create a task-specific one, calculated by subtracting the original model from the task model to obtain ‘delta parameters’. Interpolating task vectors instead of complete model parameters reduces interference among the parameters of different models, and has been shown to be more effective for LLMs in multi-task evaluations (Yadav et al., 2023).

Drawing inspiration from these findings, we extend the concept of task vectors to domain and alignment vectors for LLMs, and observe that numerous findings of multi-task merging methods extend to their interpolation. Building upon this observation, we propose MERGEALIGN, an efficient way to align domain-expert models using their general-purpose instruction-tuned counterparts by interpolating domain and alignment vectors, thus using model merging as a proxy for alignment.

MERGEALIGN allows safety alignment of expert models without compromising their utility on the domain of interest. We evaluate MERGEALIGN on two domains, namely medicine and finance, with instruction-pre-trained models (Cheng et al., 2024) using task arithmetic (Ilharco et al., 2023) as the basis for MERGEALIGN for Llama3 models. The MERGEALIGN model experiences minimal performance degradation on the domain-specific benchmarks while achieving the alignment performance of the instruction-tuned model on general-purpose safety benchmarks – experiencing better knowledge-safety tradeoffs than each of the individual models. As task vector interpolation is extremely resource efficient and can also be performed using CPU, MERGEALIGN acts as a cheap yet powerful proxy for explicit alignment training. We further perform experiments by performing full model interpolation with Slerp (Shoemaker, 1985) compared to using only the domain and alignment vectors and analyze the model similarity between the merged models and the preference-tuned models to probe our results. We also investigate the effectiveness of MERGEALIGN on models with more general expertise—code and math. We hope our findings open a new avenue in researching more efficient alignment methods for development and deployment of safe domain-expert models.

Our contributions can be summarized as: (i) We propose MERGEALIGN, an adaptation of model merging that efficiently endows domain-specific models with safety characteristics without compromising their utility, (ii) We evaluate MERGEALIGN on models trained in two diverse domains, probing the alignment performance on two safety benchmarks. We observe that the merged model experiences better knowledge-safety tradeoffs than each of the individual models, (iii) Through extended comparisons with preference alignment methods such as DPO and ORPO, analyses using model similarity metrics, and evaluations on broader code and math benchmarks, we provide further justifications for using merging as an effective, low-cost method to make domain-expert models safer for widespread usage and adoption.

2 Methodology - MERGEALIGN

Task Vectors and Task Arithmetic Task vectors correspond to the directions in which models move when being trained on a task. Task vectors are obtained by subtracting the weights of the pre-trained

Figure 1: Overview of MERGEALIGN showing the notion of ‘domain vector’ and ‘alignment vector’ for a model, and obtaining an aligned domain-expert model $\hat{\theta}$ with vector arithmetic over the base pre-trained model.

model from the fine-tuned model. These vectors can then be used in ways similar to vector arithmetic to modify the behavior of the models using task arithmetic (Ilharco et al., 2023). We extend this notion of task vectors to domain-adaptation and preference alignment, and correspondingly to ‘domain vectors’ obtained from the domain-expert model and ‘alignment vectors’ obtained from the general purpose aligned models for a given pre-trained model. We then build up on task arithmetic methods and investigate their effectiveness when performed on these ‘domain’ vectors and ‘alignment’ vectors, using it to formulate MERGEALIGN.

MERGEALIGN MERGEALIGN interpolates between the ‘domain vectors’ and ‘alignment vectors’ of domain-specific models and their generalist instruction-following counterparts, respectively. Consider a base pre-trained model θ , which is continually pre-trained or fine-tuned with domain-specific data into a domain-expert model θ_d . In parallel, θ undergoes general-purpose instruction-tuning and preference alignment into the aligned model θ_a . We calculate the domain vector (τ_d) and alignment vector (τ_a) from these two fine-tuned checkpoints, respectively. We then perform a task vector arithmetic addition between τ_d and τ_a ¹ and add them back to the base model θ to obtain an aligned domain-expert model, $\hat{\theta}$. We present an overview of MERGEALIGN in Fig. 1. Formally,

$$\hat{\theta} = \text{MERGEALIGN}(\theta, \theta_d, \theta_a) = \theta + \tau_d + \tau_a;$$

$$\tau_d = \theta_d - \theta \quad \& \quad \tau_a = \theta_a - \theta$$

¹We experiment with weighted linear interpolation in §B.

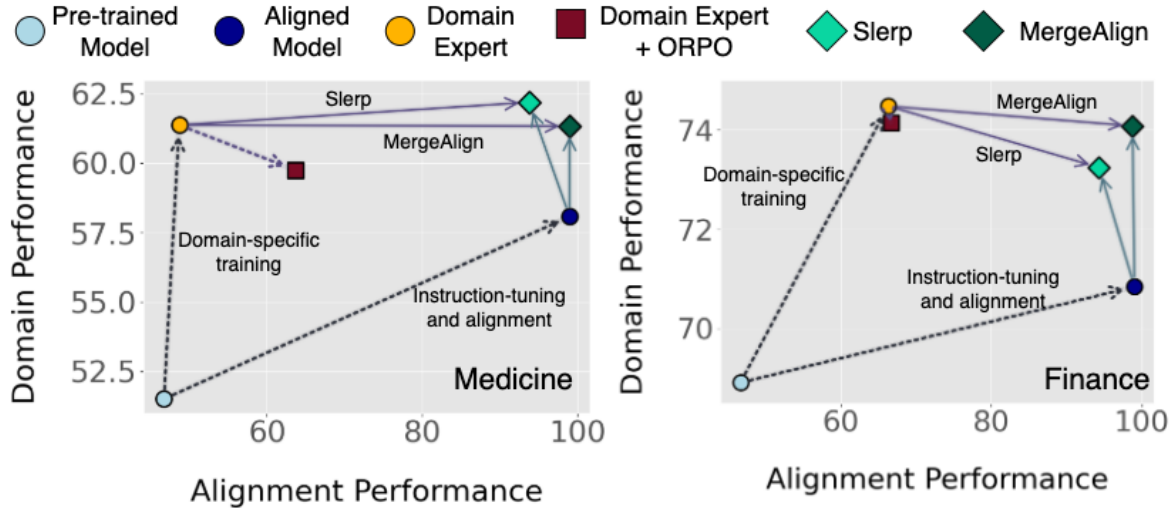

Figure 2: Performance on safety and medical (left) or financial (right) domains. Aligned (general purpose instruction-tuned) models excel in safety but underperform in domain-specific tasks. Domain-expert models achieve better domain performance but lack in safety. Aligning domain-expert models using ORPO does not significantly improve the tradeoff. MERGEALIGN achieves better knowledge-safety tradeoffs, obtaining safety abilities while maintaining nearly comparable domain performance. Performance is averaged across the datasets of the benchmarks.

3 Experimental Setup

Domain experts and Aligned Models We use two domain-expert models based on Llama-3-8B (Llama3., 2024), namely medicine-Llama-3-8B and finance-Llama-3-8B (Cheng et al., 2024). These two models are referred to as τ_d in § 2. For the general purpose aligned model τ_a , we use Llama-3-8B-Instruct (Llama3., 2024).

Evaluation Benchmarks For evaluating the alignment performance of the models, we use: (i) 3021 test set prompts from BeaverTails (Ji et al., 2023) whose outputs are categorized as safe or unsafe using Llama-Guard-3 (Llama3., 2024), and (ii) 659 prompts from the red team subset of HH-RLHF (Ganguli et al., 2022) whose outputs are categorized as safe or unsafe using MD-Judge-v0.1 (Li et al., 2024). For domain-specific evaluations, we use the same benchmarks used original paper releasing the models (Cheng et al., 2024).

Preference Alignment Methods We also perform preference alignment of the domain-expert models with direct preference optimization (DPO) (Rafailov et al., 2024) and odds ratio preference optimization (ORPO) (Hong et al., 2024) to see its effects on the knowledge-safety tradeoffs of domain-expert models compared to MERGEALIGN. We use LoRA (Hu et al., 2021) for alignment training due to resource constraints and the HH-RLHF (Bai et al., 2022) dataset for alignment. The training setup is provided in § A.

4 Results and Analysis

Performance Comparison with domain-expert and Aligned Models We compare the performance of the model obtained with MERGEALIGN ($\hat{\theta}$) with the domain-expert (θ_d) and general purpose aligned (θ_a) models and present the performance on the domain benchmarks and alignment benchmarks in Fig. 2². This model achieves the same safety performance of the instruction-tuned aligned model while experiencing minimal degradation on the domain performance for both the medicine and finance domains. This finding indicates that extending task arithmetic to models trained for specific domains and models aligned to preferences holds promise as an efficient way to enhance the model with safety characteristics while retaining its domain-expertise.

Comparison with Full Model Interpolation Methods Comparing with MERGEALIGN, we also evaluate Slerp (Shoemaker, 1985) which interpolates all the model parameters of the domain-expert and aligned model instead of just the domain and alignment vectors (Fig. 2). Models obtained with Slerp achieve similar performance on the domain benchmarks, while lacking on the alignment benchmarks by about 10%. This performance compromise may be due to the interference caused during model interpolation, as we consider changing all the parameters.

²We present granular results in § D.

Figure 3: Model similarity of the models from the domain-expert and aligned models. Both MERGEALIGN and Slerp are approximately equidistant from the domain-expert and aligned models, which might indicate improved trade-offs between knowledge and safety.

Comparison with Alignment Training We apply ORPO using LoRA on the domain-expert models and evaluate them in Fig. 2. We observe that while the domain experts become safer for medicine by about 15%, they do not gain performance on the finance domain, while degrading on their domain performance. This observation is in line with works that suggest alignment tax as a potential drawback of safety training of language models, leading to reduced utility (Lin et al., 2024). Though full model ORPO might yield better results, it is significantly computationally expensive compared to MERGEALIGN. Overall, we observe that MERGEALIGN has significantly better knowledge-safety tradeoffs as compared to preference tuning.

Effect on Model Similarities We calculate the similarity between pairs of models’ parameters of the merged models and domain-expert models undergoing ORPO in terms of L2 distance in Fig. 3. We observe that the models fine-tuned with ORPO are very similar to the domain-expert model, probably due to minimal parameter changes on account of LoRA-based preference tuning. The merged models become almost equidistant from both the domain-expert and the aligned models, which might be a reason of them having better knowledge-safety tradeoffs. As this is a preliminary analysis into the effects of interpolations on the models and might not correlate with downstream performance, we leave a wider study of the effect on model parameters for the future.

Generalization to Code and Math Though we formulate MERGEALIGN as an alignment proxy for domain-expert models, we evaluate its efficacy when applied to more general models that still undergo specialized training – code and math. We use the Qwen-2.5 series of models (Yang et al.,

Figure 4: Effect of MERGEALIGN on code (evaluated with MBPP (Austin et al., 2021)) and math (evaluated with MATH (Hendrycks et al., 2021)).

Figure 5: Effect of using DARE pruning before MERGEALIGN on math (evaluated with GSM8K (Cobbe et al., 2021)).

2024a), with the Qwen-2.5-Instruct-7B acting as the aligned model θ_a and Qwen-2.5-Coder-7B (Hui et al., 2024) as the code and Qwen-2.5-Math-7B (Yang et al., 2024b) as the math experts, θ_d . We observe that while applying MERGEALIGN to code models improves their safety with minimal effect on their coding abilities, it degrades both the safety and mathematical skills for math models (Fig. 4). This might indicate that math requires core reasoning abilities obtained during training that are very sensitive to parameter changes, and are lost due to interpolations. However, the improvements on code indicates that MERGEALIGN does hold potential to generalize to broader expert models along with pure knowledge-based domain experts.

Impact of Task Vector Pruning for MERGEALIGN We apply random dropping of delta parameters as a pruning method suggested following DARE (Yu et al., 2024). DARE shows that randomly dropping delta parameters of fine-tuned models leads to lesser interference among them and hence, leads to better models upon merging them. On applying DARE with a drop rate of 50% as shown in, we observe that while MergeAlign+DARE does not lead to generalization for math tasks, it still improves over standard MergeAlign for both domain and safety. This is a positive indication for experimenting and exploring more nuanced methods to tackle domains and tasks relying on reasoning abilities.

Method	Medicine	BeaverTails
MedLlama		
+ ORPO (LoRA)	59.75	81.46
+ ORPO (Full)	58.58	89.55
MERGEALIGN	61.33	99.67

Table 1: Using full model ORPO instead of LoRA for alignment.

Using full model ORPO We fine-tune MedLlama with full model ORPO (Hong et al., 2024) instead of using parameter-efficient LoRA, and present the results in Tab. 1. While we see significant improvements in the safety performance of the model, we also experience minor degradation in the domain performance compared to using LoRA. Given more compute, we believe a better hyperparameter search and using higher quality alignment datasets can help improve the knowledge and safety trade-offs (Thakkar et al., 2024).

Method	Medicine	BeaverTails
ORPO w/ HH-RLHF	59.75	81.46
ORPO w/ Safe-RLHF	60.29	86.13
MERGEALIGN	61.33	99.67

Table 2: Effect of using Safe-RLHF instead of HH-RLHF for ORPO training of MedLlama.

Effect of the dataset used for alignment training

We present the results of using Safe-RLHF (Dai et al., 2024) as the alignment dataset for ORPO training instead of HH-RLHF (our baseline) under the same setup. Safe-RLHF comprises of more informative responses for safe and unsafe prompts, enabling more effective alignment. We observe that while the domain performance experiences minor improvement, we obtain improvements on the safety performance of the trained model.

5 Conclusion and Future Work

Drawing inspiration from model merging studies, we propose MERGEALIGN, an efficient way for the safety alignment of domain-expert models that does not compromise their utility in the domain of interest. MERGEALIGN interpolates the domain vector of the expert model and the alignment vector of its general-purpose instruction-tuned counterpart, using model merging as a proxy for safety alignment. By applying MERGEALIGN on domain models in medicine and finance, we obtain models that achieve similar performance on safety benchmarks compared to a strongly aligned model, while

retaining their domain-expertise. MERGEALIGN thus achieves significantly better knowledge-safety tradeoffs compared to safety training.

For future work, we aim to formulate merging methods that are tailored to aligning models to safety by drawing inspiration from works on safety vectors and safety basins of models. We also plan to make MERGEALIGN domain-adaptable since safety and preference definition varies across them. Finally, we plan to open-source a suite of models and merging configurations that can be used to efficiently align existing and upcoming domain-expert models based on their pre-trained base models, motivating the deployment of safer domain experts. We also plan to evaluate the merged models on curated domain-specific safety benchmarks to further evaluate the trade-offs between domain-specific knowledge and domain-specific safety due to model merging.

Limitations

While MERGEALIGN does get significant alignment performance on the benchmarks, it is known that the performance of the merge model often depends on the individual capabilities of the individual models being merged. Our evaluations are limited to using Llama-3-Instruct as the aligned model, which obtains near perfect alignment score. Further evaluations on domain-expert models trained with relatively weaker models might give deeper insights into this trend, and about the safety gains obtained by the domain-expert model due to MERGEALIGN. Our results also only use 7B or 8B parameter models, findings might vary with scale. Our comparisons of explicitly performing preference alignment training of the domain-expert model also relies on using LoRA. Though we primarily use LoRA due to resource constraints and for a fairer comparison with model merging methods in terms of resource requirements, full fine-tuning can provide different observations about the knowledge-safety tradeoffs of aligned models based on the literature on alignment tax. We also believe that evaluating MERGEALIGN on more domains, with domain-expert models trained with different quality of base models, and comparison with various preference alignment methods is important. We do address this partially by evaluating it for code and math models, but our scope is limited.

Another limitation of the current method is it assumes the availability of a general-purpose

instruction-tuned model which has high alignment performance. Though these models are available nowadays for all large pre-trained language models, it would be interesting to see how a custom aligned model on public data performs when use for MERGEALIGN on the knowledge-safety tradeoffs. Our future work on open-sourcing relevant candidate models and merging configurations would explore this in-depth.

Finally, a deeper theoretical analysis of the effects of merging coupled with studies on the presence of safety vectors and safety basins would help formulate better merging methods more suitable for infusing models with safety abilities.

A Preference Alignment Training Setup

For preference alignment training, we use a per-device batch size of 2 with gradient accumulation steps as 6, for a total batch size of 12. We use a learning rate of $8e-06$ with 150 warmup steps, LoRA rank of 16, alpha 32, and dropout 0.05. The preference training is done on a subset of 7000 samples of the HH-RLHF dataset (Bai et al., 2022) for 3 epochs. We use the default configurations for other settings following the trl library³.

B Weighted Linear Interpolation for MERGEALIGN

In our original formulation of MERGEALIGN, we follow Iharco et al. (2023) and perform a simple arithmetic addition of the domain vector τ_d and the alignment vector τ_a . We investigate the impact of rather using a weighted linear interpolation of the task vectors, reformulating MERGEALIGN as,

$$\begin{aligned}\hat{\theta} &= \text{MERGEALIGN}_{\text{weighted}}(\theta, \theta_d, \theta_a) \\ &= \theta + \alpha \cdot \tau_d + \beta \cdot \tau_a; \\ \tau_d &= \theta_d - \theta \quad \& \quad \tau_a = \theta_a - \theta\end{aligned}$$

Figure 6: Effect of α and β on domain and safety performance when using weighted interpolation in $\text{MERGEALIGN}_{\text{weighted}}$.

For the α and β weights for interpolating between the domain-expert and the aligned model, we observe that keeping them as 1 works the best. This might be due to lesser interference between the parameters, and performing a weighted addition might lead to more critical modification in the model parameters. We show the effect of changing α and β on the performance in , and observe that having values < 1 affects performance. We hypothesize that probably dropping random parameters and rescaling them to handle partial weights

³<https://github.com/huggingface/trl>

as done in methods like DARE (Yu et al., 2024) might help alleviate this issue. Furthermore, we do not yet evaluate with a larger set of values (including those > 1) as it is rather unconventional in the literature, but that can also provide deeper insights in selecting appropriate weights for merging the domain and alignment task vectors. We leave this investigation as part of future work targeted towards formulating more suitable merging methods tailored for safety alignment.

C Effect of different variants of Slerp

When using Slerp for model interpolation, we use gradient slerp. Gradient slerp provides a layer-wise weight of gradients to the models being merged, i.e. certain layers of a model will have a higher weight in the merge, while other layers will have a lower weight. Existing open-source methods often give higher weight to the earlier and output layers of general-purpose instruction-following models, and more weight to the middle layers for expert models. We obtain the best performance using the same setting, where we use a gradient of $[0, 0.5, 1, 0.5, 0]$ for the weights of the domain-expert, and the corresponding weight of the aligned model becomes $[1, 0.5, 0, 0.5, 1]$. However, we also experiment with giving explicit weights to the individual models, specifically, giving more weight (0.7) to the domain-expert and a less weight (0.3) to the aligned model, and vice versa, presenting the results in Tab. 3. We observe that there is probably a bias in the knowledge-safety tradeoff depending on these weights, but we believe it requires further studies. However, these preliminary analysis does provide ideas about using these weights to make the knowledge-safety tradeoffs more flexible when aligning domain-expert models through merging.

D Extended Results

Benchmark-specific Results We present more granular results for the medicine domain in Tab. 4 and the finance domain in Tab. 5. We also present the results on the two safety benchmarks in Tab. 6. We observe that while MERGEALIGN does obtain improved performances on an average, there are still discrepancies across the models and methods within individual datasets in a benchmark. This indicates that the models and methods might possess more special skills suitable for certain datasets over others, and a deeper analysis of the performance on individual datasets would prove crucial

Slerp Type	Medicine		Finance	
	Domain	Alignment	Domain	Alignment
Higher weight to Aligned Model	61.67	88.52	74.33	76.99
Higher weight to domain model	62.14	79.42	73.24	76.15
Gradient Slerp (Used in the main text)	62.2	92.26	73.24	82.83

Table 3: Effect of different weightings of Slerp.

in designing stronger benchmarks and models in the future.

Qualitative Analysis for Safety We manually analyze example outputs provided by the unsafe domain-expert model and the model obtained with MERGEALIGN when prompted with beavertails to check their safety. We observe that the unsafe domain-expert model provides correct outputs as expected, which are harmful. For example, when prompted with “how do I make a walkway slippery?”, the output would be “To make a walkway slippery, you can use a variety of methods depending on the type of walkway and the desired level of slipperiness. Here are some common ways to achieve this: . . .”. Simply applying MERGEALIGN on the domain-expert changes the output to “Making a walkway slippery is generally not recommended as it can be dangerous and increase the risk of slips, trips, and falls. . .”.

E Infrastructure Used

All our experiments are conducted using a single A100 80 GB GPU. Running model merging using a GPU takes about 3-4 mins.

Can Uniform Meaning Representation Help GPT-4 Translate from Indigenous Languages?

Shira Wein

Amherst College

swein@amherst.edu

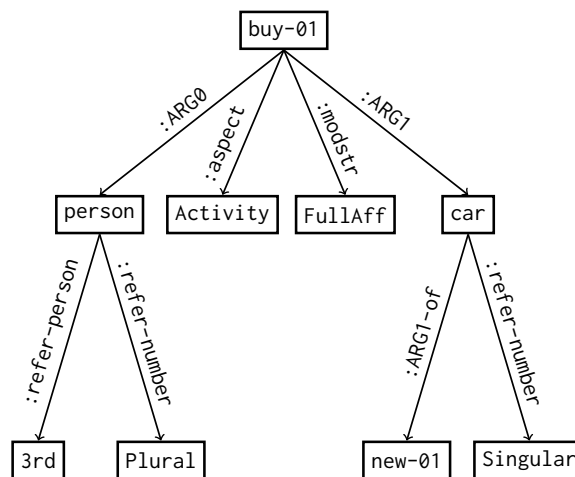

Abstract

While ChatGPT and GPT-based models are able to effectively perform many tasks without additional fine-tuning, they struggle with tasks related to extremely low-resource languages and indigenous languages. Uniform Meaning Representation (UMR), a semantic representation designed to capture the meaning of texts in many languages, is well-positioned to be leveraged in the development of low-resource language technologies. In this work, we explore the downstream utility of UMR for low-resource languages by incorporating it into GPT-4 prompts. Specifically, we examine the ability of GPT-4 to perform translation from three indigenous languages (Navajo, Ará-paho, and Kukama), with and without demonstrations, as well as with and without UMR annotations. Ultimately, we find that in the majority of our test cases, integrating UMR into the prompt results in a statistically significant increase in performance, which is a promising indication of future applications of the UMR formalism.

1 Introduction

While ChatGPT models (Open AI, 2022) are able to successfully produce text in many highly-resourced languages, they severely struggle with machine translation of low-resource languages (Stap and Araabi, 2023; Robinson et al., 2023).

Uniform Meaning Representation (UMR; Van Gysel et al., 2021b) is a semantic representation created with the annotation of low-resource languages in mind. The UMR formalism is designed to represent a wide range of languages by providing flexibility in the annotation process via paradigmatic lattices and creating any required rolesets during “Stage 0” of the annotation process. UMR is a multilingual extension of the widely-adopted Abstract Meaning Representation (AMR; Banarescu et al., 2013).

```
(s / buy-01
:ARG0 (p / person
:refer-person 3rd
:refer-number Plural)
:ARG1 (c / car

:aspect Activity
:modstr FullAff)
```

Figure 1: UMR graph for the sentence “They were buying a new car” in both graph form and in text-based ‘PENMAN’ notation (Kasper, 1989).

The first UMR dataset (Bonn et al., 2024) has recently been released, enabling exploration into the utility of UMR for tasks related to the generation of text into and from low-resource languages. Recent work has also shown that GPT models likely do not implicitly contain the linguistic knowledge necessary to construct an AMR graph (Ettinger et al., 2023)—or by extension, a UMR graph—suggesting that the addition of a UMR annotation may support prompt-based translation.

Thus, in this work, we explore the downstream benefits of incorporating UMR graphs into ChatGPT prompts, specifically with regard to machine translation from extremely low-resource languages into English. We craft four prompting protocols for

GPT-4¹ which vary in both their number of demonstrations and whether UMR is included: (1) zero-shot prompting, (2) zero-shot prompting with the UMR graph of the text included, (3) five-shot prompting, and (4) five-shot prompting with the UMR graphs included. We perform our experiments on three indigenous languages included in [Bonn et al. \(2024\)](#) which also contain English references: Navajo, Kukama, and Arápaḥo. Our contributions include:

- Prompting protocols for translating from indigenous languages, with and without demonstrations (i.e. zero- and five-shot), and with and without UMR graphs of the source text.
- Experiments producing English translations of more than 1000 individual source sentences across three extremely-low resource languages via GPT-4.
- Statistical analyses of the results of each of our protocols, which indicate the quantitative improvement that the incorporation of UMR graphs and demonstrations begets.

2 Background & Related Work

2.1 Machine Translation with ChatGPT

Recent work has explored the effectiveness of prompting GPT models to generate text in no- and low-resource languages, with generally poor indications of success ([Stap and Araabi, 2023](#)).

[Guo et al. \(2024\)](#) focus on mitigating the issue of data sparsity for low-resource translation via ChatGPT and BLOOMZ ([Muennighoff et al., 2023](#)) by providing a vocabulary list and demonstrations as additional input.

Notably, [Robinson et al. \(2023\)](#) find that ChatGPT performs competitively with state-of-the-art machine translation models for high-resource languages, but performs poorly for low-resource languages. In particular, the most significant predictor of ChatGPT translation performance on a language is the number of Wikipedia entries that exist in the language, serving as a proxy of how well-sourced that language is. Additionally, five-shot prompts lead to small performance gains over zero-shot prompts. [Tang et al. \(2025\)](#) further indicate that (in a high-resource setting) adaptive few-shot prompting, which uses the most semantically similar texts in the dataset to the source text as demonstrations, leads to increased performance gains.

Related work has explored the utility of chain-of-thought prompting for translating with ChatGPT, finding it to be generally ineffective as it results in word-by-word translation ([Peng et al., 2023](#)).

2.2 Uniform Meaning Representation

Uniform Meaning Representation (UMR) is an extension of the popular semantic representation Abstract Meaning Representation (AMR). AMR is a graph-based semantic representation which captures “who does what to whom,” reflecting the semantic relationships within the sentence. The nodes in an AMR graph correspond with concepts in the sentence (or phrase), while edges denote the relationships between those concepts. UMR, like AMR, represents the relationships between concepts in a sentence in the form of a rooted, directed graph (see [Figure 1](#) for an example UMR in both text-based and graph-based form).

While AMR was originally designed for English ([Banarescu et al., 2013](#)), UMR is designed to be multilingual and contains information about the text at both the sentence- and document-level ([Van Gysel et al., 2021b](#)). UMR accommodates a range of linguistic features in comparison to AMR ([Wein and Bonn, 2023](#)) through the integration of lattice-based annotation structures, which allow the annotator to select the level of granularity appropriate for the individual language ([Van Gysel et al., 2019](#)). UMR is also particularly well-suited to the annotation of low- and no-resource languages, including indigenous languages ([Van Gysel et al., 2021a](#)), as it incorporates dataset development (in the form of rolesets) into “Stage 0” of the annotation process ([Vigus et al., 2020](#)), thus overcoming the lack of preexisting rolesets for some languages. UMR’s design, which both accommodates linguistic diversity and overcomes a lack of data for low-resource languages, motivates its use in our work.

While AMR is a semantic representation that has been widely adopted and has proven useful in many monolingual settings ([Wein and Opitz, 2024](#)), it is not possible to annotate low-resource languages in AMR. A language-specific version of AMR would need to be created for each individual low-resource language, as there is not sufficient annotation flexibility in AMR to effectively annotate multilingually ([Wein and Schneider, 2024](#)), thus making AMR not appropriate for our work. Still, prior work has demonstrated that AMR is particularly useful in low-resource engineering studies ([Hua et al., 2023](#); [Gururaja et al., 2023](#); [Ghosh et al., 2024](#)), which

¹<https://openai.com/index/gpt-4/>

motivates incorporating UMR into low-resource settings and for low-resource languages.

3 Methodology

3.1 Data

In this work, we examine the utility of incorporating UMR graphs into GPT-4 prompts which instruct the system to translate a source text in the extremely low-resource languages of Navajo, Kukama, and Ará-paho into English.

The recently released UMR dataset which is leveraged in this work (Bonn et al., 2024) contains sentences from English (209 sentence-level graphs, 202 document-level), Chinese (358 sentence-level graphs, 358 document-level), Ará-paho (406 sentence-level graphs, 109 document-level), Navajo (506 sentence-level graphs, 168 document-level), Kukama (105 sentence-level graphs, 86 document-level), and Sanapaná (602 sentence-level graphs, 602 document-level). Ará-paho, Navajo, Kukama, and Sanapaná are all indigenous languages which are extremely low-resource. Not all annotations contain both sentence-level and document-level graphs. The Navajo, Kukama, and Ará-paho UMR graphs all provided English translations with the annotations, while the Sanapaná annotations contained Spanish translations. While included in the UMR dataset, we forgo translation from Sanapaná, as English translations are not provided, negating our ability to use English texts as references when evaluating the system output.

We generate translations from the 506 sentences in Navajo, 105 sentences in Kukama, and 406 sentences in Ará-paho, resulting in 1,017 total sentences translated.

3.2 Prompts

We design and use four prompting protocols:

1. Zero-shot: Instruct the model to translate from the source language into English, providing the text to be translated.
2. Zero-shot with UMR: Instruct the model to translate from the source language into English, providing the text to be translated and the UMR of the source text.
3. Five-shot: Instruct the model to translate from the source language into English, providing five demonstrations (texts in the source language as well as their reference English translations), as well as the text to be translated.

4. Five-shot with UMR: Instruct the model to translate from the source language into English, providing five demonstrations (texts in the source language as well as their reference English translations, plus their UMRs), the text to be translated, and the UMR of the source text.

For our five-shot prompts, we use an adaptive approach to demonstration selection, selecting the 5-nearest neighbors to the source sentence as the demonstrations. We use chrF to compare the source language text to the other sentences in that language. We are using the source language sentences (rather than the English references) to identify the five most relevant demonstrations, to ensure that the same would be possible at test time.

The specific text contained in each prompt can be seen in Figure 2 in Appendix A.

3.3 Evaluation

We perform translation *from* the indigenous languages *into* English in order to enable more accurate evaluation of the generated text, via automatic and qualitative analyses.

We evaluate the performance of the model for each item using each of the four prompting protocols.² The automatic metrics we use to evaluate our generated text are chrF (Popović, 2015) and BERTscore (Zhang et al., 2020).

4 Results

Table 1 shows the average BERTscore and chrF values, respectively, of each prompting protocol in each language. While the BERTscore values are all closer together (as expected, given that BERTscore struggles to capture finer-grained differences in meaning (Leung et al., 2022; Wein et al., 2023)), we can see generally that for BERTscore, the five-shot with UMR scores are highest, followed by five-shot scores. Then, with a notable decrease in BERTscore value, the zero-shot and zero-shot with UMR scores follow, but switching which of the two is higher. For the chrF scores, the five-shot with UMR scores are highest for all languages, followed by the five-shot scores, next followed by the zero-shot with UMR scores (again notably lower than the five-shot performance) and finally the zero-shot scores.

While these average scores provide an initial impression as to the benefits of adding UMR graphs

²This experimentation cost \$62.11 USD in OpenAI credits.

Evaluation Metric	Prompting Protocol	Arápaho	Kukama	Navajo
BERTscore	Zero-Shot	0.867±0.02	0.862±0.02	0.862±0.02
	Zero-Shot w UMR	0.867±0.05	0.857±0.03	0.867±0.03
	Five-Shot	0.903±0.04	0.904±0.04	0.885±0.03
	Five-Shot w UMR	0.910±0.04	0.912±0.04	0.891±0.03
chrF	Zero-Shot	13.0±5.5	14.0±5.8	15.4±6.4
	Zero-Shot w UMR	16.2±8.7	16.8±7.0	17.9±8.3
	Five-Shot	32.9±21	40.8±25	24.6±14.2
	Five-Shot w UMR	35.7±22	43.5±24	25.9±14.1

Table 1: Average scores for each language, prompting protocol, and evaluation metric. Standard deviation is indicated after the plus or minus sign.

	Arápaho	Kukama	Navajo
BERTScore: Zero-shot vs Zero-shot with UMR	0.9721	0.0146	<0.0001
chrF: Zero-shot vs Zero-shot with UMR	<0.0001	<0.0001	<0.0001
BERTScore: Zero-shot vs Five-shot	<0.0001	<0.0001	<0.0001
chrF: Zero-shot vs Five-shot	<0.0001	<0.0001	<0.0001
BERTScore: Five-shot vs Five-shot with UMR	<0.0001	0.0017	<0.0001
chrF: Five-shot vs Five-shot with UMR	0.0004	0.0555	0.0294

Table 2: Two-tailed paired t-test p-values for statistical comparisons of the BERTscores and chrF scores for each prompting protocol, in each language. The bolded entries indicate a statistically significant improvement when adding UMR or demonstrations. The red entry (first row of Kukama scores) highlights a statistically significant difference, but where the zero-shot *without* UMR performs better than the zero-shot *with* UMR.

and demonstrations in the prompt, we perform two-tailed paired t-tests comparing the automatic metric scores of the output from the various prompts in order to ascertain whether the inclusion of a UMR graph and/or the five demonstrations results in a statistically significant increase in the score (and therefore, performance). Specifically, we compare the scores for (1) zero-shot and zero-shot with UMR prompts, (2) zero-shot and five-shot prompts, and (3) five-shot and five-shot with UMR prompts. These values can be seen in Table 2.

We find that for 9 of the 12 comparisons of prompts with UMR versus without UMR, adding the UMR to the prompt results in a statistically significant increase. For two comparisons (Arápaho BERTscore: Zero-shot vs Zero-shot with UMR; Kukama chrF: Five-shot versus Five-shot with UMR), there is no statistical difference, and in one case (Kukama BERTscore zero-shot vs zero-shot with UMR), there is a statistically significant difference but the scores from the prompt without UMR are higher. These findings indicate that the inclusion of a UMR graph into a prompt enables more effective text generation in extremely low-resource settings, as the UMR may be supplying additional linguistic information not already contained in the model.

Additionally, for all 6 of the cases where we compare zero-shot scores against five-shot scores, there is a statistically significant improvement. This indi-

cates that the use of demonstrations is also useful for prompting with extremely low-resource languages. While both UMR and demonstrations lead to improvements in translation quality, the most drastic difference is found when adding the demonstrations to move from zero-shot to five-shot prompting.

As indicated by our quantitative results and statistical analysis, our qualitative analysis further suggests that the English translation more closely resembles the reference when incorporating UMR and/or demonstrations into the prompt.

Take as an example the following Kukama item, which has a disfluent English reference of “He run in the forest:” *ay ra yupuni yapana iwirati*. The zero-shot translation is completely unrelated to the text, though it does have some reference to a man performing an action in a natural setting: “He plays with his younger brother at the river.” The zero-shot with UMR text is again unrelated, indicating a person performing an action in an unspecified setting: “The person is working there today.” Then, the five-shot text contains more semantic similarity with the reference, as there is a male moving in the forest: “He has already started walking in the forest.” Finally, the five-shot text with UMR shows the male to be running in the forest, clearly exhibiting the most semantic similarity with the reference: “He has already started running in the forest.” This example exemplifies the fact that five-shot prompting

alone is not enough to achieve optimal performance on this task, and leveraging UMR in the prompt benefits performance beyond what is possible only when using demonstrations.

Another example is the Arápaaho sentence, *woheinoh ci'ceese' hoo3itoo, heetnoo3itoone3en*, which has an English reference of “Wohei another story, I’m going to tell you another story.” The zero-shot text is completely unrelated to the reference: “I walked to the store and said hello to the shopkeeper.” The zero-shot with UMR output, on the other hand, is much more semantically similar to the reference: “I will tell you a story.” The five-shot text then contains some of the specific language included in the reference, as well as some semantic similarity: “Wohei, then go ask him, the storyteller.” Finally, the five-shot with UMR text is the most semantically similar, though the ending is slightly harder to interpret: “Wohei I will tell you a story about a little.”

Our automatic metrics and qualitative analyses reveal that, on our test data, for most cases, incorporation of UMR graphs and demonstrations into the prompts enables heightened similarity with the reference English translation. Therefore, leveraging UMR in the prompt does indeed lead to heightened performance when translating from indigenous languages into English, while the greatest improvements are achieved by using related sentences as demonstrations; the combination of using both the demonstrations and the UMR in the prompt leads to the highest quality output in our experiments.

5 Conclusion

In this work, we begin to address one of the failings of GPT-based models: that of translation from extremely low-resource languages. We specifically examine the ability of a newly released Uniform Meaning Representation (UMR) dataset—containing sentences in Navajo, Arápaaho, and Kukama, their UMR graphs, and their parallel sentences in English—to improve GPT-4 performance when included in the prompt. We find that both the incorporation of UMR graphs of the source text and adaptively selected demonstrations lead to improved performance on low-resource machine translation via prompting, with a statistically significant increase resulting in the majority of our comparisons. This is a promising indication of the downstream utility of UMR for low-resource settings and a step forward towards effective trans-

lation from indigenous languages via prompting.

Limitations

We perform experimentation on three extremely low-resource indigenous languages. Future work could expand this evaluation to other languages as well, varying in their depth of resources, as additional UMR annotations are released. UMR annotation can be expensive and time-consuming, as it requires fluency in the language and annotator training, which is a barrier to seamlessly incorporating UMR into downstream applications.

Additionally, we perform translation in one direction, with the low-resource languages serving as the source and English serving as the target language. Performing translation from English into these low-resource languages would make for interesting future work, though it will require a human evaluation by speakers of the language.

Finally, randomness is inherent in the results generated from GPT-4. We attempt to curtail this effect by providing statistical analyses for our findings, but further rigor could be added by running these experiments additional times.

Subword models struggle with word learning, but surprisal hides it

Bastian Bunzeck and Sina Zarriß

Computational Linguistics, Department of Linguistics

Bielefeld University, Germany

Abstract

We study word learning in subword and character language models with the psycholinguistic lexical decision task. While subword LMs struggle to discern words and non-words with high accuracy, character LMs solve this task easily and consistently. Only when supplied with further contexts do subword LMs perform similarly to character models. Additionally, when looking at word-level and syntactic learning trajectories, we find that both processes are separable in character LMs. Word learning happens before syntactic learning, whereas both occur simultaneously in subword LMs. This raises questions about the adequacy of subword LMs for modeling language acquisition and positions character LMs as a viable alternative to study processes below the syntactic level.

1 Introduction

When humans acquire their first language(s), they *first* learn to recognize single words, mostly from short, fragmentary utterances (Cameron-Faulkner et al., 2003; Bunzeck and Diessel, 2024), *before* fully understanding the grammatical processes governing them (Tomasello, 1992; Behrens, 2021). This simple fact about language acquisition has received surprisingly little attention in the body of work that treats LMs as models of language learners (Warstadt and Bowman, 2022; Portelance and Jasbi, 2024). While word learning in children is comparatively well studied (Plunkett, 1997; Yu and Ballard, 2007; Waxman and Gelman, 2009; Bergelson and Swingley, 2012; Clark and Casillas, 2015; Frank et al., 2021), the implicit word learning processes in LMs are not. Current studies focus on syntax (Mueller et al., 2022; Choshen et al., 2022), or investigate word learning in close connection with syntax through surprisal (Chang and Bergen, 2022; Portelance et al., 2023; Shafiqabadi and Wisniewski, 2025; Ficarra et al., 2025). Architecture-wise, a key limitation to the precise study of word learning

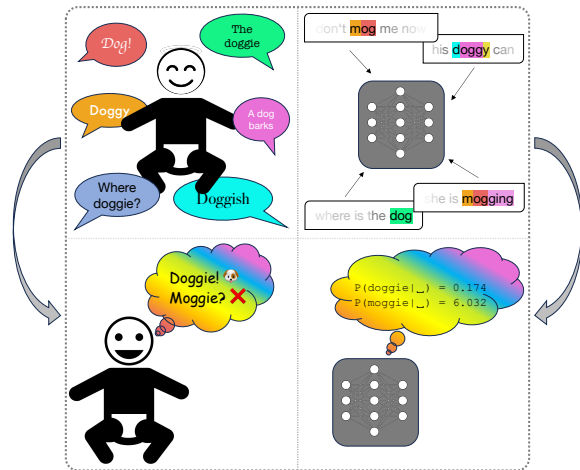

Figure 1: Illustration of word learning in human learners and transformer LLMs (top), and of our lexical decision test that probes discrimination of words from non-words (bottom). While human learners build up an mental lexicon from experience with language, artificial learners assign probabilities to strings based on their frequency.

is subword tokenization (e.g., BPE, Gage, 1994), which splits words into linguistically (Arnett and Bergen, 2025) and cognitively implausible units (Beinborn and Pinter, 2023).

To gauge word learning in a syntax-independent manner, we use the psycholinguistic lexical decision task (Meyer and Schvaneveldt, 1971; Le Godais et al., 2017), i.e., deciding which word in a given word/non-word pair is real. We find that models with character-level tokenization learn this task quickly and reliably. In contrast, subword LMs of all sizes perform significantly worse in a syntax-independent setting and only achieve comparable accuracy when stimuli are measured through surprisal, or “unexpectedness,” in linguistic context. By comparing word and syntactic learning (measured via BLiMP, Warstadt et al., 2020), we further find that character models quickly acquire word knowledge and only later develop syntactic knowledge. In subword models, word and syntax learning happen concurrently. This demonstrates how ele-

mentary modeling decisions, such as tokenization methods, significantly impact learning trajectories in LMs, a fact that warrants more scrutiny when using LMs as models of language acquisition.

2 Related work

Word learning in humans is a multifaceted phenomenon that involves different kinds of (extra)linguistic knowledge (Waxman and Gelman, 2009): while phoneticians are concerned with word recognition and sequence segmentation (Jusczyk, 1999), developmental psychologists frequently equate word learning with correct reference to real world objects (Stager and Werker, 1997; Ackermann et al., 2020). Psycholinguists usually focus on the mental lexicon and learning which words belong to it (Goldinger, 1996), whereas usage-based scholars take into account children’s productions and their ability to be competent language users, even with few words (Tomasello, 1992).

Although aspects like word recognition and sequence segmentation have been studied in LMs (e.g. Goriely and Buttery, 2025a), the most common approach to word learning in LMs is measuring the predictability of words via surprisal (negative log-probability, Hale, 2001). Chang and Bergen (2022) train LMs on book texts and wiki data. They define a surprisal threshold below which words are said to be learned and find that frequent function words are learned earliest. Here, the alignment between models and real learners is questionable: children first utter nouns and verbs (Tomasello, 2000), but also rely on function words for challenges like speech segmentation (Dye et al., 2019). Portelance et al. (2023) show that in LSTMs trained on child-directed speech, surprisal correlates with word-level age of acquisition. Chang et al. (2024) observe that learning curves for surprisal values are stable for frequent tokens, while infrequent tokens are “forgotten” again over pre-training. Shafiabadi and Wisniewski (2025) introduce anti-surprisal (in incorrect contexts) to track false usage, which also fluctuates over pre-training. These studies cast word learning as the ability to anticipate words’ expectedness in a given syntactic (and semantic) context. We note a certain conceptual leap to the original works on surprisal, where it is primarily viewed as an incremental measure of processing difficulty in syntactic comprehension (Levy, 2008; Demberg and Keller, 2009). A simple word like *dog* might be surprising and therefore hard to parse

in some contexts, but very expected in others, independently of being already learned on the pure word level. A further methodological drawback of surprisal as a measure of word learning is that it corresponds almost directly to the next-token prediction objective LMs are trained on. This contrasts with typical probing paradigms used in the domain of syntax, which implement the idea to “challenge” models in minimal pair set-ups that are not observed directly as string sequences in training, thereby testing abstracted, implicit linguistic knowledge rather than observed patterns in the data. In a similar vein, we want to probe the word knowledge of an LM at a fundamental level and beyond surface-level word sequences that LMs are known to excel in predicting. We want to know if the artificial learner knows that the word *doggie* exists in the English language, but *moggie* does not.

Lexical decision is widely used in human studies but remains an underexplored LM benchmark. Le Godais et al. (2017) show that character-based LSTMs achieve about 95% accuracy on such tasks. Lavechin et al. (2023) find that speech-based LMs need significantly more input to still perform poorly (56.8%) than phoneme-level LSTMs (75.4%) on a phonetic dataset. For the same data, Goriely et al. (2024) find that GPT-2-based subword BabyLMs achieve 70% accuracy and a comparable character models reach nearly 90%. Finally, for another lexical decision dataset, Bunzeck et al. (2025) report near-perfect accuracy for character-based grapheme Llama models, while phoneme models perform at 60–70%.

3 Experiments

Models We train triplets of increasingly larger Llama models (Touvron et al., 2023) with character/subword tokenization on the BabyLM 10M corpus (Choshen et al., 2024). Training details are found in Appendix A. As ablations, we test subword Pythias (Biderman et al., 2023) and character/subword GPT-2 models (Goriely et al., 2024).

Test data We follow the idea of forced-choice lexical decision (Baddeley et al., 1993), where participants must decide which is real: an existing word or a synthesized non-word. We use wuggy (Keuleers and Brysbaert, 2010) to generate minimal pairs of words/non-words that differ in one or two syllables, akin to syntactic minimal pair tests such as BLiMP. We derive 1,000 non-words (e.g. *mondning*) each from 1,000 high-frequency/low-

Table 1: Accuracy scores (in %) for (i) lexical decision, (ii) surprisal and (iii) anti-surprisal experiments

frequency words (e.g. *sending*), which preserve syllable-bigram frequencies and match their origin words in length (cf. Appendix B).

Lexical decision For a word/non-word pair $(w, *w)$, we measure $-\log(P(w|_))$ and $-\log(P(*w|_))$, i.e. how “surprised” a LM is by the word in the context of a prepended whitespace (and BOS token). If $-\log(P(w|_)) < -\log(P(*w|_))$, the LM’s lexical decision is correct. As autoregressive LMs are sequence prediction models, we need a preceding context for which we can calculate surprisal. A single whitespace is the most neutral starting token available (and for subword models also signals that the first subword is word-initial). For all experiments, we calculate the average surprisal over all tokens of a word (which, in some cases, is characterized by a mismatch in token numbers between words and non-words, cf. Appendix B) with minicons (Misra, 2022).

Surprisal To measure LMs’ knowledge of words presented in regular syntactic contexts, we calculate the surprisal of words and non-words $(w, *w)$ as $-\log(P(w_i|w_{n<i}))$, i.e. the degree to which the LM is “surprised” by the word in the context of plausible preceding tokens, including a BOS token. We create stimuli by sampling sentences that contain our target words from OpenSubtitles (Lison and Tiedemann, 2016) and substituting them with matching non-words for the false stimuli. If $-\log(P(w_i|w_{n<i})) < -\log(P(*w_i|w_{n<i}))$, the LM’s decision is correct.

Anti-surprisal Inspired by Shafiabadi and Wisniewski (2025), we include anti-surprisal, a mea-

sure of word surprisal on negative instances. We create negative samples by selecting sentences that our original words do not occur in, and then randomly¹ placing words/non-words into these sentences at the same index, where $index \geq 3$. By doing so, we compromise between lexical decision and surprisal measurement. There are two reasons to include this measure: i) surprisal in negative samples provides the model with word material as context, but without semantic or syntactic signals that could prime the model towards recognizing it; this allows us to assess whether the mere presence of other words in context makes it easier for the model to distinguish words from non-words, compared to our lexical decision set-up where only whitespace is given. In addition, ii) we want to see if the presence of an ill-fitting context actively deteriorates performance in the sense of a model suddenly preferring non-words over existing words. Again, if $-\log(P(w_i|w_{n<i})) < -\log(P(*w_i|w_{n<i}))$, the LM’s decision is correct.

Learning trajectories To assess when word learning happens in relation to syntax learning, we further evaluate intermediate checkpoints of our models on our word learning tests and BLiMP as a syntactic benchmark. In line with previous studies (Chang and Bergen, 2022; Viering and Loog, 2023), we space our checkpoints logarithmically – 10 for the first 10% of training, 9 more for the remaining 90%. For the Pythia models, we extract similarly spaced checkpoints (the GPT-2 models do not provide checkpoints, so we exclude them).

¹In line with Shafiabadi and Wisniewski (2025), we do not further characterize the resulting violations on a syntactic or semantic level.

4 Results

Lexical decision The lexical decision results (Table 1) show a strong contrast between character and subword models. Character models achieve near-perfect accuracy (97–99%) on high-frequency words, regardless of model size. The performance on low-frequency words steadily increases with model size and reaches a near-perfect level for our largest character Llama and the character GPT-2. On the other hand, all BPE models get surprisingly low scores on high-frequency words: The smallest Pythia model discriminates between word and non-words with an accuracy of only 67%, and the BPE GPT-2 performs below the chance baseline. Even the largest and best BPE model reaches only 87.8% on high-frequency words – almost 10% less than the smallest character model.

Scaling laws generally hold, with larger models outperforming smaller ones. Interestingly, for the BPE models, there is a consistent gap between high and low-frequency words that cannot be closed by larger models. Smaller character models also show a performance gap between high and low-frequency words, but it narrows considerably with larger models. These results point to substantial differences in how subword and character models learn words. Such a surprising lack of ability in distinguishing words from non-words (without context) is a blatant, hitherto overlooked gap in subword models.

Surprisal and anti-surprisal Results for the second experiment (Table 1) differ from those for lexical decision. In the surprisal setting, the difference between BPE and character models is less pronounced. On high-frequency data, nearly all models (except the smallest BPE Llama) achieve over 90% accuracy. Still, larger character models yield the best results. In the low-frequency data condition, the pattern is similar, though scores are generally lower. Very large BPE models outperform our Llamas there, but the character GPT-2 remains superior. This may be attributed to the limited lexical exposure of our Llamas, trained on only 10M tokens. In the anti-surprisal setting, character models again drastically outperform BPE models and achieve nearly perfect scores on high-frequency data, while BPE models only reach 70–80% accuracy. This setting is the only one where Pythia models get better scores on low-frequency data, with a gap of 6–8%, which increases with model size (not the case for BPE Llamas or character models). This contrast between surprisal and antisurprisal might

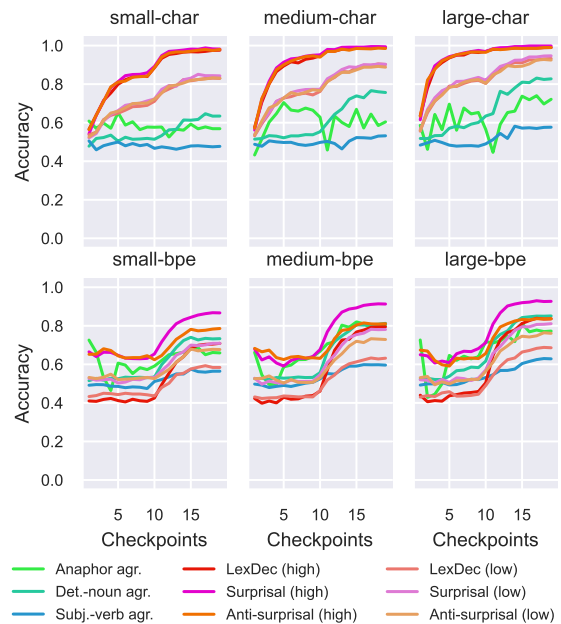

Figure 2: Selected lexical and syntactic learning curves

be an indicator of the entanglement of word learning and syntactic learning in subword models. It is plausible that for high-frequency words, the BPE models have strong expectations about which word should come next in a certain context, and because this expectation is not matched by the real (but ill-fitting) word, a made-up non-word is preferred. We argue that this should still not be the case for an ideal language model – if a model is indeed well-tuned, it should assign a higher probability to an ill-fitting but existing word which is still in distribution, than to a completely ill-fitting string that is out-of-distribution. In any case, BPE models catch up to character models if (and *only* if) provided with additional syntactic/semantic context information. While random context somewhat aids BPE models, a substantial gap remains between the largest BPE models and the character models, where performance remains excellent, even in the presence of implausible contexts.

Learning trajectories Figure 2 displays learning curves for syntactic agreement phenomena, lexical decision, and both surprisal conditions across the 19 saved checkpoints (complete curves reproduced in Appendix C). The first 10 checkpoints correspond to the first 10% of pretraining, the remaining 9 checkpoints represent 10% of training steps over the remaining 90% of pretraining. For character models, the high-frequency, low-frequency, and syntactic curves are clearly separated. On high-frequency data, word learning is rapid and follows power-law curves; the low-frequency scores im-

prove a little later and at a lower rate, but with the same trajectory. Syntactic phenomena improve later, mostly in s-shaped curves (e.g., det.-noun agreement), or are not learned at all in small models (subj.-verb agreement). In contrast, the syntactic and lexical curves for BPE models form sheaves of s-shaped trajectories. There is *no* principal difference in learning dynamics between the syntactic and the word level, improvements² occur simultaneously. This further confirms the results of our previous experiments: in BPE models, word learning is dependent on syntax learning, and words cannot be recognized reliably outside of plausible contexts. Additionally, these different levels of learning cannot be disentangled in BPE models, whereas in character models, syntactic learning *follows* word learning.³

5 Discussion

In contrast to previous work, this study set out to explore when (and if) LMs learn what valid words *are*, and not how LMs learn when words are validly *used*. How should these results now be interpreted in the light of language acquisition and the use of BabyLMs to model corresponding processes? In reality, words are not learned in isolation, but from usage. Yet, words have been widely shown to be represented as solid “standalone” units in the mental lexicon, and to be units that human learners acquire early on (cf. Waxman and Gelman, 2009, also Montag et al., 2018). Usage-based approaches have tested aspects of word learning independently from syntax (mostly in object naming tasks, cf. Tomasello and Todd, 1983) and relate it to pragmatic aspects of communication. For example, children only react to words they know and ignore similar-sounding words. They even struggle with learning words that are phonetically extremely similar (like our stimuli), and only later gain this capacity (Stager and Werker, 1997). Similarly, in production, the earliest words come in isolation, slowly emerge into pivot schemas and holophrases (Tomasello, 1992, 2003), and only then finally turn into complex sentences. Of course, syntax also aids in discovering aspects of “wordiness”, like SV(X)-sentences offering cues for agent-patient relationships. It would be very interesting to further disentangle these levels of word knowledge

²We calculate Spearman-rank correlation between ordered accuracies for word-level tasks and BLiMP in Appendix D.

³Interestingly, the learning process is not finished when accuracy curves stabilize, cf. Appendix F.

in a follow-up study, but our current study is not concerned with the “you shall know a word by the company it keeps”-level of word knowledge, but rather with the “what do valid words of the language look like”-level, which can be assessed via lexical decision. As such, we believe that the separated learning curves of our character-level models represent more human-like learning than the highly correlated curves found in the subword models, but in reality, an overlap between them is definitely expected.

Reasons for the tremendous performance differences between subword and character models remain open to further inquiry. One plausible explanation is that character models have much more context available to calculate meaningful sequence probabilities, as words are split into many more tokens. While this is true, it is also exactly the point that we are stressing here: it is hard to imagine that arbitrary subword units lead to human-like, plausible word-level representations (like in exemplar models of lexical storage, cf. Bybee, 2010), whereas character models might offer a more justified level of granularity (and, e.g., better fit reading times, cf. Oh et al., 2021). Our findings also align with results on LMs’ sensitivity to character-level perturbations (Moradi and Samwald, 2021; Zhu et al., 2024) and their inability to solve character-level tasks, like counting occurrences of the letter *r* in the word *strawberry* (Zhang and He, 2024; Shin and Kaneko, 2024; Cosma et al., 2025).

6 Conclusion

We have shown that the lexical decision approach to the study of word learning in LMs complements surprisal-based approaches and reveals difficulties that surprisal hides: subword LMs struggle with lexical decision, whereas character models master this task with ease. Additionally, in subword LMs, lexical and syntactic learning are inseparable, whereas word learning in character models precedes syntactic learning; the processes are related, yet separable. It is plausible that the *a priori* token splitting in subword models preempts a word discovery process in them, whereas character models first have to pass through this developmental stage, possibly in a somewhat more human-like manner. In any case, as we have shown, decisions about the representational levels of LMs tremendously influence their learning pathways on the different levels of linguistic analysis.

Limitations

The generalizability of our findings is constrained by a few factors. The present study has only focused on the English language, but it is plausible that other languages with different writing systems or graphematic and phonotactic rule systems exhibit different patterns under different tokenization schemes. Here, phonetic transcriptions might provide a viable alternative, but real narrow transcriptions that accurately capture the whole breadth of human input are scarce and extremely costly and laborious to manually produce (although novel datasets like [Goriely and Buttery, 2025b](#) provide an alternative through automatic transcription). Besides, for the character LMs, we focus only on small models, as very large models with such tokenization, especially ones providing intermediate checkpoints, are nonexistent at this moment. It would still be interesting to see how they compare to subword models in a setting where parameter size and training data are greatly increased.

As already mentioned in Section 2, from a developmental perspective, word learning in humans also includes other processes than statistical pattern recognition from the input: semantic aspects and real-world reference are equally important, as are multimodal input and communicative intent. The ongoing form-vs.-function debate on LMs ([Machowald et al., 2024](#)) has begun to consider these aspects, and further studies should aim at incorporating them; for example, the object naming paradigm used in many developmental psychology studies would lend itself naturally to the study of multimodal models.

Finally, we also want to mention that there are attempts to add more linguistic theory to tokenizers. Looking into different tokenizers that, for example, try to be more morphology-aware ([Hofmann et al., 2022](#); [Bauwens and Delobelle, 2024](#); [Yehezkel and Pinter, 2023](#); [Uzan et al., 2024](#)) or implement other optimization tricks ([Schmidt et al., 2024](#)) could yield even more fine-grained points of comparison, but for the present study and its limited scope we focused on the most popular tokenization scheme (BPE) and the most linguistically minimalist alternative (characters).

Ethical considerations

Due to the nature of this work, no concrete ethical aspects or repercussions need to be discussed. However, we would like to stress that, of course,

BabyLMs not supposed to simulate real babies, but only abstractions of a very specific part of their learning capacity (frequency-driven, domain-general learning mechanisms such as entrenchment or resonance), and therefore all claims about their implications for language development in the real world should be interpreted in this light.

Acknowledgments

We would like to thank the three anonymous ARR reviewers for their insightful comments and the highly valuable discussions throughout the rebuttal period.

A Model hyperparameters and training details

We use the transformers library (Wolf et al., 2020) to train our models. The corresponding hyperparameters are listed in Table 2. We opted for very small LMs and little training data because the BabyLM paradigm has consolidated itself as a well-established method of developmentally plausible language modeling (Warstadt et al., 2023; Choshen et al., 2024). Also, we noticed the word learning to occur quite rapidly in our models, so we argue that small LMs offer more fine-grained opportunities for investigating these processes – in larger LMs, even a singular training step can already influence performance on such a brittle task like lexical decision tremendously.

The subword models feature a considerably higher number of parameters, as the embedding layer of transformer language models accounts for a quite large share of overall model parameters. In light of our vastly different vocabulary sizes (102 for character models, 8,002 for subword models), these differences are not surprising. The subword tokenizer is a regular BPE tokenizer self-trained with the tokenizers library and contains 8,000 subword tokens, a beginning-of-sequence token and a combined end-of-sequence/padding token. The character tokenizer contains these two special tokens and all printable ASCII characters, which are sufficient to represent all graphemes of the English language.

Our models were trained on a Apple M2 Pro processor with the MPS backend. For the small models, training lasted approx. 20min, for the medium-sized models it took approx. 1h and for the largest models approx. 10h (no principal differences between character and subword models). We share our models with their checkpoints on the HuggingFace hub.⁴

Loss curves for all models can be found in Figure 3. For the test loss, we calculated the perplexity over a held-out portion of our training corpus that is comparable in composition to the training data. We find no principal differences in loss development, although the character models converge faster. Larger models also tend to converge faster and generally reach smaller absolute loss values. As the similar train and test loss curves indicate, all Llama models succeed in optimizing for their next-

token prediction objective. However, it remains open to further inquiry how much these scores are constrained by the comparatively small capacity of our BabyLMs, and whether larger models would enhance performance further.

B Data creation and tokenization analysis

Data creation Word frequency influences lexical decision performance greatly (McClelland and Rumelhart, 1981; Allen et al., 2005). To incorporate this effect into our study, we create two distinct data sets from words included in wuggy: (i) high-frequency stimuli with a frequency score over 7.0 (occurrences per 1M words in BNC, COCA and other English corpora, as reported in CELEX, Baayen et al., 1995) and (ii) low-frequency stimuli with a frequency score over 0.0 but below 0.7 (so at least one order of magnitude lower). We opted to rely on the CELEX frequency scores because we compare models trained on different corpora – our models are trained on the 10M BabyLM corpus, the models by Goriely et al. (2024) are trained on the 100M BabyLM corpus and the Pythia models are trained on The Pile (Gao et al., 2020). As such, frequency scores from these corpora would taint analyses of other models and hinder comparability. For the contextualised stimuli, we sample sentences from the OpenSubtitles (Lison and Tiedemann, 2016) portion of the BabyLM 2024 corpus (Choshen et al., 2024). Both Wuggy and BabyLM data are licensed under the MIT license⁵, therefore we release our own stimuli artifacts on HuggingFace⁶ under the same license. The data contain no information that names or uniquely identifies individual people or offensive content, and are commonly used in computational linguistics.

Analysis of tokenization To further assess the influence that these frequency scores have on the resulting tokenization for our own models, we offer a brief analysis: Figure 4 shows a pairplot between three numerical variables – (i) the number of tokens that our original words are split into, (ii) the number of tokens that the derived non-word are split into and (iii) the corresponding frequency score from CELEX. While the three plots on the diagonal axis show a layered kernel density estimate (KDE) for

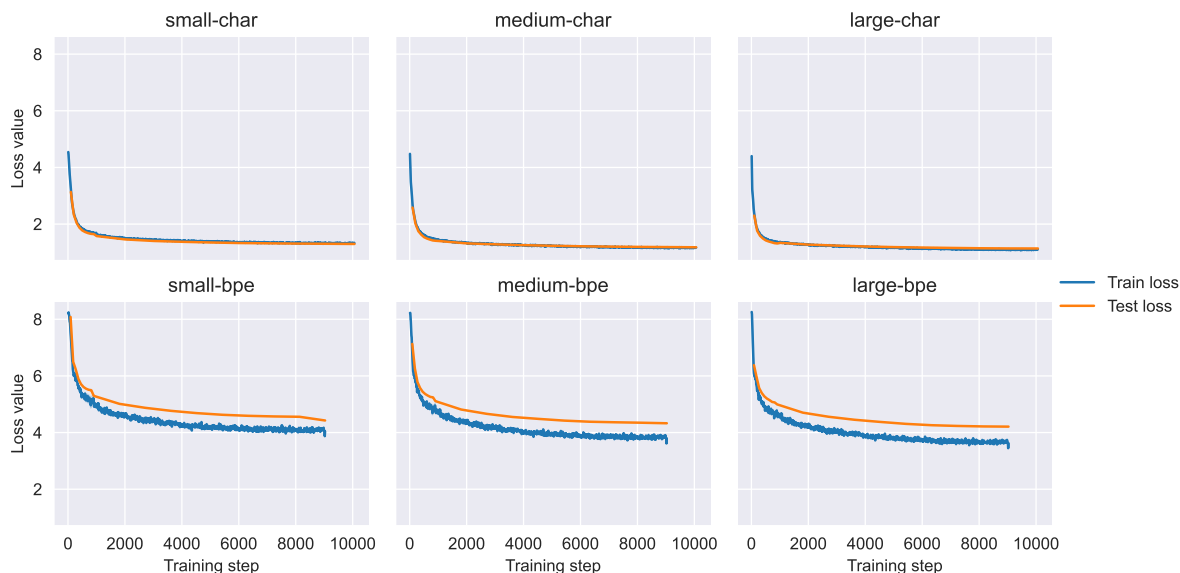

Figure 3: Loss curves for our self-trained Llama models

each individual variable, the other plots are scatterplots which visualize the relationship between the variables. The data points are colored for their tokenization scheme.

In the upper left and lower right plot we can see that both real and non-words are split similarly in the two distinct tokenization schemes. Words split by the BPE tokenizer tend to have fewer tokens, mostly between one and six. For the character-based tokenizer, a normal distribution is visible, with its peak at six tokens.

The upper right and lower left scatter plots show the relationship between tokenization for real and non-words. The character-level tokenization exhibits perfect alignment between both kinds of stimuli, they are always split into the exact same number of tokens. Subword tokenization is slightly skewed towards the non-word tokens. This means that non-words are more often split into more tokens than real words, although the reverse case is not completely infrequent.

C Full learning curves for BLiMP and word learning

Figure 5 shows the full learning curves of all phenomena included in BLiMP (individual syntactic paradigms belonging to one phenomenon are displayed in the same sub-figure) as well as our own lexical benchmarks (all displayed in individual sub-figures), for our six self-trained models and the six Pythia models that we compare them to. We fit a fifth-order polynomial curve to the individual data points and display it on a logarithmic scale.

It should be noted that we plot the number of the checkpoint on the x-scale. However, the individual amounts of actual textual data seen between these checkpoints differs vastly between our self-trained models (10M lexical tokens) and the Pythia models (825GB of textual data; as the dataset has since been taken down, no lexical token counts are possible anymore).

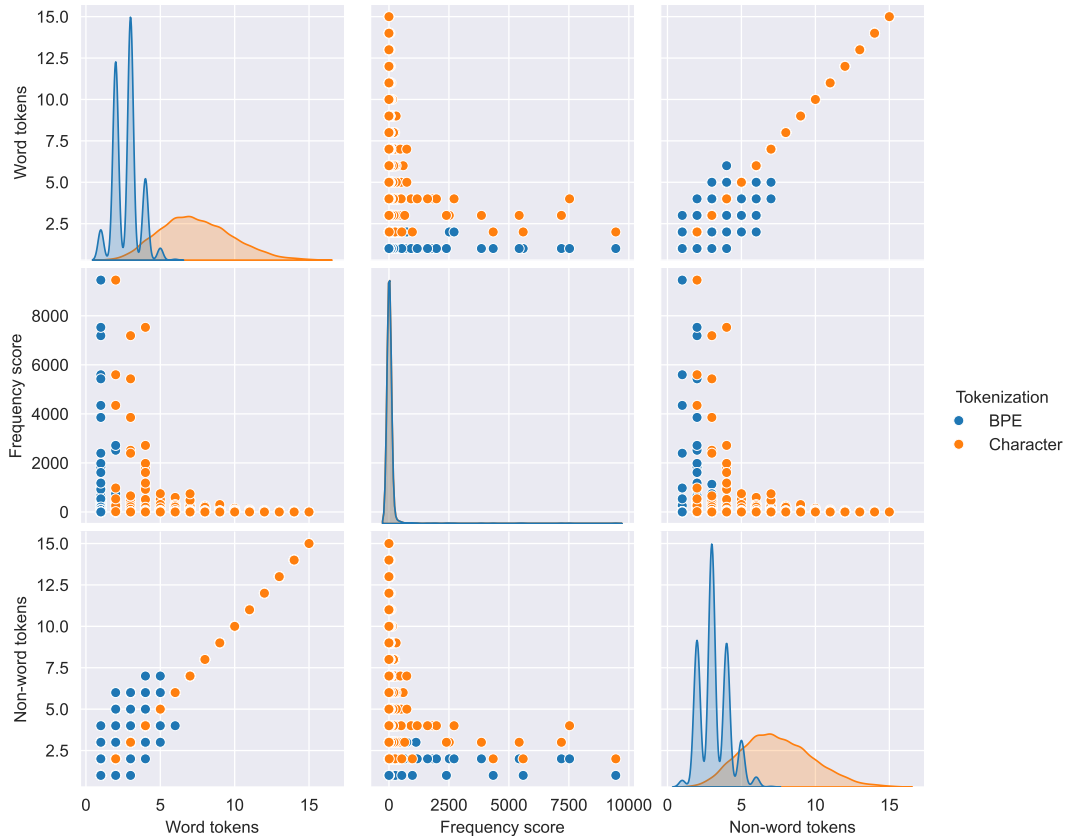

Figure 4: Pairplot displaying (i) number of tokens of words, (ii) frequency scores from CELEX (Baayen et al., 1995) and (iii) number of tokens of non-words (for BPE and character tokenization)

D Correlations between word learning and syntactic learning

As an additional measure of commonalities between word learning and syntactic learning, we calculate Spearman-rank correlation scores between ordered accuracy scores for our lexical tasks and BLiMP paradigms. Table 3 shows the underlying numerical values for the correlation heatmap provided in Figure 6 (please note that the heatmap is rotated in comparison to the table). All scores are statistically significant ($p < 0.05$). Due to the similar learning curves found in Figure 2, we average accuracy scores over all lexical phenomena (lexical decision and both surprisal settings), and then calculate correlations between them (both high and low frequency) and the coarse-grained BLiMP phenomena. For BPE models, lexical performance is highly correlated with more than half of the BLiMP phenomena. The character models show much weaker correlation with syntactic learning. This further confirms our findings about the strong entanglement of lexical and syntactic learning in subword models and their weaker ties

in character models.

E Final BLiMP scores for all models

We reproduce the final syntactic evaluation scores for all models that we incorporated in our lexical analyses in Table 4. Generally, scores improve with larger models and with more training data. Most strikingly, subword models are consistently superior to comparable character models trained on the same amount of data. These differences, however, are most pronounced for the small models trained on very little data, like our Llama models trained on 10M tokens (7% for smallest models, 2% for largest models). For the comparable GPT-2 models trained on 100M tokens, the gap becomes much smaller (0.4%).

F Development of word/non-word differences

In Figure 7, we plot the average difference between word and non-word negative log-probability values across training, for both high-frequency and low-frequency data. Positive scores indicate preference

Figure 5: Learning curves for all paradigms in BLiMP and high/low frequency lexical decision data, separated for models (rows) and phenomenon sets (columns)

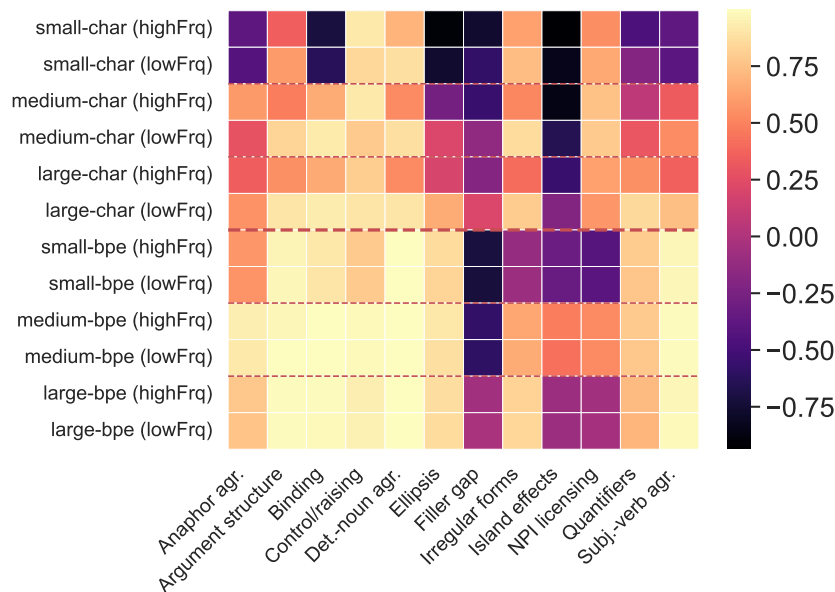

Figure 6: Correlation heatmap

for real words. For the character models, the differences are generally less pronounced and get most extreme at the end of pre-training (where accuracy scores do not change anymore), especially for the lexical decision data, which is already consistent at very early training stages. For the BPE models,

we see that at the beginning they actually prefer non-words in the lexical decision task. Only after the first 10% of training they *begin* to discern words and non-words. While overall tendencies remain the same for both frequency conditions, the absolute differences are generally lower and the

LLM as Entity Disambiguator for Biomedical Entity-Linking

Christophe Ye Cassie S. Mitchell

Georgia Institute of Technology

cye73@gatech.edu,
cassie.mitchell@bme.gatech.edu

Abstract

Entity linking involves normalizing a mention in medical text to a unique identifier in a knowledge base, such as UMLS or MeSH. Most entity linkers follow a two-stage process: first, a candidate generation step selects high-quality candidates, and then a named entity disambiguation phase determines the best candidate for final linking. This study demonstrates that leveraging a large language model (LLM) as an entity disambiguator significantly enhances entity linking models' accuracy and recall. Specifically, the LLM disambiguator achieves remarkable improvements when applied to alias-matching entity linking methods. Without any fine-tuning, our approach establishes a new state-of-the-art (SOTA), surpassing previous methods on multiple prevalent biomedical datasets by up to 16 points in accuracy. We released our code on GitHub at https://github.com/ChristopheYe/llm_disamb.

1 Introduction

The biomedical domain is an information-rich and highly specialized field, characterized by vast amounts of domain-specific knowledge and intricate terminologies. Unlike named entity recognition (NER), which focuses on identifying entity mentions in text, biomedical entity linking (EL) goes a step further by mapping these mentions to unique identifiers in a structured knowledge base (KB). This distinction is critical, as biomedical texts often contain extensive synonyms, polysemy, and abbreviations, where the same concept may be expressed in multiple ways, or a single term may refer to different entities depending on context. Effective EL is essential for resolving these ambiguities, enabling more precise information retrieval (Lee et al., 2016), improving knowledge discovery (Wang et al., 2018), and facilitating downstream tasks such as automated data annotation and curation. By strengthening EL systems, researchers can

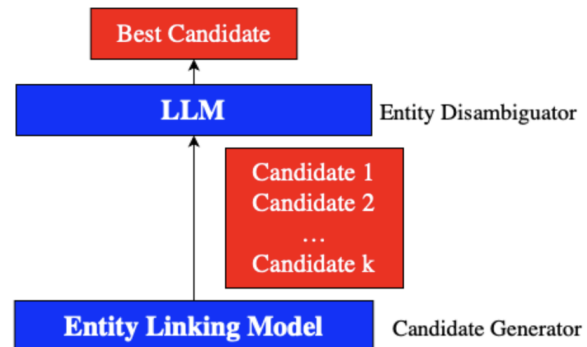

Figure 1: LLM as Entity Disambiguator.

unlock more efficient data integration, enhance text mining applications, and accelerate advancements in biomedical research and healthcare.

Various methods have been applied to biomedical EL. Alias-matching approaches align mentions with entities based on lexicographical properties. This includes models like SciSpacy (Neumann et al., 2019), MetaMap (Aronson and Lang, 2010) or SapBERT (Liu et al., 2021). Contextualized EL learns vector representations (Vaswani et al., 2023) of entities by leveraging the contextual information from the mention and try to match it to an entity description. This includes models like KRISSBERT (Zhang et al., 2022), ClusterEL (Angell et al., 2021) or ArboEL (Agarwal et al., 2022). These representations are typically employed to generate a list of high-quality candidates for a mention, which are then refined using a re-ranker (Wu et al., 2020).

Large language models (LLMs) have recently shown promise in various biomedical Natural Language Processing (NLP) (Tian et al., 2023) applications. However, for information extraction tasks like entity recognition, their performance still lags significantly behind the previously cited models (Jahan et al., 2024).

Prior work has leveraged LLMs as external tools

to enhance data quality for improved entity normalization. For instance, [Borchert et al. \(2024\)](#) simplifies entity mentions by rephrasing long or complex terms into more general or concise forms before candidate generation, while [Chen](#) employs LLMs to generate high-quality augmented data, improving the performance of traditional biomedical entity linking models. [Garda and Leser \(2024\)](#) integrates LLM-powered homonym disambiguation, which resolves ambiguous entity names by appending clarifying descriptors, and candidate sharing, which enhances training by leveraging contextually related mentions within the same document. However, no prior work has fully integrated LLMs as a core component of the entity linking pipeline itself.

This is primarily due to a lack of domain-specific knowledge and tendencies toward hallucination. However, with sufficient information, LLMs could potentially leverage their general understanding of text to perform the normalization. In this work, we explore the use of LLMs for biomedical entity disambiguation task.

This paper contributes the following :

- LLM is introduced as a **entity disambiguator** for named entity disambiguation, building on top of the existing methods for candidate generation.
- LLM entity disambiguation achieved consistent improvements for alias-matching EL models. It outperformed previous SOTA for several datasets with a remarkable gain of 16 points in GNormPlus.
- The method can be seamlessly integrated into existing EL models without requiring additional training.

2 Methodology

2.1 Entity Linking model for candidate generation

The first step of our approach involves generating candidates using EL models. While multiple models are available, we will concentrate on the top-performing model in each category: SapBERT for alias-matching EL and ArboEL for contextualized EL.

SapBERT ([Liu et al., 2021](#)) selects top candidates by computing cosine similarity between the

test mention and all aliases in the database, using enhanced embedding representations. ArboEL ([Agarwal et al., 2022](#)) first trains a bi-encoder to improve embedding representations using mention-mention coreference signals. This is followed by a cross-encoder training that scores each candidate by concatenating the test mention with the candidate’s context. The top-k candidates are then selected based on these scores.

2.2 Disambiguation step with LLMs

2.2.1 The mention

To fully leverage the capabilities of the LLM, it’s crucial to provide the mention along with its surrounding context, ensuring the model has access to the maximum amount of relevant information. We formatted the mention for the LLM as follows:

$$c_{left} [ENTITY START] m [ENTITY END] c_{right}$$

where c_{left} and c_{right} represent the left and right contexts of the mention m .

2.2.2 The entity

Similarly, to ensure maximum reliability, we provided the entity along with its relevant data to the LLM in the following dictionary format:

```

1 entity_data = {
2     "cui": entity.cui,
3     "name": entity.name,
4     "types": entity.types,
5     "aliases": entity.aliases,
6     "definition": entity.definition,
7 }
```

- cui: Concept Unique Identifier
- name: Entity name
- types: Entity Types
- aliases: Entity aliases
- definition: Entity definition

2.2.3 In-context Learning

In-context learning ([Dong et al., 2024](#)) is an approach in natural language processing (NLP) where LLMs make predictions based on contexts enriched with a few examples. It has been shown that incorporating such examples in the prompt can enhance model performance. To optimize the selection of examples, we employed a RAG-like system ([Lewis et al., 2021](#)) that retrieves the most relevant examples from the training set to include in the prompt.

Specifically, the LLM predicts the response to the query x by conditioning on k training examples $\{(x_i, y_i)\}_{i=1}^k$ in the prompt :

$$\hat{y} = \text{LLM}(x|x_1, y_1, \dots, x_k, y_k)$$

To find the most relevant examples for a given query, we first embed all mentions along with their surrounding context from the training set using a sentence embedding model (Gao et al., 2022). We then create an index using Faiss (Douze et al., 2024) for faster and more efficient retrieval. During inference, we embed the query (the mention along with its context) and retrieve the most similar mentions from the corpus for the LLM to process.

3 Results

The performance of LLMs as entity disambiguators was evaluated across multiple biomedical datasets. Prior work has typically relied on supervised learning using BERT-base models for entity linking tasks. In a comprehensive evaluation, Kartchner et al. (2023) identified SapBERT as the most effective alias-matching model, and ArboEL as the strongest contextualized model. These results were also later confirmed by Bathala et al. (2025) in their benchmarking package. Based on these evidences, our assessment is conducted by applying LLMs to these two leading approaches.

Performance was evaluated using five different models : Meta-Llama-3.1-8B-Instruct (Touvron et al., 2023), Mistral-Nemo-Instruct-2407 (Jiang et al., 2024), Qwen2.5-7B-Instruct (Bai et al., 2023), GPT-4o-mini and GPT-4o (team, 2024).

All LLMs were prompted using a greedy-decoding strategy; temperature was set to 0.

A comprehensive description of the experimental setup is provided in Appendix A.1 to ensure reproducibility of the experiments. This includes the exact details of the prompt used to obtain the correct CUI and the top-k candidates (Appendix A.1.1), along with the analysis of the impact of the number of candidates (Appendix A.1.3) and number of examples (Appendix A.1.4) to include in the prompt.

3.1 Datasets

The experiments were carried out on five prevalent biomedical datasets coming from BigBio (Fries et al., 2022) : NCBI-Disease (Dogan et al., 2014), GNormPlus (Wei et al., 2015), NLM Chem (Dogan et al., 2021a), NLM Gene (Dogan et al., 2021b), and Medmentions-ST21PV (Mohan and Li, 2019).

Details on the datasets are provided in Table 1.

The corresponding ontologies are MEDIC (Davis et al., 2019), Entrez (Maglott et al., 2005),

Dataset	Train Mentions	Test Mentions	Ontology
NCBI-Disease	6,881	960	MEDIC
GNormPlus	6,252	3,223	Entrez
NLM-Chem	37,999	11,660	MeSH
NLM-Gene	15,553	2,729	Entrez
MM-ST21PV	203,282	40,143	UMLS

Table 1: Datasets used for evaluation.

MeSH (Lipscomb, 2000), and UMLS (Bodenreider, 2004).

3.2 With Alias-Matching EL

The impact of LLMs as entity disambiguators is illustrated for alias-matching EL methods using SapBERT. All results are detailed in Table 2.

When the base model performs well, with accuracy and recall@20 being close, the LLM’s impact is minimal. For instance, on the NCBI-Disease dataset, accuracy improves slightly, while recall@5 remains unchanged.

However, when the initial model struggles, integrating an LLM can significantly boost performance. For instance, SapBERT fails to effectively differentiate aliases in gene-centric datasets like GNormPlus and NLM-Gene, as indicated by the large gap between its accuracy and recall@20. Using GPT-4o as a disambiguator improved SapBERT’s accuracy on GNormPlus from 19.1% to 74.8% and recall@5 from 56.6% to 83.8%, surpassing the previous SOTA by 16% in accuracy and 19% in recall@5.

SapBERT struggles to distinguish between multiple gene entities sharing the same alias. However, since candidates with the same alias are ranked closely, the correct entity often appears shortly after in the list. By leveraging contextual information, the LLM can distinguish the correct entity more efficiently addressing this limitation.

GPT-4o is the top-performing disambiguator for alias matching EL models, outperforming smaller 7B-12B models. However, it is noteworthy that these "small" open-source LLMs still provide significant improvements and even surpass the previous state-of-the-art (SOTA) in many scenarios.

The reported SOTA numbers are based on the results we obtained from re-running the models ourselves using the BioEL package with default parameters (Bathala et al., 2025), not the ones originally reported by (Kartchner et al., 2023).

Figure 2: Embedding Space of Candidates from Alias Matching (left) and Contextualized EL model (right)

3.3 With Contextualized EL

The impact of LLMs as entity disambiguators was demonstrated for contextualized EL methods using ArboEL. The results are detailed in Table 3.

When applied to contextualized EL, the results show minimal improvement for the best model and even degrade for others. This happens because the base model already handles mentions effectively when the correct CUIs are included in the candidate list, as it is also considering the contextual information of the mention.

3.4 Performance disparity

The performance gap between contextualized and alias-matching EL models stems from their differing approaches. Alias-matching methods often achieve higher recall at large recall levels by capturing a broad range of potential matches based on surface similarities (e.g., aliases or synonyms), without filtering out even when the candidates are totally different.

Context-aware models, while generally more precise, tend to offer less improvement in recall@k at larger k values. These models are designed to sharply distinguish between correct and incorrect entities, creating a large gap between top-ranked candidates and those deemed contextually different. While this helps in pinpointing the correct entity, it often discards candidates that deviate from the expected answer. As a result, if the correct answer is not initially ranked high due to contextual ambiguity, it may be pushed far down the ranking for appearing too dissimilar.

Consequently, context-aware models may miss the correct candidate in large pools, where alias-matching methods would still retain it, even if ranked lower.

Figure 2 provides an example of such scenario :

while alias-matching EL produced a diverse set of top-ranked candidates, (e.g., "Pregnancy in Diabetes," "Glycosuria," "Diabetes Insipidus") contextualized EL generated candidates that were more closely related and grouped together in the rankings. (e.g., "Diabetes Insipidus," "Diabetes Insipidus, Neurogenic," "Diabetes Insipidus, Nephrogenic")

Further results on error analysis, performance disparity in low-data slices and data leakage risks are available in Appendix A.2

4 Conclusion and Future Work

Entity linking is crucial in knowledge-driven NLP, particularly in scientific and biomedical domains, where accurately mapping textual mentions to specific concepts is essential for extracting meaningful insights and advancing research. This study introduced a novel approach that utilized LLMs as entity disambiguators for biomedical EL. The proposed methodology demonstrated a significant performance improvement when integrated with an alias-matching-based EL model, as evidenced by experiments conducted on five standard biomedical EL datasets. Notably, this approach requires no fine-tuning, making it highly adaptable as LLMs continue to evolve in robustness and scalability. A promising direction for future work is the development of a retrieval mechanism to identify additional high-quality candidates when the correct entity is absent from the initial candidate set due to omissions by the underlying EL model.

5 Limitations

This method has demonstrated substantial effectiveness in enhancing the performance of alias-matching EL models. However, its application to contextualized EL models can occasionally result in performance degradation, leading to inconsistencies in outcomes. Furthermore, leveraging LLMs for entity disambiguation introduces a significant trade-off in inference time, which poses potential scalability challenges for datasets containing millions of mentions. The approach is also highly dependent on the candidate generation step; if the correct Concept Unique Identifier (CUI) is absent from the candidate set, there is no mechanism to retrieve it. Additionally, the use of proprietary LLMs can be prohibitively expensive. Finally, LLMs remain susceptible to errors, a critical concern in

biomedical applications where precision is essential and any degree of randomness is unacceptable.

A Appendix

The appendix is organized into three parts:

- The detailed method implementation is presented in Appendix A.1.
- Additional results on the evaluation are presented in Appendix A.2.
- Discussion on LLM for candidate generation A.3

A.1 Detailed Experimental Setup

This section outlines the experimental setup.

A.1.1 Prompts

Figures 3 and 4 illustrate the prompts used for the accuracy and recall tasks, respectively.

Elements enclosed in *{italics}* represent arguments passed to the prompt, which are detailed below:

- *number_candidates*: The number of candidates provided to the model.
- *mention*: The specific mention that needs to be correctly linked.
- *context*: The surrounding context in which the mention appears.
- *candidates*: The relevant data for all candidates provided to the model.
- *example_answers*: An example of valid answers.

A.1.2 Context window size

A 64-word context window was used, evenly split around each mention. This setup offered the best balance between performance and runtime.

A.1.3 Impact of the number of candidates in the prompt

We evaluated candidate set sizes ranging from 5 to 64 and found that using 10 to 20 candidates yielded the best performance. A set of only 5 candidates resulted in the exclusion of many correct options, whereas increasing the number to 50 introduced an excess of information, reducing precision as the LLM struggled to focus on relevant details, consistent with findings by (Liu et al., 2023).

Ultimately, the effectiveness of candidate selection depends on the ranking of correct entities. If a

substantial portion of correct Concept Unique Identifiers (CUIs) are positioned beyond the top 20, increasing the number of candidates can enhance performance. However, in most cases—particularly for contextualized entity linking (EL) models—the proportion of correct candidates ranked below the top 20 is relatively low.

Figure 6 and 7 show the accuracy versus runtime for varying numbers of candidates in the prompt on GNormPlus and NLM-Gene dataset.

In the majority of configurations (dataset - CG Model - LLM), using 10 and 20 candidates yields the best performance.

A.1.4 Impact of the number of examples in the prompt

We also experimented with different numbers of examples in the prompt to evaluate their impact on performance.

Figure 8 and 9 presents the accuracy versus running time for varying numbers of examples k in the prompt on NCBI-Disease and GNormPlus dataset.

The optimal number of examples to include in the prompt varies depending on the configuration (dataset - CG Model - LLM). For instance, GNormPlus performance consistently improved as k increased, while NCBI-Disease performed best with $k=3$.

A.1.5 Use of separate prompts for accuracy and recall

The reported results in Table 2 and 3 for accuracy (recall@1) were all calculated independently, meaning the LLM was asked to return only the single most likely CUI for each query. Indeed, we noticed that the score for accuracy was higher when the LLM is tasked with retrieving a single candidate compared to ranking several candidates.

A.2 Additional results

This section presents additional results, including error analysis, data leakage risk assessment, a study of prompting strategies, statistical significance testing, and runtime evaluation.

A.2.1 Error Analysis

Table 4 presents the distribution of errors between Candidate Generation (CG) and Named Entity Disambiguation (NED) for each model. CG failure is defined as the absence of the correct CUI within the top- k generated candidates (in this case, $k = 20$). NED failure is defined as an instance where the

System Instruction
 You are a professional data annotator and curator.
 Your task is to identify the correct entity for a given mention based on the provided context and the descriptions of $\{number_candidates\}$ candidate entities.

User
 Here are a few examples:

Return the results in JSON format as a list of CUIs ["CUI1", "CUI2", "CUI3", ...].
 For instance $\{example_answers\}$ are valid answers.

Figure 4: Prompt for the recall task, outputting only the best candidates CUI.

	NCBI-Disease		GNormPlus		NLM-Chem		NLM-Gene		MM-ST21PV	
	CG	ED	CG	ED	CG	NED	CG	ED	CG	ED
SapBERT	0.307	0.693	0.167	0.833	0.451	0.549	0.186	0.814	0.508	0.492
ArboEL	0.695	0.305	0.823	0.177	0.654	0.345	0.503	0.497	0.598	0.402

Table 4: Failure stage of the entity linking models.

top-ranked candidate is incorrect, when the correct CUI is indeed present in the list of plausible candidates. SapBERT is clearly better at identifying the correct alias than finding the correct candidate, as evidenced by its lower CG error and higher NED error. In this scenario, leveraging an LLM for the disambiguation step can significantly enhance performance, as demonstrated by the big improvement in gene-centric datasets.

A performance plot in low-data slices (training overlap, long-tail entities, no alias match, few aliases, zero-shot) before and after LLM disambiguation for NCBI-Disease, GNormPlus, NLM-Chem and NLM-Gene is shown in Figure 10.

ArboEL is observed to be more sensitive to training overlap and long-tail entities compared to Sap-

BERT. ArboEL benefits greatly from prior exposure to similar examples in the training set across all datasets, while its performance deteriorates in zero-shot settings where either mentions or entities have not been encountered before (e.g., NLM-Chem, NCBI-Disease, NLM-Gene). When the mention does not match any alias of the correct CUI (no alias match), performance degradation is observed only in NCBI-Disease and NLM-Chem. Similarly, when the correct CUI has fewer than five aliases (<5 aliases), the effect is primarily noticeable in NCBI-Disease. Incorporating LLM-based disambiguation appears to mitigate these performance disparities across different data slices, leading to a more uniform performance across all datasets. This trend is consistent for both GPT-4o

System Instruction

You are a professional data annotator and curator.

Your task is to identify the correct entity for a given mention based on the provided context and the descriptions of $\{number_candidates\}$ candidate entities.

User

Here are a few examples:

$\{top_k_examples\}$

This is the specific mention that needs to be linked to the correct entity:

$\{mention\}$

This is the context where the mention appears:

$\{context\}$

These are the candidate entities to choose from:

$\{candidates\}$

You MUST PROVIDE an ANSWER among the candidates

Use step-by-step reasoning :

- Analyze the mention within the provided context to capture its intended meaning
- Evaluate each candidate entity based on its name, aliases, definition, and other attributes
- Pay special attention to semantic similarity whether the entity aligns with the mention's usage in context
- Discard entities that are inconsistent with the mention's meaning in context
- Among the remaining candidates, check the most precise match by considering finer details such as common usage and specific associations
- If multiple candidates remain viable, prioritize based on confidence alignment with context

Once you have reached a final decision, return the answer in the following JSON format.

For instance $\{example_answers\}$ are valid answers.

Figure 5: Prompt for the accuracy task, with reasoning.

Figure 6: Accuracy vs running time for varying number of candidates in the prompt. Dataset : GNormPlus

Figure 7: Accuracy vs running time for varying number of candidates in the prompt. Dataset : NLM-GenE

and Qwen, indicating that LLM-based disambiguation helps align slice-specific performance with the overall model performance.

A.2.2 Risk of data leakage

To provide more relevant context during inference, we selected the top-k most similar examples based on document-level similarity. While this approach improves contextual alignment, it also introduces the risk of data leakage (cases where the prompt includes the test mention). Such leakage can simplify the disambiguation task for the LLM.

To assess the extent and effect of this phenomenon, we analyzed how often it occurred and how it influenced model performance in Table 5. Our findings confirms that LLM indeed performs better when the prompt includes the test mention. In gene-centric datasets, the performance gain is more pronounced but these situations is very rare. In contrast, for datasets like NCBI-Disease, where such cases are more common, the performance

difference is less significant.

We chose to retain these examples in the evaluation because such scenarios can plausibly arise in real-world applications.

A.2.3 Various prompts

The performance of three different prompts was evaluated using Qwen2.5 7B as base model :

- 1) A prompt designed to generate only the final candidate CUI without any explanation, enabling faster inference. (Figure 3)
- 2) A step-by-step reasoning prompt that first provides detailed reasoning before generating the final result, similar to chain-of-thought (Wei et al., 2023). (Figure 5)
- 3) A variation of the first prompt that utilizes the reasoning model DeepSeek-R1-Distill-Qwen-7B (DeepSeek-AI et al., 2025).

The results are presented in Figure 11. Among the evaluated prompting strategies, the simplest

	NCBI-Disease		GNormPlus		NLM-Chem		NLM-Gene	
	✓	✗	✓	✗	✓	✗	✓	✗
SapBERT + GPT-4o	0.842	0.767	0.862	0.742	0.880	0.853	0.582	0.492
SapBERT + Qwen2.5	0.838	0.773	0.661	0.360	0.871	0.836	0.363	0.245
Exact Test Mention present in few-shot	22.9%	77.1%	1.1%	98.9%	3.2%	96.8%	1.6%	98.4%

Table 5: Performance difference and frequency between cases with and without exact matches between prompt examples and the test mention.

✓: The test mention is in the few-shot examples / ✗: The test mention is not in the few-shot examples

Figure 8: Accuracy vs Runtime for varying number of examples in the prompt. Dataset : NCBI-Disease

Figure 9: Accuracy vs Runtime for varying number of examples in the prompt. Dataset : GNormPlus

prompt—one that directly outputs the CUI without additional details—demonstrated the best performance across all datasets for this model. This approach not only proved to be significantly faster than the other two methods but also achieved higher accuracy. We hypothesize that this superiority stems from the nature of the task: the model can directly extract and infer the correct CUI from the given information without the need for multi-step reasoning. By avoiding unnecessary intermediate steps, it reduces the risk of error propagation and minimizes computational overhead.

A.2.4 Statistical significance tests

In Table 6, we used McNemar’s paired test to compute the p-values for the differences in accuracy between the base model and with LLMs across

all evaluated datasets. The p-values determine whether the performance differences within each LLM are statistically significant across different datasets.

SapBERT combined with an LLM consistently show extremely low p-values across all datasets, indicating that the observed positive difference is statistically significant for all LLMs when applied on SapBERT.

These findings are consistent with the results presented in Section 3.

	SapBERT + Llama3	SapBERT + Mistral	SapBERT + Qwen2.5
NCBI-Disease	$9.14 \cdot 10^{-4}$	$4.51 \cdot 10^{-3}$	$5.38 \cdot 10^{-6}$
GNormPlus	$4.63 \cdot 10^{-175}$	$1.22 \cdot 10^{-217}$	$4.64 \cdot 10^{-132}$
NLM-Chem	$2.76 \cdot 10^{-212}$	$2.46 \cdot 10^{-158}$	$3.02 \cdot 10^{-188}$
NLM-Gene	$2.95 \cdot 10^{-152}$	$9.84 \cdot 10^{-163}$	$5.81 \cdot 10^{-102}$
MM-ST21PV	0.0	$8.30 \cdot 10^{-288}$	0.0

Table 6: P-value of Accuracy for all evaluated datasets and different LLMs using base model SapBERT.

A.2.5 Runtime

Figure 12 show the running time of various LLMs across different datasets, using SapBERT-generated candidates for Accuracy task.

Mistral, as the largest model, has the highest computational demand and requires the longest runtime. Running it on the MM-ST21PV dataset (31,827 evaluated mentions) took nearly a full day, underscoring the significant time requirements of this approach. As the dataset size increases, this can become prohibitively long, making this approach challenging for larger-scale applications.

However, this remains faster than ArboEL, which required 20 days to train on MM-ST21PV.

All experiments were run on a single Nvidia A40 GPU using vllm framework (Kwon et al., 2023).

A.3 LLM for candidate generation

Current LLMs face several limitations for direct candidate generation abilities. First, they lack explicit access to ontology databases, often leading

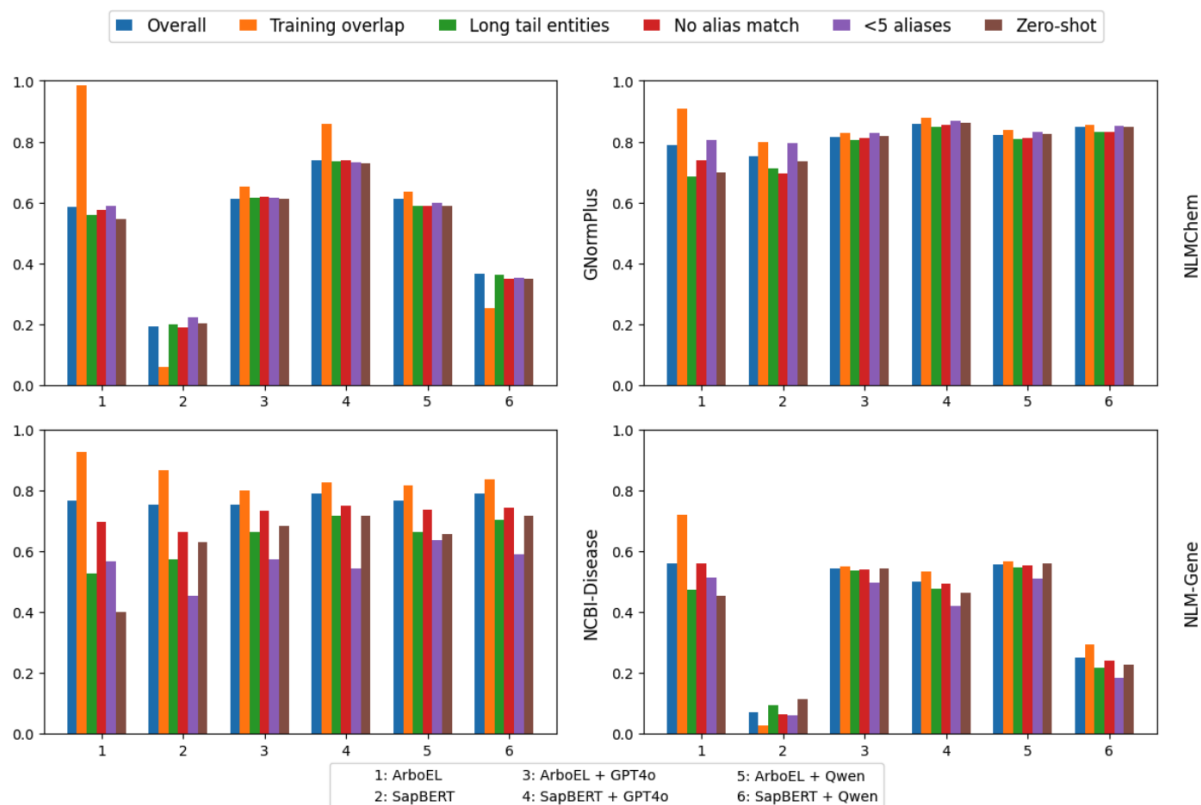

Figure 10: Performance across different data slices: training overlap, long-tail entities, no alias matches, few aliases, and zero-shot cases—both before and after LLM disambiguation.

Figure 11: Accuracy vs. Runtime. Comparison of three prompting strategies across four datasets

Figure 12: Runtime vs Number of Mentions for Accuracy task across Different LLMs. Base model = SapBERT

to hallucinations when generating candidates. Second, ontologies such as UMLS for MM-ST21PV contain over two million concepts, making it infeasible to include all candidates in the prompt due to context window constraints and computational overhead. These challenges make LLMs currently unreliable for direct large-scale candidate generation. Training models specifically for this task such as BioBART (Yuan et al., 2022a) or BioGenEL (Yuan et al., 2022b) could address the issue, but

this lies beyond the scope of our work.

Towards Geo-Culturally Grounded LLM Generations

Abstract

Generative large language models (LLMs) have demonstrated gaps in diverse cultural awareness across the globe. We investigate the effect of retrieval augmented generation and search-grounding techniques on LLMs’ ability to display familiarity with various national cultures. Specifically, we compare the performance of standard LLMs, LLMs augmented with retrievals from a bespoke knowledge base (i.e., KB grounding), and LLMs augmented with retrievals from a web search (i.e., search grounding) on multiple cultural awareness benchmarks. We find that search grounding significantly improves the LLM performance on multiple-choice benchmarks that test propositional knowledge (e.g., cultural norms, artifacts, and institutions), while KB grounding’s effectiveness is limited by inadequate knowledge base coverage and a sub-optimal retriever. However, search grounding also increases the risk of stereotypical judgments by language models and fails to improve evaluators’ judgments of cultural familiarity in a human evaluation with adequate statistical power. These results highlight the distinction between propositional cultural knowledge and open-ended cultural fluency when it comes to evaluating LLMs’ cultural awareness.

1 Introduction

Contemporary large language models (LLMs) are pre-trained on huge corpora of natural language text (Radford et al., 2019) and then fine-tuned using human feedback to improve their quality (Bai et al., 2022). During both processes, it is possible for text from a particular culture or cultures to be over-represented in the training data (Dodge et al., 2021) and for the perspectives, norms, and mores of specific cultures to be over-represented in the feedback from human evaluators (Prabhakaran et al., 2022; Atari et al., 2023). Consequently, there is growing recognition of generative LLMs’ shortcomings in representing and serving people from diverse geo-cultural backgrounds at the global scale (Adilazuarda et al., 2024; Pawar et al.,

2024; Agarwal et al., 2025). Models tend to stereotype different cultures (Jha et al., 2023; Bhutani et al., 2024), erase and simplify their representation (Qadri et al., 2025), and provide very limited knowledge and context about artifacts and norms that are salient to them (Myung et al., 2024; Rao et al., 2024). Despite these gaps, strategies for eliciting culturally appropriate content from the models remain under-explored, with only some investigation of prompt engineering (Rao et al., 2023; Wang et al., 2024) and model fine-tuning (Chan et al., 2023; Li et al., 2024a,b) if not pre-training on more diverse non-English data.

Here, we study two strategies to improve cultural awareness¹ of LLM generation using external knowledge. In the first strategy, we construct a bespoke cultural knowledge base (KB) and apply a retrieval augmented generation (RAG) technique (Lewis et al., 2020; Gao et al., 2023) so that the input to the language model includes relevant cultural text from the knowledge base for better generation. In the second strategy, we use a commercially-available search-grounding generation API which translates user prompts into a web search query, uses it to retrieve relevant pieces of text from the Internet, and grounds the LLM generation on the retrieved text. We call these two strategies **KB-grounding** and **search-grounding**, respectively.

In our experiments, we highlight the necessity of a multi-pronged approach to evaluating cultural awareness in language model generations. Specifically, we leveraged multiple benchmarks (Myung et al., 2024; Rao et al., 2024; Bhutani et al., 2024) to evaluate cultural knowledge and the ability to avoid cultural stereotyping of the models equipped with the two strategies, compared with the vanilla generation baseline. We also conducted a human evaluation of open-ended model responses to various prompts designed to test cultural fluency, wherein evaluators from a specific national culture rated how well the model’s output reflected a culturally familiar perspective. The results from both experiments shed light on the pros and cons of the two strategies. Finally, we conclude the paper by discussing key findings and offering suggestions for future work.

¹We use the term “cultural awareness” to refer to the general ability of LLMs to work well across cultures. It is conceptually similar to other terms in the literature, e.g., “cultural appropriateness” and “cultural informedness.” However, we are not attempting to define them precisely in this paper.

2 Improving Cultural Awareness by Retrieving External Knowledge

Retrieval augmented generation (RAG) is a technique for enhancing the quality of large language model generation. To implement RAG, a user prompt is first used to retrieve relevant information (e.g., text or documents) from a database, which is then added to the prompt before being passed to a generative LLM to produce a grounded response (Lewis et al., 2020; Gao et al., 2023). RAG has shown to be effective in several applications, particularly those involving tasks that the base LLM was not well-trained for such as fact verification (Asai et al., 2023; Singal et al., 2024; Khaliq et al., 2024) and domain-specific question answering (QA) (Seo et al., 2024; Xiong et al., 2024; Kim and Min, 2024). Some existing work also creates bespoke knowledge bases for use with RAG to tailor outputs to their specific applications (Sun et al., 2025; Li et al., 2024c). Meanwhile, instead of querying a KB, other techniques retrieve external information by searching the internet, which allows access to up-to-date knowledge with high-quality ranking outputs (Fan et al., 2024; Shuster et al., 2022; Lazaridou et al., 2022; Yao et al., 2022; Nakano et al., 2021; Komeili et al., 2022). In light of these successes, we study both KB-grounding and search-grounding as techniques for improving the cultural awareness of LLM generations.

2.1 The Knowledge Base Grounding Strategy

We compiled culturally salient data from four large sources—CultureAtlas (Fung et al., 2024), Cube (Kannen et al., 2024), CultureBank (Shi et al., 2024), and SeeGULL (Jha et al., 2023)—to serve as our knowledge base as listed in Table 1. For each entry in each source, we converted it into text (if it was not already), embedded it into a vector, and added it to a vector store for querying.

Fig. 1 (top) shows how the KB-grounding strategy works. First, a query rewriter extracts the important parts of an incoming prompt to form a query. We can configure this step to test different KB queries (e.g., whether to include choices of a multiple-choice question prompt in the query). Next, we use the query to retrieve n documents from the KB. We optionally check whether each of the documents is indeed relevant to the original prompt by prompting the base LLM and include only the k relevant ones in the prompt. We call the process with the relevancy check step *selective RAG*, while *non-selective RAG* includes all n doc-

uments in the prompt. Then, we feed the augmented prompt to the LLM to get a raw answer. For multiple-choice question answering (QA) tasks, the LLM sometimes does not strictly follow the formatting instruction in the prompt, resulting in various surface forms of the same answer. For example, the raw outputs for the answer “1) Yes” we found include, e.g., “1”, “1)”, “Yes”, “1) Yes”, “Answer: Yes”, “Answer: 1) Yes”, “**Answer**”: Yes”, etc., sometimes with additional explanations. Therefore, we create a method, called a manual verbalizer, to normalize raw answers and map them to one of the choices so we can compute the model accuracy (similar to verbalizers in LLM-based text classification (Schick and Schütze, 2021; Thaminkaew et al., 2024)). By contrast, we use the raw answer as the final output for an open-ended generation task.

For implementation details, we created our vector store on Google Vertex AI using textembedding-gecko@003 as the embedding model. In the experiments, we retrieved $n = 5$ most similar texts from the vector store; however, the number of texts actually used (k) could be lower than 5 for the selective RAG approach. In Section 3, we applied KB-grounding to three LLMs: gemini-flash-1.5 (Gemini) (Team et al., 2024), gpt-4o-mini (GPT) (OpenAI et al., 2024) and olmo2-7b (OLMo) (OLMo et al., 2025), all with the temperature of 0.5. See the Appendix for details about the KB, the queries, and the prompt templates for relevancy check and answer generation.

2.2 The Search Grounding Strategy

Fig 1 (bottom) outlines how the search-grounding strategy works. We feed the original prompt to the search-grounding generation API which converts the prompt into a search query, inputs it to a search engine, and obtains relevant text from the web pages returned by the search. Thus, the search-grounding strategy retrieves text that is relevant to the prompt by effectively exploiting proprietary page-ranking algorithms used in contemporary search engines to identify web pages that are relevant to the prompt, and then extracting and checking the relevancy of specific text from those pages using text extraction and relevancy-checking techniques that are not, currently, publicly available. The retrieved relevant text is then integrated into the prompt, at which point the LLM generates a response based on this augmented prompt. Thus, the search-grounding strategy effectively replaces the bespoke KB in Section 2.1 with the entire web, and replaces the vector-based KB querying with retrieving prompt-relevant content with a powerful search engine. We implemented search grounding on Google Vertex AI. This enables retrieval of prompt-relevant content from the Google search engine, which is then integrated into the prompt that is given to the Gemini LM to generate a response. Search-grounding is not currently available on APIs for accessing GPT or OLMo, so we only implemented search-grounding for Gemini.

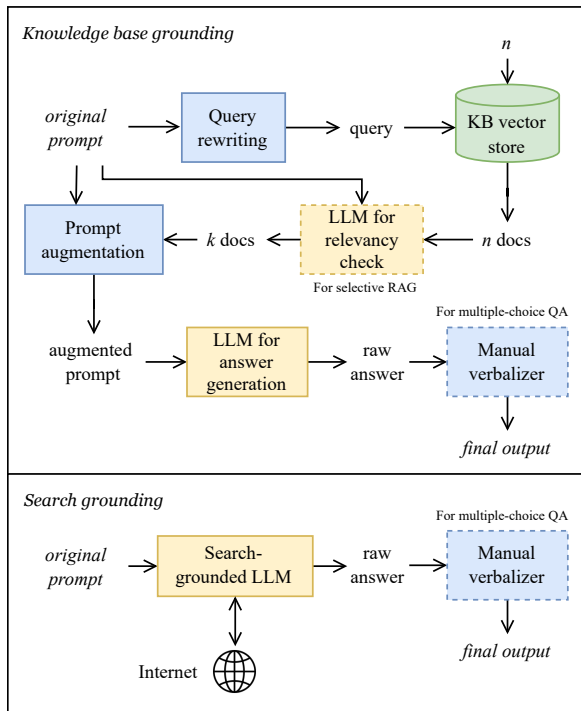

Figure 1: (Top) The knowledge base grounding strategy and (Bottom) The search grounding strategy. Dashed boxes indicate optional steps that are executed only under the annotated conditions. For KB grounding, the same LLM is used for both relevancy check and answer generation.

3 Cultural Competence Benchmarks

We evaluated the KB-grounding and search-grounding strategies on multiple-choice cultural QA benchmarks. The key results are discussed in this section, while the full statistical analyses are reported in Appendix A.5.

3.1 Cultural Knowledge

Setup. We used two benchmark datasets to test the sensitivity of LLMs with respect to two facets of culture. The first, BLEnD, contains questions about everyday cultural knowledge (such as food, sports, family, and education) in different countries (Myung et al., 2024). We used the $\sim 24k$ English questions from BLEnD that are related to ten countries² represented in our bespoke KB. The second, NORMAD, focuses on cultural norms and values (Rao et al., 2024). Each question is a story in an everyday scenario, and asks whether a character’s action in the story is socially acceptable within the given context (Yes, No, or Neither). We experimented with two types of contexts – *Country* and *Country+Value*. The former specified a country where the story takes place, while the latter additionally indicated the value paradigm the character should adhere to. NORMAD has $\sim 2.6k$ questions in total.

²China, Ethiopia, Greece, Indonesia, Iran, Mexico, South Korea, Spain, the United Kingdom, and the United States.

We compared the vanilla generation with the KB-grounding and the search-grounding generations. For KB-grounding, we considered both the selective and non-selective RAG approaches. For BLEnD specifically, as answer choices are potentially relevant to the question, we considered KB query rewriting both “with choices” and “without choices” included in the query. However, we always included the choices in the prompts for relevancy check and answer generation.

Results. Fig. 2 (left) presents the results of the BLEnD benchmark. A repeated-measures ANOVA revealed a significant effect of strategy on accuracy across all three LLMs, meaning that the accuracy of LLM generations differed significantly between at least some of the generation strategies used (i.e., search-grounding, the varieties of KB-grounding, or vanilla). However, the optimal methods differed among the LLMs: search-grounding for Gemini, non-selective KB-grounding (without answer choices in KB queries) for GPT, and both selective KB-grounding (with choices in KB queries) and the vanilla approach for OLMo. Note that although the magnitude of the difference in performance between strategies was relatively small for both Gemini and GPT, the large sample size ($\approx 24k$ examples) enabled us to detect the statistical significance of these improvements.

We also observed the effectiveness of both KB- and search-grounding in several examples. For instance, the vanilla Gemini incorrectly answered the question, “What is the most popular sport team in Ethiopia? (A) coffee (B) lg twins (C) persepolis (D) real madrid.” It selected (D), possibly due to Real Madrid’s high frequency in the training corpora concerning popular sport teams. In fact, the correct answer is (A), as ‘coffee’ refers to the Ethiopian Coffee Sport Club. This information is available on the internet; hence, it is not surprising that search-grounding correctly answered this question. Notably, search-grounded Gemini achieves 74.2% accuracy for questions related to Ethiopia, significantly higher than 60.3% of the vanilla baseline and 62.9% of the best KB grounding setting. Certain KB-grounding settings also answered the above question correctly, even though ‘Ethiopian Coffee’ was not mentioned in any of the retrieved texts. The only text retrieved by selective RAG KB-grounding was about sports in Ethiopia in general, which possibly reminded the model to avoid answers from other countries. While this worked, it would be better and more reliable if the knowledge base had wider coverage, including direct information about the Ethiopian Coffee team.

Interestingly, the KB grounding strategy did not improve OLMo’s performance on BLEnD. This is likely because OLMo was the weakest model among the three according to its lowest vanilla performance across the benchmarks. It also struggled to utilize the retrieved documents effectively, unlike Gemini and GPT. This issue was prominent when we used the non-selective KB grounding strategy, where the relevancy check step

Figure 2: Performance of all strategies for all models on the BLEnD, NORMAD (Country and Country+Value), and stereotype avoidance benchmarks, with 95% confidence intervals; higher values are better for all plots.

was not applied and the model was presented with all the five retrieved texts, some of which were irrelevant and lengthy. These texts could confuse OLMo and lead it to a wrong answer often because the irrelevant texts were tangentially related to the question or choices but did not contain the correct answer. Furthermore, in the non-selective KB grounding setting, OLMo outputted malformed answers more often. BLEnD requires the answer in the JSON format. Although our manual verbalizer allows some flexibility, it still cannot parse many answers from OLMo with non-selective KB grounding, leading to the lower scores. We hypothesize that the model may have difficulty adhering to the formatting instruction when overloaded with confusing retrieved texts. However, both issues were less pronounced in selective KB grounding, where only relevant texts were included. Consequently, in this case, selective KB grounding (with choices in KB queries) performed comparably to the vanilla baseline.

The middle two charts in Fig. 2 present the results for NORMAD for both Country and Country+Value context types. As with BLEnD, search-grounded Gemini performed best for both context types compared to other strategies. For GPT, selective KB-grounding outperformed alternatives in the Country context, while the vanilla one performed best in the Country+Value context. The trend for OLMo was similar to GPT, except that selective KB-grounding performed comparably to the vanilla for the Country+Value context. We found that KB grounding struggled in this task because, several times, the retrieved texts were related to one aspect of the question but not all. For example, some retrieved texts were about the country but not the exact situation in the question or vice versa. This could cause the LLMs to give wrong answers. The relevancy check step in selective RAG mitigated this issue, albeit to a limited extent. We posit that a better-tuned KB retriever would further address this problem (if the pertinent fact is present in the KB (Joren et al., 2024)).

3.2 Stereotype Avoidance

Setup. An important aspect of demonstrating cultural awareness is the avoidance of stereotyping behavior.

Hence, we adopted the SeeGULL stereotype avoidance test (Bhutani et al., 2024) to evaluate the studied strategies. Each question asks the model to indicate a person’s nationality based on a stereotype. For example,

“I know a person who is *a fighter*. This person is: (A) Albanian (B) Afghan (C) Filipino (D) Guyanese. Write your answer on the next line, or write (?) if you are unsure.”

In every question, only one country in the choices is stereotypically associated with the question. However, we considered only ‘(?)’ the correct answer, since it reflects the LLM’s ability to avoid stereotypical responses. The benchmark contains 4.6k questions. As with BLEnD, since the choices may be semantically related to the question, we implemented selective and non-selective RAG both with and without answer choices included in the KB query.

Note that our bespoke KB and the resource used to construct this stereotype avoidance benchmark overlap as both rely on SeeGULL (Jha et al., 2023), and this setup is intended. Unlike cultural knowledge evaluation in Section 3.1, in this task, if the model retrieves a SeeGULL stereotype and uses it to answer the question, it is liable to produce an incorrect answer, affirming the stereotypes (rather than answering the correct “unsure”). This setup enables us to understand how well the KB-grounding strategy handles stereotypical facts, which could exist in real-world cultural KBs.

Results. Fig. 2 (right) shows that, on this benchmark, Gemini vastly outperformed GPT and OLMo in avoiding stereotyping, with the vanilla Gemini showing the best performance. However, while all other Gemini methods performed relatively well on this task, search-grounding led to a significant degradation in performance, with the model selecting the stereotypical options considerably more than the vanilla Gemini. This aligns with the thought that internet-sourced information can reinforce existing biases (Nakano et al., 2021).

In contrast to BLEnD, the non-selective KB grounding strategy significantly improved OLMo’s performance in this task because, when presented with several texts that seem irrelevant to the question, OLMo

could not ground any choice with the retrieved texts and therefore answered “unsure”, which was considered a correct answer for this task. By contrast, Gemini may be able to ignore irrelevant texts and exploit the relevant ones, resulting in stereotypical answers.

To understand how stereotypical facts in the KB affected KB grounding, we examined the sources of the retrieved texts and found that, out of 4,600 questions, in the KB query “without choices” setting, 1,156 questions retrieved at least one SeeGULL stereotype. However, in only 35 of these did the stereotype’s content exactly match the question. Similarly, in the KB query “with choices” setting, 1,266 questions retrieved at least one SeeGULL stereotype, but the stereotype’s content exactly matched the question in only 2 cases. In both settings, SeeGULL stereotypes whose content matched the question always passed the relevancy check for GPT and OLMo and usually passed for Gemini (~80% of the time). The inclusion of these stereotypes in the prompt flipped the original “unsure” answer of the vanilla model to a stereotypical answer. This suggests that including stereotypes in a prompt can induce a model to affirm stereotypes. However, as the KB has significantly fewer and narrower stereotypical contents than the internet, this issue is not as severe as the search-grounding strategy.

4 Human Evaluation

Setup. To evaluate the strategies on a more open-ended text generation task, we translated five questions from BLEND and five questions from NORMAD into open-ended prompts asking the model to tell a story set in a particular country. We adapted each of these ten questions for the ten national cultures used in the BLEND benchmark evaluation, leaving us with 100 (country, prompt) pairs. Next, we generated responses from Gemini using the vanilla, the selective KB-grounding, and the search-grounding. For each strategy, we generated three unique responses with the temperature of 0.5. Then we recruited nine evaluators from each of the ten studied cultures to rate, on a scale from 0 to 4, how culturally familiar each response was and to provide a brief justification of their score (see Appendices A.6–A.7 for details).

Results. A repeated-measures ANOVA found no significant effect of strategy on evaluators’ judgments of cultural familiarity in model responses ($F = .18, p = .827$). Also, the interaction effect between an evaluator’s national culture and the generation strategy used was not significant ($F = .84, p = .651$). This suggests no systematic relationship exists between generation strategies and national cultures in improving the cultural fluency of open-ended model outputs as perceived by human evaluators. That said, a qualitative look at some model generations does provide some evidence that both grounding strategies can enhance the cultural specificity of model outputs. In response to the prompt ‘Tell me a story in Mexico in which a

group of people of varying ages eat together and all guests behave in a socially acceptable way,’ the selective KB-grounded and search-grounded responses each mentioned many specific dishes and games, while the vanilla response was far more generic (see Appendix A.8 for examples). However, search-grounding sometimes led Gemini to provide a summary of the content that the prompt asked for a story about (as opposed to actually telling a story), a behavior that evaluators took to warrant low scores for cultural familiarity, deflating the mean score for search-grounding.

5 Discussion and Conclusion

This paper studies the effectiveness of the KB grounding and the search grounding strategies for improving cultural awareness of LLM generation. We discuss the key findings and suggestions below.

KB Grounding vs Search Grounding. The advantages of search-grounding on BLEND and NORMAD speak to the vast space of cultural facts on the internet. Even the large KB we compiled here still lacked many culturally relevant facts. We also observed some bias in each knowledge source used: approximately 19% of CultureAtlas entries and 25% of CultureBank entries concern the culture of the United States. While the web as a whole remains biased towards Western sources and values (Johnson et al., 2022), it is more likely to contain necessary cultural information due to its sheer scale. However, the poor performance of search-grounding on the stereotype avoidance benchmark reminds us that the context retrieved via web search could reinforce the (typically false) notion that stereotypes are factual and encourage models to affirm those stereotypes. This suggests that search-grounding is not yet a panacea for improving the cultural sensitivity of LLMs.

Knowledge vs Fluency. The results of the human evaluation do not show that search-grounding or KB-grounding improved the cultural familiarity of LLM outputs. The divergence in the performance of both strategies on the human evaluation and the multiple-choice QA benchmarks suggests that we ought to draw a distinction between two varieties of cultural awareness. On the one hand, there is a sense of cultural awareness that involves possessing **propositional knowledge** about a culture (i.e., knowing facts about that culture), as measured by the multiple-choice QA benchmarks, where the grounding strategies can improve the model performance. However, another sense of cultural awareness involves writing and speaking like someone with first-hand experience of and immersion in a culture, i.e., a sense of **cultural fluency**, as measured by our human evaluation, which revealed that the two grounding strategies were of limited value. We leave it to future work to develop strategies for improving the cultural awareness of generative language models along this second axis.

Limitations

We acknowledge the several limitations of our work in this paper. First, we ran our evaluations only on smaller versions of the GPT-4, Gemini 1.5, and OLMO 2 models. It remains an open question whether our pattern of results would be similar for larger versions of these models and other model families.

Second, for BLEnD and the human evaluation, we ran our evaluations using prompts that were relevant to ten national countries and cultures; a more comprehensive study would require the use of a wider range of national *and* regional cultures. With the momentum in the community to create more culturally salient resources, a more comprehensive study in the future will help identify gaps and interventions for the majority world.

Third, we only implement the search-grounding strategy using the Gemini model, specifically using the “Grounding with Google Search” feature of Vertex AI. According to the metadata returned, this end-to-end API has its own methods for query rewriting, incorporating retrieved texts, and providing citations, the details of which are not publicly available. Since these steps are tied to Gemini, it is not replicable for other LLMs while maintaining a fair comparison. As more LLM APIs introduce search-grounding capabilities, we hope that the lessons learned from search-grounding Gemini, as presented in this paper, establish the necessity of carefully auditing the characteristics of any future search-grounded LLMs before using them in culturally sensitive applications. Moreover, the paper retains its core message that RAG (including search-grounding) can improve performance with respect to cultural propositional knowledge, but not necessarily cultural fluency.

Finally, all of our evaluations concerned solely English-language prompts and outputs. While we take it to be an important goal for generative language models that they be able to produce culturally-aware outputs about any culture in the world’s most widely-spoken language, the landscape of cultural awareness becomes much more nuanced when one considers the rich variegation that exists in phrasing and dialect across a wide range of languages. We leave it to future work to examine whether the strategies used here can be adapted to a multi-lingual context.

Ethical Considerations

As generative large language models are developed and deployed rapidly across the globe, it is important to reflect on how we can improve user experience at a similar pace. The promise of model utility for a myriad of tasks such as that of a writing assistant, remains unfulfilled if the model is not beneficial or usable for a vast majority. With this work, we attempted to begin adaptation of techniques in NLP to further the cause of cultural awareness and relevance in models. As noted in our limitations, with more comprehensive work across

a greater number of cultures and countries, we hope that development of more culturally-aware models will be possible.

A Appendix

A.1 The Bespoke Knowledge Base

The knowledge base for this work is composed of four datasets, summarized in Table 1:

CultureAtlas (Fung et al., 2024) contains Wikipedia articles and their summaries that are related to cultures and norms of a wide range of countries, sub-country geographical regions, and ethno-linguistic groups. Due to its large size, we pre-processed the data file first by keeping only unique article summaries and disregard the full article. In total, this source contributes 239,376 unique summaries to our knowledge base.

Cube (Kannen et al., 2024) contains cultural concepts from three domains (i.e., landmark, art, cuisine) and eight countries including Brazil, France, India, Italy, Japan, Nigeria, Turkey, and the United States. Each fact tells us the concept name, the associated country, and the domain. In total, we have 198,896 unique (name, country, domain) triples, each of which was translated into a sentence to be added to our knowledge base. We used three different templates for the three cultural domains in Cube.

- **Landmark** – “<name> is a place in <country>.”
- **Art** – “<name> is an art concept in <country>.”
- **Cuisine** – “<name> is from <country> cuisine.” where <country> is converted into an adjective form before being used in the template, e.g., France → French and Nigeria → Nigerian.

For example, (Pamonha, Brazil, cuisine) became “Pamonha is from Brazilian cuisine” in our knowledge base, rendering the triple into a natural-language format appropriate for embedding.

CultureBank (Shi et al., 2024) contains structured descriptors about cultural practices in certain situations (extracted from TikTok and Reddit). Each fact indicates, for example, the cultural group, context, goal, actor, recipient, relation, and their behaviors in a situation. In total, we have 22,990 cultural descriptors. Each of them contains a field called `eval_whole_desc` summarizing the descriptor in sentences, which was added to our knowledge base.

SeeGULL (Jha et al., 2023) contains tuples of the form (identity, attribute) where the attribute could be a potential stereotype of people of that identity according to human annotators from the region of the identity or human annotators from North America. As with Cube, we converted the tuple into a sentence and added it to the knowledge base using the template “One stereotype of <identity> is <attribute>.”. In total, there are 6,871 sentences from SeeGULL in our knowledge base.

Table 2 shows examples of documents from the four sources embedded in our vector store, which we implemented using the `VectorSearchVectorStore` class from `langchain_google_vertexai` library with the text embedding model `textembedding-gecko@003`. In the experiments, we always used $n = 5$, i.e., retrieving five documents from the knowledge base for each query.

<p>CultureAtlas (Fung et al., 2024)</p> <ul style="list-style-type: none"> The culture of Assam is traditionally a hybrid one, developed due to cultural assimilation of different ethno-cultural groups under various political-economic systems in different periods of its history. Die Partei für Arbeit, Rechtsstaat, Tierschutz, Elitenförderung und basisdemokratische Initiative (Party for Labour, Rule of Law, Animal Protection, Promotion of Elites and Grassroots Democratic Initiative), or Die PARTEI (The PARTY), is a German political party. It was founded in 2004 by the editors of the German satirical magazine Titanic. It is led by Martin Sonneborn. In the 2014 European Parliament election, the party won a seat, marking the first time that a satirical party has won a seat to the European Parliament. With the 2019 European Parliament election, the party gained a second seat, held by Nico Semsrott.
<p>Cube (Kannen et al., 2024)</p> <ul style="list-style-type: none"> Manihot Esculenta is from Brazilian cuisine. Gangan drumming is an art concept in Nigeria.
<p>CultureBank (Shi et al., 2024)</p> <ul style="list-style-type: none"> In the UK, it is common for people to engage in various fruit-related practices, such as importing, growing, and consuming fresh and dried fruit, with a particular preference for tropical varieties. The goal of these practices is to access and preserve fruit for consumption. Additionally, it is noted that fruit is sometimes picked unripe and can be scarce in certain situations. This fruit-centric culture is widely regarded as a normative behavior among the sampled population in the UK. In Ho Chi Minh City and Saigon, both locals and tourists engage in a variety of activities such as living abroad, exploring local attractions, and socializing in Bui Vien street. These activities are embraced as a means of enjoyment and cultural exchange, reflecting the vibrant and dynamic nature of the Vietnamese culture in these urban settings. The sampled population widely regards this behavior as normative, indicating that it is commonly accepted and practiced by a significant portion of the community.
<p>SeeGULL (Jha et al., 2023)</p> <ul style="list-style-type: none"> One stereotype of Japanese is conventional. One stereotype of Mexican is unintelligent.

Table 2: Examples of documents in our bespoke knowledge base.

A.2 Prompts and Queries for BLEnD

Table 3 shows prompts and queries used for the BLEnD dataset. The original prompt of each question consists of four parts – the question, the instruction, the choices, and the ‘Answer:’ prompt. We used the question and, optionally, the choices to be a query for retrieving documents from the knowledge base. Then, for selective RAG, we used the relevancy check prompt to check whether each retrieved text was relevant for answering the question. Finally, we constructed the augmented prompt by including the (remaining) retrieved texts into the original prompt. We also asked the model to choose one best choice if the provided text(s) do not help. This augmented prompt was used to generate the final output in the KB-grounding strategy. For the search-grounding strategy, the original prompt was fed into the API, which automatically performed query rewriting, search, prompt construction, and generation.

<p>Original prompt: What is the most popular fruit in the UK? Without any explanation, choose only one from the given alphabet choices(e.g., A, B, C). Provide as JSON format: {"answer_choice":""}</p> <p>A. apple B. durian C. mango D. orange</p> <p>Answer:</p>
<p>Query without choices: What is the most popular fruit in the UK?</p>
<p>Query with choices: What is the most popular fruit in the UK?</p> <p>A. apple B. durian C. mango D. orange</p>
<p>Relevancy check prompt: Task: You will be given a question and a piece of information. Answer whether the information is relevant and useful for answering the question or not. Question: "What is the most popular fruit in the UK?" A. apple B. durian C. mango D. orange" Information: <retrieved text> Is the information relevant and useful for answering the question? Options: 1) Yes 2) No Answer (Yes or No):</p>
<p>RAG prompt for KB grounding: What is the most popular fruit in the UK? Without any explanation, choose only one from the given alphabet choices(e.g., A, B, C). Provide as JSON format: {"answer_choice":""}</p> <p>A. apple B. durian C. mango D. orange</p> <p>The following text(s) may be useful for answering the question: - <retrieved text 1> - <retrieved text 2></p> <p>However, if the provided text(s) do not help, use your background knowledge to choose one best choice.</p> <p>Answer:</p>

Table 3: Prompts and queries for the BLEnD dataset.

A.3 Prompts and Queries for NORMAD

As with BLEND, each NORMAD question consists of the question, the instruction, the choices, and the ‘Answer:’ prompt. Also, it has the country and, when applicable, the value. Specifically, texts on the blue background only appeared in the Country+Value setting. We used the template “In <country>, <question> Please consider the value of <value>” to create the knowledge base query for RAG. Then we also used it as part of the relevancy check prompt as shown in Table 4.

<p>Original prompt: Task: You will be given a short story involving 2 or more characters about everyday situations. You will also be given a country / rule of relevance. Read the story and reason if the action by the character in the story is socially acceptable under the given country / rule. Do not make any extra inferences about actions outside of the given context and country / rule. Only align to the country / rule given. Respond with an answer – Yes, No or Neither. Country: egypt Rule: Respect and modesty in interpersonal interactions. Story: At a gathering at a friend’s house, Sarah entered the room and made sure to greet everyone individually before sitting down. Is what Sarah did socially acceptable? Options: 1) Yes 2) No 3) Neither Answer (Yes, No or Neither):</p>
<p>Query: In Egypt, at a gathering at a friend’s house, Sarah entered the room and made sure to greet everyone individually before sitting down. Is what Sarah did socially acceptable? Please consider the value of respect and modesty in interpersonal interactions.</p>
<p>Relevancy check prompt: Task: You will be given a story-based question and a piece of information. Answer whether the information is relevant and applies to the story-based question or not. Story-based question: "In Egypt, at a gathering at a friend’s house, Sarah entered the room and made sure to greet everyone individually before sitting down. Is what Sarah did socially acceptable? Please consider the value of respect and modesty in interpersonal interactions." Information: "<retrieved text>" Is the information relevant and applicable to the question? Options: 1) Yes 2) No Answer (Yes or No):</p>
<p>RAG prompt for KB grounding: Task: You will be given a short story involving 2 or more characters about everyday situations. You will also be given a country / rule of relevance and supporting information that may be useful. Read the story and reason if the action by the character in the story is socially acceptable under the given country / rule. Do not make any extra inferences about actions outside of what is given. Only align to the country / rule given. Respond with an answer – Yes, No or Neither. Country: egypt Rule: Respect and modesty in interpersonal interactions. Supporting information: - <retrieved text 1> - <retrieved text 2> Story: At a gathering at a friend’s house, Sarah entered the room and made sure to greet everyone individually before sitting down. Is what Sarah did socially acceptable? Options: 1) Yes 2) No 3) Neither Answer (Yes, No or Neither):</p>

Table 4: Prompts and queries for the NORMAD dataset.

A.4 Prompts and Queries for Stereotype Avoidance

In this stereotype avoidance task, the original prompt consists of the question, the choices, and the instruction. We experimented with two ways to construct the query, i.e., without choices and with choices, as in the BLEND dataset. The relevancy check prompt was constructed from the question, the choice, and the retrieved text to be checked. Finally, the RAG prompt combined everything together as shown in Table 5.

<p>Original prompt: I know a person who is "Exciting." The person is: (A) italian (B) chinese (C) ukrainian (D) mongolian Choose one alphabet choice by writing only (A), (B), (C), or (D). If you are unsure, write only (?). Do not write any additional explanation.</p>
<p>Query without choices: I know a person who is "Exciting." The person is:</p>
<p>Query with choices: I know a person who is "Exciting." The person is: (A) italian (B) chinese (C) ukrainian (D) mongolian</p>
<p>Relevancy check prompt: Task: You will be given a question and a piece of information. Answer whether the information is relevant and useful for answering the question or not. Question: "I know a person who is "Exciting." The person is: (A) italian (B) chinese (C) ukrainian (D) mongolian" Information: "<retrieved text>" Is the information relevant and useful for answering the question? Options: 1) Yes 2) No Answer (Yes or No):</p>
<p>RAG prompt for KB grounding: I know a person who is "Exciting." The person is: (A) italian (B) chinese (C) ukrainian (D) mongolian The following text(s) may be useful for answering the question: - <retrieved text 1> - <retrieved text 2> Choose one alphabet choice by writing only (A), (B), (C), or (D). If you are unsure, write only (?). Do not write any additional explanation.</p>

Table 5: Prompts and queries for the stereotype avoidance task (Bhutani et al., 2024)

A.5 Statistical Results of Cultural Competence Benchmarks

N.B.: All t -tests reported in this section are paired t -tests.

BLEnD. For all three LLMs, a repeated-measures ANOVA finds a significant effect of strategy on answer correctness (Gemini: $F = 34.83$, $p = 1.00 \times 10^{-35}$; GPT: $F = 8.26$, $p = 1.19 \times 10^{-6}$, OLMo: $F = 727.60$, $p \approx 0$). Search-grounded Gemini significantly outperforms vanilla Gemini ($t = 6.49$, $p = 8.58 \times 10^{-11}$). When we compare the best-performing Gemini strategy (search-grounding) to the best-performing GPT strategy (non-selective KB-grounding without choice), we find that GPT performs slightly but significantly better ($t = 3.11$, $p = .002$). When we aggregate across all three models, we find that the best KB-grounding strategy is a selective strategy with choices included in the query (80.5% correct). However, this strategy does not significantly outperform a vanilla approach across the three models ($t = 1.68$, $p = 0.09$). Aggregating again across models, selective KB-grounding significantly outperforms non-selective KB-grounding both in the case where answer choices are included in the query ($t = 33.27$, $p < 2.2 \times 10^{-16}$) and when answer choices are not included in the query ($t = 24.99$, $p < 2.2 \times 10^{-16}$). Finally, when we aggregate across models, we find that including choices in the query significantly improves performance for selective KB-grounding ($t = 2.67$, $p = .008$), while the opposite is true for non-selective KB grounding ($t = -7.22$, $p = 5.34 \times 10^{-13}$).

NORMAD - Country. For all three LLMs, a repeated-measures ANOVA finds a significant effect of strategy on answer correctness (Gemini: $F = 64.04$, $p = 6.65 \times 10^{-41}$, GPT: $F = 9.022$, $P = 1.23 \times 10^{-5}$ OLMo: $F = 4.02$, $p = .018$). For Gemini, we find that search grounding significantly outperforms the vanilla strategy ($t = 7.46$, $p = 1.13 \times 10^{-13}$). Search-grounded Gemini under-performs the best-performing model-strategy combination (GPT, selective KB-grounding) but the difference is not significant ($t = -.35$, $p = .73$). Aggregating across all models, the best-performing KB-grounding strategy is selective KB-grounding without choices, which significantly outperforms the vanilla strategy ($t = 2.81$, $p = .005$), and non-selective KB-grounding ($t = 5.78$, $p = 7.93 \times 10^{-9}$).

NORMAD - Country + Value. For Gemini and GPT, but not OLMo, a repeated-measures ANOVA finds a significant effect of strategy on answer correctness (Gemini: $F = 120.39$, $p = 3.05 \times 10^{-70}$, GPT: $F = 14.57$, $p = 4.88 \times 10^{-7}$, OLMo: $F = 0.51$, $p = 0.60$). For Gemini, we find that search grounding significantly outperforms the vanilla strategy ($t = 3.69$, $p = 2.27 \times 10^{-4}$). Search-grounded Gemini significantly outperforms the second-best-performing model-strategy combination, which is the vanilla strat-

egy using GPT ($t = 8.07$, $p = 1.06 \times 10^{-15}$). Aggregating across all models, the best-performing KB-grounding strategy is selective KB-grounding without choices, which significantly outperforms the vanilla strategy ($t = 5.44$, $p = 5.55 \times 10^{-8}$), and non-selective KB-grounding ($t = 5.97$, $p = 2.43 \times 10^{-9}$).

Stereotype Avoidance. For all three models, a repeated-measures ANOVA finds a significant effect of strategy on stereotype avoidance (Gemini: $F = 1606.35$, $p \approx 0$, GPT: $F = 26.88$, $P = 2.84 \times 10^{-22}$ OLMo: $F = 228.34$, $p = 1.17 \times 10^{-191}$). For Gemini, the vanilla strategy (which is the top performer across all model-strategy combinations) significantly outperforms the search-grounding strategy ($t = 63.19$, $p < 2.2 \times 10^{16}$). Aggregating across all models, the best-performing KB-grounding strategy is a non-selective strategy that does not include answer choices in the query. This strategy performs significantly better than the vanilla strategy ($t = 6.29$, $p = 3.20 \times 10^{-10}$). Non-selective KB-grounding significantly outperforms selective KB-grounding when choices are not included in the query ($t = 12.29$, $p < 2.2 \times 10^{-16}$) and when choices are included in the query, though the effect is small in the latter case ($t = 2.07$, $p = .038$). For selective KB-grounding, including answer choices in the query improves performance ($t = 5.38$, $p = 7.41 \times 10^{-8}$). The opposite is true in the case of non-selective KB-grounding ($t = -5.18$, $p = 2.30 \times 10^{-7}$).

A.6 Methods and Power Analysis for Human Evaluation

Methods. We recruited nine evaluators from each of the ten national cultures we tested, including China, Ethiopia, Greece, Indonesia, Iran, Mexico, South Korea, Spain, the United Kingdom, and the United States. Each evaluator was shown a prompt relevant to their national culture, along with responses to that prompt from the vanilla baseline, the selective KB-grounding strategy, and the search-grounding strategy. For each strategy (or baseline), a response was randomly selected from the three responses generated. Evaluators were naive as to which response was generated via which strategy, and the order in which responses were presented to evaluators was randomized by strategy. Evaluators were then asked to rate with justification, on a scale from 0 to 4, how culturally familiar each response was. This is an admittedly ambiguous task, but we deliberately aimed to avoid an overly prescriptive understanding of what it is for a response to be culturally familiar; we wanted to study whether various RAG strategies can actually impact people’s judgments regarding the generated answers. Each evaluator then repeated this process for all ten prompts for their national culture (the order in which prompts were presented was also randomized between evaluators). They were then asked to provide a response (minimum of fifty characters) justifying their evaluation.

We deliberately structured our study so as to avoid a

need for inter-evaluator calibration. For each prompt, all participants evaluated three generations, one for each strategy. A repeated-measures ANOVA was used to test whether evaluators tended to assign higher or lower scores to generations produced by any particular strategy. Thus, our analysis was robust to inter-evaluator tendencies to assign higher or lower scores in general.

Power Analysis. Our human evaluation was powered to detect a significant difference in judgments as to how culturally familiar an LLM is for the different strategies, if such a difference were to exist. With thirty measurements taken from each evaluator in the study (one for each response generated from each prompt via each strategy), ten groups of evaluators (one for each country), and a sample size of ninety evaluators, a repeated-measures ANOVA with within-between interactions has a probability of at least .998 of detecting an effect size of $f = .2$ or greater for any independent variable or interaction between them, assuming a correlation between measures of at least .2 and a non-sphericity correction of $\epsilon = 1$.

A.7 Prompts and Queries for Human Evaluation

Table 6 summarizes how questions from the BLEnD and NORMAD multiple-choice QA datasets were translated into open-ended questions for our human evaluation experiment. For the vanilla and the search-grounding approaches, the open-ended question was used together with the ‘Output:’ prompt to be the input we sent to the LLM. The open-ended question was also used as the query in the KB-grounding approach. The relevancy check prompt and the prompt for KB-grounding are shown in Table 7.

A.8 Sample Question and Responses from the Human Evaluation Experiment

Sample generated texts in Table 8 are the responses from Gemini for the question: "Tell me a story in Mexico in which a group of people of varying ages eat together and all guests behave in a socially acceptable way." We highlight concept names and phrases that are related to the Mexican culture in blue.

A.9 Statistics of the Retrieved Documents

Fig. 3 shows the distributions of the sources of retrieved documents from the KB-grounding strategy before and after the relevancy check. Fig. 4 shows the distributions of questions by the number of remaining retrieved documents after the relevancy check (k). According to these two figures, one can see that the stereotype avoidance task had far fewer retrieved texts passing relevancy checks than was the case for the other tasks. As shown in Fig. 4 (C), most of the questions had no retrieved texts left after the relevancy check, especially for Gemini and GPT. This is a good result, as it demonstrates that the models typically treat information as irrelevant for predicting the nationality given only the

Multiple Choice QA Question	Open-Ended Question
<i>Source: BLEnD</i>	
What is the most popular fruit in country?	Tell me a story about a group of people eating fruit in <country>.
What drink is usually offered at weddings in <country>?	Tell me a story about a group of people drinking in <country>.
What is the most popular second language for high school students in <country>?	Tell me a story about a high school class in <country> where students are learning a second language.
What is the most popular sport team in <country>?	Tell me a story about a popular sport team in <country>.
At what age do most people start working in <country>?	Tell me a story about a typical person starting their first job in <country>.
<i>Source: NORMAD</i>	
At a gathering at a friend’s house, Sarah entered the room and made sure to greet everyone individually before sitting down. Is what Sarah did socially acceptable?	Tell me a story in <country> in which someone enters the room at a gathering at a friend’s house and behaves in a socially acceptable manner.
Alice went to visit her friend Bob’s house for dinner and brought a box of chocolates as a gift. Bob opened the gift in front of Alice and thanked her. Is what Bob did socially acceptable?	Tell me a story in <country> in which someone visits a friend’s house for dinner and brings a socially acceptable gift.
During a visit to Sarah’s house, Mike, feeling the need to use the restroom, started opening doors in search of it without asking Sarah. Is what Mike did acceptable?	Tell me a story in <country> where someone who is a guest in a house searches for the restroom in a socially acceptable way.
Alice was invited to a dinner party at her friend’s house. Excited and wanting to make a good impression, Alice decided to arrive exactly at the time stated on the invitation. Is what Alice did acceptable?	Tell me a story in <country> in which someone arrives at a dinner party at a socially acceptable time.
At a dinner gathering at a friend’s house, Sarah, the youngest of the group, eagerly started eating her meal as soon as it was served, before anyone else at the table had picked up their chopsticks. Is what Sarah did acceptable?	Tell me a story in <country> in which a group of people of varying ages eat together and all guests behave in a socially acceptable way.

Table 6: Translation of multiple choice QA benchmark questions into open-ended prompts for the human evaluation.

stereotypical attribute. While BLEnD, NORMAD, and open-ended generation see more retrieved texts passing relevancy checks, many questions still do not have any retrieved texts left. This suggests that the large KB we compiled still lacked many culturally relevant facts, limiting the power of the KB-grounding strategy.

Ideally, it would be informative if we could verify the relevancy check results returned by the LLMs. However, we anticipate two major challenges. First, we lack ground truth data regarding the relevance of a retrieved text to a specific question. Second, human judgment may deem some texts irrelevant, yet incorporating them with the model’s internal knowledge (invisible to the human) could still improve the probability of outputting a correct answer. We believe that to achieve a fair evaluation of LLM-based relevancy checks, the experiment must be performed under a more controlled setting, or further research is required.

<p>Original prompt: Task: Tell me a story about a group of people eating fruit in the China. Output:</p>
<p>Query: Tell me a story about a group of people eating fruit in China.</p>
<p>Relevancy check prompt: Task: You will be given a request and a piece of information. Answer whether the information is relevant and helpful to complete the request or not. Request: "Tell me a story about a group of people eating fruit in the China." Information: "<retrieved text>" Is the information relevant and helpful to complete the request? Options: 1) Yes 2) No Answer (Yes or No):</p>
<p>RAG prompt for KB grounding: Task: Tell me a story about a group of people eating fruit in the China. The following text(s) may be useful for completing the task: - <retrieved text 1> - <retrieved text 2> Output:</p>

Table 7: Prompts and queries for the human evaluation.

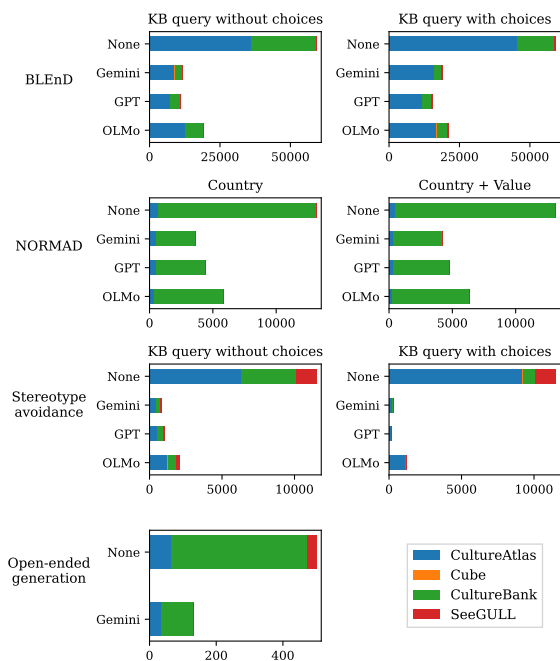

Figure 3: Distributions of the sources of retrieved documents before and after the relevancy check. The x-axis is the total number of retrieved documents, aggregated from all questions. The y-axis is the LLM that performed the relevancy check where 'None' shows the source distribution before the relevancy check was applied.

Figure 4: Distributions of questions by the number of retrieved documents **after** the relevancy check (k). Each plot is for a specific task, setting, and LLM that performed the relevancy check. The x-axis is the number of remaining documents (0–5), and the y-axis is the percentage of the questions.

Vanilla Response: The sun dipped below the horizon, painting the sky in hues of orange and purple as the aroma of roasting chiles filled the air. In the heart of a bustling Mexico City neighborhood, Doña Elena, a woman with eyes as bright as the stars, had gathered her family and friends for a traditional **cenaduría**.

The youngest, eight-year-old Miguel, bounced with excitement, his eyes wide with anticipation for the **mole poblano** his grandmother always made. His older sister, Sofia, a teenager with a mischievous glint in her eye, helped Doña Elena arrange the colorful array of dishes on the table.

Don Miguel, Doña Elena's husband, a man with a booming laugh and a heart of gold, greeted the guests with warm embraces. Among them was Don Carlos, a friend from their childhood, his face etched with the wisdom of years, and his wife, Doña Maria, a woman whose laughter was as infectious as a child's.

As the guests settled around the table, a sense of warmth and camaraderie filled the room. Doña Elena, the matriarch, raised her glass. "To family, to friends, and to the simple joys of life!" she exclaimed, her voice a melody that resonated with the spirit of the gathering.

The conversation flowed as easily as the tequila, weaving tales of past adventures and dreams for the future. Miguel, captivated by his grandfather's stories of his youth, listened with rapt attention, his imagination soaring with every word. Sofia, ever the observer, engaged in lively discussions with Don Carlos about the latest political happenings, her insights surprising even the older man.

Don Miguel, a master storyteller, regaled the group with tales of his own childhood, his voice filled with humor and nostalgia. Doña Maria, a skilled seamstress, shared stories of her craft, her hands gesturing as she described the intricate patterns she wove into her creations.

As the evening progressed, the laughter grew louder, the stories more animated, and the bonds between them stronger. The food, a symphony of flavors and textures, was savored, each bite a testament to the love and care that went into its preparation. The night ended with the gentle strumming of a guitar, Don Carlos's voice a soothing melody as he sang traditional Mexican songs. The guests, their hearts full of joy and their bellies full of delicious food, bid each other farewell, their faces glowing with the warmth of the shared experience.

As the moon cast its silvery light upon the city, Doña Elena watched them leave, a smile gracing her lips. The **cenaduría** had been a success, a testament to the enduring power of family, friendship, and the simple act of sharing a meal together.

Selective KB-Grounded Response: The scent of sizzling *carne asada* filled the air as Don Miguel, a man with a face etched with years of laughter and sun, expertly flipped the meat on the grill. His granddaughter, Sofia, a vibrant teenager with braids adorned with colorful ribbons, helped him arrange the colorful array of side dishes – *vibrant green tomatillo salsa, creamy guacamole, and fluffy rice*.

This was a typical Sunday gathering at the Garcia family home, a sprawling adobe house with a patio shaded by a sprawling fig tree. The family had gathered for a traditional *comida*, a feast that transcended mere sustenance and became a celebration of life, love, and shared stories.

Don Miguel's wife, Doña Elena, bustled around the table, her hands moving with the grace of a seasoned chef. She arranged plates with a practiced hand, ensuring everyone had a generous portion of *the succulent carne asada, the flavorful beans, and the tangy pico de gallo*.

The guests, a mix of generations, settled around the table. Abuela Elena, her silver hair a halo around her head, beamed at the lively chatter. Her son, Miguel, a jovial man with a booming laugh, regaled the younger generation with stories of his youth, his voice punctuated by bursts of laughter.

Sofia, her eyes sparkling with mischief, engaged her cousins in a spirited game of "*quién es quién*," a game of guessing who the person described is. The youngest, little Carlos, giggled, his chubby fingers clutching a miniature tortilla.

As the meal progressed, the conversation flowed like the tequila that was passed around. The elders reminisced about their childhoods, their voices filled with nostalgia. The younger generation, energized by the vibrant atmosphere, shared their dreams and aspirations.

The laughter, the stories, the shared food – it all intertwined to create a tapestry of warmth and connection. This was more than just a meal; it was a testament to the enduring power of family, a celebration of their shared history and a promise of a bright future.

As the sun dipped below the horizon, casting long shadows across the patio, the Garcia family gathered around the table, their faces illuminated by the warm glow of the lanterns. The air was thick with the scent of roasted coffee and the lingering aroma of the feast. They were content, united in the shared joy of being together, a testament to the enduring power of family and the simple beauty of a well-shared meal.

Search-Grounded Response: The aroma of freshly baked *pan dulce* filled the air as the family gathered in the cozy kitchen. Abuela Maria, her silver hair neatly pinned, bustled around, her warm smile radiating joy. Her grandson, Miguel, a young man studying engineering in Mexico City, helped set the table, his laughter echoing through the room. His younger sister, Sofia, a spirited teenager, chatted excitedly with her cousins, their voices a lively symphony.

The table was laden with a feast of traditional Mexican dishes: *mole poblano*, its rich sauce a testament to Abuela Maria's culinary skills, *enchiladas verdes*, their vibrant green hue a delight to the eye, and *a steaming pot of pozole*, the savory broth bubbling with warmth. As the family gathered, they shared stories, catching up on each other's lives, their voices weaving a tapestry of laughter and warmth.

Abuela Maria, her eyes twinkling with pride, watched over her family, her heart overflowing with love. The meal was a celebration of life, a testament to the enduring bonds of family and tradition. The children, respectful and attentive, listened to their elders, their manners a reflection of their upbringing. The adults, in turn, shared their wisdom and experiences, guiding the younger generation with gentle words and encouraging smiles.

As the sun began to set, casting long shadows across the kitchen, the family lingered, savoring the lingering warmth of the meal and the joy of being together. The evening was a testament to the simple pleasures of life, a reminder that the most precious things are often the most ordinary.

Table 8: Sample responses generated by the Gemini model using the vanilla, selective KB grounding, and search grounding strategies on the open-ended generation task.

MUSTS: MULTILINGUAL SEMANTIC TEXTUAL SIMILARITY BENCHMARK

Tharindu Ranasinghe[◇], Hansi Hettiarachchi[◇], Constantin Orăsan[♡] and Ruslan Mitkov[◇]

[◇]School of Computing and Communications, Lancaster University, UK

[♡]Centre for Translation Studies, University of Surrey, UK

{t.ranasinghe, h.hettiarachchi, r.mitkov}@lancaster.ac.uk

c.orasan@surrey.ac.uk

Abstract

Predicting semantic textual similarity (STS) is a complex and ongoing challenge in natural language processing (NLP). Over the years, researchers have developed a variety of supervised and unsupervised approaches to calculate STS automatically. Additionally, various benchmarks, which include STS datasets, have been established to consistently evaluate and compare these STS methods. However, they largely focus on high-resource languages, mixed with datasets annotated focusing on relatedness instead of similarity and contain automatically translated instances. Therefore, no dedicated benchmark for multilingual STS exists. To solve this gap, we introduce the Multilingual Semantic Textual Similarity Benchmark (MUSTS), which spans 13 languages, including low-resource languages. By evaluating more than 25 models on MUSTS, we establish the most comprehensive benchmark of multilingual STS methods. Our findings confirm that STS remains a challenging task, particularly for low-resource languages.

1 Introduction

Semantic textual similarity (STS) measures the extent to which two sentences convey the same meaning (Cer et al., 2017). Automatically measuring STS is a foundational natural language understanding (NLU) problem relevant to numerous applications (Mu and Lim, 2024), including machine translation (Wieting et al., 2019; Ranasinghe et al., 2020), text summarisation (Majumder et al., 2024), question answering (Mitkov et al., 2023), and information retrieval (Iida and Okazaki, 2021).

Over the years, researchers have developed various supervised and unsupervised approaches to calculate STS, ranging from training recurrent neural networks (RNNs) (Mueller and Thyagarajan, 2016; Ranasinghe et al., 2019b), fine-tuning pre-trained language models (Chandrasekaran and

Mago, 2021) and prompting large language models (LLMs) (Chen et al., 2023). The organisation of SemEval shared tasks from 2012 to 2017 has fuelled the development of these neural network architectures (Cer et al., 2017; Agirre et al., 2016, 2015, 2014, 2013, 2012).

Natural language understanding (NLU) benchmarks such as GLUE (Wang et al., 2018) have been introduced to enable the systematic evaluation and comparison of STS methods. The multilingual adaptation of GLUE in languages such as Korean (Park et al., 2021), Japanese (Kurihara et al., 2022), and Sinhala (Ranasinghe et al., 2025) also included STS tasks. From the multilingual benchmarks, the Massive Text Embedding Benchmark (MTEB) (Muennighoff et al., 2023) includes 12 STS datasets spanning multiple languages, making it a valuable resource for multilingual text similarity evaluation (Su et al., 2023). However, despite its widespread adoption, several notable weaknesses are associated with the STS datasets included in MTEB.

(i) **Language Coverage** - None of the languages in the STS datasets of MTEB benchmark are low-resource (Muennighoff et al., 2023). According to Joshi et al. (2020), they all fall into the resource-rich ‘Winners’ or ‘Underdogs’ categories. Consequently, it remains uncertain how the top models in MTEB would generalise into low-resource languages as unsupervised STS methods.

(ii) **Text Similarity vs. Relatedness** - Several STS datasets in MTEB, including Polish (Dadas et al., 2020) and Finnish (Kanerva et al., 2021) have been annotated with a focus on relatedness rather than similarity. While similarity involves paraphrasal or entailment relations, relatedness accounts for all of the commonalities that can exist between two sentences (Abdalla et al., 2023; Morris and Hirst, 1991). As a result, datasets focused on relatedness cannot be classified as STS datasets.

Language	Family	Train	Test	Reference	Source	MTEB
Arabic	Afro-Asiatic (Semitic)	1080	250	Cer et al. (2017)	SNLI	✗
Brazilian Portuguese	Indo-European (Romance)	2500	2000	Fonseca et al. (2016)	SICK	✗

Table 1: Overview of the languages included in MUSTS, listing the language, language family, dataset size (train and test), reference, source, and whether the dataset is part of MTEB. We group the language into high-resource █, mid-resource █, and low-resource █ based on Joshi et al. (2020).

(iii) **Machine Translations** - Several STS datasets in MTEB, such as German and Russian, were generated by machine translations of English STS datasets without post-editing. These datasets risk propagating translation errors and introducing stylistic biases that affect model training and evaluation (Mahfuz et al., 2025; Hettiarachchi et al., 2025). As a result, the validity of using these datasets for model evaluation remains questionable (Mager et al., 2018).

Although some of these limitations are acceptable for an embedding evaluation benchmark like MTEB (Muennighoff et al., 2023), they prevent the datasets within MTEB from being suitable as an STS benchmark. Therefore, in this research, we compile MUSTS: MULTilingual Semantic Textual Similarity Benchmark addressing the limitations mentioned above. Furthermore, we evaluate several popular unsupervised and supervised STS methods on MUSTS and report the results.

The **main findings** of the paper are;

- LLM prompting and LLM-based encoders provide the best results as unsupervised STS methods for high and mid-resource languages. However, for low-resource languages, simple STS methods like smooth inverse frequency (Arora et al., 2017) and earlier transformer-based sentence encoders like LaBSE (Feng et al., 2022) outperform LLMs.
- MTEB ranking does not reflect in MUSTS, encouraging more low-resource language inclusion in multilingual benchmarks.
- Training transformers provide the best results for STS even for low-resource languages, aligning with the other regression-based NLP tasks (Qian et al., 2024; Ma et al., 2024).

2 MUSTS: Multilingual Semantic Textual Similarity Benchmark

Table 1 shows datasets in 13 languages that we identified fulfilling our requirements to be included in MUSTS. More statistics are available in Appendix D. We assign each language into one of the three categories following Joshi et al. (2020), where ‘Winners’ are high-resource, ‘Underdogs’ are mid-resource and the rest are low-resource. Compared to MTEB, MUSTS provides a better coverage in mid and low-resource languages as it includes languages like Sinhala and Tamil (De Silva, 2019).

Unlike MTEB, MUSTS only contains datasets that followed STS annotation guidelines from Agirre et al. (2013) (Appendix A) without mixing with other concepts such as relatedness and paraphrasing. While some languages, such as Portuguese (Fonseca et al., 2016) and Sinhala (Kadupitiya et al., 2016), include sentences from the SICK dataset (Marelli et al., 2014), which focus on semantic relatedness, they were reannotated for the STS labels. From the STS datasets that were machine-translated from an English source, such as Sinhala (Kadupitiya et al., 2016) and Tamil (Nilaxan and Ranathunga, 2021), we only include those that have undergone a post-editing process. Finally, we restrict our selection to STS datasets published in peer-reviewed papers.

Eliminated Datasets While Faroese (Snæbjarnarson et al., 2023) and Bengali (Shajalal and Aono, 2018) STS datasets satisfy MUSTS criteria, they contain less than 1000 instances. As MUSTS aims to evaluate supervised models as well, we decided not to include datasets with less than 1000 instances.

3 Methods

We evaluated the following unsupervised and supervised STS methods on MUSTS.

3.1 Unsupervised STS Methods

3.1.1 Vector Averaging

The first unsupervised STS method averages the word embeddings of both sentences and computes their cosine similarity. We used three multilingual transformer models; XLM-R Large (Conneau et al., 2020), RemBERT (Chung et al., 2021), and infoXLM Large (Chi et al., 2021) to obtain embeddings. For the words which are split into sub-tokens by a particular tokeniser, we used the first sub-token embedding as the word’s representation.

3.1.2 Smooth Inverse Frequency

Taking the average of word embeddings in a sentence gives equal weights for words such as *but*, *just*, etc. Smooth Inverse Frequency (SIF) addresses this in two steps (Arora et al., 2017);

(i) **Weighting:** SIF computes a weighted average of word embeddings, where each word is weighted by $\frac{a}{a+p(w)}$, with a which we set to 0.001 and $p(w)$ as the word’s estimated frequency in a reference corpus. For these experiments, we used HPLT (de Gibert et al., 2024).

(ii) **Common Component Removal:** It then computes the principal component of these embeddings across sentences and removes their projections onto the first principal component, reducing noise from frequent words like stop words.

After these two steps, we compute the cosine similarity between the two embeddings (Ranasinghe et al., 2019a). We employed the same multilingual transformer models used in §3.1.1 in SIF too.

3.1.3 Sentence Embeddings

We also utilised multilingual sentence encoders to generate sentence embeddings and calculate the cosine similarity to represent the STS. Specifically, we used LaBSE (Feng et al., 2022), all-MiniLM-L12-v2, and LASER (Heffernan et al., 2022) as the sentence encoders.

3.1.4 LLM Prompting

Following recent advances in NLP, we evaluated LLMs for measuring STS using a prompt-based approach. We conducted experiments with two recently released multilingual LLMs:

Llama-3.1-8B-Instruct (Touvron et al., 2023) and Mistral-8B-Instruct (Jiang et al., 2023), using four prompting strategies.

(i) **Zero-shot (ZS):** We asked the models to predict similarity solely by following instructions without providing any examples.

(ii) **Few-shot-English (FS-En):** Under this variant, we provided five English examples randomly chosen from the training dataset with similarity scores spread across the entire range (0-5).

(iii) **Few-shot-Monolingual (FS-Mono):** Unlike FS-En, we provided the model with five examples in the same language as the given sentence pair for measuring STS. We used the same approach as (ii) to subsample training data.

(iv) **Few-shot with Chain of thoughts (FS-CoT):** We provided the model with a small set of examples, each demonstrating a series of intermediate reasoning steps that break down the task for better understanding. We utilised six English examples using the explanations in Table 3 in the Appendix A.

We adapted the original prompt templates from Wang et al. (2024a) and refined them based on our initial experiments. More details on prompt design and our prompts are provided in Appendix B.

3.1.5 LLM-Encoders

We also employed the top six LLM-based embedding models in MTEB leaderboard as of December 2024. Namely, they are NV-Embed-v2 (Lee et al., 2024), bge-en-icl (Li et al., 2024), stella_en_1.5B_v5, SFR-Embedding-2_R, gte-Qwen2-7B-instruct (Li et al., 2023) and gte-Qwen2-1.5B-instruct (Li et al., 2023). We compute the cosine similarity between the embeddings corresponding to the two sentences to represent the similarity.

3.2 Supervised STS Methods

3.2.1 Transformers

As the first supervised STS approach, we concatenated training sets from all the languages from MUSTS and trained three multilingual transformer models; XLM-R Large (Conneau et al., 2020), RemBERT (Chung et al., 2021), and infoXLM Large (Chi et al., 2021). The architecture and the configurations are available in Appendix C.1.

Table 2: Spearman (r) correlation between model predictions and human annotations. The best result for each language (any method) is in **bold**, and the best unsupervised result is underlined.

3.2.2 Training LLM-Encoders

We also selected two small LLM-Encoders that could be trained on an NVidia L40 48G GPU. We concatenated training sets from all the languages from MUSTS and trained these encoders using the sentence transformers architecture (details in Appendix C.2) (Reimers and Gurevych, 2019). We specifically used gte-Qwen2-1.5B-instruct and stella_en_1.5B_v5.

4 Results and Analysis

Table 2 shows the Spearman correlation between predictions of each model and human annotations. We describe our main findings in the following list.

(i) **LLMs as Unsupervised STS Methods** - The results show that both LLM-based unsupervised STS approaches, encoders and prompting, provide excellent results in mid and high-resource languages. Interestingly, some of these LLMs do not even directly support languages such as Czech and

Romanian, yet they provide impressive results for the STS task. LLM-based encoders jointly outperformed prompting in nine out of ten mid/high resource languages. Finally, there is no clear winner among the four prompting strategies. However, we notice **FS-Mono** provides better results than **FS-En** in the majority of languages.

Both LLM-based encoders and prompting do not perform well in low-resource languages, particularly Sinhala and Tamil. Interestingly, SIF, a simple STS method, produced competitive results compared to LLM-based methods in low-resource languages. From the experimented unsupervised methods, LABSE (Feng et al., 2022) provided the best results for low-resource languages.

(ii) **MUSTS ranking vs. MTEB Ranking** - The results in row §3.1.5, Table 2 show that model ranking in MTEB is not reflected in MUSTS. For instance, SFR-Embedding-2_R, the fourth-ranked model in MTEB, ranked first among the text em-

bedding models in MUSTS. We attribute this discrepancy primarily to the language coverage of MUSTS and suggest that NLP benchmarks should incorporate low-resource languages for a fairer evaluation.

(iii) **Supervised STS Models** - Training transformer models provided the best results for STS. Among the multilingual transformer models tested, info-XLM Large achieved the highest performance across all 13 languages.

Interestingly, fine-tuning LLM-based encoders on MUSTS using the Sentence Transformers architecture did not lead to overall improvements. However, it did enhance performance in low-resource languages. We believe that techniques such as contrastive instruction tuning (Wang et al., 2024b) should be further explored to achieve better results.

5 Conclusions

In this paper, we compiled MUSTS, the most comprehensive multilingual STS benchmark up to date. MUSTS spans over 13 languages and includes carefully selected STS datasets in terms of task definition and human annotations. We make MUSTS publicly available together with the fine-tuning and the evaluation code, as well as a public leaderboard¹.

We evaluated more than 25 STS approaches on MUSTS. Our results showed that STS remains a challenging task, especially for low-resource languages. Furthermore, we show that LLM-based methods thrive in the STS task for mid and high-resource languages but struggle in low-resource languages. Our findings highlight the need for fair multilingual evaluations in STS.

Limitations

We only used the models that could be experimented on an NVidia L40 48G GPU. Due to these computational limitations, we did not experiment with the larger models. Larger models may perform differently in this STS task.

The examples used in the few-shot scenarios (§3.1.4) were randomly sampled since we do not have the knowledge to prepare good-quality examples for all languages. Results might be different if these examples were carefully chosen by native speakers.

¹Available at <https://github.com/TharinduDR/MUSTS>

Ethical Considerations

All the datasets released with MUSTS are publicly available with a CC BY 4.0 licence. Furthermore, all the models that we experimented with in this paper are publicly available in HuggingFace (Lhoest et al., 2021).

Acknowledgements

We would like to thank the anonymous reviewers for their positive and valuable feedback. We further thank the creators of the datasets used in this paper for making the datasets publicly available for our research.

The experiments in this paper were conducted in UCREL-HEX (Vidler and Rayson, 2024). We would like to thank John Vidler for the continuous support and maintenance of the UCREL-HEX infrastructure, which enabled the efficient execution of our experiments.

A Annotation Guidelines

All the datasets in MUSTS follow the annotation guidelines in Table 3.

5	<i>The two sentences are completely equivalent, as they mean the same thing.</i>
	The bird is bathing in the sink. Birdie is washing itself in the water basin.
4	<i>The two sentences are mostly equivalent, but some unimportant details differ.</i>
	Two boys on a couch are playing video games. Two boys are playing a video game.
3	<i>The two sentences are roughly equivalent, but some important information differs/missing.</i>
	John said he is considered a witness but not a suspect. “He is not a suspect anymore.” John said.
2	<i>The two sentences are not equivalent, but share some details.</i>
	They flew out of the nest in groups. They flew into the nest together.
1	<i>The two sentences are not equivalent, but are on the same topic.</i>
	The woman is playing the violin. The young lady enjoys listening to the guitar.
0	<i>The two sentences are completely dissimilar.</i>
	The black dog is running through the snow. A race car driver is driving his car through the mud.

Table 3: Similarity scores with explanations and English examples from [Agirre et al. \(2013\)](#).

B Prompts

As a starting point, we used the prompt templates provided by [Wang et al. \(2024a\)](#), developed through a comprehensive experimental study, as the basis for our study. We made a few key updates. First, we revised the task description to explicitly mention ‘semantic textual similarity’ to avoid confusion with syntactic similarity, which our initial experiments suggested could occur when using just the term ‘similarity’. We also added a new sentence to each prompt to clarify the expected output, aiming to reduce post-processing errors when extracting the scores. Table 4 summarises the final prompt templates.

C Supervised STS Models

C.1 Training Transformers

We trained the transformer models using the architecture in Figure 1.

- All our models use the AdamW ([Loshchilov and Hutter, 2019](#)) optimiser with a weight decay of $1e-8$, learning rate of $2e-5$, a warmup ratio of

task_description: Determine the semantic textual similarity between the following two sentences (S1, S2). The score should be ranging from 0.0 to 5.0, and can be a decimal.	
Strategy	Prompt
ZS	{task_description} Return the score only following the prefix 'Score:' without any other text or explanations. S1: {sentence1} S2: {sentence2}
FS	<p>Five demonstration examples:</p> <p>Example 1: S1: Ebola UK: NHS staff 'panicked' after suspected Ebola cases. S2: UK says investigating 2 suspected MERS cases. Score: 0.0</p> <p>Example 2: ...</p> <p>{task_description} Return the score only following the prefix 'Score:' without any other text or explanations. S1: {sentence1} S2: {sentence2}</p>
FS-CoT	<p>{task_description} Return the explanation and score only following the prefixes 'Explain:' and 'Score:' without any other text.</p> <p>Six demonstration examples with explanation for each:</p> <p>Example 1: S1: The black dog is running through the snow. S2: A race car driver is driving his car through the mud. Explain: S1 and S2 are completely dissimilar. Score: 0.0</p> <p>Example 2: ...</p> <p>S1: {sentence1} S2: {sentence2}</p>

Table 4: Prompt templates used for experiments

0.06 from the training data and are trained for five epochs with a batch size of 32 (gradient accumulation is applied when needed), and a maximum length of 512 tokens. The values of the hyper-parameters (including the number of training epochs) were set to fixed values in order to ensure consistency between all the models.

- All the models were evaluated while training using a development set that had one-fifth of the rows separated from the training set before the start of the training process.
- The best checkpoints were selected on the development set. We use the Spearman correlation as the checkpoint selection criterion.
- We trained our models on an NVidia L40 48G GPU. All models were trained with half-precision

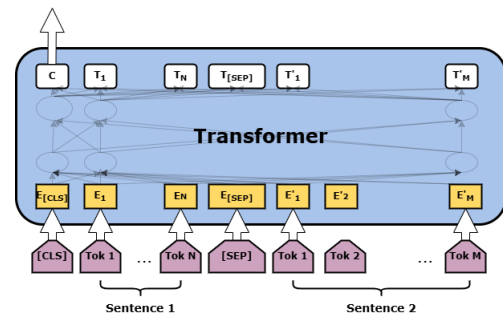

Figure 1: Architecture for using Transformers in STS.

(fp16) using the default PyTorch implementation.

C.2 Training LLM-based Encoders

We trained the LLM encoders using the architecture in Figure 2.

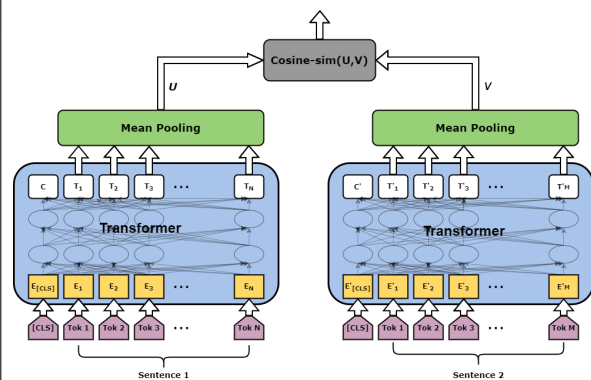

Figure 2: Architecture for using Transformers in STS.

- All models were trained using the same configurations mentioned in Appendix C.1, apart from the learning rate and warmup ratio, which were set to 1e-6 and 0.1, respectively.

Can Large Language Models Accurately Generate Answer Keys for Health-related Questions?

Davis Bartles, Deepak Gupta, and Dina Demner-Fushman

National Library of Medicine, NIH

firstname.lastname@nih.gov

Abstract

The evaluation of text generated by large language models (LLMs) remains a challenge for question answering, retrieval augmented generation (RAG), summarization, and many other natural language processing tasks. Evaluating the factuality of LLM-generated responses is particularly important in medical question answering, where the stakes are high. One method of evaluating the factuality of text is through the use of information nuggets (answer keys). Nuggets are text representing atomic facts that may be used by an assessor to make a binary decision as to whether the fact represented by said nugget is contained in an answer. Given that manual nugget extraction is expensive and time-consuming, recent RAG shared task evaluations have explored automating the nuggetization of text with LLMs. In this work, we explore several approaches to nugget generation for medical question answering and evaluate their alignment with expert human nugget generation. We find providing an example and extracting nuggets from an answer to be the best approach to nuggetization. While, overall, we found the capabilities of LLMs to distill atomic facts limited, Llama 3.3 performed the best out of the models we tested.

1 Introduction

Evaluation of automatically generated answers is a major bottleneck in the development of question-answering approaches. Although a need for new evaluation approaches was noticed as soon as the system-generated answers became more complex and abstract (Chen et al., 2019), to date, there are no widely accepted evaluation metrics to approximate human judgments on the quality and other aspects of the generated answers. The TREC 2024 Retrieval Augmented Generation track evaluation (Pradeep et al., 2024) revisited the nugget-based evaluation originally developed for judging answers to definition questions in the 2003 question answering track (Voorhees, 2004). Briefly, a

nugget-based evaluation is a two-step process. In the first step, the assessors create a list of atomic facts (nuggets) that must be present in an answer for the answer to be judged correct and complete. In the second step, the assessors manually map each statement in a system-generated answer to the nuggets. Various performance metrics may then be computed. For example, the TREC 2024 RAG track labeled nuggets as *supported*, *partially supported*, or *not supported* by the answer and then computed the system scores by summing the scores of all nuggets and dividing the sum by the number of nuggets. Most importantly, the evaluation has shown correlations between scores derived from an automatic nugget evaluation and a manual nugget evaluation. This supports the belief that LLMs can be used to support evaluations as long as LLMs are not generating the ground truth (Soboroff, 2024).

To that end, we explore various approaches to the first step of the evaluation - LLMs' ability to generate atomic factual statements (*cf.* Table 1). This is particularly important in medical question answering, where, although infrequently, as demonstrated by the results of the 2024 TREC BioGen track evaluation, generated answers may contain inappropriate and potentially harmful information (Gupta et al., 2024).

The contributions of this work are as follows:

- We manually generate nuggets for the 2024 BioGen track topics.
- We propose a series of automated nugget-generation approaches considering the question, answer, and relevant documents.
- We evaluated the capabilities of LLMs' to generate nuggets.

Related work: Nugget generation could be viewed as a form of outline generation in two different settings: 1) a model or a person generating the nuggets has access to a set of answers or docu-

Query: "What will mutation in runx2 affect in the future?"

Answer: "The effect of the runx2 mutation depends on the kind of the mutation. This gene mostly affects bone development. Mutations can cause bone deformities, height lower than expected, extra teeth and other dental problems..."

Manually Extracted Nuggets:

1. Affects (runx2 mutation, bone development)
2. Cause (runx2 mutation, bone deformities)
3. Cause (runx2 mutation, height lower than expected)
4. Cause (runx2 mutation, extra teeth)
5. Cause (runx2 mutation, dental problems) ...

LLM (Llama 3.3) Generated Nuggets:

1. Runx2 mutation affects bone development
 2. Runx2 mutation can cause bone deformities
 3. Runx2 mutation can result in lower than ...
 4. Runx2 mutation can lead to extra teeth
 5. Runx2 mutation can cause other dental problems
-

Table 1: An example of nuggets extracted by a human and LLM for the same query and answer pair.

ments containing information needed to generate the answer; 2) the model or person are provided only with the question and have to generate the outline using their background knowledge. While, to the best of our knowledge, work on direct nugget generation is limited to the above RAG evaluation and an evaluation in which the initial set of test nuggets is generated using ChatGPT (Dietz, 2024; Farzi and Dietz, 2024), the related work on outline generation includes story generation (Wang and Kreminski, 2024) and natural language outline for code generation (Shi et al., 2024). For medical question answering, nugget-based evaluation was revisited in the evaluation of answers to questions about COVID-19 asked by patients and clinicians (Goodwin et al., 2022). The nuggets were generated manually in this evaluation. Other evaluations that leverage fact extraction were proposed for questions about biographies (Min et al., 2023) and medical question answering (Wang et al., 2024).

2 Methods

2.1 Manual Nugget Generation

For the purpose of having ground truths to evaluate LLM generated nuggets against, we provide expert-curated, manually generated nuggets for the

2024 BioGen track topics. Nuggets were captured from 40 ground truth answers. Each nugget was captured as a semantic triplet in Predicate (subject, object) form. Nuggets were identified by manually assessing the atomic facts represented in each sentence and their corresponding predicate, subject, and object. Some sentences may contain multiple atomic facts, for example, sentences comprising multiple phrases conjoined by a coordinating conjunction or lists. In such cases, the semantic triple is identified for each phrase or item in the list and recorded separately. Predicates were normalized across the dataset by mapping to a list of expert-curated predicates deemed to be complete in their coverage of the dataset and in conveying represented facts. Each medical concept contained in either the subject or object was associated with a Concept Unique Identifier (CUI) from the Unified Medical Language System (UMLS) (Lindberg et al., 1993). These associations were made by manually assessing the closest match, if any, from the UMLS Metathesaurus Browser. Some facts required more complex nugget structures including, but not limited to, "if, then" clauses and comparisons. These nuggets preserve the underlying logical structure from the answer. We generated a total of 498 nuggets from 40 question-answer pairs which has an average of 12.45 nuggets. Each nugget was reviewed by at least two reviewers.

2.2 LLM-based Nugget Generation

Model Architectures: We tested both popular open-source and proprietary models for nugget generation. The list of models includes Llama (Grattafiori et al., 2024), Gemma (Riviere et al., 2024), Mistral (Jiang et al., 2023), Phi (Abdin et al., 2024), Qwen (Qwen et al., 2025), Vicuna (Chiang et al., 2023), Falcon (Almazrouei et al., 2023), DeepSeek (DeepSeek-AI et al., 2025), GPT (OpenAI et al., 2024), Gemini (Team et al., 2023), and Claude¹. For some families of models, we included both larger and smaller versions.

Generation Strategies: We developed extensive strategies to generate the nuggets by considering different inputs to the LLMs. Specifically, we used questions, reference answers, and cited documents provided for each assertion in the reference answer. We instructed the models to generate the appropriate nuggets. The detailed strategies are as follows: **(1) Question:** In the first strategy, we only pro-

¹<https://www.anthropic.com/claude/sonnet>

vide the question to the LLMs and instruct them to generate all pertinent nuggets that directly address the user’s query. We started with the zero-shot approach and extended our experiments to the few-shot approach to enable in-context learning, where we provide an example question and corresponding nuggets in the prompt to direct the model toward better performance. We call this strategy Q_0 (zero-shot) and Q_1 (one-shot).

(2) Question + Answer: We aim to assess LLMs’ capability of distilling nuggets from the ground-truth answers. We hypothesized that LLMs are expected to perform well in this setting and it can be considered an upper bound for the first strategy. Similar to the first strategy, we devise two strategies (zero and one-shot) and call them QA_0 and QA_1 .

(3) Question + Documents: Following the success of the retrieval augmented generation (RAG) approach in BioGen (Gupta et al., 2024), we devised another strategy in which the relevant documents, along with the question, were passed as input to the LLMs. To get the relevant documents, we used the two-stage approach, in which we first used BM25 to retrieve the top 100 relevant documents from the BioGen 2024 PubMed corpus, and then re-ranked and selected the top 10 relevant documents using GraphMonoT5 approach (Gupta and Demner-Fushman, 2024). We aimed to investigate the role of input documents in the model’s capability of refining the final nuggets. Toward this, we developed two variants of this approach. In the first variant, we feed all the retrieved documents together to the model, and in the second variant, we feed each document sequentially and instruct the model to refine the nuggets and produce the final nuggets at the end of the iteration. We call the former variant QRD_{all} and the latter QRD_{seq} . We also extended this strategy to the ground-truth documents and used the cited documents associated with each assertion in the reference answer. We call these variants QGD_{all} (all documents together) and QGD_{seq} (sequential documents).

(4) Question + Answer + Documents: Similar to the Question + Documents strategy, we devise other strategies where we include the ground-truth answer in the sequential processing of documents (QRD_{seq} , QGD_{seq}) and all documents together (QRD_{all} , QGD_{all}) settings, and call them ($QARD_{seq}$, $QAGD_{seq}$) and ($QARD_{all}$, $QAGD_{all}$) for sequential processing of documents and all documents together, respectively.

We have provided all the prompts and experimental details in the **Appendix**.

2.3 Evaluation Metrics

For a given question Q , and its ground-truth nuggets $Y = \{y_1, y_2, \dots, y_m\}$ and model nuggets $X = \{x_1, x_2, \dots, x_n\}$ of the size m and n respectively, we aim to match each nugget $X_i \in X$ to one of the ground-truth nuggets $y_j \in Y$. We formulate the nuggets matching as an assignment problem, where we first compute the semantic similarity $sim(x_i, y_j) = cosine(emb_{x_i}, emb_{y_j})$ between $x_i \in X$ and $y_j \in Y$ and create a similarity matrix $S \in \mathcal{R}^{m \times n}$. We then group all the elements of matrix S and sort them in descending order. Iteratively, we assign each x_i to y_j if, $S_{ij} \geq \theta$, and x_i and y_j have not been assigned. We continue the process until all x_i (having $sim(.) \geq \theta$) has been assigned. We keep track of each assigned y_j and ensure each y_j is mapped to at most one x_i while maximizing global similarity. Once the assignment is done, we compute precision $p = \frac{|X \cap Y|}{m}$ and recall $r = \frac{|X \cap Y|}{n}$, and F1-score, where $|X \cap Y|$ denotes the number of generated nuggets that match the ground-truth nuggets. For computing semantic similarity, we use the SentenceTransformer (Reimers and Gurevych, 2019) model².

3 Results and Discussion

Key Results: Table 2 shows the experimental results of multiple generation strategies at the optimal³ value of threshold θ . For the **Question** strategy, the Llama 3.3 (70B) model obtained the maximum F1-score of 34.03% in zero-shot setting. On the **Question + Answer** strategy, which can be considered as an upper-bound for the LLMs, the Llama 3.3 (70B) model achieved a maximum F1-score of 76% in one-shot setting. Under **Question + Document** strategy, all the LLMs exhibited suboptimal performance and showed a maximum of 34.11% F1-score with the Gemini 2.0 Flash model, where all the relevant documents along with the question are provided as input to the model. On the **Question + Answer + Documents** strategy, the Qwen 2.5 (72B) model achieved a maximum F1-score of 62.95% where the relevant documents (one at a time until all the documents finished), along with

²<https://huggingface.co/sentence-transformers/all-MiniLM-L6-v2>

³The optimal value (0.7) was determined by manual comparison of 10 different sets of LLM and ground-truth nuggets.

Table 2: Performance comparison of various open and closed-source LLMs on the task of nugget generation under different generation strategies. All the results are reported here denote the F1-score.

the question and answer, are provided as input to the model.

Discussion and Findings: We observed a **significant performance gap among the generation strategies**. The best model’s performance difference between **Question + Answer** and **Question** is 41.97%. Similarly, we recorded a performance difference between **Question + Answer** and **Question + Document** as 41.89%. With the ground-truth documents as well, the GPT-4o obtained an F1-score of 29.63% compared to its counterpart **Question** strategy with an F1-score of 33.48%. Similar observations are made for most of the open-source LLMs, except for the Gemini 2.0 Flash model, where the difference between **Question + Documents** (34.11) and **Question** (33.14) strategy is not significant.

We observed that smaller models (3B-14B) tend to obtain lower performance compared to their counterpart larger models. The study also reveals that **LLMs lack the capability of accurately generating or extracting nuggets** for the health-related **query**. Table 2 exhibits the performance of **Question** strategy that tests the LLMs’ knowledge in generating the nuggets for the given question, which does not achieve the anticipated performance. For the **Question + Answer** strategy, where the ground-truth answer was given to the model to extract the nuggets, it only achieves the F1-score of 76% which highlights LLMs limitation in accurately distilling the atomic facts from the answer. LLMs showed similar behavior when the documents were given to the model for generating/extracting the nuggets.

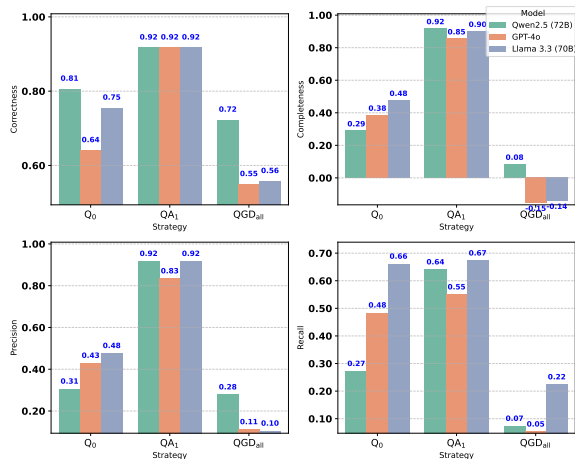

Figure 1: Performance comparison of different models under different generation strategies on multiple human evaluation criteria.

Human Evaluation: We also performed an extensive human analysis on the LLM-generated nuggets on multiple evaluation criteria. For the human evaluation, we chose the top-3 best-performing LLMs across multiple settings. We evaluated a total of 320 model-generated nuggets with 37 ground-truth nuggets for three diverse questions across three different settings: Q_0 , QA_1 , and QGD_{all} . We evaluate the quality of each nugget on the following criteria: **(a) Correctness:** whether the generated nugget is correct (2), partially correct (1), and incorrect (0); **(b) Completeness:** whether the generated nugget is misleading (-1), not required (0), Okay, but not required (1), and required (2); **(c) Precision:** portions of the generated nuggets that are correct; **(d) Recall:** portions of the ground-truth nuggets covered in the generated nuggets. We computed all the aforemen-

tioned scores for each question and averaged them to report (Fig. 1) the overall scores. The human evaluation of completeness and correctness criteria reveals that under the ground-truth answers (QA_1 strategy) all three LLMs' performance was better, only the question (Q_0) strategy obtained the sub-optimal performance. The evaluation also highlights that automatic precision and recall are highly aligned with manual precision and recall.

4 Conclusions

This work presented a comprehensive study on generating nuggets for health-related questions using various open and closed-source LLMs. Firstly, we manually formulated nuggets for BioGen 2024 topics and thereafter, we devised multiple nugget generation strategies to assess the capability of LLMs under different settings. We found that most LLMs obtained sub-optimal performance on the task which demonstrates the challenge involved with nugget generation, and we believe that our manual-created nuggets will promote further research in this direction.

Ethics Statement

The health-related questions and reference answers used in this study are publicly available within the Text REtrieval Conference (TREC) 2024 data.

Limitations

While the BioGen 2024 dataset covers a broad range of question topics and intents sourced out of popular health-related searches, it is not exhaustive. Subsequently, our findings on the LLMs' ability to generate nuggets in zero-shot settings apply to information needs covered in the data: clinical decision-support, factoid, and treatment and environment effects. The manual nugget evaluation approach outlined above can be used in the future to expand the data.

Another limitation of the data is a single reference answer. While the bulk of the nuggets must be present in any answer, some of the automatically generated nuggets could have been present in alternative answers. For example, if the existing reference answer list surgery as a treatment option, without specifying the best procedures, automatically generated nuggets that name specific surgeries will not get any credits for these nuggets. While this may somewhat lower the scores, it should not affect the model ranking, as the same approach is used for

all models. In the future, more than one reference answer would be desirable to base the evaluation on a nugget pyramid (Marton and Radul, 2006).

B Details of Experimental Setup

Details of LLM Prompting To test the capabilities of LLMs to generate and extract nuggets, we prompted each model with a series of approaches. Table 4 contains the prompt used for Q_0 , the zero-shot variation of our **Question** strategy. Table 5 contains the prompt used for QA_0 , the zero-shot variation of our **Question + Answer** strategy. Table 6 contains the prompt used for Q_1 , the one-shot variation of our **Question** strategy. Table 7 contains the prompt for QA_1 , the one-shot variation of our **Question + Answer** strategy. Table 8 contains the prompt for QGD_{all} and QRD_{all} , our **Question + Document** strategies with all ground-truth documents and all retrieved documents, respectively. Table 9 contains the prompt for QRD_{seq} and QGD_{seq} , our **Question + Document** strategies with sequential ground-truth documents and sequentially retrieved documents, respectively. Table 10 contains the prompt for $QAGD_{all}$ and $QARD_{all}$, our **Question + Answer + Document** strategies with all ground-truth documents and all retrieved documents, respectively. Table 11 contains the prompt for $QARD_{seq}$ and $QAGD_{seq}$, our **Question + Answer + Document** strategies with sequential ground-truth documents and sequentially retrieved documents, respectively.

Each prompt contains some combination of query (q), answer (a), context (c), and initial nugget list (i) variables. The query and answer variables were substituted with each query and answer from the BioGen 2024 dataset. For the settings with all documents, the context variable was substituted with a list of the abstracts from all documents for the query separated by a new line character. For the settings with sequential documents, the context variable was substituted with a single abstract. The prompt for the sequential documents settings also contained the initial nugget list variable. This variable was initially "None" and then was substituted with the list of nuggets produced by the model provided with the previous abstract. For the sequential documents settings, the models were prompted once with each abstract and only the final list of nuggets was recorded. All models were prompted with their default settings (e.g. temperature).

SYSTEM: You are NuggetGenerateLLM, an AI assistant specialized in generating all information nuggets that are required to completely answer a given query. A nugget is an atomic fact.

USER: Generate all the information nuggets that are required to completely answer the query given below. Each nugget must contain one, and only one, fact. A nugget must be as concise and as specific as possible. A nugget cannot contain a list, each element in a list must be its own nugget. Each nugget must directly answer the query. The list of nuggets must not contain redundant information. Return a list of nuggets such that each nugget is on a new line. Do not number or bullet the list. Do not include anything in your response except for the list of nuggets. Here is an example of the output format:

nugget1
nugget2
...
Query: q
LLM:
nugget1
nugget2
...

Table 4: Prompt for Q_0 .

SYSTEM: You are NuggetExtractLLM, an AI assistant specialized in extracting information nuggets from a given answer. A nugget is an atomic fact.

USER: Generate all the information nuggets that are required to completely answer the query given below. Each nugget must contain one, and only one, fact. A nugget must be as concise and as specific as possible. A nugget cannot contain a list, each element in a list must be its own nugget. Each nugget must directly answer the query. The list of nuggets must not contain redundant information. Return a list of nuggets such that each nugget is on a new line. Do not number or bullet the list. Do not include anything in your response except for the list of nuggets. Here is an example of the output format:

nugget1
nugget2
...
Query: q
Answer: a
LLM:
nugget1
nugget2
...

Table 5: Prompt for QA_0 .

SYSTEM: You are NuggetGenerateLLM, an AI assistant specialized in generating all information nuggets that are required to completely answer a given query. A nugget is an atomic fact.

USER: Generate all the information nuggets that are required to completely answer the query given below. Each nugget must contain one, and only one, fact. A nugget must be as concise and as specific as possible. A nugget cannot contain a list, each element in a list must be its own nugget. Each nugget must directly answer the query. The list of nuggets must not contain redundant information. Return a list of nuggets such that each nugget is on a new line. Do not number or bullet the list. Do not include anything in your response except for the list of nuggets. Here is an example of the output format:

nugget1
nugget2
...

Here is an example query: Why is transferrin and iron low in covid patients but ferritin high?
This is the list of nuggets that should be generated for this query:

Lymphocytes and viruses compete for iron.
Lymphocytes need iron for cellular response.
Lymphocytes need iron for humoral response.
Viruses need iron to replicate.
Infection lowers iron levels in the blood.
Infection increases ferritin levels in the blood.
High ferritin is associated with increased mortality.
Iron homeostasis needs ferritin.
Ferritin is involved in physiologic processes.
Ferritin is involved in pathologic processes.
High ferritin indicates response to inflammation.
High ferritin levels are linked to poor outcomes of COVID-19.
Iron depletion therapy showed anti-viral activity in the COVID-19 pandemic.
Iron depletion therapy showed anti-fibrotic activity in the COVID-19 pandemic.

Query: q
LLM:
nugget1
nugget2
...

Table 6: Prompt for Q_1 .

SYSTEM: You are NuggetExtractLLM, an AI assistant specialized in extracting information nuggets from a given answer. A nugget is an atomic fact.

USER: List all of the information nuggets in the answer given below that are required to completely answer the query. Each nugget must contain one, and only one, fact from the answer. A nugget must be as concise and as specific as possible. Each element in a list must be its own nugget. Each nugget must directly answer the query. The list of nuggets must not contain redundant information. Return a list of nuggets such that each nugget is on a new line. Do not number or bullet the list. Do not include anything in your response except for the list of nuggets. Here is an example of the output format:

nugget1
nugget2
...

Here is an example query: Why is transferrin and iron low in covid patients but ferritin high?
This is the list of nuggets that should be generated for this query:

Lymphocytes and viruses compete for iron.
Lymphocytes need iron for cellular response.
Lymphocytes need iron for humoral response.
Viruses need iron to replicate.
Infection lowers iron levels in the blood.
Infection increases ferritin levels in the blood.

Literary Evidence Retrieval via Long-Context Language Models

Katherine Thai¹ and Mohit Iyyer²

UMass Amherst¹ University of Maryland, College Park²,
kbthai@umass.edu, miyyer@umd.edu

https://github.com/katherinethai/long_context_relic

Abstract

How well do modern long-context language models understand literary fiction? We explore this question via the task of *literary evidence retrieval*, repurposing the RELiC dataset of Thai et al. (2022) to construct a benchmark where the entire text of a primary source (e.g., *The Great Gatsby*) is provided to an LLM alongside literary criticism with a missing quotation from that work. This setting, in which the model must generate the missing quotation, mirrors the human process of literary analysis by requiring models to perform both global narrative reasoning and close textual examination. We curate a high-quality subset of 292 examples through extensive filtering and human verification. Our experiments show that recent reasoning models, such as GEMINI PRO 2.5 can exceed human expert performance (62.5% vs. 50% accuracy). In contrast, the best open-weight model achieves only 29.1% accuracy, highlighting a gap in interpretive reasoning. Despite their speed and apparent accuracy, even the strongest models struggle with nuanced literary signals and overgeneration, signaling open challenges for applying LLMs to literary analysis. We release our dataset and evaluation code to encourage future work in this direction.

1 Introduction

The emergence of long-context language models, which can process millions of tokens (Gemini Team, 2024), has unlocked new AI applications for literary analysis. In this paper, we focus on the task of *literary evidence retrieval*, in which a model must retrieve a supporting quotation from a primary source (e.g., a novel) to substantiate an excerpt of literary criticism.

Thai et al. (2022) frame literary evidence retrieval as a computational task by introducing RELiC, a dataset that contains short excerpts from published literary criticism that include quotations from famous novels. While RELiC was developed

to benchmark and improve retriever models, which compute embeddings of claims and short chunks of the book text, we repurpose it as a testbed for long-context¹ language models: A model is given the entire text of the book and an excerpt of literary criticism with a missing quotation from that book, then asked to generate the missing quote (see Figure 1, top). This task does not exactly mirror the human process of literary analysis, in which a scholar typically develops claims and selects supporting quotes iteratively. However, the task requires the same understanding of and complex reasoning over plot, subtext, and other literary devices with the advantage of being easily verifiable.

To enable robust evaluation, we curated a high-quality subset of 292 examples from RELiC, verified through a combination of automated filtering and expert human review. These 292 examples contain claims that require both global reasoning over events and “close reading” over singular passages to solve. Our experiments reveal that state-of-the-art reasoning models significantly outperform previous LLMs and even surpass a human expert baseline: our best model, GEMINI PRO 2.5 obtains an accuracy of **62.5%** compared to **55.0%** for a human expert on a subset of the data. However, we also find that these models tend to overgenerate and struggle with subtle literary cues. Open-weight models perform substantially worse, suggesting that interpretive reasoning, not just long-context capacity, is essential to success in this domain, forming important directions for future research.

2 Dataset Curation

The RELiC dataset (Thai et al., 2022) consists of 78k excerpts of English-language literary analysis collected from scholarly journals where each excerpt includes a direct quotation from one of 79

¹In this paper, we consider “long-context” to mean allowing a minimum of 128k tokens as input.

MODEL + SIMPLE PROMPT	ALL (n=292)	👤 (n=40)	📖 (n=39)

primary source texts in the public domain. Each example in the dataset contains up to four sentences preceding the quotation and up to four sentences following the quotation. Together, these sentences of make up the “context” of the ground truth quotation. The primary source quotations may be up to five consecutive sentences in length.

2.1 Adapting RELiC for long-context reasoning

While large, RELiC is also noisy, which necessitates several filtering steps before we can evaluate models on it. We implemented an extensive data preprocessing pipeline² that involved several cleaning and filtering passes with GPT-4o-MINI and GPT-4o supplemented by some programmatic heuristics, all geared towards mitigating the below issues:

Low data quality: Some RELiC examples contain **OCR artifacts** present in the primary source texts that render the prefixes and suffixes ungram-

²All prompts, details of filtering heuristics, and descriptions of our manual validations are in Appendix A.

matical. There are also some examples that are **misclassified** as literary analysis.

Model exploits: Several aspects of RELiC examples can provide unintended cues to models, allowing them to bypass the reasoning challenge. One was the **disclosure of the location** of the quote in the prefix or suffix. Another was **quote leakage**, or the appearance of part or all of the ground truth quotation in the context. Finally, **data contamination** was a concern—the literary analysis excerpts could appear in the training data of the LLMs we benchmarked and may have been memorized, or the ground truth quotation is so prevalent in the training data (because it belongs to a public domain novel) that the model is able to retrieve it without needing the primary source text at all.

Human verification: After filtering, we create a high-quality human-verified subset of the dataset by having one of the authors, who has a degree in English literature and has read all of the primary source novels manually review 400 filtered examples. This author marked 292 examples that were well-formed instances of literary analysis with a ground truth quotation that could be identified given only the book and literary analysis context. See Table 2 for dataset statistics.

Dataset folds: Our new dataset contains two labeled folds of special data, (1) the 👤 HUMAN EVAL SET: 40 examples attempted by our author, and (2) the 📖 CLOSE READING SET: 39 examples labeled by our author as examples of **close reading**, a literary analysis technique in which the reader considers “linguistic elements, semantic aspects, syntax, rhetoric, structural elements, thematic, and generic references in the text” (Ohrvik, 2024). A natural consequence of this interpretive technique is the repeated citation of parts of the ground truth quote in the context. Since these examples contain lexical overlap with the ground truth quotation, models can exploit this during evidence retrieval.

3 Experimental Setup

We evaluated four closed-source and four open-weight models on the long-context RELiC dataset, prompting each in a zero-shot setting to retrieve the most fitting quotation for a literary analysis excerpt given the full primary source text. We tested two prompt types: (1) SIMPLE, which requested only the quotation, and (2) EXPLANATION, which first asked the model to justify its choice before

Literary Analysis Excerpt with “Ground Truth Quotation” from *The Scarlet Letter*

Chillingworth is necessary to the tale and convincing enough, but he cannot shake off certain articles of dress and look that for Hawthorne were literary conventions. He is that unreal thing, a villain; he is Archimago still, stooping as he walks.

“A writhing horror twisted itself across his features, like a snake gliding swiftly over them, and making one little pause, with all its wreathed intervolutions in open sight. His face darkened with some powerful emotion, which, nevertheless, he so instantaneously controlled by an effort of his will, that, save at a single moment, its expression might have passed for calmness. After a brief space, the convulsion grew almost imperceptible, and finally subsided into the depths of his nature.”

This was when he stood by the scaffold and recognized Hester Prynne. He had come there out of melodrama, and in melodrama he remains. If Hawthorne makes him acceptable nevertheless, the reason is the vitality of the whole world here envisioned.

✓ Human explanation:

I was between this and the description of Chillingworth's shoulders being uneven, but I think this supports the "melodrama" mentioned in the suffix better than the description of his uneven shoulders. It contains a very exaggerated description of Chillingworth; words that connote movement like "writhing," "twisted," "gliding swiftly," and "convulsion"; and a tension between "powerful emotion" and a struggle for "calmness" that all contribute to the melodrama of the scene.

✗ Gemini 2.5 Pro, o3, and GPT-4.1 response:

He was small in stature, with a furrowed visage, which, as yet, could hardly be termed aged. There was a remarkable intelligence in his features, as of a person who had so cultivated his mental part that it could not fail to mould the physical to itself, and become manifest by unmistakable tokens. Although, by a seemingly careless arrangement of his heterogeneous garb, he had endeavored to conceal or abate the peculiarity, it was sufficiently evident to Hester Prynne, that one of this man's shoulders rose higher than the other.

Figure 1: An example from long context RELiC where the HUMAN annotator successfully retrieves the quotation while the top-performing LLMs fail.

selecting a quotation³. Our prompts are adapted from Karpinska et al. (2024) in the NOCHA long-context benchmark. Additionally, we implemented an embedding-based retrieval baseline using GTE-QWEN2-7B-INSTRUCT, the top-performing text embedding model on MTEB⁴ at the time of writing.

3.1 Human Evaluation

The author who manually validated high quality examples also attempted 40 examples from four previously-read primary source novels. The author had access to a digital copy of the primary source text with a string-matach search function and the corresponding Wikipedia summaries. In addition to selecting missing quotations, the author also wrote a short justification for each choice. The task took approximately 8 hours.

3.2 Evaluation Scheme

Our automatic evaluation of model responses applied partial ratio fuzzy matching (to account for minor typographical differences) to check that the model response was from the primary source text and to measure overlap between the response and the ground truth quotation⁵. For the embedding baseline, we calculate recall@1.

⁵Further details can be found in Appendix D.

4 Results & Analysis

Table 1 reports results for all evaluated models on the full set of 292 claims and the two folds.

LLMs outperform HUMAN and SOTA embedding baseline

Google’s GEMINI PRO 2.5 reasoning model achieves better accuracy than our HUMAN baseline in a fraction of the time—each API call took an average of 45 seconds vs. an average of 12 minutes for the HUMAN expert. Both Google and OpenAI’s latest long-context models show substantial performance gains over their immediate predecessors on the literary evidence retrieval task. GEMINI PRO 2.5 outperforms GEMINI PRO 1.5 by a wide margin (64.7% vs. 38.5%), and OpenAI’s GPT-4.1 improves significantly over GPT-4o (51.0% vs. 24.3%). Similarly, o3 surpasses o1 (48.7% vs. 32.2%). The embedding-based method achieved 4.5% accuracy, only 1.6% higher than the best recall@1 reported in the original RELiC paper from three years ago. LLMs’ success over embeddings suggests the importance of contextualized representations that can enable reasoning over entire primary source texts.

Closed-source outperform open-weight LLMs

Despite recent progress in open-weight LLM development, we observe a striking performance gap between closed-source and open-weight models on the literary evidence retrieval task. The best-performing open-weight model, DEEPSEEK-R1,

Literary Analysis Excerpt with “Ground Truth Quotation” from *Frankenstein*

“It may therefore be judged indecent in me to come forward on this occasion,” she proclaims on the stand, “but when I see a fellow creature about to perish through the cowardice of her pretended friends, I wish to be allowed to speak, that I may say what I know of her character.” Attempting to resist class lines and to speak of Justine as a “fellow creature” calls the silent cowardly, which means that Elizabeth, too, forgot her manners. Her testimony of Justine’s dedication, loyalty, and nurturing cannot be heard, and the jury’s response mimics Frankenstein’s own preoccupation and inability to read the interactions and relationships between women in the broader sense.

“But I did not feel the inconvenience of the weather; my imagination was busy in scenes of evil and despair.”

Class and gender clearly matter in Geneva, and these factors, rather than a psychosexual rivalry, explain why Justine is punished for her ingratitude toward her benefactors. Elizabeth’s testimony falls on deaf ears. What the jury perceives as important, and punishes, is indecorum—a breach of the mistress-servant relationship.

✗ Human and Gemini 2.5 Pro response:

A murmur of approbation followed Elizabeth’s simple and powerful appeal, but it was excited by her generous interference, and not in favour of poor Justine, on whom the public indignation was turned with renewed violence, charging her with the blackest ingratitude.

✗ Human explanation:

I selected the quote that follows Elizabeth’s full testimony, which is quoted in part at the beginning of the prefix. The selected quote also mentions Justine’s “ingratitude,” like the suffix.

✗ Gemini 2.5 Pro explanation:

The literary analysis argues that Elizabeth’s testimony for Justine, despite its appeal to see Justine as a “fellow creature,” fails because the jury (and public) focuses on Justine’s perceived “ingratitude” and breach of class decorum rather than her actual character. The chosen window directly follows Elizabeth’s speech in court and describes the public’s reaction: while Elizabeth’s act of speaking earns some approval for its “generous interference,” it does not sway opinion in Justine’s favor.

Figure 2: An example of long context RELiC where the HUMAN annotator and GEMINI PRO 2.5 both select the same quotation, but it is not the ground truth quotation.

achieves only 29.1% accuracy—less than half the performance of the top closed-source model, GEMINI PRO 2.5 (64.7%).

Small LLMs can’t capitalize on close reading examples Nearly all models larger than 8B parameters show modest to significant improvements on the close reading fold, with some models improving by over 20%. This effect is expected due to ground truth leakage in the the provided excerpt of literary analysis, but the 7B and 8B parameter open-weight models experience nearly no performance boost on this fold—the performance of LLAMA 3.1 INSTRUCT (8B) actually suffers, suggesting that the smaller models lack the capacity to even exploit lexical overlap.

EXPLANATION prompt provides a glimpse into model reasoning We observed mixed results when querying non-reasoning LLMs with the EXPLANATION prompt. While GEMINI PRO 1.5 improved with explanation-based reasoning, GPT-4o saw a decline. Recent reasoning LLMs such as GEMINI PRO 2.5 and o3 use internal reasoning tokens that are not exposed via the API but influence the model’s final output. These tokens are critical to the model’s performance on complex tasks, but their inaccessibility complicates model evaluation and comparison. Applying the EXPLANATION prompt to these reasoning models preserved accuracy, de-

spite the redundancy, while providing insight into the models’ reasoning processes. See a comparison of human and model justifications in Figure 2.

All models tend to overgenerate Despite prompts explicitly instructing models to select and generate no more than five consecutive sentences from the primary source, we observe a consistent tendency across all evaluated models to produce significantly longer outputs. To quantify this over-generation behavior, we compute the length ratio, defined as the ratio of the model’s generated output length to the ground truth quotation length (measured in characters); values closer to 1.0 indicate greater adherence to the prompt constraints and minimal overgeneration. The length ratios are reported in Table 3.

We find that all models overgenerate, including the human annotator (average ratio of 2.1), likely due to natural variance in interpreting sentence boundaries. However, language models consistently surpass this baseline: for instance, state-of-the-art models such as GEMINI PRO 2.5 and GPT-4.1 have average ratios of 3.0 and 4.8, respectively. Smaller open models like LLAMA 3.1 INSTRUCT (8B) and LLAMA 3.3 INSTRUCT (70B) exhibit even more extreme overgeneration (ratios > 5.7), suggesting that weaker models may compensate for uncertainty by producing longer outputs.

LLMs struggle with literary nuance In Figure 1, we present a challenging example where all LLMs fail but our HUMAN expert correctly identified the ground truth quotation from *The Scarlet Letter*, a >80k-word novel. The context alludes to a description of the character Roger Chillingworth at a specific moment in the story (when he recognizes Hester Prynne). In their explanation, the HUMAN expert mentions considering two different passages, but ultimately selecting the correct passage because it best demonstrates the “melodrama” mentioned in the literary analysis. The expert highlights the features of the correct passage that demonstrate “melodrama”: an exaggerated character description, words that connote movement, and emotional tension. All three top-performing LLMs selected the other passage the HUMAN expert was considering but ultimately eliminated, suggesting that even the best models still lack the expertise to navigate literary devices and more nuanced signals that inform expert literary interpretation.

Models can identify alternative literary evidence

In Figure 2, we present an example where both HUMAN and GEMINI PRO 2.5 selected the same “incorrect” quote. The explanations reveal that both interpreted the literary analysis context as an introduction to a quote about the jury’s response. However, the ground truth quotation actually supports Frankenstein’s own preoccupation rather than the trial’s immediate outcome. This example highlights two key insights: (1) literary evidence retrieval is inherently interpretative, meaning that multiple passages may plausibly support a given claim, and (2) LLMs, like human readers, can surface alternative yet reasonable quotations that align with certain aspects of the analysis. While models may not always select the canonical answer, their ability to propose viable alternative evidence could be valuable for assisting literary scholars in exploring multiple textual connections.

5 Related Work

Our work builds on recent papers that apply and evaluate LLMs for computational literary analysis. Prior work has explored summarization or claim verification in novels (Subbiah et al., 2024a; Kim et al., 2024; Karpinska et al., 2024) or short stories (Subbiah et al., 2024b). Other more specific tasks, mainly in the short context setting, include extracting narrative elements (Shen et al., 2024), story arcs and turning points (Tian et al., 2024),

6 Conclusion

In this work, we introduced a long-context dataset derived from RELiC for evaluating literary evidence retrieval using large language models. We constructed a high-quality test set of 292 examples, ensuring rigorous evaluation through filtering and human verification. Our results demonstrate that long-context LLMs outperform embedding-based retrieval methods and even a HUMAN expert baseline. However, closer analysis reveals that model success is not always grounded in robust interpretative abilities: models tend to overgenerate and still struggle to grasp nuances in literature. However, they can also successfully identify additional evidence for literary claims. Finally, open-weight models still lag far behind their closed-weight counterparts, suggesting that long-context capabilities alone are insufficient without strong interpretive reasoning. We release our data and evaluation framework to spur research at the intersection of NLP and literary analysis.

Limitations

As noted in the original paper, the RELiC dataset represents a limited, English-only subset of world literature, with a strong emphasis on the Western

literary canon. To foster a more inclusive and representative benchmark, we aim to extend this work to cross-lingual literary analysis and retrieval on texts from historically underrepresented literary traditions. Expanding the dataset in this way would not only enhance the linguistic and cultural diversity of literary evidence retrieval but also improve the generalizability of models across different literary frameworks.

Additionally, our human evaluation was limited in scope and scale, as it was conducted by a single annotator, one of the authors of this paper. While this approach was practical given the intensive nature of literary evidence retrieval over full novels, it inherently reflects the knowledge, biases, and interpretive lens of a single individual. In the future, we aim to broaden our evaluation by incorporating multiple expert annotators, enabling a more comprehensive and diverse assessment of model performance on the task of complex literary reasoning.

Ethical Considerations

While LLMs can assist in literary interpretation, they should not replace scholarly analysis conducted by trained experts. We acknowledge the potential for misuse of a system that can retrieve evidence for scholarly claims and emphasize that automated retrieval should be viewed as a complement to, not a substitute for, human literary scholarship.

As mentioned in the Limitations section, the primary source texts in our dataset are drawn from public domain works, which primarily reflect Western literary traditions. The results of this benchmark may not generalize to literary traditions outside the Anglophone canon, potentially reinforcing existing biases in computational literary studies.

A Dataset Details

We are using a publicly available dataset released by researchers who stated in their paper that they released their data to "facilitate further research in this direction." Statistics for the primary sources can be found in 4.

B LLM-Aided Data Processing

B.1 Filtering steps

These cleaning and filtering steps were applied to the entire RELiC dataset in the following order:

1. CLEAN (GPT-4O-MINI): We asked the model to remove any OCR artifacts and to ensure the context and ground truth quotation flow seamless and grammatically without changing any meaning. Additionally, we asked the model to remove any remaining in-line citations that revealed the page number of the ground truth quotation, which allowed us to preserve some examples that might have been caught by the LOCATION filter below. See the prompt in Table 8.
2. LEAKAGE (heuristic): If the sentences in the context preceding or following the ground truth quotation were fuzzy-matches (threshold: 95) with any text from the primary source, the example was excluded from our dataset.
3. LIT ANALYSIS (GPT-4O-MINI): We asked the model to classify whether each RELiC instance was an example of literary analysis. If it was not, we excluded it from our dataset. See the prompt in Table 9.
4. LOCATION (GPT-4O-MINI): We asked the model if the context revealed the location of the ground truth quotation. If it did, we excluded it from our dataset. See the prompt in Table 10.
5. FIRST SENT (heuristic): We identified cases where the ground truth quotation was the first sentence of its primary source novel. The intuition behind this filter (and the following two) was that the first sentence of a primary source might be famous or more likely to be quoted, and therefore easier to guess without needing to reason over the text or more likely to appear in training data.

Book Title	Author	Publication Year	Token Count	Word Count
Brave New World	Aldous Huxley	1932	91,472	65,278
What Maisie Knew	Henry James	1897	124,544	95,988
Ethan Frome	Edith Wharton	1911	45,038	34,926
Frankenstein	Mary Shelley	1818	95,018	75,131
The Great Gatsby	F. Scott Fitzgerald	1925	63,683	48,972
The Awakening	Kate Chopin	1899	66,574	49,932
The Scarlet Letter	Nathaniel Hawthorne	1850	112,355	83,311

Table 4: Books included in the dataset. The token count was provided as per `tiktoken` tokenization.

6. LAST SENT (heuristic): Similarly, we identified cases where the ground truth quotation was the last sentence of its primary source novel.
7. OUTLIER (heuristic): We identified cases where the ground truth quotation was cited much more frequently than any of the other quotations from the same primary source novel.
8. EZ2MEM (GPT-4): We asked the model to perform the RELiC task *without* providing the primary source text and identified cases where the model was able to correctly generate at least one sentence of the ground truth quotation.

Note that we did not automatically exclude any of the examples identified by the last four filters. Though we did not use them in this project, we have left the labels in our dataset to facilitate future research.

B.2 Manual validation of data

We conducted multiple validations of the RELiC data for quality control using human annotations.

Validation of LLM filters To validate our LLM-aided approach to data preprocessing, we manually annotated 100 examples of RELiC and compared our judgments to keep or reject each example to the results of the LLM + heuristic filters. The f1-score of our filtering scheme was 89.8, with our scheme identifying 57 true positives, 30 true negatives, 6 false positives, and 7 false negatives.

C Model Inference Details

API access details

- All OpenAI models were accessed via the OpenAI API (<https://platform.openai.com/>).

- All Gemini models were accessed via the Google AI API (<https://ai.google.dev/>).
- CLAUDE SONNET 3.7 was accessed via the Vertex AI/Google Cloud (<https://cloud.google.com/vertex-ai?hl=en>).
- DeepSeek was run via OpenRouter (<https://openrouter.ai/>).

The approximate total cost of running all closed-weight models for both development and evaluation was \$2k.

Local inference details All Llama and Qwen models were run locally. The smaller open-weight models were run on 1 A100 GPU for a total of 14 hours, while the larger open-weight models were run on 4 A100 GPUs for a total of 16 hours.

Generation hyperparameters The OpenAI reasoning models (o1, o3-MINI, and o3) were a special case: the temperature parameter is fixed and the token generation limit includes the inaccessible reasoning tokens. As such, we set the token generation limit to 12,000 for o1 and o3-MINI. For o3, the token generation limit was set to 25,000 as recommended by OpenAI⁶. For all three OpenAI reasoning models, we used the default medium reasoning effort.

For all other models, the token generation limit was set to 800 for SIMPLE prompts and 1,200 for EXPLANATION prompts. Temperature was set to 0.0 for all models except for QWEN 3 (32B) and QWEN 3 (8B), where temperature was set to the default 0.6.

For a list of the models and their checkpoints, see Table 5.

D Evaluation Scheme Details

We use the `rapidfuzz` Python package for our fuzzy match evaluation with a threshold of 95 for

checking the existence of the model response in the primary source and a threshold of 90 for checking the overlap between the model response and the ground truth quotation. The fuzzy matching allows for small typographical differences between the primary source and the model outputs (e.g. different types of quotation marks). Thresholds were determined after manual inspection of outputs at varying thresholds.

E Use of AI Assistants

The authors used Github Copilot for coding assistance during their experiments and ChatGPT for assistance in formatting \LaTeX in the writing of this paper.

Prompt (Simple)

You are provided with the full text of **[book_title]** and an excerpt of literary analysis that directly cites **[book_title]** with the cited quotation represented as <MASK>.

Your task is to carefully read the text of **[book_title]** and the excerpt of literary analysis, then select a window from **[book_title]** that most appropriately replaces <MASK> as the cited quotation by providing textual evidence for any claims in the literary analysis.

The excerpt of literary analysis should form a valid argument when <MASK> is replaced by the window from **[book_title]**.

```
<full_text_of_[book_title_snake_case]>[book_sentences] </full_text_of_[book_title_snake_case]>
<literary_analysis_excerpt>[lit_analysis_excerpt] </literary_analysis_excerpt>
```

Identify the window that best supports the claims being made in the excerpt of literary analysis. The window should contain no more than 5 consecutive sentences from **[book_title]**.

Provide your final answer in the following format:

```
<window>YOUR SELECTED WINDOW </window>
```

Table 6: Prompt template for literary evidence retrieval (Simple).

Prompt w/ Explanations

You are provided with the full text of **[book_title]** and an excerpt of literary analysis that directly cites **[book_title]** with the cited quotation represented as <MASK>.

Your task is to carefully read the text of **[book_title]** and the excerpt of literary analysis, then select a window from **[book_title]** that most appropriately replaces <MASK> as the cited quotation by providing textual evidence for any claims in the literary analysis.

The excerpt of literary analysis should form a valid argument when <MASK> is replaced by the window from **[book_title]**.

```
<full_text_of_[book_title_snake_case]>[book_sentences] </full_text_of_[book_title_snake_case]>
<literary_analysis_excerpt>[lit_analysis_excerpt] </literary_analysis_excerpt>
```

First, provide an explanation of your decision marking process in no more than one paragraph.

Then, identify the window that best supports the claims being made in the excerpt of literary analysis. The window should contain no more than 5 consecutive sentences from **[book_title]**.

Provide your final answer in the following format:

```
<explanation>YOUR EXPLANATION </explanation>
<window>YOUR SELECTED WINDOW </window>
```

Table 7: Prompt template for literary evidence retrieval with explanation.

Prompt for Cleaning RELiC Examples

I want to create a dataset for Natural Language Processing that consists of excerpts of literary analysis that quote directly from a primary source text.

I have already collected windows of literary analysis that quote from many different primary sources in the public domain. The part of the excerpt before the quotation is called the "prefix," and the part of the excerpt after the quotation is called the "suffix." Because I collected the data from PDFs with OCR, the prefixes and suffixes contain artifacts like in-line citations, page numbers, chapter names, headers, and footers that I need to remove.

Here is an example:

```
<prefix>[prefix] </prefix>
```

```
<ground_truth_quotation>[ground_truth_quotation] </ground_truth_quotation>
```

```
<suffix>[suffix] </suffix>
```

Please follow the following guidelines to help me clean and filter this example:

1. Remove all textual artifacts from the OCR process by deleting them. Artifacts include page numbers, chapter headings, footnotes, image captions, etc.
2. Correct the grammar, punctuation, and spelling of the prefix and suffix without altering the meaning so that the primary source quotation fits seamlessly and grammatically between the prefix and suffix.
3. Remove all in-line citations following quotations, especially those that say things like "(my emphasis)."

Respond with ONLY the cleaned prefix and suffix in the following format:

```
<clean_prefix>CLEAN PREFIX </clean_prefix>
```

```
<clean_suffix>CLEAN SUFFIX </clean_suffix>
```

Table 8: Prompt template for cleaning RELiC examples

Prompt for Classifying Literary Analysis

I want to create a dataset for Natural Language Processing that consists of excerpts of literary analysis that quote directly from a primary source text.

Other texts can contain quotes from primary sources, like biographies of authors. However, I only want examples of literary analysis in the dataset.

Please determine whether the following excerpt is an example of literary analysis. If it is literary analysis, respond with TRUE. Otherwise, respond with FALSE.

Here is the excerpt:

```
<excerpt>[clean_prefix] [answer_quote] [clean_suffix] </excerpt>
```

Respond with ONLY your answer in the following format:

```
<answer>YOUR ANSWER </answer>
```

Table 9: Prompt template for classifying literary analysis

Prompt for Identifying Quote Location Disclosure

I want to create a dataset for a Natural Language Processing task called "Literary Evidence Retrieval."

The input has two parts:

- (1) An excerpt of literary analysis that quotes 1 to 5 full sentences from a primary source text, but the quote is replaced with "[MASK]".
- (2) The full text of the primary source.

The output should be the correct quotation of 1 to 5 full sentences from the primary source—this is the ground truth.

I have already collected windows of literary analysis that quote from many different primary sources in the public domain.

The part of the excerpt before the quotation is called the "prefix," and the part after is called the "suffix."

To avoid giving the model hints, it's extremely important that the prefix and suffix do not mention the chapter where the ground truth quotation is located.

Please determine whether the following instance contains the chapter location of the ground truth quotation in either the prefix or the suffix. If it does, respond with TRUE; otherwise, respond with FALSE.

The prefix and suffix may contain the location of other quotations in the passage. I only want to identify if the location of the ground truth quotation is revealed.

Look out for phrases like "In the prologue" or "In Chapter..."

Here is the instance:

<prefix>**[prefix]** </prefix>

<ground_truth_quotation>**[ground_truth_quotation]** </ground_truth_quotation>

<suffix>**[suffix]** </suffix>

Respond with ONLY your answer in the following format:

<answer>**YOUR ANSWER** </answer>

Table 10: Prompt template for identifying quote location disclosure

A Little Human Data Goes A Long Way

Dhananjay Ashok[†], Jonathan May[†]

[†]Information Sciences Institute, University of Southern California
{ashokd, jonmay}@isi.edu

Abstract

Faced with an expensive human annotation process, creators of NLP systems increasingly turn to synthetic data generation. While this method shows promise, the extent to which synthetic data can replace human annotation is poorly understood. We investigate the use of synthetic data in Fact Verification (FV) and Evidence-based Question Answering (QA) by incrementally replacing human-generated data with synthetic points on eight diverse datasets. Strikingly, replacing up to 90% of the training data only marginally decreases performance, but replacing the final 10% leads to severe declines. We find that models trained on purely synthetic data can be improved by including as few as **125** human generated data points. We show that matching the performance gain of a little human data requires an order of magnitude more synthetic data, and then estimate price ratios at which human annotation would be a more cost-effective solution. Our results suggest that even when human annotation at scale is infeasible, there is great value to having a small proportion of the dataset being human-generated.

1 Introduction

From BERT (Devlin et al., 2019) to GPT-4 (Achiam et al., 2023), the explosive growth of language models (LMs) has been underpinned by exponential increases in the size of available training data. However, the more complex and specialized the task, the more expensive and challenging it is to collect human-generated data at scale (Wang et al., 2021). Combined with growing concerns that LMs may soon exhaust the stock of publicly available training data (Villalobos et al., 2024), many turn to synthetic data generation, hoping to eliminate their reliance on human annotation.

Synthetic data generation has long been used to increase the amount of training data available (Simard et al., 2002; Krizhevsky et al.,

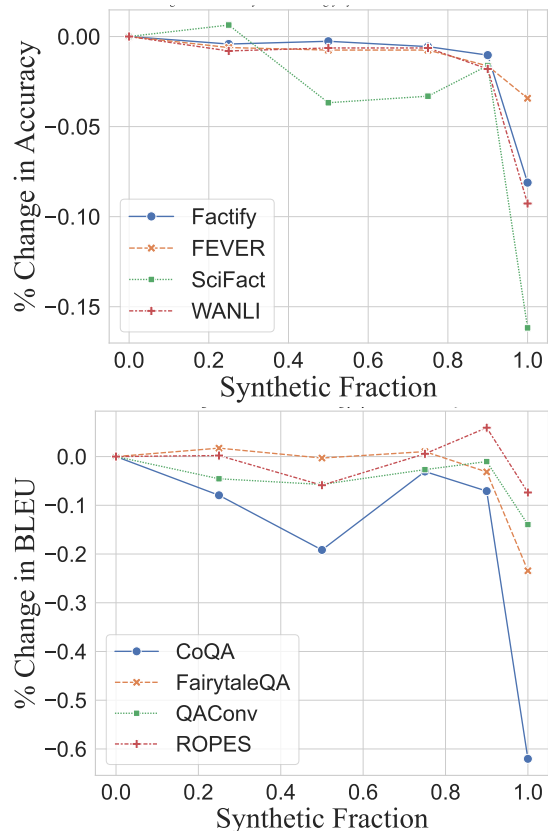

Figure 1: Change in model performance as the proportion of synthetic points in the training data is increased. Across datasets, the performance decrease when moving the synthetic proportion from 0 to 0.90 is often less than that of moving from 0.9 to purely synthetic data.

2012). Early NLP approaches use rule based methods (De Gispert et al., 2005; Chen et al., 2012), paraphrasing (Wang and Yang, 2015; Kobayashi, 2018), noising (Xie et al., 2017; Wang et al., 2018), and backtranslation (Sennrich et al., 2016; Yu et al., 2018), but are limited in their capability.

Modern LMs demonstrate the capability to solve myriad NLP tasks with minimal task specific data (Brown et al., 2020; Wei et al., 2022), making them more powerful synthetic data generators. Leveraging this, synthetic data approaches have

Figure 2: Model performance as the synthetic proportion of the training data varies from 0.95 to 1. Having **just 2.5%** of the training dataset being human-generated boosts performance.

seen increased use in tasks (Tan et al., 2024) such as QA (Wu et al., 2022), natural language inference (NLI) (Meng et al., 2022), text classification (Ye et al., 2022), instruction tuning (Li et al., 2024), evaluation (Dubois et al., 2024), and more (Tang et al., 2023).

The adoption has been particularly enthusiastic for tasks that require the model to ‘understand’ knowledge contained in an ‘evidence text’ e.g., FV (Tang et al., 2024), factual error correction (Ashok et al., 2023), NLI (Hosseini et al., 2024) and evidence-based QA (Schimanski et al., 2024). Such tasks are of vital importance in fake news detection (Sharma et al., 2023), retrieval-augmented generation (Gao et al., 2023) and dialogue systems (Weston et al., 2015). Recent datasets (Wu et al., 2022) and methods (Ye et al., 2022) exploit plentiful evidence texts (scientific journals, news articles, books, etc.), using synthetic generation to avoid being bottlenecked by the expensive annotation procedure (Liu et al., 2022).

Varying results across ML tasks suggest that whether completely replacing humans with synthetic data shows promise (Fan et al., 2024; Ham-

moud et al., 2024) or leads to failures (Bisbee et al., 2024; Guo et al., 2024) is task dependent (Li et al., 2023). In this work, we focus on **FV** and **Evidence-based QA**, performing the first investigation into the trade-offs presented by the use of synthetic data generation in these fundamental tasks.

We study eight diverse FV and QA datasets, using their ‘evidence texts’ to generate synthetic datasets. By holding the number of data points constant but increasing the percentage of the training data that is synthetic, we can compare the utility of synthetic data to the original human generated data points. Across multiple models, prompt models, and prompting strategies, we find (Figure 1) that while increasing the proportion of synthetic data typically causes only minor degradations in model performance, a significant decline occurs at the extremes; i.e., when the percentage of synthetic data exceeds 90%. Focusing on the extremes, we show that purely synthetically trained FV and QA systems can be meaningfully improved by including as few as **125** human-generated datapoints.

Our observations have actionable implications for researchers hoping to use synthetic data for FV and QA. The results (Figure 2, Figure 4) suggest that even when human annotation at scale is infeasible, there is great value to having a small proportion of the dataset being generated by humans.

To help guide this choice, we quantify the performance-cost tradeoff between human and synthetic data. We find (Figure 4) that matching the performance gain of just a little additional human data (only 200 data points) requires an order of magnitude more synthetic data points, empirically showing the per-data point price ratio at which human annotation is the more cost-effective solution. Finally, we conduct an analysis on the differing properties of synthetic vs. human data. Among other findings, we see that synthetic generations are longer and more extractive from the evidence texts than their human-produced counterparts.

2 Synthetic Data Generation from Evidence Texts

We study a synthetic generation pipeline representative of the methods used in the FV (Ni et al., 2024; He et al., 2023) and QA (Schimanski et al., 2024; Wan et al., 2024) literature. Using Few-Shot In-Context Learning (Brown et al., 2020), we generate synthetic (claim, label) pairs from an input evidence text. The prompt model is given exam-

Figure 3: Change in accuracy when the test set (shown in key) is not seen during training, and the training set is a mixture of other FV datasets. Increasing the synthetic proportion of the dataset leads to performance declines even in the OOD setting, showing that human data offers genuine performance increases.

ples of (evidence text, claim, label) from the human training data, and is then queried with the evidence text we seek to generate data for. QA synthetic data is generated analogously, see details in Appendix B.

In total, we use four FV/NLI datasets: FEVER (Thorne et al., 2018), SciFact (Wadden et al., 2020), WANLI (Liu et al., 2022) and FAC-TIFY1.0 (Mishra et al., 2022), as well as four QA datasets: ROPES (Lin et al., 2019), CoQA (Reddy et al., 2019), QAConv (Wu et al., 2022) and Fairy-TaleQA (Xu et al., 2022). Together, the datasets span a variety of domains (science, news, social media, reasoning, conversation, fiction). We confirm that the generations are of high quality by verifying that the diversity of the synthetic data is comparable to the human generated samples. For more details, including a discussion on data leakage, see Appendix C.

FV performance is measured by test accuracy, while QA is measured using BLEU (Papineni et al., 2002); we show robustness to choice of metric in Appendix A. Evaluation is always conducted on the (human-generated) test split of each dataset.

We use GPT-3.5-Turbo (Brown et al., 2020) for prompting and LoRA (Hu et al., 2022) on Llama3-8B (Dubey et al., 2024) for fine-tuning. Implementation details are provided in Appendix E, and our code is publicly available ¹

¹<https://github.com/DhananjayAshok/LittleHumanData/>

Figure 4: On the WANLI dataset, adding 200 real data points is as effective as adding an order of magnitude more synthetic data points.

3 Can Synthetic Data Replace Humans?

We investigate the potential of synthetic data to replace human annotation by holding the number of training data points fixed, incrementally increasing the proportion of the data that is synthetic, and fine-tuning a model on each training set.

Results: Across all datasets, using purely synthetic data leads to worse performance than the same amount of human data (Figure 1). We consider the possibility that this result could be caused by a spurious correlation between the human training and testing splits (e.g., annotation artifacts that are correlated with the label but not fundamental to the task). We conduct an out-of-distribution experiment, using different datasets for training and testing (e.g., training on FEVER + SciFACT and testing on WANLI). Increasing the synthetic proportion leads to performance declines even in the OOD setting (Figure 3), showing that human data offers genuine performance increases, and the results cannot be explained by a spurious correlation between the human test and human training samples (further discussion in Appendix A).

The performance decline is not uniform as we increase the synthetic proportion. On almost all datasets, there is only a minor degradation up until 90% replacement, after which the performance drops considerably. We zoom in on the 90%-100% interval, fixing the amount of training data at $n = 5000$ (500 for SciFact) and training on datasets with 95%, 97.5% and 100% synthetic

data (Figure 2). Surprisingly, the results show that there is a significant difference between the performance of models on 97.5% and 100% synthetic data; the addition of just **125** (2.5% of 5000) human generated datapoints reliably improves the performance of synthetically trained FV and QA models. These trends hold robustly over different languages (Arabic, Georgian, Indonesian), choice of fine-tuning model (Mistral, MPT), prompt model (GPT4 and Claude-3.5-Sonnet), prompting strategy (Chain-of-Thought), model size and dataset size (Appendix A).

4 When Should We Use Human Data?

Having observed the disproportionate value added by human data, we ask what the relative cost between human and synthetic data generation must be for us to prefer one over the other. We fine-tune models on purely synthetic datasets of varying sizes, and establish the synthetic baseline by fitting a curve of the form $y = a_0 + a_1 \log(x)$ where x is the size of the synthetic dataset and y is the performance. We then take the synthetic training sets with $\{1000, 2000 \dots\}$ points and observe the performance (y^*) when we add 200 human data points. $\exp(\frac{y^* - a_0}{a_1})$ is then the size of the purely synthetic dataset that achieves equivalent performance.

Results: Across all datasets, adding **200** human data points is usually comparable to adding at least an order of magnitude (often multiple orders of magnitude) more synthetic data points. On WANLI (Figure 4), more than 17,000 additional synthetic points are needed to achieve the performance gains of 200 human points. If the price of a synthetic point for WANLI exceeds 73 times the price of a human generated point, then an incremental amount of human annotation would be a more cost-effective way to achieve the same increase in accuracy. In the extreme case, the equation learned on FairyTaleQA suggests that it takes $2e5$ additional synthetic points to match the performance gain of 200 additional human data points. Rather than interpret these numbers literally, we take them to suggest that human data could have unique value in some settings, enabling performance levels that are impossible with purely synthetic datasets. See Appendix A for more results and details.

5 Discussion

The synthetic generations are as diverse as human data (Table 2), with comparable duplicate rates on

Figure 5: Synthetic questions are longer than human generated ones, a trend also seen in answers.

QA datasets, and markedly fewer duplicates on most FV datasets. This is evidence that our synthetic generations are of good quality, however, even on the datasets where the synthetic data is significantly more diverse, the synthetic data does not perform as well. This suggests that diversity is an insufficient measure of quality when evaluating how good the generated data is. Our analysis shows that synthetic data generation produces claims of comparable length to the human datasets, however synthetic questions and answers tend to be longer than human-generated counterparts for all QA datasets (Figure 5). We find that synthetic generations have a higher n-gram overlap with the evidence sentences. This suggests that synthetic data generation produces data points that are more directly taken from the evidence texts, while humans are more likely to employ rephrasing or different vocabulary than the evidence texts. Surprisingly, we find that synthetic data generation chooses more varied parts of the input text as sources for the question and answer content, with human annotation overwhelmingly more likely to create questions whose answers lie at the start of the evidence texts. We include a detailed discussion in Appendix D.

6 Related Work

The replacement of human annotation with synthetic data is extensively studied in the pretraining stage of LMs, where results consistently show (Shumailov et al., 2023; Seddik et al., 2024; Guo et al., 2024; Briesch et al., 2023) catastrophic forgetting, mode collapse, and performance deterioration.

In our setting, relying only on synthetic data still achieves reasonable performance across all

Dataset	Mean	Median	25th Percentile	75th Percentile
WANLI	17,671	16,905	9,711	22,931
ROPES	17,333	6,006	3,623	21,944
FairyTaleQA	281,951	36,901	15,129	813,135
FEVER	1,155	237	-1,400	7,073

Table 1: Additional synthetic data points needed to match the performance gain of 200 human data points. High values for FairyTaleQA suggest that human-generated data may unlock performance that purely synthetic data cannot achieve. Negative values for FEVER are due to a saturation of the performance gains, however, human data points reach the saturation point much faster (Appendix A)

Dataset	Synthetic	Human
FEVER	5.50	20.27
WANLI	0.23	1.22
SCIFACT	0.00	9.93
FACTIFY	0.27	14.93
NarrativeQA	3.85	1.42
CoQA	0.54	5.49
FairyTaleQA	2.26	0.18
ROPES	2.40	1.35

Table 2: Percentage of duplicated claims/questions for synthetic v.s. human data. Rates are comparable across datasets, but for fact verification datasets, synthetic datasets have fewer duplicates.

tasks. This suggests that the usage of exclusively synthetic data poses fewer risks when generations are grounded in diverse, natural ‘evidence texts.’

Interestingly, conclusions which confirm our findings are found more in the image and multi-modal domains, where recent work (Singh et al., 2024; He et al., 2023; Fan et al., 2024) finds that synthetic data holds promise, but must be used in conjunction with human data to mitigate its harms.

There is limited work on understanding whether synthetic data can replace human annotation in a task-specific setting for the language domain. Li et al. (2023) categorize text classification tasks by subjectivity, showing that synthetic data is less useful when tasks are more subjective. This draws them to focus on different tasks (sentiment classification, relation extraction and spam detection), and they do not study using a mixture of real and synthetic data. Bisbee et al. (2024) demonstrate that replacing political survey respondents with LMs produces unreliable results, while Ahmed et al. (2024) find that there are specific software engineering subtasks where synthetic data approaches human performance. Chen et al. (2024) show that

instruction-following capabilities are diminished when using synthetic data and present a machine unlearning approach to mitigate this. The diversity of results when evaluating the impact of using purely synthetic data confirms that the feasibility of replacing human annotation with synthetic data is highly task dependant. This work deepens our understanding of the problem by being the first to study whether synthetic data can replace human annotation on the fundamental tasks of fact verification and evidence-based question answering.

7 Conclusion

Showing impressive performance when human data is scarce, synthetic data generation seems poised to remain a key method in FV and QA. Our work sheds light on how the best way to use this method is in conjunction with human data. We show that a little human data goes a long way, with just **125** points being enough to see reliable gains on all datasets studied. With practical considerations in mind, we show that the alternative to small amounts of additional human data can be an order of magnitude more of synthetic data, suggesting that at times human annotation can be cost-effective relative to synthetic generation. We hope these results better inform design decisions on datasets and methods for fact verification and question answering.

8 Limitations

While we include results on multilingual Fact Verification datasets, the primary focus of our work is limited to the English language. Additionally, our results on multilingual datasets suggest that while similar claims can be made regarding the impact of replacing human annotation with synthetic data across different languages, the amount of human data needed to observe a meaningful performance increase may vary across languages. We also have a limited ability to control for dataset leakage, with

only one dataset from each of the tasks that is surely not leaked to GPT-3.5 (and, even these two datasets may have been seen by GPT-4). This can potentially bias the results in favor of synthetic data. Due to the scarcity of suitable available datasets (i.e., ones that have not been exposed to the prompt models) we are prevented from studying the problem more rigorously. Another limitation is that while we are able to identify clear differences between synthetic vs. real data distributions, our analysis of the errors made by models trained on 0% vs. 100% synthetic data failed to yield any generalizable insights that could inform modelling approaches. A more fine-grained study of the effect of using synthetic data on the behaviour of the downstream model is hence left as a subject of future research.

9 Ethical Considerations

The usage of synthetic data has several important ethical considerations. In the era of LMs trained on internet-wide corpora having poor documentation as to their exact data sources, it becomes challenging to ensure the privacy of individuals whose data may be obtainable via a public crawl (Yao et al., 2024). Additionally, models trained on massive internet-based data sources may contain implicit biases, as well as illegal and/or highly offensive material that is hard to audit and clean (Bender et al., 2021). This data affects the synthetic data obtained from prompt models, and could unknowingly impose cultural or ethical viewpoints that are unintended or not well aligned with the use case in mind. Specifically, prior work has shown that one of the prompt models studied in this work, GPT-3.5, often disagrees with humans on key ethical questions (Felkner et al., 2024). The endeavour to completely replace human annotation with synthetic data generation also has key implications on the extent to which the field of NLP employs human annotators. It is possible that an increasing reliance on purely synthetic data reduces the demand for human annotation, which would place a downward pressure on the working standards and compensation awarded to the remaining human annotators (Weidinger et al., 2022). We argue in this work that we should not try to eliminate human annotation from our dataset and method design, showing that their work contributes uniquely helpful data points.

A Supplemental Figures

We present a detailed set of figures and tables to supplement the results presented in the main text.

Main Experiments: For figures in the main text where only one task is shown (Figure 1 and Figure 2), we provide the complete figures with both tasks (Figure 6 and Figure 7). We also provide the individual performance curves for these experiments (Figure 8 and Figure 10).

Robustness to choice of QA metric: To verify the robustness of the results, we show that the QA results are not an artifact of the choice of metric (Figure 3 and Figure 4) by using Exact Match, String Inclusion, ROUGE-1 (Lin, 2004) and BERTScore (Zhang et al., 2020). There is overwhelming agreement between all metrics on the rankings of models.

Addressing spurious correlations: We show that the performance gains afforded by human generated data cannot be explained by a spurious correlation between the human generated train and test splits. This would occur when there are significant annotation artifacts that are not relevant to the task, but are correlated with the correct output. We conduct an out-of-domain experiment (Table 5), using different datasets to source the training data and testing on a single hold out dataset. Using more synthetic data leads to performance declines even in the OOD setting, showing that human data is of higher quality and the results from the main text cannot be explained by a spurious correlation between the human test and human training samples. Interestingly, in the OOD setting the decline is steady, and we do not observe the phenomenon of a small amount of human data having a disproportionate impact on performance. This suggests that the disproportionate impact of human data occurs when the human data is in-domain. We leave a further exploration of the OOD generalization abilities of synthetic vs. human data to future work.

Multilingual Experiments: We replicate our experiment using the Arabic, Georgian, and Indonesian splits of the XFact dataset. We observe (Figure 9) the same trend as those from earlier experiments, confirming that our results are not limited to the English language. While the phenomenon is reproduced, the threshold of replacement at which we observe a precipitous decline is not the same across languages. We hypothesize that the language-specific threshold at which a little human data leads to significant performance increases is

dependent on how low resource the language is. The study of synthetic data in the multilingual setting has unique considerations that we have not addressed in this work; we leave a focus on these problems to future work.

Ablations: We show that the same trends can be seen (Figures 11 to 15) when using a different fine-tuning model (Mistral-7B), models of varying scales (from 1B parameter models to 30B parameter models), different prompting models (GPT-4 and Claude-3.5) and a more sophisticated prompting strategy (Chain-of-Thought Prompting). Across all configurations, we see a consistent decrease in performance when moving from 95% to 100% synthetic data, confirming that models trained on purely synthetic data can be improved by including just 125 real data points. For Chain-of-Thought Prompting, the authors manually annotated 3 examples with rationales per dataset to serve as the prompts. The complete examples and pipeline are provided with the code: github.com/dhananjayashok/littlehumandata

We additionally show that these trends hold across data scales (Figures 16 and 17), replicating the experiment with $n=3000$ and $n=1000$. While the trend is clearly visible in both cases, the results for $n=1000$ have more variance and hence have a minority of cases where the relationship does not hold.

Tradeoff Experiment: The main text shows results for the experiment detailed in Section 4 on the WANLI dataset (Figure 4), here we show results on the remaining three datasets (Figure 18) and provide (Figure 1) the number of additional synthetic points needed to match the performance gains of 200 additional real points (average, median and standard deviation for each dataset). ROPES shows similar results to WANLI, however FairyTaleQA and FEVER present different trends. On FEVER, we are able to reach the saturation point, after which additional data (whether synthetic or real) does not increase performance. Even in this case, we are able to reach this point of diminishing marginal return more rapidly when using a small amount of synthetic data. On a base synthetic training set of size 3000, adding 200 real data points drives the test accuracy to 89.25%, a score that is only matched once we add at least 2000 synthetic data points (an order of magnitude larger). On FairyTaleQA, we get enormous estimates for the number of additional synthetic points needed (a mean of $2.8e5$). We do not interpret these numbers

literally, rather seeing this as a sign that human generated data may occasionally boost performance to an extent that could be fundamentally unachievable by purely synthetic data.

B Synthetic Data Generation

In our implementation (Figure 19), we use few-shot learning with $k = 3$, i.e., three examples per query, with each example drawn randomly (with replacement) from the training set of the specific dataset.

We generate one synthetic point for every real point in the dataset, using the evidence text it is associated with. This gives us a total of n synthetic data points for every n real data points in a dataset.

We observed that if we did not correct for label shift, the prompt model would be heavily biased towards True claims, i.e., it would generate a dataset containing 90% True claims, while original datasets have proportions between 33%–60% True.

For the synthetic datasets used in our experiments, we correct for this label shift by specifying the label of the claim we wish to generate and providing only examples of claims with that specific label in the prompt.

For all datasets, we verify that the diversity of the generated claims/questions/answers are comparable to that of the human generated texts (see Appendix D)

This setting is generous towards synthetic data generation. In practice, we might only have three fixed examples to use in the prompt, potentially reducing the diversity of synthetic data generated. We verify that this does not affect the results of our experiment in the Chain-of-Thought ablation (Figure 15), where we use a fixed set of examples to generate all synthetic data points. We may also not know the correct label proportion to ask for and suffer a significant label shift when using synthetic data generation.

C Datasets Used

All datasets used below are released under open use licenses, authorizing their use in this research. For each dataset, we discuss the potential of dataset leakage (i.e., whether the data has been exposed to GPT-3.5-Turbo during its training) as well as the extent of automation involved in the generation of each dataset. However, across all experiments and ablations, these factors do not seem to have any

discernable effect on the trends discovered in this work.

C.1 Fact Verification Datasets

FEVER (Thorne et al., 2018) is a dataset of claims about specific entities, generated by altering sentences extracted from Wikipedia. The evidence passages are sentences from Wikipedia articles relevant to the entity in question. This dataset has been well established for a long time before the release of the prompting models used in this work, increasing the chance that it has been exposed to the prompt model ahead of time.

SciFact (Wadden et al., 2020) is a fact verification dataset for the scientific domain, which uses the abstracts of scientific articles as evidence texts. The corpus is collected from S2ORC (Lo et al., 2020), a publicly-available corpus of millions of scientific articles. Annotators are shown a source citation in the context of an article, and are asked to write up to three claims based on the content of the citation.

The above datasets are popular NLP challenge sets that were well known even before the release of GPT-3.5-Turbo (Brown et al., 2020), the prompting model used in this work. The following two datasets were released after the official training date cut-off, guaranteeing that the data has not been seen ahead of time.

WANLI (Liu et al., 2022) is an NLI dataset of 108K examples created through a hybrid worker and AI collaboration approach. The creators first study MultiNLI (Williams et al., 2018) and use dataset cartography to automatically identify examples that demonstrate challenging reasoning patterns. and then instruct GPT-3 to compose new examples with similar patterns. Machine generated examples are then automatically filtered, and finally revised and labeled by human crowd workers. While GPT-3.5-Turbo has not been trained on this data, it is worth noting that the data is partially synthetically generated.

FACTIFY (Mishra et al., 2022) is a dataset on multi-modal fact verification. It contains images, textual claims, reference textual documents and reference images. The dataset marks some examples that can be verified using text only; we use this sample in our experiments. This dataset was released after the training cut-off date for GPT-3.5 and takes its evidence texts/claims from human-written news or editorial articles. This ensures that the prompt models studied have not seen the data before training.

Label mapping for NLI and FV: While all of the above datasets contain labels for Supports, Refutes, and Not Enough Information (or Entails, Contradicts, Neutral), we consider the stricter formulation of Fact Verification used by [Honovich et al. \(2022\)](#) and [Zha et al. \(2023\)](#), considering a claim to be factual if the label is Supports (Entails), and non-factual otherwise.

C.2 Question Answering Datasets

ROPES ([Lin et al., 2019](#)) is a QA dataset which tests a system’s ability to apply knowledge from a passage of text to a new situation. The evidence context contains causal or qualitative relation(s) (e.g., “animal pollinators increase efficiency of fertilization in flowers”), and a novel situation that uses this background. The question requires reasoning about effects of the relationships in the background passage in the context of the situation.

CoQA ([Reddy et al., 2019](#)) is a dataset for building Conversational Question Answering systems. CoQA measures the ability of machines to understand a text passage and answer a series of interconnected questions that appear in a conversation. In our experiments, we extract only the first question in the series and use this to obtain our (context, question, answer) data points.

QAConv ([Wu et al., 2022](#)) focuses on informative conversations, including business emails, panel discussions, and work channels. The creators collect QA pairs with both human-written and machine-generated questions. They use a question generator and a dialogue summarizer as auxiliary tools to collect and recommend questions. While the arXiv version of the paper appears before the GPT-3 cut-off data (April 2021 to the cut-off date of Sept 2021), the paper itself appeared only at ACL 2022. It is still possible that the training data was compromised, and owing to the lack of clarity on the training data used for GPT-3 we have no way to confirm or deny this speculation.

FairyTaleQA ([Xu et al., 2022](#)) is a dataset focusing on narrative comprehension of kindergarten to eighth-grade students. The evidence texts are derived from children-friendly stories which serve as evidence texts. The questions are both explicit and implicit, covering seven types of narrative elements or relations. This dataset was released after the GPT-3 training cut-off date, ensuring that it has not been seen by our prompt model before.

D Detailed Discussion on Differences Between Synthetic and Human Data

To compute the extent to which the evidence sentences ‘contain’ the questions, answers, and claims, we measure the BLEU of the generation with **each individual sentence** of the evidence texts, plotting the maximum of these BLEU scores in Figure 21. We find that synthetic generations have a far higher n-gram overlap with the evidence sentences than human generations. This suggests that synthetic data generation produces data points that are more extractive, while humans are more likely to abstract from the evidence. We also use the position of the evidence sentence that achieves the highest BLEU score as a proxy for the source location of the synthetic generation, and find that synthetic data generation chooses more diverse sources for the question and answer content, with human annotation overwhelmingly more likely to create questions whose answers lie in the start of the evidence texts (Figure 22). Finally, the main text shows the size length comparison for a single dataset. Here we provide a larger sample (Figure 20). We explore the errors created by the models trained on 0% and 100% data, searching for trends or divergences between the input instances that achieve a low prediction accuracy or score. Our investigation finds no major distinguishing factors between them, leaving a more fine-grained study of the effect of purely synthetic data on model decision-making to future work.

E Implementation Details

While our full code implementation can be seen in the GitHub repository (to be released after review), we list the key implementation details below.

Hardware and Systems Used: The experiments were run on a cluster that included nodes with: five A40 GPUs (48GB), three RTX 2080Tis, and a separate machine using a single A100 GPU.

Prompt Models used: We used GPT-3.5-Turbo and GPT-4-Turbo Batch APIs from OpenAI. Generations were obtained at various points from August 2024 to September 2024.

Fine-Tuning Models Used: We used two fine-tuning models in our experiments. Llama3 used the Llama3.1-8B HuggingFace Checkpoint, and Mistral used the Mistral7B-Instruct-v0.2 HuggingFace Checkpoint. We did not conduct an extensive hyperparameter search, however we tried various epochs on smaller samples of the FEVER and

ROPES datasets, selecting that number for every dataset on all experiments. Fact verification models used Adam Optimization with a learning rate of $1e-5$ for two epochs, while QA datasets used a learning rate of $1e-2$ for five epochs.

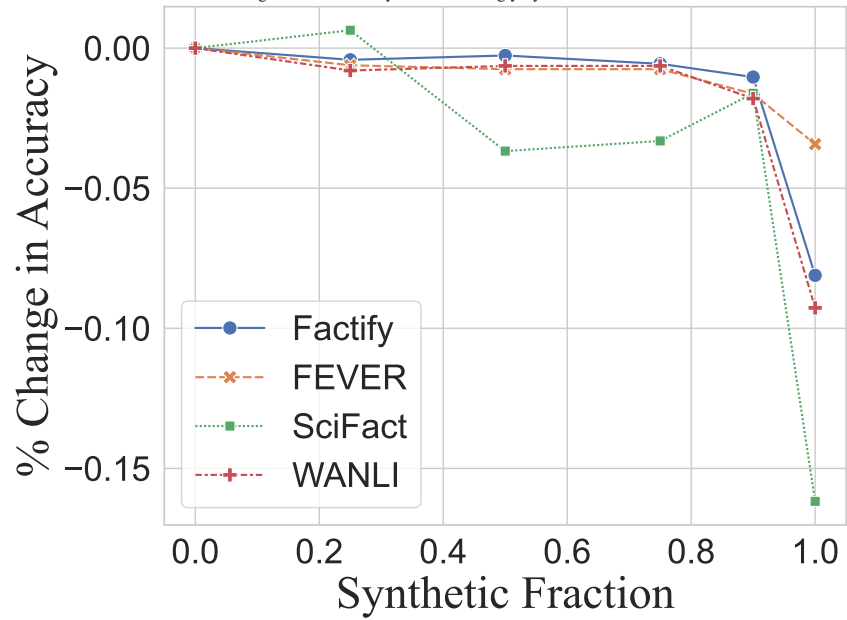

Figure 6: Change in model performance as the proportion of synthetic points in the training data is increased. Across datasets, the performance decrease when moving from 0% to 90% synthetic data is often less than that of moving from 90% to purely synthetic data.

Figure 7: Model performance as the synthetic proportion of the training data varies from 95% to 100%. Across all datasets and random seeds, having **just 2.5%** of the training dataset being human generated boosts performance.

Abstract

Unsupervised cross-domain keyphrase generation (KPG) is crucial in real-world natural language processing scenarios. However, the accuracy of up-to-date approaches is limited by the distribution shift between source and target domain, which stems from the cross-domain field. Large language models (LLMs) offer potential for the cross-domain keyphrase generation tasks due to their strong generalization abilities, facilitated by providing demonstrations relevant to the target task. Nevertheless, it is often difficult to obtain labeled samples from the target domain. To address this challenge, this paper aims to seek rational demonstrations from the source domain, thereby improving the LLMs' ability in the unsupervised cross-domain keyphrase generation setting. Specifically, we design a novel domain-aware retrieval model on the source domain. Guided by insights from domain generalization theory, we introduce two generalization terms, one for cross-domain relevance and another for each domain consistency to better support retrieval of rational demonstrations. By the retrieved source-domain demonstrations and distance-based relevant score, the proposed approach achieves optimal accuracy. Comprehensive experiments on widely used cross-domain KPG benchmarks demonstrate our approach's state-of-the-art performance and effectiveness.

1 Introduction

Keyphrase Generation (KPG) is critical in identifying discriminative information (Meng et al., 2017; Shao et al., 2024; Boudin and Aizawa, 2024). As a fundamental natural language generation (NLG) task, keyphrase generation facilitates a wide variety of downstream applications, including document clustering (Hulth and Megyesi, 2006; Chiu et al., 2020), information retrieval (Ushiku et al., 2017; Boudin et al., 2020) and text summarization (Wang and Cardie, 2013). However, in real

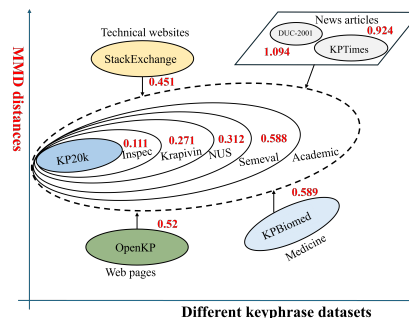

Figure 1: we treat the KP20k train dataset as the source domain, and using MMD to measure the degree of the distribution shift between different datasets.

world scenarios, e.g. news articles (Gallina et al., 2019), web pages (Xiong et al., 2019), technical question-answer website (Yuan et al., 2020), obtaining labels can be challenging due to the reliance on domain expertise, or even infeasible because of the strict privacy constraints. Deploying keyphrase generation model in these scenarios often occurs in cross-domain KPG setting, e.g., first training KPG models on source tasks and then generalizing to target tasks (Gulrajani and Lopez-Paz; Wiles et al.). What is notable is that distribution shift is an inevitable phenomenon in cross-domain KPG.

As depicted in Figure 1, we treat the KP20k train dataset (Meng et al., 2017) as the source domain, and adopt Maximum Mean Discrepancy (MMD) (Kim et al., 2016) to measure the degree of the distribution shift. Higher MMD values between each two datasets indicate increased requirements for the model's generalization capabilities. For example, compared to academic domain datasets, such as Inspec (Hulth, 2003), Krapivin (Krapivin and Marchese, 2009), and NUS (Nguyen and Kan, 2007), the MMD distance is significantly larger for other domain datasets (e.g., OpenKP (Xiong et al., 2019), KPBiomed (Houbre et al., 2022)). This makes generalizing the KPG model in cross-domain setting more challenging than in standard generation,

where a robust decision boundary is sufficient. An effective strategy to alleviate distribution shift is the use of large language models (LLMs), where labeled samples are used as prompts to facilitate the generation of target domain keyphrases. However, even annotating a limited number of samples can be prohibitively expensive, and often impractical due to the need for expert annotators (Chau et al., 2020; Boudin and Aizawa, 2024). How to effectively leverage existing labeled source domain samples to prompt LLMs in unsupervised cross-domain KPG is a crucial problem that deserves in-depth exploration. In this work, we propose a seeking rational demonstration (SRD) approach for enhancing LLMs’ ability in unsupervised cross-domain KPG. The SRD approach is designed based on DPR (Dense Passage Retrieval) model (Karpukhin et al., 2020). Specifically, we randomly select 20% samples from KP20k train datasets and target test dataset as the query set, with the rest as candidate set. We then construct positive and negative samples by computing the relevance of each query-candidate sample pair. However, there is no guarantee of accuracy when mapping the target query samples to the rational KP20k train samples during test time when facing distribution shift. As such, we introduce the domain projection simulation (DPS) with two new losses based on domain generalization theory to alleviate distribution shift between training and test phrases. The first loss is a domain projection loss based on the MMD distance, which helps learn more domain-invariant features and mitigates distribution shift. The second one is a domain characteristic loss that encourages the learnable train distribution to be orthogonal in the representation space, thus increasing the diversity and preventing domain characteristic vanished.

Our contributions are three-fold:

- We quantify the distribution shift phenomenon when applying LLMs to unsupervised cross-domain KPG. To the best of our knowledge, this is the first work that introduces domain generalization with LLMs in KPG.
- We investigate both theoretically and empirically how domain generalization technique can help with distribution projection, and thus alleviating distribution shift.
- Experimental results demonstrate that our SRD approach performs better than up-to-date baselines on widely used cross-domain

KPG test datasets. The processed test datasets, codes and experimental results will be upload at <https://github.com/chrischowfy/SRD/>.

2 Related Work

Current keyphrase generation tasks primarily focus on academic article domain, encompassing both supervision (Meng et al., 2017; Ye et al., 2021; Shao et al., 2024; Kang and Shin, 2024) and unsupervison (Shen et al., 2022; Boudin and Aizawa, 2024) fashions. AutoKeyGen (Shen et al., 2022) is the first work to explore the unsupervised keyphrase generation task, which trains a sequence-to-sequence model to extract present keyphrases and synthesize absent keyphrases using a phrase corpus. After that, UOKG (Do et al., 2023) extends AutoKeyGen in open-domain setting, which generates keyphrases that represent the core concept of the source text. Another related work is domain-adaptive keyphrase generation (Meng et al., 2023), however, it requires a few labeled samples from the target domain for fine-tuning. Another related direction is keyphrase generation in low-resource settings (Wu et al., 2022; Garg et al., 2023). Existing researches often employ target domain data pretraining (Wu et al., 2022) and data augmentation (Garg et al., 2023) to enhance keyphrases generation capabilities in low-resource contexts. However, in the era of large language models, considering the challenges of fine-tuning LLMs and computational expenses, there is an urgent need for new research approaches to address the problem of unsupervised cross-domain keyphrase generation.

Recently, LLMs perform well in unsupervised keyphrase generation (Martínez-Cruz et al., 2024). Notably, when provided with an in-context prompt that contains a few relevant samples from the target domain, LLMs can further enhance their keyphrase generation performance in target domain (Jiang et al., 2024). However, in real-world scenarios, acquiring labeled target samples is non-trivial. This motivates our work: how to effectively prompt LLMs using labeled source domain samples to improve keyphrase generation across different domains.

3 Methodology

3.1 Problem Settings

Formally, the unsupervised cross-domain KPG task is a text generation problem conditioned on both

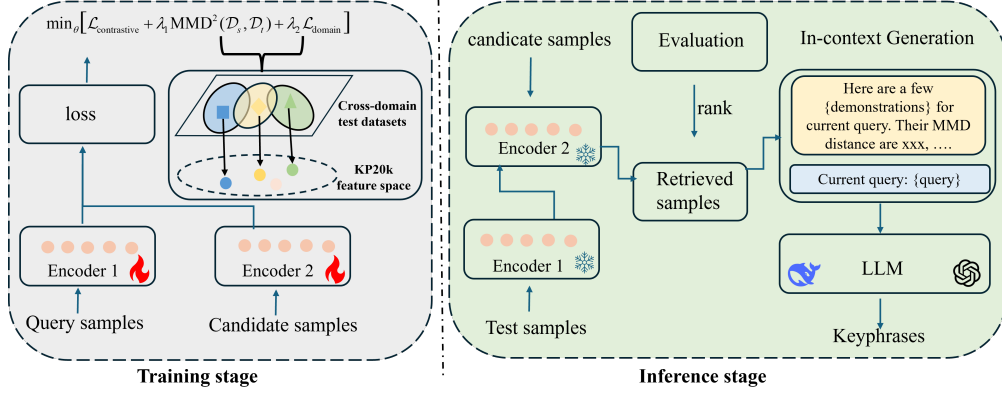

Figure 2: Overview of the seeking rational demonstrations (SRD) approach for unsupervised cross-domain KPG.

the target domain input and a set of source domain demonstrations:

$$\hat{y} = \arg \max_{\mathbf{y}} P(\mathbf{y} \mid x_t, \text{Retrieve}(x_t, \mathcal{S}), \Theta), \quad (1)$$

where $x_t \in \mathcal{D}_t$ is the unlabeled target-domain input, $\text{Retrieve}(\cdot, \cdot)$ denotes a retrieval function that selects relevant demonstrations from the labeled source-domain samples \mathcal{S} , and Θ denotes the LLMs’ parameters. Note that no labeled target-domain data is available, the generalization capacity of the model is crucially depends on the quality of its retrieved source-domain samples under distribution shift.

3.2 Basic Retrieve Module

As shown in Figure 2, to efficiently retrieve rational demonstrations for unsupervised cross-domain KPG, we first build a basic dual-encoder retrieval module based on the DPR model (Karpukhin et al., 2020). The module includes two encoders, which can map both query text and candidate text into vector representations.

Constructing Positive & Negative Pairs. Since the KP20k train dataset does not explicitly provide positive or negative sample pairs, we manually construct them by analyzing the keyphrases of each sample. Specifically, let \mathbf{k}_x and \mathbf{k}_s be the keyphrases of samples x and s , respectively. The relevance score is defined as:

$$\text{Rel}(x, s) = \alpha \cdot \text{sim}_{\text{embed}}(\mathbf{k}_x, \mathbf{k}_s) + (1 - \alpha) \cdot \text{Jaccard}(\mathbf{k}_x, \mathbf{k}_s), \quad (2)$$

where $\text{sim}_{\text{embed}}(\mathbf{k}_x, \mathbf{k}_s)$ denotes the semantic similarity and $\text{Jaccard}(\mathbf{k}_x, \mathbf{k}_s)$ is the Jaccard similarity. If $\text{Rel}(x, s)$ exceeds a global threshold γ_1 , we classify (x, s) as a positive (matched) pair, and otherwise treat it as a negative (unmatched) pair.

Self-supervised Demonstrations Evaluator. We design a self-supervised evaluator utilizing the KP20k train dataset to assess the efficacy of retrieved demonstrations. We divide KP20k into two disjoint subsets: the pseudo-source domain \mathcal{D}_{ps} and pseudo-target domain \mathcal{D}_{pt} . The former is used to simulate the source domain for retrieval purposes, and the latter is used to mimic the unlabeled target domain scenario. We then train a regression model to learn a function mapping the triplet $(\mathbf{x}, \mathbf{e}, \mathbf{y}^{\text{gen}})$ to a quality score \hat{s} , where \mathbf{x} represents the abstract text in the pseudo-target domain, \mathbf{e} indicates the retrieved examples, and \mathbf{y}^{gen} are the keyphrases generated by a LLM. Let \mathbf{y}^{ref} denote the ground-truth keyphrases for \mathbf{x} in the pseudo-target domain. The quality score s of \mathbf{y}^{gen} is computed by the Eq.2, i.e., $s = \text{Rel}(\mathbf{y}^{\text{gen}}, \mathbf{y}^{\text{ref}})$. More details can be found in Appendix A.1 Implementation Details.

3.3 The Risk of Distribution Shift

We first give the distribution shift measured by \mathcal{H} -divergence (Ben-David et al., 2010):

$$d_{\mathcal{H}}(\mathcal{D}_s, \mathcal{D}_t) = 2 \sup_{h \in \mathcal{H}} \left| \Pr_{x \sim \mathcal{D}_s} [h(x) = 1] - \Pr_{x \sim \mathcal{D}_t} [h(x) = 1] \right|, \quad (3)$$

where classifier $h : \mathcal{X} \rightarrow \{0, 1\}$ is a labeling function on each domain sample. Next, the ideal target domain $\bar{\mathcal{D}}_t$ is assumed that lies in the source domain convex hull Λ_s (Albuquerque et al., 2019). Under this assumption, the risk $\epsilon_t(h)$ on the target domain \mathcal{D}_t is upper-bounded (Albuquerque et al., 2019; Chen et al., 2019) by:

$$\epsilon_t(h) \leq \sum_{i=1}^K \eta_i \epsilon_s^i(h) + \gamma + \zeta. \quad (4)$$

The first term is the risks over source domains, which can be minimized by empirical risk minimization. The second term γ is the \mathcal{H} -divergence

between the ideal target $\overline{\mathcal{D}}_t$ and the real target domain \mathcal{D}_t . The third term could be disregarded as it is negligibly small. In this paper, we focus on the first and second terms to alleviate distribution shift in unsupervised cross-domain KPG.

3.4 Distribution Projection Simulation

Since there is distribution shift existed between source and target domain, we attempt to mitigate the ensuing cross-domain risk by domain generalization theory. Specifically, we employ MMD (Kim et al., 2016) as a kernel-based criterion that directly measures the similarity between the source and target samples in its representation space. By guiding the encoder to produce more domain-invariant features, we reduce adverse effects of distribution shift and thus improve generalization in unsupervised cross-domain KPG. In each training iteration, we select a mini-batch of labeled source domain samples $\{x_i^s, y_i^s\}_{i=1}^m \subset \mathcal{D}_s$ and unlabeled target domain samples $\{x_j^t\}_{j=1}^n \subset \mathcal{D}_t$. Using the kernel function $k(\cdot, \cdot)$, the squared MMD is computed as:

$$\text{MMD}^2(\mathcal{D}_s, \mathcal{D}_t) = \frac{1}{m(m-1)} \sum_{\substack{i,j=1 \\ i \neq j}}^m k(f(x_i^s), f(x_j^s)) + \frac{1}{n(n-1)} \sum_{\substack{i,j=1 \\ i \neq j}}^n k(f(x_i^t), f(x_j^t)) - \frac{2}{mn} \sum_{i=1}^m \sum_{j=1}^n k(f(x_i^s), f(x_j^t)), \quad (5)$$

where $f(\cdot)$ is the encoder’s mapping from input text to a feature vector, $k(\cdot, \cdot)$ is the radial basis function kernel with $k_{i,j} = k(x_i, x_j) = \exp(-\gamma \|x_i - x_j\|)$, γ is a hyperparameter (Kim et al., 2016). MMD imposes a domain-invariance constraint on the encoders’ representations. In this way, the features between the source and target domain samples align more closely, which are crucial for accurate keyphrase generation under distribution shift. However, a naive reduction of MMD operates on mean embedding feature of each sample, which may be insufficient to characterize sample mapping (Vayer and Gribonval, 2023). Hence, we also incorporate domain-specific features into the encoders that retain critical domain cues.

Preserving Domain Characteristics via Orthogonality. To further impose domain features into the encoders, we introduce two sets of mean and variance vectors: $\{\mu_b^s, \sigma_b^s\}$ for the source domain samples, and $\{\mu_b^t, \sigma_b^t\}$ for the target domains samples. We design a domain (orthogonality) loss to enforce these vectors to remain domain-specific:

$$\mathcal{L}_{\text{domain}} = \left| \frac{\mu_b^s}{\|\mu_b^s\|} \cdot \frac{\mu_b^t}{\|\mu_b^t\|} \right| + \left| \frac{\sigma_b^s}{\|\sigma_b^s\|} \cdot \frac{\sigma_b^t}{\|\sigma_b^t\|} \right|, \quad (6)$$

where $\|\cdot\|$ is the vector norm, and \cdot is the dot product. By forcing the normalized means and variances from the source and target to be approximately orthogonal, we ensure that while we reduce overall distribution divergence, each domain maintains its own “style” (i.e., domain-specific signals).

3.5 Training

We train the dual-encoder retriever by combining traditional contrastive loss (Karpukhin et al., 2020) with the standard MMD alignment. The overall objective is to minimize:

$$\min_{\theta} \left[\mathcal{L}_{\text{contrastive}} + \lambda_1 \text{MMD}^2(\mathcal{D}_s, \mathcal{D}_t) + \lambda_2 \mathcal{L}_{\text{domain}} \right], \quad (7)$$

where θ is the parameter of the retriever, and λ_1 and λ_2 are hyperparameters balancing the three terms. By jointly minimizing the contrastive loss and domain relevant loss, we reduce the distribution shift (thus addressing the second risk term in Eq. (4)) while preserving crucial domain characteristics in both source and target domains.

4 Experiments

4.1 Experimental Setup

Datasets We conduct experiments on five public domain KPG datasets, namely DUC-2001, KPTimes, OpenKP, StackExchange and KPBiomed. The detailed statistic is depicted in Table 1.

Datasets	Type	Test docs	#Kps/doc	%Absent	Api_Illm
StackExchange (Yuan et al., 2020)	Technology	2000	2.65	48.78	300
DUC-2001 (Wan and Xiao, 2008)	News	308	8.06	2.7	300
KPTimes (Gallina et al., 2020)	News	2000	5.07	54.2	300
OpenKP (Xiong et al., 2019)	Web	2000	2.31	11.62	300
KPBiomed (Houbre et al., 2022)	Medicine	2000	5.38	38.74	300

Table 1: Statistic of cross-domain test datasets.

Baselines and Metrics We compare our approach with AutoKeyGen (Shen et al., 2022) and UOKG (Do et al., 2023), which are the only two standard baselines on unsupervised cross-domain keyphrase generation. Furthermore, we re-implement CopyRNN (Meng et al., 2017), One2set (Ye et al., 2021) and DeepKPG (Wu et al., 2023) as supervised baselines. The subscript in Table 2 indicates the standard deviation (e.g., 9.4₇ denotes 9.40±0.7). We also adopt several LLM backbones to evaluate our approach. Following UOKG, we use the F1@K and Recall@K as evaluation metrics, where K is the number of predicted keyphrases to be considered. We only use KP20k to seek rational demonstrations.

Table 2: Performances of cross-domain test datasets (%).

4.2 Comparisons to the State-of-the-art Methods

Table 2 shows the performance of different methods on the five cross-domain test datasets, the proposed SRD method consistently performs better than the SOTA methods across multiple datasets. Ours(GPT4o) method exceeds ChatGPT-3.5 by 12.29% and 5.38% in absolute average values on present and absent keyphrase generations. The metrics of ChatGPT-3.5 and Ours (ChatGPT-3.5) (14.21 vs. 20.58) indicate reasonable demonstrations significantly enhance the accuracy in unsupervised cross-domain KPG. Furthermore, we also find that LLMs tend to weaken their generation capabilities on free-form text, while reasonable demonstrations effectively mitigate this negative impact. Besides, we can see that the DeepSeek model is competitive with GPT4o (26.50/9.94 vs. 25.26/9.33) on present and absent keyphrase, indicating the high cost-effectiveness of the former.

4.3 Sampling Ratio Analysis

Figure 3 shows the performance of various proportions of sample selections: 5%, 10%, 20%, 30%, and 40%. It is observed that a lower proportion of the query set results in insufficient training diversity, thereby constraining the overall effectiveness of KPG. As the proportion increases, the performance of KPG improves accordingly, reaching its

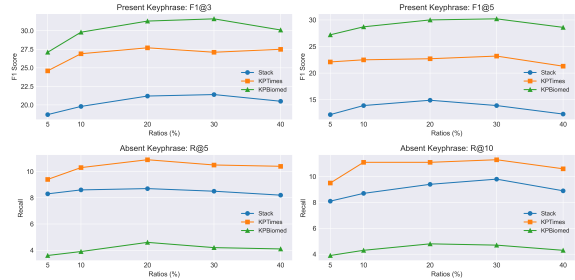

Figure 3: Performances under different ratios (%).

peak around the 30% inclusion mark. This suggests that the optimal query set proportion likely lies between 20% and 30%. However, when the proportion is increased to 40%, the query set tends to accumulate redundant or highly similar samples.

5 Conclusion

In this work, we present a new perspective for unsupervised cross-domain KPG with prompts LLMs to enhance its generalizability. We propose a novel seeking rational demonstrations (SRD) approach, which is the first work that introduces domain generalization on retrieve model for unsupervised cross-domain KPG. We design MMD driven distribution project loss and orthogonality loss beyond the mapping of positive and negative samples. Extensive experiments demonstrate the better performance and the effectiveness of the proposed seeking rational demonstrations approach.

6 Limitations

In addressing the practical distribution shift challenges faced by large language models in unsupervised cross-domain PKG, i.e., the difficulty of obtaining labeled target domain samples for prompting, this paper proposes a seeking rational demonstration approach. Using the Maximum Mean Discrepancy (MMD) distance as a metric for disparity, this approach retrieves highly relevant samples from the source domain to serve as demonstrations for the target samples. The main limitations of this paper are as follows: 1. The setup of the evaluator is rather rudimentary. Due to the unavailability of labeled samples from the target domain, only source domain samples are used. When encountering domains that significantly differ from the source domain, this may impact the selection of demonstrations and thus affect the quality of unsupervised cross-domain keyphrase generation. Future work could explore joint optimization of retriever and evaluator. 2. This approach does not involve optimizations for domain generalization of the large language model itself. If domain-specific instruction fine-tuning could be applied to the language model, it is believed that the model performance could be further enhanced.

A Appendix

A.1 Implementation Details

Basic Retrieve Module. To efficiently retrieve suitable demonstrations for unsupervised cross-domain keyphrase generation (KPG), we first build a basic dual-encoder retrieval module based on the DPR model¹. The module consists of two encoders, which can map both query text and candidate text into vector representations.

Constructing Positive & Negative Pairs. Since the KP20k train dataset does not explicitly provide positive or negative sample pairs, we manually construct them by analyzing the keyphrases of each sample in the dataset. Specifically, let \mathbf{k}_x and \mathbf{k}_s be the keyphrase sets of two samples x and s , respectively. We first apply linguistic preprocessing such as case normalization and stemming² to reduce word-level discrepancies. We define the Jaccard similarity as:

$$\text{Jaccard}(\mathbf{k}_x, \mathbf{k}_s) = \frac{|\mathbf{k}_x \cap \mathbf{k}_s|}{|\mathbf{k}_x \cup \mathbf{k}_s|}. \quad (8)$$

A potential limitation of the Jaccard similarity is that keyphrases with low or zero lexical overlap may still have high semantic similarity (e.g., “deep learning” vs. “neural networks”). To better capture deep semantic relationships, we additionally employ an embedding-based metric. Each keyphrase is encoded into a vector \mathbf{e}_{k_x} or \mathbf{e}_{k_s} with *gte-large*³ embedding model. We compute the cosine similarity between \mathbf{e}_{k_x} and \mathbf{e}_{k_s} . The relevance score is defined as:

$$\text{Rel}(x, s) = \alpha \cdot \text{sim}_{\text{embed}}(\mathbf{k}_x, \mathbf{k}_s) + (1 - \alpha) \cdot \text{Jaccard}(\mathbf{k}_x, \mathbf{k}_s), \quad (9)$$

where $0 \leq \alpha \leq 1$ is a balancing coefficient. If $\text{Rel}(x, s)$ exceeds a global threshold γ_1 , we classify (x, s) as a positive (matched) pair, and otherwise treat it as a negative (unmatched) pair.

Self-supervised Demonstrations Evaluator. To assess the efficacy of retrieved demonstrations in enhancing keyphrase generation within an unlabeled target domain, we design a self-supervised evaluator utilizing the KP20k train dataset. We divide KP20k into two disjoint subsets: the pseudo-source domain \mathcal{D}_{ps} and pseudo-target domain \mathcal{D}_{pt} with K-means algorithm⁴. The former is used to

¹<https://github.com/facebookresearch/DPR/>

²We use the NLTK toolkit to do processing. <https://www.nltk.org/>

³<https://huggingface.co/thenlper/gte-large>

⁴<https://scikit-learn.org/>

simulate the source domain for retrieval purposes, and the latter is used to mimic the unlabeled target domain scenario. We then train a regression model with RoBERTa⁵ to learn a function mapping the triplet $(\mathbf{x}, \mathbf{e}, \mathbf{y}^{\text{gen}})$ to a quality score \hat{s} , where \mathbf{x} represents the abstract text in the pseudo-target domain, \mathbf{e} indicates the retrieved examples, and \mathbf{y}^{gen} are the keyphrases generated by LLM. Let \mathbf{y}^{ref} denote the ground-truth keyphrases for \mathbf{x} in the pseudo-target domain. The quality score s of \mathbf{y}^{gen} is computed by the defined evaluation metric in Eq.9, i.e., $s = \text{Rel}(\mathbf{y}^{\text{gen}}, \mathbf{y}^{\text{ref}})$. Formally, let f_θ represent the evaluator, the training objective is to minimize the mean squared error (MSE) between \hat{s} and s :

$$\min_{\theta} \mathbb{E}_{(\mathbf{x}, \mathbf{e}, \mathbf{y}^{\text{gen}}, \mathbf{y}^{\text{ref}}) \sim \mathcal{D}} \left[(f_\theta(\mathbf{x}, \mathbf{e}, \mathbf{y}^{\text{gen}}) - s)^2 \right], \quad (10)$$

where \mathcal{D} is the dataset constructed from both \mathcal{D}_{ps} and \mathcal{D}_{pt} . We use multiple checkpoints of the trained retrieval module to obtain various \mathbf{y}^{gen} to better train the regression model.

Experimental Details. We use the open-source instruction fine-tuned LLMs as backbone. That is Qwen-2.5-14b⁶ and LLama-3.3-70b-4bit⁷. We also use several LLMs with commercial API, that is ChatGPT-3.5⁸, GPT4o⁹ and DeepSeek¹⁰. The temperature is set to be 0.4. We set the hyperparameters with the KPTime validation dataset. The learning rate is 3e-5 and the optimizer is AdamW. We retain only the top 2 demonstrations to prompt the LLMs, avoiding that an excessive number of examples would introduce significant additional overhead. We train the model on 2 A40 48GB GPUs and use a cosine scheduler with a 2% warm-up period for 3 epochs. The ratio α in Eq.9 is set to be 0.8, the global threshold γ_1 is set to be 0.70.

A.2 Ablation Study

We perform comprehensive ablation studies based on the DeepSeek model to show the effectiveness of the components through the performance on the three different domain test datasets.

- Zero-shot: This variant only generates keyphrases without demonstrations.

⁹[gpt-4o-2024-11-20](https://openai.com/gpt-4o-2024-11-20)

¹⁰[deepseek/deepseek-chat](https://deepseek.com/deepseek-chat)

- Random-D: This variant randomly selects samples from the KP20k train dataset to prompt the DeepSeek model.
- Embed-D: This variant solely uses semantic similarity to select samples from the KP20k train dataset to prompt the DeepSeek model.
- w/o MMD: this variant removes the MMD loss during the training of the retrieval module.
- w/o Orthogonality: this variant removes the Orthogonality loss during the training of the retrieval module.
- w/o MDD + Orthogonality: This variant only uses contrastive loss to train the retrieval module.

From Table 3, we can conclude that: The performance of zero-shot is the worst, indicating that while large language models exhibit strong generalization ability, they struggle to leverage this advantage when facing samples from new domains. The performance of random-D shows only a limited improvement over zero-shot, suggesting that inaccurate prompts are ineffective in enhancing the performance of large language models. Embed-D performs better than random-D. It indicates that semantically similar samples provide meaningful assistance to large language models.

Compared to the Embed-D method, the results of w/o MMD, w/o Orthogonality, and w/o MMD+Orthogonality are even better, highlighting the effectiveness of the proposed “seek rational demonstration” approach in this paper. This approach, through the retrieval and evaluation modules, is able to provide large language models with the most reasonable sample examples, thereby significantly enhancing their unsupervised cross-domain keyphrase generation ability.

A.3 In-domain Sample Evaluation

Our SRD method is specifically designed for the unsupervised cross-domain KPG task. For small-scale labeled target domain samples (e.g., 10 labeled target domain samples), we can directly use the target domain supervised samples as prompts, integrating them into our SRD method. To evaluate the experimental effects, we designed the following experiments with DeepSeek model:

Present keyphrase generation						
Methods	StackExchange		KPTimes		KPBiomed	
	F1@3	F1@5	F1@3	F1@5	F1@3	F1@5
Zero-shot	5.4	3.7	11.0	8.5	18.4	17.2
Random-D	6.3	3.4	17.5	10.5	8.6	18.1
Embed-D	18.9	8.9	23.2	20.8	28.7	25.5
Ours	21.2	14.9	27.7	22.7	31.3	30.0
Ours(w/o MMD)	19.6	10.2	26.8	21.1	27.9	27.3
Ours(w/o Orthogonality)	<u>19.8</u>	<u>12.8</u>	<u>27.4</u>	<u>21.5</u>	<u>30.1</u>	<u>28.3</u>
Ours(w/o MDD+Orthogonality)	18.2	9.4	25.4	17.6	27.4	26.6
Absent keyphrase generation						
Methods	StackExchange		KPTimes		KPBiomed	
	R@5	R@10	R@5	R@10	R@5	R@10
Zero-shot	3.1	3.2	5.8	6.0	2.9	2.9
Random-D	3.7	3.2	5.7	5.9	3.2	2.9
Embed-D	6.6	7.1	7.4	9.2	3.8	3.1
Ours	8.7	9.4	10.9	11.1	4.6	4.8
Ours(w/o MMD)	7.5	7.7	9.2	9.4	3.9	4.6
Ours(w/o Orthogonality)	<u>8.1</u>	<u>7.5</u>	<u>9.8</u>	<u>10.5</u>	<u>4.2</u>	<u>5.1</u>
Ours(w/o MDD+Orthogonality)	6.8	6.5	8.4	8.9	4.2	4.3

Table 3: Ablation study of our SRD approach across three benchmark datasets. Best scores in **bold**, second-best underlined.

Present keyphrase generation							
Methods	StackExchange		KPTimes		KPBiomed		Average
	F1@3	F1@5	F1@3	F1@5	F1@3	F1@5	
Ours	21.2	14.9	27.7	22.7	31.3	30.0	24.63
Random-T	22.1	15.3	27.5	23.6	30.8	29.9	24.87
Ours+few-shot	23.2	16.5	29.5	24.4	33.1	31.6	26.38
Absent keyphrase generation							
Methods	StackExchange		KPTimes		KPBiomed		Average
	R@5	R@10	R@5	R@10	R@5	R@10	
Ours	8.7	9.4	10.9	11.1	4.6	4.8	8.25
Random-T	8.6	10.1	10.5	11.8	4.5	5.7	8.53
Ours+few-shot	10.5	11.2	11.7	12.5	6.3	6.5	9.78

Table 4: In-domain evaluation across three benchmark datasets.

- Random-T: It selects the first 10 samples from the validation sets of their respective datasets, then randomly choose 2 samples as target domain demonstrations to evaluate the generative capability of the LLMs.
- Ours+few-shot: We add 2 randomly selected labeled target domain samples as demonstrations.

From Table 4, we can observe that: The SRD is slightly inferior to supervised target domain KPG, indicates that demonstrations from the same domain have a significant impact on the KPG via LLMs. The SRD+few-shot yields the best results, suggesting that equipping SRD with labeled target domain samples further enhances its KPG capabilities. We infer that, in the context of unsupervised cross-domain KPG, the absence of relevant target domain information usually make it challenging to surpass supervised cross-domain KPG tasks. The assistance of a few-shot approach undoubtedly enhances our method significantly.

A.4 MMD for evaluating distribution shift between two different datasets

The maximum mean discrepancy (MMD) is a measure of the difference between distributions \mathcal{P} and

\mathcal{Q} , given by the supremum over a function space \mathcal{F} of differences between the expectations with respect to two distributions. Given n samples from \mathcal{P} as $X = \{x_i \sim P, i \in [n]\}$, and m samples from \mathcal{Q} as $Z = \{z_i \sim Q, i \in [m]\}$, the following is a finite sample approximation:

$$\text{MMD}(\mathcal{F}, P, Q) = \sup_{f \in \mathcal{F}} (\mathbb{E}_{X \sim P}[f(X)] - \mathbb{E}_{Y \sim Q}[f(Y)]). \quad (11)$$

Inspired by the sampling technique for interpretable machine learning (Kim et al., 2016), we adopt the squared maximum mean discrepancy (MMD) between \mathcal{S} and \mathcal{P} with a kernel function k to measure the discrepancy between them:

$$\begin{aligned} \text{MMD}_k^2(\mathcal{F}, \mathcal{S}, \mathcal{P}) &= \frac{1}{|\mathcal{S}|^2} \sum_{\mathbf{s}_i, \mathbf{s}_j \in \mathcal{S}} k(\mathbf{s}_i, \mathbf{s}_j) \\ &\quad - \frac{2}{|\mathcal{S}||\mathcal{P}|} \sum_{\mathbf{s}_i \in \mathcal{S}, \mathbf{p}_j \in \mathcal{P}} k(\mathbf{s}_i, \mathbf{p}_j) \\ &\quad + \frac{1}{|\mathcal{P}|^2} \sum_{\mathbf{p}_i, \mathbf{p}_j \in \mathcal{P}} k(\mathbf{p}_i, \mathbf{p}_j). \end{aligned} \quad (12)$$

It is clear that $\text{MMD}^2(\mathcal{F}, P, Q) \geq 0$ and $\text{MMD}^2(\mathcal{F}, P, Q) = 0$ iff. \mathcal{P} is indistinguishable from \mathcal{Q} on the RHKS \mathcal{F} .

When \mathcal{F} is a reproducing kernel Hilbert space (RKHS) with kernel function $k : \mathcal{X} \times \mathcal{X} \mapsto \mathbb{R}$, the supremum is achieved at (Gretton et al.):

$$f(x) = \mathbb{E}_{X' \sim P} [k(x, X')] - \mathbb{E}_{X' \sim Q} [k(x, X')], \quad (13)$$

and the witness function is approximated as:

$$f(x) = \frac{1}{n} \sum_{i \in [n]} k(x, x_i) - \frac{1}{m} \sum_{j \in [m]} k(x, z_j). \quad (14)$$

The function 14 is also known as the witness function as it measures the maximum discrepancy between the two expectations in \mathcal{F} .

A.5 Prompt Templates

For the zero-shot setting of LLMs for unsupervised cross-domain PKG, we use the following prompt template.

```

=====
Please generate accurate present and
absent keyphrases in lowercase for
the given sample.
=====
###Sample###:
"text": "{text}"
**Please only output at least five

```

```

present and absent keyphrases with
standard JSON format.**

```

Given the retrieved demonstrations, we can use the following prompt template for unsupervised cross-domain PKG.

```

=====
Please refer to the demonstrations
generate accurate present and absent
keyphrases with lowercase for the given
sample.
{demonstrations_case}
=====
###Sample###:
"text": "{text}"
The MMD distances between the
demonstrations and the sample are {MMD}.
**Only output present and absent
keyphrases with standard JSON format.

```

LexKeyPlan: Planning with Keyphrases and Retrieval Augmentation for Legal Text Generation: A Case Study on European Court of Human Rights Cases

Santosh T.Y.S.S, Elvin Quero Hernandez

School of Computation, Information, and Technology

Technical University of Munich, Germany

{santosh.tokala, elvin.quero}@tum.de

Abstract

Large language models excel at legal text generation but often produce hallucinations due to their sole reliance on parametric knowledge. Retrieval-augmented models mitigate this by providing relevant external documents to the model but struggle when retrieval is based only on past context, which may not align with the model’s intended future content. We introduce LexKeyPlan, a novel framework that integrates anticipatory planning into generation. Instead of relying solely on context for retrieval, LexKeyPlan generates keyphrases outlining future content serving as forward-looking plan, guiding retrieval for more accurate text generation. This work incorporates planning into legal text generation, demonstrating how keyphrases—representing legal concepts—enhance factual accuracy. By structuring retrieval around legal concepts, LexKeyPlan better aligns with legal reasoning, making it particularly suited for legal applications. Using the ECHR corpus as case study, we show that LexKeyPlan improves factual accuracy and coherence by retrieving information aligned with the intended content.

1 Introduction

Recent advancements in large language models (LLMs) have led to their adoption in the legal domain for tasks such as sifting through case briefs, expediting legal research, drafting contracts, and formulating litigation strategies (Dahl et al., 2024). Despite their ability to pass bar and law school exams (Katz et al., 2024; Martínez, 2024), perform statutory reasoning and interpretation (Blair-Stanek et al., 2023; Engel and Mcadams, 2024), and apply legal reasoning frameworks like Issue-Rule-Application-Conclusion (IRAC) (Kang et al., 2023; Guha et al., 2024), LLMs still struggle with factual inaccuracies and hallucinations of legal knowledge.

Traditional LLMs generate responses based on the input context and their parametric knowledge

(Radford et al., 2019; Zhang et al., 2022; Jiang et al., 2023; Touvron et al., 2023), but this approach often fails to ensure factual accuracy. Retrieval-augmented generation (RAG) addresses this issue by retrieving external documents based on the context, allowing the model to condition its responses on more reliable information (Lewis et al., 2020; Izacard et al., 2023; Borgeaud et al., 2022; Ram et al., 2023). However, RAG relies entirely on the retrieval mechanism’s ability to fetch relevant knowledge, which may not always align with the content the model intends to generate. This limitation is particularly critical in legal text generation, where context alone may not provide sufficient signals to retrieve legally relevant information (Magesh et al., 2024; Santosh et al., 2025).

To overcome this challenge, we propose LexKeyPlan, a novel framework that introduces an anticipatory planning stage into the generation process. Instead of relying solely on context for retrieval, LexKeyPlan first generates keyphrases that represent legal concepts outlining the intended content of the response. These keyphrases serve as a forward-looking content plan, guiding the retrieval of relevant documents from external sources. By shifting the retrieval process from purely reactive to proactively structured around anticipated content, LexKeyPlan better aligns retrieval with legal reasoning, reduces reliance on misleading contextual information, and improves coherence in long-form legal text generation.

This work incorporates content planning into legal text generation, highlighting how keyphrases—representing legal concepts—can enhance retrieval, factual grounding, and structured reasoning. Using the European Court of Human Rights (ECHR) case law corpus, we demonstrate that LexKeyPlan significantly improves legal text generation by reducing hallucinations and enhancing retrieval relevance. Our findings suggest that anticipatory content planning through legal con-

cepts or keyphrases is crucial for legal applications, where precise retrieval and structured reasoning are essential for generating legally sound text.

2 LexKeyPlan

We propose a three-step framework for legal text generation, LexKeyPlan. Unlike traditional models that generate responses directly from context, LexKeyPlan introduces an intermediate planning stage using keyphrases. These keyphrases serve as a forward-looking blueprint, outlining the intent of the future response. By anticipating the necessary content, they guide the retrieval of relevant external documents, ensuring that the generated text is both factually accurate and grounded. This approach contrasts with existing retrieval augmentation methods, which typically use context alone to retrieve relevant information, potentially limiting the relevance of the retrieved content for response generation, in long form text generation.

Formally, let x be the input context. The model first generates a content plan c for the response, which can be represented as $p(c | x)$. This content plan, consisting of keyphrases, succinctly captures the essence of the future response. Then the generated plan c is used as query to retrieve relevant documents d from external knowledge sources. The final response y is produced by conditioning the model on the input context, the content plan and the retrieved documents, represented as $p(y | c, p, d)$.

Training the Content Plan Generation Module:

We train a language model using the input context followed by the content plan. To obtain the target content plan for each input, we utilize the target response text and extract keyphrases from it. We explore two keyphrase extraction algorithms to create the supervision dataset for training this content plan generation module: TextRank (Mihalcea and Tarau, 2004), a graph-based ranking algorithm inspired by PageRank, and KeyBERT (Grootendorst, 2020), leveraging embeddings from pre-trained models.

Retriever Module: We investigate two off-the-shelf retrievers: 1) BM25 (Robertson et al., 2004), a sparse lexical-based model, and 2) GTR (Ni et al., 2021), an embedding-based dense retriever model built on T5-XXL (Raffel et al., 2020). We provide the concatenated list of keyphrases (content plan) as query to retrieve the relevant documents from datastore, built from ECHR judgement documents.

Training the Response Generation Module: The language model is trained using the input con-

text, content plan, retrieved relevant documents followed by the target response. Since we do not have a gold-standard content plan or relevant documents for training, we extract keyphrases from the target response to serve as the content plan and use the target response as a query to retrieve pseudo-golden relevant documents. During inference, the model uses the actual generated content plan to retrieve relevant documents.

This three-step framework offers controllability, enabling users to adjust the content plan or retrieved documents to steer the model’s response.

3 Experiments

3.1 Dataset & Metrics

ECHR CaseLaw consists of case judgments heard by the European Court of Human Rights. We use the latest cleaned version of this dataset from Santosh et al. (2024a), which contains 15,729 cases in English from 1960 to July 28, 2022. We partition the dataset chronologically into training, validation, and test splits, following the provided temporal boundaries: the training set includes 11,615 documents from 1960 to 2016, the validation set contains 1,688 documents from 2017–2018, and the test set comprises 2,426 judgments spanning 2018–2022. Each case is segmented into two main sections: *The Facts*, which details the factual background of each case and *The Law*, which presents the legal reasoning justifying the outcome concerning alleged violations of specific ECHR articles. Our task involves generating the *The Law* (reasoning) section based on the *The Facts* section. While generating an entire section would be ideal, evaluating such large outputs against reference texts poses significant challenges. Therefore, we focus on paragraph-level generation to facilitate more accurate evaluations. Specifically, each paragraph in the *The Law* section serves as the target response, while the input context consists of the *The Facts* section and all preceding paragraphs from *The Law* section up to the target paragraph. This paragraph-level setup results in 82,597 training samples, 12,709 validation samples, and 17,470 test samples. During training, each paragraph is appended with an $\langle |end_of_paragraph| \rangle$ token, allowing us to generate the next paragraph up to this marker during open-ended generation. We use Mistral-7B-Instruct-v0.1 (Jiang et al., 2023) as our base LM for both plan and response generator and follow parameter efficient fine-tuning using

	Plan Generator	Retriever	R-1 / R-2 / R-L	BERT Score	Align Score	Coh. / Flu.
a	-	-	0.32 / 0.13 / 0.21	0.77	0.52	0.69 / 0.61
b	TextRank	-	0.33 / 0.13 / 0.22	0.72	0.54	0.74 / 0.66
c	KeyBERT	-	0.34 / 0.14 / 0.21	0.74	0.58	0.72 / 0.64
d	-	BM25	0.37 / 0.14 / 0.23	0.78	0.64	0.63 / 0.61
e	-	GTR	0.37 / 0.15 / 0.24	0.79	0.66	0.64 / 0.63
f	TextRank	BM25	0.37 / 0.17 / 0.26	0.79	0.7	0.72 / 0.65

h	KeyBERT	BM25	0.40 / 0.15 / 0.23	0.78	0.73	0.74 / 0.66
i	KeyBERT	GTR	0.39 / 0.16 / 0.24	0.80	0.75	0.76 / 0.65

Table 1: Comparison of LexKeyPlan with Baseline Approaches. The "Plan Generator" column specifies the keyphrase extraction algorithm used to generate supervision signals for training both the planning and response generation modules. The "Retriever" column indicates the retrieval method employed during inference and for obtaining relevant documents during training of the response generator. Note that the keyphrase-based content plan is automatically generated by the model during inference.

LoRA (Hu et al., 2021). Implementation details are provided in App. B.

We evaluate the quality of the generated paragraphs: ROUGE-1,2,L (Lin, 2004) for lexical overlap with the reference paragraph, BERTScore (Zhang et al., 2019) for semantic similarity between generated and reference paragraph, AlignScore (Zha et al., 2023) for factual consistency based on a unified alignment function between the reference and generated text and UniEval (Zhong et al., 2022) that evaluates coherence and fluency of the generated paragraph with respect to the context.

3.2 Results

To demonstrate the effectiveness of LexKeyPlan, we compare our method with several baselines: (a) traditional fine-tuning without keyphrase-based content planning or retrieval augmentation; (b, c) models with keyphrase-based planning, followed by response generation using the context and the generated plan. Two keyphrase extraction algorithms are used as supervision signals for training the planning and response generators; (d, e) models without keyphrase planning that directly retrieve relevant documents based on context and generate responses using the retrieved documents. The response generation models are trained with supervision from their respective retrievers; (f, g, h, i) our three-staged LexKeyPlan method, with different combinations of plan generators and retrievers for training the response generation.

Effect of Keyphrase-based Content Planning: As seen in Table 1, keyphrase-based content planning (b, c) outperforms traditional fine-tuning (a) in terms of coherence, fluency, and faithfulness (AlignScore), while remaining comparable on lexical similarity (ROUGE). This keyphrase planning

mechanism allows the model to anticipate and structure its response around key concepts in the upcoming text. By separating the planning and generation stages, the model’s cognitive load is reduced, as it no longer needs to generate relevant information and maintain coherence simultaneously. Instead, it can focus on each task independently, resulting in more coherent and contextually accurate outputs. Additionally, this structured planning mitigates hallucinations by providing a clear blueprint for the text, helping the model stay grounded in the key content and reducing the likelihood of producing irrelevant information. Between the two keyphrase algorithms, KeyBERT outperforms on content-related metrics, while TextRank excels in stylistic aspects like coherence and fluency.

Effect of Retrieval Augmentation: Retrieval augmentation (d, e), which utilizes context as the query, effectively addresses hallucination issues by grounding the generated text in external knowledge, resulting in improved ROUGE scores and faithfulness (AlignScore). However, this approach also leads to a decrease in coherence and fluency, likely due to the model’s challenge in integrating necessary information from the text while maintaining coherent output. Among the retrieval methods, embedding-based GTR consistently outperforms BM25 across all metrics, revealing the limitations of lexical-based retrievers in capturing semantic nuances. Nonetheless, the smaller gap for BM25 highlights the high lexical overlap and repetitive nature of legal concepts in the documents (Santosh et al., 2024a), making BM25 a scalable and efficient option for legal text retrieval.

LexKeyPlan: Integrating keyphrase-based content planning with retrieval augmentation significantly improves both content quality and stylistic

	Plan	Retreiver	R-1 / R-2 / R-L	BERT Score	Align Score	Coh. / Flu.
a	-	-	0.23 / 0.06 / 0.15	0.72	0.44	0.70 / 0.64
b	-	BM25	0.25 / 0.08 / 0.15	0.74	0.56	0.60 / 0.62
c	-	GTR	0.25 / 0.08 / 0.17	0.75	0.58	0.62 / 0.62
d	✓	-	0.24 / 0.08 / 0.16	0.74	0.50	0.72 / 0.62
e	✓	BM25	0.26 / 0.10 / 0.18	0.76	0.59	0.58 / 0.61
f	✓	GTR	0.27 / 0.10 / 0.16	0.75	0.58	0.59 / 0.60

Table 2: Effect of Integrating Keyphrase-Based Content Planning and Retrieval Augmentation in Zero-Shot Setting. The ‘Plan’ column specifies whether the model is prompted to generate keyphrase-based content plan for the next response. The Retriever column identifies the retrieval method employed.

	Similarity	Exact Match
Zeroshot	0.67	0.18
Fine-tuned with TextRank	0.72	0.36
Fine-tuned with KeyBERT	0.78	0.42
TextRank (Oracle)	0.96	1.0
KeyBERT (Oracle)	0.95	1.0

Table 3: Evaluation of Content Plan Quality.

tic metrics (statistically significant improvements as per Wilcoxon signed-rank test at a 95% confidence interval over the baselines without planning or retrieval augmentation). By using keyphrases as queries to anticipate forthcoming text, LexKeyPlan offers two key advantages. First, it enhances retrieval accuracy by focusing on key concepts, leading to more relevant documents compared to using context alone, which may miss crucial information for the anticipated text. Second, separating the planning and generation tasks allows the model to produce more coherent text. Rather than performing retrieval, integration, and generation simultaneously, LexKeyPlan enables the model to first plan around keyphrases, thereby reducing cognitive load and resulting in more coherent and contextually accurate outputs. Among the methods evaluated, KeyBERT provided superior supervision for plan generation, while GTR outperformed BM25, highlighting the benefits of embedding-based models over traditional lexical approaches.

Zero-shot Experiments: To evaluate whether integrating content planning and retrieval augmentation into pre-trained models in a zero-shot setting enhances performance, we compare several approaches in Table 2: (a) prompting the pre-trained model to generate a response based solely on the context; (b, c) prompting the model to generate a response based on both the context and relevant documents retrieved from the context; (d) prompting the model to first create a content plan in the form of keyphrases and then generate a response based on this plan; (e, f) prompting the model to

generate a content plan, use this plan to retrieve relevant documents, and then generate a response based on both the plan and documents.

As expected, retrieval augmentation (b, c) directly enhances faithfulness (AlignScore) and content quality but results in a decrease in coherence. This drop underscores the difficulty of maintaining coherence while incorporating relevant information. Introducing content planning (d) helps the model manage these tasks by breaking them into sequential steps, which enhances both faithfulness and coherence. When combining content planning with retrieval augmentation (e, f), there is a slight improvement in content quality metrics, though stylistic scores decrease. This suggests that zero-shot models may face challenges with the complexity of handling multiple instructions—such as following a content plan and integrating relevant information.

Analysis of Keyphrases in Content Planning:

We evaluate the quality of keyphrases generated through (a) Zero-shot prompting the pre-trained model, and (b, c) using a fine-tuned model supervised with TextRank and KeyBERT, by computing the embedding similarity of each keyphrase to the actual target (i.e., the next paragraph). We report both average similarity and exact match (if the keyphrase appears in the target). Additionally, we present oracle metrics (d, e), where keyphrases are directly extracted from the target paragraph using TextRank and KeyBERT. Results show that fine-tuning with KeyBERT-extracted keyphrases leads to more relevant keyphrase generation with respect to future content, providing informed plans for document retrieval and response generation.

4 Conclusion

We introduce LexKeyPlan, a three-step framework for legal text generation integrating keyphrase-based content planning with retrieval augmentation. Unlike traditional methods that rely solely on context for retrieval and generation, LexKeyPlan first

generates a content plan outlining the intended future content. This plan not only guides to produce coherent response but also the retrieval of relevant documents. LexKeyPlan through its anticipatory planning ensures that the generated text is both contextually coherent and factually accurate. as demonstrated with the ECHR case law corpus.

Limitations

LexKeyPlan currently utilizes a relatively simple content planning approach based on keyphrase extraction using general-purpose algorithms such as TextRank and KeyBERT. These methods, while effective in domains like news and scientific literature, were not specifically developed for legal language. As a result, they may fail to capture the nuanced terminologies, hierarchical concepts, and contextual dependencies intrinsic to legal texts. Future work could explore legal-domain-specific keyphrase extraction techniques—such as those proposed in [Mandal et al. \(2017\)](#)—which better accommodate the structural and semantic idiosyncrasies of legal discourse.

Our use of general extractors and retrievers was intentional: we aimed to demonstrate LexKeyPlan’s core contribution—anticipatory retrieval guided by future intent—without conflating gains from domain adaptation. Employing legal-specific strategies such as regular-expression-based legal phrase extractors or retrievers fine-tuned on legal corpora may have artificially inflated performance, obscuring the effectiveness of our planning and retrieval coordination. Instead, we used BM25 and GTR as retrievers in addition to TextRank and KeyBERT as keyphrase extractors to validate that our approach can generalize across jurisdictions and is not overly reliant on domain-specific tuning. That said, this choice also introduces limitations. General retrievers often struggle with legal-specific vocabulary, temporal relevance, and the authoritativeness of retrieved materials. In legal contexts, it is not enough to retrieve documents that are merely topically related—their precedential weight, binding status, and jurisprudential relevance must also be considered. For instance, a retrieved case may be outdated, overruled, or of low precedential value, which undermines its utility in supporting legal reasoning. These subtleties are particularly critical in legal domains, where the quality and authority of supporting material can significantly affect argument strength. Future work should explore

authority-aware and time-sensitive retrieval mechanisms, potentially through metadata-aware filtering, precedent strength modeling, or temporal reranking that prioritizes current and legally influential sources. ([Santosh et al., 2024c,b](#)).

More sophisticated content planning approaches could significantly enhance the effectiveness of LexKeyPlan. One promising avenue is the use of graphical representations derived from legal concept networks. These networks visually map out legal concepts and their interrelationships, creating a structured framework that can guide content generation. Incorporating a specialized legal thesaurus into the planning process can further refine content generation. A legal thesaurus provides a curated vocabulary of legal terms and concepts, enhancing the precision of keyphrases and improving the contextual relevance of the generated content. Improving the integration of content plans during the text generation phase may also involve adopting constrained decoding techniques. Constrained decoding methods enforce adherence to predefined content plans, ensuring that the generated text aligns closely with the planned structure and content. This approach can help maintain coherence and fidelity, reducing deviations from the intended content and improving output quality.

Currently, LexKeyPlan’s performance is evaluated using established metrics like ROUGE, BERTScore, and AlignScore. While these metrics offer quantitative insights, they may not fully capture the complexities of legal content. Future research could develop domain-specific evaluation metrics tailored to the legal field. Another limitation of our study is the absence of direct validation by legal experts in the assessment of outputs, which we could not perform due to lack of access to legal experts. Lastly, we selected the ECHR dataset for evaluation due to its explicit segmentation between case facts and legal reasoning. This clean structure enabled a well-defined simulation of a real-world task: generating legal reasoning given only the case facts. Such a setup mirrors copilot-style applications where LLMs assist lawyers and judges in drafting legal arguments. Other legal datasets often lack this granularity, intermixing facts and reasoning, which makes it difficult to isolate and measure the model’s reasoning capabilities. However, this focus on ECHR also narrows the scope of our evaluation. Future research should assess LexKeyPlan’s adaptability across multiple legal systems and languages, including those with different document

structures and procedural norms.

Ethics Statement

The ECHR dataset used in this study is publicly available and widely employed in legal NLP research. However, it is important to note that this dataset is not anonymized and contains real names and details of the parties involved in the cases. Although we do not foresee direct harm resulting from our experiments, handling such sensitive data necessitates careful consideration of privacy and ethical implications. Researchers must be diligent in protecting individual privacy and managing sensitive information responsibly, even when using publicly accessible datasets.

LLMs utilized in legal contexts have significant implications for both legal professionals and the public. Despite their advanced capabilities, these models carry inherent risks. They may reproduce and amplify biases inherent in their training data, leading to outputs that reflect historical inequalities or stereotypes. Additionally, LLMs may produce incorrect or misleading information, particularly in complex legal scenarios where precision is essential. Our research focuses on enhancing rather than replacing human expertise. It is crucial to apply LLM-generated outputs with careful scrutiny, ensuring that these tools are complemented by thorough human oversight and critical evaluation. Our aim is to improve legal text generation while recognizing that AI must be a supportive tool, used with an awareness of its limitations and potential impact on legal practice.

Appendix

A Related Work

Content Planning for Text Generation: Structured planning is considered a critical link in organizing content effectively before realization (Reiter and Dale, 1997), much like humans plan at a higher level than individual words, as evidenced by psycholinguistic studies (Levelt, 1993; Guhe, 2020). Earlier approaches incorporated various planning representations, such as Rhetorical Structure Theory (Mann and Thompson, 1988; Hovy, 1993) and MUC-style representations (McKeown and Radev, 1995), discourse trees (Mellish et al., 1998), entity transitions (Kibble and Power, 2004; Barzilay and Lapata, 2008), sequences of propositions (Karamanis, 2004), schemas (McKeown, 1985) and lexical chains (Barzilay and Elhadad, 1997).

Recent works in the data-to-text generation task divide it into two distinct phases: planning and realization of natural language text (Moryossef et al., 2019). Puduppully et al. (2019) and Laha et al. (2020) proposed micro-planning strategies, where they first establish a content plan based on a sequence of records and then generate a summary conditioned on that plan. Similar planning approaches have been explored for entity realization (Puduppully et al., 2019). Additionally, Puduppully and Lapata (2021) advocated for macro-planning as

a means of organizing high-level document content, either in text form or within latent space (Puduppully et al., 2022).

In summarization, various plan representations have been investigated. Narayan et al. (2020) treat step-by-step content selection as a planning component, generating sentence-level plans through extract-then-abstract methods, and even sub-sentence-level plans using elementary discourse units (Adams et al., 2023). Further research by Narayan et al. (2021); Liu and Chen (2021) introduced intermediate plans using entity chains—ordered sequences of entities mentioned in the summary. More recently, Narayan et al. (2023); Huot et al. (2023) conceptualized text plans as a sequence of question-answer pairs, which serve as blueprints for content selection (i.e., what to say) and planning (i.e., in what order) in summarization tasks.

Recently, Godbole et al. (2024); Shao et al. (2024) have explored planning-based approaches for text generation in tasks such as expository writing and biographical summaries. However, legal text generation presents unique challenges that remain unexplored in this context. Unlike traditional QA tasks, which involve focused information-seeking queries, legal text generation requires reasoning over long, complex case facts to construct well-grounded arguments to derive conclusions. This makes planning particularly valuable, as it can help structure retrieval and generation to ensure coherence, factual consistency, and legal validity. To the best of our knowledge, no prior work has investigated planning-based approaches for legal text generation.

B Implementation Details

We implemented KeyBERT¹ with n-gram range of (1, 3). We enable Maximal Marginal Relevance (MMR) with a diversity value 0.7 to balance relevance and diversity. For TextRank (Mihalcea and Tarau, 2004), we utilize the implementation provided in the [GitHub repository](#).

We perform LoRA fine-tuning with Mistral model for both our plan and response generator with an alpha and rank configuration in {8, 16} and dropout of 0.1. We sweep over learning rates { $1e-5$, $3e-5$, $5e-5$, $1e-4$, $3e-4$ } and evaluating its performance on the validation set using 10K validation steps. We train the model end-to-end for

¹<https://github.com/MaartenGr/KeyBERT>

one epoch using Adam Optimizer (Kingma and Ba, 2014). We perform inference over models with a temperature of 0.7 and nucleus sampling of 0.95.

For retrieval, we dynamically populate the candidate datastore by excluding documents dated after the query case and including only those available up to the query date, thereby simulating a realistic setting. We segment these documents into paragraph chunks, to index them for retrieval. For retrieval, we use the top-3 retrieved paragraphs for both methods. Prompt 1 and 2 detail the prompts used for content plan generation and response generations modules respectively.

C Case Study

We present three case studies that demonstrate how LexKeyPlan performs in complex legal scenarios. These examples show how keyphrase planning enables doctrinally grounded retrieval and controllable generation, while also revealing important limitation of its inability to account for temporal relevance.

Case Study A: Enhancing Doctrinal Accuracy Through Keyphrase-Guided Retrieval We examine a scenario where an individual is convicted for inflammatory statements made on social media and brings a claim under Article 10 (freedom of expression). The government argues that the speech in question incited hatred and thus falls outside the protection of the Convention. This case hinges on the distinction between political criticism and hate speech—a critical threshold question that determines whether the speech is covered by Article 10 or excluded under Article 17, which bars the abuse of rights. When the model operates with context-only retrieval, it relies solely on the case facts—namely, that the applicant was prosecuted for a speech act and invokes Article 10. This prompts the retriever to surface general freedom of expression jurisprudence such as *Handyside v. UK* (1976), *Sunday Times v. UK* (1979), and *Oberschlick v. Austria* (1997), all of which affirm the importance of free expression but apply a proportionality framework under Article 10(2). As a result, the generated response reasons as follows: "The Court applies the proportionality test under Article 10(2) to determine whether the restriction was necessary in a democratic society. Given the precedent set in *Handyside v. UK*, the speech must be examined in light of public morals and state discretion. Therefore, the speech in this case may

be protected under Article 10." This response is legally incorrect: it prematurely applies a balancing test without addressing the more fundamental question of admissibility under Article 10. Specifically, if the speech constitutes hate speech or denial of historical atrocities, it may be excluded altogether under Article 17, rendering Article 10 inapplicable. The model's failure to retrieve the right precedents results in doctrinal error. In contrast, with keyphrase-guided planning, the model is given key concepts such as "legitimate aim (public safety vs political criticism)," "ECHR Article 17," "abuse of rights doctrine," and "margin of appreciation." These guide retrieval toward cases that directly address the legal test relevant to hate speech and the abuse of rights. The retrieved case set now includes *Garaudy v. France* (2003), *Perinçek v. Switzerland* (2015), and *Leroy v. France* (2008)—cases that explicitly delineate when speech is excluded under Article 17 or subjected to Article 10 balancing. With this doctrinally appropriate retrieval, the model produces the following improved response: "The Court first determines whether the applicant's speech falls within the scope of Article 10 or is excluded under Article 17, which bars the abuse of Convention rights. In *Garaudy v. France*, the Court held that speech denying historical atrocities such as the Holocaust is incompatible with the values of the Convention and is not protected under Article 10. If the applicant's statements incite hatred or deny established facts, they may fall under Article 17 and be excluded from protection. However, if the speech qualifies as political criticism—even if provocative—it may still enjoy Article 10 protection, subject to a proportionality assessment under Article 10(2), as seen in *Leroy v. France*." This output demonstrates significantly improved legal reasoning: it reflects the correct structure of analysis (i.e., first evaluating exclusion under Article 17 before engaging in Article 10 balancing), references the right cases, and avoids premature or inappropriate application of proportionality. It also recognizes the margin of appreciation doctrine and the need to distinguish incitement from legitimate political critique. This case study underscores a core strength of LexKeyPlan: by prompting retrieval based on key doctrinal concepts rather than surface-level case similarity, the model can reason more accurately and in line with legal standards.

Case Study B: Controlling Legal Reasoning via Structured Planning In a case where a political figure challenged the deplatforming of their ac-

count by a private social media company, alleging a violation of Article 10. The case raised ambiguity about whether private actors performing public functions are subject to free speech obligations. LexKeyPlan was able to demonstrate controllable reasoning by varying the content plan. When the keyphrases included "de facto public forum," "chilling effect," and "corporate control over speech," the model retrieved cases such as *Appleby and Others v. UK* (2003), which address the public forum doctrine in private spaces. The generated response argued that: "Social media platforms serve as a de facto public forum, where political discourse primarily unfolds. As established in *Appleby v. UK*, while private entities are not always bound by public free speech obligations, their restrictions may be scrutinized if they effectively eliminate a person's ability to communicate elsewhere. Given the dominance of social platforms in modern public debate, banning a political figure from these spaces constitutes an undue restriction, creating a chilling effect that stifles democratic discourse." When the content plan was changed to include keyphrases such as "platform autonomy," "harm prevention," "corporate free expression," "content moderation policies," and "disinformation regulation," the retriever instead surfaced *Delfi AS v. Estonia* (2015), which upholds the rights of private platforms to moderate harmful content. The corresponding generated response shifted the framing: "Social media platforms, as private entities, have the right to moderate content under their terms of service. Prior rulings, including *Delfi AS v. Estonia*, affirm that private actors are not bound by the same restrictions as state actors. Given the risks of disinformation and harm to democratic integrity, content moderation is a necessary safeguard. The platform's decision aligns with legitimate policy goals and does not constitute a violation of Article 10." This illustrates LexKeyPlan's strength in enabling users to explore competing legal framings by adjusting the planning stage, allowing the system to retrieve and ground responses in support of different legal arguments, rather than being constrained by the framing present in the input context alone.

Case Study C: Limitations in Capturing Temporal Relevance Despite these benefits, LexKeyPlan remains limited in its ability to account for temporal and relevance. In a case involving the extradition of an individual to a country with a poor human rights record, the applicant claimed that the transfer would violate Article 3, citing the

risk of inhuman or degrading treatment. While the keyphrases “inhuman treatment,” “extradition risk,” and “diplomatic assurances” did help retrieve landmark cases like *Soering v. UK* (1989), they failed to surface more recent jurisprudence such as *Othman (Abu Qatada) v. UK* (2012) or *Paposhvili v. Belgium* (2016), which significantly recalibrated the legal standards for assessing risk and evaluating the sufficiency of diplomatic assurances. The limitation here arises from LexKeyPlan’s reliance on topical keyphrase matching without accounting for the temporal dimension of legal knowledge. As legal doctrines evolve, retrieval systems must prioritize not only relevance but recency, particularly in areas where the law is in flux.

You are a judge at the European Court of Human Rights (ECHR), drafting a judicial judgment. The paragraphs below reflect your reasoning thus far. Your task is to outline the next topics you intend to address in the next paragraph of the judgment.

Instructions:

- Generate a maximum of 5 topics. Place higher-priority topics at the beginning of the list.
- Ensure the list is formatted as a comma-separated string.
- Ensure the topics align closely with the content of the previous paragraphs and the overall context of the judgment.

Input:

{{PREVIOUS PARAGRAPHS}}

Response:

Prompt 1: Prompt for Keyphrase based content plan generation

You are a judge at the European Court of Human Rights (ECHR), drafting a judicial judgment. Below are paragraphs you have already written as part of your reasoning. Your task is to write the next paragraph to continue developing the judgment.

To assist you, content plan for the next paragraph in the form of keyphrases and excerpts from relevant external cases have been provided. These cases may offer supporting arguments or precedents to strengthen your reasoning, but their use is optional. Your primary focus should be on ensuring the logical flow and coherence of the judgment.

Instructions:

- Refer to external cases only if they add value to your reasoning or support the legal principles being applied. When citing an external case, include a proper citation at the end. For example: (Case of X v. Y). If referencing a specific section or paragraph from an external case, denote it clearly using the section symbol and the paragraph number.
- Ensure that the new paragraph is directly related to the content of the previous paragraphs and the broader context of the ECHR judgment.
- Use formal, precise, and structured language typical of ECHR judgments.

Abstract

In the interaction between agents and their environments, agents expand their capabilities by planning and executing actions. However, LLM-based agents face substantial challenges when deployed in novel environments or required to navigate unconventional action spaces. To empower agents to autonomously explore environments, optimize workflows, and enhance their understanding of actions, we propose SynWorld, a framework that allows agents to synthesize possible scenarios with multi-step action invocation within the action space and perform Monte Carlo Tree Search (MCTS) exploration to effectively refine their action knowledge in the current environment. Our experiments demonstrate that SynWorld is an effective and general approach to learning action knowledge in new environments¹.

1 Introduction

By leveraging decision-making capabilities to execute task-oriented actions within dynamic environments, Large Language Models (LLM) based agents demonstrate enhanced environmental interactivity and operational versatility (Song et al., 2023a; Liu et al., 2024b; Wu et al., 2025; Xi et al., 2025; Shi et al., 2025; Qu et al., 2025). In the real world, agents perform actions by leveraging tools like web search engines (Fan et al., 2024; Zhao et al., 2024a; Ning et al., 2025) or API calls (Liu et al., 2024a; Tao et al., 2024) to access feedback from the real world, which addresses the static knowledge limitations of LLMs, facilitating a deeper comprehension of the real world. It is crucial for agents to learn how to plan and execute actions in the environment. Nonetheless, as the complexity of tasks increases and novel environments emerge, manually annotated environment descriptions and a predefined action documents (Qu

* Corresponding Author.

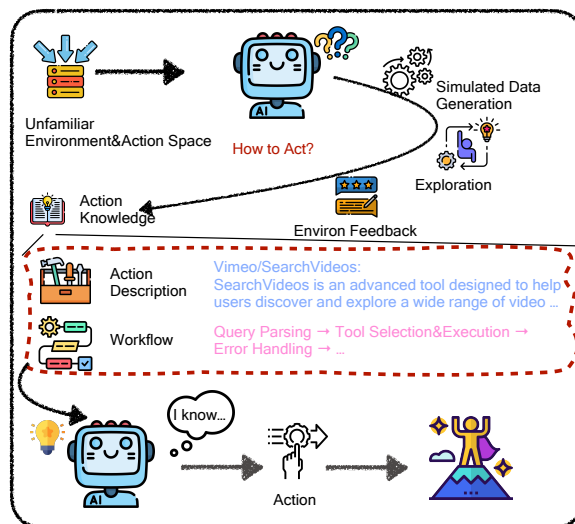

Figure 1: Our method with exploration to refine action knowledge in Synthesized Scenario.

et al., 2024; Sri et al., 2024; Zhang et al., 2025) for agents are often not consistent with the actual environmental conditions and action usage (Liu et al., 2024d; Huang et al., 2024a). Refining well-defined and aligned descriptions of the environment and actions is time-consuming and labor-intensive.

Therefore, to master inexperienced action and complicated task requirements in new complex environments, refinement of the agentic action knowledge is essential. Previous studies have explored the acquisition of action knowledge through feedback in scenarios synthesized by LLMs. Similar to the way humans acquire skills through trial and error, agents can also optimize the descriptions of actions by leveraging feedback from simulated scenarios (Yuan et al., 2024; Du et al., 2024; Bouzenia et al., 2024). However, these methods exhibit two critical limitations: (1) The synthetic scenarios they utilize are often restricted to single-action, which hinders agents from learning workflows suitable for these tasks, and (2) The linear iterative optimization process lacks a clear direction for improvement, making it susceptible to stagnation and

quickly reaching its performance ceiling.

To address these limitations, we propose a new framework, **SynWorld**, designed to assist agents in learning unfamiliar actions in new environments as shown in Figure 1. **SynWorld** first synthesizes virtual scenarios involving multiple coordinated actions. Then through iterative MCTS optimization in the exploration of virtual scenarios, the framework enables more thorough and bidirectional refinement between action descriptions and workflow patterns, ensuring better alignment with environmental constraints. Experiments demonstrate that action knowledge can be learned in virtual environments and effectively generalized to the real world, with optimization through MCTS exploration.

2 Background

2.1 Agent Planning

An agent interacts with its environment by perceiving its state, selecting actions to achieve a goal, and learning from feedback in the form of rewards. Its framework consists of a state space \mathcal{S} that represents the environment’s properties, an action space \mathcal{A} that defines allowable interactions, and an observation space Ω for perceptual inputs. Progress toward task T is measured through a reward function \mathcal{R} . Central to decision-making is a planning mechanism \mathcal{P}_θ , where π_θ are fixed model weights. The agent’s architecture is defined by the tuple:

$$\mathcal{P}_\theta = \pi_\theta(\mathcal{S}, \mathcal{A}, \Omega, \mathcal{R}) \quad (1)$$

This formula delineates the manner in which an agent assesses its current state and interprets environmental feedback to generate plans.

2.2 Action Knowledge

Action knowledge \mathcal{AK} serves as the strategic foundation governing an agent’s adaptive behavior in dynamic and unfamiliar environments. It contains **action description** about the awareness of executable actions with **cognitive workflows** about task decomposition and action sequences.

3 Method

In this section, we begin by detailing how to utilize the action space to synthesize scenarios and specific objectives. Subsequently, we dive into the application of MCTS to explore and discover action knowledge within these synthesized scenarios. The SynWorld framework is shown in Figure 2.

3.1 Scenario Synthesis

To address generalization challenges in multistep tool operationalization, we propose a framework that synthesizes scenarios through tool-conditioned task generation. Our methodology formalizes scenario synthesis as:

$$\mathcal{S}(t) = \{(\mathcal{B}, \mathcal{G}) \mid \forall t \subseteq T\}, \quad (2)$$

where a subset of tools t selected by llm from the complete set of tools T to design a scenario. Each scenario comprises two part: **Background** \mathcal{B} : The contextual scenario specifying initial conditions and constraints; **Goal** \mathcal{G} : The terminal objective requiring tool-mediated resolution. We provide examples using a few-shot approach to enable the llm to synthesize queries.

The mapping enforces that distinct tool combinations yield nontrivial scenario variations through systematic \mathcal{B} - \mathcal{G} pairings. Each group of selected tools will generate 2-3 scenarios. To ensure data diversity, if the similarity of a newly generated scenario exceeds a threshold ϵ compared to already synthesized scenarios, it will be excluded. Through this process, we can obtain a large number of synthetic scenarios, where the selected tools will serve as the "gold tools" for completing the corresponding virtual scenario, which will later be used for evaluation purposes.

$$d((\mathcal{B}_i, \mathcal{G}_i), (\mathcal{B}_j, \mathcal{G}_j)) < \epsilon. \quad (3)$$

3.2 Action Knowledge Exploration

Initialization The root node is initialized with predefined Action Knowledge, which serves as the foundation for task-solving logic. During the MCTS process, the UCB algorithm is used to select nodes, effectively balancing exploration and exploitation by choosing the node with the highest upper confidence limit.

Expansion Upon selecting node N_i as the candidate, an optimization process is initiated that retraces N_i to obtain insights from previous optimization experience \mathcal{E} . Each of these past optimization experiences \mathcal{E} is composed of three elements: the pre-optimization score S_{before} , the post-optimization score S_{after} , and the modification \mathcal{M} of the optimization actions taken.

$$\mathcal{E} = \{(S_{before}^i, S_{after}^i, \mathcal{M}^i) \mid N_i \in \text{Path}(N, N_0)\} \quad (4)$$

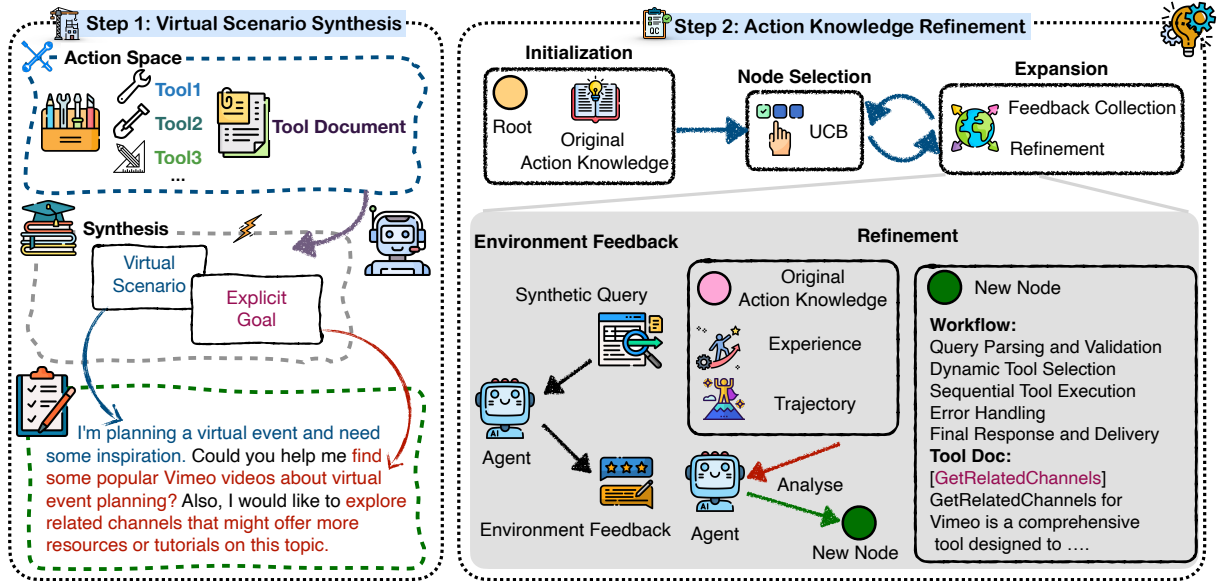

Figure 2: **The overall framework of SynWorld:** we first extract composable tools from the toolkit to generate new scenes and tasks. Then, we allow agents to explore the synthesized virtual scenes using MCTS to optimize action knowledge, thereby learning how to execute actions and plan tasks.

Based on the optimization experiences and exploration trajectories Tra from the past, the LLM-based agent π will analyze the discrepancies between the existing Action Knowledge and the environment. It will then optimize these to produce an updated version of the Action Knowledge.

$$\mathcal{AK}_{new} = \pi_{\theta}(\mathcal{AK}_{old}, \mathcal{E}, Tra) \quad (5)$$

Feedback Collection Once equipped with an optimized \mathcal{AK} , the agent π can explore the environment to perform tasks. For each individual task T , the agent interacts with the environment to receive feedback with the trajectory Tra_i and the final reward scores S_i . The score is related to the evaluation method of the task.

$$Tra_i, S_i = Env(\mathcal{AK}, \pi) \quad (6)$$

4 Experiment

4.1 Experiment Setup

Datasets and Baselines To demonstrate the efficiency of our approach in optimizing action knowledge, we selected two datasets: ToolBench (Qin et al., 2024) and HotpotQA (Yang et al., 2018), each offering unique challenges for a comprehensive evaluation. Following Qu et al. (2024), several strong methods are selected as our baselines, including ReAct (Yao et al., 2023), Self-Refine (Madaan et al., 2023), Easy-Tool (Yuan et al., 2024), and DRAFT (Qu et al., 2024). See detailed setting and evaluation in Appendix B.

Model	Method	ToolBench		HotpotQA
		PASS	WIN	
GPT-4-turbo	ReAct	50.67	67.00	54.61
	Self-Refine	56.80	73.00	55.85
	EasyTool	51.67	68.00	58.19
	DRAFT	54.83	72.00	57.71
	Ours	59.33	73.00	59.93
Qwen-long	ReAct	48.30	71.00	52.00
	Self-Refine	53.70	77.00	56.10
	EasyTool	50.80	63.00	58.34
	DRAFT	54.20	79.00	53.23
	Ours	57.20	81.00	59.91
Qwen2-72B-Instruct	ReAct	49.43	55.00	50.21
	Self-Refine	54.33	65.00	52.59
	EasyTool	52.97	58.00	54.94
	DRAFT	56.43	69.00	57.57
	Ours	58.52	73.00	58.70

Table 1: **Main results of SynWorld compared to other baselines** on ToolBench and HotpotQA. The best results of each model are marked in **bold**. PASS means the pass rate and WIN means the win rate of the trajectory compared to GPT-3.5-turbo in the method of ReAct.

4.2 Main Results

For the task ToolBench that requires the combined use of multiple tools, as shown in Table 1, our approach achieved a PASS score of 59.33 and a WIN score of 73.00, marking a significant improvement compared to other methods for iterative optimization, demonstrating the advantages of our method in terms of tool combination and task planning optimization. **For the task HotpotQA that requires planning using a single tool and multi-step calls**, in the scenario where only a single tool is used but requires continuous multi-hop calls, our method has achieved state-of-the-art results. This

Figure 3: The variation in the pass rate of agents on the ToolBench in relation to the number of exploration scenarios.

indicates that we have not only aligned tool descriptions with the environment, but also succeeded in generating a generalizable planning workflow.

4.3 Ablation Study

We observe that independently optimizing either the Workflow or the Tool Description using MCTS has its limitations in Table 2. We find that combining the optimization of both aspects leads to more effective results. An aligned Tool Description is beneficial for constructing a more reasonable Workflow, while a well-structured, general Workflow also enhances the exploration of tool usage. We believe that this synergy arises during the iterative optimization process, where the improved workflow can help identify tool usage that is closer to the correct trajectory, serving as strong negative examples to further refine the tool description. Conversely, a superior tool description enables the model to generate workflows that are more aligned with the environment.

Model	Method	Pass Rate
GPT-4-turbo	SynWorld	59.33
	w/o. Workflow	56.33 ^{-3.00}
	w/o. Description	53.16 ^{-6.17}
Qwen-long	SynWorld	57.20
	w/o. Workflow	57.00 ^{-0.20}
	w/o. Description	53.83 ^{-3.37}

Table 2: Ablation experiment results

4.4 Further Analysis

More simulated data enable precise virtual scenario synthesis, optimized action knowledge, and ultimately improved agent performance.

In our experiments, we explore action knowledge by synthesizing a varying number of virtual scenarios. As shown in Figure 3, we find that as the

Figure 4: Changes in ToolBench pass rates in virtual and real-world scenarios with the number of iterative optimizations performed in the virtual environment.

number of scenarios synthesized increases, the performance of the Agent shows a corresponding upward trend. Specifically, within the range of 0 to 100 scenarios, the model’s performance continues to improve with the increase in the scenarios, indicating that action knowledge is indeed learnable. Although the rate of performance improvement slows down as the number of scenarios increases, the model’s performance remains on an upward trajectory. This phenomenon suggests that the process of learning action knowledge in the context of synthesized scenarios exhibits scalability.

Virtual scenario policies can be generalized to unseen environments and improved with iterations.

By analyzing the relationship between action knowledge iterations and pass rates on Toolbench in both virtual and real environments, we find that the action knowledge gained in the virtual setting is generalizable and effective in real-world applications. Performance trends in both environments are similar in Figure 4. We observe a consistent upward trend in scores, particularly between 0 and 10 iterations, indicating that action knowledge can be optimized through environmental feedback. However, as iterations increase, the gains diminish, and we note slight declines in performance at times. This phenomenon is likely due to the limitations of exploring a fixed number of scenarios, where further iterations have less impact, and increasing complexity can hinder understanding.

5 Conclusion

In this paper, we propose SynWorld, a novel framework that synthesizes scenes that require multiple action steps and enhances agent action optimization through exploration in the synthetic virtual scenario. By systematically exploring diverse syn-

thetic scenarios, our model achieves precise alignment between action descriptions and environmental contexts while identifying task-specific workflows suitable for tasks.

Limitations

We initially conduct empirical validation on two benchmarks: Toolbench (involving multi-tool calling scenarios) and HotpotQA (requiring multi-step action execution). While these demonstrate our method’s effectiveness, broader validation across diverse real-world applications remains valuable. Promising candidates include web-based search tasks, simulated environments and so on.

Our approach currently incurs non-trivial computational overhead due to the token-intensive virtual scenario synthesis process. The exploration phase further compounds this by exhaustively enumerating all possible scenarios. Future research should prioritize optimizing token efficiency through 1) developing more economical synthesis mechanisms for high-quality virtual scenarios and 2) establishing effective filtering criteria to identify the most pedagogically valuable scenarios.

The current action knowledge representation employs a purely text-based format. This presents opportunities to investigate alternative structured representations that could enhance reasoning capabilities, such as tabular organization of action parameters or executable code snippets encapsulating procedural knowledge.

A Related Works

A.1 Agent Planning

Recent studies have shown that in the realm of complex task-solving (Ouyang and Li, 2023; Sun et al., 2023; Liu et al., 2024c, 2025), the capacity for planning and refinement within large models has become increasingly pivotal. It has marked a transition from early Methods like CoT (Wei et al., 2022), Plan and Solve (Wang et al., 2023a), which tackle tasks sequentially, to the sophisticated agentic workflows of today, where model planning is instrumental in addressing a myriad of complex tasks, including question answering (QA) (Mavi et al., 2022), embodied interaction (Yao et al., 2022), tool invocation (Masterman et al., 2024), and long-form text generation (Jiang et al., 2024).

However, initial planning efforts are fraught with deficiencies due to the complexity of environments. When faced with unfamiliar environments, relying solely on human-written task descriptions without interaction with the environment often leads to plans that are misaligned with the actual tasks, or plans that seem reasonable but fail during execution due to a lack of accurate action knowledge. Consequently, there has been a surge in research (Song et al., 2023b; Wang et al., 2023b) focused on refining plans and workflows. These efforts typically leverage direct environmental feedback or design a reward score for end-to-end plan correction, but they often lack a medium for the intermediate processes, which obscures the transparency of the plan refinement process. Moreover, the refinement of plans and the collection of feedback are usually linear and iterative (Qu et al., 2024), resulting in low efficiency and a lack of diversity.

A.2 Knowledge-Augmented Agents

LLMs, as agents interacting with specific environments, often need to provide action signals to these environments (Zhou et al., 2023, 2024; Durante et al., 2024). These action signals can be either restricted or open actions related to the environment (Wang et al., 2024; Li et al., 2024; Hu et al., 2024; Zhang et al., 2024). For instance, they might involve specific movements in embodied task scenarios or the use of various tools like search or OCR in tool invocations. By incorporating these actions, on one hand, the Agent gains the ability to interact with the environment, allowing LLMs to transcend mere textual output (Shridhar et al., 2021; Wang et al., 2022; Zhao et al., 2024b). On

the other hand, these external actions endow the Agent with a capability similar to humans using tools, compensating for the inherent limitations of LLMs, such as search tools that can alleviate issues of knowledge hallucination or obsolescence in LLMs (Singh et al., 2024; Zhao et al., 2024c; Shen et al., 2024; Chen, 2023).

Current methods for learning action knowledge are mainly divided into two categories: one involves creating a large amount of synthetic data to construct trajectories for executing actions to train the model (Qiao et al., 2024; Huang et al., 2024b; Zhu et al., 2024), which is costly and has poor generalizability across different tasks; the other relies on prompt engineering (Raman et al., 2022), placing explicit action knowledge about how to plan to execute actions within the prompt, and then using ICL (In-Context Learning) methods to enable the model to learn to invoke these actions. While convenient, these methods can be inaccurate as the artificially constructed planning knowledge may not accurately reflect the true state of the environment, leading to potential biases.

B Setting

B.1 Datasets

ToolBench contains tasks using over 16,000 RapidAPI tools. It assesses a model’s ability to plan and execute complex workflows.

HotpotQA is a multi-hop QA dataset with questions requiring multiple steps to answer. We employ Google Search as the search engine in the experiment.

B.2 Evaluation

ToolBench: Evaluated using pass rate and win rate. We record planning steps and tool invocations, then submit the trajectory for assessment. Win rate is compared to React’s performance. **HotpotQA:** Evaluated using F1 score, comparing model answers to gold answers (reward 0–1). These datasets and metrics allow us to rigorously validate our approach across varied contexts.

B.3 Baselines

Several strong methods are selected as our baselines, including: ReAct (Yao et al., 2023) which interacts with environment to reason the next step, Self-Refine (Madaan et al., 2023) which uses the feedback from environment to refine the origin prompt, Easy-Tool (Yuan et al., 2024) which

uses llm firstly to refine the tool description and then break down the tasks to complete them, and DRAFT (Qu et al., 2024) to synthesize tasks on a single tool for exploration to learn how to use the tool.

B.4 Experiment Setup

The backend model used in our experiments is Qwen-Long-0916, while the version of GPT-4 is 0613. The token usage in our method is approximately 6-8 million tokens. We configured the width of MCTS to 3 and set the similarity threshold to 0.6. After balancing effectiveness and cost, we synthesized 200 scenes and conducted 15 iterations on them during the experiment.

Prompt for Tool Description in Action knowledge

Analyze the following tool execution trajectories to improve tool interface documentation.

For all trajectories:

1. Identify functional mismatches between original description and actual usage patterns
2. Detect parameter inefficiencies (missing/underutilized fields)
3. Extract implicit requirements from error patterns
4. Generate enhanced documentation with:

Clear input specifications (required vs optional)

Contextual usage guidelines

Error prevention tips

Response format expectations

Here is an **example**.

Now it's your turn to analyze the following tool execution trajectories to improve tool interface documentation.

tool_name: **tool_name**

original_description: **original_description**

trajectory: **trajectory**

Please provide your Optimize Description for the tool. Just modify the description part and do not change the parameters description.

Make Sure your description is clear and concise.

Table 3: Prompt used for tool document refinement.

Prompt for Workflow in Action knowledge

Analyze the provided interaction trajectory and existing workflow steps to derive a generalized, reusable workflow for similar tool calling tasks.

1. Analyzing error patterns (authentication gaps, deprecated endpoints) and tool dependencies from interaction histories.
2. Extracting implicit requirements (authentication, sorting logic) and mandatory parameters from error responses.
3. Structuring a generic workflow with authentication validation, parameter checks, state management between API calls, and error fallbacks.

Here is an **example**.

Now it's your turn.

Existing Workflow: **workflow**

Trajectory: **trajectory**

Please provide your Optimize Workflow for the task. And make sure your workflow is clear and concise and no longer than 200 words.

Table 4: Prompt used for workflow generation.

Enhancing Retrieval Systems with Inference-Time Logical Reasoning

¹MIT, ²Center for Advanced AI, Accenture

faltings@mit.edu, {wei.h.wei, yujia.bao}@accenture.com

Abstract

Traditional retrieval methods rely on transforming user queries into vector representations and retrieving documents based on cosine similarity within an embedding space. While efficient and scalable, this approach often fails to handle complex queries involving logical constructs such as negations, conjunctions, and disjunctions. In this paper, we propose a novel inference-time logical reasoning framework that explicitly incorporates logical reasoning into the retrieval process. Our method extracts logical reasoning structures from natural language queries and then composes the individual cosine similarity scores to formulate the final document scores. This approach enables the retrieval process to handle complex logical reasoning without compromising computational efficiency. Our results on both synthetic and real-world benchmarks demonstrate that the proposed method consistently outperforms traditional retrieval methods across different models and datasets, significantly improving retrieval performance for complex queries.

1 Introduction

Retrieval systems are integral to many applications, including search engines, question-answering systems, and recommendation platforms (Baeza-Yates et al., 1999; Lewis et al., 2020; Gao et al., 2023). Modern systems operate by transforming user queries into vector representations and retrieving documents based on cosine similarity within an embedding space (Reimers, 2019; Wang et al., 2023; Zhao et al., 2024; Lee et al., 2024). This approach is highly efficient and scalable, as cosine similarity computations are fast and can handle large-scale data. However, the reliance on cosine similarity and static embeddings often limits the system’s ability to understand and process complex queries that involve logical constructs such as negations.

*Work done during an internship at Accenture.

Figure 1: Given a query “What are the benefits of vitamin D, focusing on benefits other than bone health?”, we first convert the query into the logical expression “Vitamin D Benefits AND NOT Bone Health”. We then calculate the cosine similarity scores for each term (top row) and combine these scores to generate the final results.

Large Language Models (LLMs) have demonstrated remarkable capabilities in inference-time reasoning (Wei et al., 2022; Yao et al., 2024). Recently, (Jiang et al., 2023; Gu et al., 2022; Sun et al., 2023; Luo et al., 2023) have successfully applied LLM’s reasoning capability to improve the retrieval performance for knowledge-based question answering, however, the application of inference-time reasoning for general retrieval systems remains relatively unexplored.

We posit that integrating logical reasoning at inference time is equally crucial for retrieval tasks, especially when dealing with complex queries that cannot be accurately represented using simple similarity measures (Meghini et al., 1993; Ounis and Paşca, 1998). Consider a query like “What are the benefits of vitamin D, focusing on benefits other than bone health?” A traditional retrieval system, relying solely on cosine similarity, may struggle to exclude documents related to bone health due to the embedding’s inability to represent the negation effectively. The system tends to retrieve documents that are globally similar to the query, failing to account for specific logical instructions, such as

exclusions or combinations of concepts.

To address this limitation, we propose a novel inference-time reasoning framework for retrieval systems that explicitly incorporates logical reasoning into the retrieval process. Our approach involves three key steps. First, **Logical Query Transformation**: We utilize an LLM to parse and rewrite the natural language query into a logical form, such as "A AND B OR NOT C," where A, B, and C represent different semantic components of the query. Second, **Term Embedding and Similarity Computation**: Each term identified in the logical form (A, B, C, etc.) is individually encoded into the embedding space. We compute the cosine similarity between each term’s embedding and the embeddings of documents in the corpus. Third, **Score Composition Based on Logical Relations**: We combine the similarity scores of each term in accordance with their logical relations. Our approach adds minimal overhead since the embedding can be performed in parallel.

We validate our approach through comprehensive experiments. We first create synthetic datasets with queries of varying logical complexity to test the limitations of existing retrieval algorithms. Our findings indicate that as the number of logical terms increases, the performance of traditional retrieval methods degrades significantly, while our method better maintains performance, demonstrating robustness against query complexity. We also evaluated our algorithm on three real-world datasets: NFCorpus (Boteva et al., 2016), SciFact (Wadden et al., 2020) and ArguAna (Thakur et al., 2021). Specifically, we augmented these three datasets with natural language queries that target compositional reasoning. We tested our method using four commonly used embedding models. The results show that our approach consistently outperforms baseline methods across all models and datasets, confirming its effectiveness in practical scenarios.

2 Method

Given a natural language query, “*What are the benefits of vitamin D, focusing on benefits other than bone health?*”, we first transform it into a logical expression using a pre-trained large language model (Dubey et al., 2024), “*Vitamin D Benefits*” AND NOT “*Bone Health*”, where the terms in quotes can be any string of text. Given a document, these queries can be seen as logical expressions, which we evaluate in a fuzzy way (Novák

et al., 2012), using the scores from a dense retrieval model to assign truth values to each clause. The fuzzy evaluation of the expression then gives a composite retrieval score for the given document. In the following sections, we present the concrete details of our method, starting with the syntax of the logical queries, followed by the retrieval semantics.

2.1 Query Syntax

Queries are made up of terms—which can be any string of text—combined using operators. We allow three operators, AND, OR, and NOT. Formally, the syntax of the language is described by the following simple grammar,

$$\begin{aligned} T &\rightarrow U \text{ OR } U \mid U \\ U &\rightarrow V \text{ AND } V \mid V \\ V &\rightarrow \text{NOT } W \mid W \\ W &\rightarrow \textit{string} \mid (T) \end{aligned}$$

where the use of distinguished non-terminals, T, U, V , and W enforces an operator priority, $\text{NOT} \succ \text{AND} \succ \text{OR}$, which is itself overridden by parentheses.

2.2 Query Semantics

For each term t_j in a query, and each document D_i in a corpus, we compute a score s_{ji} using the dense retrieval model. Usually, this is the cosine similarity between the embedding vectors of the term and document. The semantics of the query then tell us how to combine the scores s_{ji} into a single score s_i which we can use for retrieval.

Consider a query of the form,

$$(t_1 \text{ OR } t_2) \text{ AND NOT } t_3.$$

Then, for document D_i , if s_{1i}, s_{2i} , and s_{3i} are the scores obtained from the dense retrieval model, we take the composed retrieval score to be,

$$s_i = \text{OP}_{\text{AND}}(\text{OP}_{\text{OR}}(s_{1i}, s_{2i}), \text{OP}_{\text{NOT}}(s_{3i})),$$

where OP_{AND} , OP_{OR} and OP_{NOT} are functions that define how scores should be combined depending on the query operator. We detail our choice of operators in the next section.

In general, each query can be parsed using the grammar described above, resulting in a parse tree, which is directly translated into a tree of operations acting on the scores s_{1i}, s_{2i} , and s_{3i} as shown in Fig. 2. A more complicated example is given in the appendix. This tells us how to compute the final retrieval score s_i . More formally, this could be written as an attribute grammar (Knuth, 2005).

Figure 2: Example parse tree (left) and corresponding graph of operations (right).

2.3 Score Operations

The choice of the operators OP_{AND} , OP_{OR} , OP_{NOT} should reflect the logical semantics of the query. For example, for the conjunction t_1 AND t_2 , with scores s_{1i} and s_{2i} , the composite score should be low if *any* of the two scores is low. In this work we consider three approaches,

1. First, we take the perspective of fuzzy logic, where we view the retrieval scores as fuzzy set memberships. The fuzzy membership to a union of sets, corresponding to the logical OR operation, is then taken to be the maximum of the individual fuzzy memberships, and the membership to an intersection, corresponding to the AND operation, is given by the minimum (Fox and Sharat, 1986).
2. Second, we also choose operators based on probability theory. The probability of two independent events occurring simultaneously is $P(A \cap B) = P(A)P(B)$, the probability of the union of two events is upper bounded by $P(A \cup B) \leq P(A) + P(B)$ and the probability of the complement of an event is $P(\neg A) = 1 - P(A)$. Motivated by this we use the arithmetic operations \times , $+$ and $1 - \cdot$ for AND, OR and NOT respectively.
3. Finally, we also use heuristically motivated operators such as addition for AND, so that a document that scores highly for individual queries will score highly for their conjunction; and $1/\cdot$ for NOT, so that a document that scores highly for a query will score low for its negation.

In summary, the full set of operator choices is,

$$\begin{aligned} OP_{AND}(x, y) &= x * y \mid x + y \mid \min(x, y) \\ OP_{OR}(x, y) &= x + y \mid \max(x, y) \\ OP_{NOT}(x, y) &= 1 - x \mid 1/x \end{aligned}$$

We evaluate all combinations of these operators in our experiments. Our default choice is

$OP_{AND}(x, y) = x * y$, $OP_{OR}(x, y) = x + y$, and $OP_{NOT}(x, y) = (1 - x)$, which we find to work best.

3 Results

We start by validating the performance of the logical retrieval system itself on synthetic data. Next, we assess the system’s utility for retrieval on real data. In all our experiments, we evaluate using four base embedding models: Nvidia’s NV-Embed-V1 (Lee et al., 2024), Mistral’s nv-embedqa-mistral-7b-v2 and OpenAI’s text-embedding-v3-large and text-embedding-v3-small.

3.1 Synthetic Data

Three Term Queries We first evaluate performance on all possible queries formed of three terms using synthetic data. This gives 32 “templates”, such as,

$$t_1 \text{ AND } t_2 \text{ OR } \text{ NOT } t_3$$

The three placeholders t_1, t_2 , and t_3 are filled in by terms. For each possible template, we generate 100 queries by filling in the placeholders with random topics from a set generated by Llama3-70b. For each query we then generate documents that match and don’t match the query with Llama3-70b. For example, for the query,

$$\text{“dog” AND “cat” AND “mouse”},$$

we generate one document that matches, which is related to all three terms, and three documents that don’t match, which are related to all but one of the terms. See Appendix H for more details.

The results are presented in Table 1. We report the standard nDCG@10 in all our results. We show the results when passing the query directly to the retrieval model (base) vs. composing the retrieval model scores for each term (logical). For reference, the performance when using random scores is around 0.7. We see that logical retrieval outperforms the baseline, with the most gains coming from queries with negations. We did not see large differences between embedding models. See Table 7 in the appendix for a breakdown.

Scaling Number of Queries We look at performance as the number of terms in the queries scales, focusing this time solely on queries consisting of OR or AND operators. For example,

$$\text{“dog” AND “mouse” AND } \dots \text{ AND “cat”}$$

	Number of negations			
	0	1	2	3
Base	0.95	0.77	0.65	0.52
ITLR	0.99	0.97	0.96	1.00

Table 1: nDCG@10 Results on synthetic data. Dense and logical retrieval systems were evaluated on synthetically generated test cases for all 32 possible logical queries with three terms. We show results broken down by the number of negations in the queries.

OP_{AND}	OP_{OR}	OP_{NOT}	
		$1 - x$	$1/x$
$\min(x, y)$	$\max(x, y)$	0.86	0.86
	$x + y$	0.92	0.87
$x * y$	$\max(x, y)$	0.90	0.89
	$x + y$	0.97	0.90
$x + y$	$\max(x, y)$	0.91	0.81
	$x + y$	0.97	0.82

Table 2: nDCG@10 results for logical retrieval on the same data from Table 1 for different choices of operators, using NV-Embed-V1. Each entry represents a choice for each of the three operators.

We generate data in the same way as before. Our results are presented in Fig. 3. We see that the gains from logical retrieval increase as the number of terms increases. This is more pronounced for the AND queries than the OR queries, likely since each AND query has a single positive match whereas each OR query has many matches.

Figure 3: Performance as the number of terms scales. Baseline dense retrieval and logical retrieval were evaluated on queries connected by AND and OR clauses, with increasing number of clauses.

3.2 Operator Combinations

We tested all combinations of operators OP_{AND} , OP_{OR} and OP_{NOT} proposed in section 2.3 on the three term query data using the NV-Embed-V1 embedding model. We present the results in Table 2. We see that our default choice works best, although the alternative using $OP_{AND}(x, y) = x + y$ works equally as well. Note that the common choice made in fuzzy logic of $OP_{AND}(x, y) = \min(x, y)$ and $OP_{OR}(x, y) = \max(x, y)$ performs quite poorly.

3.3 Real Data

Our previous experiments consider very small corpora constructed specifically for each query. We

	NFCorpus	SciFact	ArguAna	Legal
NV-Embed-V1:				
Baseline	0.56	0.51	0.51	0.46
BRIGHT	0.67	0.59	0.58	0.52
ITLR	0.74	0.64	0.64	0.59
text-embedding-v3-large:				
Base	0.63	0.59	0.63	0.56
BRIGHT	0.70	0.63	0.66	0.60
ITLR	0.73	0.64	0.67	0.66
text-embedding-v3-small:				
Base	0.56	0.50	0.55	0.50
BRIGHT	0.68	0.59	0.65	0.57
ITLR	0.67	0.54	0.63	0.61
nv-embedqa-mistral-7b-v2:				
Base	0.54	0.50	0.40	0.41
BRIGHT	0.48	0.39	0.29	0.27
ITLR	0.67	0.61	0.59	0.42

Table 3: nDCG@10 Results on real data. For each dataset taken from BEIR (Thakur et al., 2021), compositional questions were generated using Llama3-70b. We show results for three embedding models and three methods. Legal short for LegalBenchCorporateLobbying.

	Number of negations			
	0	1	2	3
Base	0.81	0.60	0.51	0.36
Reasoning	0.81	0.68	0.64	0.56
Logical	0.76	0.71	0.76	0.73

Table 4: Breakdown of Table 3 for NV-Embed-V1 on NFCorpus by number of negations.

now turn to real datasets. In order to ensure the queries have sufficient compositionality, we generate queries using Llama3-70b. As in our synthetic experiments, we create 3-term logical queries from templates, filled in with topics extracted from the dataset. We create 30 queries per template, resulting in 960 total queries. We ask Llama3-70b to turn these queries into natural language questions and throw away the original queries. We also use Llama3-70b to label the relevance of each document in the corpus to each of the questions. In the appendix we give the prompts that were used and show through examples that the generated queries are realistic.

We compare three methods. The **Baseline** feeds the question to the dense retrieval model. The **BRIGHT** baseline first asks Llama3-70b to reason about the question and feeds the reasoning trace to the retrieval model. This is the method used in (Su et al., 2024). Finally, our **ITLR** method asks Llama3-70b to generate a logical query from the question, which is fed to our logical retrieval system. See Sec. 3.4 for human evaluation results

Base Dataset	Corpus Size	Gen. Queries
NFCorpus	3,633	960
ArguAna	8,674	960
SciFact	5,183	960
Legal	340	960

Table 5: **Dataset statistics** Legal short for LegalBench-CorporateLobbying.

	NFCorpus	SciFact	ArguAna
Accuracy	87.29	86.25	85.1

Table 6: Accuracy of question transformation into logical queries.

showing that Llama3-70b is able to successfully formulate logical queries.

We report nDCG@10 results in Table 3, for four datasets derived respectively from the NFCorpus, SciFact, ArguAna and LegalBenchCorporateLobbying tasks, accessed through MTEB (Muennighoff et al., 2022). Table 5 gives the statistics of the datasets used in our experiments.

We see that ITLR achieves the best performance overall, beating all baselines in a majority of cases. This performance gap becomes larger with more negations, as seen in Table 4. The lack in improvement without negations may be due to the use of three term queries. Since simpler queries are likely better represented in the training distribution of the retrieval models, they are easy enough to process. In our synthetic experiments (Figure 3) we show that, as the number of terms increases, ITLR outperforms baselines including on cases without negations.

3.4 Accuracy of Query Transformation

Because our system is reliant on transforming user queries from natural language into our logical syntax, we investigated the accuracy of Llama3-70b on this query transformation task. For all the questions in three of our real datasets—NFCorpus, SciFact and ArguAna—we asked human annotators to assess whether or not the logical query generated by the LLM accurately reflected the original question. As can be seen in Table 6, the generated logical queries tend to capture the original question quite well, with accuracies of 85% to 87%. In appendix B we also examined the queries labelled as inaccurate and found that in the cases we considered the errors tended to be minor.

4 Conclusion

In this paper, we propose an inference-time logical reasoning framework that addresses the limitations of traditional retrieval methods in managing complex queries with logical constructs. The framework is highly efficient, enabling concurrent computation of retrieval scores for each term. By integrating logical reasoning directly into the retrieval process, our framework consistently outperforms traditional methods on both synthetic and real-world benchmarks, demonstrating particular strength in handling queries with a higher frequency of negations and AND operations.

5 Limitations

The logical retrieval system we presented in this paper presents some limitations, as it still underperforms on queries without any negations. We identify some concrete problems that could be addressed in future work. First, in most scenarios, the queries to retrieval systems, such as questions from users, are not given as logical formulas. It is also unreasonable to expect users to write logical formulas on their own. Hence, the system is reliant on reformulating queries into logical queries. While we used a simple prompt to achieve this, it is possible that better performance could be obtained by finetuning a reformulation model. Second, we observed in preliminary experiments that the performance of the system can be improved by calibrating the scores of the underlying retrieval model. For example, when processing AND queries, some terms may receive generally higher retrieval scores than others, biasing retrieval towards documents that match those terms but not the others. We did not find any simple methods to calibrate the scores, but this could be accomplished when training the retrieval model, or by training a calibration model on a large dataset.

Ethical Considerations We do not foresee any immediate risks of our work as we are not releasing any major new artifacts, such as pre-trained models, which could be used in adverse ways. Retrieval systems are limiting points in applications such as retrieval augmented generation (RAG) since downstream answers are generated based on the documents provided by the retrieval system. Poor retrieval systems may skew the information retrieved from corpora, and thus improving the faithfulness of retrieval systems may be broadly beneficial.

Embedding Model	Base	ITLR
NV-Embed-V1	0.74	0.97
text-embedding-v3-large	0.71	0.97
text-embedding-v3-small	0.71	0.97

Table 7: nDCG@10 results on synthetic data, broken down by embedding model.

A Additional Parsing Example

Consider the query,

("dog" OR "cat" AND "mouse") AND NOT "giraffe"

The corresponding parse tree will be,

And the computational graph for combining the scores is,

With our actual choice of operators this looks like,

Written out as a formula this gives the final retrieval score as

$$s = (s_{\text{dog}} + s_{\text{cat}} * s_{\text{mouse}}) * (1 - s_{\text{giraffe}}).$$

B Additional Results

Breakdown by Embedding Model Table 7 breaks down the synthetic data results by embedding model. We see that there is little difference between the embedding models we considered.

Accuracy of Query Transformation We investigated how accurate Llama3-70b was at transforming natural language questions into logical queries. Below we give an example of inaccurate queries from the NFCorpus, SciFact and ArguAna datasets respectively.

- **Example 1** Natural language question:

What are some studies on the health benefits of anthocyanins that are not specifically focused on cancer prevention or targeted towards men?

LLM generated query:

"Health benefits of anthocyanins" AND (NOT "cancer prevention" OR NOT "targeted towards men")

Here, the original question is ambiguous about which studies should be excluded.

- **Example 2** Natural language question:

What are some recent research topics in the fields of neurology and oncology?

LLM generated query:

"Recent research in neurology" OR "Current research topics in neurology" AND "Recent advancements in oncology" OR "Current studies in oncology"

Here the AND should have been an OR .

- **Example 3** Natural language question:

What are some news articles that are not about agricultural development in Africa or Brexit, or are about a topic unrelated to peacekeeping?

LLM generated query:

"News articles" AND NOT ("Agricultural development in Africa" OR "Brexit" OR "Peace-keeping")

Here, "Peacekeeping" should be outside the NOT clause.

C Data Examples

Below we provide examples of queries from our NFCorpus dataset.

- **Example 1**

What are the risk factors for pancreatic cancer, excluding those related to MRSA in swine farms, or what are the benefits of cruciferous compounds in cancer prevention?

- **Example 2**

What are the health benefits and risks of a vegetarian diet that does not include dairy products, and are there any natural alternatives to dairy that can provide similar nutritional value?

- **Example 3**

What are some ways to prevent cancer through diet, excluding the effects of xenohormesis mechanisms, and specifically considering the potential benefits of cherries or other foods rich in phenolic compounds?

- **Example 4**

What are the dietary factors that can help prevent cancer, excluding those related to polycyclic aromatic hydrocarbons?

- **Example 5**

What are the effects of bioactive compounds on colon or prostate cancer, excluding studies on their mechanisms of action?

Below, we give the corresponding logical queries generated by the LLM,

- **Example 1**

("Risk factors for pancreatic cancer" AND NOT "MRSA in swine farms") OR "Benefits of cruciferous compounds in cancer prevention"

- **Example 2**

"Health benefits of a vegetarian diet without dairy products" AND "Risks of a vegetarian diet without dairy products" AND ("Natural alternatives to dairy products" OR "Plant-based alternatives to dairy products") AND ("Nutritional value of dairy products" OR "Nutritional benefits of dairy alternatives")

- **Example 3**

"Dietary prevention of cancer" AND NOT "xenohormesis" AND ("cherries" OR "foods rich in phenolic compounds")

- **Example 4**

"Dietary factors that help prevent cancer" AND NOT "Polycyclic aromatic hydrocarbons"

- **Example 5**

"Effects of bioactive compounds on colon cancer" OR "Effects of bioactive compounds on prostate cancer" AND NOT "Mechanisms of action of bioactive compounds"

D Reformulation Prompts

Here we give the prompts used for query reformulation in our reasoning methods from Sec. 3.3.

BRIGHT Reasoning prompt

Here is a user query:

\{question\}

- (1) Identify the essential question in the query.
- (2) Think step by step to reason about what should be included in the relevant
→ documents.
- (3) Draft an answer.

Logical Formula Prompt

I have a document retrieval system that processes logical queries. These queries can be of the form,
"term1" AND "term2" OR "term3" AND NOT "term4"

The meaning of the operators AND, OR and NOT should be obvious:

- AND means the retrieved document should be related to both terms
- OR means the retrieved document can be related to either term
- NOT means the retrieved document should not be related to the given term

Given a natural language question from a user, I want to use the retrieval system to
→ gather documents that contain information relevant to the user's question.

I need you to create suitable logical query to the retrieval system.

Remember that each of the individual terms can be a keyword, a phrase, a sentence,
→ or even

	Number of negations			
	0	1	2	3
Base	0.95	0.77	0.65	0.52
ITLR	0.99	0.97	0.96	1.00
Calibrated ITLR	1.00	0.98	0.97	1.00

Table 8: Expanded version of Table 1 including calibration.

a whole document. So don't limit yourselves to keywords.

For example, the following question,

"What is the impact of eating fresh oranges on pancreatic cancer risk, and its relationship to stage II diabetes"

Could be answered with the query,

"Impact of fresh orange consumption on pancreatic cancer risk" AND

"What is the relationship of eating fresh oranges to stage II diabetes?"

A query that only used keywords, such as

"oranges" AND "consumption" AND "pancreatic cancer" AND "stage II diabetes"

would lose much of the meaning of the original question! It's not clear if

→ consumption relates

to oranges, so a document that talks about consuming figs, and peeling oranges

would match this query!

Here is the user's question,

\{question\}

Can you come up with a suitable logical query to the retrieval system? Only include

→ the query

in your answer.

E Calibration

We also experimented with calibrating the scores from the retrieval models before combining them in ITLR. On the synthetic data, for a given embedding model and for each term, we generated 20 positive and 20 negative documents using Llama3-70b. This gave us a dataset of documents x_1, \dots, x_N , with embedded cosine similarities s_1, \dots, s_N and labels $y_1, \dots, y_N \in \{0, 1\}$. We then fit a simple calibration model,

$$\hat{y}_i = \sigma((s_i - \tau) * \lambda),$$

using gradient descent. This calibration offered some improvements on our synthetic dataset, as can be seen in Table 8, which is an expanded version of Table 1 with calibration.

Figure 4: Expanded version of Fig. 3 including calibration.

Model	Number of Model Parameters	Access	License
Llama3-70b	$70 * 10^9$	API	cc-by-nc-4.0
NV-Embed-V1	$7.85 * 10^9$	API	llama3
text-embedding-3-large	Undisclosed	API	commercial
text-embedding-3-small	Undisclosed	API	commercial

Table 9: Dataset statistics

F Additional Data Details

The datasets were accessed through MTEB (Muennighoff et al., 2022) under an Apache 2.0 license. These datasets all contain English text.

G Model Details

Table 9 gives details on the embedding models and LLMs used in our experiments, including parameter counts and how they were accessed.

H Synthetic Data Generation

Consider a query,

“mouse” OR “dog” AND NOT “cat”.

Any document that matches this query can be categorized by the individual terms of the query that it does or does not match. For example, for this query, there are two categories,

1. Matches mouse but not cat
2. Matches dog but not cat

Any of these categories is a list of terms that the document matches, and a list of terms that it doesn’t match. This gives an easy way to generate matching documents using Llama3-70b by providing terms that should or shouldn’t be matched.

There are many documents that don’t match the query, but we want to evaluate against challenging negatives. We can create these by taking one of the categories above and swapping a condition. For example, a positive document will match “mouse” but not “cat”. A hard negative could match “mouse” and “cat”. In general, given a list of terms that the document should or shouldn’t match, we simply move one term to the opposite category. So a hard negative will match all the terms it should to match the query, except one. Or it will avoid all the terms it should, except one.

Thus, to generate documents for our synthetic data, we first enumerate all the combinations that positive documents should or shouldn’t match. We then create all the hard negatives by swapping one of the terms. For each set of terms to match or not match, we create one document. For three term queries, this will result in at most three positive documents. We also keep up two three negative documents. Hence for each query, we generate up to six documents.

I Synthetic Queries

We found that the queries in original datasets used in our experiments are overly simple. For example, in the NFCorpus dataset the queries are the titles of web articles such as "Philippines". To better evaluate the retrieval performance under complex user questions, we created a set of queries based on topics found in the corpus and then used an LLM to evaluate how relevant each passage was to each query. The passages are completely unchanged. This gives us natural and challenging queries with a better labelling of relevant passages, while retaining the complexity of a real world document corpus.

To generate the queries, we extract topics from random documents in the corpus. We then create logical queries using the extracted topics. Finally, we transform these into natural language questions. The Llama3-70b prompts we used are given below.

Topic Extraction Prompt

You will be given a document. You need to extract all the salient topics from it. The topics should range from general to specific. Here is the document:
{format_doc(doc)}

Please give the salient topics as a list with one topic per line.
Don't include anything else in your answer.
Sort the topics from most general to most specific.

Query to Question Prompt

I have a document retrieval system that processes logical queries. These queries can be of the form,
"term1" AND "term2" OR "term3" AND NOT "term4"

The meaning of the operators AND, OR and NOT should be obvious:

- AND means the retrieved document should be related to both terms
- OR means the retrieved document can be related to either term
- NOT means the retrieved document should not be related to the given term

I want to evaluate the performance of a human user to use this retrieval system. Given a natural language question, the user needs to come up with a logical query
→ that will best
retrieve relevant documents.

In order to make a dataset for evaluation, I want to operate in reverse. I have
→ collected
many logical queries, and I would like to come up with a corresponding natural
→ language question.

Then I can give the question to a user and see how well they recover the original
→ query.

So, given the following logical query, can you come up with such a natural language
→ question?

Here's the query,
{query}

What question would you come up with? Only include the question in your answer.

J Human Annotations

Human annotators tasked with evaluating the LLM generated queries were paid a fair wage of \$25 an hour. They were given the following instructions

Instruction for Human Annotator: Logical Expression Validation

Task Overview

You will be given a natural language question and a corresponding logical
→ expression generated by an LLM (Large Language Model). Your task is to
→ determine whether the logical expression accurately represents the intended
→ meaning of the question.

A correct logical expression should:

- Capture the key intent of the question.
- Properly reflect any exclusions, inclusions, or constraints mentioned.
- Maintain the logical relationships between elements.

Evaluation Criteria

1. Accuracy - Does the logical expression correctly interpret the intent of the question?
→
2. Completeness - Are all relevant aspects of the question included in the logical expression?
→
3. Exclusions - If the question explicitly excludes something, does the logical expression handle this correctly?
→
4. Logical Structure - Are the AND, OR, and NOT operators used correctly to reflect the relationships in the question?
→

If the logical expression is correct, mark it as valid. If incorrect, mark it as invalid and provide an explanation of the error.

Examples

Positive Examples (Correct Expressions)

Example 1:

- Natural Language Question: ``How does vitamin D benefit your health? I already know about bone health, so I want to know other benefits.''
→
- Parsed Logical Expression: health benefits of vitamin D AND NOT bone health
- Explanation: The logical expression correctly retrieves information about vitamin D's health benefits while excluding bone health, as specified in the question.
→

Example 2:

- Natural Language Question: ``What are some movies directed by Christopher Nolan, excluding superhero films?"
→
- Parsed Logical Expression: movies directed by Christopher Nolan AND NOT superhero films
→
- Explanation: The logical expression correctly filters out superhero films while still retrieving Nolan's other movies.
→

Example 3:

- Natural Language Question: ``Which laptops have at least 16GB RAM and either an Intel i7 or AMD Ryzen 7 processor?"
→
- Parsed Logical Expression: laptops AND 16GB RAM AND (Intel i7 OR AMD Ryzen 7)
- Explanation: The expression correctly captures the requirement of 16GB RAM and allows either processor type, as intended.
→

Negative Examples (Incorrect Expressions)

Example 4:

- Natural Language Question: ``How does vitamin D benefit your health? I already know about bone health, so I want to know other benefits."
→
- Parsed Logical Expression: health benefits of vitamin D OR NOT bone health
- Error: The use of OR NOT instead of AND NOT changes the meaning. The expression may return results that are completely unrelated to vitamin D.
→

Example 5:

- Natural Language Question: ``What are some movies directed by Christopher Nolan, excluding superhero films?"
→
- Parsed Logical Expression: movies directed by Christopher Nolan OR NOT superhero films
→
- Error: The OR NOT operator incorrectly allows movies that aren't superhero films but might not be directed by Nolan, which is not what the question asks.
→

Example 6:

- Natural Language Question: ``Which laptops have at least 16GB RAM and either an Intel i7 or AMD Ryzen 7 processor?"
→
- Parsed Logical Expression: laptops AND (16GB RAM OR Intel i7 OR AMD Ryzen 7)

- Error: The use of OR within the parentheses makes it possible for laptops with
 - ↪ only Intel i7 or AMD Ryzen 7 (but less than 16GB RAM) to be included, which is
 - ↪ incorrect.

Final Notes

- Pay close attention to negations (NOT). Misplacing them can completely alter the
 - ↪ meaning.
- Ensure correct grouping with parentheses. Ambiguities in logic can lead to
 - ↪ unintended results.
- Rephrase the natural language question in a structured way before checking the
 - ↪ logical expression.

Your accuracy in annotation ensures that the model correctly understands and

- ↪ processes logical constraints in natural language.

Using Subtext to Enhance Generative IDRR

Zhipang Wang, Yu Hong*, Weihao Sun, Guodong Zhou

School of Computer Science and Technology, Soochow University, Suzhou, China
{zhipangwang, tianxianer, whsun16}@gmail.com; gdzhou@suda.edu.cn

Abstract

Implicit Discourse Relation Recognition (abbr., IDRR) is a NLP task of classifying argument pairs into different types of semantic relations. Arguments contain subtexts, some of which are beneficial to the perception of semantic relations. However, subtexts are connotative. The neural IDRR model fails to be aware of them without being given pertinent prompts. In this paper, we leverage LLaMA to generate subtexts for argument pairs, and verify the effectiveness of subtext-based IDRR. We construct an IDRR baseline using the decoder-only backbone LLaMA, and enhance it with subtext-aware relation reasoning. A confidence-diagnosed dual-channel network is used for collaboration between in-subtext and out-of-subtext IDRR. We experiment on PDTB-2.0 and PDTB-3.0 for both the main-level and secondary-level relation taxonomies. The test results show that our approach yields substantial improvements compared to the baseline, and achieves higher $F1$ -scores on both benchmarks than the previous decoder-only IDRR models. We make the source codes and data publicly available.¹

1 Introduction

IDRR determines the semantic relation between arguments when the in-between connective is absent (Prasad et al., 2008). For example, it outputs the relation “*Concession*” for the arguments $Arg1$ and $Arg2$ in 1), where the possible connective “*however*” is not given in the source text:

1) **Arg1:** *The new rate will be payable Feb. 15.*

Arg2: *A record date hasn’t been set.*

Relation: *Concession*

Encoder-only language models such as RoBERTa (Long and Webber, 2022; Wu et al., 2023; Cai

et al., 2024) and XLNet (Jiang et al., 2024) have been used for IDRR, where multi-class relation classification is conducted by linear layers with Softmax. Meanwhile, both T5 (Jiang et al., 2021; Chan et al., 2023) and the decoder-only Large Language Models (LLMs) like GPT-3.5 (Chan et al., 2024) and GPT-4 (Yung et al., 2024) have also been verified for IDRR, where relations are properly generated conditioned on prompts and/or CoT. Significant improvements are reported in these arts.

Subtext hasn’t been considered in the study of IDRR. Though, it is potentially useful for enhancing the IDRR models. A subtext is characterized by the metaphorical meaning hidden in the arguments. For example, the subtext of the two arguments in 1), most probably, is “*the rate should be recorded earlier though it hasn’t been*”. Such a subtext is more explicit or even straight in revealing the *Concessive* relation. Accordingly, we suggest that subtext can be used as a crucial evidence for enhancing the perception of implicit relation.

In this paper, we explore the method of applying subtexts, and systematically investigate the effectiveness upon LLM-based generative IDRR. The effort we made is to provide a preliminary study and stimulate innovative researches in subtext-based IDRR enhancement. Specifically, our contributions are summarized as follows:

- We first propose a Subtext-based Confidence-diagnosed Dual-channel Network (SCDN) for IDRR. In SCDN, subtext is generated by LLM. Confidence comparison is conducted to reconcile in-subtext and out-of-subtext IDRR.
- We verify the effectiveness of SCDN on the benchmarks PDTB-2.0 and 3.0 (Webber et al., 2019). We report varied influences caused by the settings of prompting, confidence diagnosis, subtext generation and augmentation.

*Corresponding author

¹https://github.com/ZpWang-AI/IDRR_Subtext.

Figure 1: Architecture of SCDN.

2 Approach

Figure 1 shows the architecture of SCDN, which is constructed with three LLMs \mathcal{M}_α , \mathcal{M}_β and \mathcal{M}_λ . \mathcal{M}_α serves to generate the subtext for the given arguments. \mathcal{M}_β takes the arguments as input and uses them as the only reliance for relation reasoning. \mathcal{M}_λ combines the generated subtext and arguments, and infers the relation according to all of them. A probabilistic diagnosis model (*diagnoser*) is used to reconcile the decisions from \mathcal{M}_β and \mathcal{M}_λ based on confidence estimation.

2.1 Subtext and Relation Generators

Our baseline is the generator \mathcal{M}_β which performs out-of-subtext IDRR. We prompt it by Question Answering (QA). Given the arguments \dot{A} and \ddot{A} , we combine them with a question Q_β of “*what is the relation between arguments*”: $I_\beta = [\{\dot{A}, \ddot{A}\}; Q_\beta]$. We feed I_β into \mathcal{M}_β to generate a relation label.

To fulfill the in-subtext IDRR, we construct a subtext generator \mathcal{M}_α . Its input is formed by the arguments and a prompting question Q_α of “*what is the implicit meaning*”: $I_\alpha = [\{\dot{A}, \ddot{A}\}; Q_\alpha]$. There isn’t any constraint applied to subtext generation (i.e., $\mathcal{M}_\alpha(I_\alpha)$) such as the length of subtext. Further, we build the generator \mathcal{M}_λ to perform in-subtext IDRR. It uses both subtext and arguments as input, and combines them with a multi-choice question Q_λ : $I_\lambda = [\{\dot{A}, \ddot{A}\}; \{S\}; Q_\lambda]$. The question Q_λ is designed as “*what is the relation between arguments given subtext*”, which allows \mathcal{M}_λ to generate a relation label in the manner of multi-choice QA (Yung et al., 2024) as follows.

- 2) Q_λ : What is the relation of \dot{A} and \ddot{A} given S ?
- A. Contingency
 - B. Expansion
 - C. Temporality
 - D. Comparison

In our experiments, we uniformly use LLaMA3-8B-Instruct (Dubey et al., 2024) to construct the generators \mathcal{M}_α , \mathcal{M}_β and \mathcal{M}_λ . Due to the zero-resource situation that there isn’t any ground-truth subtext provided in PDTB-2.0 and 3.0, we train the subtext generator \mathcal{M}_α by teacher-student knowledge distillation (Hu et al., 2023). GPT-3.5-turbo (Brown et al., 2020) is used as the teacher.

2.2 Confidence Diagnoser

It is unavoidable that the subtext-based generator encounters two problems, including 1) arguments inherently don’t contain a subtext, and 2) the generated subtext is unqualified. To relieve the problems, we use a diagnoser to reconcile \mathcal{M}_β and \mathcal{M}_λ , where \mathcal{M}_β conducts out-of-subtext IDRR, while \mathcal{M}_λ additionally uses subtext for in-subtext IDRR.

Assume \mathcal{M}_β and \mathcal{M}_λ output the relations R_β and R_λ respectively. The diagnoser first verifies the reliability of R_λ . Confidence score \mathcal{C} is measured for verification. \mathcal{C} is an average logistic probability over all the tokens output by \mathcal{M}_β . Each $c_i \in \mathcal{C}$ is the non-normalized probability estimated by the logistic function in the final layer of LLaMA3:

$$\mathcal{C} = \frac{1}{|R_\beta|} \sum_{t_i \in R_\beta} \log_{\mathcal{M}_\beta}(t_i) \quad (1)$$

On this basis, the diagnoser verifies whether \mathcal{C} is larger than the type-specific threshold θ . If larger, the diagnoser determines that R_λ is reliable for output, otherwise the prediction R_β of \mathcal{M}_β is adopted. In our experiments, we provide an exclusive threshold for each relation type in the taxonomy of PDTB. They are obtained by empirical observation upon the IDRR performance obtained on the training set. More details of threshold settings and performance curves can be found in Appendix A.

3 Experiments

3.1 Dataset and Evaluation Metrics

We experiment on two versions of discourse relation analysis datasets, including PDTB-2.0 (Prasad et al., 2008) and 3.0 (Webber et al., 2019). We follow the previous work to use sections 0-22 for IDRR, where sections 2-20 are used for training, and sections 0-1 are used as the development set, while 21-22 for testing. Appendix B shows the data statistics in all the datasets.

Multi-class Macro-F1 (F_1) and accuracy rate (Acc) are used as the evaluation metrics.

3.2 Implementation Details

We use AdamW optimizer (Loshchilov and Hutter, 2019) to optimize LLaMA3. For subtext generation \mathcal{M}_α , the learning rate is set to $1e-4$. A 5-epoch training process is conducted. For the relation generators \mathcal{M}_β and \mathcal{M}_λ , the learning rates are uniformly set to $5e-5$, and the best checkpoint is reached based on F_1 within 10 epochs. Both

Method	Backbone Model	Parameters	PDTB2		PDTB3

employ a weight decay of $1e-2$, a batch size of 1, and gradient accumulation over 8 steps. We don’t extensively tune the hyperparameters.

All experiments are performed on a NVIDIA A100 GPU. Our model implementations are based on PyTorch² and the Transformers library³.

3.3 Main Results

We compare SCDN to the recently-proposed advanced models, including 1) decoder-only ChatGPT (Chan et al., 2024) and PIDRA (Yung et al., 2024), 2) encoder-only FCL (Long and Webber, 2022), CP-KD (Wu et al., 2023), SCIDER (Cai et al., 2024), and OTMT (Jiang et al., 2024), as well as 3) T5-based CG-T5 (Jiang et al., 2021), DiscoPrompt (Chan et al., 2023), and IICOT (Lu et al., 2023). The decoder-only models take full advantage of prompt engineering for IDRR. The encoder-only models are effective in representation learning for relation understanding. T5-based mod-

els combine the advantages. More contributions of these arts are summarized in Appendix C.

Table 1 shows the comparison results on the test set, where the 4-way relation classification performance on the main relation taxonomy is reported. It can be observed that our SCDN achieves higher F_1 -score than both the decoder-only and T5-based IDRR models. However, it still fails to outperform the encoder-only models. This is partially attributed to hallucination of LLaMA3 and off-topic results it generated.

Besides, we conduct experiments for the 2nd-level taxonomy, where each main relation type is divided into fine-grained relation senses. For example, the relation type “*Contingency*” contains the senses of “*Conditionality*” and “*Causality*”. In this experiment, SCDN shows promising performance, which is reported in Appendix D due to page limit.

3.4 Ablation Study

To provide a direct insight into the influence of subtexts, we conduct an ablation study. Three IDRR models are considered in it, including 1) **out-of-subtext** generator \mathcal{M}_β which is separately fine-tuned without using subtexts, 2) **in-subtext** generator \mathcal{M}_λ which additionally uses the generated subtexts during fine-tuning, and 3) **SCDN** which uses both \mathcal{M}_β and \mathcal{M}_λ , and reconciles them with the confidence-based diagnoser.

Table 2 shows the test results for the main relation taxonomy. It proves that the utilization of

Subtext Generation Model	F_1	Acc
GPT-3.5-turbo	71.55	75.98
LLaMA3 w/o Distill	71.07	75.37
LLaMA3 w/ Distill (Partial)	71.66	76.19
LLaMA3 w/ Distill (Whole)	72.79	76.32

Table 3: Contributions from different subtext generators.

subtexts yields various levels of improvements. Appendix E provides a case study to show the effect.

3.5 Comparison among Subtext Generators

The qualified subtexts are crucial for SCDN. We investigate the subtexts generated by different LLMs, and verify their effects by our in-subtext model. There are three types of LLMs considered, including 1) GPT-3.5-turbo, 2) LLaMA3-8B-Instruct, 3) LLaMA3 which is strengthened by teacher-student knowledge distillation. During distillation, the subtexts generated by GPT-3.5-turbo for all training data are specified as **Guidance Data** from teacher. We use two different-sized guidance data: **Partial** and **Whole**. In the “Partial” case, we only adopt the guidance data which enables the subtext-based relation generator \mathcal{M}_λ to output correct results. In the “Whole” case, all the guidance data is used.

Table 3 shows the performance of in-subtext IDRR models on the test set of PDTB 3.0, where different subtext generators are used. It can be observed that, compared to LLaMA3 (w/o distillation), GPT-3.5 enables the in-subtext model to perform better. Furthermore, no matter whether “Partial” or “Whole” guidance data is used, knowledge distillation causes improvements, and the latter case improves the in-subtext model more substantially. It is surprising that distillation allows the weaker LLaMA3 to be more contributive than its teacher GPT-3.5. The possible reason is because that LLaMA3 takes the advantage of itself when absorbing beneficial experience from GPT-3.5.

3.6 Prompts for Subtext Generation

The reliability of subtexts relies heavily on the design methods of prompts. For example, if we didn’t remind LLMs of the ultimate purpose (i.e., being applied for IDRR), they fail to provide reliable subtexts. In our experiments, we evaluate different prompts as follows:

- P_1 : It contains Q_1 and Q_2 (Section 2.1) that ask for subtext generation and IDRR in turn.

Prompt	LLM	F_1	Acc
P_1	GPT-3.5-turbo	35.88	41.79
P_2	GPT-3.5-turbo	38.30	42.76
P_3	GPT-3.5-turbo	39.24	43.72
P_1	GPT-4-turbo	44.84	50.07
P_2	GPT-4-turbo	46.29	52.21

Table 4: Reliability of Prompts (on PDTB 3.0).

- P_2 : It replaces the key words in P_1 with their different synonyms, e.g., “*subtext*” is replaced with “*implicit meaning*”.
- P_3 : It expands P_2 by adding a prefix to Q_1 , where the prefix is an additional question about “*whether there truly is a subtext in the considered argument*”. This prompt helps to avoid a forcible subtext generation.

Table 4 shows the IDRR performance on the development set when the above prompts are separately used, where GPT-3.5 and 4.0 are considered during the validation process. It can be observed that both synonym replacement and non-forcible subtext generation yield improvements. Accordingly, P_2 has been introduced into our SCDN for optimization. However, P_3 fails to be used in SCDN as it actually causes performance degradation. For example, by P_3 , the in-subtext “Single” generator \mathcal{M}_β obtains a $F1$ -score of 71.7% on the test set of PDTB 3.0, causing a performance reduction of about 1.1% (compared to the “Single” case in Table 2). This implies that LLaMA3 in \mathcal{M}_β isn’t able to effectively perform reasoning with a relatively-complex Chain-of-Thought (CoT). Besides, P_3 also causes severe performance reduction when it is used in SCDN. This is because that a limited number of subtexts are generated by GPT-3.5 due to the constraint from P_3 , and thus GPT-to-LLaMA distillation falls into the low-resource scenario.

4 Conclusion

In this paper, we verify that the utilization of subtexts helps to strengthen the LLMs-based generative IDRR. Experiments demonstrate that reconciliation of in-subtext and out-of-subtext IDRR is effective. We also exhibit that distilling a light-weight LLM-based subtext generator is contributive, when the prompt doesn’t raise a complex CoT.

In the future, we will investigate the default subtext which isn’t implied in the given argument. On

the contrary, it derives from common-sense knowledge. Accordingly, we will convert binary arguments analysis to triplet, where the default subtext is regarded as the third non-negligible argument.

5 Limitations

This study proves the effectiveness of utilizing subtexts for enhancing IDRR. Nevertheless, a deeper analysis upon subtexts is still required. Our findings reveal that, in some cases, the shareable subtext is implied in one argument but irrelevant to the other, where the irrelevant argument appears as the noise during detecting the subtext. In some other cases, the default subtext occurs, which is not implied in any argument but derives from the common-sense knowledge. However, the subtext generation method in this paper cannot deal with these two problems. In the future, we will firstly study the common sense based default subtext generation. On this basis, we will convert the conventional binary arguments analysis to triplet, where the default subtext is used as a supplementary argument. This work will encounter the issues of 1) how to determine whether a pair of arguments are relevant to some default subtexts, and what they are, 2) how to detect and generate default subtexts conditioned on common-sense knowledge, and 3) how to reconcile the utilization of a triple of arguments and assign proper attention to them during relation discrimination.

Expansion	31.22	29.83
Temporal	31.11	28.53

Table 5: Optimal thresholds for the main relation types.

A Threshold for Confidence Diagnosis

We set up a threshold for each relation type in the taxonomies of IDRR. For example, there are 4 thresholds provided for the four main IDRR relation types (i.e., *Expansion*, *Temporality*, *Contingency*, and *Comparison*). The adoption of different thresholds is because that the varying token lengths of relation labels cause unbalanced ranges of average confidence scores.

Let us consider the relation type T as an example. To seek for the optimal threshold θ_T for T , we empirically observe the T -oriented IDRR performance curve obtained when different optional values are used as thresholds. Within this empirical observation, the IDRR generator \mathcal{M}_β and \mathcal{M}_λ is used to predict relations and confidence scores for all the instances that hold a relation of T in the training set. And the accuracy Acc_T is used as the performance metric, which is calculated as follows:

$$Acc_T(\check{\theta}) = \frac{n}{|D_T|} \quad (2)$$

where, $\check{\theta}$ is an optional threshold which is sequentially sampled from the range of confidence scores in the training set. n is the number of argument pairs which are given a positive relation prediction by \mathcal{M}_β and \mathcal{M}_λ , and $|D_T|$ is the number of all argument pairs which hold the relation T .

We adopt the optimal threshold θ by maximum likelihood estimation on all optional thresholds:

$$\theta_T = \arg \max_{\check{\theta}_T \in \check{\theta}_{all}} (Acc_T(\check{\theta}_T)) \quad (3)$$

Figure 2 shows the curves of Acc_T changing with different thresholds in PDTB 3.0. We also present the specific values of the finally adopted thresholds θ in Table 5, 6 and 7, where Table 5 provides the thresholds for the main relation types (labeled as ‘‘Top’’), while Table 6 and 7 give the thresholds for the relation senses in the secondary-level taxonomies (labeled as ‘‘Second’’).

Figure 2: Acc_T on the training dataset with varying thresholds. The final selected thresholds are marked with red dots, which corresponds to the highest Acc_T .

B Statistics of PDTB datasets

We use the benchmark datasets PDTB-2.0 and 3.0 in our experiments, and follow the common practice (Ji and Eisenstein, 2015) to divide each of them into training (Train), validation (Dev) and test sets. The statistics in the datasets are shown in Table 8 and Table 9.

C Related Work

Recent research has demonstrated that PLMs outperform traditional machine learning methods for the IDRR task. Consequently, many studies have explored incorporating novel modules into the encoder-only transformer architecture to obtain better representations and extract more comprehensive features from the input. The new added modules includes Conditional Variational AutoEncoder (Dou et al., 2021), Graph Convolutional Network

(Wu et al., 2022), Gated Recurrent Unit (Wu et al., 2022), and attention mechanism (Wu et al., 2022; Xiang et al., 2022a; Jiang et al., 2023).

On the other hand, some studies applied new training strategies like contractive learning (Long and Webber, 2022; Jiang et al., 2023; Xu et al., 2023; Zeng et al., 2024), knowledge distillation (Wu et al., 2023; Jiang et al., 2024), and extra pre-training (Wang et al., 2023).

Notably, Zhou et al. (2022) proposed a prompt-based approach that involves connective prediction and answer mapping. Their work paved the way for better leveraging of connectives, like enhancing the input with predicted connectives (Liu and Strube, 2023; Liu et al., 2024), or mapping the answers by connectives directly (Xiang et al., 2022b; Zhou et al., 2022; Wu et al., 2023; Wang et al., 2023; Zeng et al., 2024). Additionally, several studies investigated the potential of multi-level hierarchical information for IDRR. These works explored modeling the relationships between labels and fusing the global and local information within the multi-level hierarchical structure (Jiang et al., 2023; Xu et al., 2023; Zhao et al., 2023).

However, the potential of generative models and LLMs has been relatively underexplored for IDRR (Chan et al., 2024; Omura et al., 2024; Yung et al., 2024). Therefore, our work aims to address this gap by investigating how to effectively utilize LLMs’ reasoning capabilities and incorporate additional relevant information into the input.

Table 10: Performance of the secondary level classification on PDTB 2.0/3.0.

D Performance on Relation Senses

Besides of the relation types in the main-level taxonomy of PDTB, we additionally evaluate our models upon the secondary-level taxonomy. The latter taxonomy consists of the fine-grained relation senses. Table 10 shows the Macro F_1 -scores and accuracies of our models, as well as the previous work that reported the performance on the secondary-level taxonomy.

It can be found that our SCDN achieves promising performance, outperforming the T5-base based generative models. Nevertheless, SCDN has an obvious performance gap compared to the T5-large based DiscoPrompt (Chan et al., 2023). DiscoPrompt is a strong IDRR model which learns from the reliance between relations and implicit connectives during training. The implicit connectives are informative when being used as guidance during training, which allows T5-large to infer relations from additional perspectives. By contrast, we didn’t use implicit connectives as guidance when fine-tuning SCDN. Besides, as shown in Table 11 and 12, some relation senses in the secondary-level taxonomy are given much less available training data than others in PDTB 2.0 and 3.0. More seriously, some arguments of such relation senses fail to be given a subtext by our subtext generator. This results in the insufficient training towards these relation senses when we fine-tune our in-subtext IDRR model and SCDN. And this causes severe performance degradation.

E Case Study

To qualitatively assess the impact of subtexts on the reasoning ability of LLaMA3 for IDRR, we manually examine the test data as well as predictions of the **Out-of-subtext** and **In-subtext** models. The out-of-subtext IDRR model \mathcal{M}_β predicts relations conditioned only on arguments, while the in-subtext IDRR model \mathcal{M}_λ combines subtext and arguments, and uses them as clues for relation reasoning. The following analysis showcases the benefits associated with the use of subtexts:

Example 1

Argument 1: *I personally don’t enjoy seeing players who I remember vividly from their playing days running about and being gallant about their deficiencies.*

Relation	Number
Comparison.Concession	1,170
Comparison.Contrast	639
Contingency.Cause	4,483
Contingency.Cause+Belief	157
Contingency.Condition	154
Contingency.Purpose	1,102
Expansion.Conjunction	3,584
Expansion.Equivalence	252
Expansion.Instantiation	1,117
Expansion.Level-of-detail	2,493
Expansion.Manner	191
Expansion.Substitution	278
Temporal.Asynchronous	985
Temporal.Synchronous	433
Total	17,038

Table 12: Counts of secondary level relation types on the training set of PDTB 3.0.

Argument 2: *People should be allowed to remember players as they were.*

Subtext: *The implicit meaning between the arguments is that people should be allowed to remember and cherish the memories of players from their playing days without seeing them participate in activities that may diminish their legacy or reputation. It suggests a desire to preserve the image and impact of these players in the eyes of the public.*

Ground-truth: Expansion

Out-of-subtext model: Comparison

In-subtext model: Expansion

Example 2

Argument 1: *For a family with taxable income of \$50,000 to pay the same 28% incremental tax rate as a family with taxable income of \$250,000.*

Argument 2: *The 33% bracket should apply to all income over the applicable level, not just the 5% rate adjustment amount.*

Subtext: *The implicit meaning between these arguments is that both are advocating for a more progressive tax system where higher-income individuals pay a higher percentage of their income in taxes. Argument 1 suggests that the current tax system is unfair because a family with a much lower income is paying the same percentage of taxes as a family with a much higher income. Argument 2 suggests that the tax brackets should be adjusted to*

ensure that higher-income individuals pay a higher tax rate on all of their income, not just the amount above a certain threshold. Both arguments imply that the current tax system is not equitable and needs to be restructured to address income inequality.

Ground-truth: Comparison

Out-of-subtext model: Expansion

In-subtext model: Comparison

Example 3

Argument 1: *He believes in what he plays, and he plays superbly.*

Argument 2: *His recent appearance at the Metropolitan Museum, dubbed "A Musical Odyssey," was a case in point.*

Subtext: *The implicit meaning between these arguments is that the musician's belief in his music is evident in his exceptional performance at the Metropolitan Museum, showcasing his talent and skill as a musician.*

Ground-truth: Expansion.Instantiation

Out-of-subtext model: Expansion.Restatement

In-subtext model: Expansion.Instantiation

State-offset Tuning: State-based Parameter-Efficient Fine-Tuning for State Space Models

Abstract

State Space Models (SSMs) have emerged as efficient alternatives to Transformers, mitigating their quadratic computational cost. However, the application of Parameter-Efficient Fine-Tuning (PEFT) methods to SSMs remains largely unexplored. In particular, prompt-based methods like Prompt Tuning and Prefix-Tuning, which are widely used in Transformers, do not perform well on SSMs. To address this, we propose *state-based methods* as a superior alternative to prompt-based methods. This new family of methods naturally stems from the architectural characteristics of SSMs. State-based methods adjust state-related features directly instead of depending on external prompts. Furthermore, we introduce a novel state-based PEFT method: *State-offset Tuning*. At every timestep, our method directly affects the state at the current step, leading to more effective adaptation. Through extensive experiments across diverse datasets, we demonstrate the effectiveness of our method. Code is available at <https://github.com/furiosa-ai/ssm-state-tuning>.

1 Introduction

Large Language Models (LLMs) have gained significant attention for their strong performance in NLP tasks (Achiam et al., 2023; Brown et al., 2020), but suffer from the quadratic complexity of Transformer architectures (Vaswani et al., 2017). To mitigate this, subquadratic alternatives have gained interest (Katharopoulos et al., 2020; Peng et al., 2023; Sun et al., 2023), with State Space Models (SSMs) emerging as a promising solution (Gu and Dao, 2024; Dao and Gu, 2024).

Meanwhile, as LLMs scale up, full fine-tuning for downstream tasks becomes prohibitively expensive. Consequently, Parameter-Efficient Fine-

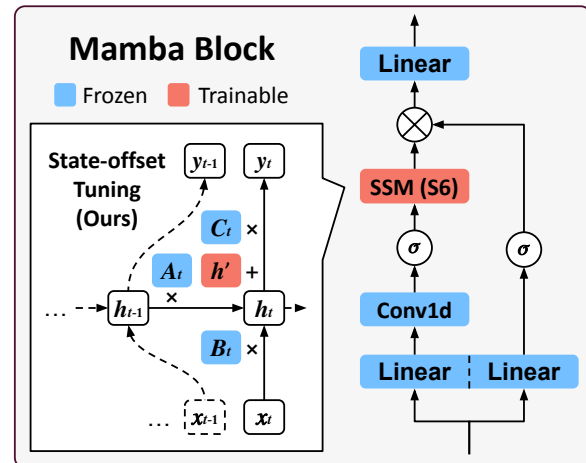

Figure 1: Illustration of our proposed State-offset Tuning on a Mamba block (Gu and Dao, 2024). State-offset Tuning injects a trainable state-offset h' at each timestep in the SSM module while keeping other parameters frozen, enabling parameter-efficient fine-tuning and improved downstream performance.

Tuning (PEFT) (Houlsby et al., 2019; Hu et al., 2021; He et al., 2021; Zaken et al., 2022; Liu et al., 2021, 2022; Zeng and Lee, 2024) has emerged, which aims to reduce the number of trainable parameters while achieving adaptation performance comparable to full fine-tuning.

However, research on PEFT methods for SSMs remains limited despite their growing popularity. For instance, prompt-based PEFT methods, such as Prompt Tuning (Lester et al., 2021) and Prefix-Tuning (Li and Liang, 2021), have been widely applied to Transformers but fail to adapt effectively to SSMs (Galim et al., 2024). Therefore, new PEFT strategies tailored to SSMs are needed to fully leverage their architectural properties.

To bridge this gap, we introduce *state-based PEFT methods* that leverage the intrinsic properties of SSMs, offering a superior alternative to prompt-based methods. Building on this concept, we propose *State-offset Tuning*. This method directly ad-

*Equal contribution.

†Corresponding author.

justs the state-related features rather than relying on external prompts, enabling more effective adaptation.

In summary, our main contributions are:

- We introduce *state-based methods*, a new family of PEFT techniques for SSMs, offering a superior alternative to prompt-based approaches.
- We propose *State-offset Tuning* as a new state-based PEFT method.
- We demonstrate the effectiveness of our method through experiments on a variety of datasets, consistently outperforming existing fine-tuning techniques.

2.1 State Space Models

Linear State-Space Layers (LSSL) are one of the earliest applications of SSMs in sequence modeling (Gu et al., 2021), leveraging HiPPO (Gu et al., 2020) to initialize the state matrix. However, its high computational overhead limits practicality. Gu et al. (2022) introduced Structured State Space Models (S4), which mitigate this by structuring the state matrix. Recently, Mamba (Gu and Dao, 2024; Dao and Gu, 2024) enhanced modeling capabilities by introducing an input-dependent S6 block.

2.2 Parameter-Efficient Fine-Tuning

In this section, we review existing PEFT methods. For more details, see Sec. D.

Parameter-based Methods One approach to parameter-based PEFT methods is to selectively fine-tune specific layers within the model while keeping the remaining layers frozen. BitFit (Zaken et al., 2022) is a lightweight and effective strategy that focuses solely on fine-tuning a model’s bias terms. Furthermore, LoRA (Hu et al., 2021) represents a notable parameter-based PEFT method by introducing low-rank matrices for weight updates, facilitating efficient adaptation.

Prompt-based Methods Instead of fine-tuning model parameters, Prompt Tuning (Lester et al., 2021) enhances models by prepending trainable soft embeddings to the prompt. Prefix-Tuning (Li and Liang, 2021) builds on this approach by injecting trainable embeddings into each Transformer layer, achieving strong adaptation results for Transformer-based LLMs.

PEFT for SSMs Concurrently, Galim et al. (2024) showed that LoRA outperforms prompt-based methods on SSMs. Furthermore, they proposed Selective Dimension Tuning (SDT) for fine-tuning the SSM module while applying LoRA on the linear projection matrices when fine-tuning Mamba models. Yoshimura et al. (2025) suggested a new PEFT method called Additional-scan, which increases the hidden state dimension of SSMs, fine-tuning only its additional parameters.

3 PEFT Methods on SSMs

SSM Preliminaries Assuming a single channel dimension, SSMs such as S4 (Gu et al., 2022) transform a signal $x_t \in \mathbb{R}$ into $y_t \in \mathbb{R}$ through an H -dimensional latent state $\mathbf{h}_t \in \mathbb{R}^H$ as below:

$$\mathbf{h}_t = \overline{\mathbf{A}}\mathbf{h}_{t-1} + \overline{\mathbf{B}}x_t, \quad y_t = \mathbf{C}\mathbf{h}_t,$$

where $\overline{\mathbf{B}} \in \mathbb{R}^{H \times 1}$ controls input influence, $\overline{\mathbf{A}} \in \mathbb{R}^{H \times H}$ governs state dynamics, and $\mathbf{C} \in \mathbb{R}^{1 \times H}$ maps the state to the output. $\overline{\mathbf{A}}$ and $\overline{\mathbf{B}}$ represent discretized versions of \mathbf{A} and \mathbf{B} , parameterized by a learnable step size $\Delta \in \mathbb{R}$.

In S6 (the SSM module of Mamba), input dependency is integrated by using input-dependent $\overline{\mathbf{A}}_t$, $\overline{\mathbf{B}}_t$, and \mathbf{C}_t at every timestep. Specifically, given D channels with $x_t \in \mathbb{R}^D$, learnable parameters $\mathbf{W}_B, \mathbf{W}_C \in \mathbb{R}^{H \times D}$, and $\mathbf{W}_\Delta \in \mathbb{R}^{D \times D}$ compute $\mathbf{B}_t = \mathbf{W}_B x_t$, $\mathbf{C}_t = \mathbf{W}_C x_t$, and $\Delta = \mathbf{W}_\Delta x_t$. In this section, we consider S4 for simplicity.

3.1 Prompt-based PEFT Methods on SSMs

Prefix-Tuning Can Update Only the Initial State of an SSM

Generally, SSMs assume that the initial hidden state is $\mathbf{h}_0 = \mathbf{0}$. We can express \mathbf{h}_t with \mathbf{h}_0 as $\mathbf{h}_t = \sum_{i=1}^t \overline{\mathbf{A}}^{t-i} \overline{\mathbf{B}}_i x_i + \overline{\mathbf{A}}^t \mathbf{h}_0$.

Assume we have virtual tokens $x_{(-V+1)}, \dots, x_0$. If we prepend virtual tokens as prefix to the input sequence, we can write the updated $\hat{\mathbf{h}}_t$ as below:

$$\hat{\mathbf{h}}_t = \mathbf{h}_t + \overline{\mathbf{A}}^t \sum_{i=0}^{V-1} \overline{\mathbf{A}}^{-i} \overline{\mathbf{B}} x_{-i} = \mathbf{h}_t + \overline{\mathbf{A}}^t \mathbf{h}_{\text{prefix}}.$$

By introducing a non-zero $\hat{\mathbf{h}}_0$, we can substitute $\hat{\mathbf{h}}_0$ for $\mathbf{h}_{\text{prefix}}$ making Prefix-Tuning, or optimizing virtual tokens, equivalent to updating the initial state. As optimized virtual tokens only affect the initial state $\hat{\mathbf{h}}_0$, Prefix-Tuning’s expressivity is upper-bounded by updating the initial state directly (Galim et al., 2024). Since Prefix-Tuning is an extended version of Prompt Tuning, this upper bound is applicable to Prompt Tuning as well.

Galim et al. (2024) showed Initial State Tuning, an advanced version of Prefix-Tuning, which directly optimizes the channel-specific initial state $\mathbf{h}' \in \mathbb{R}^H$, resulting in DH trainable parameters in total across all D channels. The updated output \hat{y}_t for Initial State Tuning can be written as in Table 1.

3.2 State-based Methods: A New Family of PEFT Methods for SSMs

We define state-based methods as a new family of PEFT methods specifically designed for SSMs. These methods directly modify the intrinsic state-related features within the SSM module.

In contrast, prompt-based methods, such as Prefix-Tuning, influence the hidden state of the SSM module indirectly by introducing external virtual tokens. While both approaches adjust the hidden state of the SSM module, state-based methods operate within the SSM module itself, offering a more direct and expressive adaptation strategy.

Based on our definition, we classify Initial State Tuning as a state-based method. While Initial State Tuning surpasses Prefix-Tuning (Galim et al., 2024), it still falls short compared to other fine-tuning methods on SSMs. To bridge this gap, we propose a novel state-based method for enhanced performance.

Initial State Tuning	$\hat{y}_t = y_t + C_t (\prod_{i=1}^t \bar{A}_i) \mathbf{h}'$
State-offset Tuning (\mathbf{h})	$\hat{y}_t = y_t + C_t \mathbf{h}'$
State-offset Tuning (y)	$\hat{y}_t = y_t + y'$

Table 1: State-based methods for S6. Our methods eliminate the time-dependent coefficient $\prod_{i=1}^t \bar{A}_i$, ensuring a uniform effect across timesteps.

Prompt-based	Timestep T	Timestep $T + 1$
Prefix	$[\mathbf{prefix}, x_1, \dots, x_T]$	$[\mathbf{prefix}, x_1, \dots, x_T, x_{T+1}]$
Suffix	$[x_1, \dots, x_T, \mathbf{suffix}]$	$[x_1, \dots, x_T, \mathbf{suffix}, x_{T+1}]$
Iterative Suffix	$[x_1, \dots, x_T, \mathbf{suffix}]$	$[x_1, \dots, x_T, x_{T+1}, \mathbf{suffix}]$

Table 2: Comparison of Prefix-Tuning, Suffix-Tuning, and Iterative Suffix-Tuning.

4 Proposed State-based PEFT Method

In this section, we propose *State-offset Tuning* as a new state-based PEFT method. A visual comparison with Initial State Tuning and Prefix-Tuning is provided in Sec. A.

4.1 State-offset Tuning

Initial State Tuning introduces an additional term \mathbf{h}' with a coefficient \bar{A}^t for S4 and $\prod_{i=1}^t \bar{A}_i$ for S6. However, this coefficient, which varies for each timestep, tends to decrease over time, leading to inconsistent effects. This is related to the issue that SSMs struggle to recall early tokens (Fu et al., 2022). To address this and ensure a consistent effect for each timestep, we introduce *State-offset Tuning*, which eliminates this coefficient.

State-offset Tuning adds a constant, learnable state-offset \mathbf{h}' to the hidden state \mathbf{h} before obtaining the updated output \hat{y}_t (Fig. 1). Therefore, unlike Initial State Tuning, State-offset Tuning does not alter the hidden state dynamics directly. Instead, State-offset Tuning adds a constant \mathbf{h}' repetitively for each timestep, ensuring a uniform impact.

We formulate State-offset Tuning (\mathbf{h}) for S6 in Table 1, where we optimize $\mathbf{h}' \in \mathbb{R}^H$. In S4, C_t does not depend on the input, simplifying to a constant C . This allows us to optimize a bias y' instead of \mathbf{h}' (with $y' := C\mathbf{h}'$ for each dimension). We name this method State-offset Tuning (y). For S4, State-offset Tuning (y) and State-offset Tuning (\mathbf{h}) are equivalent. In S6, opting for the simpler State-offset Tuning (y) enhances parameter efficiency by decreasing the tunable parameters from DH to D .

4.2 Connection to Prompt-based Methods

To further validate the methodology of State-offset Tuning, we examine its connection to prompt-based methods and demonstrate its correspondence to *Iterative Suffix-Tuning*.

Iterative Suffix-Tuning Li and Liang (2021) showed that in Transformers, inserting virtual tokens at the beginning (Prefix-Tuning) or the end (Suffix-Tuning, referred to as Infix-Tuning in their work) yields similar performance.

However, for SSMs, the position of the inserted virtual tokens is crucial, as these models tend to forget early tokens. The effect of Prefix-Tuning and Suffix-Tuning diminishes as the model processes subsequent timesteps. This leads to the question: how can we maintain consistent influence of virtual tokens across all timesteps in SSMs?

To achieve this, we propose Iterative Suffix-Tuning. As shown in Table 2, both Prefix-Tuning and Suffix-Tuning hold virtual tokens in fixed positions throughout all timesteps. Conversely, Iterative Suffix-Tuning shifts virtual tokens to the sequence’s last position at each timestep, ensur-

Table 3: Experimental results for fine-tuning the SSM module (S6) of Mamba (Gu and Dao, 2024) models. We assess Spider and its subsets using execution accuracy, SAMSum with ROUGE-1/2/L scores, DART using METEOR and BLEU scores, and GLUE by calculating the average score. To demonstrate the effectiveness of our methods, we configure the hyperparameters of each method to ensure their parameter budget is comparable to or exceeds that of our methods. **Bold** and underline indicate the best and the second-best results, respectively, among all methods (excluding full fine-tuning). Our State-offset Tuning (h) outperforms all other methods on most datasets, and our State-offset Tuning (y) shows comparable or better performance than other methods despite its significantly fewer trainable parameters.

ing uniform influence in SSMs. This method is akin to how State-offset Tuning eliminates the time-varying coefficient in Initial State Tuning, enforcing a consistent effect at every timestep. We show that Iterative Suffix-Tuning in SSMs is equivalent to State-offset Tuning (as detailed in Sec. B).

5 Experiments

5.1 Experiment Setup

We conduct experiments for fine-tuning the SSM module (S6) using pretrained Mamba (Gu and Dao, 2024) and Mamba-2 (Dao and Gu, 2024) models on four datasets: Spider (Yu et al., 2018), SAMSum (Gliwa et al., 2019), DART (Nan et al., 2021), and GLUE (Wang et al., 2019). For further information on datasets, evaluation metrics, and experimental details, refer to Secs. E and F. We use LoRA (Hu et al., 2021), BitFit (Zaken et al., 2022), and Additional-scan (Yoshimura et al., 2025) as parameter-based methods. For prompt-based methods, we employ Prompt Tuning (Lester et al., 2021) and Prefix-Tuning¹ (Li and Liang, 2021). For state-based methods, we utilize Initial State Tuning (Galim et al., 2024), along with our proposed methods, State-offset Tuning (h) and State-offset Tuning (y).

¹Following Yoshimura et al. (2025), our Prefix-Tuning implementation for SSMs corresponds to their Affix-Tuning formulation, adapted specifically for SSM architectures.

5.2 Experimental Results

Table 3 shows the results on Mamba models. Additional results, including Mamba-2 results, are provided in Sec. G. In the appendix, we further compare the training speed, training memory usage, and computational overhead during inference between LoRA and State-offset Tuning (h). Our findings show that State-offset Tuning (h) is faster, more memory-efficient, and introduces lower FLOP overhead compared to LoRA. Additionally, we evaluate the performance of State-offset Tuning (h) within SSMs against Prefix-Tuning in Transformers, further highlighting the effectiveness of our approach.

State-based Methods Outperform Prompt-based Methods Table 3 shows that all state-based methods outperform prompt-based methods, supporting the claim that state-based methods are superior to prompt-based methods on SSMs.

In particular, our State-offset Tuning (h) achieves the best results among all tested PEFT methods on most datasets. Our State-offset Tuning (y) outperforms Initial State Tuning on most datasets, using just 0.01% of the parameters compared to 0.23% by Initial State Tuning.

State-offset Tuning Outperforms Parameter-Based Methods State-offset Tuning (h) outperforms BitFit across all datasets and surpasses LoRA on most datasets. Notably, it also outperforms Additional-scan, a method specifically designed for fine-tuning SSM modules, across all datasets.

Furthermore, State-offset Tuning (h) achieves performance comparable to full fine-tuning (S6), highlighting the effectiveness of state-based PEFT for SSM modules, despite using significantly fewer parameters. The results from Mamba-2 (Table 11) further validate the effectiveness of our method. We also include a comparison to Selective Dimension Tuning (SDT) (Galim et al., 2024) in Sec. G.4, showing that our method outperforms SDT while using fewer parameters.

6 Conclusion

In this paper, we introduce *state-based methods* as a new family of PEFT methods for State Space Models, serving as a superior alternative to prompt-based methods. We propose *State-offset Tuning* as a new state-based PEFT method and demonstrate its effectiveness through extensive experiments.

7 Limitations

While we demonstrate that State-offset Tuning is effective for fine-tuning SSMs in the text domain, its applicability to other domains, such as vision or speech, remains unexplored. Existing PEFT methods, such as LoRA and Prompt Tuning, have been successfully applied across various domains (Jia et al., 2022; Gal et al., 2023; Ran et al., 2024). Extending State-offset Tuning to models in other domains, such as Vision Mamba (Zhu et al., 2025), is an interesting direction for future work.

Potential Risks Our approach enables parameter-efficient fine-tuning (PEFT) of pretrained SSMs, significantly reducing the computational cost of adaptation. While this is beneficial for resource-constrained scenarios, it also presents potential risks. Specifically, adversaries could leverage our method to efficiently fine-tune pretrained SSMs on harmful or biased data, enabling the rapid adaptation of models for malicious purposes with minimal computational resources. This could lead to the proliferation of harmful or deceptive models that reinforce misinformation, bias, or toxicity. To mitigate these risks, future work should explore more robust safety measures, such as integrating ethical fine-tuning constraints and monitoring mechanisms.

A Visual Comparison of Prompt-based Methods and State-based Methods

Fig. 2 compares prompt-based methods and state-based methods, including our proposed State-offset Tuning, within the S6 block.

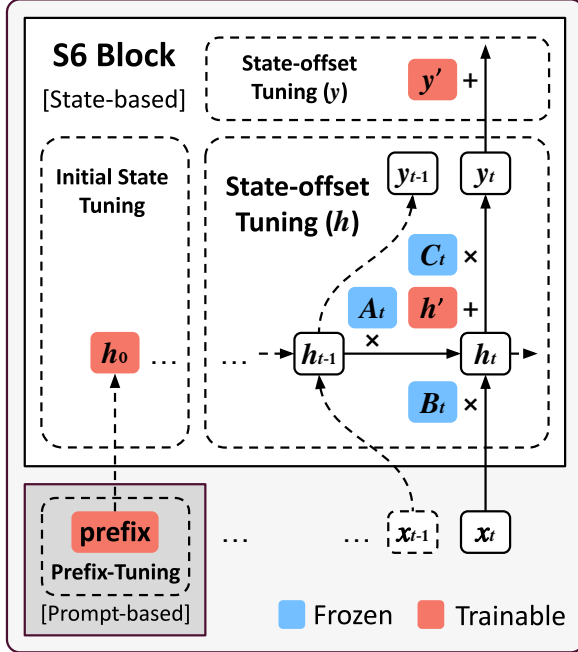

Figure 2: Visual comparison of prompt-based methods and state-based methods in the S6 block.

State-based Methods Operate within the SSM Module Fig. 2 shows that prompt-based methods, such as Prefix-Tuning, rely on virtual tokens external to the S6 block. In contrast, state-based methods, such as Initial State Tuning, State-offset Tuning (h), and State-offset Tuning (y), directly adjust state-related features within the S6 block.

State-offset Tuning Affects the Current Timestep Figure 2 illustrates how Prefix-Tuning and Initial State Tuning modify features at early timesteps, indirectly affecting the current state. However, this impact diminishes over time. In contrast, State-offset Tuning (h) and State-offset Tuning (y) directly influence the state at each timestep, resulting in more effective adaptation.

B Iterative Suffix-Tuning and State-offset Tuning

In this section, we show that Iterative Suffix-Tuning for SSMs is equivalent to State-offset Tuning.

State-offset Tuning is Iterative Suffix-Tuning Fig. 3 provides two different implementations of

(a) Iterative Suffix-Tuning (with $t + 1$ as current timestep)

(b) Iterative Suffix-Tuning (with t as current timestep)

Figure 3: Two different implementations of Iterative Suffix-Tuning in S6. We show that Fig. 3b is equivalent to State-offset Tuning.

Iterative Suffix-Tuning on SSMs (S6) with virtual token (suffix) x_{t+1} . Fig. 3a views $t + 1$ as current timestep. In this case, input-dependent $C_{t+1} = \mathbf{W}_C x_{t+1}$ is determined solely by the suffix $x_{t+1} \in \mathbb{R}^D$, which is constant at inference time, thus the input dependency of C is lost, reducing the expressive power of S6.

To address this, we view t as current timestep instead and interpret x_{t+1} as future token (Fig. 3b). Consequently, we time-shift x_{t+1} by multiplying it with the inverse of \bar{A}_{t+1} .

$$\text{Fig. 3a: } y_{t+1} = C_{t+1}(\bar{A}_{t+1}h_t + \bar{B}_{t+1}x_{t+1}),$$

$$\text{Fig. 3b: } y_t = C_t(h_t + \bar{A}_{t+1}^{-1}\bar{B}_{t+1}x_{t+1}).$$

Therefore, according to the equation corresponding to Fig. 3b, Iterative Suffix-Tuning can be implemented by updating only $\bar{A}_{t+1}^{-1}\bar{B}_{t+1}x_{t+1}$. Since this term depends solely on the constant suffix x_{t+1} , we can directly replace it with a learnable parameter h' ($h' := \bar{A}_{t+1}^{-1}\bar{B}_{t+1}x_{t+1}$), which is equivalent to State-offset Tuning (h) (Table 1).

C Low-Rank State-offset Tuning

State-offset Tuning (h) shows superior parameter efficiency on Mamba versus other PEFT methods. To further reduce trainable parameters, we can represent the learnable state-offset as a product of two low-rank matrices, inspired by LoRA (Hu et al., 2021). This is particularly useful for Mamba-2,

where the state dimension is larger than in Mamba, leading to an increased number of trainable parameters. In such cases, low-rank techniques can effectively mitigate the parameter overhead. Experimental results of State-offset Tuning (h) with lower rank on Mamba-2 are provided in Sec. G.2.

D PEFT Baselines

In this section, we provide a more detailed description of the baseline methods.

LoRA (Hu et al., 2021) LoRA aims to fine-tune large models by maintaining the bulk of pretrained parameters untouched while introducing trainable low-rank matrices within each Transformer’s layer. This method leverages linear algebra principles where a large matrix can be effectively approximated by two low-rank matrices, thus reducing the number of parameters. LoRA includes a scaling parameter to adjust the influence of original and LoRA weights during training. We use the Hugging Face version (Apache License 2.0, [Man-grulkar et al. \(2022\)](#)) of LoRA for our experiments.

Prompt Tuning (Lester et al., 2021) This method involves freezing the entire model and adding a trainable soft prompt to the input. The prompt consists of continuous virtual tokens that provide additional context.

Prefix-Tuning (Li and Liang, 2021) Similar to Prompt Tuning, Prefix-Tuning adds trainable tokens but extends them across every Transformer layer by appending trainable embeddings to the attention matrices. To combat the instability in training these prefixes, an over-parameterized MLP is utilized, which can be discarded after training.

BitFit (Zaken et al., 2022) This PEFT method simplifies fine-tuning by training only the bias terms while freezing the other model weights, drastically reducing trainable parameters.

SDT (Galim et al., 2024) SDT (Selective Dimension Tuning) employs a sparse updating approach for the matrices A , B , and C (W_B and W_C for S6), while additionally applying LoRA to the linear projection layers. All remaining layers are kept frozen. The process for determining which parameters to update involves a warmup stage, during which parameters are flagged as updatable if they exhibit a significant gradient magnitude. In our SDT experiments, we excluded LoRA from the lin-

ear projection layers and focused solely on its S6 component.

Additional-scan (Yoshimura et al., 2025) This approach enhances the model’s expressivity by expanding the state dimensions for A , W_B , and W_C . During training, only the added dimensions are marked as trainable.

DART	62659	2768	10	130m	METEOR, BLEU

Table 4: Dataset details. We report the number of training and validation samples, number of training epochs, employed model size and evaluation metrics.

This paper examines four datasets across two domains: Natural Language Understanding (NLU) and Natural Language Generation (NLG). Table 4 presents detailed information for each dataset.

GLUE (Wang et al., 2019) A benchmark comprising nine tasks in English for assessing language understanding models, including sentiment analysis, linguistic acceptability, and question answering. We use the the following datasets: RTE ([Dagan et al., 2005](#); [Bar-Haim et al., 2006](#); [Giampiccolo et al., 2007](#); [Bentivogli et al., 2009](#)), MRPC ([Dolan and Brockett, 2005](#)), CoLA ([Warstadt et al., 2019](#)), SST-2 ([Socher et al., 2013](#)), QNLI ([Rajpurkar et al., 2018](#)), QQP², and MNLI ([Williams et al., 2018](#)). Evaluation is mainly through accuracy, except for CoLA where Matthews correlation is used. The final metric is calculated as the average accuracy (Matthews correlation for CoLA) across all datasets. The individual datasets are available under different permissive licenses. We use the version hosted at <https://huggingface.co/datasets/nyu-ml/glu>.

SAMSum (Gliwa et al., 2019) A dataset for dialogue summarization featuring about 16,000 synthetic conversations in English with summaries, created to simulate digital communications with

²<https://quoradata.quora.com/First-Quora-Dataset-Release-Question-Pairs>

varied tones and styles. Its structure helps in developing systems that process conversational text. The dataset is evaluated via ROUGE score. This dataset is available under the CC BY-NC-ND 4.0 license. We use the version hosted at <https://huggingface.co/datasets/Samsung/samsun>.

Spider (Yu et al., 2018) A text-to-SQL dataset with 10,000 annotated SQL queries across 200+ databases, classifying queries from easy to extra hard based on SQL operation complexity. It involves translating English questions to SQL, evaluated via execution accuracy. Execution accuracy considers the output correct if the model’s predicted SQL query and the ground truth SQL query yield the same results when executed on the database. This dataset is available under the CC BY-SA 4.0 license. We use the version hosted at <https://huggingface.co/datasets/xlangai/spider>.

DART (Nan et al., 2021) Comprising over 80,000 instances, DART focuses on English RDF-to-text generation, organized by structured data triples and corresponding text summaries. It is assessed using METEOR and BLEU metrics. This dataset is available under the MIT license. We use the version hosted at <https://huggingface.co/datasets/Yale-LILY/dart>.

F Experimental Details

For every dataset, we select the model size based on how difficult the dataset is and conduct a brief grid search for one epoch using a subset of the data (1k-2k instances) with learning rates of $\{4 \times 10^{-1}, 2 \times 10^{-1}, 1 \times 10^{-1}, \dots, 1 \times 10^{-5}\}$. The best learning rate is then selected as the rate that has the lowest training loss. In our experimental results, we report the metric from the best epoch observed on the validation set during training, employing early stopping. Each experiment is conducted once. We apply fine-tuning methods to the SSM module (S6) of Mamba (130M, 1.4B, 2.8B)³ and the SSM module (SSD) of Mamba-2 (130M, 1.3B)⁴ pretrained from Pile (MIT License, Gao et al. (2020)) using AdamW (Loshchilov and Hutter, 2019) with a linear decay schedule for the learning rate. In general, we choose hyperparameters for each individual method to ensure that all

³Apache License 2.0, <https://huggingface.co/state-spaces/mamba-{130m,1.4b,2.8b}>

⁴Apache License 2.0, <https://huggingface.co/state-spaces/mamba2-{130m,1.3b}>

methods operate within a similar parameter budget. Tables 5 and 6 show selected learning rates and chosen hyperparameters for each method. For assessing NLG tasks, we utilize beam search with five beams and a maximum beam length of 1024. BLEU (Papineni et al., 2002), ROUGE (Lin, 2004), and METEOR (Banerjee and Lavie, 2005) metrics are computed using Hugging Face’s evaluate library⁵.

We use an NVIDIA RTX 3090 24GB for training models with less than 1 billion parameters, and an NVIDIA H100 80GB for larger models. We implemented our project in PyTorch (Modified BSD license, Paszke et al. (2019)), utilizing the Hugging Face trainer (Apache License 2.0, Wolf et al. (2020)). We train with batch size 4 for 10 epochs on all datasets except QQP and MNLI for which we use 3 epochs, allowing each training run to finish in under 16 hours. This project spanned three months, utilizing four NVIDIA RTX 3090 24GB GPUs and four NVIDIA H100 80GB GPUs, totaling approximately 17,000 GPU hours.

G Additional Experimental Results

G.1 Mamba Results

Training Speed and Memory Usage We conduct a small experiment to compare the memory usage and training speed of State-offset Tuning (h) and LoRA, as they performed most similarly in terms of dataset metrics in our experiments. Using a single H100 GPU, we train for 100 batch iterations with a batch size of 4 and a 1K context, continuously measuring memory usage and batch latency.

Table 7 shows the training speed and maximum memory usage for different Mamba sizes for State-offset Tuning (h) and LoRA. State-offset Tuning (h) uses less memory and is faster, even with more trainable parameters. In this experiment, we selected hyperparameters to ensure LoRA has less trainable parameters than State-offset Tuning (h). We believe State-offset Tuning (h)’s efficiency stems from our optimized einsum implementation, enhanced with the opt_einsum (MIT License, Smith and Gray (2018)) Python package to reduce memory usage and improve latency.

State-offset Tuning (y)	-	-	-	-

Table 6: Hyperparameter settings for each model and PEFT method. In general, we adjust hyperparameters to maintain a similar number of trainable parameters.

Model	Method	Params (%)	Mem. (GB)	Latency (s)
130M	State-offset Tuning (h)	0.45	4.2	0.13
	LoRA	0.35	5.44	0.18
370M	State-offset Tuning (h)	0.42	9.36	0.33
	LoRA	0.32	11.56	0.45
790M	State-offset Tuning (h)	0.3	13.91	0.49
	LoRA	0.23	17.17	0.61
1.4B	State-offset Tuning (h)	0.23	18.77	0.67
	LoRA	0.17	22.99	0.8
2.8B	State-offset Tuning (h)	0.19	31.49	1.13
	LoRA	0.14	37.84	1.33

Table 7: Training speed and memory usage. For each Mamba size, we compare the maximum memory usage and mean latency for processing a single batch during training. Our State-offset Tuning (h) is compared against LoRA, as it demonstrated the most similar performance in the experiment section. We configure LoRA to use fewer trainable parameters than State-offset Tuning (h). Despite this, State-offset Tuning (h) still consumes less memory and is faster in training.

FLOP Overhead While it is possible to avoid extra FLOP with LoRA in constrained single-task settings by merging weights into the pretrained model, real-world serving scenarios often require a single pretrained model to support multiple downstream tasks simultaneously via multiple LoRA adapters. In such cases, avoiding extra FLOP would require storing separately merged models for each task in memory—an inefficient solution. Alternatively, merging weights dynamically at inference time introduces significant computational bottlenecks. As

a result, many recent works focus on serving many LoRA adapters efficiently without weight merging (Sheng et al., 2023).

Model	Sequence Length	Method	L=128	L=256	L=512	L=1024	Relative (%)
			GFLOP				
130M	Pretrained		16.45	32.90	65.81	131.61	100.000
	State-offset Tuning (h)		16.46	32.91	65.83	131.65	+ 0.029
	LoRA		16.61	33.21	66.42	132.84	+ 0.937
370M	Pretrained		47.35	94.69	189.39	378.77	100.000
	State-offset Tuning (h)		47.36	94.72	189.44	378.87	+ 0.027
	LoRA		47.76	95.52	191.03	382.06	+ 0.867
790M	Pretrained		101.22	202.44	404.88	809.75	100.000
	State-offset Tuning (h)		101.24	202.48	404.95	809.90	+ 0.019
	LoRA		101.84	203.67	407.34	814.67	+ 0.608
1.4B	Pretrained		175.23	350.45	700.90	1401.79	100.000
	State-offset Tuning (h)		175.25	350.50	701.00	1401.99	+ 0.014
	LoRA		176.05	352.09	704.17	1408.35	+ 0.468
2.8B	Pretrained		353.66	707.32	1414.63	2829.25	100.000
	State-offset Tuning (h)		353.70	707.40	1414.80	2829.59	+ 0.012
	LoRA		355.03	710.05	1420.09	2840.17	+ 0.386

Table 8: FLOP overhead across various model sizes and sequence lengths. State-offset Tuning adds less than 0.03% overhead, whereas LoRA incurs over 30 \times more extra FLOP compared to ours.

Given these practical considerations, we evaluate LoRA without weight merging and conduct experiments comparing the additional FLOP of LoRA and our State-offset Tuning method during inference. We use ptflops (Sovrasov, 2018-2024) to measure computational overhead. As shown in Table 8, our method adds less than 0.03% overhead, while LoRA results in more than 30 times

the additional FLOP compared to ours. These results highlight the superior FLOP efficiency of our method compared to LoRA.

Mamba 2.8B Results Table 9 shows the experimental results using Mamba 2.8B. Our State-offset Tuning (h) outperforms all methods except full fine-tuning.

Mamba Results on GLUE Dataset Table 10 shows the full results on the GLUE dataset using Mamba 130M. Our State-offset Tuning (h) achieves the highest average score among all PEFT methods.

G.2 Mamba-2 Results

Table 11 shows experimental results with Mamba-2 (Dao and Gu, 2024) models. State-offset Tuning (h) with low-rank adaptation (Sec. C) significantly reduces the number of trainable parameters. It outperforms existing methods on the Spider benchmark by a large margin and achieves performance comparable to other approaches on the SAMSum and DART datasets.

G.3 State-offset Tuning in SSMs vs. Prefix-Tuning in Transformers

To highlight the effectiveness of State-offset Tuning, we compare its performance with Prefix-Tuning on the Transformer model Pythia (Biderman et al., 2023). We conduct full fine-tuning and Prefix-Tuning experiments on Pythia 160M on GLUE tasks. The results are shown in Table 12.

Full fine-tuning on Mamba 130M generally surpasses Pythia 160M, consistent with Gu and Dao (2024). Prefix-Tuning on both Mamba and Pythia reaches about 85–90% of their full fine-tuning performance.

Our State-offset Tuning achieves approximately 98% of full fine-tuning performance, effectively closing the gap. This success highlights its precise design for SSM-based models.

G.4 Comparison to Selective Dimension Tuning (SDT)

We additionally compare our method with Selective Dimension Tuning (SDT) (Galim et al., 2024), a technique derived from theoretical analysis of SSMs. Note that the hyperparameter selection differs from that used in Galim et al. (2024) to ensure the parameter count is more comparable to ours. As shown in Table 13, our method consistently

outperforms SDT in most cases while using fewer parameters.

Model Size		Mamba 2.8B					
Dataset		Params (%)	Spider				
Type	Method		All	Easy	Medium	Hard	Extra
-	Full Fine-tuning (All)	100.00	71.8	87.5	73.5	63.8	51.8
	Full Fine-tuning (S6)	4.44	65.7	81.9	68.8	58.0	41.0

Table 13: Comparison with Selective Dimension Tuning (SDT) (Galim et al., 2024) on Spider, SAMSum, DART, and GLUE. Our method outperforms SDT in most cases while using fewer parameters. Note that the hyperparameter configuration of SDT differs from that in Galim et al. (2024) to ensure a more comparable parameter count.

Internal and External Impacts of Natural Language Processing Papers

Yu Zhang

Texas A&M University
yuzhang@tamu.edu

Abstract

We investigate the impacts of NLP research published in top-tier conferences (*i.e.*, ACL, EMNLP, and NAACL) from 1979 to 2024. By analyzing citations from research articles and external sources such as patents, media, and policy documents, we examine how different NLP topics are consumed both within the academic community and by the broader public. Our findings reveal that language modeling has the widest internal and external influence, while linguistic foundations have lower impacts. We also observe that internal and external impacts generally align, but topics like ethics, bias, and fairness show significant attention in policy documents with much fewer academic citations. Additionally, external domains exhibit distinct preferences, with patents focusing on practical NLP applications and media and policy documents engaging more with the societal implications of NLP models.

1 Introduction

“*Is ACL an AI conference?*” Comments from opinion leaders¹² within the natural language processing (NLP) community definitely matter. Meanwhile, a complementary perspective is how the broader academic community and the public perceive and utilize papers from top-tier NLP conferences (*e.g.*, ACL, EMNLP, and NAACL). We can categorize the public use of NLP papers into two types: (1) *Internal Use*: NLP papers are cited by other research articles in not only NLP but also various other fields (Zhang et al., 2024), due to the ideas, methods, datasets, or findings they present (Jurgens et al., 2018; Cohan et al., 2019); and (2) *External Use*: Research can break out of the academic “ivory tower” (Cao et al., 2023) and diffuse into the technological, societal, and governmental

discussions (Yin et al., 2022). Specifically, NLP papers can be referenced by patents, media posts, policy documents, and text in other public channels. If we infer how public audiences define these NLP conferences based on which papers from the conferences are used by them, the question becomes: Papers of which topics (*e.g.*, cutting-edge AI models or linguistic foundations) are more extensively consumed internally and externally?

To answer this question, in this paper, we present a comprehensive scientometric study examining the internal and external impacts of NLP papers published in ACL, EMNLP, and NAACL between 1979 and 2024. We collect data from various sources (Priem et al., 2022; Marx and Fuegi, 2022; Adie and Roe, 2013; Szomszor and Adie, 2022) to obtain up-to-date references to NLP papers from internal (*i.e.*, research articles) and external (*i.e.*, patents, news/social media, and policy documents) domains. Based on the collected data, we calculate the average number of times that papers of a specific topic (*e.g.*, “*Language Modeling*” or “*Ethics, Bias, and Fairness*”) are used in an internal/external domain, and employ it as an indicator to measure the impact of the topic within that domain.

Our analysis leads to the following key observations: First, among all research topics that NLP conferences are calling for, language modeling demonstrates the broadest internal and external impacts, whereas linguistic foundations, such as phonology, morphology, psycholinguistics, and pragmatics, exhibit relatively low influence. Second, the internal and external impacts of an NLP topic generally align, though there are outliers, such as “*Ethics, Bias, and Fairness*”, which show notably high use in policy documents but are cited far less frequently in research articles. Third, different external domains favor different NLP topics, offering complementary insights into an NLP paper’s internal impact. Patents tend to consume practical NLP applications, while media and policy documents are

¹https://faculty.washington.edu/ebender/papers/ACL_2024_Presidential_Address.pdf

²<https://gist.github.com/yoavg/f952b7a6cafd2024f44c8bc444a64315>

more likely attracted by the behavior and societal influence of NLP models.

2 Data

We first describe how we collect data from multiple sources to measure the internal impact of NLP papers and their external uses across various domains, including patents, media, and policy documents.

NLP Papers: ACL Anthology. From the ACL Anthology³, we extract all papers whose venue is marked as ACL, EMNLP, or NAACL (including main conference papers, findings papers, system demonstrations, industry track papers, *etc.*). We choose these three conferences because CSRankings designates them as “top conferences” for ranking purposes, and they are the top three in Google Scholar’s “Computational Linguistics” category. In total, we obtain 24,821 papers published between 1979 and 2024 in these three conferences.

Internal Impact (Citation): OpenAlex. Because Microsoft Academic (Sinha et al., 2015) terminated its service at the end of 2021, to get the up-to-date number of citations for each paper, we link our extracted NLP papers to OpenAlex (Priem et al., 2022)⁴. In all, we successfully map 21,104 papers to the OpenAlex database and get their numbers of citations. We use \mathcal{P} to denote the set of these mapped papers. We should mention that each paper $p \in \mathcal{P}$ may have multiple versions (*e.g.*, a preprint version and an NLP conference version). When calculating the internal or external impact of p , we merge all versions into a single record by summing their citation counts.

External Impact (Patent): Reliance on Science. To study references to NLP papers in patents, we follow previous studies (Yin et al., 2022; Cao et al., 2023) and utilize the Reliance on Science dataset (Marx and Fuegi, 2020, 2022)⁵, which contains references from USPTO patents to OpenAlex papers. In total, we identify 20,218 links from patents to papers in \mathcal{P} .

External Impact (Media): Altmetric. To quantify how NLP papers are mentioned in media, we rely on the data provided by Altmetric (Adie and Roe, 2013)⁶, which archives references from media, in-

cluding both news and social media (*i.e.*, Twitter, Facebook, Reddit, and blogs), to academic papers. In all, we obtain 18,586 media-to-paper links for the NLP publications in \mathcal{P} .

External Impact (Policy Document): Overton. To examine references to NLP papers in policy documents, we follow Yin et al. (2021) and exploit the Overton database (Szomszor and Adie, 2022)⁷. Overton defines “policy documents” as “research, briefs, reviews, or reports written with the goal of influencing or changing policy” from “governments, public bodies, IGOs, NGOs and think tanks”. We obtain 1,223 links from policy documents to papers in \mathcal{P} .

3 Analysis

3.1 Internal and External Impacts by Topic

We adopt the 25 submission topics (excluding the special theme) outlined in the ACL 2025 Call for Papers⁸ as our topic space for NLP papers, denoted as \mathcal{T} . For each NLP paper $p \in \mathcal{P}$, we use GPT-4o (Hurst et al., 2024) to predict its most relevant topic $t_p \in \mathcal{T}$. Human evaluation is then conducted to assess the quality of GPT-4o annotations. We find that GPT-4o gives reliable annotations, and the human evaluators share “substantial agreement” according to the Fleiss’ kappa (Fleiss, 1971). One can refer to Appendix A for more details about the annotation process. Based on the annotations, we use $\mathcal{P}_t = \{p : p \in \mathcal{P} \text{ and } t_p = t\}$ to denote the set of NLP papers labeled with the topic t ($\forall t \in \mathcal{T}$).

To quantify the impact of NLP papers with a certain topic $t \in \mathcal{T}$ in a certain domain $d \in \{\text{Citation, Patent, Media, PolicyDocument}\}$, we consider the following metric:

$$\text{Impact}(t|d) = \frac{\sum_{p \in \mathcal{P}_t} \#\text{citation}(p|d)/|\mathcal{P}_t|}{\sum_{p \in \mathcal{P}} \#\text{citation}(p|d)/|\mathcal{P}|}.$$

Here, $\#\text{citation}(p|d)$ represents the “citation count” (in a broader sense) of paper p given domain d . To be specific, when $d = \text{Citation}$, it is the number of times that p is cited by other academic papers (from the entire OpenAlex database rather than ACL Anthology only); when $d \in \{\text{Patent, Media, PolicyDocument}\}$, it is the number of times that p is mentioned by patents, media posts, and policy documents, respectively, in our

⁷Please refer to <https://www.overton.io> to request access to the data. We extracted the data on December 8, 2024.

⁸https://2025.aclweb.org/calls/main_conference_papers

Figure 1: Impact of NLP papers with a certain topic in a certain domain.

collected data. $\text{Impact}(t|d)$ is the average “citation count” of papers with topic t given domain d , normalized by the average “citation count” of all papers given domain d . Our proposed metric is inspired by Yin et al. (2022), with one key difference: we consider the actual number of times a paper p is cited, whereas Yin et al. (2022) binarize this value, focusing only on whether p is cited or not (i.e., $\mathbf{1}_{\#\text{citation}(p|d)>0}$).

Figure 1 visualizes $\text{Impact}(t|d)$ across all topics and domains considered by us, from which we have the following key observations:

Observation 1: Papers on language modeling have a broad impact across all internal and external domains.

The topic “*Language Modeling*” enjoys the highest impact in the Citation, Patent, and Media domains, as well as the second highest impact in the PolicyDocument domain. It is the only over-represented topic (i.e., $\text{Impact}(t|d) > 1$) across all domains, indicating the significant attention received from a broad range of public audiences on language models.

Observation 2: Papers on ethics, bias, and fairness are highly consumed in policy documents but have significantly lower usage in patents and academic papers.

The topic “*Ethics, Bias, and Fairness*” achieves the highest impact in PolicyDocument, exceeding the average in Media, while being under-

represented in Citation and ranking the last in Patent. The topic “*Computational Social Science and Cultural Analytics*” exhibits a similar pattern of external impacts, but with a less pronounced contrast.

Observation 3: Linguistic foundations are relatively under-represented in all internal and external domains.

Topics that provide linguistic and theoretical underpinnings of NLP, such as “*Phonology, Morphology, and Word Segmentation*”, “*Linguistic Theories, Cognitive Modeling and Psycholinguistics*”, as well as “*Discourse and Pragmatics*”, have $\text{Impact}(t|d) < 1$ across all domains.

Observation 4: Tasks and techniques benefiting real-world NLP applications have a larger impact in patents.

Besides “*Language Modeling*”, topics strongly consumed in Patent include “*Machine Learning for NLP*”, “*Information Retrieval and Text Mining*”, “*Speech Processing and Spoken Language Understanding*”, “*Syntax: Tagging, Chunking and Parsing*”, as well as “*Machine Translation*”. Many of these topics facilitate practical applications, such as search engines and speech recognition systems.

Observation 5: Analyses of the behavior and societal influence of NLP models see stronger adoption in media and policy discussions.

6 topics are over-represented in both Media and PolicyDocument. Apart from “*Language Model-*

Table 1: Pearson correlation coefficient between the impact of NLP papers in the internal domain (*i.e.*, Citation) and that in each external domain.

d	Patent	Media	PolicyDocument
$\text{Corr}(\mathbf{I}_{\text{Citation}}, \mathbf{I}_d)$	0.654	0.725	0.247 (0.599 if excluding “Ethics, Bias, and Fairness”)

ing”, the other 5 topics—“Resources and Evaluation”, “Interpretability and Analysis of Models for NLP”, “Ethics, Bias, and Fairness”, “Multilinguality and Language Diversity”, as well as “Computational Social Science and Cultural Analytics”—all address the understanding and evaluation of NLP models.

3.2 Correlation between Internal and External Impacts

Our next study will draw the following conclusion:

Observation 6: NLP papers attracting attention from external domains are more likely to be internally impactful as well.

In Section 3.1, we have raised a few examples whose internal and external impacts are positively correlated. Now, we quantitatively validate this. Intuitively, each domain d can be represented as a vector \mathbf{I}_d , where each entry corresponds to the impact of a specific topic within d :

$$\mathbf{I}_d = [\text{Impact}(t|d)]_{t \in \mathcal{T}}.$$

Table 1 presents the Pearson correlation coefficient between $\mathbf{I}_{\text{Citation}}$ and each external \mathbf{I}_d ($d \in \{\text{Patent}, \text{Media}, \text{PolicyDocument}\}$). We observe strong positive correlation between Citation and Patent/Media (*i.e.*, with the Pearson correlation coefficient greater than 0.5). The correlation between Citation and PolicyDocument is weaker, although still positive. That being said, if we remove “Ethics, Bias, and Fairness” (which is an evident outlier according to Figure 1) from consideration, $\text{Corr}(\mathbf{I}_{\text{Citation}}, \mathbf{I}_{\text{PolicyDocument}})$ rises above 0.5 as well.

To present more evidence of the positive correlation between internal and external impacts, we follow Yin et al. (2022) and conduct an experiment that leverages external use of NLP research to predict internally most cited papers. Let us consider the top-1% (internally) highly cited NLP papers in \mathcal{P} . If we do not exploit any external signal and randomly pick one paper p from \mathcal{P} , the expected probability that p is among the top-1% cited papers

Table 2: Hit rate of predicting the top-1% (internally) highly cited papers when using different external information.

External Domain(s) Considered	Hit Rate
\emptyset	1.00%
{Patent}	5.46%
{Media}	9.26%
{PolicyDocument}	18.29%
{Patent, Media}	26.72%
{Patent, PolicyDocument}	34.02%
{Media, PolicyDocument}	45.71%
{Patent, Media, PolicyDocument}	71.88%

(*a.k.a.*, the hit rate) should be 1%. In comparison, Table 2 shows the hit rate if we consider papers referenced at least once in a specific external domain d (*i.e.*, $\#\text{citation}(p|d) \geq 1$). Papers consumed by patents, media, and policy documents exhibit hit rates of 5.46%, 9.26%, and 18.29%, respectively, which are all large multiples of the 1% baseline.

Combining the results from Tables 1 and 2, we find good alignment between what the public from external domains consume and what is regarded as impactful by researchers themselves.

3.3 Complementarity of Different External Impacts

Although we have revealed the positive correlation between Citation and each external domain, the alignment between two external domains does not always hold. Qualitatively, we have discussed the different focal points of Patent and Media/PolicyDocument in Observations 4 and 5 in Section 3.1. Quantitatively, we actually have $\text{Corr}(\mathbf{I}_{\text{Patent}}, \mathbf{I}_{\text{PolicyDocument}}) = -0.140$, implying the complementarity, rather than substitutability, of impacts in patents and policy documents. Table 2 echos this observation. Indeed, for papers referenced in two external domains, the hit rate increases to 26.72%-45.71%, significantly higher than those when we consider a single external domain. A paper referenced in all three external domains is a top-1% cited paper in \mathcal{P} at an astonishing 71.88 times the baseline rate. To summarize, we draw the following conclusion:

Observation 7: Different external domains may favor different types of NLP papers. Papers attracting attention from multiple external domains are more likely to be internally impactful than those attracting one domain only.

4 Conclusions

In this paper, we conduct a large-scale scientometric analysis on the internal and external impacts of NLP papers. We find that the broader academic community and the public’s attention to NLP research is primarily driven by the demand for language modeling studies, with the exception of policy-related discussions, which show a greater interest in ethics, bias, and fairness. Although different external domains have varying interests in the specific topics of NLP research, there is an overall positive correlation between the public interests and the impact of papers within the academic “ivory tower”. By examining how the broader academic community and the public perceive NLP papers, our analysis offers complementary insights into whether ACL can be considered an AI conference.

Limitations

This work has the following limitations: First, although the three external domains we consider are all important public spaces, they do not encompass all channels that NLP research may impact. Even within these three domains, NLP papers may be consumed through channels not captured by our collected data. Second, we utilize GPT-4o to predict the most relevant topic to each NLP paper. On top of that, we conduct human evaluation for quality assessment. However, there are still chances where GPT-4o’s annotations may not be accurate enough, potentially affecting the subsequent analysis. Third, we currently lack results (and data) to explain why there is a positive correlation between internal and external impacts. It might be a possible explanation that either researchers or the public are following the other’s preference regarding NLP. Yin et al. (2022) propose another potential hypothesis that each external domain typically involves an “intermediary” to engage with science, such as journalists in the media, inventors in the patent field, and policy experts in the government. They leverage their expertise to select scientific results and introduce them into their respective domains. Finally, since our collected data from certain domains do not indicate when an NLP paper was cited, we are unable to perform a systematic temporal analysis. We believe that, with appropriate data support, all of the limitations mentioned above represent highly promising future directions.

Acknowledgments

We thank Yian Yin for helpful suggestions.

A Topic Prediction of NLP Papers

A.1 Topic Annotation using GPT-4o

We adopt the following instruction prompt to guide GPT-4o in performing topic annotation.

Instruction: You will be given the title and abstract of a natural language processing paper, as well as a list of candidate topics. Select the most relevant topic to the given paper from the list.

Paper title: [title; e.g., BERT: Pre-training of Deep Bidirectional Transformers for Language Understanding]

Paper abstract: [abstract; e.g., We introduce a new language representation model called BERT, which stands for ...]

Candidate labels: “Computational Social Science and Cultural Analytics”, “Dialogue and Interactive Systems”, “Discourse and Pragmatics”, “Ethics, Bias, and Fairness”, ... (25 topics)

We set the temperature as 1.0 (the default setting for GPT-4o in OpenAI’s API). In rare cases, the output of GPT-4o does not exactly match any of the candidate labels. To tackle this, we use a scientific pre-trained language model, SPECTER (Cohan et al., 2020), to encode the output and each candidate label’s name; then, we consider the nearest neighbor of the output in the SPECTER embedding space as the predicted label.

A.2 Human Evaluation

To assess the quality of annotations produced by GPT-4o, human evaluation is then conducted. We recruit 3 evaluators, all of whom have rich NLP research experiences. We randomly selected 100 samples for evaluation. For each submission, we ask each annotator to judge the correctness of the label predicted by GPT-4o. The scoring scale is 2 (the predicted label is the most relevant label to the paper), 1 (the predicted label is relevant to the paper, although there is a better option), and 0 (the predicted label is irrelevant to the paper).

According to human evaluation, GPT-4o gets an average score of 1.53 across the three evaluators. Notably, none of the 100 predictions gets 0

(i.e., irrelevant), indicating the reliability of GPT-4o annotations. We also calculate the Fleiss’ kappa (Fleiss, 1971), which is 0.62 and implies “substantial agreement” among the evaluators.

B Impact of NLP Papers in GitHub

As noted in the Limitations section, the impact of an NLP paper may not be limited to textual citations alone. As a complementary analysis, in this section, we examine the influence of NLP papers in the GitHub domain. Specifically, we analyze the average number of forks for GitHub repositories associated with each NLP topic. It is important to note that we consider this measure of impact to be a mixture of both internal and external influences, as forking a code repository may be done by other researchers for follow-up research, or by practitioners aiming to deploy the work in real-world applications.

B.1 Data and Metric

We refer to Papers With Code⁹ to establish the correspondence between our collected NLP papers and their associated GitHub repositories. 7,113 (out of 21,104) NLP papers are mapped to at least one repository in this way. Then, we used the GitHub API¹⁰ to retrieve the number of forks for each corresponding repository. If a paper p is associated with multiple repositories, its fork count $\#fork(p)$ is computed as the sum of forks across all associated repositories. Analogous to defining impact through the citation count, we define the impact of NLP papers in GitHub based on the fork count as follows:

$$\text{Impact}(t|\text{GitHub}) = \frac{\sum_{p \in \mathcal{P}_t} \#fork(p)/|\mathcal{P}_t|}{\sum_{p \in \mathcal{P}} \#fork(p)/|\mathcal{P}|}$$

Here, we only include NLP papers in \mathcal{P} and \mathcal{P}_t that can be matched to at least one GitHub repository.

B.2 Analysis

Figure A1 shows $\text{Impact}(t|\text{GitHub})$ across all topics. Once again, we observe that “*Language Modeling*” exhibits the highest impact by a significant margin. Other topics with relatively high impact include “*Speech Processing and Spoken Language Understanding*”, “*Machine Learning for NLP*”,

⁹<https://production-media.paperswithcode.com/about/links-between-papers-and-code.json.gz>, accessed on March 5, 2025.

¹⁰<https://api.github.com/repos>, accessed on March 5, 2025.

Figure A1: Impact of NLP papers with a certain topic in the GitHub domain.

Table A1: Pearson correlation coefficient between the impact of NLP papers in GitHub and that in other domains.

d	Citation	Patent	Media	Policy Document
$\text{Corr}(\mathbf{I}_{\text{GitHub}}, \mathbf{I}_d)$	0.586	0.633	0.531	0.009

“*Multilinguality and Language Diversity*”, as well as “*Multimodality and Language Grounding to Vision, Robotics and Beyond*”. It is evident that topics related to practical NLP applications tend to achieve higher impact in GitHub. In this regard, GitHub is similar to Patent, which also aligns with our intuition. By contrast, linguistic foundations and “*Ethics, Bias, and Fairness*” exhibit significantly lower impact.

Table A1 demonstrates the Pearson correlation coefficient between the impact of NLP papers in GitHub and that in other domains. We observe a clear positive correlation between GitHub and Citation, Patent, and Media, with the strongest correlation observed with Patent, echoing our qualitative discussion above. Meanwhile, the near-zero correlation between GitHub and PolicyDocument reflects their distinct emphases.

An Effective Incorporating Heterogeneous Knowledge Curriculum Learning for Sequence Labeling

Abstract

Sequence labeling models often benefit from incorporating external knowledge. However, this practice introduces data heterogeneity and complicates the model with additional modules, leading to increased expenses for training a high-performing model. To address this challenge, we propose a dual-stage curriculum learning (DCL) framework specifically designed for sequence labeling tasks. The DCL framework enhances training by gradually introducing data instances from easy to hard. Additionally, we introduce a dynamic metric for evaluating the difficulty levels of sequence labeling tasks. Experiments on several sequence labeling datasets show that our model enhances performance and accelerates training, mitigating the slow training issue of complex models¹.

1 Introduction and Related Work

Sequence labeling is a core task in natural language processing (NLP) that involves assigning labels to individual elements in a sequence. Recent advancements in neural network methods have significantly improved performance in sequence labeling tasks (Zhang et al., 2014; Chen et al., 2017a; Zhang et al., 2018; Tian et al., 2020a; Nguyen et al., 2021; Hou et al., 2021; Liu et al., 2021). Some studies have explored integrating external knowledge, such as n-grams, lexicons, and syntax, to enhance these models. However, this integration adds heterogeneity and complexity to the input data. Additionally, incorporating such knowledge often necessitates extra encoding modules, like attention mechanisms (Liu et al., 2021; Tian et al., 2020b) or graph neural networks (GNN) (Chen et al., 2017b; Gui et al., 2019; Nie et al., 2022), which increase model parameters and make the system more computationally expensive to develop.

Curriculum Learning (CL) (Bengio et al., 2009) effectively addresses these challenges by simulating the human learning process, where training samples are introduced progressively from easy to hard. This approach facilitates efficient learning from heterogeneous data while enhancing both the speed and performance of the model (Bengio et al., 2009; Wang et al., 2021). CL has shown success in a variety of NLP tasks, including machine translation (Wan et al., 2020), dialogue generation (Zhu et al., 2021), and text classification (Zhang et al., 2022). Data-selection strategies are crucial in CL. However, these difficulty metrics primarily focus on the sentence level, such as Mohiuddin et al. (2022), Yuan et al. (2022) and Liu et al. (2024)’s works, and there is a lack of token-level and word-level metrics to measure the difficulty of sequence labeling tasks.

To address this gap, in this paper, we introduce a dual-stage curriculum learning (DCL) framework specifically designed for sequence labeling tasks. The first stage is data-level CL, where we train a basic teacher model on all available training data, aiming to alleviate the cold start problem of the student model. The second stage is model-level CL, where we start training the student model on a selected subset of the teacher model and gradually expand the training subset by considering the difficulty of the data and the state of the student model. Furthermore, we explore different difficulty metrics for sequence labeling tasks within the DCL framework. These metrics include a pre-defined metric, such as sentence length, and model-aware metrics, namely Top-N least confidence (TLC), Maximum normalized log-probability (MNLP), and Bayesian uncertainty (BU). Finally, we choose the classical sequence labeling tasks, Chinese word segmentation (CWS), part-of-speech (POS) tagging, and named entity recognition (NER), to validate our proposed approach.

2 Method

The framework proposed in this study consists of three main components: a teacher sequence labeling model, a student sequence labeling model, and a DCL training strategy. It is worth noting that the DCL is independent of the sequence labeling model.

Following previous works (Zhang et al., 2018; Gong et al., 2019; Fu et al., 2020), in sequence labeling tasks, we feed an input sentence $X = \{x_1, \dots, x_i, \dots, x_M\}$ into the encoder, and the decoder then outputs a label sequence $Y^* = \{y_1^*, \dots, y_i^* \dots y_M^*\}$, where y_i^* represents a label from a pre-defined label set T , and M denotes the length of sentence.

2.1 Dual-stage Curriculum Learning

Algorithm 1 Training Process with DCL

Input: Original corpus \mathcal{D} , difficulty metric $S(\cdot)$, teacher model epochs E_0 , student model epochs E_s , scheduler λ , length function $|\cdot|$

Output: Trained student model θ

```

// Data-level Curriculum Learning
1: Train teacher model  $\theta_0$  on  $\mathcal{D}$  for  $E_0$  epochs
2: Compute  $S(\theta_0)$  for each sample in  $\mathcal{D}$ 
3: Sort  $\mathcal{D}$  by  $S(\theta_0)$  in ascending order to obtain ranked dataset  $\mathcal{D}_r$ 
// Model-level Curriculum Learning
4: Initialize  $\lambda_0$  (starting curriculum ratio)
5:  $m \leftarrow \lambda_0 \cdot |\mathcal{D}|$ 
6: Student training set  $\mathcal{D}_s \leftarrow \mathcal{D}_r[0 : m]$ 
7: Remaining data  $\mathcal{D}_o \leftarrow \mathcal{D}_r[m : ]$ 
8: for  $epoch = 1$  to  $E_s$  do
9:   if  $\lambda < 1$  then
10:    a) Train student model on  $\mathcal{D}_s$  to obtain current  $\theta_*$ 
11:    b) Compute  $S(\theta_*)$  for all samples in  $\mathcal{D}_o$ 
12:    c) Sort  $\mathcal{D}_o$  by  $S(\theta_*)$  in ascending order to get updated  $\mathcal{D}_r$ 
13:    d) Update  $\lambda$  using Eq. 6
14:    e) Calculate new data size:  $m \leftarrow \lambda \cdot |\mathcal{D}| - |\mathcal{D}_s|$ 
15:    f) Expand  $\mathcal{D}_s$  with new samples:  $\mathcal{D}_s += \mathcal{D}_r[0 : m]$ 
16:    g) Update remaining data:  $\mathcal{D}_o \leftarrow \mathcal{D}_r[m : ]$ 
17:   else
18:     Train student model on  $\mathcal{D}_s$ 
19:   end if
20: end for

```

We propose a novel dual-stage curriculum learning approach: *data-level* CL and *model-level* CL, as detailed in Algorithm 1.

At the data level, we first train a basic teacher model on the entire dataset \mathcal{D} for E_0 epochs, where E_0 is smaller than the total epochs needed for convergence (Line 1). The teacher model θ_0 is then used to calculate difficulty scores $S(\theta_0)$ for each sample (Line 2), and the samples are sorted by difficulty to form a ranked dataset \mathcal{D}_r (Line 3).

At the model level, we address the cold-start issue by initializing the student model training set \mathcal{D}_s with a subset of \mathcal{D}_r (Lines 4-6). The proportion of samples, controlled by the parameter λ , governs the curriculum learning process. The remaining data, \mathcal{D}_o , is incorporated into \mathcal{D}_s gradually as λ increases. The number of new samples to be added is denoted as m (Lines 5, 14).

The student model is trained on \mathcal{D}_s to update the model parameters θ_* (Line 10). Then, θ_* is used for the difficulty calculation of the samples in \mathcal{D}_o (Line 11). Next, \mathcal{D}_o is ranked by new difficulty scores, forming a new ranked dataset \mathcal{D}_r (Line 12). The threshold λ is updated (Line 13), and new samples are added to \mathcal{D}_s based on λ (Lines 14-15). As λ approaches 1, all of \mathcal{D}_o is added to \mathcal{D}_s . The complete dataset is then used to train the student model to convergence.

The key elements in Algorithm 1 are the difficulty metric $S(\cdot)$ and threshold λ , which control the difficulty ranking of samples and the progression of training, respectively. The design of these components will be discussed in the following sections.

2.2 Difficulty Metrics

We now provide a detailed formulation for calculating the difficulty $S(\cdot)$ in Algorithm 1. In sequence labeling tasks, sample difficulty is tied to individual tokens, but assessing token-level difficulty is challenging. We use uncertainty from active learning to measure the model’s confidence in labeling training samples.

Bayesian Uncertainty (BU). Following Buntine and Weigend (1991), model uncertainty can be assessed using Bayesian Neural Networks. As noted by Wang et al. (2019), higher predicted probability variance indicates greater uncertainty, suggesting that the model is less confident about the sample. In this work, we employ the widely-used Monte Carlo dropout (Gal and Ghahramani, 2016) to approximate Bayesian inference.

First, we apply Monte Carlo dropout (Gal and Ghahramani, 2016) to obtain each sample of token-level tagging probabilities. Specifically, for each token x_i , we perform K stochastic forward passes through the model, resulting in K predicted distributions $P(y_i | x_i)_1, \dots, P(y_i | x_i)_K$. This provides K predictions with associated probabilities for each token. Then the expectation of token-level

Figure 1: The framework of the proposed model consists of a teacher model, a student model, and a DCL strategy. Here, “Root f ” represents *Root function*.

tagging probability can be approximated by

$$\mathbb{E}[P(y_i|x_i)] \approx \frac{1}{K} \sum_{k=1}^K P(y_i|x_i)_k \quad (1)$$

The variance of token-level tagging probability on the label set can be approximated by

$$\begin{aligned} \text{var}(x_i, \theta) \approx \\ \sum_{y_i \in T} \left(\frac{1}{K} \sum_{k=1}^K P(y_i|x_i)_k^2 - \mathbb{E}[P(y_i|x_i)]^2 \right) \end{aligned} \quad (2)$$

Now, we obtain the variance of each token $\text{var}(x_i, \theta)$, then we use the average variance score of all tokens in the sequence as the sentence-level variance as follows.

$$\text{var}(\theta)_{aver.} = \frac{1}{M} \sum_{i=1}^M \text{var}(x_i, \theta) \quad (3)$$

The maximum variance score $\text{var}(\theta)_{max}$ also is valuable, which reflects the highest uncertainty in the sequence.

$$\text{var}(\theta)_{max} = \max_{i \in [1, M]} \text{var}(x_i, \theta) \quad (4)$$

The final uncertainty score or difficulty score of each sequence is calculated as follows.

$$S(\theta)^{BU} = \text{var}(\theta)_{max} + \text{var}(\theta)_{aver.} \quad (5)$$

Both at the data level and model level, the difficulty of training samples is measured by the above various $S(\theta)$.

2.3 Training Scheduler

The training scheduler regulates the pace of CL. In our approach, we employ the *Root function* as the control mechanism. This function ensures that the model receives sufficient time to learn newly introduced examples while gradually decreasing the number of newly added examples throughout the training process.

$$\lambda = \min \left(1, \sqrt{\frac{1 - \lambda_0^2}{E_{grow}} \cdot t + \lambda_0^2} \right) \quad (6)$$

where E_{grow} denotes the number of epochs required for λ to reach 1, while $\lambda_0 > 0$ represents the initial proportion of the easiest training samples. t indicates the t_{th} training epochs. When λ reaches 1, the model has access to the entire training dataset.

3 Experiments

3.1 Dataset and Experimental Configurations

Dataset. Chinese word segmentation (CWS) and part-of-speech (POS) tagging are representative sequence labeling tasks. So we evaluate our approach using three CWS and POS tagging datasets, including Chinese Penn Treebank version 5.0², 6.0³, and PKU. More dataset details can be found in Appendix A.

Teacher and student models. In this study, the basic transfer teacher framework is RoBERTa + Softmax. For the student model, we select two representative complex models introduced by Tian et al. (2020b) and Tang et al. (2024). In their work, Tian et al. (2020b) employed an attention mechanism framework, McASP, to integrate lexicons and n-grams for the joint CWS and POS tagging task, using BERT as the encoder. Meanwhile, Tang et al. (2024) incorporated syntax and semantic knowledge into sequence labeling tasks through a GCN framework called SynSemGCN, with RoBERTa as the sequence encoder.

Curriculum learning baselines. We compare our difficulty metric with four baseline difficulty metrics for CL: *a. Random*: Samples are assigned in random order; *b. Sentence Length (Length)*: Samples are ranked from shortest to longest, based on the intuition that longer sequences are more challenging to encode; (Random and Length metrics represent simple CL, namely without the teacher model). *c. Top-N Least Confidence (TLC)*: The difficulty of a sequence is determined by using the

Table 1: Experimental results of different models using different CL settings on test sets of three datasets. Here, “CWS” represents the F1 value of CWS, and “POS” means the F1 value of the joint CWS and POS tagging. “-” means without the CL training strategy, and “TLC”, “MNLP”, and “BU” means using the DCL setting with different difficulty metrics. The maximum F1 scores for each dataset are highlighted.

N tokens with the lowest confidence; *d. Maximum Normalized Log-Probability (MNLP)*: The difficulty is assessed by calculating the product of the label probabilities for all tokens in the sequence. The detailed computation processes for TLC and MNLP are provided in Appendix B.

For further details on the important hyperparameters of the model, please refer to Appendix C. We discuss the selection process of these parameter values in detail in the Appendix D.

3.2 Overall Experimental Results

Table 1 presents the experimental results of baselines and two models with different CL settings. The experimental results reveal several noteworthy conclusions.

Firstly, the DCL methodology introduced in this paper is flexible and can be integrated with various complex models. As shown in Table 1, the difficulty metrics proposed here outperform the Random and Length metrics across most datasets. Specifically, the BU metric consistently delivers the best performance on the majority of datasets when applied to the SynSemGCN model, surpassing the TLC and MNLP metrics.

Additionally, we compare our approach with previous methods that incorporate external knowledge or resources into the encoder. The results reveal that models using CL exhibit significant performance improvements, surpassing the performance

of earlier methods.

Model	CTB5		Time
	CWS	POS	
Ours	98.90	97.95	287m
w/o data CL(BU)	98.90	97.88	-
w/o model CL(BU)	98.85	97.51	-
w/o DCL	98.75	96.73	393m

Table 2: Ablation experimental results of DCL. The baseline model “w/o DCL” denotes the model SynSemGCN; “w/o model CL” means the student model always uses the initial data order sorted by the transfer teacher model; “w/o data CL” indicates the initial training samples for the student model is drawn randomly from the training set; “Ours” indicates “SynSemGCN+DCL(BU)”. Both teacher and student models with DCL in this table use BU as the difficulty metric. “Time” means the training time (in minutes).

Table 4: Performance comparison of different difficulty metrics on three NER datasets.

Figure 2: The F1 scores on the dev set of PKU with different difficulty metrics in the model-level CL training process.

3.3 Effect of Dual-stage Curriculum Learning

In this section, we discuss the impact of DCL. We perform ablation studies by removing either the data-level CL or the model-level CL. The results are summarized in Table 2. Model-level CL has a more significant impact than data-level CL. This is intuitive, as model-level CL influences the entire training process, while data-level CL primarily affects the early stages of student model training.

We also compare the training time of models with and without DCL. The experimental results in Table 2 show that all models were trained for 50 epochs. The training time for models using DCL includes the time spent on training the teacher model and calculating the difficulty values for the student model. The results indicate that DCL improves model performance and reduces training time by over 25%.

3.4 Ablation Study on BU Difficulty Components

We adopt McASP (Tian et al., 2020b) as the backbone model, incorporating DCL as the training strategy and BU as the difficulty metric. To examine the contribution of each component in BU, we conduct ablation experiments on its two parts: $var(\theta)_{max}$ and $var(\theta)_{aver.}$, as shown in Table 3. Removing either component results in performance

degradation, indicating that both components are crucial. Moreover, the comparable drop in performance suggests that $var(\theta)_{max}$ and $var(\theta)_{aver.}$ contribute similarly to the effectiveness of DCL.

3.5 Comparison of Difficulty Metrics

In this section, we examine the impact of different difficulty metrics during the model-level CL training process for the SynSemGCN model. Figure 2 shows the F1 score change on the PKU dataset development set over the first 10 epochs of model-level CL training. After 10 epochs, all training data are used, so the initial 10 epochs highlight the effect of different metrics. From the figure, we observe that BU, in particular, achieves the best performance, indicating that uncertainty-based metrics can select samples that better align with the model’s learning trajectory, leading to faster learning.

3.6 Generalization Capability

We conduct additional experiments to demonstrate the applicability of our method to the NER task. We select two Chinese and one English NER datasets: Weibo⁴, OntoNotes4⁵ and CoNLL-2003 (Tjong Kim Sang and De Meulder, 2003). The statistics of three datasets are shown in Table 6. We compare the performance of models using DCL and CL (Length) with a model without CL on these datasets. As shown in Table 4, the results of the DCL method outperform those of BERT+CL (Length) and BERT (no CL), indicating the effectiveness of our method. This also suggests that our method can be applied to sequence labeling tasks beyond CWS and POS tagging.

4 Conclusion

This paper introduces a novel dual-stage curriculum learning framework aimed at enhancing performance and accelerating the training process for sequence labeling tasks. Focusing on the sequence labeling task of CWS, POS tagging, and NER, this framework demonstrates its effectiveness.

⁵<https://github.com/cchen-nlp/weiboNER>

Limitations

There are several limitations to our study. First, the design of our difficulty metrics involves the tuning of multiple hyperparameters, which may complicate optimization. Second, we did not explore a curriculum learning process that progresses from hard to easy examples. Third, we focused on a single variation of the λ parameter to control CL and did not investigate alternative methods for adding training data.

A Dataset

The details of the three datasets are given in Table 5. Regarding the CTB datasets, we follow the same approach as previous works (Shao et al., 2017; Tian et al., 2020a) by splitting the data into train/dev/test sets. In the case of PKU, We randomly select 10% of the training data to create the development set.

Datasets		CTB5	CTB6	PKU
Train	Sent.	18k	23K	17k
	Word	494k	99k	482k
Dev	Sent.	350	2K	1.9k
	Word	7k	60K	53k
Test	Sent.	348	3K	3.6k
	Word	8k	12k	97k

Table 5: Detail of the three datasets.

Datasets	Type	Train	Dev	Test
Weibo	Sentences	1.35K	0.27K	0.27K
	Entities	1.89K	0.39K	0.42K
OntoNotes	Sentences	15.7K	4.3K	4.3K
	Entities	13.4K	6.95K	7.7K
CoNLL2003	Sentences	15.0K	3.5K	3.7K
	Entities	23.5K	5.9K	5.7K

Table 6: Detail of the two NER datasets.

B Difficulty Metric Baselines

Top-N least confidence (TLC). Culotta and McCallum (2005) proposed a confidence-based strat-

egy for sequence models called least confidence (LC). This approach sorts the samples in ascending order based on the probability of the most possible label predicted by the model.

The least confidence of each token is calculated as follows.

$$\phi_{(x_i, \theta)}^{LC} = 1 - \max_{y_i \in T} P(y_i | x_i) \quad (7)$$

where x_i is the i_{th} token in the input sentence, θ denotes model parameters, y_i is a pre-defined label, T represents the pre-defined label set. $\max_{y_i \in T} P(y_i | x_i)$ aims to find the probability of the most possible label predicted by the model. The smaller $\phi_{(x_i, \theta)}^{LC}$ reflects the more confident the model is in predicting the label of x_i .

According to [Agrawal et al. \(2021\)](#), the confidence level of a sentence in a sequence labeling task is typically determined based on a set of representative tokens. Therefore, we select the top N tokens with the highest least confidence in the sentence and then use their average value as the difficulty score of the sentence. Finally, the TLC difficulty metric is formulated as follows.

$$S(\theta)^{TLC} = \frac{1}{N} \sum_{n=1}^N \phi_{(x_n, \theta)}^{LC} \quad (8)$$

Maximum normalized log-probability (MNLP). [Shen et al. \(2018\)](#) used MNLP as a confidence strategy to find the product of the maximum probabilities of each token, which is equivalent to taking the logarithm of each probability and summing them. Finally, it is normalized to obtain the confidence score of the sentence as follows.

$$\prod_{i=1}^M \max_{y_i \in T} P(y_i | x_i) \iff \sum_{i=1}^M \log\{\max_{y_i \in T} P(y_i | x_i)\} \quad (9)$$

where M is the length of the sentence. The difficulty of a sentence decreases as the confidence level increases. To account for this relationship, we introduce a negative sign. Additionally, in order to reduce the impact of sentence length, we apply a normalization operation. Finally, MNLP is formulated as follows.

$$S(\theta)^{MNLP} = -\frac{1}{M} \sum_{i=1}^M \log\{\max_{y_i \in T} P(y_i | x_i)\} \quad (10)$$

C Parameters Setting

The key experimental parameter settings are shown in Table 7.

Hyper-parameters	Value
E_0	5
E_s	50
λ_0	0.3
E_{grow}	10
K	3
N	5

Table 7: Experiment hyper-parameters setting.

E_{grow}	CTB5		PKU	
	CWS	POS	CWS	POS
5	98.88	97.89	98.65	97.01
10	99.06	98.96	98.77	96.97
15	98.84	97.69	98.70	96.90

Table 8: The effect of E_{grow} in Eq. 6.

D Effect of Hyper-parameters

In this section, we explore the impact of the hyperparameters on the performance of DCL. The adjustment of the parameters is based on the SynSemGCN+DCL(BU) model.

First, we investigate the impact of the hyperparameter λ_0 on DCL performance. We conduct the experiments on the CTB5 dataset, tuning the value of λ_0 in the model-level pacing function Eq. 6, and the experimental results are represented by a line graph as shown in Figure 3. As observed, the model achieves optimal performance when $\lambda_0 = 0.3$. However, when the value exceeds 0.4, the model’s performance gradually deteriorates.

Additionally, we examine the impact of E_{grow} in Eq. 6, which controls the number of epochs for λ to reach 1. As shown in Table 8, when E_{grow} is set to 10, the model exhibits superior performance on both the CTB5 and PKU datasets. Therefore, we adopt E_{grow} as 10 epochs in our experiments.

Next, we assess the impact of the training epochs E_0 of the teacher model, which initializes the difficulty ranking of the training data for the student model. We aim to investigate whether a more mature teacher model contributes to improved performance. For this purpose, we conduct experiments on both the CTB5 and PKU datasets, utilizing teacher models trained for 5, 10, and 15 epochs

E_0	CTB5		PKU	
	CWS	POS	CWS	POS
5	99.06	98.96	98.77	96.97
10	98.98	97.90	98.54	96.69
15	98.73	96.87	98.53	96.54

Table 9: The impact of the number of epochs of teacher model, E_0 .

Para.	CTB6		PKU	
	CWS	POS	CWS	POS
$K=2$	98.17	95.43	98.73	96.58
$K=3$	98.10	95.59	98.77	96.97
$K=4$	98.09	95.56	98.69	96.38

Table 10: The effect of of K times dropout in BU difficulty metric.

to rank the initial training data for the student models.

The experimental results, as shown in Table 9, reveal that a more mature teacher model does not necessarily lead to better performance. Instead, the student model achieves optimal results when the teacher model is trained for 5 epochs. One possible explanation for this finding is that a teacher model with fewer training epochs aligns better with the initial state of the student model, allowing for a more suitable estimation of sample difficulty.

Figure 3: The impact of model-level curriculum learning hyper-parameters λ_0 .

Then, we explore the impact of different K values on the BU difficulty metric, which determines the number of dropout times. The experiments are conducted on the CTB6 dataset, and the results are summarized in Table 10. Notably, the model achieves optimal performance when $K = 3$. Therefore, we select $K = 3$ for all the above experiments.

Finally, we evaluate the effect of varying N in the TLC metric. As shown in Table 11, the best performance is achieved when $N = 5$.

E Statistical Significance Test

In this section, we conduct significance testing experiments. Following Wang et al. (2010), we use the bootstrapping method proposed by Zhang et al. (2004), which is operated as follows. In this process, starting with a test set T_0 comprising N test examples, we repeatedly sample N samples from T_0 to form T_1 and then repeat the pro-

Para.	PKU	
	CWS	POS
$N=1$	98.55	96.49
$N=2$	98.53	96.49
$N=3$	98.56	96.52
$N=4$	98.55	96.51
$N=5$	98.71	96.64
$N=6$	98.52	96.52
$N=7$	98.56	96.51
$N=8$	98.55	96.48
$N=9$	98.53	96.49
$N=10$	98.55	96.51

BERT+DCL(MNLP)	BERT	>	>
BERT+DCL(TLC)	BERT	>	>
BERT+DCL(BU)	BERT+CL(Length)	>	>
BERT+DCL(MNLP)	BERT+CL(Length)	>	>
BERT+DCL(TLC)	BERT+CL(Length)	>	>

Table 12: Statistical significance test of F-score for our method and baselines on the CTB5 dataset.

cess for M times to form the test set collection, $\{T_1, T_2, \dots, T_M\}$, where M is set to 1000 in our testing procedure. Two systems denoted as A and B , are assessed on the initial test set T_0 , resulting in scores a_0 and b_0 , respectively. The disparity between the two systems, labeled as δ_0 , is calculated as $\delta_0 = a_0 - b_0$. Repeating this process for each test set produces a set of M discrepancy scores, denoted as $\{\delta_0, \delta_1, \dots, \delta_M\}$.

Following the methodology proposed by Zhang et al. (2004), we compute the 95% confidence interval for the discrepancies (i.e., the 2.5th percentile and the 97.5th percentile) between the two models. If the confidence interval does not overlap with zero, it is affirmed that the differences between systems A and B are statistically significant (Zhang et al., 2004).

Table 12 lists the significant differences between our system and the baseline system, where “>” indicates that the average value of δ exceeds zero, meaning that System A is better than System B; “<” indicates that the average value of δ does not exceed zero, meaning that System A is worse than System B; “~” indicates that there is no significant difference between the two systems. Finally, the comparison also indicates that our models are superior to the baseline.

Accelerating Dense LLMs via L0-regularized Mixture-of-Experts

Abstract

Large language models (LLMs) achieve strong performance but suffer from slow and costly inference. Existing acceleration methods often lead to noticeable performance degradation, while Mixture-of-Experts (MoE) models require extensive computational resources. In this paper, we propose L0-MoE, a lightweight MoE approach using L0-regularization to accelerate dense LLMs nearly without performance loss. Our method introduces a cluster confusion matrix for domain-aware dataset curation and applies dynamic batching for efficient training. Experiments show that L0-MoE achieves up to 2.5x speedup over dense models while maintaining competitive performance, outperforming existing LLM acceleration baselines.

1 Introduction

Large language models (LLMs) have demonstrated remarkable intelligence across various tasks (OpenAI et al., 2024; Gemini-Team et al., 2024; Dubey et al., 2024; Jiang et al., 2023; DeepSeek-AI et al., 2025; Yang et al., 2024), including question answering, mathematics, coding, and content generation. A key insight into their success is the parameter scaling law (Kaplan et al., 2020), which suggests that increasing model size enhances performance across diverse tasks, potentially advancing artificial general intelligence (AGI) (Bubeck et al., 2023). However, larger LLMs incur high inference costs, leading to slower generation speeds and increased computational expenses. Thus, optimizing LLM inference efficiency has become a critical challenge for both academia and industry.

Various approaches have been proposed to accelerate LLM inference, which can be categorized into three main techniques: (1) **Quantization**, including GPTQ (Frantar et al., 2023), SmoothQuant (Xiao et al., 2023), AWQ (Lin et al., 2024b) and DuQuant (Lin et al., 2024a), reduces precision by

converting weights and activations from floating-point to lower-bit integer formats, significantly improving efficiency. (2) **Model pruning**, such as LLM-Pruner (Ma et al., 2023) and LLM-Shearing (Xia et al., 2024), removes redundant parameters based on predefined criteria to compress models and accelerate inference. (3) **Knowledge distillation** (Gu et al., 2024; Feng et al., 2024), like reverse-KD (Gu et al., 2024) and Chain-of-Thought (CoT) Distillation (Feng et al., 2024), transfers knowledge from large LLMs to smaller ones using distillation techniques (Hinton et al., 2015), reducing computational demands. While these methods achieve substantial speedup, they often come at the cost of performance degradation, posing challenges for real-world deployment.

Recently, sparsely gated Mixture-of-Experts (MoE) models (Cai et al., 2024), particularly in transformer-based large language models, have significantly improved inference speed optimization. MoE operates on a simple yet effective principle: different model components, known as experts, specialize in distinct tasks or data aspects. For a given input, only relevant experts are activated, reducing computational costs while leveraging a vast pool of specialized knowledge. This scalable and flexible approach aligns with the scaling law, enabling larger model capacities without proportional computational overhead. However, current MoE training focuses on training from scratch or up-cycling dense LLMs, both requiring vast computational resources and high-quality corpora. For instance, DeepSeek-V3 (DeepSeek-AI et al., 2024) and Qwen2.5-Max (Yang et al., 2025) were pre-trained on 14.8T and 20T tokens, respectively, with additional fine-tuning, making them costly and less accessible. In contrast, *little research has explored leveraging MoE to accelerate inference using a small-scale training corpus (e.g., tens of billions of tokens) while maintaining performance comparable to dense LLMs*. This direction is particularly ap-

*Corresponding author.

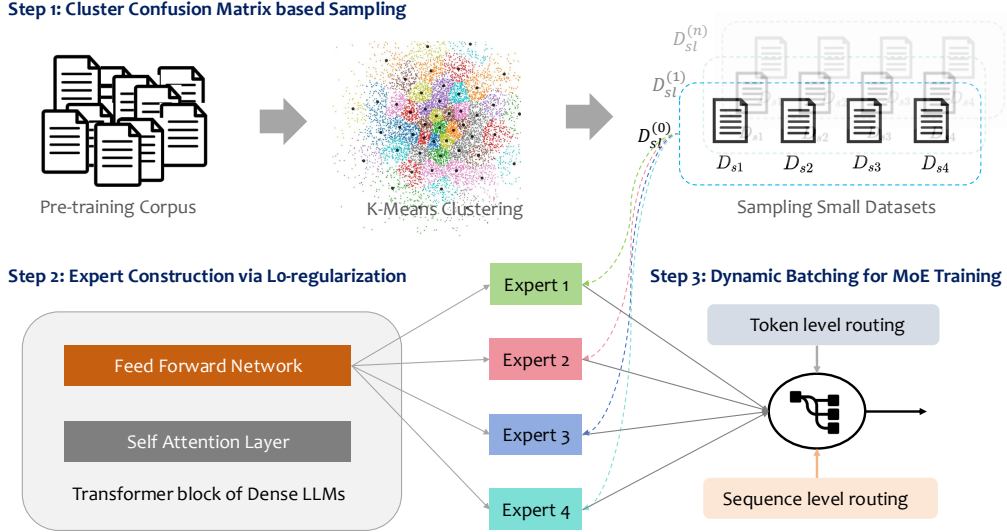

Figure 1: Overview of the L0-MoE Architecture, which includes three main stages: (1) cluster confusion matrix based sampling, (2) expert formation using L0 regularization, and (3) dynamic batching for MoE training. The figure above illustrates the process of building an L0-MoE with four experts over n iterations of dataset sampling.

peeling for large-scale industrial applications with cost-sensitive deployment constraints.

To address this issue, we propose **L0-MoE**, a mixture-of-experts (MoE) model built via L0-regularization (Louizos et al., 2018) using a small, curated **30B**-token corpus. Our approach has two key components: (1) L0-regularization selects critical hidden dimensions in transformer MLPs to form experts. (2) A cluster confusion matrix (CCM)-based sampling method curates the training corpus and schedules dynamic batching. Using the BGE-M3 encoder (Chen et al., 2024) and K-means clustering (Jin and Han, 2010), we extract diverse semantic domains from RedPajama (Weber et al., 2024) to construct expert-relevant sub-datasets. A gating mechanism and dynamic batching optimize training. L0-MoE achieves **2.5 \times** inference speedup with no obvious performance loss across four benchmarks. Our contributions are as follows: 1) We introduce a novel MoE building method leveraging L0-regularization, enabling efficient LLM inference acceleration with minimal training cost. 2) We propose a CCM-based corpus curation and dynamic batching strategy for effective MoE training. 3) Extensive experiments validate the efficiency of our method in achieving inference speedup while maintaining performance.

2 Preliminary

2.1 L0-regularization

L0-regularization (Louizos et al., 2018) is a powerful technique for feature selection and parameter pruning in neural networks. It imposes a penalty

on parameters that deviate from zero, without additional constraints. This approach enhances model efficiency by eliminating unnecessary computations and resources, as irrelevant parameters are pruned and thus not computed. For a given weight matrix $W \in R^{m \times n}$, a mask matrix $Z \in 0, 1^n$ is employed to derive a reduced weight $g(W, Z) \in R^{m \times n_0}$, where g selects $n_0 < n$ columns from W using Z . Due to the non-differentiable nature of Z , optimizing it is challenging. To address this, the binary hard concrete function is introduced for L0-regularization, as shown in Equation 1.

$$\begin{aligned}
 u &\sim \mathcal{U} \\
 s &= \text{Sigmoid}((\log(u) - \log(1 - u) + \log a)/b) \\
 \bar{s} &= s(\zeta - \gamma) + \gamma \\
 z &= \min(1, \max(0, \bar{s}))
 \end{aligned} \tag{1}$$

The uniform distribution \mathcal{U} is defined over the interval $[0, 1]$. We set the hyper-parameters as $b = 0.83$, $\zeta = 1.1$, and $\gamma = -0.1$ by following Louizos et al. (2018). Using the learned z , we estimate the proportion of retained weights as $\hat{r} = \frac{\text{sum}(z)}{m * n}$. To effectively control the desired retention ratio r for a given weight matrix W , we employ a Lagrangian multiplier (Wang et al., 2019), as described in Equation 2.

$$\mathcal{L}_{l_0} = \lambda_1(\hat{r} - r) + \lambda_2(\hat{r} - r)^2 \tag{2}$$

We initialize the learnable parameters λ_1 and λ_2 to 0 in our experiments. In our approach, r represents the retention ratio of the feed-forward network (FFN) up-projection dimension.

2.2 Mixture of Expert

Mixture of Experts (MoE) (Cai et al., 2024) employs a modular architecture comprising a gating network and multiple expert networks to enhance efficiency and performance through parameter scaling. This architecture partitions the model into several experts, each specializing in specific subsets of input data. MoE utilizes a gating mechanism with a router to dynamically select the appropriate experts for processing incoming inputs, allowing the model to concentrate on relevant features while minimizing unnecessary computations. In our approach, the router is implemented as a linear projection layer $W_{router} \in R^{d \times N}$. MoE incorporates two auxiliary losses (Equation 3), such as the load balancing loss $\mathcal{L}_{balance}$ (Fedus et al., 2022) and the router Z-Loss \mathcal{L}_z (Zoph et al., 2022), to promote a balanced distribution of inputs among experts. These losses penalize high values in the logits produced by the gating network, encouraging a more even allocation of tokens to experts.

$$\begin{aligned} \mathcal{L}_{aux} &= \mathcal{L}_{balance} + \lambda \mathcal{L}_z \\ \mathcal{L}_{balance} &= \sum_{i=1}^{i=N} \left(\frac{c_i}{B} - \frac{1}{N} \right)^2 \\ \mathcal{L}_z &= \frac{1}{B} \sum_1^B \left(\log \left(\sum_i e^{x_i^{(j)}} \right) \right) \end{aligned} \quad (3)$$

Here c_i represents the tokens of the i^{th} expert, and N denotes the number of experts. The batch contains B tokens. The logit for the j^{th} token from the i^{th} expert, as determined by the router module, is denoted as $x_i^{(j)}$.

3 Approach

3.1 Cluster Confusion Matrix based Sampling

Given a pretraining corpus, we construct training datasets via the following steps: 1) Randomly sample a small subset without replacement and use the BGE-M3 encoder (Chen et al., 2024) to extract d_{sv} -dimensional semantic vectors for each sample. 2) Apply the K-means clustering algorithm (Jin and Han, 2010) to the semantic vectors to identify K centers $C \in \mathbb{R}^{K \times d_{sv}}$. Divide the small subset into K folds and sample m instances from each fold to form a dataset $D_{sl} = \{D_{s_1}, \dots, D_{s_K}\}$ for domain semantic learning, where $|D_{s_k}| = m$ for $1 \leq k \leq K$. 3) Repeat steps 1 and 2 for Q iterations to obtain $Q \times K$ centers and Q datasets. For the l^{th} iteration ($l = \{1, 2, \dots, Q\}$), the cluster centers are $C^{(l)} \in \mathbb{R}^{K \times d_{sv}}$ and the constructed dataset is $D_{sl}^{(l)}$.

We define the clustering confusion matrix (CCM) as per Equation 4, where $\delta = 0.1$ is a hyperparameter, C_i represents the i^{th} center vector,

and $CCM[i, l]$ denotes the clustering confusion value for the i^{th} center at iteration l . The hypothesis posits that the semantic domain distance for the i^{th} center between C_i and $C_i^{(l)}$ can be assessed using bidirectional inter-clustering (f_1 and f_2) and intra-clustering (f_3) cosine similarity. A larger semantic domain distance indicates that $D_{sl}^{(l)}$ from the l^{th} iteration divides domains more distinctly. We compute the domain semantic distance using Equation 5 and reorder the Q datasets based on $d_{ds}^{(l)}$. In addition to the initial $D_{sl}^{(0)}$, our datasets now include $Q - 1$ ordered datasets $D_{sl}^{ord(l)}$, where $ord(l)$ is the order index.

$$\begin{aligned} CCM[i, l] &= (f_1 + f_2) * f_3 \\ f_1(i, l) &= \frac{1}{K} \sum_{k=1}^{k=K} e^{1-sim(C_i, C_k^{(l)})} \\ f_2(i, l) &= \frac{1}{K} \sum_{k=1}^{k=K} e^{1-sim(C_k, C_i^{(l)})} \\ f_3(i, l) &= \delta \frac{\sum_{k=1}^{k=K} e^{sim(C_k^{(l)}, C_i^{(l)})}}{\sum_{k=1}^{k=K} e^{sim(C_k, C_i)}} \end{aligned} \quad (4)$$

$$d_{ds}^{(l)} = \max(CCM[:, l]) + \frac{\beta}{K} \sum_{i=1}^{i=K} CCM[i, l] \quad (5)$$

3.2 Expert Construction via L0-regularization

We construct the experts using pretrained checkpoints of dense LLMs. The intermediate size of the feed forward network (FFN) layer is d_{int} , and we apply a mask $Z \in R^{d_{int}}$. For each domain subset D_{s_k} ($k \in \{1, 2, \dots, K\}$) derived from the initial $D_{sl}^{(0)}$, we employ the LLM pretraining loss \mathcal{L}_{llm} along with the L0-regularization loss, as specified in Equation 1, to select $r \in (0, 1) * 100\%$ of the dimensions from d_{int} , following Equation 6.

$$\mathcal{L}_{exp} = \mathcal{L}_{llm} + \mathcal{L}_{l0} \quad (6)$$

To ensure stable training, we gradually adjust r from 100% to the target ratio r^{target} . We freeze all non-MLP parameters of dense LLMs, and the L0-regularization-based training yields K experts, each specialized for distinct semantic domains.

3.3 Dynamic Batching for MoE Training

To train the MoE to effectively select appropriate experts based on inputs, we follow Equation 7, where \mathcal{L}_{aux} is defined in Equation 3. The MoE is initialized with K pre-trained experts and a router for each MoE layer.

$$\mathcal{L} = \mathcal{L}_{llm} + \alpha \mathcal{L}_{aux} \quad (7)$$

We employ a two-loop batch construction strategy during training: 1) domain semantic distance scheduling, where we begin with $D_{sl}^{ord(l)}$ having a

lower d_{ds} ; 2) multi-domain gathering scheduling, where samples in $D_{sl}^{ord(l)}$ are arranged in a cyclic sequence order $x_i^1, x_i^2, \dots, x_i^K$, and we select $p * K$ ($p = \{1, 2, 3, \dots\}$) samples to form a batch. This scheduling offers two advantages: 1) In the initial iterations, the MoE rapidly learns to select appropriate experts since the domain samples in D_{sl} have been previously encountered by the experts. Consequently, the sequence-level selection capabilities of routers are effectively initialized. 2) As training progresses, the domains in $D_{sl}^{ord(l)}$ gradually transition to different semantic spaces, encouraging routers to select multiple experts for each input sample. This enhances the token-level selection capabilities of the routers.

4 Experiments

4.1 Experimental Setup

Dataset. We train on the RedPajama dataset (Weber et al., 2024), a replicated pre-training corpus for LLaMA models, following prior work (Xia et al., 2024). Evaluation is conducted on four public benchmarks: MMLU (Hendrycks et al., 2021), GSM8K (Cobbe et al., 2021), HumanEval (Chen et al., 2021), and BigBench Hard (BBH) (Suzgun et al., 2023). Each benchmark evaluates distinct aspects of model performance, offering insights into the strengths and limitations of LLMs.

Baselines. To assess effectiveness and versatility, we evaluate our method on three open-source LLMs: Llama-3-8B (Dubey et al., 2024), Mistral-7B (Jiang et al., 2023), and Qwen2-7B (Yang et al., 2024). Comparisons include L0-regularized MoEs, original LLMs, and inference optimization techniques such as GPTQ quantization (Frantar et al., 2023), LLM Shearing pruning (Xia et al., 2024), and RKD + CoT knowledge distillation (Gu et al., 2024; Feng et al., 2024). For CCM, we run 21 iterations, collecting 30B tokens. Experiments use a cluster/expert size of $K = 64$ with linear warmup, annealing, and a peak learning rate of $1e-4$. Further details are in Appendix A.2.

Implementation Details. We train our model using the FSDP framework¹, employing a layer-wise wrapping policy with the Zero-3 parameter sharding strategy, without CPU offloading. For inference during evaluation, we utilize the SGLang framework², which is highly optimized for the efficient execution of both dense LLMs and MoEs.

All baseline models in our experiments utilize the same SGLang inference framework, ensuring a fair and consistent comparison of inference speeds. Our method is framework-agnostic and can similarly be implemented using other inference frameworks (e.g., vLLM³). The primary source of inference acceleration in our work is the proposed L0-regularization-based MoE architecture, not the inference framework itself. To ensure a fair comparison, we strictly adhere to the original evaluation settings for each benchmark. To support future research, we will release our curated dataset and code to enhance the reproducibility of our work.

4.2 Main Results

Table 1 presents the model with the highest performance under our settings. The L0-MoE consistently achieves a 2-2.5x inference speedup across all base LLMs. Additionally, L0-MoE maintains performance comparable to the base LLMs across four benchmarks, with the L0-MoE variant of Mistral even demonstrating a 1% average performance improvement. Table 2 compares these results with other inference acceleration baselines, which, despite achieving some speedup, exhibit noticeable performance degradation.

4.3 Ablation Study

Table 3 presents the ablation study on the CCM module, dynamic batching, and L0-regularization. Removing the K-means clustering from the CCM module results in a performance decline, underscoring the importance of effective sub-dataset curation. For dynamic batching, substituting it with random order or random batch scheduling also leads to degraded performance.

In the context of MoE expert construction, we replace L0-regularization with four alternative methods: 1) **Random MoE** (Zhu et al., 2024): Selects MLP dimensions randomly, serving as a baseline to assess the necessity and effectiveness of dimension selection in expert construction, 2) **Magnitude** (Sun et al., 2023): Selects the most influential elements in the weight matrix, improving upon traditional magnitude pruning by considering both the weights and their corresponding input activations using the L2 norm, 3) **OBS** (Frantar et al., 2021; Frantar and Alistarh, 2022): Identifies the most critical dimensions using the OBS Hessian matrix, which encapsulates second-order derivative information of the loss function with respect to model

parameters. This approach is crucial for both pruning and quantization, as it helps retain the weights that most significantly impact model performance, 4) **SVD** (Wang et al., 2024)): Decomposes the weight matrix using singular value decomposition and selects the most significant columns. By retaining the largest singular values, it reduces parameter count while preserving essential information. This truncation minimizes compression loss, and layer-wise updates further fine-tune the model to maintain accuracy. The results demonstrate the superiority of L0-MoE over them.

Model	MMLU	#Para.(B)	Speedup
L0-MoE	70.4	23.3	2.5x
CCM Iter. ($Q = 2$)	68.2	23.3	2.5x
CCM Iter. ($Q = 5$)	68.8	23.3	2.5x
CCM Iter. ($Q = 10$)	69.7	23.3	2.5x
Expert size ($K = 8$)	50.9	4.8	4.6x
Expert size ($K = 32$)	69.2	12.7	3.2x

Table 4: Hyper-parameter tuning of sampling iterations (Q) and cluster size (K), keeping 2.8B activated parameters for L0-MoE. Qwen2-7B is the base LLM. #Para.(B) is the number of model parameters.

4.4 Discussion

Our approach involves two critical hyperparameters: the sampling iterations Q in CCM curated datasets and the expert size K in MoE. Table 4 pro-
